Multiple regression analysis was performed based on the entry method to verify the possibility of predicting the trust based on the experiences of being a victim or witness of unethical behaviour at work. All independent variables were entered into the equation simultaneously. The following variables related to unethical behaviours were introduced to the regression models: (i) discrimination; (ii) isolation and ignorance; (iii) violation of dignity and integrity; (iv) humiliation and depreciation of employees; and (v) demonstrating position of power by a superior. The global score of trust and its relevant aspects, i.e. control mutuality, commitment, satisfaction, communal relationships, and exchange relationships were dependent variables. The same predictors related to unethical behaviours at work either from the witness' or victim's perspectives were entered into the regression models. Finally, the designed models included predictors of unethical behaviours at work from either the victim's or witness perspective to assess contributions of these factors to explaining the variance in each dimension of trust. In order to identify the multicollinearity between predictors in regression analysis, the variance inflation factors (VIFs) were calculated. Since the maximum value of VIF was 2.827, no issue of multicollinearity among the predictors was identified. All statistical analyses were done with SPSS version 25 for Windows (IBM, 2016). The level of significance was set at $p < 0.05$ in all statistical tests.

Results

Prediction of trust in organisation (dependent variable)

Based on the enter method, it was found out that severity of experiences of being the victim of unethical behaviour at work significantly predicted the level of trust in organisation, $F(5,216) = 5.30$; $p < 0.001$, and this predictor explained a significant amount of the variance (11%) in the variable of trust (R2 = .109). The results showed that only the predictor of being a victim of humiliation and depreciation significantly contributed to the levels of trust (b = -.245, t (216) = - 2.429, p = .016). This implicated that employees who had been more often victimized and humiliated had lower levels of trust into organisation (see Table 2).

Table 2: Summary of Multiple Regression Analysis for trust based on the experiences of being a victim of unethical behaviour at work

Predictor	*B*	*SE*	β	*t*	*p*-value	95%CI	VIF
DV: Trust							
(*constant*)	39.819	2.448		16.264	.000	34.993-44.644

Demonstrating position of power by a superior	-0.962	0.612	-0.158	-1.571	.118	-2.169-0.245	2.437
$R^2 = 0.109$, $_{adj}R^2 = 0.089$, SE = 8.06, $F(5,216) = 5.30$, $p < .001$							

The results also indicated that the levels of trust are significantly predicted by the severity of unethical behaviour that were witnessed at work, $F(5, 180) = 4.607$; $p = 0.001$. The predictor of witnessing unethical behaviour explained 11% of the variance in the variable of trust ($R^2 = .113$). The results showed that the predictor of witnessing humiliation and depreciation significantly predicted the risk of decreasing trust in organisation (b = -.213, t (180) = - 1.977, $p = .050$). This indicated that only the predictor of witnessing humiliation and depreciation of employees in organisation contributed to the risk of decreasing trust in organisation (see Table 3).

The Prediction of Control Mutuality (Dependent Variable)

The regression model predicting dependency of control mutuality on the severity of experiencing unethical behaviour on the part of a victim at work was significant, $F(5, 216) = 4.53$; $p = 0.001$. The predictor explained the 10% of variance in the variance of control mutuality, ($R^2_{adj} = .095$). The coefficients in the regression model were not significant (see Table 4).

Table 4: Summary of Multiple Regression Analysis for Control mutuality based on the experiences of being a victim of unethical behaviour at work

$R^2 = 0.104$, $_{adj}R^2 = 0.079$, SE = 6.28, $F(5,181) = 4.185$, $\boldsymbol{p = .001}$							

The prediction of commitment (dependent variable)

The results suggested that the variable of being a victim of an unethical behaviour at work was significant in predicting levels of commitment, $F(5, 216) = 4.374$; $p = 0.001$, and the variable explained the 9% of variance ($R^2 = .092$). The results showed that only the predictor of being a victim of humiliation and depreciation significantly contributed to the decrease in levels of engagement, (b = -.270, t (216) = - 2.684, $p = .008$). This implicated that an employee who is more often victimized and humiliated shows lower commitment to organisation (see Table 6).

Table 6: Summary of Multiple Regression Analysis for Commitment based on the experiences of being a victim of unethical behaviour at work

Predictor	*B*	*SE*	β	*t*	*p*-value	95%CI	VIF

The prediction of satisfaction (dependent variable)

The results indicated that dependency of satisfaction levels based on experiences of being the victim of an unethical behaviour at work was significant, $F(5, 217) = 6.870$; $p < 0.001$. This predictor explained 14% of variance in the variable of satisfaction ($R^2 = .137$). The coefficients in the regression model indicated that none of the factors significantly predicted satisfaction levels (see Table 8).

Table 8: Summary of Multiple Regression Analysis for Satisfaction based on the experiences of being a victim of unethical behaviour at work

The prediction of social relations

The results indicated that dependency of social relation based on the experiences of being a victim of an unethical behaviour at work was significant, $F(5, 216) = 3.878$; $p = 0.002$, and the model explained 8% of variance in the variable of ($R^2 = .082$). The results showed that only the variable of being a victim of the demonstrating the position of power by superiors significantly predicted the level of trust in social relations (b = -.209, t (216) = - 2.070, p = .040). This indicated that an employee who was more often victimized by their superiors, had a lower level of trust in social relations (see Table 10).

Table 10: Summary of Multiple Regression Analysis for Social relations based on the experiences of being a victim of unethical behaviour at work

The model predicting the effects of the experiences of being a victim of an unethical behaviour at work on social relationships was significant, $F(5, 181) = 4.772$; $p < 0.001$. The variable explained 12% variance in the variable of social relations ($R^2 = .116$) The results showed that only witnessing a demonstration of power positions significantly predicted the decrease of trust in social relationships (b = -.236, t (181) = - 2.051, p = .042). This outcome suggested that a worker who more often witnessed a demonstration of the power positions by their superiors had lower levels of trust in social relations within an organisation (see Table 11).

Table 11: Summary of Multiple Regression Analysis for Social relations based on the experiences of being a witness of unethical behaviour at work

The prediction of Exchange Relationship

The model predicting the effects of being the victim of various types of unethical behaviour at work on the variable of exchange relationship was significant, $F(5, 217) = 2.690$; $p = 0.022$. The model explained the 6% variance ($R^2 = .058$). The results showed that predictor of being a victim of a demonstration of the power positions by superiors significantly predicted the increase in exchange relationship (b = .241, t (217) = 2.353; $p = .019$). Thus, an employee more often victimized by their superiors displayed a higher level on the exchange relationship scale (see Table 12).

Table 12: Summary of Multiple Regression Analysis for Exchange relations based on the experiences of being a victim of unethical behaviour at work

Discussion

The present study investigated the relationship between trust and unethical practices witnessed or experienced by employees in Polish companies. The multiple regression analysis identified unethical behaviours that had an effect on the decrease and also, surprisingly, increase in multidimensional trust in the organisation. We have identified that all dimensions of trust in an organisation are significantly associated with unethical behaviour when

experienced directly by an employee, i.e. in case of being a victim. A similar situation occurred when an employee perceived unethical practices, although there was one exception, since employee's trust dependent on engagement was unchanged. Our research showed that unethical practices either experienced or witnessed include the factor of humiliation and depreciation, which most strongly undermines trust in the organisation, both in the situation of being a witness and a victim. We also found out that the significant effect on trust was exerted by the demonstrating of the position of power by a superior. However, this factor played a twofold role, since the demonstration of the power position either undermined trust on a social level (the significant decrease in trust) or enhanced trust in terms of exchange relations. The latter issue seems to be counter-intuitive and as such requires a tentative explanation. In sketching such an explanation, it is reasonable to resort to cultural factors (e.g. Ratajczak 2007) that influence human behaviour in workplace, accepting Hofstede's view on the dimensions of national cultures (Hofstede, Hofstede, Minkov 2010; Subocz 2012), namely: power distance, collectivism versus individualism, femininity *versus* masculinity, uncertainty avoidance, long-term versus short-term orientation. The Polish culture is thought to be more oriented towards high uncertainty avoidance, masculinity, short-term orientation, rather large power distance while oscillating between collectivism and individualism. Thus, it is possible that the demonstration of the position of power by a superior, when it is witnessed but not directly experienced by an employee, is perceived by this employee as an expression of certainty masculinity and superior's caring about company as a whole (collectivism); at the same time, the large power distance between the witness and the superior as well as the short term orientation contribute to form a traditional view on one's work and as such might give the impression of safety within strict hierarchy of roles in the organisation. This, in turn, within can result in enhancing the impression of higher level of control mutuality from employee's perspective.

Here, it is worth commenting on the importance of employee-superior relations in Polish organisations. Our study clearly shows that the demonstrating of the power position by superiors diminishes our confidence in the organisation in a social dimension; however, on the other hand, it induces positive feelings linked with expectations of future benefits. It seems that this situation may reflect a certain dependency dilemma of the employee in Poland. When deciding to be associated with an organisation, he e or she begins to experience mixed feelings of trust: on the one hand, he or she wants to adapt to the organisational structure (to conform to an external code of ethics, i.e. norms, values) and, on the other hand, hopes to have further profits and benefits resulting from their own work. This study has several limitations. Namely, the research sample was limited to graduate students, mainly women. Therefore, future research should provide a more representative sample.

Conclusions

To conclude: there will always be ethical problems in organisations where business is involved. Our research shows that unethical practices can primarily relate to factors related to humiliation and depreciation of employees as well as the demonstration of the power position by a superior. Presumably, it is for these reasons that conflicts and injustices can occur in Polish companies, and consequently decreasing trust in organisation. Therefore, further research as well as interventions are needed to find out ways to improve the ethical climate of organisations in Poland in order to counteract these specific unethical practices witnessed or experienced by employees.

Acknowledgment

COVID-19, Oil Prices and the US Policy Uncertainty

Claudiu Tiberiu ALBULESCU

Politehnica University of Timisoara, Management Department, Timisoara, Romania
claudiu.albulescu@upt.ro

Abstract

This paper investigates the effect of COVID-19 and crude oil prices on the United States (US) economic policy uncertainty (EPU), with a focus on the pre-pandemic phase of the sanitary crisis. Using daily data for the period January 21 – March 13, 2020, our Autoregressive Distributed Lag (ARDL) model shows that the new infection cases reported at global level, and the fatality ratio, have no significant effect on the US EPU during the first phase of the crisis, whereas the oil price negative dynamics leads to increased uncertainty. However, analyzing the situation outside China, we discover that both new case announcements and the COVID-19 associated death ratio have a positive influence on the US EPU.

Keywords: COVID-19, Economic Policy Uncertainty, Oil Prices, ARDL Bound Testing.

Introduction

The outbreak of the new coronavirus crisis (COVID-19) monopolizes these days the worldwide public agendas. Originating in China (Hubei region), the COVID-19 affected over 100,000 people and more than 100 countries at the beginning of March 2020. The World Health Organization (WHO), which daily monitors the COVID-19 figures since January 21, 2020, declared the coronavirus a pandemic on March 11. Although the spread of the virus started to decline, after the middle of February in China, the infection cases grew exponentially outside China. The European countries, but also the United States (US), were severely touched.

In this context, the purpose of this research note is to investigate the effect of COVID-19 and crude oil prices on the United States (US) economic policy uncertainty (EPU), with a focus on the pre-pandemic phase of the sanitary crisis. On the on hand, COVID-19 has triggered fear and anxiety in the society, nourished both by the daily reported new infection cases and by the increasing fatality ratio. On the other hand, the virus started to affect the real economy since February 2020, generating a crash on financial and commodity markets. Likewise, COVID-19 induced additional uncertainty in the economy, amplified by a delayed reaction of authorities, and by a lack of a clear strategy to fight against the disease.

This is also the case of the US authorities, which initially refused to take actions. President Trump declared that the situation is "very much under control" in the US, and that the scientists will find "soon" a solution to this problem. Nevertheless, the COVID-19 numbers triggered a strong reaction of US financial markets, first on February 28, 2020, and second, on March 13, 2020, immediately after Mr. Trump declaration according to which the coronavirus represents a "national emergency" issue. In addition, in the context of the coronavirus crisis, the Saudi Arabia decided to flood the market with oil and the international prices dropped over 20% on March 9, 2020. Against this background, we may ask if the coronavirus crisis influences the policy-induced economic uncertainty in the US, during the first wave of the sanitary crisis. We tempt to respond to this question by analyzing the impact of new infection case announcements, and COVID-19 death-associated ratio, on the US economic policy uncertainty (EPU). We use daily data over the period January 21 – March 13, 2020, resorting to the WHO situation reports. We also test the impact of crude oil prices on the US EPU. Given that the US is an oil-dependent country, as one of the world largest producers, it is expected that a crash of crude oil price will amplify the economic uncertainty.

The relationship between EPU and oil prices has already been investigated. Chen et al. (2020) show that the impact of oil price shocks on EPU is positive at all frequencies, a result in line with Kang et al. (2017), but contrasting that

Cite this Article as: Claudiu Tiberiu ALBULESCU "COVID-19, Oil Prices and the US Policy Uncertainty" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

reported by Antonakakis et al. (2014). At the same time, Ma et al. (2018) notice that EPU is important to forecast oil futures prices, whereas Aloui et al. (2016) show that EPU influences the oil price returns only in certain periods. Nevertheless, none of these studies focuses on the recent situation generated by the COVID-19 crisis, with few exceptions (e.g. Albulescu, 2020). Therefore, we fill in this gap and test the impact of coronavirus numbers and West Texas Intermediate (WTI) prices on the US EPU (we use BRENT crude for robustness purpose). As far as we know, this is the first paper addressing the impact of the COVID-19 crisis on the US policy-induced economic uncertainty.

Only few works try to identify the causes underlying EPU (e.g. Albulescu et al., 2020; Chen et al., 2020; Duca and Saving, 2018). Indeed, most of existing studies address the impact of EPU on economic activity (Nyamela et al., 2020; Sahinoz and Cosar, 2018), financial volatility (Mei et al., 2018; Tiwari et al., 2019), bank valuation (He and Niu, 2018) or firm performance (Iqbal et al., 2020; Wu et al., 2020). Consequently, we add to the set of analyses investigating the drivers of EPU, with a focus on the officially reported coronavirus numbers. The rest of the paper presents the data (Section 2), the methodology and results (Section 3) and the conclusions (Section 4).

Data

The WHO data show that China was in the pre-pandemic phase of the crisis the most affected country in the world. However, the virus rapidly spread in other countries like Italy, Spain, Iran, or South Korea. Therefore, it is expected that the impact of COVID-19 on the US EPU increases with the crisis propagation outside China. Figure 1 shows that the US EPU increased exponentially during the first wave of COVID-19 and it is positively correlated with the COVID-19 numbers.

Fig. 1: COVID-19 new infection cases and the US EPU

Figure 2 highlights that the death ratio has continuously increased, with a similar trend as that of the EPU index.

Fig. 2: COVID-19 death ratio and the US EPU

Our daily data are extracted from the WHO situation reports and refer to the new reported cases of infection and death ratio. The EPU statistics come from Baker et al. (2016) - http://www.policyuncertainty.com/us_daily.html, whereas the WTI crude oil prices are obtained from the US Energy Information Administration. All series are expressed in natural log.

Empirical Investigation

Methodology

Given that our series are either I(0) and I(1) (Table 1), we use the ARDL model proposed by Pesaran et al. (2001) to investigate the relationship between the retained variables.

Table 1: ADF unit root test

	EPU	**COVID-19$_{TNC}$**	**COVID-19$_{NCOC}$**	**COVID-19$_{TDR}$**	**COVID-19$_{DROC}$**	**WTI**
Level	-3.224**	-3.692***	0.541	-5.843***	0.079	1.276
First difference	-11.69***	-13.31***	-7.413***	-8.359***	-6.946***	-9.071***

*Notes: (i) ***, ** and * means significance at 1%, 5% and 10%; (ii) the optimal lag selection is based on AIC information criterion; (iii) COVID-19$_{TNC}$ refers to total new infection cases, COVID-19$_{NCOC}$ shows the new cases reported outside China, COVID-19$_{TDR}$ is the total death ratio, COVID-19$_{DROC}$ is the death ratio outside China.*

We therefore test the following specification that integrates the short-run adjustments into the long-run equilibrium (Albulescu, 2015):

$$\Delta EPU_t = c + \delta_{EPU} EPU_{t-1} + \delta_{COVID\text{-}19} COVID\text{-}19_t + \delta_{oil} Oil_{t-1} + \sum_{i=1}^{p} \alpha_i \Delta EPU_{t-i} + \sum_{i=1}^{p} \beta_i \Delta COVID\text{-}19_{t-i} + \sum_{i=0}^{p} \gamma_i \Delta Oil_{t-i} + \theta ECT_{t-i} + \varepsilon_t \quad (1)$$

where: (i) Δ and δ are short- and long-run terms respectively (ii) "i" represents the maximum number of lags, (iii) the error correction adjustment term is denoted by ECT and the speed of adjustment is ϑ, (iv) ε is the error term.

Results

We first validate the existence of the long-run relationship applying the bound test (Tiwari and Albulescu, 2016). The bound analysis shows in all cases the existence of cointegration (Table 2).

Table 2: Bound test results

Model specification	F-statistic	**Critical values**		Conclusion
		Lower bound (I(0))	Upper bound (I(1))	
COVID-19$_{TNC}$	10.54	3.10	3.87	cointegration
COVID-19$_{NCOC}$	12.64	3.10	3.87	cointegration
COVID-19$_{TDR}$	10.36	3.10	3.87	cointegration
COVID-19$_{DROC}$	11.53	3.10	3.87	cointegration

Notes: (i) Critical values at 5% significance level; (ii) COVID-19$_{TNC}$ refers to total new infection cases, COVID-19$_{NCOC}$ shows the new cases reported outside China, COVID-19$_{TDR}$ is the total death ratio, COVID-19$_{DROC}$ is the death ratio outside China.

In the second step (Table 3), we present the results of the ARDL estimations for the four models we test, considering the total new infection cases (Model 1), the new cases reported outside China (Model 2), the total death

ratio (Model 3) and the death ratio outside China (Model 4). The first model shows that at equilibrium (long run), the total new infection cases had no effect on the US EPU, but a decrease of crude oil price leaded to a higher uncertainty, as expected. The short-run results show no impact of COVID-19 figures and WTI prices on the US EPU. However, the situation is different for Model 2, where the new infection cases reported outside China increased the uncertainty. At the same time, Model 4 shows that an increase of 1% in the logarithmic level of the death ratio recorded outside China, leaded to an increase of 0.18% of the uncertainty index in the long run. This result remains robust when we use the BRENT crude as a *proxy* for the international oil prices (these results can be provided by the author, upon request).

Table 3: Results of the ARDL specification

	Model 1: COVID-19$_{TNC}$	**Model 2: COVID-19$_{NCOC}$**	**Model 3: COVID-19$_{TDR}$**	**Model 4: COVID-19$_{DROC}$**
Long-run equation				
COVID-19$_{t+1}$	0.040	0.068**	0.057	0.182*
WTI$_t$	-2.208***	-1.426**	-2.401***	-1.240*
c	13.06***	10.00***	13.97***	9.431***
Short-run equation				
ΔEPU$_{t-1}$	0.456*	0.481**		
ΔCOVID-19$_{t+1}$		-0.010		
ΔCOVID-19$_{t-1}$			0.018	
WTI$_{t-1}$			-0.921	-0.878
ECTt	-0.947***	-1.017***	-0.958***	-0.992***
Tests on residuals				
Serial correlation	NO	NO	NO	NO
ARCH effects	NO	NO	NO	NO
Notes: (i) ***, ** and * means significance at 1%, 5% and 10%; (ii) Breusch-Godfrey LM test for serial correlation is used; (iii) ARCH effects for conditional heteroscedasticity (with 4 lags).				

Conclusions

The rapid propagation of COVID-19 pandemic generates shock waves on the financial and commodity markets, as well as in the real economy. The depth of the new economic downturn will depend on the policy response to the coronavirus crisis. This paper investigates how COVID-19 official numbers (new infection cases and death ratio) affect the US EPU.

The findings show that the global COVID-19 numbers have no significant impact on the US EPU. Nevertheless, these results are largely influence by the situation reported in China, which seems to win the fight against the virus. When we assess the situation outside China, we clearly notice a positive influence of COVID-19 numbers on the US EPU. We therefore underline an amplification of COVID-19 risk to financial and real economy, generated by an increased, policy-induced economic uncertainty in the US.

Technical Modernization of Weapon Systems

Kazimierz KOWALSKI

General Tadeusz Kościuszko Military Uniersity of Land Forces, Faculty of Management, Wroclaw, Poland, kazimierz.kowalski@awl.edu.pl

Abstract

Problems of modernization of weapon systems in their life cycle are presented in the paper. In the introduction he inevitability of the modernization process of crucial weapon systems was emphasized. Furthermore, the concept of weapon system, life cycle of the weapon system and modernization of weapon systems where presented. The main part of the paper was focused on the objective need of modernization of weapon systems, and in particular types of weapons. A proposal to determine the level and efficiency of modernization of weapon systems where presented. Determination of the efficiency index of the modernization of the weapon system was proposed. Some data regarding the upgrade of the Leopard 2A4 tank to the Leo2PL version was presented. In the end the significance of the modernization process in the life cycle of weapon systems was emphasized due to, above all, the significant costs of the modernization process and the inevitability of the modernization process of key weapon systems that are characterized by at least 30 years of an operational and maintenance phase lasting.

Keywords: Modernization, Weapon System, Life Cycle.

Introduction

The issues of life-cycle management of man-made systems are described by extensive world and national literature (Stark 2011; Mitkow 2013).

NATO pays considerable attention to issues related to the life cycle of defense systems. As part of NATO's organizational structures, there is the Life Cycle Management Group (AC / 327), which has developed a number of strategic level documents describing the issues of rational management of defense systems life cycle. The basic document in this area is the publication of the Allied Administration AAP-48, which is the implementation guidelines for NATO Policy in the field of Systemic Life Cycle Management (SLCM). This publication describes the activities, methods and techniques required to implement NATO SLCM policy.

AAP-48 translates the principles of NATO policy in the SLCM area into a common framework based on the ISO / IEC 15288 civil standard (Systems Engineering - System Life Cycle Processes) describing the working methodology and integrated approach to life cycle management for defense capabilities in NATO.

Rational management of the life cycle of defense systems (including weapon systems - WS) is extremely important due to the very high costs of the life cycle of these systems (reaching tens of billions of zlotys) (Kowalski 2012).

The inevitability of the modernization process of crucial weapon systems is primarily due to their at least 30 years of operation. During this time, at least two factors affect the failure to adapt their ability to current requirements. The first is the changing threat that these systems should counteract, and the second is continuous technical progress enabling improvement of key parameters affecting capabilities of these systems.

As it results from the above, it is necessary to implement actions aimed at adapting the capabilities of weapon systems to current requirements of modern battlefields.

Cite this Article as: Kazimierz KOWALSKI "Technical Modernization of Weapon Systems" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The modernization of weapon systems is seen through the modernization of their key subsystem - a type of military equipment. That is why in the further part of the article the concept of modernization of the WS and modernization of military equipment is presented similarly.

Therefore, a research question was asked: how to avoid the problem of underestimating the costs of training in project management? Empirical research was preceded by literature studies (in-depth desk research); then, case studies of military projects were carried out. The obtained results were additionally confronted with the experts' statements (i.e., project managers and members of project teams) from the IT, banking, logistics, financial, and development/construction sectors. The research was conducted in the years 2018-2020. The preliminary analytical work results allowed for the following hypothesis: there is a possibility of eliminating the problem of underestimating the costs of training in project management by using the multidimensional analysis of "STOP costs." The hypothesis will be verified in the course of further research aimed at determining the effectiveness of the tools as mentioned above in business practice.

The Weapon System

There are many definitions of “system” in the literature on the subject. One of the broadest conceptually and shortest at the same time states that "The system is a being (B) manifesting its existence through the synergistic interaction of its elements (E)" (Cempel 2008). Mathematical definition, defines the system (S) as a set (set, complex) of interacting elements (E) constituting a deliberately oriented whole.

$$S = B\,(E, A, R), \quad E = [E1, ..., En], \quad A = [A1, ..., Am], \quad R = [R1, ..., Rk] \qquad (1)$$

where: S – a system,
E – a set of a system elements,
A – a set of attributes (properties),
R – a set of relations between elements and attributes.

The WS is defined as a set of cooperating weapon types (along with their related equipment) with personnel, material and technical means, services and means of transport/shipment (if required). The above-mentioned elements are to ensure self-sufficiency of the weapon system, defined by the type of weaponry, in operation (after: http // www.jcs.mil / Doctrine / DOD-Terminology) (DOD Dictionary 2020). A graphic presentation of the concept of weapon system is shown in Fig. 1.

Fig. 1: The idea of weapon system

Source: Own study based on (DOD Dictionary 2020)

Life Cycle of Weapon Systems

In NATO, by adapting the classification set out in ISO / IEC 15288, the entire product life cycle has been divided into six stages: concept, development, production, use, support, withdrawal, Fig. 2.

Fig. 2: Illustration of systems life cycle processes
Source: Own study based on (NATO Standard AAP-48 2013)

However, according to the model adopted by the Polish Ministry of National Defense, the life cycle model of the WS includes the following phases and stages (Fig. 3):

1) identification phase - implemented as part of the Operational Needs Review, comprising the stages of:

   a) identification of needs for operational capabilities,
   b) defining operational requirements,
2) analytical and conceptual phase, including the determination of feasibility,
3) implementation phase, including stages:
   a) definition of design assumptions,
   b) design and development,
   c) production and acquisition,
4) operation and maintenance phase, including the stages:
   a) implementation of weapon systems into the Armed Forces,
   b) operation and maintenance of WS, including:
      - utilization,
      - material and technical support,
      - withdrawal of weapon systems from utilization in armed forces.
5) removal phase, including the stages:
   a) removal from the operating environment,
   b) liquidation.

Fig. 3: Graphical presentation of weapon systems life cycle processes in Polish Armed Forces
Source: Own study based on (Decision No. 141 2017).

WS modernization process in its life cycle is generally carried out in two phases, realization and O&M. In the realization phase, in the area of modernization, it is important to design the future WS in such a way that its further rational development is possible. In particular, it is about the possibility of increasing the capabilities of WS by replacing critical modules (assemblies, subassemblies).

The modernization process in the O&M phase consists in physical changes of the WS in the form of interference in the existing WS structure aimed at improving the WS (increasing its capability). The modernization process in the O&M phase should be planned when the WS life cycle model is developing, and in particular when the SPW life cycle cost is estimating (Kowalski, Wojciechowski 2012).

The completion of the last stage of the WS life cycle in the Polish Armed Forces is subject to its decommissioning, if it does not meet the requirements of the Armed Forces due to at least one of the following conditions:

- utilize worktime standard,
- physical wear and tear, preventing further use when the repair is unprofitable or impossible,
- combat, technical and operational parameters that do not meet the requirements of the army when **modernization is unprofitable or impossible**,
- organizational and regular post changes in the Armed Forces, resulting in no prospects for the WS further operation.

Modernization of Weapon Systems

According to the current nomenclature in the Armed Forces of the Republic of Poland (DD-4.22A 2017), the increase in the capabilities of WS can be achieved through the process of its modification or modernization.

Modification is understood as the process of improvement of WS, consisting in the exchange, replacement or extension of existing components, functions or software without changing its principal purpose. As a result of the modification, no new WS is created (i.e. it maintains its existing material index).

Whereas, the modernization process, which is also a process of improvement of WS, involves changing its operational parameters. Especially critical operational parameters. As a result of this process, new WS is created (receives a new material index).

As follows from the above, the modernization of WS significantly changes its capabilities and is a much more complex and costly process than the modification process. Therefore, the frequency of execution of the WS modification process is definitely greater than its modernization.

Thus, the essence of the modernization of WS is to increase its capability - combat value , Fig. 4. Combat value (combat values, utilitarian values, qualitative values and other values), resultant of all features of the tested military equipment, i.e. tactical and technical parameters, reliability, durability, technological solutions and the ability to perform various combat tasks regardless of terrain and weather conditions (Wołejszo 2000).

Fig. 4: Graphical presentation of the process of modernizing a weapon system (the meaning of symbols in the text)

Source: Own study

The initial combat value of WS is WB_0 at the time of its entry into service. The decrease the combat value of WS during its operation is symbolized by the A_1 curve. This decrease continues to the contractual allowable level of combat value (WB_{min1}). In order to prevent exceeding the allowable level of combat value, the modernization process (M_1) is carried out, thanks to which the combat value of WS increases to the value of WB_{mod1}. A significant fact is that the level of combat value of military equipment after modernization (WB_{mod1}) is higher than its initial level of combat value (WB_0). The relationships presented above are repeated in time (WB_{min2}, WB_{min3} - admissible levels of combat value decline after modernization of M_2 and M_3; A_2, A_3 - curves of the decrease in combat value after modernization of M_2 and M_3; M_2, M_3 - subsequent modernizations; WB_{mod2}, WB_{mod3} – a level of military equipment combat value after the modernization M_2 and M_3).

Of course, the cyclicity of changes is not equal for each time interval. Also the lines symbolizing the change (increase) in the level of allowable combat value (line C) and the level of combat value after modernization (line B) may correspond to the value of various functions (this is not always a linear function as shown in the Fig. 4).

It should be noted that the absolute increase in the level of combat value of WS obtained as a result of the modernization process is definitely greater than the increase obtained as a result of the modification process.

Assessing WS in the O&M phase in terms of the possibility of modernization, WS can be divided into three basic categories:

1. Modern WS that meets the requirements, not being modernized.
2. WS that meets the requirements to a limited extent, with modernization potential justifying its further operation.
3. Obsolete WS that does not meet the requirements and does not have the modernization potential justifying its further rational operation.

Need for Modernization of Weapon Systems

The need to modernize weapon systems is mainly due to a gap in its capabilities. The capability gap is defined by the extent to which the established action plan cannot be met by current WS. Such a gap may be due to a lack of

capability, non-compliance of existing capability solutions and / or the need to replace existing capability solutions with those that will prevent future threats.

Operational requirements often require more capabilities than the weapons system can provide. The capability gap describes the difference between the capabilities of the weapon system and operational requirements. The purpose of assessing the capability gap is to identify its size and identify weaknesses in the weapon system (including support equipment). The capability gap analysis mainly covers two aspects. The first, in response to the functional needs of this capability, is to assess the capabilities of the weapon system. The second aspect is to compare the status of required capabilities and fulfill capabilities in all considered categories one by one. The comparison of status should follow criteria such as "being able to support well", "being able to support under certain conditions" and "not being able to support". At the same time, an analysis should be carried out whether the first two criteria will ensure that the required capabilities are obtained (Dong, Daguo, Yang et al. 2018).

Determining the level of modernization of weapon systems

Improving weapon systems raises the question of effectiveness and efficiency of this process. The effectiveness of modernization should be defined as an action that leads to the intended effect of the purpose of this action. Therefore, an effective action will be such action as a result of which the set goal has been achieved (100%). Effectiveness can be equated with the rationality of action. The action is considered rational, taking into account the criteria of praxeology, when the methods and means adopted by the subject of the action lead to the achievement of the intended goal.

The measurable intended effect of the modernization of WS may be the combat value of WS after modernization.

The combat value of WS in relation to combat vehicles (tanks, infantry fighting vehicles, armored personnel carriers) is calculated based on specific indicators. These indicators reflect the critical characteristics of a specific combat vehicle. These critical features include: firepower, mobility and survivability (Halota, Kurpas 2016). In tactical terms, mobility is equated with maneuverability. Mobility is classified into three categories: strategic mobility, operational mobility and tactical mobility.

To calculate the combat value of combat vehicles in the Polish Armed Forces, a universal combat value assessment methodology is used, based on the Techniqe for Assessing Comperative Force Modernization (TASCFORM) method. This method is based on an estimated comparison of the modernity of individual systems using Equipment Potential Capability Comparison (EPOCC) standard.

A detailed methodology for calculating the combat value of a combat vehicle (e.g. tanks) is presented in (Magier 2016)). The outline of the aforementioned methodology is presented below in a demonstrative manner, as well as factors that determine the critical values of combat vehicles in more detail.

According to the above method, the combat value of a combat vehicle is calculated from the formula:

$$WB = S_{og} \cdot M_{an} \cdot P_{rz} \tag{2}$$

where: WB – combat value,
S_{og} – firepower,
M_{an} – mobility,
P_{rz} – survivability.

Combat vehicle firepower is understood as a set of factors determining the quantity, quality and effectiveness of the basic armament (e.g. tank cannon) and associated systems and subsystems. The firepower is calculated from the formula:

$$S_{og} = W_{ba} \cdot R_{fn} \cdot SKO \tag{3}$$

where: S_{og} – firepower,

W_{ba} – cannon combat value,
R_{fn} – indicator of fire intensity increase,
SKO – indicator of quality of the Fire Control System.

Maneuverability of combat vehicles means the ability to move in a tactical and operational sense, as well as an element of active defense. It is a very broad concept and in the general case determines the agility and maneuverability of the vehicle and the ability to overcome terrain in all conditions (Błaszczyk, Papliński, Rybak 2004). This property is increasingly important for the survival of combat vehicles (especially infantry fighting vehicles and tanks) during combat. The maneuverability of combat vehicles is determined by:

- the ability to reach maximum and average travel speeds in various climate and road conditions, especially average off-road speeds, both in forward and reverse,
- driving range on one refueling in any field conditions,
- ability to overcome various terrain, natural and artificial obstacles (vertical walls, ditches, hills, etc.), including overcoming fords and deep water obstacles and terrain contaminated with weapons of mass destruction,
- the quality of the propulsion unit and the type of propulsion system used,
- ease of steering (type of steering mechanism and main brakes),
- the type and quality of the suspension and the track mechanism, including smooth terrain while traveling at any speed,
- adapted for long-distance transport (transportability),
- the ability to self-digging and paving passages in the minefield.

Maneuverability, in the adopted methodology, is determined from the relationship:

$$M_{an} = 1 + k_{jed}/100 \cdot X_{el} \tag{4}$$

where: M_{an} – maneuverability,
k_{jed} – unit power factor [kW/t],
X_{el} – engine flexibility coefficient.

It should be noted that the NATO has a "maneuverability model" version (2) MRMMZ - Field Standards Database (map sheet 5322 Lauterbuch-Germany). The decisive parameter here is the pressure on the soil calculated according to the empirical formula (Halota, Kurpas 2016). The main mobility parameter is described in the above model, as the proportion of track contact length with the ground to the distance between track centers. This parameter should be between the values 1.41 ÷ 1.78. Examples, coefficient values for selected combat vehicles are:

- T-72 tank and derivatives - 1,43,
- Leopard 2 tank - 1,57,
- AHS Krab Self-Propelled Howitzer SPH - 1,67.

Survivability is a characteristic that characterizes the survival ability of a combat vehicle (functional capability retained) and its crew in the event of a hit. The main role in determining this feature is the armor which is characterized by a number of attributes and additional protection systems. Survival can be characterized by the following information:

- the type of material used for armor protection (armored steel, light alloys, composite materials, etc.) and processing technology,
- the thickness of individual armor plates (armor knots),
- the method of making basic armor knots (welding, casting, layering, etc.) and the method of joining them,
- armor plate inclination angles,
- degree of radiation weakening,
- geometrical dimensions of a combat vehicle (height x width x length),
- data on the armor of "weak links" inside the combat vehicle (e.g. ammunition stores, fuel tanks, etc.),
- how to cover the outer surface of the armor that reduces radiation,

- data on the system of protection against weapons of mass destruction and the fire and explosion system used.

The list of combat values of selected tanks, calculated using the EPOCC methodology, is presented in the Tab. 1.

Table 1: combat value list for selected tanks

Feature/Tank	M-1A1	L2A4	Leo-2A5	T-64B	T-72M	T-80U	Chall-2	PT-91M
Sog	71,87	57,37	70,02	9,98	14,15	40,15	59,54	27,67
Man	1,23	1,2	1,2	1,13	1,14	1,25	1,14	1,14
Prz	0,11	0,1	0,1	0,08	0,08	0,09	0,12	0,09
WB	**9,72**	**6,88**	**8,40**	**0,90**	**1,29**	**4,52**	**8,15**	**2,84**

Source: Own study based on (Magier, 2016)

As it results from the presented data (Tab. 1), as a result of the modernization of the Leopard 2A4 tank to the Leopard 2A5 version, its combat value was increased by 1.52. However, the modernization of the T-72M tank to the PT-91M version resulted in an increase in its combat value of 1.55. Which in percentage in the first case meant an increase of 22%, in the second case the combat value increased by as much as 120%.

Determining the effectiveness of modernization of weapon systems

In general, effectiveness is a measure of the expenditure incurred for the effects obtained (Jałowiec 2013). In relation to modernization, the measurement of its effectiveness will consist in determining measurable indicators that will enable it to be determined. Costs can be a measurable measure of the expenditure of modernizing weapon systems, expressed in monetary units, incurred in connection with modernization activities. On the other hand, the obtained effect, as a result of modernization, can be a new measurable combat value of WS (usually higher).

$$E_{MOD} = \frac{NK}{WB_2 - WB_1} \tag{5}$$

where: E_{MOD} – effectiveness of modernization,
NK – financial expenses for modernization (currency),
WB_1 – combat value before modernization,
WB_2 – combat value after modernization.

Of course, it is possible to achieve other effects (primary or secondary) such as e.g. obtaining the ability to perform selected operational processes or even maintaining the ability to perform them.

In order to compare the effectiveness of modernization of the same type of WS, expenditure should be related to standardized effects (e.g. increase in combat value by 1.00).

Due to the inability to obtain reliable data (in generally available sources, data on modernization costs are very dispersed and shared with other costs) in the article it was not decided to determine the estimated efficiency values of modernization of military equipment.

However, based on reliable information from the Ministry of National Defense, we can estimate the value of the Polish upgrade of the Leopard2A4 tank to the Leo2PL standard. The scope of modernization works will allow to increase ballistic resistance and improve observation systems to the level offered by variant 2A5 or higher (Wilk 2018]. It can therefore be assumed that the combat value of the Leo2PL tank will not be lower than the Leo2A4 tank.

Taking into account the above assumption (increase in the combat value by 1.52) and the amount of the modernization contract amounting to PLN 2.415 billion for 128 Leo2A4 tanks, we can calculate the effectiveness of the modernization as costs of the increase in the combat value by 1.00. In this case, the costs of increase in the combat value by 1.00 amount to PLN 12.433 million.

Conclusion

Modernization of weapon systems is inevitable due to a minimum of 30 years of their life cycle in the armed forces. We should evaluate the modernization of weapon systems in the category of its effectiveness, i.e. the expenditure incurred on the results obtained (intended or not). The main assumed effect of the modernization of the WS is usually an increase in its combat value. Nevertheless, in many cases, the purpose of modernization is also to acquire the ability of domestic industry to implement specific processes of operation of the modernized weapon system.

In the presented modernization of the Leopard2A4 tank to the Leo2PL version, the increase by 1.00 in combat value "costing" PLN 12.433 million relates to the weapon system, whose main subsystem is the Leo2PL tank. The above amount includes costs incurred, inter alia, for the modernization of trainers, training of operational staff, technical documentation and others. This cost also includes expenses incurred for the R&D upgrade phase, which will not be taken into account for potentially subsequent upgraded Leopard2A4 tanks.

The classic approach to calculating the combat value of combat vehicles (tanks, infantry fighting vehicles) takes into account three key critical features: firepower, mobility and survivability. Due to the growing importance of conducting combat operations in an urbanized environment, it seems reasonable to include, in calculating the combat value of combat vehicles, an additional critical feature which is the operational (tactical) awareness of the combat vehicle crew.

Annotation

Enterprise potential management, as a specific function of management, is implemented by planning the development of enterprise potential, organizing the process of its formation and use, motivating management to rational use of enterprise potential, as well as controlling and regulating the formation and use of capacity. It should be recognized that despite the high level of formalization of the process-functional approach to managing the potential of the enterprise today the object of management is rather poorly formalized, namely - the potential of the enterprise. Due to the diversity of potentials there is a large number of types of their development. The article proposes a system of principles of capacity management in the coordinate system of organizational development. The list of principles is formed so as to level the diversity of potentials of the enterprise, and the coordinate system of organizational development is considered as one that integrates different types of development into one whole.

Keywords: Potential, Management, Organizational Development, Organizational Change, Enterprise.

Introduction

The development of any business depends on its potential. It should be recognized that, regardless of the type of activity of enterprises, their form of ownership, as well as size, there are certain components of the potential of enterprises that are common to all entities, as well as those that are unique to specific enterprises. This indicates that the potential of the enterprise is a rather complex object of management, which requires technical and technological, information and communication, intellectual and organizational development. The coordinate system of organizational development has an integrative character. It determines the rationality of the formation and use of the enterprise potential. Given this, the urgent task for business leaders is to identify the principles of managing the potential of the enterprise in the coordinate system of organizational development. Unfortunately, nowadays, these principles have been studied in a rather fragmented manner, which indicates the incompleteness of the theory of enterprise capacity management.

Literature Review

The concept of "organizational development" is quite diverse. It is considered as organizational change, as a system of scientific and methodological justification for the preparation and implementation of organizational change, as a set of processes that accompany organizational change, as well as a strategy of enterprise behaviour in the market. Thus, Shcherbyna V. and Popova E. studying organizational development, come to the conclusion that "a stable core of organizational development is the quality of changes that occur, which is determined by the socio-cultural specifics of the organization" (Shcherbyna V., Popova E., 1996). Melnyk S. understands organizational development as "an organized process that disrupts the dynamic development of the organization's structure and directions for achieving a new state of dynamic equilibrium, which will be maintained relatively stably in the renewed structure" (Melnyk S., 2009).

Totsky V. and Lavrenenko V. define organizational development as "a long-term, thorough, comprehensive process of change and development of the organization (enterprise) and the people working in it ...", and also allocate structural (creation of favourable framework conditions for achieving the goals of organizational development through changes in regulation) and personnel (measures for staff development and their incentives for change) aspects (Totsky V., Lavrenenko V., 2005). Gerasymchuk V. considers organizational development as "a large-scale, planned systematized process in the enterprise, which responds to changes in the environment - internal and external" (Gerasymchuk V., 1995).

Novak V. and Rodchenko V. define organizational development as "a process of comprehensive organizational improvement of the system, the purpose of which is to streamline the components of economic activity and transform various parts of the system to maintain long-term life and adapt to changes in the environment" (Novak V., Rodchenko V. , 2009). Kolesnikov G. considers organizational development as a process of improving "formal and informal aspects of organizational activities", highlighting among the formal: organizational management structure, management processes, distribution and coordination of rights, duties, responsibilities, organization of work of managers and others. The informal side of organizational activities includes the improvement of knowledge, skills and experience, i.e. training, career growth using effective methods of motivation and formation of corporate culture (Kolesnikov G., 2007). At the same time, Shvindina G. argues that organizational development is a part of the overall strategy of the organization, and the very strategy of organizational development means a system of "direct actions and long-term programmes to initiate and implement constructive changes in organizational architecture for the success of the organization and its members" (Shvindina G., 2016).

The team of authors believes that from the standpoint of a structural approach, organizational development can be presented in such a sequence as: "values, organizational culture, culture of organization, organizational climate, organizational behaviour, organizational interaction" (Gudzynsky, O., Sudomyr, S., Gudzynska, Yu 2012).

Gorbatovska N. considering the theoretical foundations of organizational development of the enterprise in modern conditions of variable environment, defines it as "an organized process that disrupts the dynamic development of the organization and aimed at achieving a new state of dynamic equilibrium, which in the updated structure will be relatively stable" (Gorbatovska N. ., 2012).

Amelina I. considering the theoretical foundations of organizational development of the enterprise in modern conditions of variable environment, defines it as "an organized process that disrupts the dynamic development of the organization and aimed at achieving a new state of dynamic equilibrium, which in the updated structure will remain relatively stable" ., 2008).

Ladonko L. and Tikhun I. examining existing approaches to defining the essence and goals of the process of organizational development, identified the place and role of strategic organizational changes in innovative development of the enterprise, and reflected the relationship and differences between organizational change and organizational development for a number of factors: level of managerial decision-making, duration of influence, scale of actions, social orientation of the process (Ladonko L., Tikhun I., 2014).

It should be noted that despite the existence of the relationship and interdependence between organizational development and organizational change, but not all organizational change characterizes development, but organizational development is always a change, i.e. the very concept of development involves the implementation of organizational changes that ensure development enterprises.

Thus, organizational development is considered as: a set of concepts and models (theoretical basis) of organizational development; the process of qualitative and structural changes in the organization; practical activities to improve the organization; development strategy.

Thus, organizational development is characterized by the following properties: focus on the medium and long term, focus on the process of change (development), the introduction of change methodology, staff involvement in the process, the use of various methods to achieve goals.

Studies that cover the problems of organizational development have a fairly wide range of subjects that they cover. Nevertheless, they can be divided into those that relate exclusively to theoretical aspects of organizational development (Legeza N., 2019) and those that have a deeply applied focus. Today, most studies belong to the second group. Thus, the authors who study organizational development consider it in the system of assessing the creditworthiness of enterprises, as a stage of technology of financial and analytical management, a component of legitimizing the use of unmanned aerial vehicles, tools for innovation management, a tool for overcoming destructive phenomena in personnel management. empirical and expert evaluation and data analysis.

Zabrodska G.I. and Zabrodska L.D. combining different visions of the essence of this concept rightly note that, " organizational development is a scientific and methodological support for the implementation of long-term programmes of qualitative organizational change, using a systematic set of business processes that adapt to external conditions and internal integration and ensure growth efficiency of functioning and achievement of the purposes of the organization, by perfection of processes of the decision of problems and updating therefore increase of potential of the enterprise is provided… "(Zabrodska G., Zabrodska L., 2017). Agreeing in general with the above interpretation, we note that organizational change is largely beyond the strategic development of the enterprise, and is often implemented at the tactical and operational levels. In addition, it should be noted that organizational change cannot be limited to scientific and methodological support for their implementation.

Organizational decisions should be considered through the prism of the theory and practice of management decisions, as organizational decisions are their subspecies. The scientific literature traditionally distinguishes the stages of technology for making management decisions, namely (Kniaz S., Kulyk Y., Zinkevych D., 2009): formation (identification of the problem situation, analysis of factors that caused the problem situation, consideration of alternative solutions to the identified problems), selection (selection of criteria or criteria by which to choose the best solution from a number of alternatives, analysis of existing alternatives based on the selected criterion (criteria)), approval (documentation of the chosen solution and bringing it to the performers) and implementation (creation of conditions to implement the decision, control and regulate the process of execution of the decision) decision. These stages are also characteristic of organizational decisions. In view of this, organizational changes are a consequence of scientific and methodological support not only for the implementation but also for the formation, selection and adoption of organizational decisions (Kniaz S. et al., 2019).

Purpose of Research

The purpose of the article is to identify and reveal the economic and managerial essence of the principles of enterprise potential management in the coordinate system of organizational development. To achieve this goal, you must perform the following tasks:

- specify the place of the potential of the enterprise in the coordinate system of organizational development;
- identify the starting points of capacity management and establish relationships between them.

Results of the research. As a result of review and analysis of scientific literature there is a reason to say that in the management system of enterprise potential organizational development is a consequence of organizational decisions that can be implemented in three vectors, namely: the vector of organizational structure of enterprise capacity management, the vector of distribution of functions and powers subjects of the management system for managing the potential of the enterprise, as well as the vector of formation and implementation of rules and procedures in the management system of the enterprise relating to the management of the potential of the enterprise. Fig. 1. shows the place of the potential of the enterprise in the coordinate system of organizational development. During the implementation of organizational decisions, the subjects of enterprise management receive information about changes in the characteristics of the object of organizational development, as well as management information from the external environment. On the basis of this information, corrective decisions can be made, often of a tactical and operational nature.

Managing the potential of the enterprise in the coordinate system of organizational development requires the adherence of management to a number of principles. Under the principles of enterprise potential management, we understand the rules, regulations, basic starting points that underlie the process of enterprise potential management and in accordance with which the company will develop. Examining the literature on this issue (Tkachenko S., 2014) found a fairly common approach to the classification of principles into two groups: 1 group - basic (general, general scientific) principles that must be followed at all levels of government; Group 2 – specific ones, which reflect the peculiarities of the functioning of the object of management.

Fig. 1: The place of the potential of the enterprise in the coordinate system of organizational development
Note: The dotted line shows the feedback from the object to the subjects of management, as well as the receipt of information from the environment to the subjects of management.

Thus, Tkachenko S., studying the processes of functioning of the elements of the subsystem of analytical information processing of functionally developed control systems, identifies a group of basic (system approach, new tasks, unification of design solutions, continuous development, minimization of input and output information, combination of functional and programme-target approach) and specific principles that are formed based on management tasks (Tkachenko S., 2014). However, the application of this approach to the division of principles in relation to the management of the potential of the enterprise into groups is considered inefficient and impractical. Krush P. and Boyko T. describing the components of the management system of production potential of the enterprise, among the principles on which the management system is based are such as, "systemic, reasonable, comprehensive, adaptive, purposeful, dynamic, optimal, predictable, flexible" (Krush P., Boyko T., 2015).

Lyzunova O. and Sirenko Yu. Studying the potential management of a metallurgical enterprise, the basic principles of production potential management include "optimality, objectivity, flexibility, complexity, realism, efficiency, adaptability, organizational innovation" (Lyzunova O., Sirenko Yu. , 2017).

Zakharenko M. among the basic principles of planning the potential of the enterprise refers to the coherence of strategic and current plans; social orientation of the plan; ranking of planning objects according to their importance; adequacy of planned indicators; consistency of the plan with the parameters of the external environment of the components of production potential; variability of the plan, its balance, validity, flexibility (Zakharenko M., 2018).

The author's vision of the classification of the principles of enterprise potential management is shown in Fig. 2, which is necessary to ensure the rationality of the approved organizational decisions.

Fig. 2: Principles of enterprise potential management:

The principle of economic efficiency and safety is also closely related to the principle of applying a scientific approach to managing the potential of the enterprise. In the scientific literature there are author's positions, which argue the feasibility of using an intuitive approach when making decisions of economic nature. The most famous in this direction is J. Soros (J. Soros, 1999), who on the example of the analysis of financial markets and his own

experience made a very successful attempt to put forward a theory of market reflectivity and explain that investors in organized currency and stock markets, decision to buy or the sale of assets is guided by intuition rather than common sense, which is based on deep economic analysis. Admittedly, we can partially agree with this author's theory. Nevertheless, this theory, firstly, applies exclusively to financial markets, and secondly, it reflects only part of reality. There are a number of researchers who use technical analysis of the dynamics of indicators that characterize financial markets and their arguments for decision-making by investors are much more convincing than those of Soros J. For example, Mandelbrot B., studying economics, found that price fluctuations can follow from a latent mathematical order that is not described by standard curves. This assumption was analyzed and proved on the basis of the fractal geometry developed by him. Later, fractal geometry formed the basis of technical analysis of financial markets (Mandelbrot B., Hudson R., 2006), (Williams B, 2000), (Schwager J., 2001). Malishenko K.A. rightly notes that "… fractal market analysis" is a new direction of market forecasting, which is based on the most advanced, of the currently existing, mathematical model. Unlike classical technical analysis, fractal analysis is a scientifically sound method of predicting the price…"(Malyshenko K., 2014).

Based on the above, we note that the application of a scientific approach to managing the potential of the enterprise allows on a systematic basis to analyze objectively the causal links between factors that link in one logical series the reason for the need to form the potential of the enterprise, its state, level of potential consistency of the available potential with the purposes of its formation. There is a reason to believe that the scientific approach is aimed at overcoming subjectivism in decision-making. This task is usually based on a combination of alternative methods of analysis, which allows you to verify the accuracy of the results of the analysis of factors and indicators, as well as through the application of the practice of collegial management decisions.

In the management of enterprise potential, the principle of economic efficiency and safety is basic and it is, to a large extent, related to all other principles. In this case, the essence of this principle should be understood as a bivector criterion, which, on the one hand, has a target - economic benefits from the formation and realization of enterprise potential, and, on the other hand, economic security of the enterprise. For businesses, economic benefits can usually take the form of making a profit, achieving an increase in the market value of equity or assets, acquiring ownership of certain property, including intellectual property rights, and gaining control over other businesses. In turn, economic security, as noted by Sosnovska I.M. "…is a level of protection of all types of enterprise potential from internal and external threats, which ensures stable operation and effective development and requires management by the company's management. The content of this concept includes a system of tools that ensure the competitiveness and economic stability of the enterprise, as well as contribute to improving the welfare of employees… "(Sosnovska I., 2015).

As rightly noted by Georgiadi N.G. "… Economic security reflects the actual and potential level of protection of confidential management information from disclosure, leakage and unauthorized access. The implementation of the principle of economic security in the management of the potential of the enterprise is largely influenced by factors such as financial and technological capabilities of the enterprise; its size and location; nomenclature of products; internal document management system; content, volume and types of confidential information, the level of information education of employees of the enterprise, etc.… "(Georgiadi N., 2009), (Georgiadi N. and others, 2019). In practice, the principle of economic efficiency and safety is implemented through the introduction of an integrated management system using multi-level, combined means of accumulation, storage, processing and use of management information. The introduction of these systems aims to combine automated algorithms for processing economic information with human capabilities of perception and interpretation of data based on poorly formalized factors of internal and external environments of the enterprise. The implementation of these tasks also involves the identification of possible sources of disclosure, leakage and unauthorized access to management information, as well as the development and implementation of measures to protect management information.

The principle of economic efficiency and safety in essence, to some extent, similar to the principle of rationality in the implementation of organizational changes in the management of enterprise potential. However, the concepts of "economic efficiency" and "rationality" are not identical. What they have in common is only the presence of benefit, expediency in application. However, the rationality of organizational change can be measured not by economic indicators, but only by management. For example, by accelerating the processing of management information, reducing interpersonal tension in the workforce, improving the level of perception of change in the organization, and so on. Achieving these and other management effects may be accompanied by certain costs, which in terms of economic efficiency is impractical, but from a managerial point of view is a necessity.

The principle of economic efficiency and safety is also closely related to the principle of applying a scientific approach to managing the potential of the enterprise. In the scientific literature there are author's positions, which argue the feasibility of using an intuitive approach when making decisions of economic nature. The most famous in this direction is J. Soros (J. Soros, 1999), who on the example of the analysis of financial markets and his own experience made a very successful attempt to put forward a theory of market reflectivity and explain that investors in organized currency and stock markets, deciding to buy or the sale of assets is guided by intuition rather than common sense, which is based on deep economic analysis. Admittedly, we can partially agree with this author's theory. Nevertheless, this theory, firstly, applies exclusively to financial markets, and secondly, it reflects only part of reality. There are a number of researchers who use technical analysis of the dynamics of indicators that characterize financial markets and their arguments for decision-making by investors are much more convincing than those of Soros J. For example, Mandelbrot B., studying economics, found that price fluctuations can follow from a latent mathematical order that is not described by standard curves. This assumption was analyzed and proved on the basis of the fractal geometry developed by him. Later, fractal geometry formed the basis of technical analysis of financial markets (Mandelbrot B., Hudson R., 2006), (Williams B, 2000), (Schwager J., 2001). Malishenko K.A. rightly notes that "… fractal market analysis" is a new direction of market forecasting, which is based on the most advanced, of the currently existing, mathematical model. Unlike classical technical analysis, fractal analysis is a scientifically sound method of predicting the price of… "(Malyshenko K., 2014).

Based on the above, we note that the application of a scientific approach to managing the potential of the enterprise allows on a systematic basis to objectively analyze the causal links between factors that link in one logical series the reason for the need to form the potential of the enterprise, its state, level of potential , consistency of the available potential with the purposes of its formation. There is reason to believe that the scientific approach is aimed at overcoming subjectivism in decision-making. This task is usually based on a combination of alternative methods of analysis, which allows you to verify the accuracy of the results of the analysis of factors and indicators, as well as through the application of the practice of collegial management decisions.

The following is the principle of focusing the management of enterprise potential on consumer needs of the market. The essence of this principle is that the primary source for establishing or adjusting the goals of forming and realizing the potential of the enterprise is its external environment, and specifically the target audience, i.e. existing and potential consumers of goods or services. Even Henry Ford, said that the purpose of the company is not to make a profit, but to meet consumer needs. He was convinced that only by meeting the needs of certain social groups it is possible to find their place in the market, by achieving a high level of competitiveness and, consequently, it is possible to make a profit (Ford G., 2017). Consumer needs, and especially their change, are indeed important management information that can be the basis for decisions on the formation of a new component of the company's potential or to adjust existing components of the company's potential. These solutions are usually innovative, as they require the use of new production technologies, innovative materials, development of innovative products, introduction of new vectors of work with the target audience in the market, the introduction of innovations in marketing and advertising strategies to promote new products to consumers. Given this, the principle of focusing the management of enterprise potential on consumer needs of the market is directly related to such principles as the principle of compliance with the created supply of goods under international quality standards, as well as the principle of stimulating creativity in managing enterprise potential. In the context of Ukraine's implementation of the course of European integration, especially in the period since the signing of the economic part of the Association Agreement between Ukraine and the EU, the following of the first of these principles is extremely important. The Association Agreement obliged Ukrainian producers, in particular those who are subjects of foreign economic relations with EU countries, to move to European quality standards. This led to the abolition of the so-called GOSTs in force in Ukraine until recently, which after the collapse of the USSR became interstate standards and led to the process of harmonization of DSTU with EU directives and regulations. For example, in the food market, the EU requirements for Ukraine are reduced to the implementation of the NASSP system (system of risk analysis, hazards and control of critical points). Statistics on the implementation of this system are in fact the answer to the question of Ukraine's compliance with EU directives on food safety and organic food. According to the State Food and Consumer Services, by the end of 2019, more than 200,000 enterprises in Ukraine were to implement NAASP, of which 4,540 enterprises had to be audited by the end of 2019. That is, in general, although with a certain slowdown, the implementation of EU standards in Ukrainian legislation is the same as in the implementation of enterprises. It should also be acknowledged that the fastest transition to EU standards is by exporting companies. As for the principle of stimulating creativity in managing the potential of the enterprise, its

essence is to create a creative environment in the team, which, on the one hand, contributes to the readiness of employees to change, and, on the other hand, is conducive to the promotion and implementation of creative ideas, their transformation into technological and product innovations. Practical adherence to this principle in practice is quite a challenge, as numerous studies indicate that many work teams are opposed to change. For employees of enterprises, changes and innovations are associated with the automation of production, job cuts, replacement of people with robots, and so on. In addition, the creation of an environment for employees to produce innovations requires the construction of a flexible system of personnel management, which would be able to: 1) recognize employees who can think creatively and employees who are valuable in clearly defined tasks, able to work in tightly regulated modes of conditions; 2) create appropriate conditions for productive work of both the first and second groups of employees; 3) identification of critical limits of productivity of employees in each of the groups; 4) organization of optimal forms of work of employees of different groups on the implementation of joint projects. Savitska N.V. examining the problems of formation and development of creative potential of enterprises rightly notes that, "… management of creative activity of the enterprise takes place at the strategic and tactical levels… most authors mistakenly identify creative management strategies with innovative strategies of enterprises new products and technologies, a strategy to expand the range of functionality and other properties of existing products and technologies, as well as a strategy to reduce the cost of existing products and technologies. The first of the strategies can be implemented both before and during the commercialization of innovations. In turn, the other two of the selected strategies can be implemented by enterprises only during the commercialization of innovations, in particular at the stage of improvement and modification of innovative products "(Savitska N., 2012). Thus, following the principle of stimulating creativity in the management of the potential of the enterprise requires the formation of the creative potential of the enterprise, building a strategy and tactics for managing it.

Another important principle of enterprise capacity management is to take into account the provisions of the concept of sustainable development. Enterprises are part of both components of sustainable development - the economy and society. Satisfying the consumer needs of society, companies often harm the environment. This is due to economic selfishness and irresponsibility of entrepreneurs to future generations for the opportunity to enjoy the benefits of nature, which are in today's generations (Kniaz S., 2016). The essence of this principle is to form and develop the potential of the enterprise so that the implementation of the goals set by the enterprise takes into account the needs of modern society, without compromising the ability of future generations to meet their needs.

Thus, based on the above, we conclude that the selected principles of enterprise potential management constitute a certain system of management visions (Fig. 3), the following of which will contribute to the rationality of the approved organizational decisions.

Fig. 3: The system of principles of enterprise potential management

Note: the numbering of the principles is the same as in fig. 2

The selected principles allow us to focus on the main areas of enterprise capacity management, which will ensure the rationality of the approved organizational decisions.

Conclusions

It is substantiated that the management of enterprise potential is not spontaneous, it is a purposeful process, to ensure the rationality of which it is necessary to apply a systematic approach, in particular in determining key priorities and making decisions on compliance with these priorities. Studies have shown that the basis of systematic management of enterprise potential is a number of interacting principles, namely: the principle of economic efficiency and safety of enterprise potential management; the principle of application of the scientific approach in management of the enterprise potential; the principle of orientation of management of the enterprise potential on consumer needs of the market; the principle of conformity of the created offer of the goods on the conditions of the international quality standards; the principle of stimulating creativity in managing of the enterprise potential; the principle of rationality in the implementation of organizational changes in the management of enterprise potential; the principle of taking into account the provisions of the concept of sustainable development in the management of enterprise potential.

Annotation

The potential of the enterprise is considered as a system of opportunities to achieve development goals within the functions defined by the structure of the enterprise. In turn, the management of the enterprise potential is disclosed as a specific function of management. It is proved that it is based on a specific object of management - of the enterprise potential. It is substantiated that the management of this object is carried out by the heads of the enterprise using management methods and technologies, the selection and application of which is carried out within the general management functions (planning, organizing, motivating, controlling and regulating). Since the potential of the enterprise is a complex object of management, which includes production, marketing, investment and other potentials, there is a reason to believe that the goals of managing the potential of the enterprise is a

complex, hierarchical system. Their implementation requires constant monitoring and regulation of the object of management.

Keywords: Enterprise, Potential, Management System, Functional Approach, Management Goals.

Introduction

The development of any business depends on its potential. At the same time, it should be recognized that regardless of the type of activity of enterprises, their form of ownership, as well as size, there are certain components of the potential of enterprises that are common to all businesses, and there are those that are specific to specific enterprises. Strictly speaking, this difference in potentials largely determines the vectors and intensity of enterprise development, their competitiveness and investment attractiveness. Nevertheless, it is known that among the total number of enterprises there are those that have a significant potential, but its implementation is low. This situation and the reasons for this may be due to both objective and subjective factors, in particular - irrational capacity management, underdeveloped system of organizational development, lack of signs of innovation in solving problems of management and engineering technology. The problem is not systematic and fragmentary theoretical and methodological and applied provisions for managing the potential of the enterprise in the coordinate system of organizational development.

Literature Review

Exploring the potential of enterprises, most economists focus on determining its essence and structure (Bykova N.V., 2011), (Rovenska V.V., 2012), (Piliavskyi V.I., 2019) problems of capacity formation and use, (Zbrodska O.V., 2011), (Hnatieva T. and Livinskii A., 2019), (Garayev M., 2019), (Shabatura T., 2019), (Dergachova V., Ovcharova S., & Martynenk, O., 2019) its evaluation (Kviatkovska L.A., 2011), (Boykivska G.M., 2011), (Zadneprovska G.I., 2015), (Burachek I., & Pravda O., 2015), (Dogadaylo Ya., 2017), (Vasylyk N.M., 2018), (Piletska S.T., Korytko T.Yu. 2018), (Azhaman I .A., Zhydko O.I., 2019), (Samorodov B.V., Saukh I.V., Vygovska N.G., 2019), (Sydorova A., & Hontjuk V., 2019)) and management (Shot A.P., 2009), (Durbalova N., Sedikova I., 2019) . Among these scientific works are those that are devoted to the study of the potential of the enterprise as a whole (Rovenska V.V., 2012), (Dogadaylo Ya., 2017), (Garayev M., 2019), as well as works in which such types of potentials, such as: anti-crisis (Piletska S.T., Korytko T.Yu. 2018), innovative (Zadneprovska G.I., 2015), (Piliavskyi V.I., 2019), competitive (Durbalova N., Sedikova I., 2019), economic (Azhaman I.A., Zhydkov O.I., 2019), (Shabatura T., 2**01**9), investment (Garayev M., 2019), resource (Zbrodska O.V., 2011), (Vasylyk N.M., 2018), financial (Samorodov B.V., Saukh I.V., Vygovska N.G., 2019), personnel (Shovkun L.V ., 2010), (Burachek I., & Pravda O., 2015), (Sydorova A., & Hontjuk V., 2019) and export (Stakhorskyi O.O., 2010), (Bykova N.V., 2011), (Dergachova V., Ovcharova S., & Martynenko, O., 2019). Based on the polyvector studies of the enterprise potential, we can say that their systematization and coordination with each other is quite uncertain. This highlights the problem of clarifying the essential characteristics and types of the enterprise potential.

The scientific literature considers both general aspects of the management process (planning, analysis, control, assessment of the level of use of components) and the model of enterprise potential management in particular (organization, evaluation, diagnosis, search for sources and reserves of components of enterprise potential) (Knyaz S., 2020). Thus, Luchkova M. considers the management of strategic potential and determines its following structure: determining the current level of use of strategic potential, assessing the level of use of strategic potential, making and implementing appropriate decisions on strategic potential management; control over the use of the strategic potential of the enterprise (Luchkova M.S., 2011). Vasylkivskyi D. examines the management of marketing potential of the enterprise and notes the sequence of actions: definition and formation of the structure of potential; analysis of competitive advantages and capabilities of the enterprise; identifying the interaction of each element of potential; integrated assessment of the competitiveness of the enterprise (Vasylkivskyi D.M., 2011). Otenko I. notes that the management of the economic potential of the enterprise is both current and strategic. Applying a functional approach, the author has formed a mechanism for managing the economic potential of the enterprise, the main functions of which are,"coordination; assessment and analysis; planned; motivation that promotes the activation of the processes of self-development of employees of the enterprise and the maximum return of creative and innovative potential of management staff and management; organization; monitoring and technological control (previous, guiding, subsequent); marketing ”(Otenko I.P., 2015). Authors Vasylieva T.A.,

Leono, S.V., Kryvych Y.M. researching management of innovative potential note that the management process itself is, "… a systematic, dynamic, planned and complex activity to ensure the strategic viability of the enterprise by finding creative ideas for introduction of new goods and services, as well as methods of their promotion through continuous improvement of technology, increasing competitiveness… "and describe the very sequence of the management system, highlighting the relevant stages: goal setting, diagnosis of innovation potential, development strategy for further development, monitoring and evaluation of results Vasylieva T.A., Leonov S.V., Kryvych J.M., 2011). Research on the formation and management of competitive potential was carried out by Petrovych J. and Lushchak N., who determined that the management of competitive potential is a complex process that must constantly change under the influence of innovative development of society and economy,but it must be provided with innovative content to improve product quality, optimization of technological processes, improving the organization of sales activities (Petrovych J., Lushchak N., 2011). Bozhanova O. researching theoretical approaches to managing the economic potential of the enterprise, substantiates the feasibility of using modern management concepts, including the interaction of systemic and situational approaches. Also, the author argues that the management of economic potential should be implemented through the implementation of specific and certain functions depending on the sectoral characteristics of enterprises, their size, organizational forms of activity (Bozhanova O., 2010). Tolpezhnikov R. proposed an organizational and economic mechanism of adapted management of the potential of an industrial enterprise, which is formed from a set of interdependent elements of internal potential (control unit and resource block) and micropotential (financial potential - financial and credit potential - market value) and adapted to external environment. Based on the functional approach, the author substantiates that the interaction of these components can provide a positive strategic effect (Tolpezhnikov R., 2012). Grabchuk O. and Bovsunovska G. formed a general scheme of enterprise potential management, which includes eight stages: formation of information base on potential management, analysis and selection of priorities from the enterprise mission in the formation of management strategy, evaluation of financial results, evaluation of enterprise potential, system definition relationships between financial results and enterprise potential, development of enterprise potential management strategy, implementation of enterprise potential management strategy using selected methods and tools, analysis and control of management strategy (Grabchuk O. and Bovsunovska G., 2016). Rzayev G. investigating the problematic issues of management, related to ensuring the effective use of enterprise potential, justifies the need for systematic monitoring of the level of enterprise potential, which will track changes in key external and internal factors, analyze performance, make adjustments to the management system potential of the enterprise (Rzayev G., 2014). Zakharenko M. the organizational and economic bases of formation of system of management of potential of the enterprise are considered, characteristic features of its elements which need to be considered at formation of potential and its further effective use are defined. The author highlighted in the management system of production potential of the subsystem: target; providing; managed and managing (Zakharenko M., 2018). Shandrivska O., Kuziak V. and Beck O. researching the approaches to management of enterprise potential and its strategic development described in scientific works, define it as "… process of acceptance and realization of the administrative decisions directed on an estimation and realization of possibilities of improvement of the enterprise potential, setting new value and ensuring the strategic development of the enterprise "and form an appropriate model for managing the strategic development of the enterprise, which contains such key elements as: formulating the mission of the enterprise, setting goals, forming a strategy for enterprise development, comprehensive analysis of enterprise potential (state and development, efficiency and formation), the formation of the optimal structure of potential on the basis of synergistic interaction of its components in accordance with the strategic goals of the enterprise, the choice of the most effective alternative to enterprise development, the formation of enterprise development strategy (Shandrivska O., Kuziak V. and Beck O., 2013). Gonchar O. studied the functional and organizational aspects of enterprise potential management on the basis of synergy and determined that the formation and improvement of enterprise potential are determined by the strength of the relationship and interaction of its elements, and taking into account the synergistic effect of enterprise potential elements will allow gaining competitive advantages, combinations of resources, increasing the value of the enterprise as a set of tangible and intangible assets, increasing the resilience of the economic system to uncertainties and risks that arise in the process of evolution "(Gonchar O., 2015).

Thus, in the theory and practice of modern management functional approach is quite popular.

Purpose of Research

The purpose of the article is to distinguish the stages of managing the formation of enterprise potential from the standpoint of a functional approach. To achieve this goal it is necessary: to clarify the essence of the concept of

"enterprise potential"; to reveal the essence of enterprise potential management from the standpoint of a functional approach.

Research results. The application of a functional approach is a necessary but insufficient condition for clarifying the essence of the concept of "enterprise potential". Thus, functions can be considered from the standpoint of management, production, technology and more. Given this, in addition to functional, it is advisable to use a structural-system approach.

Let's clarify the basic functional and structural characteristics that are relevant for any enterprise, as well as derivative functional and structural characteristics of enterprises (Table 1).

Table 1: Functional and structural characteristics of the enterprise

Features	Structures	Functions
Basic		
Management	Management system	Planning; organization; motivation; control; regulation
Production and technological	Production and technological system	- Procurement or creation of resources; - production; - sales
Derivatives		
Marketing	Marketing and advertising system	- Marketing and advertising management; - conducting marketing research and advertising campaigns
Logistics	Logistics system	- Resource flow management; - development of logistics structure
Innovative	The system of innovative activity of the enterprise	- Innovation management; - development and implementation of innovations
……	…….	…….
Information	Information support system	Information support management; - collection, processing, storage and use of information; - providing managers and subordinates of the enterprise with technical means and software products for the collection, processing, storage and use of information; - establishment of communications

On the basis of basic and derivative functionally structural characteristics of the enterprise it is possible to allocate and construct classification of potentials of the enterprise on a number of signs, namely:

by its content:

- management, production, marketing, logistics, innovation, information, etc. (these are the potentials of the enterprise to implement certain functions). Enterprises that work in the market for a long time usually have a developed structure. Each structural component of the enterprise implements one or more functions. To perform these functions in the structure of the enterprise they form the appropriate staff, develop strategies and tactics to achieve the goals set for employees, develop certain rules and procedures of subordination, formalize methods and technologies of functional implementation of this structural component. In turn, the functional and structural characteristics of newly established enterprises are quite limited. Often such enterprises have the most simplified structure, in which there are no structural components, but rather a functional division of responsibilities between employees for certain sectors of activity. Under such conditions, enterprises, for the most part, have only managerial and production potential);

by nature:

- basic (managerial and production) and derivative (all other potentials) potentials. Basic potentials are characteristic of all enterprises without exception, their presence is a condition for the functioning of any enterprise. As for the derivative potentials, they are typical for enterprises with developed management systems and production and technological systems;

according to the level of development of the functional structure of the enterprise:

- developed (high or low) potential (high potential occurs when the company owns and successfully uses a certain functional structure. In turn, in conditions when a certain functional structure exists but is poorly implemented, then there is a low potential);
- undeveloped (zero) potential (this type of potential occurs when the company does not implement a certain function and there is no appropriate structure for this).

Thus, the potential of the enterprise should be considered as a system of opportunities to achieve development goals within the functions defined by the structure of the enterprise. It should be recognized that the structure of the enterprise may be more or less developed, for example, despite the fact that any enterprise accumulates, stores, processes and uses information for engineering and technological and management decisions, but not all enterprises have an information system. The same applies to logistics systems, marketing and advertising, security, innovation, and so on. Based on this, there is a reason to believe that the level of potential of the enterprise depends on the level of development of the functional structure of the enterprise. If the information support system is not developed, then the information support function is underdeveloped, and this is evidence of the low level of information support potential of the enterprise. Further research should be conducted in the direction of building a structural and functional model for identifying the competitive advantages of enterprises, taking into account the identified features of the potential of enterprises.

Based on the generalization of the above literature sources, there is a reason to believe that in the scientific literature at the enterprise level management is considered as an open system, the characteristics of which depend on the size of the enterprise, its level of diversification and market share, innovation, professionalism of managers, etc. Regardless of the specifics of building a management system, it performs general and specific functions under any circumstances. There are some differences among management theorists regarding the list of these functions, but in general, among the general functions are such as: planning, organizing, motivating, controlling and regulating. As for specific functions, their list is much larger, because these functions are based on specific objects of management, such as production activities of the enterprise, supply, sales, investment activities, marketing, innovation, as well as various types of potential - production, technology, intellectual, personnel, innovation, investment, etc. In view of this, the specific functions of the enterprise management system include production management, supply management, sales management, investment management, marketing management, innovation management, production capacity management, technological capacity management, intellectual capacity management, human resources management , management of innovation potential, management of investment potential, etc. Fig. 1. shows the place of the potential of the enterprise as a specific function in the management system of the enterprise.

Fig. 1: The place of enterprise potential in the enterprise management system

As you can see, the subjects of management, namely managers, defining the mission, vision and building goals of enterprise development (enterprise development goals, or system of enterprise goals is a hierarchically and functionally ordered set of mutually agreed tasks, as have clear deadlines and criteria). Traditionally, the system of enterprise goals distinguishes three hierarchical levels - strategic, tactical and operational at each of which are formed and implemented, respectively, strategic, tactical and operational plans for enterprise development. The key conditions for ensuring the effectiveness of enterprise goals are their realism, relevance and consistency) managing the potential of the enterprise through its planning, organization, motivation, control and regulation.

In the context of these general functions there is the use of management methods and technologies, the application of which is aimed at the object of management - the enterprise potential

Given that the company may be at the stage of formation or development, its potential may be formed or undergo changes that lead to its loss, reproduction or growth (increase). In fig. 2 it is shown a fragment of the causal-structural model of the formation of the enterprise potential, which is in its state of formation.

Fig. 2: A fragment of the causal-structural model of forming the potential of the enterprise from the standpoint of a functional approach

At the stage of the enterprise formation of its potential it is accompanied by a number of successive stages of management, namely: definition of the purposes of formation of the enterprise potential taking into account factors of internal and external environment of the enterprise; organizing activities to build the potential of the enterprise; motivating employees to implement the set tasks within the measures defined at the previous stage; controlling the process of forming of the enterprise potential; regulation of the process of forming of the enterprise potential (Fedulova I., 2009).

Each of these stages is aimed at structural modeling of enterprise potential. Thus, Fig. 2 considers the formation of the enterprise potential on the example of its components such as production potential. Deciding on the formation of this component of the potential of the enterprise requires market research, assessing the capabilities of the enterprise and on the basis of this formation of strategic production goals of the enterprise (Knyaz S., 2015). Based on these goals, it is possible to determine the required amount of production capacity, area, raw materials, materials, etc. This information is necessary to create the material and technical conditions for the production activities of the enterprise. Having created them actually there is a production potential which can be used for ealization of the established strategic purposes.

At the stage of realization of production potential the management system of the enterprise is directed on control and regulation of processes of use of production capacities, areas, resources, etc. taking into account change of factors of internal and, especially, external environments for timely acceptance and realization of corrective administrative decisions. (Georgiadi N. and others, 2020).

In conditions when the enterprise functions in the market for a long time, that is at a stage of the development the task of heads of the enterprise is so to carry out management of its potential from which it was reproduced and grew. In fig. 3 it is shown options for increasing the potential of the enterprise. In this case, the reproduction of potential means the restoration of the company's ability to implement those tasks that were performed in the past, in particular to produce the same as in the past, the volume of products, occupy the same market share, perform previously committed, etc.

At the stage of realization of production potential the management system of the enterprise is directed on control and regulation of processes of use of production capacities, areas, resources, etc. taking into account change of factors of internal and, especially, external environments for timely acceptance and realization of corrective administrative decisions. (Georgiadi N. and others, 2020).

In conditions when the enterprise functions in the market for a long time, that is at a stage of the development the task of heads of the enterprise is so to carry out management of its potential from which it was reproduced and grew. In fig. 3 it is shown options for increasing the potential of the enterprise. In this case, the reproduction of potential means the restoration of the company's ability to implement those tasks that were performed in the past, in particular to produce the same as in the past, the volume of products, occupy the same market share, perform previously committed, etc.

Conclusions

Under the potential of the enterprise should be understood as a system of opportunities to achieve development goals within the functions defined by the structure of the enterprise. Management of enterprise potential is a specific function of management, which is implemented on the basis of management methods and technologies, the selection and application of which is carried out within the general management functions. From the standpoint of functional-structural approach, the classification of enterprise potentials is specified, in particular, classification features and types of potentials (in terms of content - management, production, marketing, logistics, innovation, information, etc .; by nature - basic (management and production) and derivatives (marketing, logistics, innovation, information, etc.) potentials, according to the level of development of the functional structure - developed (high, low) and undeveloped (zero) potentials).

It is substantiated that at the enterprise level modeling of its potential should have a causal-structural character, where the objects of functional-process management are the goals of capacity formation (market sector share, level of competitiveness, etc.), internal factors of the enterprise that characterize the enterprise potential (market sector share, areas of production capacity, stocks of raw materials, number of workers, etc.), as well as types of potential (production, technological, sales, marketing, etc.). It is substantiated that such objects should be focused on such management processes as: a) definition of the purposes of formation of potential of the enterprise taking into account factors of internal and external environment of the enterprise; b) organizing activities to build the potential of the enterprise; c) motivating employees to implement the set tasks within the measures defined at the previous stage; d) controlling the process of forming the potential of the enterprise; e) regulation of the process of forming the potential of the enterprise. It is under the conditions of forming the potential of the enterprise on the basis of the causal-structural model that it is possible to achieve rationality in the management of the enterprise potential.

Abstract

The main goal of this study was to identify the level of human capital among public university students who involved in social entrepreneurship activities in Malaysia. This study was conducted using a quantitative approach, where stratified random sampling was used on 797 students from three category of university (research, focus and comprehensive) who involve in social entrepreneurship activity. The data was analyzed using SPSS. This study revealed that the students who involved in social entrepreneurship activity in university shows high level of human capital. Student involvement in social entrepreneurship activities contributes to good leadership skills, social problem-solving skills, the ability to generate new ideas innovatively, creative thinking in helping to improve the socio-economic status of the less fortunate through business activities. In addition, they are also more competitive than students who are not involved in these activities. There is still not much information about current status of social entrepreneurship activity among students in Malaysia. Hopefully, this study can contribute to the new body of knowledge about current level of human capital among students who involved in social entrepreneurship activity in Malaysia.

Keywords: Social Entrepreneurship Activity, Human Capital, Public University.

Introduction

Social entrepreneurship in Malaysia has started since the establishment of Yayasan TEKUN Nasional and Amanah Ikhtiar Malaysia (AIM) in 1986. Social entrepreneurship is a process that combines the concept of entrepreneurship and social development (Kadir & Sarif, 2015). Most poor communities participate in social enterprise projects such as technical skills training and microfinance financing schemes to help them out of poverty (Kadir & Sarif, 2015). In May 2015, the government introduced the Malaysian Social Entrepreneurship Development Plan (MaGIC, 2015). It is estimated that there are 100 social enterprises operating and most of them are focused on education, poverty, rural development, environmental sustainability, employment for the marginalized and at-risk youth (MaGIC, 2015). In addition, 35% of social enterprises in Malaysia belong to Micro, Small, And Medium Enterprise (MSME), while 53% belong to Co-operatives and only 12% of social enterprises are Non-profit Organization (NGO) (British Council, 2018). In 2017, social enterprises managed to contribute an average income of RM 234,0718 and more than two-thirds of social enterprises (72%) operating as micro enterprises managed to generate an annual income of RM250,000 (British Council, 2018). To further enhance individual involvement in social enterprises, Social Enterprise Accreditation (SE. A) is formed in 2019 aims to confirm the status of social enterprises to help them gain access to various support and business growth opportunities (MEDAC, 2019). The Government has also launched the National Entrepreneurship Policy (DKN) 2030, a long-term plan that aims to produce as many Malaysians to involved in social entrepreneurship by 2030 (MEDAC, 2019).

Cite this Article as: Nor Suhaida Bt AWANG, Wan Fauziah Bt WAN YUSOFF and Raudah Bt MOHD ADNAN "The Current Status of Social Entrepreneurship Activity Among Public University Students in Malaysia: Empirical Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In addition, among the efforts planned and implemented to attract students in institutions of higher learning to venture into the field of social entrepreneurship is through educational platforms. This is because social entrepreneurs are not born with certain behavioral and characteristics that make them successful. Instead, they have been educated with skills and a supportive environment in their educational institutions, that influenced them to engage in social entrepreneurship activities (Light, 2006). Example of the most popular club that promotes social entrepreneurship activity among students at public universities is SIFE. SIFE is an international non-profit organization that works with business leaders and university students to make a difference in society. The club was established in the United States, then adapted by Malaysia under the of Mara University of Technology (UiTM). SIFE was later rebranded to Enactus (Entrepreneurial Action by Us) in 2012. Currently, there are an estimated 1923 students involved from 34 universities throughout Malaysia. There are over 90 projects community and directly impacted 99, 515 people (Website Enactus).

However, according to the report by Thomson Reuters Foundation (2016), the level of knowledge of Malaysians about social entrepreneurship is still low. This lack of knowledge leads to the lack of involvement of Malaysians in social entrepreneurship activities. This indirectly leads to the problem of difficulty in obtaining skilled manpower in social entrepreneurship activities. Lack of access to a skilled and quality human capital is one of the challenges faced by social entrepreneurs in Malaysia (MaGIC, 2015). In addition, Malaysia currently has 1.2 million university students. Therefore, these students are seen as a source of human capital with great potential to meet the needs of a skilled and quality workforce in the field of social entrepreneurship. However, studies on the level of human capital of university students involved in social entrepreneurship activities are still low. Hence, there is a need to identify the current status of the level of human capital among students who involved in social entrepreneurship activities in public universities in Malaysia. The aim of this study is to identify the current level of human capital among students who involved in social entrepreneurship activity.

Literature Review

Human Capital

Schultz (1959); Becker (1964); Mincer (1974) in Davidsson and Honig (2003) assert that human capital is knowledge that helps individuals improve their cognitive abilities and in turn can produce more productive and efficient activities. Becker (1980) argues that human capital is related to the economy of society and the country because individuals are inseparable from knowledge, skills, health or values. He emphasized two important elements as a future investment in human capital, namely education and training. Educational institutions such as schools and universities, can increased the level of human capital. Another scholar who looked at human capital from an economic perspective was Schultz, (1961) who introduced the theory of human capital. He argues that knowledge and skills are elements of capital resulting from deliberate investment. A clear example is that the increase in economic output in Western countries is a positive effect of investment in human capital. In other words, there is a relationship between increased human capital investment and increased employee income (Schultz, 1961). In line with Becker's view, Schultz also agrees with this concept of human capital investment. Thus, developed countries that invest in education, health and long-term training will strengthen their economic structure and improve the living standards of their communities (Schultz, 1961).

According to Hamat and Nordin (2012) human capital is defined as the characteristics possessed by a person that make them more productive. This capital cannot be transferred from one person to another but one must strive to obtain it. It is formed or nurtured through education, training and information seeking efforts. In development efforts, 'capital' is very important. Material capital such as land, money, factories and other infrastructure is very important and necessary, but it is simply not enough. All of that would not be able to add value without the creative and dynamic role of human beings to move and process it. Skills are not merely technical skills. Skills also include aspects of leadership ability, cognitive skills (thinking and analysing), language and communication skills as well as social skills (Mohamad & Salleh, 2009). These various skills are very clear in their importance in today's world and in the knowledge-based economy. An individual needs to be able to lead himself and others and know how to think critically and creatively and be able to analyse a situation to make good decisions (Mohamad & Salleh, 2009). According to Yussof (2003) human capital theory and rate of return approach has proven that education is able to increase one's productivity and income which in turn can lead to economic growth. The development of human capital in public universities is very important for this institution to produce people who can raise the name of the country not only in terms of skills and expertise but also by highlighting good attitude and personality (Mohamad & Salleh, 2009).

Human Capital Among Students Who Involved in Social Entrepreneurship Activity

The application of social entrepreneurship culture is not only focused on academics but also in co-curriculum and programs implemented by institutions such as the establishment of the Enactus club. Majority 80% of students agree that they can apply knowledge about entrepreneurship, soft skills, leadership skills and management skill through social entrepreneurship activities at their university in real life situations (Abdullah, Johari, Bakri & Razak, 2015). In another research study by Erturgut & Soysekerci (2012), 77% of students considered that social entrepreneurship activities can increase the level of creativity and innovation while 34% of students think that the networking and soft skills acquired allow them to find a job after graduation. This study is also in line with the study by Dobele (2016) that social entrepreneurship activities affect the attitude of independence, creativity, empathy, rational thinking, and high entrepreneurial skills of individuals. It encourages the solution of social problems in society and contributes to the sustainable economic development of the country. Rahman, Ismail and Sahid (2019) have conducted a study on the level of strategic domain social entrepreneurship, namely entrepreneurial personality, human capital and social capital among students. He found that the longer students are actively involved in social entrepreneurship activities (3 years and above), the more likely they are to have entrepreneurial personality traits and good human capital. In conclusion, exposure of social entrepreneurship activity to students can create human capital that have soft skills, social skills and can meet the needs of the corporate industry and the current market (Prabhu, 2019).

Figure 2.1: Theoretical Framework

Methodology

This study was conducted to see the effect of social entrepreneurship activities on the development of human capital of students in public universities. The study was conducted on 797 students involved in Enactus clubs at public universities. This study uses stratified random sampling technique. The questionnaire is available on a 5-point Likert scale from 1 (not agreed) to 5 (complete agreement). This questionnaire was sent to the respondents via google drive, walk-in, face to face and by post to increase the return of feedback. The total number of respondents was 797 students. Finally, the descriptive analysis was conducted using SPSS software.

Results

Overall, all elements of human capital among students who involved in social entrepreneurship activity showed a high mean score of 4.0745 (Table 4.1). Specifically, the statement that has the highest mean score is Moi1 item which is "Have good leadership skills" with mean score 4.1129. In terms of frequency percentage, the highest percentage of Moi1 items is 44.8% of students "agree" that their involvement in social entrepreneurship activities can improve their leadership skills. While 34.5% stated "strongly agree" with the item Moi1. Apart from that, the second highest mean score is on Moi3 item which is "Improving the ability to generate new ideas innovatively" with mean score 4.1054. In terms of frequency percentage, the highest percentage of Moi3 item is 52.8% of students stated that they "agree" and 29.6% of students stated "strongly agree" social entrepreneurship activities can improve their ability to generate new ideas innovatively. Meanwhile, the statement that shows the lowest mean score is on the item Moi2 which is "Improving skills to solve social problems sustainably to the less fortunate in terms of socio-economy" with mean score 3.9925. As a percentage of frequency, for Moi2 items, the highest percentage is 52.3% of students "agree" their involvement in social entrepreneurship activities can improve their skills to solve social problems sustainably to the less fortunate in terms of socio-economy while only 24.6% of students stated "strongly agree".

Table 4.1: Level of student's human capital who involved in social entrepreneurship activities

Note: F=Frequency, SD= Strongly disagree, D= disagree, N=Neutral, A=Agree, SA= Strongly Agree

	Item	F	SD %	D %	N %	A %	SA %	Total	Mean	S. D	Level
Moi1	Good leadership skills	F	3	14	148	357	275	797	4.1129	0.7892	High
		%	.4	1.8	18.6	44.8	34.5	100			
Moi2	Improve the skills of solving social problems	F	3	12	169	417	196	797	3.9925	0.7434	High
		%	.4	1.5	21.2	52.3	24.6	100			
Moi3	Ability to generate new ideas innovatively	F	2	8	130	421	236	797	4.1054	0.7151	High
		%	.3	1.0	16.3	52.8	29.6	100			
Moi4	More creative in helping to improve the socio-economic status of the less fortunate through business activities.	F	2	10	134	413	238	797	4.0979	0.7284	High
		%	.3	1.3	16.8	51.8	29.9	100			
Moi5	More competitive than other students Good leadership skills	F	2	17	156	375	247	797	4.0640	0.7811	High
		%	.3	2.1	19.6	47.1	31.0	100			
	Overall mean								4.0745	0.6202	High

The results of analysis for three university categories are as in the figure below. The focused university is showing the highest level of human capital with a mean score of 4.1159. In particular, the item "Have good leadership skills" shows the highest mean score of 4.1699. Then it is followed by item "Ability to generate new ideas innovatively" with mean score 4.1560. Third highest mean score is on the item "More creative in helping to improve the socio-economic status of the less fortunate through business activities" with mean score 4.1365. The fourth highest mean score is the item "More competitive than other students" with mean score 4.1114. Meanwhile, the item with the lowest mean score is on the item "Improving skills to solve social problems sustainably to the less fortunate in terms of socio-economy" which is a mean score of 4.0056.

In addition, the university with the second highest level of human capital is a research university with a mean score of 4.0927. The item with the highest mean score in the research university is "More creative in helping to improve the socio-economic status of the less fortunate through business activities" which is a mean score of 4.1202. The second highest mean score is the item "Good leadership skills" and "Ability to generate new ideas innovatively" which they share the same value of mean score 4.1030. While the items with the lowest mean score are "Improving

skills to solve social problems sustainably to the less fortunate in terms of socio-economy" and "More competitive than other friends" which is a mean score of 4.0687.

Finally, the university with the lowest mean score overall is a comprehensive university with a mean score of 3.9815. The item with the highest mean score is "Have good leadership skills" and that is the mean score of 4.0244. second highest value of human capital for comprehensive university is the item “Ability to generate new ideas innovatively” with mean score value 4.0195. It is followed by item “More creative in helping to improve the socio-economic status of the less fortunate through business activities” with mean score value 4.0049, item “More competitive than other students” with mean score value 3.9756 and item “Improve the skills of solving social problems” with mean score value 3.8829. Meanwhile, the item with the lowest mean score is the item "Improving skills to solve social problems sustainably to the less fortunate in terms of socio-economy" which is a mean score of only 3.8829. In conclusion, all human capital items in this study showed a high mean score (Table 4.2).

Table 4.2: Descriptive Analysis for human capital in three university categories

Category	Item	Mean	S. D	N
Focus University	Good leadership skills	4.1699	.74488	359
	Improve the skills of solving social problems	4.0056	.72849	359
	Ability to generate new ideas innovatively	4.1560	.71937	359
	More creative in helping to improve the socio-economic status of the less fortunate through business activities.	4.1365	.73293	359
	More competitive than other students	4.1114	.75772	359
	Overall Mean	4.1159	.60625	359
Research University	Good leadership skills	4.1030	.81877	233
	Improve the skills of solving social problems	4.0687	.70985	233
	Ability to generate new ideas innovatively	4.1030	.69334	233
	More creative in helping to improve the socio-economic status of the less fortunate through business activities.	4.1202	.70293	233
	More competitive than other students	4.0687	.79030	233
	Overall Mean	4.0927	.61475	233
Comprehensive University	Good leadership skills	4.0244	.82509	205
	Improve the skills of solving social problems	3.8829	.79579	205
	Ability to generate new ideas innovatively	4.0195	.72734	205
	More creative in helping to improve the socio-economic status of the less fortunate through business activities.	4.0049	.74424	205
	More competitive than other students	3.9756	.80707	205
	Overall Mean	3.9815	.64371	205

Table 4.3 summarizes the mean score value of the student’s human capital. According to Salkind (2012), the mean score value is divided into three categories that is low (1.00-2.33), medium (2.34-3.66) and high (3.67-5.00). Overall, level of human capital among students from focus university, research university and comprehensive university have a high mean score value that is above 3.67. Focus universities having the highest mean scores (4.1159) followed by research universities (4.0927) and comprehensive universities (3.9815).

Table 4.3: Summary level of human capital among students involved in se activities at public universities

	Type of University	Min	S. D	Level of Min	Ranking
Human capital	Focus University	4.1159	0.60625	High	1
	Research University	4.0927	0.61475	High	2
	Comprehensive University	3.9815	0.64371	High	3
	Overall	4.0745	0. 62027	High	

Other than that, this study also analysed the data using Kruskal Wallis test to find out the differences of human capital level of students based on three categories of university namely comprehensive, focused and research. Kruskal Wallis test is a non-parametric test used to compare mean rank amongst more than two scores under different group of independent variables (IV), when we have data from three groups and above of respondents and data (DV) is not normally distributed. The result is shown in the table 4.3 below. Based on Table 4.4, the results of Kruskal Wallis test found that significant value of the level of human capital of students involved in social entrepreneurship activities is 0.055 (above the value of 0.05). Thus, the results of the study show that there is no statistically significant difference in the level of human capital of students who involved in social entrepreneurship activities based on three categories of public universities.

Table 4.4: *Kruskal Wallis* test

	Type of University	Total	*Mean Rank*	*Sig.*	*Chi-Square*	*df*
Human capital	Focus University	359	406.53	.055	5.794	2
	Research University	233	402.70			
	Comprehensive University	205	381.61			

Discussions

The results of this quantitative study found that students involved in social entrepreneurship activities have a high level of human capital. Specifically, the statement that has the highest mean score is the Moi1 item which is "Have good leadership skills". For example, as a president, they need to be smart to manage the members under their supervision. Students need to be wise to give assignments based on the skills possessed by the existing members. For example, for club owners who like to talk, the club president will put them in a marketing group. Therefore, they are able to carry out activities to promote and sell products produced by the Enactus Club well. This shows that SE activities successfully produce students with good leadership skills through interaction with the multi-racial community (Abdullah, Johari, Bakri, & Razak, 2015).

Second, the results of the study found that students involved in social entrepreneurship activities have the ability to generate new ideas innovatively. The results of this study are in line with the study of Erturgut and Soysekerci (2012) which is social entrepreneurship activities foster creative and innovative thinking among the students involved. Social entrepreneurship activities have a positive influence on social innovation (Mokhtar, Abdullah & Kin, 2016). It can develop the ability of individuals to combine resources effectively and produce innovative solutions to social problems. As a result, social entrepreneurship activities promote the solution of social problems in society, improve social well-being, and contribute to the development of a sustainable national economy (Dobele, 2016). Another study by Erturgut and Soysekerci, (2012) also found that 77% of students considered that social entrepreneurship activities promote innovative and creative thinking.

Third, the results of the study show that the effect of human capital which has a second highest mean score is on the item Moi4 which is "More creative in helping to improve the socio-economic status of the less fortunate through business activities". According to UNICEF (2007), young people, from the age of 10 to 18, have the creativity and energy to implement new initiatives that can transform their communities. These findings prove that social entrepreneurship activities can not only help the poor but also produce students with high creativity (Ernst, 2018).

Involvement in social entrepreneurship activities in higher education institutions has the potential to develop social awareness, creativity, and individual sensitivity to problems in society (Dobele, 2016).

Fourth, the statement that has a high mean score is item moi5 which is "More competitive than other friends". This shows that students who are involved in social entrepreneurship activities are more prominent than their peers who are not involved in social entrepreneurship activities. The results of this study are supported by previous studies that identify that involvement in social entrepreneurship activities can produce sustainable and competitive human capital (Hashim, 2009).

Lastly, the element of human capital that shows the lowest mean score is the item Moi2 which is "Improving the skills of solving social problems sustainably to the less fortunate in terms of socio-economy". Although the mean score is low compared to other items, but the level of this mean score is at a high level. According to Astin and Sax (1998) volunteer activities such as social entrepreneurship activities can improve interpersonal skills such as the ability to solve problems and be able to understand the problems faced by society. According to Rahim and Lajin (2015) social entrepreneurship activities can cultivate problem-solving skills, and experience dealing with real issues.

Conclusions

Overall, social entrepreneurship activities among students at public universities in Malaysia can produce students with a high level of human capital. This activity is very important and needs to be implemented continuously in order to produce graduates who are skilled and social entrepreneurship minded. Next get involved in social enterprise as their career choice. Governments, educational institutions, program organizers need to work together to help students strengthen their level of human capital. In addition, this study also contributes to new knowledge in the field of social entrepreneurship in Malaysia. Research about students in social entrepreneurship in Malaysia focuses on understanding concepts about phenomena (Zakaria & Bahrein, 2018) with minimal empirical research (Rahman, Ismail, & Sahid, 2019). The main approach used in this study is quantitative research. Hence, it will help to increase the empirical data about the current status of social entrepreneurship activity among public university students in Malaysia. Therefore, the results of this study show that social entrepreneurship activities can develop high level of human capital.

Abstract

Effective interaction of all subjects of the educational services market in terms of economic transformation remains an important issue on the agenda, especially during the development of new technologies and teaching methods. Accordingly, the formation of mechanisms that increase the effectiveness of organizations in the field of education is a very difficult task. The aim of the research is to develop methodological approaches to the formation of an effective integrated mechanism of interaction in the school-University system. To achieve this goal, the main factors influencing the interaction process were identified and grouped, approaches to evaluating the performance of the University depending on the goal were clarified, as well as a methodological approach to the formation of a comprehensive mechanism for interaction between the school-University system was proposed. The proposed mechanism of complex interaction in the school-University system can be adapted for any educational institution, and has shown its effectiveness in the process of testing in one of the educational institutions. Research methods: analysis and synthesis, method of constructing hierarchies, economic and statistical, dynamic, situational analysis, tabular interpretation of statistical information.

Keywords: Economic Efficiency, Assessment Methods, School-University Interaction, System Approach

Introduction

Close interaction of all subjects of the educational services market in the context of economic transformation remains an important factor in changes and the emergence of new trends in the educational space, as well as the formation of human capital as the basis for effective economic and social development of the country. Their impact on professional training and professional orientation of the population, especially young people, is an important and topical issue of national security of the state. Today in Russia, the problems associated with the imperfection of mechanisms of interaction in the school-University system in the market of educational services have become relevant.

Thus, the importance of studying theoretical concepts that explain performance and factors of interaction organization in the school-University system, which allow limiting the negative trends of these processes, increases. All of the above issues, as well as their close relationship, determine the great relevance of the issues under study.

Materials and Method

Comprehensive research on the activities of higher education institutions, including evaluating the effectiveness of the interaction mechanism in the school-University system, can be found in the works of Antropova (2012), Barkov (2014), Berezka (2017), Novozhilov (2012), Petunin (2018), Skvirsky (2012), Todosiychuk (2009), Chigarin (2015), Robst (2001), Šipilova (2013), Nadtochy et al. (2016), Stevens (1946), Stevens (2005), Karpunina et al. (2014).

The purpose of the research is to develop methodological approaches to the development of an effective integrated mechanism of interaction in the school-University system.

The study was conducted in the following stages:

1. Identification of diagnostic indicators for evaluating the performance of universities.

2. Grouping of performance indicators of the school - University Interaction mechanism depending on the classification features presented in the literature and supplemented by the authors.

3. Systematization of approaches to evaluating the performance of the University depending on the goal.

4. Development of a comprehensive mechanism for effective and efficient interaction in the school-University system.

5. Approbation of the proposed method of complex diagnostics of the interaction mechanism in the school-University System.

The following research methods were used in the study: analysis and synthesis, the method of constructing hierarchies, economic and statistical, dynamic, situational analysis, tabular interpretation of statistical information.

Results

One of the primary elements of the research performance of universities is the development of a system of indicators that provide the diagnosis and grouping of data on the evaluation activities of universities, as well as their classification. A systematic approach involves studying all aspects of the activities of the respective missions of interaction between schools and universities. The primary task of the system approach is to identify and study the degree of complexity of the system itself, taking into account additional links. These relationships bring the system to a more manageable level within specific limits, while accumulating a certain level of isolation and contributing to the growth of the system's competitiveness and effectiveness (Antropova, 2012).

The authors suggest grouping performance indicators depending on various classification features to identify opportunities for improving the effectiveness of the school - University interaction mechanism (table 1).

Table 1: Classification of performance indicators of the interaction mechanism in the school – University system

№	Classification feature	Performance indicators
1	the management level	1.1) operational – reflects the degree of achievement of short-term goals, does not require a complex level of analysis, is expressed in absolute terms and is used at the basic level of decision-making;
		1.2) tactical – defined as an intermediate level that determines the level of achievement of the goals of interaction in the school-University system that are of a medium-term nature;
		1.3) strategic – a generalizing complex indicator that reflects the qualitative aspects of universities ' activities based on the results of achieving strategic goals of interaction;
2	the competitiveness level	2.1) financial – reflects the essential characteristics of economic stability and sustainability of higher education institutions, as it assesses the economic results of decisions made and can be an indicator of compliance with a specific strategy for the development of the University;
		2.2) marketing – charcterized positioning of the University on a specific segment of the market of educational services;
		2.3) functional-cost – determines the quality level of the service delivery process or satisfaction with the service, including the conditions that can provide it;
		2.4) potential – characterizes qualitative changes in information support, intellectual capital and infrastructure for the implementation of stable development of the system;
3	the volume of properties studied	3.1) partial volume comprises part of the properties of the interaction process;
		3.2) generalized – consists of a set of properties expressed by a coefficient that consists of many indicators;
4	the ranking level	4.1) the primary level analyzes the compliance of results and goals;
		4.2) the secondary level identifies the reasons for deviation of fact indicators from the plan;
5	the assessment level	5.1) the level of the University-complex – characterizes the interaction of the school complex and the entire University;
		5.2) level of structural division – describes the interaction of a separate structural division and the school complex or its structural division.

Source: compiled and supplemented by the authors on the basis of Todosiychuk (2009), Antropova (2012)

There are several approaches to evaluating the performance of a University, depending on the goal, reflecting different views on the assessment of the mechanism of interaction in the school-University system (table 2).

Table 2: Approaches to evaluating the performance of the University

№	Name of the approach	Brief characteristic
1	economic	assessment of an educational institution as an economic entity without taking into account its social and scientific values, including social orientation; accounting and financial indicators are used;
2	regulatory	assessment of the quality of educational services through accreditation, certification and licensing, including international accreditation
3	parametric	implementation of state standards and quality management systems of the University, including ISO 9000, as well as assessment and certification of the corresponding standards of higher education institutions
4	rating	a certain list of procedures is applied for evaluating indicators that characterize the selection of potential consumers of educational services in the competitive environment of the higher education market
5	target	it is focused on achieving its goals in the most effective way; thus, performance can be measured by the level of achievement of the organization's goals

Source: compiled and supplemented by the authors on the basis of Todosiychuk (2009)

An assessment of the financial and economic performance of various types of Russian universities has shown that today, in conditions of budget deficit, state higher education institutions are funded on a residual basis, while private universities do not receive financial assistance from the state budget at all and are fully self-funded. At the same time, private higher education institutions experience much more negative external influences than state universities. First of all, this concerns the formation of their revenue part in terms of a decrease in the number of students, restrictions on license volumes and prices for educational services provided by them in an acutely competitive market.

Thus, evaluating effectiveness in the educational sphere is a very difficult task. The social and economic effect is distributed over time and cannot be directly quantified (Skvirsky, 2012). The national education system has been in a state of reform for many years, which does not always have a positive impact on the effectiveness and quality of educational services.

An important point in the formation of the school-University interaction mechanism is to consider the essence of the concepts of efficiency of budget organizations, since it differs significantly from the efficiency of a commercial organization. According to Chigarin (2015), the effectiveness of higher education institutions can be expressed in the following indicators:

- the number of information products of scientific, methodological and practical nature used in the training process;

- the degree of satisfaction of parents, students and graduates with the quality of the educational process;

- the degree of satisfaction of the employer's representatives with the skills and competencies of University graduates;

- the degree of satisfaction of students with the organization of the educational process, additional services and relationships of educational institutions at different levels;

- the number of commercialized intellectual innovation products that have been developed and implemented at the University (Molchan et al., 2019).

The effectiveness of higher education institutions should be studied more widely due to the economic, social, career guidance, adaptation, and innovation aspects. Social effectiveness is the most important for evaluating the school-University interaction system. Economic efficiency can also have an impact on social efficiency, using the positive impact of targeted use of financial resources, etc.

The authors understand the effectiveness of higher education as the level of achievement by University graduates of the maximum results in training, which make it possible to ensure that the acquired competencies in the process of obtaining higher education correspond to public innovative, economic and social goals.

The effectiveness of the University can only be considered in relation to the effectiveness of school education, since applicants come to the University with the knowledge obtained at school. Therefore, there is a question of developing an effective integrated mechanism for the school-University interaction system.

According to the authors, a comprehensive mechanism for school-University interaction should take into account the requirements for the formation of knowledge and competencies that arise as a result of the influence of all interested parties (employers, management and guardianship councils, parent committees and committees on offenses, universities and schools themselves). In this way, the system of cooperation between school and University should also be implemented in the following areas: educational-methodical, scientific-methodical and career guidance. In addition, it should perform such career guidance, development, adaptation, and corrective functions (Fig. 1).

Fig. 1: Complex mechanism of interaction in the school-University system (compiled by the authors)

As a result of the implementation of the proposed mechanism, schools increase their competitiveness due to a higher percentage of graduates who have entered universities, students have the opportunity to get acquainted and decide on the choice of profession, undergo social adaptation and acquire social motivation to study at the University. In turn, universities get efficiency from such interaction by meeting already adapted and motivated students with clear ideas

about their future profession, familiar with the forms and methods of teaching at the University, which leads to fewer deductions in the 1st year.

Table 3 shows the results of testing the proposed mechanism on the example of data from one of the universities.

Table 3: Comprehensive diagnostics of the interaction mechanism in the school-University system

Source: compiled by the authors

According to the results obtained, the authors conclude that the interaction is, on the one hand, quite effective, as the profit and revenue increases, the number of students and teachers, and the number of groups of students increases. On the other hand, all indicators show an insufficiently high growth rate per student.

Conclusion

The results of the study showed that there are opportunities for the long-term development of interaction in the school-University system in the market of educational services and the labor market. The study of the educational services market allowed authors to conclude that the relations between the interaction participants are adaptive: on the one hand, universities in their formation and development should take into account the demand for professional and qualification composition of educational services from students, take into account the vacancies offered by employers, and, on the other hand, they should actively influence schools through the formation of a marketing strategy, taking into account the prospects for development and innovative changes in the economy.

The proposed mechanism of interaction between school and University improves the quality of educational services and brings them in line with the needs of customers of higher education institutions. Effective school-University interaction is a universal mechanism for improving the level of customer satisfaction and performance of educational institutions.

The proposed mechanism of complex interaction in the school-University system can be adapted for any educational institution, as it has proved its effectiveness in the process of testing in an educational institution.

Assessment of The Similarities of Selected European Countries in Terms of Socio-Economic Diversity

Małgorzata GRZYWIŃSKA-RĄPCA

Faculty of Economic Sciences, University of Warmia and Mazury in Olsztyn; Poland
malgo@uwm.edu.pl

Abstract

The purpose of the article was to separate groups of European countries taking into account measures of socio-economic development, i.e. the index of social development. The analysis also took into account features such as life expectancy, expected and average years of education, and gross national income per capita. The hypothesis was formulated that the data on socio-economic development adopted for analysis differentiate countries and may be the basis for creating groups of countries bringing together similar territorial units. The application of statistical multidimensional analysis methods has allowed the separation of statistically uniform clusters. The study showed that the measures adopted for analysis differentiate countries in terms of socio-economic development. The most developed countries: Austria, Belgium, Denmark, Finland, Germany, Luxembourg, the Netherlands, Sweden, Great Britain, and the least: Cyprus, Czech Republic, France, Greece, Italy, Malta, Portugal, Slovenia, Spain.

Keywords: HDI, Quality of Life, Socio-Economic Development, European Countries.

Introduction

Monitoring socio-economic indicators provides important quantitative information and empirical analytical knowledge on prosperity, change and trends in one society or groups of societies that can be used for different objectives, including, for example, social and economic policy-making (Noll, 2018).

The set of measures for socio-economic development is constantly improving. This is since the number of disciplines, including analyses in the field of so-called Quality of life, where analysis of only GDP level is not always a enough measure (Hagerty, M. R., et al. 2001). The concept of quality of life should be of interest in non-economic spheres, e.g. in the case of the United States. so that the analyses complement each other and allow for analysis in a broader perspective. In the literature of the subject meets different approaches (Dabrowa, 2018). The multifacetedness and multidimensionality of research related to the material and intangible quality of life of households is possible due to the diversity of activities by different institutions. Thus, the Central Statistical Office provides detailed data on the quality of life, such as, for example, the quality of life of the European Union. subjective assessments of income earned, housing assessment, level of access to social assistance, sense of security or leisure arrangements. The EU-SILC and Household Budget Research survey cluster on quality of life in a very broad sense, considering the consumer economy (subjective household assessments on the current and future financial situation of households). In addition to national data sources, research clustering on the collection of databases on measures for socio-economic development is carried out by the Statistical Office of the European Union (Eurostat). The data on the basis of which the analyses were carried out are derived from UNDP (United *Nations Development Programme*). It shall carry out measurement and analysis in the area of reducing socio-economic differences using m.in. HDI (Human*Development Index).*

Research on the material and intangible quality of household life shall be carried out in different scopes and aspects. According to Szukiełojć – Bieńkuska (2015) the quality of life should be studied in a multidimensional way. Among other things, the author distinguishes the following thematic areas: material living conditions, health, education, economic activity and economic security. Measurement and diverting in the area of quality of life is also carried out by the OECD. As part of the work carried out by the OECD, international indicators have been established to measure and compare regional living conditions for households. A multifaceted approach indicates the impact of various

Cite this Article as: Małgorzata GRZYWIŃSKA-RĄPCA“ Assessment of The Similarities of Selected European Countries in Terms of Socio-Economic Diversity” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

factors affecting household welfare. Thanks to the adopted indicators for assessing the quality of life, it is possible to determine not only the causes of development, but also to indicate the direction of possible changes. The level of regional diversity is very often deepened over time. It is linked to the accumulation and interplay of economic, political and cultural causes (Stawasz, 2004). According to this theory, areas with high economic development are growing faster and faster, while the poor are stagnant. The level of economic development of a given region is related to the material situation of its inhabitants (Grzywińska-Rąpca, 2019). Household material conditions are closely linked to the assessment of the quality of life of households, which is difficult to define unambiguously (Boris, 2015). Economists use multiple indicators to measure the quality of life of individuals to make social, political and economic decisions (Somarriba, Pena, 2009). The analyses highlight macroeconomic factors such as growth and inflation rates instability or cultural factors such as social capital (Veenhoven, 2000; Boelhouwer,2002). In microeconomic analyses, the discussion also concerns the impact of income inequality (Panek, 2009; Turczak, Zwiech, 2016).

HDI As A Measure of Socio-Economic Development

Commonly used by researchers (Antczak, 2012) the spatially adjusted socio-economic development measure is the Social Development Index (HDI). This is an indicator that considers three dimensions of social development, namely health, education and living standards.

The following indicators have been selected from each of the above areas (areas of life):

1. Health (life expectancy at birth),
2. Education (average length of education, expected length of education),
3. Standard of living (gross national product per capita according to the purchasing power parity of the currency in US dollars (PPP$) (Çilingirtürk, Koçak, 2018; Hozer – Koćmiel, 2018; Bravo, 2014; Silva, 2014). They are presented in the Figure 1.

Fig. 1: Calculating the human development indices—graphical presentation

Source: own study on the basis http://hdr.undp.org/sites/default/files/hdr2019.pdf

According to the authors, […] *the Human Development Index (HDI) is a measure of summing up achievements in three key dimensions of human development: long and healthy life, access to knowledge and a decent standard of living. The HDI is the geometric mean of the normal indexes for each of the three dimensions*". (Conceição, 2019).

The advantage of using this indicator is the non-financial aspect, which should be an advantage over the level of GDP commonly used to determine the level of development of a country. The HDI is a component of averaged and standardized indexes and takes values between 0 and 1. The following compartments are created for the classification:

- Very high human development 0.800 and above
- High human development 0.700–0.799
- Medium human development 0.550–0.699
- Low human development below 0.550

According to Śleszyński (2016) around 30% of countries are among the highly and highly developed countries.

According to the annual Human Development Reports, Norway has been the leader in the HDI ranking since 2009, for which the index was 0.954 in 2018. Other highly ranked countries are Australia, Switzerland, the Netherlands, the United States, Germany, and New Zealand. For years, Poland has maintained a similar position, oscillating between 30 and 40 in the group of highly developed countries (Antczak, 2012, Śleszyński, 2016). In 2018, Germany had the highest HDI in the group selected for analysis of European countries (Figure 2).

Fig. 2: The value of the Social Development Index (HDI) in 2018.

Source: own study on the basis of http://hdr.undp.org/en/data#

Statistical multidimensional methods have been used to distinguish between groups of countries with a similar level of socio-economic development, given the possibility of distinguishing groups with similarities regarding several characteristics. The variables adopted for analysis are shown in Table 1.

Table 1: Selected measures for socio-economic development

The analysis clustered on measures such as HDI, life expectancy, average years of study, expected years of study and gross national income per capita. Selected gauges characterize individual European countries considering the theoretical ground. Table 2 shows a summary of the statistical characteristics for the variables adopted for analysis.

Table 2: Statistical characteristics for variables adopted for analysis

Specification	HDI	Life expectancy at birth	Average length of education	Expected length of education	Gross national product per capita
	(index)	(number of years)	(number of years)	(number of years)	($)
Average	0,89	80,27	16,63	11,99	36208,01

Coefficient of variation	3,75	3,17	9,19	9,05	28,89

Source: own study

According to the data presented in Table 3, the average HDI value for the countries adopted for analysis is 0.89, which, according to theoretical assumptions, allows this group to be classified as highly developed countries. Among the 26 European countries adopted for analysis, the HDI ranges from 0.816 (Bulgaria) to 0.939 (Germany). The value of the upper quartile (0.92) indicates that 25% of the 26. above 0.92. The designated volatility factors indicate the highest variation for characteristics: gross national income per capita. The volatility factor in this case is 28.89%.

Group selected European countries based on socio-economic measures

The characteristics chosen based on the literature (*Human Development Report 2019…*) review and previous studies setting out the level of socio-economic development for selected European countries would allow several ranking lists of those countries to be drawn up. However, multidimensional methods of statistical analysis were used for more complete analysis. In the first stage, Ward's agglomerate grouping was carried out using a square of euclidean distance on standardized data (Fig. 3).

Figure 3: Grouping of countries - Ward's method Dendrogram Warda

Source: own study using Statistica 13.3.

The grouping presented using the Ward method allowed the extraction of homogeneous groups due to the variables adopted for analysis. It is worth noting that in the Ward method, the researcher is not able to indicate the number of concentrations at the start of the grouping procedure. By referring to the grouping in Figure 2 and the methodological assumptions indicating that three clusters were avoided in object groupings. The intersection was made at 20. distance of binding and on this basis three groups of countries were formed. The division of countries into cluster, based on selected diagnostic characteristics, was carried out using aggregation analysis algorithms. The k-medium method was used for this purpose. This is one of the non-hierarchical methods of grouping. This procedure requires an arbitrary decision on the number of clusters to which the initial collection of objects will be divided (Walesiak, Gatnar, 2009). The main idea of this method is the allocation of objects to k groups, which shows minimal variability inside the resulting clusters and at the same time maximizes variability between groups. The high volatility between highlighted clusters and the relatively low intra-aggregates indicates a proper grouping of countries due to the variables analyzed. The distributions of variables within the aggregates are shown in Figures 4, 5, 6, 7, and 8.

Figure 4:Variable Distribution Chart: Human Development Index (HDI)

Figure 7: Variable distribution chart: expected length of education

Source: own study using Statistica 13.3.

Figure 8: Variable distribution chart: gross national product per capita

Source: own study using Statistica 13.3.

High variability among the distinguished clusters and relatively low variability in the clusters prove that countries are properly grouped by the analyzed variables. The results of the *F* statistics presented in Table 3 show that all variables discriminate well between clusters at the significance level of 0.05.

Table 3: Results of the analysis of variance of discriminant variables

Variable	Intergroup variation	df	Intragroup Variation	df	Statistic *F*	Value *p*
Human development index (HDI)	1,865136E-02	2	0	23	23,25187	0,000003

Source: own study

The first cluster, which includes countries such as Cyprus, the Czech Republic, France, Greece, Italy, Malta, Portugal, Slovenia, Spain is characterized by HDI levels ranging from 0.85 to 0.90. Life expectancy (assuming that this is the number of years a newborn could survive if the mortality patterns change during his life) in the first concentration to which the countries of Central and Western Europe are mainly qualified, is almost 82 years (81.87). The expected years of learning in this cluster are 16.5 years (16.45). Gross national income for first cluster ranges from $24,909.34 to $40,510.78.

In the second cluster, the highest statistics values can be observed in most cases. This cluster included countries such as Austria, Belgium, Denmark, Finland, Germany, Luxembourg, the Netherlands, Sweden, the United Kingdom. It is a cluster with a high level of gross national income per capita. The average gross income per capita ranged from $39,507.29 to $65,543.05. The average expected bed timeinthe guests of life and expected years of learning for this cluster are 81.63 and 17.77, respectively.

The third cluster includes Bulgaria, Croatia, Estonia, Hungary, Lithuania, Latvia, Poland, Slovakia. The countries eligible for third-rate concentration do not show homogeneity as a result of both geographical locations, past (centrally planned economies) and, above all, from the period of political transformation. These are in most central and eastern European countries currently concentrated as part of the International Economic and Political Initiative (Trisea). The HDI value for this cluster ranges from 0.8157 to 0.8815. The countries of this concentration have the lowest gross

domestic product per capita. The average value of this variable for the third cluster is $26825.43. Countries eligible for this cluster based on 2018 data can be expected to obtain higher values adopted for variable analysis in subsequent years. This may be the result of cooperation between the Trisea States at different levels, activities related to one of the main objectives of the Trisea organisation– namely the dynamism of economic development.

The second cluster isolated the following countries: Austria, Belgium, Denmark, Finland, Germany, Luxembourg, Netherlands, Sweden, United Kingdom. These states, taking into account their economic development (which was not the subject of the conducted analyzes), provide their inhabitants with conditions enabling them to meet their needs in the field of social development. The second largest of the analyzed variables was the first cluster linking the countries of the south-western Europe region.

Summary

The analysis of groupings on the basis of hdi and health and economics meters was studied by 26 European countries. The results show that in 2018, the countries with the highest values of the variables adopted for analysis are Austria, Belgium, Denmark, Finland, Germany, Luxembourg, the Netherlands, Sweden, the United Kingdom. This is probably due to high variable levels for these countries.

In conclusion, the analyses carried out using the Ward and K-medium methods can be concluded that there is a wide variation in living standards in the Group of European countries. This is indicated, for example, by the coefficient of variation for the variable: gross national product per capita. It is also worth stressing that further measures of socio-economic development should be introduced when grouping and comparing groups of countries. In subsequent analyses, the study on the diversity and grouping of European countries will include unemployment, migration as well as the rate of household savings. The use of this latter measure appears justified because the household savings rate is the ratio of household gross savings to disposable gross income, adjusted for a change in household pension rights in households. Gross savings, on the other hand, are defined as part of the gross disposable income and not spent on final consumption. When gross disposable income increases faster than final consumption expenditure, then the savings rate increases. According to Angel and Gołasia (2013) household savings, it is one of the most important determinants of growth and economic development.

Financial Self-Exclusion: Why Do Households Give Up Activity On the Market of Financial Services and Products?

Agnieszka STRZELECKA

Koszalin University of Technology, Faculty of Economic Sciences, Department of Finance, Poland
agnieszka.strzelecka@tu.koszalin.pl

Abstract

The aim of this research was to identify and assess the socio-economic characteristics of financially self-excluded households and to identify the reasons for the inactivity of households on the market of financial services and products. The source of empirical data were the results of a survey conducted among 1,000 households in Central Pomerania (Poland). The analysis of the characteristics of financially excluded households in relation to the remaining entities included in the analysis was performed with the use of non-parametric statistical tests (chi-square, Fisher's test, Mann-Whitney's U test). The conducted research showed that the following types of households are particularly vulnerable to financial self-exclusion: households from rural areas and small towns; households of the elderly; households with dependent children; households of pensioners and employees. Financially self-excluded households were, on average, smaller, with a lower proportion of dependent children and a lower proportion of people who were gainfully employed. The research also found that the main reasons for financial self-exclusion of the surveyed households were: reluctance to use financial services/products, preferring to use cash, retirement age, low level of household income, lack of possibility to use a financial product/service due to: too high a price, difficult access to financial products and services and the conditions needed to be met in order to be able to use the product/service). The results obtained in the course of this research contribute to both literature and practice. These research results may be an important source of information both for financial institutions, as well as for entities that deal with reducing financial exclusion, including financial self-exclusion of households.

Keywords: household, financial decisions, financial exclusion, financial self-exclusion, reasons for financial self-exclusion, non-parametric statistical tests, Central Pomerania, Poland

Introduction

In recent years, there has been a heightened interest in the subject of financial aspects of the functioning of households, as evidenced by the development of a sub-discipline of finance, which is personal finance (household finance). The need for financial education of the population is emphasized, as well as the importance of skilful and rational management of the household budget. Households' financial decisions relate to the use of financial services and products and are determined by a number of factors. Our previous research has shown that socio-economic characteristics affect household financial decisions regarding: saving (Strzelecka, Zawadzka 2020), incurring debt (Strzelecka, Zawadzka, Kurdyś-Kujawska 2020a) and using financial services and products to purchase voluntary insurance for life (Strzelecka, Zawadzka, Kurdyś-Kujawska 2020a). This paper will examine the characteristics of households which, by their own choice, give up and do not use financial services and products - so it will deal with the phenomenon of financial self-exclusion of households.

The aim of this research is to identify and assess the socio-economic characteristics of financially self-excluded households and to identify the reasons for the inactivity of households on the market of financial services and products. In the study, *financial self-exclusion* was defined as the non-use of financial services and products by households, by their own choice.

The rest of the paper is structured as follows. Next section provides a literature review on the financial exclusion of households, which was the basis for empirical research, the results of which are presented later in the paper. The third section presents research methodology and data sources used for the analyzes. Next, the households included in the study were characterized. The fifth section presents the results of empirical research on the financial self-exclusion

of the surveyed households, taking into account the characteristics of financially self-excluded entities (using non-parametric statistical tests: chi-square test, Fisher's test and Mann-Whitney U test) and the causes of the analyzed phenomenon. The last section concludes.

Literature Review

Financial exclusion is a relatively new concept, and research in this field began in the 1990s (Zhang, 2013). A significant barrier to conducting research in this area is the lack of a clear definition of financial exclusion, which causes difficulties in determining the scale of this phenomenon and defining groups particularly exposed to the risk of financial exclusion. According to the definition proposed by the European Commission (2008), financial exclusion means the process in which the population faces problems in accessing and/or being able to use financial services and products offered on the mainstream market that are appropriate to their needs and enable them to lead a normal life in the society (European Commission 2008). This approach to the issue of financial exclusion takes into account: (a) access to a wide range of banking services (e.g. using bank accounts, investing savings, using loans, mobile banking); (b) access to safe and profitable forms of saving, and (c) access to insurance products (European Commission, 2008).

Research on this issue focuses largely on the first of the above-mentioned aspects, and financial exclusion is often equated with hindered access to banking services, in particular to bank loans and credits (such an approach was taken into account, among others, in the following works: Mutambara, 2016; Kata, Walenia, 2015; Ziemba, Świeszczak, Marcinkowska, 2014; Szafrańska, 2013). A measure of financial exclusion may also be the percentage of adults (in a given country) who do not have a bank account (Alińska, 2011). However, in the case of some groups of households for which a bank account is necessary to receive e.g. remuneration for work, this measure does not allow to determine the actual scale of financial exclusion. This also applies to the issue of being underbanked, i.e. a situation in which a given entity, despite having a bank account, makes little use of it (Błędowski, Iwanicz-Drozdowska, 2010). There is an approach in the literature according to which having a bank account is the first stage of financial inclusion, because using a loan or collecting savings in a bank is largely conditioned by its possession (Coffinet and Jadeau, 2017).

Financial exclusion can be considered from two perspectives. According to the first of these approaches - the narrower one - this phenomenon applies to people who do not use any financial services or products. According to the second approach - the broader one - financial exclusion applies to people who use banking products to a small extent (Solarz, 2014). The literature also proposes an approach according to which entities that do not have access to financial services and products and do not use any products of this type are financially excluded, while entities that use them to a small extent are referred to as marginally included (Anderloni et al., 2008). For the purposes of the research, this paper adopts a narrower approach to the studied phenomenon, and financial self-exclusion is defined as the non-use of financial services and products by households of their own choice. This will make it possible to identify the characteristics of entities which, by their own choice, give up activity on the market of financial services and products, as well as to determine the causes of this phenomenon among the surveyed households.

As evidenced by the results of research conducted so far, the causes of financial exclusion can be seen both on the demand side and on the supply side (Adeyemi, Pramanik and Meera, 2014; Ziemba, Świeszczak and Marcinkowska, 2014; Barboni, Cassar and Demont, 2017). In the first of these groups, the most frequently indicated causes are: household income level; household location; gender, occupation of the household head; level of education of the household head; reluctance to use financial services/products; fear of over-indebtedness and loss of financial liquidity; lack of trust in financial institutions; bad experiences from the past (e.g. credit refusal); psychological factors, cultural considerations (Anderloni et al., 2008; Ziemba, Świeszczak and Marcinkowska, 2014; Pandey, Bhatia and Pandey, 2015; Sain, Rahman and Khanam, 2016). On the supply side, on the other hand, the most common causes of financial exclusion are: the price of the product/service; distribution channels; the form of service provision; quality of products/services, geographical availability of facilities; conditions necessary to be met for the use of a financial product/service (e.g. credit risk assessment); information on available financial services/products (Anderloni et al., 2008; Ziemba, Świeszczak and Marcinkowska, 2014; Bhatia and Pandey, 2015; Sain, Rahman and Khanam, 2016).

One of the research aspects undertaken in this area are factors that influence the financial exclusion of households, including financial self-exclusion. The research results show that the analyzed phenomenon may be influenced by a number of factors, the most common of which are: low level of income, low level of education, lack of permanent employment, unemployment, location of the household in rural areas or in small towns, young age , retirement age (Błędowski and Iwanicz-Drozdowska, 2010; Dungey, Doko Tchatoka and Yanotti, 2018). Therefore, people

particularly at risk of financial exclusion, as evidenced by the results of research presented in the scientific literature, include primarily: unemployed, low-income people, people without permanent employment, inhabitants of rural areas, women, young people, older people, people with low levels of education, immigrants and people with disabilities (Corr, 2006; Anderloni et al., 2008; Coffinet and Jadeau, 2017; Dungey, Doko Tchatoka and Yanotti, 2018).

Materials and Methods

The main source of empirical data were the results of a survey conducted among 1,000 households in Central Pomerania in Poland. The survey was carried out in the second quarter of 2019 using the direct questionnaire technique. In the course of the research, the number of correctly completed questionnaires was 746 (return rate 74.6%). The respondents were asked to provide information for 2018, with the selected questions covering the years 2004-2018. Since the studied sample was not representative, the results of the study cannot be generalized, which is a limitation of the research.

The analysis of the characteristics of financially self-excluded households in relation to the other units included in the analysis was performed using: the chi-square test, the Fisher test or the Mann-Whitney U test (to compare two groups with respect to other variables) (Nahm, 2016; Hopkins, Dettori and Chapman, 2018). To determine the reasons for the financial self-exclusion of the surveyed households, the data from the questionnaire were used, and the reasons which, according to the respondents, were indicated as important or very important were taken into account. The assessment of this phenomenon was made using a five-point Likert scale, where 1 - meant a cause that was irrelevant for a given household, and 5 - a very important cause (Cummins and Gullone, 2000; Joshi, Kale, Chandel andPal, 2015; Kandasamy, Kandasamy, Obbineni et al. al., 2020).

In order to determine the factors related to financial self-exclusion of households, the following set of socio-economic characteristics and the corresponding categories were adopted on the basis of the literature review and data contained in the questionnaire:

1. **SELF_EXCL** – financial self-exclusion of the household - does not use financial services and products by its own choice: yes, no
2. **AGE** – age of the head of a household (years)
3. **GH** - gender of the head of the household: female, male
4. **EDU** - education of the head of a household: basic, basic vocational, secondary, post-secondary, higher
5. **EC** - economic education of the head of the household: yes, no
6. **TSE** - socioeconomic type of household (main source of income): employees, farmers, self-employed, pensioners, other
7. **INC** - average monthly net income per person in a household: up to PLN 1,000; PLN 1,001-1,500; PLN 1,501-2,000; above PLN 2,000
8. **INC_DIV** - diversification of sources of income in a household - more than one type of source of income: yes; no
9. **DPH** - household development phase: single young person's household; young marriage/partnership without a child; single person with a dependent children; marriage/partnership with dependent children; marriage/partnership in middle or old age without dependent children; single household older person; other
10. **LHM** - number of household members
11. **SHME** - share of household members engaged in gainful employment in the total number of members of the household
12. **SCH** – share of children in the total number of people in the household
13. **LOC** - household location: village, city up to 50,000 residents, city of over 50,000 residents
14. **FO** - form of ownership of a residential unit: privately owned apartment, own house, flat rented from a private person, other

The assumed goal was achieved with the use of the following research methods: (a) literature studies, (b) survey assessment method - in order to collect primary data, a questionnaire study was conducted using a direct questionnaire; (c) empirical data analysis using descriptive and comparative methods, as well as statistical methods. The results of the analyses are presented in tabular and graphical form. form.

Characteristics of the studied households

Among the studied group of 746 households, entities from rural areas were the dominant ones (46.2%). Next, there were households from cities with more than 50,000 inhabitants (27.2%) and from smaller towns (up to 50 thousand inhabitants - 26.5%). Taking into account the development phase and the composition of the household as the classification criterion, it was found that the most numerous group were married couples/partnerships with dependent children (47.1%), where the head of the household was a man (62.2%), aged 45 (on average). Nearly 65% of the respondents were entities in which the head of the household had secondary education at most. 27.9% of respondents declared having higher education. The largest group among the surveyed households (61.1%) were units for which the basic source of income was the remuneration obtained from contract work. Taking into account the level of income, it was found that 17.6% of entities had an average monthly net income per person in a household not exceeding 1,000 PLN. In turn, for over 1/3 of the respondents (36.6%) the amount of the analyzed income category was higher than 2,000 PLN/person. More than half of the group (50.9%) diversified their sources of income and was characterized by a constant increase in income in the years 2004-2018. 61.4% of the surveyed households recorded a constant increase in expenditure in the analyzed period. It was also found that the dominant group of the analyzed entities amassed funds in the form of savings (60.05%), allocating an average of 14.5% of the total income for this purpose. Among the surveyed group, every third household was in debt (34.3%) and spent on average 17.6% of its total income on its repayment. The dominant group of respondents (71.7%) indicated that they were unfamiliar with the concept of financial exclusion.

Empirical Results

When conducting the research on financial self-exclusion among the households included in the analysis, the preferences of the surveyed entities in the use of financial services and products were first established. The results obtained in this aspect are presented in Figure 1.

Fig. 1: The structure of the surveyed households in Central Pomerania, including activity in the use of financial services and products [%, N=753]

Source: Author's own study.

On the basis of answers for the key survey question that was used to collect data on who is financially self-excluded (Fig. 1), it was established that financial self-exclusion marked 6% of the surveyed entities ("*we do not use financial*

services and product as our own choice"). In the course of the conducted research, it was also found that more than half of the surveyed households declared using many financial services and products (52%). 37% of respondents indicated that they make little use of financial services and products as their own choice. Barriers in access to financial services and products constituted the main reason for the fact that 4% of the surveyed population made little use of these opportunities, while for 1% of respondents it was the reason for a complete lack of activity on the market of financial services and products.

So what causes households to give up the possibility of using financial services and products? In search of an answer to this question, it was first established whether there are differences in the socio-economic characteristics of households that choose to give up activity on the market of financial services and products, and other entities included in the study. Identification of the features influencing households' debt began with determining whether there is a statistically significant relationship between financial self-exclusion and the socio-economic characteristics of the households studied. For this purpose, the non-parametric chi-square test, the Fisher's exact test and the Mann-Whitney U test were used. The results of these calculations are presented in Table 1.

Table 1: Comparison of the surveyed households in relation to self-exclusion for the variables included in the analysis

Source: Authors' own study.

The non-parametric tests used showed that a statistically significant relationship with the self-exclusion of a household was noted for the following nine characteristics of the surveyed entities: **AGE** - age of the head of a household (Mann-Whitney U test; p=0.001); **EDU** - education of the head of the household (Fisher's test; p=0.0187); **TSE** - socio-economic type of the household (Fisher's test; p=0.0004); **INC_DIV** - diversification of sources of income in a household - (chi-square test; p=0,002); **DPH** - household development phase: (chi-square test; p=0.0005); **LHM** - number of household members (Mann-Whitney U test; p=<0.001); **SHME** - share of household members engaged in gainful employment (Mann-Whitney U test; p=0.005); **SCH** - share of children in the total number of people in the household (Mann-Whitney U test; p=0.004) and **LOC** - household location (chi-square test; p=0.0118). Financially self-excluded households were characterized, on average, by older household heads (mean age 54) than the units from the second group included in the analysis (mean age 44) and a lower level of education (nearly 80% of them had at most secondary education). Taking into account the socio-economic type of a household, determined on the basis of the main source of income of a given unit, it was found that entities that, by their own choice, did not use financial services and products were primarily households of employees (45.7%) and pensioners (39.1%). Nearly 80% of financially self-excluded entities did not diversify their sources of income. Taking the development phase of the household as the classification criterion, it was observed that among financially self-excluded entities, the largest group were households with dependent children (26.1%), single elderly people (26.1%) and middle-aged or elderly marriages/partnerships with no dependent children (21.7%). Subsequently, it was found that there is a statistically significant difference between the size and composition of financially self-excluded households compared to other units included in the study. Entities which, by their own choice, were not active on the market of financial services and products were characterized, on average, by a lower number of household members, a lower share of paid members and a lower share of dependent children in the total number of household members (Table 1). Financial self-exclusion concerned mainly rural households (43.5%) and entities located in smaller towns (43.5%).

The next stage of the analysis covered the determination of reasons for financial self-exclusion of the surveyed households. Table 2 presents the results of the research on this issue, taking into account the percentage of households which indicated a given cause as important or very important.

Among the surveyed group of households, the main reason for financial self-exclusion was reluctance to use financial services and products - nearly half of the respondents indicated this reason as important or very important. This was followed by retirement age (43%) and preference for using cash (41%). An important cause of the analyzed phenomenon among the surveyed entities was also the unfavorable financial situation of the household, related to a

too low level of income. Among other significant reasons for financial self-exclusion, the respondents also indicated demand factors related to the inability to use financial services and products, such as: inability to manage new technologies, lack of access to a computer and mobile devices, lack of access to the Internet, lack of knowledge about existing opportunities in the use of financial services/products, lack of trust in financial institutions and fear of losing financial control. A number of supply factors were also indicated which limited the activity of the surveyed entities on the market of financial services and products; these were mainly: product price (too high costs associated with the use of financial services and/or products), availability of products and services (including the form of providing the service, limiting the possibility of using it, e.g. the Internet, lack of information about available financial services/products, geographical availability of branches, e.g. no bank branch in the place of residence) and the conditions that must be met in order to be able to use the product/service (e.g. no creditworthiness).

Table 2: Reasons for financial self-exclusion of the surveyed households [%, N=46]

Description	Percentage of households*
reluctance to use financial services and/or products	46%
retirement age	43%
preferring to use cash	41%
low level of household income	37%
inability to manage new technologies	37%
too high costs related to the use of financial services and/or products	33%
lack of knowledge about the existing possibilities of using financial services/products	33%
no access to a computer, mobile devices, the Internet	33%
fear of getting into debt and living on credit	30%
the form of service provision, limiting the possibility of using it (e.g. the Internet)	26%
lack of trust in financial institutions	24%
fear of losing financial control	24%
low or no savings	24%
limited availability of financial services and/or products	20%
no permanent employment	20%
lack of habit or need to save	20%
no information about available financial services/products	17%
geographic availability of branches (e.g. no bank branch in the place of residence)	15%
the location of the household which prevents the use of the service/product	15%
no incentives to save with an intensive campaign to encourage incurring liabilities	15%
no permanent source of income	13%
young age	13%
a barrier related to meeting the conditions enabling the use of a given service/product (e.g. no creditworthiness)	11%
household over-indebtedness	11%
low quality of products and services	9%
lack of household financial management skills	7%
inheritance of negative behavior patterns	7%
focus on fast consumption with the use of credits and loans	4%
refusal by a financial institution to provide a service	4%
low level of education	2%
low level of economic and financial education	2%

** Due to the fact that the respondents could indicate more than one reason why they do not use financial services and products, the percentage of households does not add up to 100%.*

Source: Authors' own study.

Conclusions

The aim of the research presented in this paper was to identify and assess the socio-economic characteristics of financially self-excluded households and to identify the reasons for the inactivity of households on the market of financial services and products. The main source of empirical data was the result of a survey conducted in 2019 on 1,000 households (746 correctly completed questionnaires) in Central Pomerania (Poland). In the study, financial self-exclusion was defined as the non-use of financial services and products by households, by their own choice. This feature was noted for 6% of the surveyed households.

Main findings of this paper confirm the results of research presented in the literature. The conducted research proved that the following types of households are particularly exposed to financial self-exclusion: households from rural areas and small towns, households of the elderly; households with dependent children; entities whose main source of income are pensions and those whose primary source of income is related to the performed contract work. Moreover, it was found that entities which choose not to use financial services and products do not diversify (for the most part) their sources of income. Financially self-excluded households were, on average, smaller, with a lower proportion of dependent children and a lower proportion of people who were gainfully employed.

Further analyzes showed that the main reason for financial self-exclusion of the surveyed entities was the reluctance to use financial services/products and the preference to use cash. An important reason was also retirement age and low level of household income. The surveyed households also indicated reasons relating to the inability to use a financial product/service due to: too high a price, difficult access to financial products and services, and the conditions that must be met in order to be able to use the product/service. Therefore, these reasons relate to both demand and supply, which confirms the results of empirical research presented in the scientific literature to date (e.g. Corr, 2006; Osei-Assibey, 2009).

Since the studied sample was not representative, the results of the study cannot be generalized, which is a limitation of the research. However, the results obtained in the course of this research contribute to both literature and practice. In the first aspect, the obtained results complement the current research results presented in the literature on the financial self-exclusion of households, taking into account the factors influencing this phenomenon and its causes. In practice, on the other hand, these research results may be an important source of information both for financial institutions that are interested in the best possible adaptation of financial services and products for households and acquiring new customers, as well as for entities that deal with reducing financial exclusion, including financial self-exclusion of households.

The timeliness and significant importance of the research issues undertaken here justify continuing the research in this area. Further research questions arise, including the direction and force of the impact of individual factors on the financial self-exclusion of households. The search for an answer to this question will constitute the next stage of research.

Acknowledgment

The study was carried out as part of the research project entitled: *Smart development of Central Pomerania - an innovative approach to creating the competitive advantage of the region*, financed by the Minister of Science and Higher Education in Poland under the "Dialog" program (contract number: 0131/DLG/2019/10), action: *Financial exclusion of agricultural households and its importance for the development of financial services in the region of Central Pomerania in the context of creating an offer of innovative financial services that support the creation and development of smart specializations*.

Abstract

The paper in the theoretical part deals with the issue of neuromarketing and gender differences in the context of shopping behavior. The main goal is to identify statistically significant differences in the evaluation of consumer shopping behavior and neuromarketing in the context of gender equality. The research sample consisted of 204 respondents, of whom 126 were men and 78 were women aged 18 to 59 years with an average age of 33.69 years. Respondents' data were obtained by occasional sampling. The data needed for the analysis were obtained through the authors' questionnaire, which was the primary source of data. Two research hypotheses were established for the paper. The obtained data were processed and interpreted at the level of descriptive statistics. At the level of induction statistics, we used the Mann-Whitney U test. The results were processed by mathematical-statistical methods in IBM Statistics SPPS 22.00. The results of the analysis confirmed the existence of statistically significant differences between male and female consumers when evaluating shopping behavior and neuromarketing.

Keywords: Gender differences, Neuromarketing, Purchasing behaviour

Neuromarketing

Since the 1970s, studies that deal with the principles of brain function have started to appear. Young (2002) states that twenty years have passed since the first ideas of using and measuring brain activity in the context of consumer behavior arose. This concept was developed by psychologists at Harvard University in 1990. In 1996 the neuromarketing research by Shizgalo and Conover was carried out. In the research, there were combined neuroscience and mathematic theories that can make human behavior predictable. Gerald Zaltman – professor of Harvard Business School who is thought as "father of neuromarketing" in 1999 used FMRI method for brain observation. The word Neuromarketing was coined by Ale Smidts in 2002. The first scientific research in neuromarketing was made by neuroscience professor of Baylor College of Medicine Read Montague in 2003. Worldwide companies as Coca-cola, Ford, or Google invested a big amount of funding to marketing at that time however results of researches kept as confidential from the general public.

In this context, it is appropriate to refer to Nobel Laureate Francis Crick statement, that the idea that all human feelings, thoughts, and actions, even consciousness itself, are just the products of neural activity in the brain. According to Morin (2011), neuromarketing is a field, that bridges the study of consumer behavior and neuroscience. It is a modern and developing area with great potential for application to functional areas of marketing. It arises after merging concepts of neurology, psychology, human neurophysiology, and neurochemistry areas. Vysekalová (2011) state, that neuromarketing connects knowledge of neuropsychology, cognitive psychology, and neuroscience in neuromarketing environment. Daugherty and Hoffman (2017) state that marketing uses theories, ideas, and approaches from the several disciplines (thinking, anthropology, sociology, etymology, neuroscience, biology, finance or arithmetic). Researchers in the field of neuromarketing are examining the human

Cite this Article as: Robert STEFKO, Anna TOMKOVA, Jana KOVALOVA and Ivana ONDRIJOVA "Consumer Purchasing Behaviour and Neuromarketing in the Context of Gender Differences" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

brain and nervous system to understand better the impact of marketing by measuring users' direct and indirect neurological processes. Morin (2011) state, that neuromarketing is to marketing what neuropsychology is to psychology. While neuropsychology studies the relationship between the brain and human cognitive and psychological functions, neuromarketing promotes the value of looking at consumer behavior from a brain perspective.

Neuromarketing deals with designing marketing materials to evoke specific neurological reactions that trigger emotions or responses that are linked to purchasing. Neuromarketing deals with designing marketing materials to evoke specific neurological reactions that trigger emotions or responses that are linked to purchasing (Gotter 2019). Neuromarketing suspects, that emotional basics influence decisions about products purchase (Badoc and Bayle-Tourtoulou 2014). Limbeck (2012) underlines the fact, that purchase decision arises in the brain part called the limbic system, which is involved in behavioral and emotional reactions.

Fournier (2018) adds that the limbic system is responsible for endorphins production, hormone levels, body temperature, and motor functions. Limbic system function was accidentaly discovered by James Olds and Peter Milner (1954) during the experiment with electric stimulation of the rat brains which indicated "the brain reward system". These claims are supported by several psychological theories and researches in neuromarketing and neuropsychology fields (Sahakian, Gottwald 2018; Georges a kol. 2014).

Neuromarketing offers cutting edge methods for directly probing minds without requiring demanding cognitive or conscious participation (Morin 2011). The field of neuromarketing analyses the human brain to predict and potentially even manipulate consumer behavior and decision making. The aim of neuromarketing is to combine neuroscience methods with neuromarketing theories to reveal the real, even out of sight, influence of marketing on consumer beahvior (Lim 2018). Tomková and Ondrijová (2018) infer that the aim of neuromarketing is to get information about consumer´s brain activity during the influence of marketing stimuli while its advantage, unlike the questionnaire survey, is that the results are not influenced by a consumer prejudice or a choice to reveal real feelings, emotions, values and attitudes. Fortová (2015) claims that neuromarketing studies consumer reactions to marketing stimuli via monitoring brain activity. Harrell (2019) states, that neuromarketing deals with measurement of physiological and neural signals. The main goals is to investigate customers' motivations, preferences, and decisions, which can help inform creative advertising, product development, pricing, and other marketing areas. The aim is to find out how consumer decision-making is affected and what part of the brain is activated at the moment of decision-making. For example, it uses the following medical technologies: magnetic resonance imaging (fMRI), electroencephalography (EEG), etc. (Kozel 2006).We can conclude that this field brings new research methods with the potential to reveal still hidden information in the human mind.

Why does the neuromarketing cause ethical concern? While neuromarketing has far-reaching use in practice, it is important to deal with a matter of ethics. Neuromarketing and ethic principle difficulty comes from the fact, that researchers can unconsciously cross the line of privacy, what interrupt consumer autonomy protection (Ondrijová, Tomková 2017). Findings that come from the research could be damaged or used against them. Murphy et al. (2008) state that the privacy of individuals joined in neuroscience researches taking place in medical institutions, is usually protected by the law. However, if neuroscience research is conducted for commercial purposes, then the protection law is ineffective and privacy provision depends on the moral values of the researchers. The year 2012 was important for ethics from a neuromarketing perspective, when The Neuromarketing Science and Business Association, based in the Netherlands, approved a code of ethics, which came from the need to unify the rules of neuromarketing research, as many companies followed different standards. Harvard Review of Psychiatry study also demonstrates that the world´s top neuromarketing companies provide very little information about their ethical standards (Morin 2011).

A significant role in this field is played by consumers, who often do not know, that they are part of the research or are affected by various neuromarketing tools. This is a reason, why is necessary to find a compromise between neuromarketing research, consumer protection, and maintaining ethical standards. Ducu (2016) states, that neuromarketing research has a very practical goal: to inform effective marketing strategies and advertisement campaigns. On the other hand there is a growing need to develop an ethics of the technologies involved in the neuromarketing research, and a business ethics that takes into consideration the applications of neuromarketing research.

Gender Differences

Despite the well-known idea, that men and women react to marketing stimuli differently, it is important to keep them under review. Due to more objective neuromarketing, we have a better opportunity to understand gender differences that lead to more accurate and personalized targeting and elimination of deficiencies (Vecchiato et al. 2014). Gender is a major factor that affects consumer purchasing behavior. Birknerová, Frankovský, Zbihlejová, and Parová (2017) explain gender in socio-structural, interpersonal, and individual level. Man and woman's brain is diametrically opposed to the structural and behavioral levels. These differences are formed from birth, last whole life, and influence attitudes, and behavior that affect shopping behavior and consumer decisions. Women and men have different behavior and decision making while shopping. The reason for these differences is in their upbringing and socialization, which later influences their attitudes, behavior, perception, motivation, or values (Lakshmi, Aparanjini and Lahari 2017). Hyde (2016) states, that for the understanding of psychological and gender differences, it is important to know individual education experiences, culture gender stereotypes, gender equality, and biosocial interaction. Jäncke (2018) states, that gender differences are shaped by experience, education, culture, or a combination of these.

Hyde (2016) underlines the fact that in a matter of emotions, empathy, moral judgment and social behavior, differences between men and women are insignificant, or even disappear during the study of bigger samples or use of objective tools, except those, that person exhibits about herself or himself. Results of questionnaire surveys can indicate not relevant results forasmuch as in culture context exist typical gender stereotypes and social expectations (Ellemers 2018; Williams and Dempsey 2014; Christov-Moore et al.2014; Derntl, Finkelmeyer, Eickhoff et al. 2010) with which men and women naturally identify themselves. Uva, Freitas and Paiva (2015) research were focused on study of gender and TV advertisements using electroencephalography. In this neuromarketing research, 10 men and 10 women participated, and their nervous activity during watching a video was recorded by electroencephalography (EEG). However, statistically significant differences between male and female were identified for all the electrodes, there were also identified differences in brain frequencies and activity of brain areas related to emotions, mainly of anterior cingulate cortex (ACC) which have been higher for men than for women. Men usually have better depth perception since they have a bigger pariental lobe. It is also the reason, why do they prefer pictures over reading. Due to the bigger amygdala, men are more aggressive than women. Female brains have a larger prefrontal cortex, which impacts emotions and how they're regulated. That is the reason, why are emotions the most effective way to speak to them. Female brains also allow for more intuitive reasoning and the part of the brain responsible for worrying is larger. Thanks to the larger corpus callosum, they are able to multi-task and distribute their thinking. They also have a bigger hippocampus, that is reason why theirs level of nuance in emotional details is much greater (Adelson-Yan 2013).

Table 1: The main known gender differences

The main known gender differences	
Women	**Men**
- advertisements are often more detailed	- adverts usually focus on one main object - usually pick up on one or two very obvious kinds of cues
- appreciate very fine distinctions	- will need to be shown the big picture as they think in a macro way
- like a collaborative style dialogue	- are less likely to process complex metaphors
- prefer strong colours and evocative images	- do not really respond to any colours and images seem irrelevant
- prefer more feminine qualities in advertisement	- enjoy humour in adverts (usually more crude and aggressive) - prefer hard data and concise language.

(Source: Lakshmi, Aparanjini and Lahari 2017)

There exist number of studies that confirm different purchasing behaviours in the context of gender perspective. The research by Mitchell and Walsh (2006) shows that women are more perfectionist than men. Gender differences were also studied by Birknerová and Frankovský (2014), who were in their research focused on manager work, where they identified statistically significant differences between emotional intelligence aspects between men and women. Men had higher score in aspects as emotional control, self-motivation, stress management, low impulsivity level, assertiveness, adaptation, and relationships.

There is interesting Puccinelli´s (2013) research, who emphasizes that colors linked with shopping have a significant impact on men more than on women. Men associate red color with savings and it has a positive effect on them during shopping. Also, when prices were highlighted with this color, men´s perception of savings increased, unlike other colors. While this color made women skeptical. Women associated black color with saving. Another part of his research was focused on price information where women exhibit better memory for price information and deeper processing of information than men.

We also agree with Beverland (2006) findings where he emphasized the impact of music on the customer during shopping. The choice of the appropriate music and its appropriate volume led to the reinforcing of the brand, the pleasure of customers, and the attraction of new customers. However, quiet music gave them the unwanted feeling that they had to communicate with the vendors while louder music influenced the overall impression. Therefore, choosing inappropriate music can reduce the time spent in the store, even cause leaving, and subsequently avoiding the store.

In favor of men DaimlerChrysler company in Ulm researched, which vehicles are the most attractive. Researchers showed respondents, at an average age of 31, 66 pictures of different cars - 22 sports cars, 22 sedans and 22 small cars. The study was carried out using an fMRI. Sports cars have illuminated the area of the brain associated with reward and power much more than other models. Among the sports cars that had the strongest reactions to the brain were: Ferrari 360 Modena, BMW Z8 and Mercedes. Walter, a psychiatrist at the Ulm University Hospital who was involved in the study, found that sports cars do not only look more attractive to men but also demonstrate success, wealth and dominance (Wells 2003).

On the other hand, women got higher score in aspects like empathy, emotion expressing, and emotional appreciation. In a matter of emotional intelligence, men had higher score in self-control and sociability, what indicates that they have healthy control over their desire, good regulation of pressure and stress, and they are focused on social relationship and social influence. Women can better perceive and express emotions for keeping close relationships.

Research

Following the theoretical elaboration of the issue of neuromarketing and gender differences, the research focuses on identifying statistically significant gender differences in the assessment of Consumer purchasing behavior and Neuromarketing. This research was carried out via author's questionnaire.

Research Sample

The research sample consisted of 204 respondents, of whom 126 were men and 78 were women aged between 18 and 59 years, with an average age of 33.69 years (SD=12,422). Data from respondents were obtained through occasional selection.

Research Methodology

The main objective of the paper is to identify the differences in the assessing of consumer purchasing behaviour and neuromarketing in the context of gender. For this contribution, the following research hypotheses were established:

H1: We assume that there are statistically significant differences in the assessing of the Consumer purchasing behaviour between men and women.

H2: We assume that there are statistically significant differences in the assessing of the Neuromarketing between men and women.

The data needed for the analysis were obtained through the questionnaire of the authors, which was the primary source of the data. The questionnaire was divided into parts: The first part consists of statements that focus on the Consumer purchasing behaviour (items 1-10). The second part consists of statements that focus on the Neuromarketing and Ethic in it (items 10-20). The third part contained closed-ended categorization questions needed to classify respondents by age and gender.

The research participants were to respond on the scale from 1 to 4 what extent they agree with the given statement (1 = definitely no, 2 = rather no than yes, 3 = rather yes than no, 4 = definitely yes). The data obtained were processed and interpreted at the level of descriptive statistics. At the level of inductive statistics, we used the Mann-Whitney U test, which is suitable for analyzing the data available to us and does not require a normal distribution. The results were processed by the mathematical-statistical methods in IBM Statistics SPPS 22.00.

Results and Discussion

Based on the Mann-Whitney U test, we found that there are statistically significant differences in assesing of the 8 items of questionnaire between men and women. Table 2 shows the results of testing the hypothesis which examines the existence of differences between men and women in the assesment of Consumer purchasing behaviour and Neuromerketing.

Table 2: Statistically significant differences between men and women in the assesment of Consumer purchasing behaviour and Neuromarketing

	Q3	Q4	Q8	Q12	Q14	Q18	Q19	Q20
Mann-Whitney U	3490,000	3522,000	3646,500	3798,500	3690,500	3472,000	3532,000	3728,000
Wilcoxon W	10993,000	11025,000	11027,500	11179,500	11193,500	10975,000	10913,000	11109,000

(Source: own processing)

The existence of statistically significant differences confirms the results in Table 3.

Table 3: Comparisons of the assesment of Consumer purchasing behaviour and Neuromarketing in terms of Gender

Gender		**Mean Rank**	**Median**	**Mean**	**Standard deviation**
Q3_ Product color is important for me	Female	115,68	3,00	2,82	,942
	Male	90,11	2,00	2,36	,980
Q4_ If something grab my attention, I have to buy it.	Female	114,16	3,00	2,45	,929
	Male	90,37	2,00	2,05	,969

Q8_ Social networks have an impact on my product choice.	Female	112,64	2,00	2,31	,877
	Male	91,14	2,00	1,97	,884
Q12_ I would be willing to participate in neuromarketing research.	Female	110,67	3,00	2,60	,877
	Male	92,39	2,00	2,29	,987
Q14_ It is possible to influence a customer to buy a specific product by using neuromarketing tools.	Female	111,94	3,00	3,11	,624
	Male	91,75	3,00	2,80	,802
Q18_ Neuromarketing ethics is essential.	Female	113,71	4,00	3,51	,685
	Male	89,96	3,00	3,07	,972
Q19_ It is necessary to create legislation strictly following ethics.	Female	113,03	4,00	3,46	,701
	Male	90,19	3,00	3,04	,978
Q20_Neuromarketing basics education for costumers, where they can get new information, should be instituted..	Female	110,45	3,00	3,08	,829
	Male	91,81	3,00	2,78	,871

(Source: own processing)

Statistically significant differences in the individual Consumer purchasing behaviour components were recorded in items 3,4, and 8.

In item no. 3 „*Product color is important for me*" Higher scores were made by females whose average answers were 2.82, so they were closer to the answer „rather yes" unlike males 2,36. Statistically significant differences were also found in item no. 4 „*If something grab my attention, I have to buy it.*" In this case, again females had higher score (2.45), unlike males 2,05. Females ranged on a scale between "rather no than yes" and "rather yes than no" and males closer to the answer "rather no than yes". In item last item of assessment of Consumer purchasing behaviour no. 8 „ *Social networks have an impact on my product choice.*" females (2.31) again scored slightly higher, against male with score 1.97. In both cases, they were on the same side of the scale in answering "rather no than yes". And statistically significant differences in the individual Neuromarketing components were recorded in items 12, 14, 18, 19 and 20. Even in this case, in all assessed items, females scored slightly higher than males.

In item no. 12 „I would be willing to participate in neuromarketing research" females got higher scores (2,60), unlike males 2,29. We conclude, that females would be willing to participate in neuromarketing research, considering their answers „rather yes than no", unlike males, whose answer was „rather no than yes." Even though in item no. 14 „It is possible to influence a customer to buy a specific product by using neuromarketing tools." Female score (3,11) was higher than male (2,80). In both cases, they were in the same part of a scale and approach to the answer „rather yes than no".

In item no. 18 „Neuromarketing ethics is essential" females scored 3,51 and males 3,07. Although this difference is not significant, females expressed their degree of agreement with this statement. Also in item no. 19" It is necessary to create legislation strictly following ethics." identified differencies are not significant, however females with score 3,46 would demand following ethical principles more than males with score 3,04.

In both cases, they were on the same side of the agreement of the rated scale.

In the last item of assessment of Neuromarketing no. 20 „Neuromarketing basics education for costumers, where they can get new information, should be instituted..“ females (3,08) scored higher than males (2,78 In both cases, they were on the same side of the agreement of the rated scale and preffered answer „rather yes than no“.

We can confirm the existence of statistically significant differences in the evaluation of consumer purchase behaviour between men and women in favour of women. We deduce that men are more sensitive to scent, delightful music, cleanliness, lighting, and interior design of a store. They care more about product brand and packaging design. They are also more sensitive to the product price. On the other hand, women care more about the color of the product, they are more likely to be influenced by social networks when choosing a product. We have also observed the existence of statistically significant differences in the evaluation of neuromarketing in favour of women. We conclude, that women would be more initiative in neuromarketing investigation. Women believe that it is possible to influence a customer´s product choice by neuromarketing tools. They also emphasize ethics in neuromarketing and declare, that in their opinion, the state needs to create legislation that would be followed. Women emphasize the implementation of neuromarketing basics teaching that can enrich customer´s knowledge about the issue.

Based on the Mann-Whitney U test, we found that there are statistically significant differences in the assessing of the Consumer purchasing behaviour between men and women. Therefore, the hypothesis H1 has been confirmed. And we also confirmed H2, because we found that there are statistically significant differences in the assessing of the Neuromarketing between men and women. We can´t follow only the information that respondents provide about themselves in quantitative and qualitative research, because many times they mean something different than they mention or they do not state their final decision.

The brain, even unconsciously, constantly calculate, what is the most advantageous for him at the moment. A difference between what people think and what they say is caused by one of the neural network algorithms that has proven to be the most useful for life (Tomková, Ondrijová 2018).

Since neuromarketing companies are reluctant to share their information, researches are limited. Krugrman (1971) claimed, that reading and speaking are located in the right hemisphere while visual perception is located solely in the left hemisphere. So newspaper is appropriate for the right hemisphere and television for the left one. The other important findings were related to other functions and their classification, such as the emotion experience situated on the right side, and the cognitive functions of perception on the left side. High level of involvement of the individual activated the right hemisphere, and conversely low level activated the left hemisphere. In the context of television advertising, the brain uses recognition while in the context of print ads uses recall. He also described some differences between families with the lower and higher economic position. Svetlík (2012) states, that his theories have some deficiencies as his statements were not supported by any empiric research and therefore they have a large number of opponents, which include scientists but also people who are directly involved in marketing. In 1996 Shizgal a Conover have conducted the research in neuromarketing field where they combined neuroscience and mathematical theories in the belief that they can be applied in social sciences to predict behavior (De Sousa 2018).

Our research is focused on gender differences in the assessment of neuromarketing attributes. Based on Mann-Whitney test we found out that there are statistically significant differences in the assessment of consumer purchasing behavior between men and women, in favor of women. We also found out, that in favor of women, there are statistically significant gender differences in neuromarketing assessment. In general, we conclude, that men are more sensitive to scents, pleasant music, cleanliness, lighting, and interior design of the store. They care more about the brand and design of the product packaging. They are also more sensitive to the price of the product. On the other hand, women care more about the color of the product, they are more likely to be influenced in their product choice by social networks and they give importance to ethics in neuromarketing.

Hsu a Cheng (2018) examined the impact of gender on the neural substrates of theories on consumer behavior and to examine whether gender influences brain activation associated with word-of-mouth communications.The fMRI results showed that the males treat product quality perception as a constant. On the other hand, females results suggest a dynamic representation for product quality perception (i.e. not a constant). Vecchiato et al. (2014) performed an experiment in order to investigate cognitive and emotional changes of cerebral activity evaluated by neurophysiologic indices during the observation of TV commercials. They showed that there are results suggesting that it is possible to differentiate the communication according to the gender. Cuesta, Nino and Martinez (2018)

analyzed the mechanisms of action of 3 psychophysiological variables widely used in this field: eye-tracking, galvanic skin response and facial emotion. They found some gender differences in terms of visual attention.

The paper aimed to identify and specify the differences in the assessment of neuromarketing between men and women. This aim was achieved by the questionnaire method and results were processed by statistical program. The aim of the paper was supported by the theoretical framework in which we have been focused on marketing, business and neuromarketing. Neuromarketing is answering questions related to emotions that are important for people during making purchase decisions. These findings are used to improve psychology and marketing efficiency. They are applied mainly for product design, promotion and advertising improvement, store design and improvement of customer experiences in all spheres.

Acknowledgment

This paper is supported by the grant VEGA 1/0807/19 Research on the determinants of trading behavior and marketing effects in the area of neuromarketing and the relation to neuro-linguistic programming.

Abstract

the relevance of scientific research is determined by clearly expressed growing economic imbalances in the world agri-food markets and a more balanced and balanced (without structural distortions and tariff restrictions) agri-food policy within the Eurasian Economic Union. The historical and economic analysis of scientific views on the development of the agri-food market in the post-Soviet region will allow in the future, will serve as the foundation for modeling and designing organizational and economic tools to smooth out market imbalances, which will improve the institutional efficiency of the market (in our case, agri-food), as well as is one of the fundamental issues of the new institutional economy. The conducted historical and economic analysis of scientific views on the development of the agro-food market of the Eurasian Economic Union, a new global union created in the territory of the post-Soviet space, the region made it possible to identify the prevailing fundamental foundations and formed views of scientists on the problem under study.

Keywords: Historical and Economic Analysis, Agro-Food Market, Eurasian Economic Union, Common Economic Space, Economic Security, Food Security.

Starting to consider the historical and economic analysis of the development of the agro-food market of the Eurasian Economic Union in the context of constant geo-economic instability of the world economy, it is necessary to separately dwell on the existing scientific views that are most widespread on this problem, since they are the formed quintessence of historical thought based on the basis of historical experience. Many scientists have been studying this problem for many years and have devoted a number of their studies to the consideration of the agri-food market in the post-Soviet space within the framework of the Eurasian Economic Union, so A.I. For many years Altukhov has been studying the problems of the functioning and development of agri-food markets in Russia, mainly specializing in the study of the grain market and the grain-food subcomplex.

When considering integration in the agrarian sphere, the EAEU justifies the need to integrate the agrarian spheres of the partner countries on the basis of improving the territorial-sectoral division of labor in agro-industrial production. In particular, he proposes to create interstate formations specializing in the production of certain types of food products and agricultural raw materials: between Russia and Kazakhstan - for wheat; between Belarus and Russia - on rye, sinew, sugar from sugar beet, etc. [1].

Another prominent scientist S.Yu. Glazyev notes that the EAEU helps partner countries to overcome problems in

Cite this Article as: Kuraev Aleksey Nikolayevich, Zhakhov Nikolay Vladimirovich, Krivoshlykov Vladimir Sergeevich, Melnikova Elena Nikolaevna and Belostotskiy Alexey Alexandrovith“ Historical and Economic Analysis of Scientific Views on The Development of The Agri-Food Market in The Post-Soviet Economic Region” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

their national economies, since the absence of borders reduces costs, which in turn creates favorable conditions for joint investments, which are drivers of economic growth. States united by common economic interests and tasks operate more successfully in the global economy, gaining real competitive advantages by eliminating barriers that inhibit joint development and developing coordinated development strategies and policies [2].

A.G. Paptsov systematized the directions and threats to the development of the agri-food market in the context of the globalization of the world economy. As part of the study of the integration problems of the EAEU countries, it advocates the early development of cooperation between partner countries in the agricultural sector (development of a single agri-food policy, creation of a single organizational and economic mechanism for interaction at the above national level), especially against the background of the possible creation of a free trade zone between the United States and EU (Transatlantic Trade and Investment Partnership) [3].

Considering the features of the formation of the market mechanism in the agro-industrial complex of Russia since the 90s of the XX century A.F. Serkov and within the framework of the study of the EAEU agrarian market indicates the need to develop forecast balances, forecasting the development of the agro-industrial complex of partner countries and key agrarian markets of the Eurasian Economic Union in the future. Proposes to implement a uniform legal regulation of the agricultural market of all EAEU partner countries [4].

Within the framework of the EAEU integration association I.G. Ushachev [4] proposes to create a Eurasian commodity distribution system for agricultural products, raw materials and foodstuffs, while it is assumed that the routes of trade flows between the EU and China should pass through Belarus and the Russian Federation.

Director of the Center for International Trade Research, RANEPA A.Yu. Kno-bel, examining the prospects for the development of the Eurasian Economic Union, notes that the creation of a mechanism for redistributing gains within the EAEU will contribute to the implementation of a positive economic effect from the conclusion of agreements on free trade with non-CIS countries. The main current problem of integration processes within the union is insufficiently fully utilized opportunities for creating additional resources (low production efficiency, low rates of labor productivity) [5].

A significant theoretical contribution to the development of the agri-food market of the Eurasian Economic Union was made by Belarusian scientists. V.G. Gusakov proposed strategies for the development and formation of cluster agro-industrial structures in Belarus in the Eurasian Economic Union. Vladimir Grigorievich presented in the monograph the approach of the cluster institutional space as a new type of activity, as an instrument of the modern economic integration system of management within the framework of interstate economic unions, in particular the EAEU [6].

Z.I. Ilyina devoted all her professional activities to the study of economic problems of agriculture, including the agri-food market. In terms of creating a single market for agricultural products between the Republic of Belarus and the Russian Federation, there is a big problem in the form of trade barriers, which can be overcome only through the creation of a unified regulatory and legal framework. In the same work, a number of recommendations are proposed for eliminating non-tariff barriers in the markets of the two countries, and these recommendations can be expanded for the single EAEU market. Methodological recommendations are of great scientific and practical value (Methodological recommendations on the formation of an organizational and economic mechanism for balancing the national food market in the context of the development of integration processes (within the CES), 2015), which can be used as the basis for the formation of a sustainable single agri-food market EAEU partner countries [7].

In his last works, N.D. Avarsky substantiates the need for the development of organic agricultural production and the formation on its basis of the market for organic agricultural products. The main argument in favor of the development of organic agricultural production is the need to reduce greenhouse gas emissions and adaptation of the agricultural sector to the negative consequences of climate change [8].

L.N. Baigot analyzed the main risks for Belarus in the framework of accession to the WTO, and proved that the liberalization of the foreign trade regime of the Republic of Belarus is inexpedient and can lead to dissociation of relations within the EAEU [9, 10].

In his works, K.G. Borodin draws attention to the fact that the insufficient level of regulation of agri-food markets by

the state can lead to a shortage of agricultural raw materials on the domestic market. Konstantin Grigorievich notes the extremely disastrous consequences of the embargo on the domestic agri-food markets of Russia due to the low share of large enterprises that are able to better adapt to the impact of the embargo and sanctions and underdeveloped market infrastructure [11].

As E.Yu. Vinokurov, the formation of a single market for goods among the partner countries has not yet been completed. One of the reasons hindering the integration of national markets into the single market of the EAEU countries are non-tariff barriers, which confirms the need to conduct a study on the problem of sustainability of the single agri-food market.

The integration process and the degree of market stability are significantly complicated by the uncoordinated macroeconomic policies of partner countries (in particular, the devaluation of national currencies in 2011 in Belarus and 2014-2015 in Russia has already led to interstate conflicts) [12].

In his doctoral dissertation A.V. Pilipchuk substantiates the structural model of the formation of the innovation-cluster system of the EAEU food economy, based on the coordination of three areas: business, consumers, and the scientific and innovative sphere.

The implementation of the model makes it possible to purposefully identify and strengthen the competitive advantages of organizations and sectors of the food industry of the Eurasian Economic Union at the national and union levels [13].

A.P. Shpak focuses on the need to implement a coordinated agro-industrial policy by the members of the economic union, which will affect the effectiveness of the implementation of the aggregate resource potential of the partner states and ultimately ensure the optimization of the production volumes of competitive agricultural products and food, meet the needs of the general agricultural market, as well as increasing exports of agricultural products and food [14].

The research topic of the agri-food market of the Eurasian Economic Union is interesting not only to scientists from the countries of the aforementioned union, but also to foreign scientists.

Studying the evolution of Eurasian integration, Alena Vieira notes that the partner countries have not achieved significant success and there is a high probability of returning to their original positions [15].

Analyzing the tariff policy and structure of imports of partner countries, Asel Isakova comes to the conclusion that the effect of foreign trade was only in trade between Russia and third countries. According to the author, the benefits of tariff policy within the Union are limited. The Eurasian Union has slowed down the pace of integration interaction in comparison with the first years of its existence due to the lack of adherence to the ideals of integration on the part of Russia/

Professor Gholam Mostafa and Monovar Mahmoud investigate the history of the EAEU and conclude that, despite significant efforts, the integration union did not justify itself. Moreover, the reason for the lack of progress is indicated by the dominance, influence and pressure on partner countries from Russia [17].

Sean Roberts in his work notes the significant difficulties that the Eurasian Union faced in the last years of its existence, the most significant of which are inter-integration barriers [18].

Exploring the single market of the EAEU, Dr. David Tarr notes that partner countries have great growth potential if non-tariff barriers are reduced and the procedure for interstate trade is simplified [19].

Summarizing the considered opinions of foreign scientists, we note that in the aggregate, a position is formed that it is impossible to create an alliance of countries based on the Eurasian economic model. The EAEU relies on a mechanism for the redistribution of oil and gas revenues, in which Russia deliberately relinquishes part of the revenues due to it in favor of other member states, in order not only to induce economic interest to remain part of the Union,

but also to maintain and increase their political influence due to this. The Eurasian Economic Union is an unsuccessful

attempt to reintegrate the post-Soviet space.

Summing up the historical and economic analysis of scientific views on the development of the agri-food market in the post-Soviet region, based on the opinion of a significant number of theoretical and practical developments on the problems of the functioning of the agri-food market and the peculiarities of the work of the EAEU of Russian and foreign scientists, we can conclude that that the overwhelming number of studies by foreign scientists is reduced to the inappropriateness of the functioning of the Eurasian Economic Union, and domestic works on this issue note only integration problems in the functioning of the union (primarily non-tariff barriers). This only confirms the need for additional global research on the indicated problem.

Abstract

the structural formation of the digital ecosystem of the region should not be regarded as an end in itself, since it is only "a means of solving a wide range of problems of socio-economic development." The goal of systemic restructuring is to form the structure of the region's economy, contributing to the achievement of the regional socio-economic system of proportions and the achievement of the goals set, corresponding to the generally accepted ideas about a high level and quality of life of the population, taking into account the necessary contribution to their provision of the national economy. The paper presents the contours of the interaction of the subjects of the regional economy in the digital ecosystem of the region, which take into account the structural and substantive complexity of the processes accompanying the development of regional socio-economic systems, state regulation, representing a system of measures implemented by the executive authorities in the course of coordinated interaction with the population, civil institutions society, business structures, educational and research organizations. A feature of state regulation in modern conditions is its subject-object nature and focus on ensuring the systemic development of the formation of the digital ecosystem of the region, i.e. balanced development, ensuring the proportionality of the main subsystems of the regional economy that form its structure. In order to ensure the formation and development of the digital ecosystem of the region as a subsystem of the regional socio-economic system, in the process of coordinated and orderly interaction of its elements aimed at increasing the level and quality of life of the population, it is necessary to use a set of state regulation instruments grouped according to the following criteria: economic, tax budgetary, legal, institutional, institutional and infrastructural, administrative.

Keywords: Regional Economy, Digital Economy, Ecosystem, Government Regulation, Systemic Development.

While maintaining a commitment to abandoning the sectoral approach to structuring the regional economy, we will consider the systemic development of the regional economy in terms of the interaction of individual groups of subjects that form its structure in the context of the formation of the digital ecosystem of the region. The structural transformation of the region's economy should not be viewed as an end in itself, since it is only "a means of solving a wide range of problems of socio-economic development." The goal of systemic restructuring is to form the structure of the regional economy, contributing to the achievement of the regional socio-economic system of proportions corresponding to generally accepted ideas about a high level and quality of life of the population, taking into account

Cite this Article as: Zhakhov Nikolay Vladimirovich, Gubanova Elena Vitalievna, Bessonova Elena Anatolyevna, Orlovtseva Oksana Mikhailovna and Grunina Olga Anatolyevna“ The Contours of Interaction of Subjects of The Regional Economy in The Conditions of The Formation of The Digital Ecosystem of The Region ” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the necessary contribution to their provision of the national economy.

We believe that the primary is systemic development, which, according to GB Kleiner's definition, represents "balanced development that ensures the proportionality of the main subsystems of the economy" [1]. The position of GB Kleiner is extremely close to us. Indeed, we consider the regional economy as a system with a hierarchical structure, including subsystems identified by industry, behavioral, technological or other characteristics. The development of subsystems and, in general, the regional socio-economic system is a complex and contradictory process.

The regional system should develop in a balanced way, i.e. ensuring parity, appropriate proportionality and efficiency of development of the structural elements included in the system. Recognizing the relevance of improving the behavioral composition of the structure of the regional economy by organizing effective management interaction of the main groups of stakeholders in regional development, the structural development of the regional socio-economic system will mean the process of improving the structural composition of the subjects of the regional economy, aimed at increasing the level and quality of life of the population [2,3].

Structural development is a category that specifies the format and direction of the systemic development of the regional economy, in order to achieve the goals of which it is necessary to carry out state regulation. At the same time, systemic development presupposes a coordinated interaction of the structural elements of the regional economy, aimed at achieving the goals of each participant in the process of meeting their needs and, in general, the needs of the regional economy.

Figure 1: Toolkit for state regulation of the systemic development of the agricultural sector of the regional economy [9]

The systemic development of the regional economy in the conditions of the formation of the digital ecosystem of the region is balanced (i.e., corresponding to the ideas about the optimal structure and proportionality of the agrarian subsystem of the regional socio-economic system), the development of the subjects participating in the formation of the regional economy in order to ensure sustainable as a the quality of life of the population of the region.

In other words, taking into account the special significance and relevance of the behavioral type of the structure of the regional economy in the conditions of the formation of the digital ecosystem of the region, the system development should be understood as the process of orderly interaction of the subjects of the regional economy in accordance with the proportions determined by them as a result of coordinated activities. As mentioned above, the systemic development of the region's economy in the context of the formation of the digital ecosystem of the region needs state regulation, which must meet the requirements of the following basic principles: complexity; parity of group,

intragroup and regional interests; consistency; purposefulness; efficiency; optimality [4-6].

The environment favorable for the effective use of the instruments of state regulation is classical liberalism, ideas about which are best formed in the works of F. A. Hayek: personal independence and motivated need for cooperation; private property and the market; legal state [7,8]. A refinement to the above set of characteristics is that the xecutive bodies of state power should be considered as a provider of fair competition.

The difference between the author's approach to the grouping of methods and tools of state regulation in the conditions of the formation of the digital ecosystem of the region is the identification of three contours: federal, regional, subsystem. The allocation of a subsystem contour is expedient in connection with the previously justified need to deviate from the sectoral approach in favor of structuring the regional economy from the position of groups of subjects interested in its development (behavioral type of the structure of the regional economy), demonstrating active behavior and participating in management interaction. In this regard, the subsystem contour acquires the boundaries of the socio-economic subsystem of the regional economy, in relation to the formation of the digital ecosystem of the region.

Legend: inner contour - group interaction of elements of the regional socio-economic subsystem; the central contour is the regional level of management interaction; rounded outline - digital ecosystem of the region; external circuit - federal level of management interaction

Figure 1: Contours of interaction of subjects of the regional economy in the digital ecosystem of the region

Summarizing all of the above, the following conclusions should be drawn:

1. Taking into account the structural and substantive complexity of the processes accompanying the development of regional socio-economic systems, state regulation, representing a system of measures implemented by the executive authorities in the course of coordinated interaction with the population, civil society institutions, business structures, educational and research organizations, with the goal of stabilizing and achieving a balanced functioning of the economy in modern institutional conditions is justified and necessary [10].

2. A feature of state regulation in modern conditions is its subject-object nature and focus on ensuring systemic development, i.e. balanced development, ensuring the proportionality of the main subsystems of the regional economy that form its structure. The focus of this study is the behavioral type of the structure of the regional economy in the conditions of the formation of the digital ecosystem of the region, represented by groups of subjects interested in its development. This circumstance actualizes the scientific search in the direction of selection of means and methods of state regulation that contribute to ensuring the structural and, in general, systemic development of the regional economy in the context of the formation of the digital ecosystem of the region.

3. In order to ensure the formation and development of the digital ecosystem of the region as a subsystem of the regional socio-economic system, in the process of coordinated, orderly interaction of its elements aimed at increasing the level and quality of life of the population, it is necessary to use a set of state regulation tools grouped according to the following criteria: economic, fiscal, legal, institutional, institutional and infrastructural, administrative.

Abstract

Normal classes aimed at improving professional communication skills and abilities represent a system with gradual increase in cognitive activity of students, complexity of intellectual tasks. An important stage in the formation of professional communication skills while teaching English for Professional Purposes (ESP) to the future specialists in agriculture can be attributed to classes conducted on the basis of the business game, conventionally called "Debate". This type of work is the most difficult in terms of organization, and includes tasks directly aimed at the formation and development of professional communication skills. It should be noted that it is the complexity of forms of mental work, rather than language or information saturation, that allows us to separate this type of work into an independent stage. In addition, the business game presupposes the use of theoretical and linguistic material studied in previous classes, and also implies the obligatory appeal of students to new texts on the same topic. To find correct and convincing arguments in the business game, students turn to other sources of information. For modern students the Internet is the main source for information. Students carry out cognitive and search activities, they independently work with numerous texts. Such regular work, which is initiated by the teacher and does not need to be specially controlled, is built on the use of students' cognitive motives, activates their interest in studying the course, creates conditions for healthy competition in the learning process. All of the above has a positive effect on improving the language and communication skills of students, significantly affects the ability to make arguments and express one's opinion, allows us to talk about higher levels of comprehension and elaboration of problem tasks.

Keywords: professional communicative competence, business game, non-language specialist, English for professional purposes (ESP)

Introduction

This problem is the main topic of investigation in many scientific works (Ellis, 2002; Maley, 1982; Popper, 2004; Selezneva, 2017; Simon, 2000).

Cite this Article as: Oleh LAZARIEV, Yuliia FERNOS, Svitlana KARYCHKOVSKA, Vasyl KARYCHKOVSKYI, Svitlana MASLOVATA and Halyna OSIPCHUK“ Business Game in the Process of Purposeful Formation of Professional Communicative Competence of Future Non-language Specialists” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

As the research has shown, there can be distinguished four levels of communicative competence in a polylogue: 1) first level skills - the ability to compare one's own point of view with the point of view of the interlocutor; 2) second level skills - the ability to request information, clarify and supplement the speech of the interlocutor; 3) third level skills - the ability to comply with the goals and topics of discussion, as well as maintain leadership in the discussion; 4) fourth level skill - the ability to formulate the essence of the problem and convince the interlocutor that you are right.

The formulation of criteria for assessing the skills that are developed while conducting a dispute in the language learning process differs from the ones above, due to the specifics of the requirements for the professional communicative competence of future specialists in agriculture, but meets the general goals and objectives highlighted in the methodology for carrying out such types of work.

In the mentioned studies of scientists, attention is drawn to the issues of teaching oral communication in the field of science, technology, production and economics, or attention is focused on the development of polylogical speech, which is considered as a kind of monologue and dialogue. Taking into account the goals and objectives of the ESP course, our attention is focused on the opportunities provided by these forms of work for the development of professional communication skills.

The methodological basis for preparation of various types of classes that involve problem-based learning, is the standard requirements for the organization of classroom activities: defining goals and objectives of classes (goals for the development and improvement of linguistic, communicative and professional communicative competence are formulated separately); determination of the goals of actions performed in the process of solving problem tasks and situations; the choice of the method of actions for the implementation of problem situations, the choice of algorithm and type of work depending on the stage of work on the thematic block; evaluation of the result of actions in accordance with fixed criteria for each type of work.

Results

Studies of typical tasks for the development and improvement of professional communication skills and abilities showed that work on reading was not singled out as a separate component. On the basis of relevant studies of the features of professional communication of future specialists in agriculture, we have determined the professional specificity of the content of reading skills. Among the main methods of working with the text are the following: setting reading goals, choice of search orientation; highlighting semantic information blocks; identifying sources of information, fixation of information; compiling a concise summary. The selected techniques correspond to the following stages of working with the text, such as determining the authorship of the text, clarifying the topic, purpose and goals of the text; structuring information from the text.

These techniques and stages of work were used in the process of organizing work to improve professionally oriented communication. The work on the formation of the described above ability to read was not taken out into a separate methodological unit of training, but it was implicitly included in the general system of methods and techniques, was a prerequisite for successful completion of tasks in the classroom.

As a rule, 15-25 minutes are enough to perform a problem task, depending on the level of complexity. If there is a need to note the time that is allocated in the structure of the lesson for completing a problem task, it is necessary to take into account its complexity and the level of language training of students. It takes more time to analyze specific situations with the analysis of speeches and work on mistakes, especially if a video of the lesson is viewed to analyze the work done. The research has shown that the optimal time for this type of work is 45-55 minutes. The business game "Debate" usually takes two classroom sessions (Graboy, 2003).

The business game takes place according to a certain scheme and allows you to process the studied material, gives effective results, since students are offered creative problem tasks that require mental effort, their activity is activated, the emotional mood rises, professional communication skills and abilities are developed and improved.

Thus, in accordance with the scheme of organization of the business game "Debate", two spaces are planned: the space of dispute - the organization of the space of debate; translation and analysis space.

The game involves two subgroups (conditionally SG 1 and SG 2). The debate is going according to the given problem situation. Each subgroup defends its own point of view. A prerequisite for a successful presentation is the structure and argumentation of the text, which assume the presence of examples that illustrate the precedents of the solutions proposed by a subgroup. The subgroup consists of four participants, each of whom holds and maintains a certain position during the debate. Points of view that will be defended by the subgroup are determined in advance.

Representatives A and B are the main participants in the debate, the speakers representing the main thesis. The position of the speaker can be taken by students with any level of language training, as the text of the presentation is prepared at home. Speakers are always in the foreground.

The main functions of representatives A and B are as follows: for representative A - representation of SG 1, which states, and for representative B – representation of SG 2, which denies; presentation of the topic, justification of its relevance; definition of terms used; demonstration of the claiming party's point of view (SG 1); substantiation of aspects of consideration of the offered theme; giving arguments that will be proved during the game; transition to the proof of the proposed arguments; representative B refutes the arguments put forward; defining a clear statement of the general line of assertion.

The work of the objecting subgroup has its own features which should be drawn to the students' attention. First of all, the subgroup that denies has to respond to all thesis components of the subgroup claiming and respond to each argument. If the aspect cannot be refuted, more important arguments and comparisons are given. In the case of refutation the debate essence all components of the speech are considered: definitions, aspects, arguments, evidence, opponent arguments, etc.

Each of the main representatives (A and B) has a support group. The support group is off the battlefield and is fully aware of what is going on in the debate ring. But at the same time, each member from the support group realizing what is happening can go to the "battlefield", take a temporary place of the main representative and help him in the discussion, supplementing, clarifying the argument.

Representatives A1 and B1 closely monitor the discussion, focusing on the speech and argument weaknesses of the opponent. Their task includes refuting the thesis of the objecting subgroup, it is forbidden to make new arguments; asking cross-cutting questions.

Representatives A2 and B2 substantiate and develop the main thesis of the subgroup, which was presented by representatives A and B, which involves the following actions: restoring the point of view of the subgroup with the help of hypotheses, examples, evidence; providing new evidence; repetition of important aspects of previous evidence; detailed development of the subgroup thesis; giving a clear formulation of the subgroup thesis; answering to cross-cutting questions.
Representatives A3 and B3 highlight the moments when the dispute comes to a standstill, arguments are repeated or when a situation of misunderstanding arises.

Work on the organization of translation and analysis begins after the end of the dispute. There are two representatives working in this space: 1) content analyst - the responsibilities of the student holding this position include the analysis of the discussion in terms of content; he has to describe briefly the essence of the problem under discussion, what theses justifications both subgroups had; the speech of the student holding this position is, in fact, a summary; 2) action

analyst – the task of the student acting in this position is to analyze the discussion in terms of the participant actions; and how these actions unfolded the result of dispute, in addition, this participant records violations of the rules to be debated; the purpose of allocating this position in a separate element of the analysis is to focus on the peculiarities of the behavior during the dispute and observance of formal rules of communication; special attention in the action analysis is paid to fixing possible errors in reasoning, the list of which is in front of a student: questions instead of answers, going around in circles, confusing statistics, confused cause and effect, incorrect conclusions, poor generalizations, bias, human attack , not a position, and an argument like " the right thing".

These two participants are external observers of the dispute and do not take a direct part in it. But they can ask questions on understanding like correctly understood that…; did not understand, could you clarify or repeat.

The whole game is regulated by the organizer, who monitors the sequence of theses and questions and the compliance of representatives with their functions. In early classes the function of the organizer is performed by a teacher, in the following – the most progressive students.

In the course of the game the following aspects are assessed: 1) language competence: the level of proficiency in language and grammar units worked in the thematic block; no language errors; language skills; 2) intellectual competence: the ability to think critically; cultural level, the ability to involve knowledge from various sources during the dispute; 3) professional communicative competence: the ability to assess own position and the position of an interlocutor, the ability to record the position of the opponent, using separation, establishing a connection with the subject and objectives of the conversation, its self-sufficiency and plausibility, reliability; ability to formulate and justify one's own position; the ability to oppose, ask questions, make additions, form elements of controversy, influence the arguments of the addressee of the conversation, supplement the interlocutor or deny it; ability to reach a general conclusion; 4) the ability to work collectively: the ability to assess one's own capabilities and take an optimal place in teamwork, if the participants in the dispute are not appointed by the teacher; the ability to perform the function assumed, the expression of a sense of duty and responsibility.

The organization of a business game according to the presented scheme allows you direct practicing and improving communicative professional skills, as evidenced by the list of parameters to be controlled. When conducting a business game, not only the result presented in the general conclusion is important, but also the process of dispute, observance of the forms of game organization, as productive activity is stimulated, professional communication skills are improved. The substantive complexity of the topic discussed is not of fundamental importance. Specific situations can be suggested for discussion topics, interesting in terms of professional point of view and problems. The study used problem situations designed to form, develop and improve the communication skills of future agricultural professionals; problem tasks offered in English textbooks; situations found on the Internet.

It should be noted that during the research, along with the business game "Debate", the role-playing game "Meeting" was used, which also involves compliance with the participants' positions, fairly strict arguments, and compliance with certain rules of performance. Undoubtedly, the role-playing promotes the development of professional communication skills. The study found that the role-playing game "Meeting" is very effective in consolidating new lexical and grammatical material, as it allows you to update using basic vocabulary. However, the use of role-playing games proved to be less effective compared to the educational effect found during business games. The disadvantages of role-playing include the following: the lack of motivation for students to seek additional information.

The study showed that students follow the path of minimizing intellectual effort, preferring theatrical forms of self-expression, they are confined to the informative material presented in the basic textbook; the absence in the game of specially defined forms of work focused on reflection and analysis.

The main characteristic of formal debates is the existence of rules according to which there is a clash of opposing views. The organization of debates according to certain rules allows to keep the topic of discussion, does not allow to turn the discussion into a dispute when the opponent is attacked, and not the arguments.

Independent preparation of students for the debate involves the repetition of all material from the thematic block, the need to rethink the content of familiar texts, taking into account the request of a particular situation, a deeper penetration into linguistic and subject information. The effectiveness of this type is also due to the need of constant comparing and analyzing familiar (practiced in class) and new (independently extracted from other sources) information. The process of preparation for classes (independent work of students) is built on the basis of cognitive motives. Students are distracted from already familiar texts and enter a range of new issues that are a powerful stimulus for the formation of search and cognitive activity.

New information found by students in addition to known facts sometimes contradicts the theoretical material offered in the basic textbook. At the heart of this contradiction are intercultural differences in the cultural and production norms of Great Britain, the United States and Ukraine. The presence of such paradoxes is a prerequisite for the submission of arguments of theses prepared by subgroups, as the task of interpretation, as a rule, does not specifically include the setting for the existence of arguments in terms of the legal system of a particular state. This approach allows new and unexpected (for the teacher and the opposing subgroup) options for reasoning the problem. In addition, the differences in the cultural and production norms of different countries allow a more meaningful approach

to understanding such Ukrainian norms, to see and rethink the nuances that become apparent due to specially organized forms of work.

Conclusion

Therefore, the main task of the course which is determined within the framework of an interdisciplinary approach was solved at the classes held within the framework of problem-based learning: development and improvement of professional communication skills.

As it has been noted in the study, this professionally oriented foreign language course is designed for students with a high level of language knowledge, defined during the selection control before the start of the course. This circumstance explains a certain methodical courage in setting the objectives of the course.

The fact that the course is elective and can be ignored by students forces us to look for new and more effective ways of working that attract students not by spectacular forms of work or entertainment content of the course, but by those based on cognitive motives. All efforts of the teacher are directed on satisfaction of student cognitive need to solve the problem situations on their own, at the raised level of independent creative activity.

Finally, the teacher solves another, no less important task to develop and improve the language and communicative competence of students in the language studied. Achieving positive results in solving linguistic tasks of the course is ensured through a systematic appeal to the studied texts, the actualization of language material in the process of professional-oriented communication. Work on communication and language skills and abilities is included in the process of formation and improvement of professional communication skills and is constantly monitored by the teacher. In the description of the forms of work it was already noted that the indispensable criterion for successful completion of the task with the help of one of the types of work in problem-based learning is the systematic control of language and speech competencies and the formation of communicative professional competence.

The effectiveness of the systematic inclusion of this type of work in the curriculum of an ESP course was proven during the study. Questionnaire of students conducted at the end of the study shows that the business game "Dispute" is rated the highest by students, students note that during the course they acquire reflection skills, which allow them to achieve higher results during the study of other disciplines taught in Ukrainian.

Abstract

The paper substantiates the financial support of the decentralization process in Ukraine. The necessity of reforming the existing system of financial support of the decentralization process has been proved. The main tasks of public authorities of Ukraine in the conditions of decentralization have been determined. The purpose of the article is to substantiate financial support areas for the decentralization process in Ukraine. The study's methodological basis is the Ministry of Finance of Ukraine's data, the Ministry of Regional Development, Construction, Housing and Communal Services of Ukraine. It has been proved that Ukraine's united territorial communities' (UTC) financial resources are formed by 90.0% due to tax revenues. It has been proposed to expand the list of non-tax revenues for UTC budgets at the expense of other resources to stabilize UTC development's financial support. It has been proved that the growth rates of expenditures in local budgets of Ukraine in 2018 – 2019 were higher than the growth rates of revenues, which led to a deficit. It has been substantiated that a significant differentiation in revenues and expenditures by UTC groups indicates economic inequality in the development of UTC territories and resource provision, which is reflected in the amount and quality of public services received by residents in the respective UTCs. It has been determined that in order to intensify the process of financial incentives for sustainable development of territorial communities, it is necessary to ensure effective communication between executive authorities and local governments, organizational and methodological assistance to local governments, dissemination of information on successful practices of cooperation projects, European experience of UTC financial resources in EU countries for Ukraine. It has been proposed to ensure local authorities' financial autonomy and stability by transferring powerful sources of budget revenues, previously assigned to the central government, and the expansion of the financial base of administrative-territorial formations.

Keywords: Local Governments; Resource Potential; Decentralization; Local Finances; Financial Incentives

Introduction

Ukraine's state policy in the field of local self-government is based on the interests of residents of territorial communities and provides for the decentralization of power - the transfer of the powers, resources, and responsibilities from bodies of executive power to local governments. This policy is based on the European Charter of Local Self-Government provisions and the best world public relations standards in this area.

The legislative basis for changing the system of government and its territorial basis at all levels was formed in 2014 after the adoption of the concept of reforming local self-government and territorial organization of power, which consists of three areas: basic (formation of united communities of the basic level of administrative-territorial structure of Ukraine); creation of new districts, which will deal with only related to the competence of the district issues (communal property, secondary medicine, boarding schools, etc., the rest of the powers of the districts belong to the competence of united communities); final - change the form of management of regions (oblasts) [1]. Such a community's essential systemic features are stable economic, social, informational, political, cultural, and environmental ties and relations, distinguishing it as a relatively independent system of human life's spatial organization.

In 2014-2015 Ukraine took significant steps towards reforming local self-government: the process of unification of territorial communities, decentralization of public administration, and finances; several regulations aimed at legal regulation in this area were approved, budget and tax reforms were carried out provided strengthening of the financial basis for the livelihood of territorial communities.

Analysis of recent research and publications. The study of theoretical and applied principles of financial support of the decentralization process in Ukraine and the formation of financial capacity of territorial communities were discussed in the works of Weingast (1997), Akai, N., & Sakata, M. (2002), Rodden, JS, & Rose-Ackerman, S (1997) , Bartolini, D., Sacchi, A., Salotti, S., & Santolini, R. (2018), Bisogno, M., Cuadrado-Ballesteros, B., Santis, S., & Citro, F. (2018) and Romans, W., Ulasiuk, I. and Petrenko Tomsen, A. (2018) , Alina Korbutiak, Zhanna Lysenko, Nataliya Sokrovolska, Artur Oleksyn, Eduard Yurii (2019)), Palchuk V., Babyuk I., Chepel O. and other scientists. These scientists' achievements have theoretical and practical significance in the area and became the basis for further research on the justification of ways to support the process of decentralization of Ukraine financially. Given the rapid changes in the country's socio-economic and political sphere and the development of Ukraine's decentralization process, the outlined topic needs further comprehensive research and coverage.

The works of foreign scholars, in particular Weingast (1997), Akai N., & Sakata M. (2002), Rodden J.S., & Rose-Ackerman S. (1997) emphasize the positive features of the decentralization process. In the authors' opinion, decentralization provides more opportunities for local communities and local authorities to attract investors .

The positive impact of fiscal decentralization on the formation of financial resources of local government and the national budget was noted in the researchers of the following scientists: Bartolini D., Sacchi, A., Salotti S., & Santolini R. (2018), Bisogno M., Cuadrado-Ballesteros B., Santis S., & Citro F. (2018) and Romans W., Ulasiuk I. and Petrenko Tomsen A. (2018).

Foreign scholars suggest the use of tax autonomy, which will improve the budgets of all government levels. Decentralization of tax collection will help strengthen budgetary discipline during the financial crisis. In Ukrainian scientists' works by A. Korbutiak, Zh. Lysenko, N. Sokrovolska, A. Oleksyn, Eduard Yurii (2019), N. Orlova and O. Kozyrieva (2019), O. Marukhlenko (2018), it is emphasized that in the process of decentralization reforms in Ukraine, there are still many problems that need to be solved. The works of V. Palchuk, I. Babyuk, and O. Chepel outline the ways of forming capable territorial communities, namely: the creation of UTC, transfer of financial support, and other powers to the local level and attraction of investments, expansion of UTC funding sources, preservation of enterprises located on the UTC territory and creation of a UTC profile of resource potential.

The purpose of the article is to substantiate financial support areas for the decentralization process in Ukraine.

The methodological basis of the study. The leading research method is a comprehensive analysis of the financial and budgetary components of the decentralization of management at the local level.

Main Part of Research

State policy regarding the formation of territorial communities includes a significant number of regulations governing their activities and powers. During the period of power decentralization and preconditions creation for the capable

territorial communities formation, a number of legislative acts were adopted, including the laws of Ukraine: "On Cooperation of Territorial Communities", "On Amendments to the Tax Code of Ukraine and Some Legislative Acts of Ukraine on Tax Reform", "On Amendments to the Budget Code of Ukraine on the Reform of Intergovernmental Relations", "On the Principles of State Regulatory Policy", "On Voluntary Association of Territorial Communities", "On Local Elections", "On Amendments to Certain Laws of Ukraine on Organization of the first elections of deputies of local councils and village, settlement, city mayors", "On amendments to the Budget Code of Ukraine on the peculiarities of formation and implementation of budgets of united territorial communities", "On amendments to the Budget Code of Ukraine on the inclusion of certain administrative fees in local budgets".

The reform of local self-government bodies envisages the unification (consolidation) of territorial communities. This is due to the fact that excessive resources in such communities are spent on the maintenance of the administrative apparatus, while the implementation of crucial local development projects lacks funds, providing additional resources to the vast majority of existing local communities will not provide their capacity. Therefore, the reform of local self-government, taking into account the positive European and its own historical experience, relies on the obligatory unification (consolidation) of territorial communities.

The purpose of local self-government reform is to ensure its ability to independently, at its own expense, address issues of local importance, i.e., to provide territorial communities with more resources and mobilize their internal reserves. The primary tool for the socio-economic policy is the budget, so budget policy promotes sustainable and significant economic development. At the present stage of local government, the basis is budget decentralization.

Reforming the territorial organization of power and administrative-territorial organization in Ukraine is one of the fundamental reforms that affect many areas of people's lives. Successful implementation of this reform, which has to result in a radical change in social development management's basic principles, is a vital prerequisite and guarantee for solving other systemic problems of Ukrainian society's socio-political and socio-economic development.

Since the approval of the Concept of Reforming Local Self-Government and Territorial Organization of Power, the necessary legal framework for reform has been formed. In particular, amendments to the Tax and Budget Codes of Ukraine (fiscal decentralization) were made, the State Strategy for Regional Development was approved, and a new Law on Regional Policy was adopted, changes in the administrative-territorial system were observed. The peculiarity of decentralization of power in Ukraine is that reforming local self-government, administrative-territorial organization, and state regional policy is underway simultaneously.

On December 28, 2014, the Verkhovna Rada of Ukraine adopted amendments to the Tax and Budget Codes of Ukraine. Those changes determined the new financial basis of local governments, established a new distribution of national taxes and introduced new local taxes, as well as established a new system of budget equalization.

On January 23, 2019, the Cabinet of Ministers of Ukraine initiated the transition to a new stage of decentralization reform, which envisages consolidation of already achieved successes and formation of capable communities, change of territorial organization at the level of districts and communities, clear delineation of powers and functions of local democracy regulation.

The most problematic parts of this task in Ukraine at the moment are the following: outdated legislation, which no longer provides sufficient autonomy to address issues of local importance of local governments effectively; inconsistency of organizational and financial capabilities of local self-government bodies with the needs of territorial communities development; the insufficient practice of direct participation of territorial communities in solving issues of local importance. The analysis of modern methodological bases of research and elaboration of sustainable development strategies testifies to the absence of domestic generally accepted and used modern methods, which often lead to many unsuccessful decisions in the field of sustainable development management.

In order to solve the already mentioned problems in reforming territorial communities and preventing the emergence of new ones, public authorities' main tasks can be outlined in figure 1 (Fig. 1).

Fig. 1: The main tasks of public authorities of Ukraine in the context of decentralization.
Source: compiled by the authors based on [9-13]

Reform of local self-government and decentralization of power involves overcoming many obstacles: the dependence of territories on the center; infrastructural and financial weakness of communities; rural degradation; high level of community subsidies; low level of investment attractiveness of territories, etc.

Results

During the period of decentralization reform, starting from 2014 to the present, more than 800 united territorial communities have been created in Ukraine. After amendments to the tax and budget legislation, the main taxes that fill local budgets (cities of regional significance, districts, united territorial communities) were: 60% personal income tax, 5% excise tax on the sale of excisable goods, 100% single tax, 100% property tax (real estate, land, transport), 100% land tax, 100% profit tax on communal property enterprises, 100% fee for the provision of administrative services and 25% environmental tax. Local governments have the right to service the revenues of their budgetary institutions and development funds in state-owned banks and not to depend on the State Treasury. Ukraine's decentralization process main direction is budget financing of territorial communities' development at the expense of local budgets.

The dynamics of the composition and structure of Ukraine's local budgets' revenues and expenditures for 2014-2019 are given in the table. 1.

Table 1: the dynamics of the composition and structure of Ukraine's local budgets' revenues and expenditures for 2014-2019 years

Year	Revenues of the general fund of local budgets (including transfers from the state budget), UAH billion	Including official transfers from the state budget, UAH billion	Share of official transfers from the state budget in the revenues of the general fund of local budgets,%	Expenditures of the general fund of local budgets, UAH billion	Including transfers to the state budget, UAH billion	Share of official transfers to the state budget in expenditures of the general fund of local budgets,%	Deficit "-", surplus «+» of general fund of local budgets, billion UAH
2014	231.7	130.6	56.37	225, 6	2.118	0.94	6.022
2015	294.4	173.9	59.07	280.1	3.144	1.12	14.269
2016	366.1	195.4	53.37	350.5	4.171	1.19	15.448
2017	502.1	272.6	54.29	496.1	5.967	1.20	5.756
2018	562.4	298.9	53.14	570.6	7.306	1.28	- 8.540
2019	560.5	260.3	46.44	566.2	8.725	1.54	- 6.270

Compiled by the authors based on data from the Ministry of Finance of Ukraine

Revenues of the general fund of local budgets in 2019 increased by 2.4 times compared to 2014, expenditures for the same period increased by 2.5 times. The growth rate of expenditures was higher than the growth rate of revenues, which led to a deficit in local budgets in 2018 - 2019. The most important was the budget system's change equalization of local budgets by expenditures, the system of equalization of revenues. As a result, only 50% of the additional income is withdrawn from administrative-territorial units' budgets that earn more than they have expenditures (provided that the tax capacity index is more than 1.1). Such withdrawals are directed to provide a basic grant. In contrast, in administrative-territorial units that do not earn the amount required for expenditures, the necessary subsidy is only 80% of the required amount (provided that the tax capacity index is less than 0.9). Such a system stimulates communities to increase local budget revenues – those who earn more, get more. According to the Ministry of Regional Development, Construction, Housing and Communal Services of Ukraine in 2019, the budgets of 806 UTCs established on Ukraine's territory received UAH 39.4 million. For the purpose of analysis, all UTCs are divided into five groups based on the population living in this territorial community's site. The analysis of UTC revenues and expenditures for 2019 provided an opportunity to draw the following conclusions (Table 2).

Table 2: analysis of revenues and expenditures by UTC groups created on the territory of Ukraine in 2019

Groups	Grouping criteria	Number of UTC / Specific weight in the total amount of UTC,%	Total population in the UTC group, thousand people	The average amount of own income received by UTC of the respective group, UAH million	The average amount of expenditures made from the budget of the UTC of the relevant group, UAH million.	The difference between the average amounts of revenues and expenditures of UTC budgets of the respective group, UAH million /%
Group 1	Population over 15 thousand people	95 / 24.1	2001.1	87.2	131.4	- 44.2 / Excess of expenses over incomes in .5 times

Group 2	Population from 10 to 15 thousand people	128 / 18.8	1561.6	53.5	74.6	- 21.1 / Excess of expenses over incomes in 1.39 times
Group 3	Population from 5 to 10 thousand people	268 / 22.5	1874.9	30.8	43.2	- 12.4 / Excess of expenses over incomes in 1.40 times
Group 4	Population up to 5 thousand people	288 / 11.8	979.1	16.2	21.7	-5.5 / Excess of expenses over incomes in 1.34 times
Group 5	UTC - cities of regional significance	27 / 22.8	1891.0	418.5	635.0	- 216.5 / Excess of expenses over incomes in 1.52 times
Together		806 / 100.0	8307.7	606.2	905.9	- 299.7 / Excess of expenses over incomes in 1.49 times

Compiled by the authors based on data from the Ministry of Regional Development, Construction, Housing and Communal Services of Ukraine

The number of UTCs created in Ukraine is dominated by group 4 - UTCs with a population of up to 5 thousand people. The number of people living on UTC territory is dominated by group 5 - cities of regional importance. A comparison of the average amount of own-source revenues and the average amount of expenditures for all UTC groups showed a negative difference, i.e., on average, for all UTCs expenditures exceeded revenues by 1.49 times. The largest gap between the amount of expenditures and the amount of UTC revenues has 5 groups - cities of regional importance where expenditures exceeded revenues by 1.52 times in 2019. Thus, it can be stated that UTC's revenues do not cover the amount of expenditures required for the operation of UTCs themselves, which indicates the subsidization of UTC budgets. UTC income per capita analysis shows that the least financially viable are UTCs of 4th and 3rd groups with a population of up to 5 thousand people and from 5 to 10 thousand people. The cities of regional significance have the highest level of income per 1 inhabitant of UTC. Analysis of UTC budget expenditures showed that the management staff's maintenance expenditures in terms of UTC groups are as follows: Group 1 - 18.9%, Group 2 - 21.5%, Group 3 - 24.4%, Group 4 - 29.2%, Group 5 - 12.6%. The volume of capital expenditures from UTC budgets in 2019 amounted to UAH 12.8 billion (*General information. Decentralization*). UTC groups' significant differentiation in revenues and expenditures indicates economic inequality in the development of territories and resource provision of UTCs, which is reflected in the volume and quality of public services received by residents in the respective UTCs.

The dynamics of the structure of UTC financial resources for the period 2014-2019 are as follows (Table 3).

Table 3: dynamics of the structure of UTC financial resources created on the territory of Ukraine, for the period 2014-2019, UAH million

Indicator	**2016**	**2017**	**2018**	**2019**	**Deviation of 2019 data from 2014 data,%**
Total income	3577.2	10124.4	22433.5	30727.5	An increase of 8.59 times
including: - tax revenues	3263.7	9164.5	20596.8	28214.5	An increase of 8.64 times
Share of tax revenues in total revenues,%	91.24	90.51	91.81	91.82	0.64

Compiled by the authors based on data from the Ministry of Finance of Ukraine

Analysis of UTC financial resources' structure created on Ukraine's territory for the period 2014-2019 showed that more than 90.0% of UTC revenues are from tax revenues. The total share of all other revenues is less than 10.0 %. To stabilize the state of financial resources, it is advisable to increase the share of other revenues to finance UTC activities.

Decentralization reform in the EU has certain features that distinguish these countries from other countries. A local government regulates each territory of the EU. The European Charter of Local Self-Government declares that local authorities have the right to their own financial resources, which they can freely dispose of (paragraphs 1.3); the order of financial resources formation has to be flexible and correspond to the functions performed by local authorities (paragraphs 2,6); part of the financial resources ought to be formed at the expense of local taxes and fees, the amount of which local authorities have the right to set (paragraph 4,5); protection of the financially weak local government is carried out at the expense of financial equalization or at the expense of grants which are not intended for financing of concrete projects (paragraph 7,8). It is expedient to use the experience of forming UTC financial resources in the EU countries for Ukraine.

As in other countries, a strategic approach to sustainable territorial planning is being actively developed and introduced in Ukraine. In modern conditions of development, the functions implemented during the planning process change significantly, the very role of planning in the local government system is being modified.

Sustainable development of the territorial community is a mode of functioning that focuses on the positive dynamics of the population's welfare, provided by a sustainable, balanced reproduction of social, industrial, financial, resource, and environmental potential. Local self-government bodies have to ensure the sustainable development of the territorial community, guided by local self-government principles and creating preconditions for the transmission of the minimum economic, environmental, and social debt to future generations. The purpose of local government is to achieve together with the territorial community sustainable socio-ecological development with an effective economic mechanism to meet human needs and preserve the natural environment.

Thus, in current conditions, sustainable development of the territorial community involves the ability to self-development and progress, i.e., ensuring sustainable production growth, creating reliable conditions and guarantees for entrepreneurship, creating a favorable climate for investment and innovation; rational use of natural resources and preservation of the ecological balance of the territory; stable growth of the quality of life of all residents of the territorial community; increase efficiency.

To provide for the irreversible transition to sustainable development, it is necessary to ensure both the coordination of government actions at the state, regional and local levels, and a clear definition of sustainable development planning for local communities, i.e., local economic development planning with three components - social welfare, equal access for all residents to public services, health, cleanliness, environmental safety and security.

Modern planning of sustainable development of territorial communities mostly means abandoning the industrial economy model, which has long been a national ideal.

Sustainable development planning of territorial communities is a hierarchical process that aims to increase the socio-ecological and economic sustainability of the functioning of territories or its individual territorial communities.

Social sustainability includes proper health care, safe and healthy housing, and high-quality education for all residents of the community; maintenance of public safety and law and order; strengthening the spirit of the community, its cohesion, which creates a sense of belonging to a particular area, i.e., the development of local identity; promoting creative expression, preserving traditions, etc.

Ecological sustainability is the care and preservation of the environment and the satisfaction of basic human needs in clean air, ecologically clean food products, ensure of landscaping, implementation of energy-saving measures, and provision of housing and communal services. Economic stability is one of the crucial components that determines the economic progress of community development. Achieving economic sustainability is preceded by creating a favorable environment for doing business, attracting local and foreign investment in the local economy, providing maximum assistance to companies operating in the local community, retraining to meet future business needs, creating a financially viable economic base. All these factors affect job creation and thus prevent the outflow of population from the newly created community. This approach contributes to economic growth, meeting human needs while preserving the environment for future generations.

In general, sustainable development's success depends on the success of local economic development, especially on the conditions in which the business is located. High quality of life, developed economy, favorable business climate, friendly environment contribute to the formation of a culture of life, work and leisure, focused on sustainable development.

To achieve these goals, action plans have to be aimed at developing the economy and increasing the local community's competitiveness. They include tools such as activities, programs, and projects aimed at attracting investment, supporting entrepreneurship, starting new businesses, maintaining existing businesses, developing local markets, creating clusters, industrial innovation or industrial research parks, business incubators, business centers, business support funds, establishing inter-municipal cooperation, creating public-private partnerships, marketing the territory, establishing a communication system, etc. The system of tools for planning sustainable development of territorial communities can be classified into three groups, each reflecting a specific goal (Table 4).

Table 4: tools for planning sustainable development of territorial communities for a specific purpose

Goal	Tools
1	**2**
Support the development of existing and the creation of new local businesses	Education, training, advice, information, support, targeted preferential loans, simplified conditions permit, available to rent at the beginning of activities, incentives, transparent access to business-oriented information, and clusters.
Attracting business and investment in the territory:	The algorithm of the procedure of opening a new enterprise, the investor's road map, creation of investment products, territory design, preparation of industrial sites, creation of industrial parks, marketing of attraction of investments in the territory, development of investment passports, promotion of the territory, the definition of competitive advantages, criteria for the investor, etc.
Development of local development institutions	Activities of economic development agencies or local and regional development agencies, urban development centers, business incubators, business centers, public organizations, business associations, permit centers, administrative service centers, chambers of commerce and industry, information and advisory centers, recruitment agencies investments, business support funds, etc.

When developing plans for the strategy of sustainable development of territorial communities, they have to be based on six basic postulates: economic development is created by business; jobs ensure the well-being of the community and affect the growth of both individual incomes of residents and the growth of total social product; local authorities and public organizations create conditions for business development; advanced infrastructure is the main element of community competitiveness; quality services provided by local authorities to the community and business are a key element of competitive advantage; effective management of a city or region is ensured by system management (planning, organization, motivation, control), local resources, the cooperation of stakeholders and tripartite partnership.

After the strategy's approval, a crucial element of its effective implementation is the process of monitoring and evaluating the planned results to minimize the risk, which will become an effective tool for long-term territorial development.

One of the tools to ensure sustainable and holistic development of the territorial community is monitoring - formalized and regular monitoring of the strategic plan's implementation, analysis of information, adjustments, updating tasks, and other functions. Monitoring is the process of regularly collecting and analyzing key data (indicators) to identify progress made in implementing a strategic plan. Tools such as SWOT-analysis, PESTLE-analysis, A-B-C analysis, etc. are used to monitor the implementation of the territorial community's sustainable development strategy. [13, 18].

The critical characteristics of planning in the context of globalization are technological innovations, modernization of jobs and the content of employees, and the emergence of internal local economic forces based on competition from local factors of information, creativity, and knowledge.

An interesting example of sustainable development of territorial communities can be revitalization projects, for which the EU allocates funds and which are implemented by EU member states. For Ukraine, such projects are perceived as projects to restore outdated infrastructure (historic architecture, abandoned castles, houses, parks, etc.). According to EU legal documents, funds for the revitalization project can be allocated provided that, firstly, the object of value to the community is subject to restoration and includes a component of improving the infrastructure component. Secondly, this object must be used to increase economic activity in the community, and third - the project must contain a socio-environmental component: to increase equal access of community members to the standard service or increase the level of environmental safety health of residents. The concept of "revitalization" is not identical to the term "overhaul". This restoration is not only technical but also social and cultural. For example, in Poland (Lesser Poland Voivodeship, Rabka-Zdrój), the following two revitalization projects have been implemented:
- a project to revitalize the railway station building based on ideas proposed and discussed with the community (the renovated station building has a small waiting room, a cafe, a public meeting room, a small library, and free access to a computer room with Internet);
- the project of revitalization of the local park (lighting of the park was carried out, now the park has a 3D cinema, a cafe, a stage for performances).

Conclusion

The main reasons hindering the sustainable development of territorial communities in Ukraine are the instability of socio-economic conditions in the country, the lack of scientifically sound, clearly defined strategy for its sustainable development, effective economic reform and state regulation, imperfect legislative and regulatory framework for adequate financial market conditions, legal, information and communication space, imperfection of legal, organizational, economic bases of activity of executive bodies and local governments, physical and legal persons concerning formation of a high-grade living environment.

Opportunities for cooperation of territorial communities and development of territories are currently used incompletely. To intensify this process, it is necessary to ensure, first of all, effective communication between executive authorities and local self-government bodies on the ground, organizational and methodological assistance to local self-government bodies, dissemination of information on successful practices of cooperation projects, etc. In the future, various forms of cooperation can be widely used to combine the efforts and resources of united territorial communities in the implementation of investment projects.

In the future, it is necessary to ensure effective communication between executive authorities and local governments, organizational and methodological assistance to local governments, dissemination of information on successful practices of cooperation projects.

Thus, decentralization is currently the most effective and efficient way for local governments to ensure financial autonomy and sustainment by transferring powerful sources of budget revenues previously assigned to the central government and expanding administrative-territorial formations' financial base.

Abstract

The processes of conceptualization of modern approaches to public administration in the security and defense field reflect current theoretical problems and practical imperatives of its development. Based on public administration methodology the experience of formation and functioning of conceptual models of public administration in the security and defense field in the retrospect of the military-political processes in Europe and the world is generalized. The transformation of traditional approaches is considered in the dynamics of socio-political changes in the beginning of XXI century. The priorities of the democratic states' national policy in the security field at the present stage have been actualized. It has been consistently held that the main priority of security and defense governance should be to ensure stability in the areas adjacent to the area of responsibility of the security system through cooperation, since instability and conflict in these areas can pose a threat to participating countries. The trend towards globalization and regionalization will facilitate the countries aspiring to join the process of European unification to become members of the latest European collective security systems in the future, as will do some neutral countries. In the formation of modern collaborative system of European security, it is expedient to return to the idea of finding ways to understanding the East and the West, to compromise between their natural worldview paradigms on the democracy principles.

Keywords: state governance in the security field, military-political processes, conceptual approaches to governance in the security field, collective security system, cooperation.

Introduction

Changes in the content of wars and armed conflicts in the dynamics of the XX - early XXI centuries directly influenced the development of conceptual positions and approaches to the assessment of modern military-political processes. The security concepts that emerged in different periods, in turn, influenced further development of the ideas of peace and security, their determinants and imperatives. Transformations of governance approaches in the dynamics of the last century have led to qualitative changes in its main components in accordance with changes in the military-political situation at the global, regional and national levels (L.Novak-Kalyayeva et al., 2018). The concepts of war and peace, the role of the army in the society, collective security, etc. were fundamental to national security and defense strategies. At the beginning of the XXI century, the factor of national security and defense again became largely decisive in solving interstate political and economic problems. In today's world, there is a

practice when odious powerful states are using weaker countries for wars on their own behalf as well as terrorist and criminal groups as tools to destabilize states against which aggression is directed. Therefore, ensuring the survival and development of the civilized world objectively dictates the need to rethink views on the problems of military security and state defense.

An appropriate methodological framework necessary to solve modern problems in this field have been created in the studies of the nature and essence of war, military construction, national and collective security, their political and military aspects, including the relationship and interaction of these processes. The conceptualization of approaches to state governance in the security and defense field, in particular, in the European region, is considered holistically and takes into account the historical preconditions of this process. The analysis of security and defense problems requires consistency, that is possible only on the basis of an interdisciplinary study of security and defense problems, and was carried out by such researchers as R. Cohen (2001), R. Cooper (2002), E. Conteh-Morgan (2001), A. Dmitriev (2014), Fleychuk (2018), M. Mihalka (2005), A. Pelykh (2017), O. Zhitnik (2015) and others. However, a comprehensive approach to the research in the context of modern global security imperatives can significantly enrich it, which confirms the relevance of the topic.

The purpose of the article is to reveal the special features of the processes of conceptualization of modern approaches to public administration in the security and defense field and to determine the current security imperatives.

Conceptual models of public administration in the security and defense field

The security system is mainly considered as a set of interconnected state and non-state actors engaged in the protection and realization of national domestic political interests, as well as material and spiritual resources of this activity. We share A. Pelykh's (2015) point of view who believes that the concept of "military-political model of the state in the national security governance" should be interpreted as a formalized reflection of the development of national security system and determination of theoretical and organizational principles of its operation, development, implementation, evaluation, correction of the state' military policy in the context of officially defined foreign political course of the state and military doctrinal provisions… ." The military security system, as part of enhancing the national security system, is designed to plan and implement a set of measures aimed at maintaining the readiness of the state, society and citizens to prevent and repel possible aggression. First of all, we are talking about the actors of state governance of the national security, components of the security sector and implementation of mobilization training of the economy and population. The concept "national system of state governance in the security and defense field" is directly related to such categories as "national system of military security", "national system of national security", "defense capabilities system" and all the other systems or subsystems that are logically related to security.

Structural and functional features of national and global models of state governance in the security and defense field determine the formation of state security policy on the basis of specific models of the security sector governance. The latter, conceptually, can be divided into two types: Anglo-Saxon and continental (German-French). They are distinguished by the level of governance centralization, which determines the specifics of the organization of each political and administrative system, depending on national traditions and historical experience.

Discussions in the scientific and professional military-political environment allowed us to identify 2 types of specific models of international security according to different criteria Bozhko, S.(2005). International security models belonging to the first type are constructed depending on the number of actors in the security system. There are four main competing models:

1. Unipolar security model, which involves strengthening the system of military-political alliances led by the United States. Thus, NATO, according to some analysts, should ensure stability in the transatlantic subsystem of international relations, harmonize relations between the United States and European countries in the strategic field, ensure US military presence in Europe and guarantee prevention of conflicts on the continent.

2. "Concert of States", the essence of which is to create a union of several major powers that could take responsibility for maintaining stability in the world and for preventing and resolving local conflicts. The model was formed after the Napoleonic Wars in Europe (19th century) and was a kind of a system of congresses and conferences, through which the five empires of that time sought to rule not only Europe but almost the whole world. This model has become the prototype of an international intergovernmental organization for peacekeeping. In geopolitics, this system of European security, based on its basic principle, is called, the system of "balance of power" (G.Kindler, 2003).

Not providing guarantees of existence without wars, according to R. Cooper (2002), this system of European security ensured a balance between the leading countries on the basis of maintaining the multipolarity (polycentricism) in Europe. Thanks to it, it was not allowed to establish the hegemony of any state. The principle of balance of territorial sovereignty in relations between nation-states has become the main system-forming factor of this informal formation. This model was homogeneous because its elements had a unified approach to ensuring their national security and shared the same views on the organization of state and public life in the society (R. Cohen, (2001).

3. Multipolar model. Its supporters insist that the United States should recognize the unfoundedness of its claims to world leadership and enter into a partnership dialogue with other centers of power. These ideas are still especially popular in the Russian political and academic establishment and have even been elevated to the status of official foreign policy doctrine. Opponents of this model emphasize that it is unable to ensure stability because it is based on the vision of the international relations system as a field of eternal competition between the "centers of power". And this, in turn, inevitably leads to conflicts between the latter due to the constant redistribution of spheres of influence.

4. Global (universal) model. It supports the position that international security can be ensured only at the global level, when all members of the world community participate in its creation. According to one version, the creation of this model is possible only when all countries and peoples share a certain minimum of universal values and there is a global civil society with a single system of government. Less radical versions of this model come down to the fact that it will become the result of the gradual evolution of the already existing system of international security regimes and organizations with the leading role of the United Nations.

The second type of international security models is determined by the nature of relations between participants in such security systems. Discussions revolve mainly around three models of the second type: collective, general and cooperative.

1.Collective security is a concept that appeared in the diplomatic practice in the 1920s and 1930s. The main elements of the collective security model are the existence of a group of states united by a common goal (protection of their security) and a system of military-political measures against the aggressor. In turn, there can be different types of collective security, which differ from each other in what type of interstate coalition underlies it and what goals are set by members of the collective security system. In general, collective security focuses on military-strategic issues and is not aimed at addressing other aspects of international security (economic, civil, environmental and other dimensions). According to O. Zhytnyk (2015), this fact limits the possibilities of using this model in modern conditions.

2.The general security model is designed to emphasize the multidimensional nature of international security, including not only traditional "hard" but also "soft" security, as well as the need to take into account the legitimate interests of not only a narrow group of states but all members of the world community. The institutional basis of general security should be not only and not so much the military-political alliances (as in the case of collective security), but global organizations such as the UN (A. Rotfeld , 2004).

3.Cooperative security is a model that has been popular since the mid-1990s. This model, according to its supporters, combines the best aspects of the two previous concepts. The cooperative security model prefers peaceful, political means of resolving disputes, but at the same time does not exclude the use of military force not only as a last resort but also as a tool of preventive diplomacy and peacekeeping. It encourages cooperation and contacts between different types of civil and civilizational system, and at the same time can rely on the existing system of military-political alliances in addressing specific issues. Finally, recognizing the nation-state as the main actor of international activities, this model requires great attention to the use of international and transnational organizations (G.Zavorotnya, 2006).

At the same time, the development of a cooperation security model is far from complete. Such issues as determining which institutions should become the core of the new system of international security, the limits of the use of force in modern international relations, the prospects of national sovereignty, the fate of existing military-political alliances, how to prevent the revival of bloc politics, etc. are not fully resolved. Historical experience shows that the political influence of countries in the international arena is largely determined by their economic and military power. State governance in the security and defense field in democracies operates a system of national security, a subsystem and an organic component of which is the security and defense sector. The latter includes the armed forces, other military formations, law enforcement agencies and special services, structures of the defense-industrial complex, etc. The activities of all of these and other relevant forces and means, as T. Stykalin (2015) emphasizes, are covered by a single system of strategic planning and coordinated by senior political leadership authorized by the

heads of state power bodies who have the right to issue orders to use force or threaten its use in order to resolve the tasks to protect the national interests .

A. Pelykh (2015) systematized military-political models of national security governance according to the following criteria: with regard to the international political status military-political models can be bloc, non-bloc and neutral; on a geopolitical basis - global, regional, satellite; according to the form of realization of external and internal functions of the military force by the state - militaristic, defensive-offensive, defensive-repressive-restrictive and defensive.

In the security field the functioning of state governance systems in a developed democracy is common to the vast majority of European countries, in particular to EU member states. The level of democracy of security governance systems is different and depends mainly on the level of centralization of power in a particular country. However, democratic civilian control over the security and defense sector has become the basis for determining the level of democracy in these systems in the dynamics of the late XX - early XXI centuries.

Transformation of traditional approaches in the dynamics of socio-political changes at the beginning of XXI century

Conceptually, modern security models are developing in a constant dialogue of public policy with the philosophy of liberalism, according to which, in A. Kalyayev's (2019) opinion, the presence of a developed civil society is the main guarantor of security of the individual, society and the state. Modern public statements by the leaders of leading states and international legal documents on national security, as a rule, focus on liberal approaches to its provision. Their essence comes down to a simple approach to security as an indisputable priority of man and, in this context, an unquestionable imperative for the state (A. Kalyayev et al., 2019). At the same time, sometimes the content of statements and documents does not correspond to the real domestic and foreign policy of states on national security issues. The vast majority of them focus on the geopolitical dimension of security in choosing a conceptual approach to national security. According to K. Holovina (2011), the main attention is paid to the protection and development of these opportunities, rather than the division of national security into spheres (economic, political, etc.). Moreover, there is a clear emphasis on identifying, preventing and neutralizing threats to survival .

German experience in developing a modern model for the development of the security and defense sector is linked to the implementation of the Innere Fuhrung approach in the armed forces (Bundeswehr). The conceptualization of this approach took place during the introduction of civil control and accountability to society as a system-forming principle. This manifests itself in various institutional forms and is regulated by relevant legislative acts. This model, by its specifics, according to A. Dmitriev (2014), can be considered unique . The armed forces, in general, and the military personnel, in particular, are seen not as an aggression force, but as an element of deterring the enemy from aggression. Therefore, the main idea is to prevent war by military deterrence. This thesis is not new and it still retains significant discussion potential.

Characteristic to this approach is the shift of the traditional formula in the system of relations between the soldier and the commander from unquestioning subordination to cooperation between them. The ultimate mission of the soldier is to preserve peace. Therefore, the task of preventing war is considered mandatory, and political cooperation is necessary to ensure peace. In everyday military life, this becomes a defining moment in the observance of democratic behavior models - the principles underlying them. For the German security and defense sector, "Innere Fuhrung"" is primarily a political and cultural paradigm (T.Sommer, 2001). The experience of Germany is quite successfully used in other countries where the processes of democratization of society and governance continue, in particular in Ukraine.

Due to the changing security situation in Europe and the world, the positions of the leadership of nation-states on the goals, conditions, permissible limits, forms and consequences of the use of armed forces are changing significantly. The modern interpretation of the purpose and tasks of the army, in general, and the Bundeswehr, in particular, is based on the broadest vision of defense. German experts quite reasonably claim that modern defense cannot be reduced to an armed repulse of the aggressor along the perimeter of the borders of a certain country, the EU or NATO. The expediency of expanding the security space (including by strengthening the military presence of NATO and the EU) is seen in the context of the prospect of blocking the spread of the any crisis on the borders of the united Europe, purposefully and consistently overcoming the negative effects of globalization. These include, as experts note, the economic confrontation of the largest powers, the destruction of multilateral trade agreements and rules, political confrontation between the largest powers, cyberattacks, spreading fake news, loss of confidence in collective security agreements (Forum, 2019).

Changing the priorities of the national security policy in democracies

The Ukrainian crisis of 2014 was an occasion for the EU countries to reconsider their foreign and defense policies. The new security policy aims to protect "internationally established rules and regulations" from attempts by individual countries to regain their "dominance" and "zone of influence". In general, the experience of democracies shows that modern “security sector” at all levels of governance is focused on meeting challenges and potential threats. According to O.Zhytnyk (2015), it is "embedded" in a democratic society, which serves as a kind of an "external guarantor" that humanitarian and political rights within the "security sector" are ensured to the maximum extent possible at all levels and in all dimensions.

At the turn of the XX - XXI centuries, in this context, national security was understood mainly as the physical survival of the state, namely: the protection of its sovereignty, territorial integrity and the existing political system. At the same time, the ability of the state to adequately respond to any external threats was considered fundamentally important. Therefore, ensuring the security of people (citizens) to some extent receded into the background. E. Conteh-Morgan (2001), in particular, noted that “the widening scope and intensification of a global free market is beneficial to some states, but in others it has eliminated a "social contract" between the state and the society, accompanied by a strong perception that economic globalization is largely a process of "disorganized capitalism." The pervasive nature of these transnational and global forces generates dissatisfaction and multilevel (individual, group, and national) insecurity”.

Instead, the modern understanding of the essence of "national security" has acquired a clear military-political context, which, in turn, provides an appropriate strategic view of the principles, approaches and ways to ensure national security and proper defense measures against potential enemies, as well as search for potential allies.

For many countries, issues of national security are becoming doctrinal in nature, which certainly affects the priority for solving national problems. According to S. Bozhko (2005), national doctrines and concepts adopted as the main directions of security become the framework that determines current decisions and provides guidelines for the perspective. Thus, for the United States, According to T.Stukalin (2018), the doctrinal vision of national security has the following structure: fundamental (permanent) interests, which are to ensure security, prosperity and freedom of the American people; the country's mission at a specific historical stage (a doctrine that reflects national interests in a specific vision of the incumbent president); specific targets developed and achieved by the presidential “team”, government agencies, influence groups, commercial and non-governmental organizations – the national security actors. The multiplicity of subjects is determined by the specificities of the American institutional system. The key factors determining the process of developing approaches to national security in the United States are, in particular, the extent of the reality of the external threat, the political role of the president and the level of inter-party confrontation at the central level of government. The greater the external threat is accepted in government circles, the more centralized the process of shaping the state national security policy becomes and the more actively it is controlled by the president.

Such a response system, according to V. Konyshev (2010), significantly reduces the risks of using inadequate approaches of the administration, which could jeopardize national interests, and also makes it possible to avoid risky and ambitious foreign policy initiatives. As V. Belashov (2001) emphasized, traditional security assurance is envisaged by maintaining the balance of large powers within a multipolar world order.

For example, it is traditional for France to pursue a flexible balancing policy and to withdraw from any bilateral alliances in favor of multilateral ones. France is also characterized by a certain distancing from NATO and other European countries in matters of national security, including the use of military means, as well as pursuing its own nuclear policy. The President of the Republic plays a special role in the conceptual approaches to security and defense. According to the 1958 Constitution, the President is "the guarantor of national independence. In developing policy documents in the national security field, the president relies on advisers from the president's office. The participation of other executive bodies in the development of national security issues is much more modest. The role of political parties and representative bodies in determining the country's national security policy is limited by the constitution. In addition, the dominance of the executive power over the legislative one in France effectively nullifies the factor of inter-party struggle in defining conceptual approaches to security issues. However, most French parties develop their own foreign and defense policy programs and publish documents on various aspects of security. At the same time, there is a de facto absence of serious differences in national security policy between the factions of the French National Assembly, regardless of the severity of the current situation and the extent of the reality of external threats.

Britain, despite leaving the EU, remains an active member of NATO and does not relinquish its role in creating a European security environment. A.Marinin (2016) believes that the UK national security strategy is based on new

approaches that combine the readiness of special services for emergencies and the ability of ordinary citizens to participate in ensuring security on the ground. In November 2015, the basic document on military and foreign policy planning for the next five years - "National Security Strategy and Review of Strategic Defense and Security of the United Kingdom" (hereinafter - the strategy) was adopted. This document formulates the government's approaches to political, defense, economic and other aspects of the kingdom's security, adapted to existing and projected threats and challenges . According to the new strategy, the purpose of Britain's national security is to protect the population, territory, economy, infrastructure and way of life, reduce the possibility of threats to the kingdom, its interests and the interests of allies. The security threats in the modern world in the Strategy, in particular, include: changing the balance of economic and military power of the world's leading countries; the growth of rivalry between states and the emergence of more powerful non-state players; threats of terrorism, extremism and instability; cyber threats; destruction of the system based on international law, which affects the achievement of consensus and countering global threats. The strategy defines the principles of Britain's relations with NATO, the United States and other countries, including Russia, as well as with overseas territories and regions (A.Marinin, 2016). The main measures taken by the UK government under the new National Security Strategy are the creation of a “national register of potential risks” that will be accessible to all citizens; improving coordination between the military, the police, intelligence and diplomats within the country - in order to better respond to new threats by increasing the number of security forces by 4,000; creating a team of 1,000 civilian professionals to work in hot regions around the world in order to assist normal life; establishing in the United Kingdom four regional counter-terrorist units and four regional intelligence units to assist the police, etc.

The position of Poland is characterized by peculiar thrust, the state of national security of which in the XXI century is significantly influenced by global processes characterized by high dynamics and the presence of non-traditional threats. The greatest dangers include terrorism, international organized crime, economic instability, mass migration, and cybercrime. In the current geopolitical situation, the Polish military-political leadership has developed approaches to national security, which are reflected in the Constitution of the country and the National Security Strategy of the Republic of Poland (2014), international legal acts signed with the participation of the Republic of Poland and a number of strategic documents. The analysis of modern threats leads to the improvement of national forces and security measures in the direction of integration with the international security system, which allows a simultaneous use of elements of state defense and crisis management. Unified planning and training of military and civilian components at each level of response, a comprehensive approach to the timely solution of disparate problems, as well as creation of stable mechanisms for financing these processes are the basis for strengthening the state's defense capabilities and effective tools for its development (O. Zatynaiko, 2013).

According to Poland's National Security Strategy, its membership in the North Atlantic and European Unions guarantees the security of the state, provides an opportunity for its comprehensive development, and strengthens the position of the Republic of Poland in the international arena. The Polish leadership continues to consider the country's membership in NATO to be the most important factor in ensuring national security. Poland supports the plans to further advance the alliance to its borders with Russia and seeks to fulfill its allied commitments to strengthen the bloc's presence in various parts of the world. Emphasizing the leading role of the United States in ensuring stability and security in Europe, Poland is in favor of maintaining the American military presence on the continent in general and in its territory in particular. One of the priorities of the country's foreign policy is to strengthen its position in the European Union. The Polish leadership is considering the possibility of deepening political and economic integration, as well as carrying out concerted actions within the organization that contribute to the achievement of national goals and the protection of state interests.

"Strategy for development of national security system of the Republic of Poland until 2022" defines the main areas of cooperation between various institutions of state power, local governments and public organizations to ensure the protection of national interests, security of the individual, society and the state. In addition, the document takes into account the main provisions of the NATO Strategic Concept and the European Security Strategy. Proponents of national security policy, which is based on the provisions of the concept of political realism, dominate international politics. At the same time, they do not reduce forceful methods of ensuring national security only to using the military force. They increasingly consider political, economic, information-psychological and other levers of influence on other states as important and additional to force methods means of realization of national interests in conditions when asymmetric hybrid methods of influence became dominant.

Thus, stability of the political system, effectiveness of the armed forces, other security agencies, the relationship between them, the society and the government must be determined by the law, recognized by the society and implemented by political power.

Discussion

The country's integration into a particular military-political alliance allows it to strengthen its defense capabilities at the expense of the Allied forces. In recent years, this course is beginning to acquire new features, the essence of which is to redistribute the role of the military and political functions of military alliances. In order to ensure and strengthen the external security of the world community members, first of all the nation-states, it is necessary to create such a system of international security, which is based on a set of obligations, guarantees and capabilities of its entities. The main purpose of the modern system of international security is, of course, to ensure and strengthen the external security. However, in the current context, joining the structures of such a system requires the participant-states to significantly increase their level of internal security. This is possible only if democratic institutions are strengthened at the national level and under the following conditions: promoting the continued development of civil society, ensuring the rule of law, protecting fundamental human rights and civil liberties; strengthening the fight against organized crime and corruption; promoting sustainable economic development, etc. (NATO-Ukraine, 2003).

The most widespread and effective basis for creating a security system is the presence of a threat, because only when aware of the real shared threat do national elites show willingness to cooperate, develop a common identity that is not limited to borders and reinforced by a common goal. Thus, given that transnational phenomena, in particular international terrorism, religious and ethnic conflicts, international crime, migration, environmental catastrophes, etc., are increasingly becoming a source of threat to Europe, it is expedient to consider a cooperation-based model of the security system with the participation of the international security actors on the European continent NATO + European countries, proposed by R. Cohen (2001).

New element of the cooperative security model is a common commitment to providing individual security and strengthening the stability of socio-economic development. Security based on collaboration "is a strategic system formed around the core of liberal democracies, united by a network of formal and informal alliances and institutions that share common values, as well as practical and transparent cooperation in the economic, political and military spheres. Within the framework of a cooperative security model, the goals of individual states in the national security field are interconnected by four security rings that strengthen the system as a whole". According to R. Cohen (2002), members of a cooperative security system should be prepared for collective diplomatic, economic, and, if necessary, military action in territories that are outside their common space but threaten their prosperity and stability.

Conclusion

Thus, the main priority in the security and defense field should be to ensure stability in the areas adjacent to the area of responsibility, hence instability and conflict in these areas can pose a threat to countries participating in the cooperative security system. Today, there are three military-political security systems in Europe: the Euro-Atlantic security system based on NATO, which is the most powerful military-political organization in the world, the main force of which is the United States; European Union or the European security system, which in connection with the aggressive actions of the Russian Federation has been rapidly created based on the liberal democracy principles; the Eurasian security system, which includes the member states of the CSTO - Collective Security Treaty Organization, the former Soviet republics led by Russia. This group, proclaiming democratic values, unfortunately due to the desire of the Russian Federation to restore its geopolitical influences, cannot, in our opinion, claim to be effective in resolving security issues (A.Rotfeld, 2004). A separate group consists of the so-called non-integrated countries. Among them are neutral countries seeking to integrate into Western European collective security organizations and those that have not yet decided on the vectors of their choice.

From the point of view of the need to create a global security system, the issue of uniting all these systems and all non-integrated countries is on the agenda. The trend towards globalization and regionalization should help countries that aspire to join in the process of European unification to become members of the latest European collective security systems in the future. This may also affect some neutral countries. In the formation of a modern system of European security based on cooperation, one could return to the basic idea laid down by the OSCE founders in creating this organization - finding ways to understand the East and the West, to compromise between their natural worldview paradigms, but on the principles of democracy.

The Internationalization of Companies: Comparative Analysis Between Behavioral Models and Economic Models

Mohamed Noor MAIOUI

Email: maioui.mohamednoor@gmail.com

Abstract

A large number of theoretical publications and empirical studies are devoted to the analysis of the internationalization of companies. Many conceptual frameworks have been adopted to understand this phenomenon. The internationalization of enterprises is a field of research that has shaped several developments in the last decade. Several authors have developed different models with the objective of analyzing factors of international development. This article deals with a literature review of the main models of internationalization. Two typologies of models are analyzed. Models qualified as behavioral and models qualified as Economics.

Keywords: Internalization, Economic model, Behavioral model, comparative analysis.

Introduction

The transaction costs approach views internationalization as an attempt to minimize costs (Mucchielli, 1998) and increase internalization (Buckley and Casson, 1998). The eclectic paradigm (O.L.I.) “Enterprise, Localization and Internalisation”) emphasizes the objective of maximizing the benefits of internationalization (Dunning 1988, 1998). Since the mid-1970s, based on the sequential analysis of the internationalization process, this model has been the subject of numerous theoretical critiques and empirical verification tests.

Some authors have condemned its certainty and its analysis of the irreducible "progressive" (Andersen 1993). Other authors have criticized “the linearity, irreversibility and contingency of the model” (Rezendé 2006), while others have underlined the limits of this structure because it cannot explain the current globalization and the behavior of large companies. in the context of globalization.

However, there is a division between economic models and behavioral models. On the one hand, economic models or classic models focus on the economic logic emitted by these models on a company X that wants to internationalize. In this sense, by using basic economic models, an unprecedented logic takes hold and thus focuses on elements that are almost mathematically sound.

On the contrary, behavioral models focus on the behavior of human elements within the company and therefore these elements result in decisional and even economic volatility depending on the behavior of each decision-maker within the company who wants to internationalize. Following no logic, behavioral models sometimes lead us to make decisions that are neither optimal for us nor for the general interest. First, "emotional biases" such as jealousy or envy, which by comparing us to others and to the social group to which we belong, anchor our decisions in relation to a specific frame of reference. Then the "social preferences", such as a taste for cooperation, fairness, reciprocity that make us conform to social rules and norms.

Analysis of internationalization behavioral models

Most of the early empirical work dealing with the process of internationalization finds its foundations in the behaviorist or "behavioral" theory of the firm (Cyert and March, 1963), considering internationalization as the product of a series of incremental decisions (Johansonet Vahlne, 1977). By postulating the principles of limited rationality, satisfaction and social and political organization in order to understand the decision-making processes

present within companies, this work marks a significant divergence from previous theories where the economic principles of profit maximization, perfect knowledge of markets and rational decision-making processes.

Models dealing with the process of internationalization of companies have focused on the characteristics of the firm (such as the decision-making process, the manager, etc.) to understand its behavior internationally (Andersen, 1993). Given the large number of models dealing with the process of internationalization of companies, it is obviously difficult for us to develop them all in detail. However, among all of this work, two avenues of analysis can be identified (Andersen, 1993; Gankema, Snuif and Zwart, 2000).

The models originally developed by Johanson and Wiedersheim-Paul (1975) and Johanson and Vahlne (1977) known as the Uppsala model; the work initiated by Bilkey and Tesar (1977), Cavusgil (1980), Reid (1981) and Czinkota (1982) grouped together under the name of Innovation models and which particularly emphasize internationalization as a process of innovation for the company. All of these models relating to the internationalization process (Uppsala model and Innovation models) emphasize the essentially incremental and cumulative nature of this dynamic (Ageron and Huault, 2002). Based on behaviorist theory, they analyze this strategy as a learning process comprising stages (for example, three in number in the model developed by Johanson and Wiedersheim-Paul in 1975 or six in the model developed by Bilkey and Tesar in 1977) through which the company passes.

In each of the models, the gradual nature of the firm's internationalization process can mainly be attributed to the lack of knowledge of the firm on the one hand and the uncertainty associated with the decision to internationalize (Andersen, 1993). One of the major contributions of these models is therefore the highlighting of an "internationalization path", of an evolutionary process comprising stages or stages that the company goes through successively.

The Uppsala Model

The Uppsala model finds its origins, according to Cheriet (2010), in the theory of the growth of the firm and that of the behavior of organizations and s' contrasts with the trends that maintain that companies can have an international dimension when they are created Cheriet (2010). This model considers that the development of business activities abroad takes place incrementally and sequentially (Pantin, 2006). Doing this this way, companies could reduce the uncertainty inherent in foreign markets and build on a broader "experiential" knowledge of international operations. The "U" model links the learning effect, the psychic distance, the mode of internationalization used and the network effect (Cheriet, 2010).

In the mid-1970s, researchers in the Department of Business Studies at Uppsala University made empirical observations that contradicted the established economics and normative literature on international affairs of the time. According to this literature, companies choose, or should choose the optimal mode of entering a market by analyzing their costs and risks according to the characteristics of the market and taking into account their own resources (e.g. Hood & Young, 1979). However, empirical observations from a database of Swedish affiliates abroad, as well as a number of sectorial studies of Swedish companies in international markets, indicated that Swedish companies frequently began to internationalize with ad hoc exports (Carlson, 1975; Forsgren& Kinch, 1970; Hornell, Vahlne &Wiedersheim-Paul, 1973; Johanson, 1966; Nellbeck, 1967).

They would then formalize their entries through agreements with intermediaries, often agents who represented the focal companies in the foreign market (Hornell, Vahlne &Wiedersheim-Paul, 1973). Usually, as sales increased, they replaced their agents with their own sales organization and as growth continued, they began to manufacture in the overseas market to overcome trade barriers that were still in place after the Second World War (Hornell, Vahlne &Wiedersheim-Paul, 1973), we have qualified this dimension of the internationalization model of the establishment chain. Another feature of the pattern was that internationalization often started in foreign markets close to the domestic market in terms of psychic distance, defined as factors that make it difficult to understand foreign environments (Nellbeck, 1967). Firms would then gradually enter other markets more distant in terms of psychic distance (Johanson&Wiedersheim Paul, 1975; Vahlne &Wiedersheim-Paul, 1973). This process has its origins in foreign liability, a concept that originally explained why a foreign investor had to have a specific advantage in the company in order to more than compensate for this liability (Hymer, 1976; Zaheer, 1995). In addition, the researchers present internationalization as a process ranging from a simple “export” corresponding to a strong perception of risk and a low resource commitment to the establishment of a “production subsidiary” combining a low perception of risk and a strong commitment of resources going through the intermediary stages of “agent” and “commercial representation”.

The" U "model has met with a number of criticisms, even calling it into question (Angué and Mayrhofer, 2010). It has mainly been criticized for its deterministic character and its analysis, in stages, not generalizable (Cheriet,

2010). The model has also been the subject of empirical invalidations (Angué and Mayrhofer, 2010; Cheriet, 2010). For their part, Boutary, El Mabrouki, Minialai, Monnoyer (2014) support the relevance of the model, but propose to revisit it to assess, in a contextualized manner, the process of internationalization of companies from developing countries.

Despite these numerous empirical confirmations, the U model has been severely criticized by international economics and management scientists during these three decades, both in terms of theoretical foundations and associated empirical constructs.

On the other hand, forty years after the publication of the primary Uppsala model, Johanson and Vahlne (2017) firmly presented their latest model as a general model. During this edition, they emphasized the key features of recent firms: "process instead of structure-oriented, a network instead of a stand-alone unit, pro-active and entrepreneurial instead of passive" (Johanson et al., 2017). We argue however that the Uppsala model's recent application to the trendy business world may miss the main focus of the dynamic combination of business networks, specifically ignoring the connection between the supplier and therefore the buyer. There's little doubt that the capabilities and knowledge development processes from Uppsala's general model (2017) become even more relevant for keeping the end-to-end of companies configuration alive. Firstly, to define them as a sense-making development during the internationalization process for both MNEs and EMNEs, the authors combine these two variables of capabilities and knowledge development as "dynamic capabilities" to confirm these development processes can catch up with the dynamic changes of the business environment. Secondly, we reaffirm the importance of commitment at a private firm level or a network perspective.

The extent of commitment is subject to the dynamic capability accepted by the firm's counterparty. Here the concept is to retain the "commitment processes" united of the variables to drive the change for opportunity development in terms of resource allocation for every finely-sliced economic activity. Third, the authors borrow the link commitment from Uppsala's business network model (2009) for illustrating the supplier and buyer relationship. The intention is to upgrade this variable as "relationship development processes," within which all participants inside the company can re-negotiate the deliverables and subsequent developments thereafter, like how organizing or re-allocating the investments may help to boost the performance or maybe enhance the end-to-end efficiency.

Lastly, instead of defining the firm's network position supported its committed performance; the general view is to broaden their application to multiple networks. Following technological advances, the firm may enter the network with a relevant field or a full new industry to diversify its business portfolio and sustain overall profitability. Considering its dependence continues to be on network effects (Thomas, Autio & Gann, 2014), here we propose a replacement variable of "ecosystem position" to hide more of the worth capture process. Ecosystem is defined because the collaborate arrangements through which the firms recombine their individual offerings into a coherent and buyer-oriented solution (Adner, 2006). it's seen as open communities comprised of various actors, like direct suppliers, complementors, regulatory authorities, policy makers, or related actors. (Thomas et al, 2014).

Another extension of the ecosystem has emerged due to the generativity of an enabling technology or digitalization platforms by aggregating heterogeneous alternatives to the external actions (Dattée, Alexy & Autio, 2018). The proposed conceptual model is supposed to supply a general model depicting the cumulative processes of internalization between the suppliers and therefore the buyers and further complement the company's transformation, even beyond the efficiency considerations.

The Strategic Decision-Making Model

Decision-making is the main driving force behind company policy, since through this process, the ideas and ambitions of the manager and other company actors are transformed into strategic actions. It is also the least visible facet of company policy. In this sense, any decision that converges towards the internationalization of a company is intended to be a strategic decision that companies adopt to expand their activity into new successful markets. However, relocating or creating a subsidiary in a foreign country presents a major challenge for the activity and the organization of the company due to the lack of knowledge to manage in foreign markets (Aharoni, 1966).

Thus, to fill this gap, Sami Basly (2006) in his article "The internationalization of the firm: are the theories of organizational learning obsolete? Started by identifying what organizational knowledge is in an international environment and what are its aspects, to then analyze how organizational knowledge has been developed and how cognitive and behavioral learning approaches contribute to this development. This current was developed later by Johanson and Vahlne (1977), these two authors recognize a primordial role in knowledge, in their view, and knowledge brings together an objective component and an experiential component. And so organizational knowledge, according to Basley, (2007), consists of getting an idea of the situation in the international market

through two main processes: the first process consists of acquiring knowledge of the target market (s) and the second process consists of to develop organizational knowledge of internationalization.

Knowing why this market and not others is very important for identifying opportunities and threats in foreign markets, and distinguishing between operational knowledge relating to foreign operations and local stakeholders, and institutional knowledge which encompasses everything.

Organizational knowledge, shows how to proceed with our activity in another country, it is an organizational competence based on the capacity to absorb and accumulate knowledge from our first-hand experience. This abundance of information will serve as a database when the company finds itself in a situation where it must make an irreversible decision.

Consequently, we cannot neglect the contribution of each of this knowledge for the organizational development of a company internationally, and therefore market learning and organizational learning are complementary and essential to have reliable organizational knowledge. However, there is little work that transposes organizational knowledge and learning into the field of internationalization (Welch et al, 2001). In this sense, two modes are used by companies to develop organizational knowledge internationally.

The first, which is mainly cognitive, gathers all explicit qualitative and quantitative information that we can have on a market through several tools such as market studies for example.

The second enshrines a tacit behavioral logic in which the company accumulates its knowledge through its first-hand experience, which is information that is transmitted through direct communication between directors and managers.

These two modes of knowledge development seem independent, but they are both important for developing a global organizational knowledge of the situation. For market knowledge, cognitive information is important for decision making and forecasting. But the longer the company stays in a foreign market, the more experience and tacit knowledge it gains that helps it solve problems. As for organizational knowledge, tacit information which will later be translated into explicit knowledge will help to face different organizational challenges.

The Network Model

A number of studies have demonstrated the role of networks in the internationalization of companies. Coviello and Munro (1995, 1997) conducted empirical studies on the internationalization of small software companies. They found that on-network relationships have an impact on the selection of foreign markets as well as on the mode of entry into the context of ongoing network processes (Coviello and Munro 1995, 1997).

Their results led them to develop a model combining the process model and the network approach. In a study of the international expansion of Japanese automotive component suppliers, Martin, Swaminathan and Mitchell (1998) found that the inter-organizational relationships of suppliers, especially those with buyers, affected their pattern of international expansion. Other researchers have studied networks in studies of internationalization strategy (Welch & Welch, 1996), the location of foreign direct investment (Chen & Chen, 1998), the first step abroad (Ellis, 2000), the The internationalization of companies (Chetty &Blankenburg Holm, 2000), the internationalization of companies in emerging markets (Elango&Pattnaik, 2007) and rapid internationalization (Loane& Bell, 2006), to name but a few.

The research that has been done to date has generally looked at how networks influence internationalization, without discussing how these networks were created and without taking into account the structure of the network in the country or countries where companies have entered (Elango&Pattnaik, 2007). Based on case analyzes, Coviello (2006) developed a model of "how do networks of new international companies evolve?" during the first phase of internationalization. Our focus differs from Coviello in that we focus on business networks as the market structure in which the internationalization firm is anchored and on the corresponding business network structure of the foreign market (Coviello, 2006).

If our objective is to develop a more general corporate network model for the internationalization of companies, the work of Coviello (2006) is nevertheless of great interest, because it shows that the "insidership" in networks, developed before the he entry into a new market, even before the company was founded, contributes to the specific internationalization process underway. The studies on which the 1977 model was based indicated that received theories about markets and marketing were not helpful in trying to understand the market situation of individual

firms. An international business-to-business marketing research program began in Uppsala in the mid-1970s to develop a better understanding of business and marketing markets.

Early observations that firms develop long-lasting relationships with important customers were an important input to this research program (Forsgren and Kinch, 1970; Johanson, 1966). An interaction approach focused on adaptation and exchange between suppliers and customers has been used as a theoretical framework for the study of commercial relations (Hakansson&Ostberg, 1975). A large-scale empirical study of the international marketing and purchasing of industrial products (the IMP project), carried out in the late 1970s and early 1980s by researchers from Sweden and four other European countries, was based on the 'interaction approach (Ford, 1997; Hakansson, 1982; Turnbull & Valla, 1986). The work carried out during the project demonstrated that close and lasting commercial relationships between suppliers and customers are indeed important, whether within a given country or between countries (Hallen, 1986). Since then, a number of studies have shown the importance of relationships in the internationalization process - customer follow-up strategies for example (Bonaccorsi, 1992; Erramilli& Rao, 1990; Majkgard& Sharma, 1998; Sharma &Johanson, 1987). Studies of the IMP project have also shown that such relationships usually involve a number of managers who coordinate the activities of different firms and together create interrelated routines (Cunningham and Homse, 1986). Moreover, these relationships seem to develop through social exchange processes in which the companies involved implement the relationship in an interactive and sequential manner (Kelley & Thibaut, 1978).

Since these firms are in turn involved in a number of additional business relationships, the firms operate in networks of connected business relationships (Anderson, Hakansson and Johanson, 1994; Cook and Emerson, 1978; Hagg &Johanson, 1982). The term connected means that the exchange in one relationship is related to the exchange in another. These networks of connected relationships are called business networks. The company can create new knowledge through exchanges in its network of interconnected relationships. Knowledge creation is the result of the confrontation between the knowledge of producers and the knowledge of users. The process of knowledge creation is not distinct from other activities in business relationships; rather it is integrated into it. Knowledge does not arise only from the company's own activities, but also from the activities of its partners, and since these partners also have other partners with whom their activities are coordinated, the focal company is indirectly engaged in a process of knowledge creation that extends far beyond its own horizon. Thus, a network of business relationships provides a company with an extensive knowledge base (Hagg &Johanson, 1982; Kogut, 2000). Penrose (1966) and the resource-based view (RBV) (Barney, 1986) assume that resources are heterogeneous and that these idiosyncratic sets of resources lead to the creation of value, regardless of market conditions. The corporate network view begins with these same assumptions and adds that exchanging within a network enables a business to gain knowledge about its relationship partners, including their resources, needs, capabilities, strategies, and more relationships.

The Analysis of the economist's model.

The latest developments in the world economy, such as the strengthening of international trade, the rise of emerging economies and the speed of economic progress, are enabling companies in emerging economies to catch up with their technological backwardness and to innovate. And compete on the international stage. Firms in emerging economies are increasingly international and face competition from foreign firms (Dunning and Lundan, 2008). For these companies, internationalization can bring many benefits, but also challenges. On the one hand, internationalization allows these companies to generate innovation, increase their productivity and acquire new points of sale and new technologies.

In this sense, economic modeling has thus been able to provide economic analysis with experimental bases: the model appears as an experimental framework which is equivalent to that which can be found in laboratory sciences.
For the past fifteen years, economic modeling has given rise to significant methodological literature. In particular, this enabled the specificity of models to be established as instruments of "mediation" between theory and reality (Cartwright, 1987). From this literature clearly emerges the complex positioning of models vis-à-vis the real: they can sometimes be radically disconnected from the real (they are then totally abstract models), and in other cases they can maintain relations of various orders with reality - reproduction of data, forecasting, definition of ideal types, preparation of economic policies. But, like any representation, they necessarily stand out from reality: they constitute constructions based on hypotheses (implicit or explicit) and, as experimental frameworks; they are based on conditions of isolation. Even if they have a relationship with reality, they are only a representation of it, partial or ideal.

The OLI model (Eclectic Paradigm)

The theory developed by Dunning (1977) constitutes a first major contribution to the analysis of international investment flows in the 1970s, although the first multinational firm developed in the middle of the 17th century under the name of "East India Company". ". Eclectic theory is conceived as a synthesis of the theories of internationalization and the theory of transaction costs, each of which provides only partial explanations of the location of firms. In this approach, Dunning was inspired by the work of Hirsch (1976) relating to arbitration carried out by a firm between the three methods of exploring the foreign market: either foreign direct investment, or export or sale License. By distinguishing the different costs relating to each modality, the simple comparison between these costs determines the choice of the most profitable modality for the firm. Hirsch's approach thus assumes perfect information on all costs, which cannot be the case on a global scale given the large asymmetry of costs and benefits. In addition, this approach, which is part of the static (non-strategic) models, only considers the choice of an isolated firm for which only the cost matters in the location decision. It is within this arbitration framework that Dunning (1981) constructs a simple two-country model in which firms choose between the three methods of entering the foreign market (FDI, License or Exports). This choice is made on the basis of the three types of advantages that a firm must have in order to internationalize and summarized by the OLI paradigm. It is:

- Ownership advantage (O) which results in the possession of a specific asset or specific advantage of the firm. It is a product or technology that other firms or companies do not have or do not have access to (patent, trademarks, trade secrets, etc.);

- Location advantage (L) which means that the asset must be durable for the company to operate abroad rather than in the country of origin. This is an advantage of locating abroad. The point here is to look for outlets that minimize the costs of production, marketing, etc.

- Internalization advantage (I) which is explained by the fact that there is less advantage to outsource than to operate this specific asset yourself. This is an advantage to internalization, in order to circumvent or avoid the risk of selling technology to other firms so as not to be exposed to competition.

Dunning distinguishes 2 types of inputs required by any business to produce beneficial outputs: The first type concerns resources within the reach of any business regardless but specific to a precise location (natural resources, market structure, government legislation, etc.). The second type is created by the company itself (like technological innovations) or can be acquired from other organizations as a right of use. The latter plays an important role in the sense that it offers endowments of property which, although linked to the location of firms, their use is not confined to location. These endowments are mobile between countries but not between firms, a phenomenon explained by the theory of direct investment (product differentiation, entrepreneurial capacities and multiplier economies). Thus, rental endowments and property approaches alone cannot explain all forms of commerce.

The final point of the approach concerns the use by the firm of its ownership advantages by internalizing its capital rather than externalizing it. This is explained by the firm's desire to avoid disadvantages or capitalize on the imperfections of public authorities and the market system. For the buyer, it is about the price of certain resources, their delivery time, etc. For the seller, internalization is encouraged by a market without price discrimination and with high information control costs. Public interventions in the allocation of resources (license of technologies, difference in tax policies) can also encourage the internalization of activities.

Thus, the choice of how to enter the foreign market depends on the conjecture between these three types of benefits. Indeed, a move abroad through FDI is only possible if the three specific advantages (O, L and I) are combined. On the other hand, if the cost advantage of L location does not exist in the presence of the other two O and I benefits, the firm prefers to export to foreign markets. Licensing will be the most favourable choice if it has only one advantage in industry O; Dunning (1988).

However, this theory remains marked by its purely microeconomic approach to the question of location and the absence of a macroeconomic analysis in terms of the comparative advantages of countries (Kojima, 1990). In addition, in the approaches of Hirsch and Dunning, the choice of the modality of market penetration results from a simple static trade-off between costs or benefits, which narrows the framework for analyzing location. This theory is also criticized by the absence of strategic interactions between firms in the isolated choices made by these firms, without taking into account the actions and choices of local and foreign competing firms. However, Dunning (1993) himself attempted to go beyond the static framework of his model for a dynamic approach to eclectic theory, by considering the evolution over time of the three types of advantages O, L and I.

The ILCM (International Life Cycle Model)

The international product cycle is a model that structures international trade in products. It focuses on the idea of the main advantages and production characteristics. When a product reaches mass production, the production process tends to shift outside of the country of origin. The country that generates a product idea often becomes the consumer of that product.

Following the failure of the Heckscher-Ohlin model to adequately illustrate the model of international trade, Raymond Vernon proposed the theory of the product life cycle. Raymond Vernon applies two methods to develop his theory, the labor-saving and capital-utilizing product model that caters to high-income groups.

The author uses the United States to illustrate changes in the commercial market. The products that are produced and consumed at a new stage come from the United States. However, when production reaches the point of mass production, most of the techniques used will be foreign. At the third stage of production, moves to developing countries.
In summary, this model shows the comparative changes in the trading market. The country that benefits the most goes from a country that came up with the idea to the country where the actual production takes place.

According to Raymond Vernon, products can be classified into three stages depending on the shelf life of the product and the trading behavior in the international trade market.

- **Standardized products,**
- **New products,**
- **Maturation products.**

The theory of the product cycle then introduces five stages of production: introduction, growth, maturity, saturation, and decline.

Step 1: Introduction
The first for any producer is to promote a new product in the market. At this point, customers do not know the product; therefore, sales and profits will be lower. Competition will also be weak in the market.

Step 2: Growth
At this point, the popularity of the product in the market will have increased. The production company needs to increase its promotional budget. The number of sales will also increase, hence the decrease in production cost.

Step 3: Maturity
Compared with the growth phase, the increase in sales volume and demand level is relatively small at this stage. Many consumers are familiar with the product and it is difficult to find new customers. Even though the number of competitors has increased at this stage, business is still juicy at this stage; everything seems to be favorable to producers. Foreign demand will also increase at this point, especially in developed countries. The increase in foreign demand will see the producing country create similar companies abroad.

Step 4: Saturation
At this point, competing companies will have taken part of the market. The production companies are doing their best to attract new customers, but there will be no increase or decrease in sales volume at this point.

Stage 5: decline
At this point, the product begins to decline in sales which ultimately affects profit margins. The economic viability of continuing to operate decreases considerably. At this point, the business can choose to stop production or sell the business. Another possible scenario is that the production company transfers its activities to a developing country.

Company-specific knowledge forms the basis of a company's competitive advantage. It is generated by investment in R&D and other proprietary information, which may be hidden from third parties. Company-specific knowledge can be viewed as an intangible asset, which dissipates over time through depreciation, diffusion and obsolescence.

Therefore, R&D is considered the main determinant of competitive advantage, during the introductory and initial growth phases of the product cycle. Marketing takes over as the main determinant of competitive advantage during the growth phase. Production becomes the main determining factor as the product matures.
Distance is introduced into the frame as a factor that affects interactions. The cost of interactions with suppliers, customers, agents and subsidiaries increases with geographic, cultural, legal and other economic distance components. "Distance premium", for example the difference between the interior distance and the economic distance.

Foreign costs of market services, and other interactions, also vary during the product cycle. Being strongly correlated with service intensity and knowledge intensity, which peak at the start of the cycle and decrease as the product approaches maturity, the distance bonus is an important component of the "responsibility of the company". foreign ", which affects the modes as well as the sequence of internationalization.

R & D, production and marketing activities are a determining factor of competitive advantage, evolve throughout the product cycle. The framework considers the implications of these changes for the internationalization of companies marketing products belonging to different phases of the cycle.

During the introductory phase of the cycle, commercialization is the main determinant, when investment in R&D peaks, technological superiority has a major impact on competitive advantage, and may even grant innovative companies a monopoly position. Production and marketing are of secondary importance in shaping the competitive position during this phase.

Behavioral Models Versus Economists Models

The ideals of conventional economics have driven economists through the treacherous forest of the financial world. It has provided them with a template to base everything on which they do. The new and evolving field of behavioral economics however is founded on concepts of its own. Others are equivalent to conventional economics, whereas others are polar opposites. We will explore these similarities and distinctions here.

Starting with parallels, the two forms of economy are seeking to achieve a deeper understanding of humanity. Both are attempts to take past experience and use it to predict what people will do next or how they will react to such scenarios. In order to make a good investment, one must try to predict future actions. Here's where the two methods diverge when one takes a hard left and the other a hard right. Traditional economics works under the premise that all people are rational beings. They can only make decisions based on what is best for them and their condition and "calculate everything when it comes to human rationality, behavioral economics is the very antithesis of traditional economics. Behavioral economics dictates that people are behaving very irrationally. People aren't perfect. They have urges and customs that they cannot regulate. Only a small percentage of the population would take the time and effort to take only measured risks or try to do some cost-benefit analysis of the situation before diving straight into it. We don't always learn from our past experiences, so we want to make the same mistakes over and over again.

The irrationality of human nature disallows the concept of developing a single unifying principle that suits all, and instead seeks to construct models that are unique to the specific situation to which they would be applied.

With regard to scientific methods, we can notice that the biggest differences are between the process and the system. Economic models have been trying to capture structural parameters for over 100 years and somehow measure them, particularly for political and corporate governance. Much older behavioral models try to concentrate on individual activity, desires for worth and economic decisions. Systemic parameters are often postmortems, while educated guesses are the subject of action processes.

Conclusion

To conclude this article, the various models that have been invoked have helped us to better understand the various approaches to the internationalization of companies. However, other studies have pointed to some limitations of the models: linearity of the process, non-reversibility, presence of stage jumps or direct implementation of certain firms, lack of analysis in terms of stage duration, etc. These critical studies are reinforced by the multifaceted nature of this type of business and the distinct organizational profiles of multinational firms and companies.

However, several limitations have been observed with regard to behavioral models as well as the economist models used in this research. Several researchers question the sequential and cumulative nature of the internationalization

process, especially when it comes to companies developing internationally from the outset. Many companies achieve a significant volume of their sales (25% of turnover) internationally in the first two or three years of their creation, without going through the different stages of the Uppsala model. Andersen (1993) criticizes the Uppsala model, showing that it does not specify the reasons or factors (internal, external) that may influence the process of internationalization of companies, including the brakes related to conservatism. It does not explain the mechanism by which "experiential knowledge" acquired gradually in foreign markets affects the commitment of resources. The model does not explain how the internationalization process will proceed. It does not explain how and why this process is being undertaken; and who would be the facilitators? Similarly, there is a blurring of the reasons and conditions for moving from one stage to another in the process.

On the other hand, the economic models do not objectively clarify the reasons why companies are internationalizing. In this sense, the OLI paradigm seems redundant to distinguish between the benefits of business ownership or the business-specific benefits (competitive advantages or key skills) and the benefits of internalization. In addition, it is also considered static; it does not explain the nature of the interrelationships between the determinants (company ownership benefits, market location benefits and the benefits of internalizing transaction integration), nor the strategic decisions that influence companies' entry choices, nor the change in environmental conditions (impact of social and political changes. Moreover, the applicability of the OLI or OLMA proposals seems low in the case of companies.

Abstract

One of the priorities of the 'National Policy' on Industry 4.0 is to holistically and rapidly transform industry strength of Malaysia in both a comprehensive and accelerated way and an integral component is the adoption of appropriate legislation against the misuse of ICTs for criminal purposes. The study shows that Malaysia's possible economic loss from cybercrime with the financial sector hitting its worst, it could hit a record of US$ 12.2 billion. With the advent of technology, cybercrime is increasing and it can be interpreted from the figures that either in investigation or legislation, there is something which needed to be looked into. Currently, the legislation on cybercrimes are in piece meals and Malaysia needs a comprehensive cybercrime legislation in order to achieve a good prosecution in cybercrime cases. Thus, the purposes of this study are to find out why existing law is ineffective, and examine on how other jurisdictions deal with cybercrime. Therefore, the main aim is to propose a comprehensive new law to tackle cybercrime effectively and efficiently. Both quantitative and qualitative analysis will be used in this study. In addition to conducting a comprehensive analysis by reviewing the laws in other selected jurisdictions, selected interviews with relevant government departments, nongovernmental organisations and legislatures will be conducted. A revised criminal policy aimed at protecting society from cybercrime, through the implementation of relevant legislation, needs to be followed as a matter of priority. Ineffective legislative framework results in encouraging criminals to conduct criminal cyber activities.

Keywords: Cybercrime; Legislation; Disruption

Introduction

Cybercrime, also referred to as 'computer crime', requires the use of cyber space as a weapon for unlawful ends, such as violations of privacy, theft on identity, fraud etc. Since offenders are more difficult to trace, economies of scale are greater and it is easier for cyber criminals to function on an international scale, cybercrimes are distinct from conventional crimes. More than three thousand complaints were reported In Malaysia during the three months period of movement control order (MCO) period in (March – June) which is an increase of nearly 100% compared to the same time in the pervious year. All these reported cases happened in urban areas with fast the internet connection and speed. Most of the cases are relating to cyberbullying, hacking attempts, spammers, cyber intrusions and cyber fraud. Cyber fraud cases involve misappropriation of personal data, soft loan scams and online scams. Based on the statistics obtained from the Malaysia Royal Police, nearly ten thousand cases of cybercrime amounting to nearly 300 million were committed during the first six months of 2020 in Malaysia. This is an alarming increase of cybercrime and there is an urgent need for Malaysia Royal Police, Malaysian Communications and Multimedia Commission, CyberSecurity and Bank Negara to act urgently to combat cybercrimes in Malaysia.

Legislation relating to Cybercrime in Malaysia

There has been called for review of current laws of Computer Crime Act 1997, Evidence Act 1950 and Penal Code. Suggestions have made to introduce a new legislation to combat cybercrime effectively. The Ministry of Communications and Multimedia also called to amend or incorporate new cybercrime and cyberbullying laws when the Ministry announced to introduce a national cyber security policy developing digital entrepreneurs' cybersecurity systems and infrastructures.

Present laws are insufficient or ineffective and do not cover or describe cybercrime such as state-sponsored cybercrime and civil liability, online impersonation, cyberbullying, cyber-harassment, cyberstalking. Therefore, due to the rise in cybercrime cases in Malaysia, it is necessary to enact a new law to combat cybercrime.

Issues Relating to Cybercrime in Malaysia

The issue of this study, therefore, is that Malaysia does not have an effective legal system to combat cybercrime in the age of disruption. The research problem can be summarised as follow:

(1) There is a surge in cybercrime cases in Malaysia.
(2) Current legislation is not effective and inadequate to combat cybercrime in the age of disruption.
(3) Cybercrime is one of the world's leading criminal enterprises endangering the country's security.

The research questions are:

(a) Why the current legislation is not effective to combat cybercrime?
(b) How the legislation in other selected Jurisdictions namely the United States, the United Kingdom & Australia tackle the issue of cybercrime?
(c) Why is Malaysia in need of need of a new legislation to combat cybercrime?

The ultimate purpose of this research is to propose a new legislation to combat cybercrime in accordance with the 'National Policy on Industry 4.0'. The specific Objectives are;

(1) To investigate the efficiency of current legislation to combat cybercrime in Malaysia;
(2) To examine how cybercrime in other jurisdictions is managed especially the United States, and Australia.
(3) To suggest the most suitable approach to be applied in Malaysia.
There is no single piece of legislation to combat cybercrimes including online fraud, identity theft, impersonation, etc.

Analysis on the Issues Relating to Cybercrime in Malaysia

The act of trying to get unauthorised access to computers or networks and the unlawful communication to an unauthorised individual is criminalised under the Computer Crimes Act 1997 (CCA).

Various activities carried out by licensees and those identified and regulated under the 'Communication and Multimedia Act 1998' (CMA) are forbidden from network services from being used fraudulently or inappropriate way. If any type of cybercrime is committed then Penal Code will be invoked. Penal Code is pertinent in handling a wide range of cybercrime cases and in fact, it is the only legislation which can be used to prosecute where any other legislation does not specifically spell out the crime or when the specific crime does not fall within the scope of any of the cyber-law legislation.

Cybercrime legislation in Malaysia are based on the sector involved. Network and reliability falls under the jurisdiction of Malaysian Communications and Multimedia Commission (MCMC) and thus it is governed by the Communications and Multimedia Act 1998. Issues relating to violation of personal data and relating issues fall under the jurisdiction of Personal Data Protection office and governed by Personal Data Protection Act 2010. Other statutory bodies which have the jurisdiction over cybercrimes relating to financial issues are Securities Commission of Malaysia (SC) and Central Bank of Malaysia under the Computer Crimes Act 1997.

Because of the exponential growth of connected devices, especially during the 'Fourth Industrial Revolution' (4 IR), fighting cybercrime will be increasingly difficult. A new law would help to protect people's rights and well-being,

as any complaint could be resolved by legal means. One instance of a cybercrime that has affected 300,000 computers in 150 countries is the latest Wannacry malware attack.

Based on CyberSecurity Malaysia statistics, there is an increase in cyberbullying cases involving students in recent years although the statistics is based on the cases reported and there are a number of unreported cases throughout the country. DIGI Telecommunications Sdn. Bhd. conducted a survey and it was reported that there is an increase in cyberbully cases among the students.

The CSM needs more authoritative and pro-active measures at a time when cyber treats are growing, including cyber take-downs of bad guys when their criminal actions are detected. In fact, instead of waiting to detect incidents, the team should be able to track the cybercriminals and bring down their server. Current legislation still does not allow the CSM to take action and it is necessary to consider granting the CSM greater powers.

The need to reinforce cyber defences is also consistent with the emergence of the IR 4.0, which is embedded in our lives and society with technology. The Penal Code fails; it is either too ambiguous, vague or under-inclusive targeted actions, leaving weakness in the legislation which in turn results in inefficiency is dealing with a wide range of sophisticated cybercrime issues. Under the Penal Code, it is a requirement to prove *mens rea* and *actus reus* and it has to be proved beyond reasonable doubt. If it cannot be proved that the perpetrator cannot be prosecuted and the whole claim will fail no matter how much distress or damage have caused to the victim. In addition, cybercrimes such as state sponsored cybercrime are not covered or set out by current law and subject such states to civil liability.

In the wake of global cyber threats, such as the WannaCry and Petya (NotPetya) attacks, the need for a coordinated response has become more urgent. Cyberattacks, cybercrime, and cyber espionage have become more widespread and unavoidable than ever before as warfare progresses. In Malaysia, existing legislation is insufficient or ineffective to address these problems. In November 2016, a foreign actor targeted Saudi Arabia's aviation agency by sending a virus specifically intended to penetrate government agencies.

Findings and Recommendations

The examination of cybercrime laws and the effectiveness of the current legislation in other jurisdictions highlighted that there is a need for new legislation to be implemented in Malaysia. The information on other jurisdictions was collected mainly through literature review. It also follows a qualitative research approach; where the data are gathered through the method of semi-structured in-depth interview methods by using open-ended questions in order to obtain a comprehensive description of the experiences of the respondents. The legal resources such as statute, cases and international agreements will be reviewed for study. The library, electronic journals and conferences will be sources of materials and data and interviews with the respondents. In order to establish more precisely the mechanisms involved an open-ended interviews with above stated policy makers and the public. The purpose of interviews is to capture different perspectives on the necessity of having a new legislation in Malaysia and to determine whether there really is a need of having a new legislation or amendment of existing legislation since there are calls to implement a new comprehensive legislation to combat cybercrime. The interviews will be conducted by using loosely structured with questions relating various aspects of the legislation and developments in society.

In this analysis, the comparative research method will be used to analyse law enforcement in some jurisdictions, especially in the United Kingdom, Australia and the United States. The reasons for choosing these jurisdictions are that United Kingdom and Australia are being the commonwealth countries and the United States is selected for being the country advanced in cybercrime legislation. Hence it is a worth looking at their practice. This is to ensure that there will not be a direct legal transplant and the approach that should be introduced in Malaysia has to be in line with evolvement of new technology. The legislation in Japan will be look into since Japan has embrace IR4.0 successfully. The empirical method is used by evaluating the efficacy of the applicable legislation and discussing the concerns in the jurisdictions listed above. In summary, therefore, the methodology used in this study consists of the review of the material from which the data and information collected are derived from the books, documents, proceedings, statutes and conventions; and the data collected from the conduct of in-depth interviews with the relevant authorities to support the research findings.

Hence the findings were based on the research which used both qualitative and quantitative approaches. Data collected were categorized and later conclusions were made to the findings.

Conclusion

One of the challenges of embracing IR4.0 is the challenge of transforming the nation into a Digital Nation while protecting the Digital Sovereignty of Malaysia. To overcome these challenges, it is important that a new legislation be introduced to combat cybercrimes. The findings of this research will contribute to the Government in drafting a new legislation to combat cybercrime in the age of disruption.

An Extended Unified Theory of Acceptance Model to Explain the Adoption of Electronic Payment System in Malaysia: A Conceptual Framework.

Abstract

As the level of adoption toward electronic is becoming stringent, certain factors are considered influential toward such behavior. This paper attempts to propose the key factors that affect the adoption of electronic payment system in Malaysia and the mediating factor that influence of each one of the factors in Malaysia. It offers a comprehensive framework that broadens the existing UTAUT model with important constructs such as government incentive and the mediating role mobile device proficiency. An extensive systematic literature review of the literature relating to electronic payment adoption was conducted. Lastly, this study settled on a conceptual model after reviewing previous studies and recommend an empirical investigation for validation in future for researchers and practitioners. Discussions and conclusions including academic and practical implications are also presented.

Keywords: Electronic Wallet, Technology Adoption, User's Intention, Mobile Device Proficiency, Technology Skills.

Introduction

As the advancement in technology is critical, it aims at simplifying our daily activities. Given it current advancement at a larger scale such has encourage a growing participation among technology users. Given the continuous increase of technology users, fintech is also expanding. With Malaysia been regarded as a country with the potential to become a global fintech hub. The potential of fintech market in Malaysia, is relatively based on the largely unbanked and underbanked population, coupled with high rates of smartphone penetration, such offers huge potential for new fintech firms, so as to offer the much-needed services that are lacking by traditional financial institutions. The companies compete by offering convenience and ease of use of financial technology through the transaction process., the most popular fintech startup in Malaysia consist of, apppay, ghl systems berhad, billplz, boost, alipay, touch 'n go, swapit, hellogold.

With the present of Fintech Companies in Malaysia, the level of adoption is becoming stringent. According to Prensky, (2001) in Malaysia, most of its citizens are perceived to be digital natives. Yet, in spite of the nation's dependence on technology in terms of collecting information and communication, most of its citizens appears not to use or possess the required skills that is expected from digital natives (Bennett, Maton, & Kervin, 2008). However, it's evident without such skills it becomes extreme difficult for individuals to deal with the various forms of financial technology services so as to access and process information for their financial need. Therefore, such indicate that mobile proficiency in terms of electronic payment system is an important determinant on individual adoption. In terms of addressing the adoption and acceptance of the new technology, the basic challenge that frequently requires a fundamental change is the individual behavior, which is an overwhelming task to control or influence. Various forms of carrots and sticks

Cite this Article as: Tamsin ROSMAINI and Ishaq JAAFAR "An Extended Unified Theory of Acceptance Model to Explain the Adoption of Electronic Payment System in Malaysia: A Conceptual Framework" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

approach could be utilized to promote such change (Hillman, 1991). One of those campaigns involves the use of government incentives, which as of late has received substantial consideration with regard to electronic payment adoption in Malaysia. According to Meyer et al., (2008) calls have been made to the Government to assist with regard to bridging the chasm of technology adoption by offering incentives, and such has paved way for the Malaysian government to promote its cashless policy through e-Tunai Rakyat incentive which entitles Malaysians aged 18 and older with an annual salary of less than RM100, 000 a chance to benefit from the once in a life time RM30 incentive. It is however vital to examine the factors that affects individuals' intentions in terms of using e-payment system. Consequently, this paper attempts to propose a model that comprises of factors that lead to influencing individual intention with regard to the use e-payment system in Malaysia. The paper is structured in sections as follows: literature review, and proposed model; subsequently, future research; last section concludes our study.

Literature Review

This section, we provide a systemic literature review, especially related to the Electronic Payment (E-Payment), and the related theoretical background that underpins this research.

A systematic literature review on the term "electronic payment system adoption" was conducted from four databases Emerald Insight, Science Direct, Jstor, Springer and Taylor and Francis online. Based on the search by keyword "electronic payment system" used in the quality journals, the returned results in border prospective are shown in Figure 1 with enough theoretical empirical findings. A high-level review on the term "electronic payment system adoption" from the four databases returned 25563 documents out of which 19474 are academic journals and conference papers. To further refine this research on the keyword electronic payment, 210 academic journals and conference papers were peer-reviewed with time scale of last 35 years. The search duration was selected within the period from 1975 to 2020 with the more contemporary research on management fields and timeframe since Fishbein, M., & Ajzen's (1975) published "Belief, Attitude, Intention, and Behavior: An Introduction to Theory and Research" which was influential to focus relationship between the existing attitude and subjective norms against behavioral intention. Systematic literature review concluded that most of the relevant articles related to electronic payment technology adoption are available in Scopus indexed journals and conference papers.

Fig. 1: Search results of "Electronic payment system adoption" from different databases.

Electronic Payment (E-Payment)

Generally, the term electronic payment refers to online transactions that are conducted via the Internet, although there are many other forms of fintech (Mellon, 2015). Therefore electronic payment can be defined as the process of payment made without the use of paper instruments (Skan, J., Dickerson, J., & Masood, 2015). The electronic payment systems

consists of online credit card transaction, electronic wallet (e-wallet), electronic cash (e-cash), online stored value systems, digital accumulating balance systems, digital checking payment systems and wireless payment systems (Ryu, 2018). In today's business transactions individuals tend to use debit card as a form of payment. Currently, electronic wallet is most prevailing payment service system. By the use of e-wallets, consumers only need to enter the information once and can be used on any site to perform any form of financial transaction. Thus, the use of e-wallets will improve efficiency in transaction. Today, there are many companies that have developed and provide the e-wallets, including major companies such as grabpay and touch and go in Malaysia.

Internet transaction is a term-based transaction or payment system that involves making payment through the internet with the actual presence of the buyer and the seller. However, this requires both the buyer and the seller to connected to the internet with the same online payment platforms form of transaction is widely known as online payment and the most widely used method incorporate the use of debit card or credit card. According to BNM (2017), the country's central bank, online banking transactions totaled MYR463.7 billion ($118.74 billion) in 2016, a 31.7% increase from MYR352.1 billion ($107.59 billion) in 2015. Meanwhile, banking transactions carried out on mobile devices, which BNM counts as separate from online transactions, jumped by more than 60%, rising to MYR33.0 billion ($8.45 billion) last year from MYR20.6 billion ($6.29 billion) in 2015.

Internet banking provides a fast and convenient way of performing common banking transactions, such as transferring funds from the customers' savings account to their current account, or even to a third party's account. Through Internet banking, customers could also repay their loan and card outstanding amount, make payments to relevant parties, such as utility bills, assessment tax, and others. The essence of Internet banking service is to provide comfort to the registered internet banking users so as to perform their daily transaction with ease (Oliveira et al., 2016).

All internet banking transactions are secured to ensure that users' information could not be stolen (Chen, 2013). However such is due to the users precaution practice, which comprises of hiding their Login ID, password or PIN confidential; inspecting on whether that they have logged into the right website; logging-off at the end of each session and clearing the memory cache and history after logging out from the website; and protecting their personal computer from viruses and malicious programmes by installing an up-to-date hackers firewall and a reputable anti-virus program.

Electronic cash (e-cash) is a term used to describe the stored value and can be exchanged through the system created by the entity (not the government) without the use of paper documents or coins, but can be used in lieu of currency issued by the government. The basic concept of e-cash is a payment processing via the internet through a unique token that has been authenticated that represents money from the consumer to the merchant. Consumers will make a deposit a sum of money or a credit card, then the bank will give tokens (unique number encrypted) in some denominations of money to be used for shopping at the merchant site. Merchant will exchange the token back to the bank to get the actual money. Digicash is a pioneer company in the development of e-cash and there are some companies that still developing the idea of digital cash, such as GoldMoney, Bitcoin, etc.

Online stored value is the system that allows consumers to make online payments instantly to merchants and other individuals based on the value stored in the online account. One of the very popular online stored value systems is Paypal. The system called peer-to-peer (P2P), because the payment is made between one individual to another within the same entity. In Malaysia there are online stored value system which is quite popular in online payments including Vcash.

Mobile payment allows individual to make payments to their preferred merchants by through the means of mobile phones (Ivarsson, 2008). Bill payments and purchase of goods and services are among the cashless transactions that can be made. For an individual to benefit from such payment system, an account is required to be open with the selected choose of the mobile payment service providers. Non-bank mobile payment services are provided using an e-money account.

Theoretical Background

Various forms of research model have been developed so as to determine user's acceptance of technology information. Davis (1985), first introduced the technology acceptance model (TAM) to determine the behavior of computer usage. Such a model was incognizant of some factors such as perceived usefulness and perceived ease of use so as to predict

the behavioral attitude and user's intention of information technology use. Contrary to TAM, Venkatesh et al., 2008 developed a new model which is known as the unified theory of acceptance and use of technology or UTAUT was developed to identify users motivation in relation to the use of technology also known as UTAUT theory came into existence through the integration of theories such as theory of reasoned action (TRA), the technology acceptance model (TAM), motivational models (MM), theory of planned behavior (TPB), combined TAM and TPB (C-TAMTPB), the model of the PC utilization (MPCU), innovation diffusion theory (IDT) and social cognitive theory (SCT). The unified or UTAUT mainly has four constructs namely performance expectancy, effort expectancy, social influence and facilitating conditions that affects the intention and use of such technology.

- Performance expectancy indicated how certain individuals feels with regard to the use of technology which could help and provide them with certain advantages such as speed security and convenience of transacting

- Effort expectancy refers to the level of perceived ease of user at the point of using such technological service. It also refers to a system that is easy to understand and use without much skills need.

- Social influence referred to as the perceived influence of key individuals that encourage individuals to use such technology system. Such key individual is likely to family couples and organization.

- Facilitating conditions refers to individual's perception of the resources and support to use such technology

Based on the UTAUT performance expectancy effort expectancy and social influence affect the behavioral intention to use the technology, while the behavioral intention and facilitating conditions determines the use technology.

We designed a model that focuses on the factors that influences the individual intention toward the intention to use electronic payment system in Malaysia and its mediating influence. The proposed model was adopted based on the UTAUT model so as to investigate the customer's intention to use electronic payment system in Malaysia.

Much research has been developed and modified based on the UTAUT proposed model so as to get variables that correspond to the context of their research, in this proposed model, an external factor and a mediating variable where considered and added to the UTAUT model. The external factor and the mediating variable consist of government incentive and mobile device proficiency respectively. Both factors were considered to be critical factors in relation to this study which focuses on electronic payment system adoption in Malaysia.

To improve electronic payment usage, a reward system has been provided by the government, which aims at reducing the usage and dependency of physical cash. While this may curb the use of electronic payment system, its effect on users trust in the electronic payment system has been raised into concern. Electronic payment users may wonder whether these financial incentives will affect their containment and intention to use. In these circumstances, the relationship between individual intention to use electronic payment system and the role of government incentive can inadvertently be underpinned. Lee & Song (2010) suggests that that when a company engages in offering an apology, compensation or corrective action such may aide toward affecting individual behavior. Although limited studies exist in terms linking the relationship between government incentives, the literature can be helpful in hypothesizing the relationship linking the two variables. As has emerged previously, a reward system could be critical element in staring an online transaction. One may, therefore, expect that the reduction perceived risk felt by consumers in the presence of reward mechanism can inevitably increase intention to use and trust in such system. This study aimed at inquiring into the effect of the reward program as offered by the Malaysian government in relation to electronic payment usage, which is most widely applied as a sales promotion tool for the foodservice industry, on customer trust , commitment and loyalty (Kim et al., 2009).

Mediating Role of Mobile Device Proficiency

Mobile device (e.g. smartphone) proficiency is gradually becoming more important in terms of performing our day to day task. Therefore, inadequate proficiency can lead to preventing group of individuals from obtaining the benefits of technology utilization. With the growing prominence of technology users, a distinct set of abilities referred to as mobile device proficiency has emerged that allows individuals to effectively cope with the ubiquitous service such as mobile application (Helsper, Van Deursen, & Eynon, 2015). Notably, the lack of inadequate mobile device proficiency could

lead to preventing individuals from benefiting from the many advantages that is currently been offered by fintech which could be found in the form transportation, entertainment, health, and communication (Van Deursen, & van Dijk, 2015). Under the circumstances of smartphone decencies in the use of financial technology services, low proficient individuals will face challenges obtaining theses and a myriad of the other benefits offered by smart devices and become digitally excluded. In Malaysia , for instance, it evident that a significant number of individual appeared to not use or possess the necessary skills that is expected from digital native have despite Educators in Malaysia tend to assume that most students today are digital natives(Bennett, Maton & Kervin, 2008).

In describing the attributes of mobile information literacy, Clark, Coward, Rothschild, Reynal, & Richter (2017) first and foremost most people patriciate in online activities via mobile device. Secondly the current framework that exist are PC centric and developed for pc users. Thirdly the key differences concerning the device characteristics that are between the pc and the mobile device which consist of size portability information design and hardware features mean many information behaviors differences. Fourth the existing skills or proficiency in mobile devices or in smartphones could serve as a barrier toward adoption. Lastly, other business organization such as electronic payment service providers are begging to work in these areas, by making mobile skills training a priority.

The level of skills that is required to operate a smartphone is very different from that of personal computer or a feature phone. Such difference come in the form of affordability and the limitations of each technological device shapes how people interact with information. This is true for both physical interaction such as touching and pinching rather than clicking and information architecture and design-based interaction (Güler, Kılıç & Çavuş, 2014). Mobile specific tendencies include interacting through apps versus a browser, coming online via handful of walled garden applications, information consumption rather than production, conducting shorter and location focused searches (and viewing fewer result), and a focus on social activities over more serious (Kim, Tavitiyaman, & Kim, 2009).

It's proven that the lack of the required skills or the proficiency in a technological device could serve as a significant barrier toward internet adoption and uses, which ultimately leads to further digital divides (Van Biljon, Van der Merwe, & Van Heerden, 2014). Based on the relationship between performance expectancy and mobile proficiency denotes whether users are able to notice improvements in their skills when adopting the technology (Khalifa, & Shen, 2008; Pituch & Lee, 2006). Effort expectancy significantly influences mobile device proficiency, and that users' skills is strengthened when the system is easy to use, and found to be useful (Chang, & Tung, 2008; Lee & Lehto, 2013). Hence, zuagbe et al., (2019) describe perceived ease of use as a significant determinant toward e-Skills in library technology acceptance intention. In relation to government incentive, individual tend to perceive reward as a motivating mechanism which allows individual to put more effort in an activity. Reward systems usually reflect the values and could attract or repel prospective talents and shape individuals behavior (Edvardsson, 2008; Garbarino, 1975; Rynes, 1987). Steel et al., (2016) suggest that punishment impacts skilled behavior more than reward in a complex, task dependent fashion. When users use Facebook as an equipment for educational purpose by exploring the site using English language, great opportunities arise for users to learn English language with millions of users at the same time (Initiative, 2006). The interaction with friends on Facebook drives both local and global research collaboration, and improves language proficiency (Rowlands et al., 2011). Furthermore, Kafai et al., 1998) in their study of ''game design as an interactive learning environment for fostering students' and teachers' mathematical inquiry'' found that conceptual design tools enriched the instructional design process of both students and teachers. In relation to the present setting, facilitating conditions refer to the belief that with necessary resources, capability, and a sense of control, the use of roleplay games in class would improve students' Japanese language proficiency.

Therefore, given the signifies of mobile devices for electronic payment users, without the appropriate mobile and digital skills, there are population that are bound to be left behind, even if they are technically connected to the internet. Hence mobile device proficiency can be regarded as a mediating variable as evident the figure below.

Fig. 2: Conceptual Framework

Conclusion

The aim of this conceptual paper is to systematically review the current literature on electronic payment technology adoption and investigating associated theories and models, how the factors of electronic payment system is contributing to the adoption of in the financial technology industry. Prior findings are reexamined systematically so as to uncover the factors affecting electronic payment adoption from both qualitative and quantitative researches. Two factors government incentive and mobile device proficiency are the piece of proposed conceptual framework having significant relationships with electronic payment system adoption. Government incentive was considered as an independent variable to electronic payment service adoption as dependent variable and mobile device proficiency is used as mediator between the relationship of effort expectancy, performance expectancy, social influence, facilitating conditions and government incentive with electronic payment system adoption as evident in Figure 2. The conceptual framework is suggested on the grounds of exiting literature, theory and models, nevertheless its empirical examination is left for future researchers and practitioners.

Future Research

The six-hypothesis built on the proposed conceptual framework will facilitate toward contributing in the empirical validation of UTAUT model. We will motivate a study that focuses on proving the empirical result of the antecedents of technology adoption in context of electronic payment system and other self-serving technologies. However, more empirical research is required to further examine the impact of perceived waiting time, transactional cost, cultural, and perceived benefit on technology adoption in both electronic payment and self-service technology settings so as to further validate the already implemented technology acceptance models and related theories.

Abstract

This study aimed to know the tastes, preferences and consumption and buying habits of bread in the Bragança region. A quantitative and cross-sectional study was developed based on a questionnaire applied online to 215 consumers who buy food products in the Municipality of Bragança. Most consumers were Portuguese (67%), female (61.9%), lived in urban areas (85.6%) and like bread (99.1%). Wheat bread (72.1%) and whole grain bread (64.7%) are the most consumed, despite not being bread from the Bragança region (47.9%). The three types of bread in the Bragança region that are best known and also the most consumed were Nogueira, Rebordainhos and Argozelo bread. Most consumers eat bread at least once a day (62.3%), 1 to 2 slices/small breads a day (76.7%), usually at breakfast (67.9%). The preferred type of accompaniment are vegetable fats (66.5%) and dairy (65.6%). The most valued attributes were the freshness (92.2%), the fresh bread smell (87.6%), the fluffy texture (80.8%), the crispy crust (76.1%), the price (56.2%) and the long lasting (55.2%). Most consumers buy bread at the supermarket (55.2%). The quality of the bread (96.9%) and the hygiene and cleaning of the space (93.7%) are the factors most valued by the consumers at the time of the purchase. Taking into account the nationality, differences were identified in the type of bread consumed, the time of consumption and the chosen accompaniment. In fact, foreigners prefer to consume whole grain bread and special bread with cheese or cottage cheese at any time of the day. Portuguese consumers prefer rye or brown bread with jam or honey.

Keywords: Bread, Consumption habits, Consumer, Market research.

Introduction

Food choices depend on consumers' beliefs and attitudes (Biloukha & Utermohlen, 2000; Roux, Le Couedic, Durand-Gasselin & Luquet, 2000). Increasingly, attentive and informed consumers use several criteria to assess whether or not a food product meets their expectations and requirements. The main characteristics of a product are related to the price, the brand, the quality seal, the country of origin, the appearance of the store and information about the production and composition of food (Gellynck, Kühne, Bockstaeleb, Walle & Dewettinck, 2009).

Nowadays, there is a growing consumer concern about health (Küster-Boluda & Vidal-Capilla, 2017). Consumers realize that a careful diet can provide a better quality of life, preventing diseases (Borges, Pirosi, De Paula, Ramos & Chaves, 2011; Küster-Boluda & Vidal-Capilla, 2017). The traditional Mediterranean Diet, Intangible Cultural Heritage of Humanity since 2010, is currently considered an excellent model of a prudent and healthy diet (Azcona, 2016), given the existing scientific evidence on its protective role in the prevention of various diseases, namely, chronic diseases, cardiovascular diseases, degenerative diseases, cancerous diseases, among others (Naska & Trichopoulou, 2014). Cereals, mainly in the form of bread, in addition to vegetables, are a basic product of the Mediterranean diet (Oldways, 2009; Gil, Ortega & Maldonado, 2011; de Lorgeril, 2013; Trichopoulou, Martínez-González, Tong, Forouhi, Khandelwal, Prabhakaran, Mozaffarian & de Lorgeril, 2014). Bread is a food considered to be appetizing, healthy, highly nutritious and low price (Dewettinck, Van Bockstaele, Kühne, Van de Walle, Courtens & Gellynck, 2008; Cauvain & Young, 2009).

Man learned to make bread more than 4000 years ago, a food that has been part of the diet for many centuries (Dewettinck, Van Bockstaele, Kühne, Van de Walle, Courtens & Gellynck, 2008; Cauvain & Young, 2009) registering, since it was introduced in the diet, high frequencies of consumption and in large quantities (Montoya, 2013). Reasons why consumers perceive bread as a basic and traditional food (Gellynck, Kühne, Bockstaeleb, Walle & Dewettinck, 2009).

Bearing in mind that consumers have the habit of accompanying their meals with some type of bread or making it a basic food in their meals (Dewettinck, Van Bockstaele, Kühne, Van de Walle, Courtens & Gellynck, 2008; Cauvain & Young, 2009; Jeżewska-Zychowicz, 2016), bread has long been in a position of global importance in international nutrition (Cauvain, 2004).

Although the type of cereal and/or the ingredients may vary (Dewettinck, Van Bockstaele, Kühne, Van de Walle, Courtens & Gellynck, 2008; Cauvain & Young, 2009), as well as production techniques (Martin, 2004), the basic ingredients of bread are, in particular, cereal flour, water, yeast or other fermenting agent and salt (Martin, 2004; Barbarisi, De Vito, Pellicano, Boscaino, Balsamo, Laurino, Sorrentino & Volpe, 2019). Water and flour are the main ingredients of a bread recipe and affect texture and crumb. Salt, as an ingredient, performs various sensory and technological functions. Sensory function is related to taste, while technological functions are related to changes in the properties of the dough during baking and fermentation. The addition of salt affects the volume or height of the dough. Reducing the level of salt can have an adverse effect on consumers' perception of the bread's full flavor (Jeżewska-Zychowicz, 2016; Barbarisi, De Vito, Pellicano, Boscaino, Balsamo, Laurino, Sorrentino & Volpe, 2019).

Optional ingredients can be added to improve processing, or to produce special breads, which generally have greater nutritional value (Dewettinck, Van Bockstaele, Kühne, Van de Walle, Courtens, Gellynck, 2008; Cauvain & Young, 2009). For example, bread prepared with sea water has a lower percentage of salt and a higher content of macro and micronutrients (Barbarisi, De Vito, Pellicano, Boscaino, Balsamo, Laurino, Sorrentino & Volpe, 2019). An alternative for the enrichment of bakery products is the incorporation of fibers, amino acids and bioactive compounds from whole flours or whole grains of cereals. Cereal brans are rich in phytochemicals, such as phenolic compounds, flavonoids, glucans and pigments, causing influence on the physicochemical and nutritional aspects of breads. These compounds are known to have health benefits in view of the protective effect in relation to cardiovascular diseases, colon cancer, obesity and gastrointestinal diseases. Fiber-rich foods, in turn, reduce forms of cancer, coronary heart disease and regulate blood glucose levels (Miranda-Ramos, Sanz-Ponce & Haros, 2019; Pauline, Roger, Nina, Arielle, Eugene & Robert, 2020). Other ingredients can be changed to improve the diet without modifying eating habits, being certain that the changes that occur in the composition of the bread will have a significant impact on the intake of protective and risk factors, such as sodium intake (Bassett, Gimenez, Pinho & Sammán, 2013; Antúnez, Alcaire, Giménez & Ares, 2017). The addition of new optional ingredients to meet the new demands and needs of consumers makes innovation in traditional products in the bakery industry a successful reality (Dettori, Floris & Dessì, 2020).

As already mentioned, bread is considered essential in a balanced diet (Gellynck et al., 2009; Nascimento, Santiago, Santos, Mesquita-Bastos, Silva & Calhau, 2019; Pauline et al., 2020), due to nutritional quality of its fibers, grains, vitamins, a wide range of important nutritional components that provide a positive effect on human health (Maihara, Silva, Baldini, MigueL & Fávaro, 2006; Gellynck et al., 2009). Bread provides the daily diet with a moderate amount of energy and significant amounts of different macro and micronutrients. It stands out in its content, carbohydrates, proteins, fibers, iron, zinc and vitamin B1, although it also provides significant amounts of magnesium, potassium, vitamin B3, vitamin B2 and folic acid (Montoya, 2013; Nascimento et al, 2019). According to Kourkouta, Koukourikos, Iliadis, Ouzounakis, Monios and Tsaloglidou (2017), bread, when consumed in balanced amounts, can provide the body

with many essential nutrients for its proper functioning, with the average consumption being equivalent to 2 to 3 slices of bread a day (O'Connor, 2012).

So, this research aimed to learn about the tastes, preferences and habits of consumption and purchase of bread in the Bragança region and to verify whether the tastes, preferences and consumption habits are associated with the consumer's nationality.

Methodology

In order to achieve these objectives, a quantitative and cross-sectional research was developed. In this context, bibliographic material on the subject under study was consulted in order to construct a questionnaire using Google Docs. The questions, in addition to being based on similar research applied in several countries, were previously discussed with two experts in the field of Social Sciences. Given the large number of people surveyed and the subsequent treatment of information, closed-type questions were valued in this research. Subsequently, a pre-test was carried out, in an environment and context similar to the real survey (Prodanov & Freitas, 2013), to ensure that the questionnaire was well written and organized, as to the clarity and precision of the terms, as well as the form, order of questions and introduction (Gil, 2008). Data collection through the pre-test was carried out from 16 to 23 June and 26 responses were obtained. Taking into account the results of the pre-test, and since there was no suggestion of alteration to the structure, the responses of the pre-test were included in the final sample of the study.

The data collection took place from June to August 2020. The sample was obtained through a non-probabilistic sampling, like snowball, since not all elements of the universe had the same known probability of becoming part of the sample (Marconi & Lakatos, 2002). On the other hand, the individuals to whom the questionnaire was sent had the possibility to invite new participants from their network of friends and acquaintances, as long as they usually made their purchases of food products in the municipality of Bragança.

The questionnaire was structured in three sections. The first section included questions of sociodemographic nature, namely, nationality, gender, age, education, professional occupation, size of the household, number of dependents in the household. Also, the questionnaire included questions related to dietary restrictions and knowledge about different types of bread from Bragança region. The second part contained questions associated with consumer preferences, namely, the type of bread, the most important organoleptic characteristics of the bread, the frequency of bread consumption and the type of accompaniment used in the consumption of bread. Finally, the third part included questions related to the consumer's buying habits, namely, frequency of purchase, place of purchase and factors most valued by the consumer when buying bread.

The software used to edit and process the data was IBM SPSS version 26.0 (Statistical Package for Social Sciences). Descriptive statistics were calculated, namely, the calculation of absolute and relative frequencies for variables of qualitative nature (nominal and ordinal variables) and measures of central tendency and dispersion for variables of quantitative nature (Pestana & Gageiro, 2014; Maroco, 2018). Pearson's chi-square test was used, at a significance level (α) of 5%, to compare proportions. This test allows testing the null hypothesis, H_0: *Tastes, preferences, consumption and buying habits are not associated with the respondent's nationality*, against the alternative hypothesis, H_1: *Tastes, preferences, consumption and buying habits are associated with respondents' nationality*. According to Maroco (2018), the rule of statistical decision is to reject the null hypothesis when p-value (probability of significance) $\leq \alpha$.

When invited to participate in this study, respondents/consumers were informed about the scope and purpose of this research The anonymity as well as the confidentiality of the data collected were guaranteed. In addition, a legal opinion was requested from the Data Protection Commission of the Polytechnic Institute of Bragança, on the content of the questionnaire. After meeting the conditions relating to data protection, authorization was requested, for the filling and dissemination of the questionnaire among employees, to the heads of two organizations with high representativeness, in terms of employability, in the region of Bragança, namely, the City Council of Bragança and the Polytechnic Institute of Bragança.

Results

The results presented in Table 1 show that, of the total number of participants (n = 215), the majority had Portuguese nationality (67%) and were female (61.9%). The average age of consumers was 34.69 years old (standard deviation =

13.677), the mode was 23 years and the median was 29 years. The age of the respondents was between 18 and 77 years old, with the majority (58.6%) with an age between 18 and 35 years old. Most respondents had higher education (85.6%), were not active (51.2%) and lived in urban areas (85.6%). In addition, the families in the municipality of Bragança lived in households with three or less people (60.0%) and no minor dependents (75.3%).

Table 1: sociodemographic characteristics of the respondent (n = 215)

Household with minor dependents	No	162	75.3
	Yes	53	24.7

Figure 1 shows the distribution of foreign respondents by nationality. As can be seen, the overwhelming majority were Brazilian nationals (83.1%).

Fig. 1: Nationality of foreign respondents (n = 71)

Of all respondents, the majority did not have any food restrictions (60.0%) (Figure 2), however, a significant percentage had at least one food restriction (40.0%).

Fig. 2: respondents' food restrictions (n = 215)

Of the respondents who were on a special diet (n = 86), most tried to avoid or were on a diet low in salt (60.5%) and fat (53.5%) (Figure 3).

Fig. 3: respondents with dietary restrictions (n = 86)

Of the total consumers surveyed, who made their purchases of food in the region of Bragança, a significant percentage assumed not to know any type of regional bread (30.7%). However, the majority knew at least one type of bread (69.3%) (Figure 4).

Fig. 4: knowledge of the existence of regional bread types (n = 215)

As shown in Figure 5, of the various types of regional bread, the three best known were in descending order, Argozelo bread (77.2%), Nogueira bread (67.8%) and França bread (50.5%). The lesser known breads (12.8%), with less than 20.0% of the answers, were in decreasing order, Carragosa bread (6.7%), Gimonde bread (4.7%), Campo Redondo bread (0.7%) and Baçal bread (0.7%).

Fig. 5: type of Regional Bread that the respondent knows (n = 149)

Taking into account the results presented in Table 2, the majority of consumers like bread (99.1%). They recognize some importance in nutritional terms, reasons why bread is part of their diet (95.8%). Most consumers eat bread at least once a day (62.3%), usually at breakfast (67.9%) and at the middle of the afternoon (54%). The preferred type of accompaniment are vegetable fats (66.5%), such as margarine and olive oil and dairy products (65.6%), namely cheese, cottage cheese, among others.

Table 2: tastes, preferences and bread consumption habits (n = 215)

Variable	Group	Frequencies	
		Absolute (n)	Relative (%)
Do you like bread?	Yes	213	99.1
	No	2	0.9
Do you include bread in the diet?	Yes	206	95.8
	No	8	3.7
	Missing	1	0.5
Importance of bread in the diet	None, it's useless	26	12.1
	Some, it's very energetic	125	58.1
	A lot, it is essential	64	29.8
Consumption frequency	Rarely	8	37
	Once a week	13	6.0
	2 to 3 times a week	60	27.9
	≥ 1 time a day	134	62.3
Daily amount consumed	None	11	5.1
	1 to 2 slices/breads	165	76.7
	3 to 4 slices/breads	31	14.4
	> 4 slices/breads	8	3.7
Time of consumption	Breakfast	146	67.9

	Dairy	141	65.6
	Jams	49	22.8
	Meat	95	44.2
	Vegetable fats	143	66.5
Are you aware of the composition of the bread?	Yes	172	80.0
	No	43	20.0

Of the respondents who claim to know the nutritional composition of bread (n = 172), most identify that, depending on the type of flour used, the bread contains starch (87.8%). However, only a minority consider that bread contains glucose (39.0%), proteins (19.2%) and lipids (11.0%). These results show that the level of knowledge in relation to the nutritional content of bread is not sufficient, since even those who claim to know the composition of the bread were unable to identify the compounds present in the bread in greater quantity (Figure 6).

Fig. 6: compounds present in greater quantity in bread (n = 172)

Figure 7 shows that the majority of consumers in the Bragança region prefer wheat bread (72.5%) and whole grain bread (64.5%).

Fig. 7: types of bread (n = 215)

The least consumed breads are made from flours alternative to the traditional ones, namely chestnut bread (0.5%), soy bread (0.5%) and organic bread (2.8%), products that compared to the relatively recent ones on the market (Figure 7).

According to the results shown in Table 3, only 10.7% of respondents are not responsible for the purchase of bread in their household. Among those responsible for the purchase of bread (n = 192), regional bread is the one that is most frequently purchased (47.9%), although it is not always bread from the Bragança region. Regarding the frequency of purchase, most consumers buy bread 2 to 3 times a week (29.7%) or once a week (28.6%) and are indifferent to whether or not the bread is packaged (45.3%) or ends up buying unpackaged bread (35.4%).

Table 3: bread buying habits in the Bragança region

Variable	Group	Frequencies	
		Absolute (n)	Relative (%)
Are you responsible for buying bread? (n = 215)	Yes	119	55.3
	Sometimes	73	34
	No	23	10.7
Most frequent bread buying (n = 192)	Industrial	70	36.5
	Regional	92	47.9
	Homemade	30	15.6
Buy frequency (n = 192)	< 1 once a month	7	3.6
	1 once a month	5	2.6
	2 to 3 times a month	29	15.1
	1 once a week	55	28.6
	2 to 3 times a week	57	29.7
	Every day	39	20.3
Package (n = 192)	Indifferent	87	45.3
	Packed	37	19.3
	Unpacked	68	35.4

The preferred place to buy bread is the supermarket (55.2%) (Figure 8), and for more than 90.0% of consumers, the quality of the products (96.6%) and the hygiene and cleaning conditions space (93.7%) were the most important factors in choosing the place to buy bread (Figure 9).

Fig. 8: place of bread purchase (n = 192)

Fig. 9: decisive factors in choosing the place to buy bread (n = 192)

In Figure 10, it can be seen that the three types of regional bread from Bragança region that were most often purchased or even every day were Nogueira bread (15.6%), Rebordainhos bread (14.6%) and Argozelo bread (11.0%). Interestingly, they are also among the four types of bread in the Bragança region best known by respondents.

Fig. 10: buying frequency of buying Bragança regional bread (n = 192)

The attributes of bread most valued by most consumers were, the freshness of the bread (92.2%), the smell of fresh bread (87.6%), the fluffy texture of the bread (80.8%), the crispy crust of the bread (76.1%), the price (56.2%) and the long lasting of the bread (55.2%) (Figure 11).

Fig. 11: attributes valued when choosing bread (n = 192)

For the verification of the null hypothesis, H_0: *Tastes, preferences, consumption habits are not associated with the respondent's nationality*, against the alternative hypothesis, H_1: *Tastes, preferences, consumption and shopping habits are associated with the respondent's nationality*, was used the Chi-Square test. Whenever the conditions for the use of this test were not met, it was used the Chi-square test with Monte Carlo simulation. The results are shown in Table 4.

Table 4: tastes, preferences and bread consumption habits according to nationality (n = 215)

* There are statistically significant differences in proportions taking into account the nationality of the respondents.

Taking into account the nationality of consumers, differences in proportions were identified, in the type of bread consumed, at the time of consumption and in the chosen accompaniment (p-value < 0.05). Foreigners consume whole grain bread and special bread at any time of the day, preferring dairy products as an accompaniment, namely cheese and cottage cheese. Portuguese consumers, on the other hand, choose rye bread or brown bread to a greater extent, preferring jams as an accompaniment, namely, marmalade, jam, honey, pumpkin jam, among others (Table 4).

Conclusion

Initially, it was planned, for this research, the application of the questionnaire through a structured interview, addressing individuals in public places in the municipality of Bragança, such as squares, fairs and events. However, given the context experienced by the Covid-19 pandemic, this process proved unfeasible. Therefore, it was decided to apply the questionnaire online, at the risk of not obtaining answers from consumers of all ages and with various education levels and/or training. In fact, the application of the online questionnaire made it impossible or limited access for consumers of

older ages and for consumers who had neither the means nor the computer skills necessary to participate in this research. On the other hand, the development of cross-sectional population studies, despite providing valuable information on eating habits, since they are studies that relate to a single moment, do not allow to follow the habits of consumers who change with the evolution of time and, especially with the appearance of new substitute products on the market.

Bread consumed in balanced amounts not only does not contribute to obesity, it also provides the body with many nutrients essential for its proper functioning (Kourkouta et al., 2017). So, this research aimed to learn about the tastes, preferences and habits of consumption and purchase of bread in the Bragança region and to verify whether the tastes, preferences and consumption habits are associated with the consumer's nationality. The group of consumers was constituted by a majority of Portuguese, female individuals that lived in urban areas and liked to eat wheat and whole grain bread purchased at the supermarket despite not being bread from the Bragança region.

The three types of bread in the Bragança region that are best known and also the most consumed were Nogueira, Rebordainhos and Argozelo bread. Most consumers eat bread at least once a day, 1 to 2 slices/small breads a day, usually at breakfast. The preferred type of accompaniment are vegetable fats and dairy. The most valued attributes were the freshness, the fresh bread smell, the fluffy texture, the crispy crust, the most affordable price and the long lasting of the bread.

As previously mentioned, most consumers buy bread at the supermarket because they value the most factors such quality of the bread and the hygiene and cleaning of the space. Taking into account the nationality, differences were identified in the type of bread consumed, the time of consumption and the chosen accompaniment. In fact, foreigners prefer to consume whole grain bread and special bread with cheese or cottage cheese at any time of the day. Portuguese consumers prefer rye or brown bread with jam or honey.

The results of this research allowed to verify that consumers who shop in the municipality of Bragança do not know and, consequently, do not consume or rarely consume regional bread. As has been shown, there are many varieties of regional bread, normally produced in villages located in the municipality based on tradition, which is why Portuguese consumers prefer to eat rye or brown bread. So, there is a potential for the development of the regional bread market. The market strategy should be based on the creation of a PDO (Protected Designation of Origin) or other seal of quality. This strategy, however, involves a previous work of association of regional bread producers around a common objective, namely, the valorization of regional production.

Abstract

The Covid-19 pandemic has changed almost every aspect in life, including in business. At the beginning of covid-19 pandemic, many companies issued special communications from their Chief Executive Officers (CEOs) to give assurance to their customers on their commitment and their ability to continue fulfilling the needs and wants of their customers. As the pandemic became more serious each day, companies in Indonesia redirected their Corporate Social Responsibility (CSR) efforts to try to alleviate the weight of the Covid-19 pandemic for society, especially for their customers. This paper aims to investigate how customers perceived the CSR Covid-19 messages from companies, and how their perception of the CSR motives behind these messages affects brand equity, brand trust and brand advocacy. Research questionnaires were distributed in areas with the highest number of Covid-19 cases in Indonesia (Jakarta, East Java and West Java) with the minimum target of 300 respondents. A Structural Equation Modeling (SEM) was conducted to discover the relationship between the aforementioned variables in the research model.

Keywords: Corporate Social Responsibility, CSR Motives, Trust, Brand Equity.

Introduction

As the global competition increases, the pressure to find ways of participating in sustainable development and meeting ethical expectations are also increasing. Companies need to find innovative ways to engage primary stakeholders. Maignan and Ferrell (2004), described a framework and some propositions that explain how Corporate Social Responsibility (CSR) interacts with marketing through the understanding of the Stakeholder Theory perspectives (how organization activities have impacts on stakeholders). Stakeholders showed concerns not only for issues that affected their own welfare but also for issues that did not affect them directly. In accordance with marketing definition (AMA, 2007), marketing has diverse stakeholders that should be satisfied in their need, such as customer and society. CSR activities provide marketers with the construction of perceived identities and reputations that are identification-worthy (Balmer, et.al., 2011).

Companies have pursued a wide variety of CSR initiatives that showed some cross-cultural variations in the CSR platforms – or orientations – that companies adopted across industries and in different countries. By opting for a

particular CSR strategy, companies presumably aim to address a specific stakeholder's concerns and meet the stakeholder's expectations (Stokes, et.al, 2013). CSR is the idea that reflects the social imperatives and the social consequences of business success. Concerning the effectiveness of CSR, company must take the characteristics of the CSR activities' targets into account.

In emerging markets, organizations face challenges in adoption and managing CSR strategies that are in line with company brand values (Karaosmanoglu, et.al., 2016). Consumers in emerging markets are increasingly aware of and concern with CSR activities conducted by the company. The perceived CSR motivations will have an impact on consumer support for these activities (Ellen, et.al., 2006). CSR motives can be categorized in two types: social (public-serving), and economy (firm-serving) (Kim & Kim, 2014).

At the beginning of covid-19 pandemic, many companies issued special communications from their Chief Executive Officers (CEOs) to give assurance to their customers on their commitment and their ability to continue fulfilling the needs and wants of their customers. As the pandemic became more serious each day, companies in Indonesia redirected their Corporate Social Responsibility (CSR) efforts to try to alleviate the weight of the Covid-19 pandemic for society, especially for their customers. This paper aims to investigate how customers perceived the CSR Covid-19 messages from companies, and how their perception of the CSR motives behind these messages affects brand equity, brand trust and brand advocacy.

Literature Review

CSR Motivation: Firm vs Public Serving Motive

A company, as an entity, is perceived by society as an institution with profit as its main goal. Companies are often seen as willing to do anything, in both positive and negative manners, in order to maximize their profits. As a results, when companies conducted CSR activities, which actually a very positive action, customers are often suspicious of the actual reasons behind this positive gesture. This leads to the attribution of motives behind the CSR activities.

In general, there are two types of CSR motives, namely firm-serving motives (to benefit the company) and public-serving motives (to actually help the communities or to support an issue). Firm-serving motives are the motives that drive a company to conduct CSR activities in order to gain benefits for the company itself, for example, to gain more profit, more sales, or to build a positive image of the company. If a CSR activities is perceived as giving more benefit to the company instead of to the society, customers might attribute this type of CSR motive to the company. In general, customers might accept a strategic motive but they will evaluate negatively a selfish motive that exploits the CSR activity (Ellen, et.al., 2006).

Public-serving motives are the motives behind CSR activities that is based on the actual desire to sincerely help society or to support an important issue for the company. Customers might attribute this motive to a company's CSR activities if customers perceived the CSR activities as giving more benefit to society or to the environment compared to the profit gained by the company. Customers will give more positive evaluation to a CSR activity perceived as a value-driven activity and that the company is acting sincerely to help the society and/or the environment (Ellen, et.al., 2006).

Cause Related Marketing

Vadarajan & Menon (1988) in La Ferle, et.al. (2013) describe cause-related marketing (CRM) as "the process of formulating and implementing marketing activities that are characterized by an offer from the firm to contribute a specified amount to a designated cause when customers engage in revenue providing exchanges and satisfy organizational and individual objectives." Likewise Cui et al. (2003) in La Ferle, et.al. (2013) refer to CRM as "a general alliance between businesses and non-profit causes that provide resources and funding to address social issues and business marketing objectives."

A corporation can have multiple options such as cause-related marketing (CRM) and corporate philanthropy. Cause-related marketing (CRM) directly links sales with amount of donation, by promising to donate a certain amount of money to a nonprofit organization or social cause after consumers purchase products or services (Varadarajan & Menon, 1988 in Chen & Huang, 2016). Corporate philanthropy is another type of CSR campaign. A company can make a monetary or in-kind (people or equipment) contribution to a worthy cause simply because the firm wishes to be a good corporate citizen, without any expectation of a benefit tied to that effort (Lii and Lee, 2012, Shaw and Post, 1993 in Chen & Huang, 2016).

Corporate Social Marketing

Corporate social marketing (CSM) refers to "a means whereby a corporation supports the development and/or implementation of a behavior change campaign intended to improve public health, safety, the environment, or community well-being" (Kotler & Lee, 2005, p. 114). This intended influence on behavior distinguishes CSM from other corporate social initiatives, such as corporate philanthropy and cause-related marketing, whose main aim is to raise goodwill, money, and/or recognition of a cause, but not to influence or change one's behavior (Bloom et al., 1997, Kotler and Lee, 2005 in Inoue & Kent, 2012).

The major goal of corporate social marketing (CSM) initiatives is to persuade consumers to perform desired pro social behavior (Bloom et al., 1997; Kotler and Lee, 2005 in Inoue & Kent, 2014). This intended influence on behavior change distinguishes CSM from other types of corporate social responsibility (CSR) activities implemented by firms, such as corporate philanthropy and cause-related marketing, whose main aim is to raise goodwill, money, and recognition of a cause, but not to influence or change one's behavior (Bloom et al., 1997; Kotler and Lee, 2005 in Inoue & Kent, 2014).

Social Justice Value

Social justice value is defined as a consumer orientation towards poverty and the efforts to improve social justice. This orientation affects consumers' reaction to the practice of corporate ethics. The consumers' social orientation moderates the effectiveness of CSR communications and suggests that CSR activities will be more effective for consumers with high social concerns, since they are the ones who will be more motivated to pay attention to the CSR communications of a company (Du, et.al., 2010).

Brand Equity

Brand equity is a vital concept in marketing, management and branding studies (Baalbaki & Guzmán, 2016 in Marques, et.al., 2020) since higher levels of brand equity are often translated into higher cash flows and increased competitiveness (Pepe et al., 2011, Yoo et al., 2000 in Marques, et.al., 2020).

Two focal brand equity perspectives have been recognized in the literature –financial-based and consumer-based brand equity (Davcik et al., 2015 in Marques, et.al., 2020). Financial-based brand equity focuses on studying and measuring financial value as the measure of brand success (Davcik et al., 2015, Veloutsou and Guzman, 2017 in Marques, et.al., 2020). In contrast, the consumer-based brand equity paradigm represents the extent to which a consumer response is affected by the brand (Keller, 1993 in Marques, et.al., 2020).

Brand equity refers to the value inherent in a well-known brand name. Brand equity as intangible brand assets is associated with brand-name awareness, brand beliefs, brand loyalty, perceived brand quality, and favorable brand symbolisms as well as associations that provide competitive advantage and future earnings (Keller and Lehmann, 2006, Sun et al., 2016, Sun et al., 2018 in Sun, et.al., 2019).

Trust

Trust relates to a trustee's willingness to engage in a vulnerable relationship by expecting positive behavior and intentions from the trustor (Melewar, Foroudi, Gupta, Kitchen, & Foroudi, 2017 in Ozdemir, et.al., 2020). Personal trust is grounded in personal relationships, such as with national brands, as opposed to system trust, which is embedded in institutions (Nuttavuthisit & Thogeersen, 2017 in Ozdemir, et.al., 2020).

Brand trust is achieved through mutual experiences and activities and is a necessary concept for a successful relationship between a company and its customers (Anderson & Narus, 1990 in Chae, et.al., 2020). Brand trust increases the likelihood that consumers will be able to choose their products (Erdem & Swait, 2004 in Chae, et.al., 2020). Even if there is a lack of rationality in the transaction relationship, maintaining and trading continuously creates long-term friendly relations between suppliers and consumers (Kim, 2005 in Chae, et.al., 2020).

Brand Advocacy

Advocacy is a form of customer loyalty that goes beyond buying a certain product or a certain brand repetitively, but also related to the desire to consume a new product offered by the company, favorable Word-of -Mouth (WOM), or even ignoring negative information about the company (Du, et.al., 2007). Customer loyalty is a competitive advantage in a more competitive business environment. Loss of customers will affects the company performance including its financial performance.

Research Methods, Model and Hypotheses

This research used primary data collected through online cross-sectional survey. Research survey is conducted in areas where the Covid-19 cases are the highest, namely: Jakarta, East Java, and West Java. The minimum number of target respondents is 300 respondents, chosen with purposive sampling technique.

Data collected from research survey is processed with Structural Equation Modeling (SEM), in order to examine the relationships between research variables. The research variables are Perceptions of CSR Motives (independent variable), Social Justice (moderator), Brand Equity, Brand Trust and Brand Advocacy (dependent variable), with all indicators measured with a 6-point Likert Scale. There are 6 research hypotheses, as follows:

H1 : Perceptions of CSR Motives will be different according to the type of CSR activities (CRM/Philanthropy vs CSM).
H2 : CSR Motives affect brand trust
H3: CSR Motives affect Brand Equity
H4 : Trust positively influence Brand Equity
H5 : Trust positively influence Brand Advocacy
H6 : Brand Equity positively influence Brand Advocacy

Results

Pretest was conducted in Jakarta and surrounding areas (Jakarta, Bogor, Depok, Tangerang and Bekasi or more commonly known as Jabodetabek). The pretest collected data from 35 respondents, and then the data was processed with SPSS software, to test the reliability and validity of the research variables.The pretest questionnaire used Telkomsel's philanthropy activities as an example, and the respondents must be aged 17 years old or older and have been a subscriber of Telkomsel services for at least 1 year.

The result for pretest's reliability and validity tests, it can be concluded that all variables are reliable, except for one dimension from CSR Motives (Egotistic driven). The researchers have decided to keep the dimension (Egotistic driven) in the main survey questionnaire, since there were only 35 respondents in the pretest and it is likely that the reliability score will improve when the number of respondents is a lot higher.

From validity test, it can be concluded that almost all indicators are valid, except for CM13. The researchers have decided to keep the indicator since the number of respondents is only 35, and it is likely that the validity score for CM13 will be higher with more respondents. Based on the pretest results, quesionnaires for main survey are then prepared.

For the main survey, the research questionnaires were distributed in three areas where the Covid-19 cases are the highest in numbers, namely Jakarta, East Java and West Java. The number of respondents collected were 304. Questionnaires were distributed online. The respondents must be 17 years old or older, residents of Indonesia and have subscribed for at least 1 year to the internet and communication services of Telkomsel, the state-owned and leading company of telecommunication industry in Indonesia. Telkomsel was chosen because of the philanthropic CSR activities they performed during covid-19 pandemics, and also because the service of Telkomsel is available in all-over Indonesia. Before filling in the questionnaires, respondents were exposed to a news article describing CSR philanthropic activities of Telkomsel during the covid-19 pandemic. The results will be discussed below.

For respondents profile, 45% (136 respondents) were male and 55% (168 respondents) were female. The majority of the respondents were 18-25 years old (62%) and only 8% of the total respondents were 26-30 years old and 31-35 years old (respectively). The majority occupations were students (41%) and employees (28%). As for educational level, 50% of respondents (153 respondents) were high school graduates and 47% of them (142 persons) were college/university graduates. As for spending, 118 respondents (39%) spend between Rp 1-3 million/month (USD 71-213/month), 87 respondents (29%) spend between Rp 3-5 million/month (USD 213-355/month) and only 53 respondents (17%) spend between Rp 5-10 million/month (USD 355-710/month). As for the duration of Telkomsel services subscription, 46% of respondents (139 respondents) have been Telkomsel subscribers for 5 years or longer, and another 28% of respondents (86 respondents) have subscribed to Telkomsel for 3-5 years.

Validity

The data was processed with AMOS. The convergent validity was evaluated using three criteria:
1. Construct Reliability (CR) of all dimensions must be higher than 0.7 (Hair, et.al., 2019).

2. Average Variance Extracted (AVE) must be higher than 0.5 (Hair, et.al., 2019).
3. The factor loadings of all items must be higher than 0.5 (Fornell & Larcker, 1981).

The convergent validity results can be seen in Table 1.

Table 1: Convergent Validity

Variables	Item	SLF≥0,5	CR	AVE	Remarks	
Value Driven	CSR1	0,612	0,767	0,529	Valid	Reliable
	CSR2	0,807			Valid	
	CSR3	0,791			Valid	
Egoistics Driven	CSR4	0,747	0,737	0,584	Valid	Reliable
	CSR5	0,781			Valid	
Stakeholder Driven	CSR6	0,642	0,828	0,551	Valid	Reliable
	CSR7	0,888			Valid	
	CSR8	0,781			Valid	
	CSR9	0,634			Valid	
Strategic Driven	CSR10	0,823	0,901	0,752	Valid	Reliable
	CSR11	0,914			Valid	
	CSR12	0,862			Valid	
Brand Trust	BT1	0,884	0,899	0,640	Valid	Reliable
	BT2	0,731			Valid	
	BT3	0,781			Valid	
	BT4	0,741			Valid	
	BT5	0,784			Valid	
Perceived Quality	PQ1	0,908	0,889	0,728	Valid	Reliable
	PQ2	0,849			Valid	
	PQ3	0,798			Valid	
Brand Image	BI1	0,875	0,835	0,628	Valid	Reliabel
	BI2	0,798			Valid	
	BI3	0,792			Valid	
Brand Loyalty	BL1	0,814	0,886	0,723	Valid	Reliable
	BL2	0,874			Valid	
	BL3	0,861			Valid	
Brand Advocacy	AD1	0,852	0,916	0,733	Valid	Reliable
	AD2	0,841			Valid	
	AD3	0,857			Valid	
	AD4	0,875			Valid	

The next stage is to determine the discriminant validity, which is verified if the root-square value of AVE for the construct is higher than the correlation score with each of all the other latent variables (Fornell & Larcker, 1981). Table 2 below showed that all root-square value extracted for each latent variable, all of them have higher scores compared to between-constructs correlation scores. This means that the research model has discriminant validity.

Table 2: Discriminant Validity

	Brand Loyalty	Value Driven	Stakeholder Driven	Egoistics Driven	Strategic Driven	Brand Trust	Perceived Quality	Brand Image	Brand Advocay
Brand Loyalty	**0,850**								
Value Driven	0,462	**0,727**							
Stakeholder Driven	-0,004	0,176	**0,742**						
Egoistics	0,300	0,604	0,413	**0,764**					

Driven

ModelFit

Goodness-of-fit index (GOFI) is the indicator of the fit between the research model and the data (Malhotra, 2007). The model fit of the measurement model is summarized in Table 3.

Table 3: Goodness-of-fit Index - Measurement Model

Goodness of Fit Criteria	Value	Remarks
Relative/Normed Chi-Square (X^2/df)	2,115	*Good Fit*
Goodness of Fit Index (GFI)	0,854	*Poor Fit*
Adjusted Goodness of Fit Index (AGFI)	0,812	*Poor Fit*
Standardized Root Mean Square Residual (SRMR)	0,065	*Good Fit*
Root Mean Square Error of Approximation (RMSEA)	0,061	*Good Fit*
Non-Normed Fit Index (TLI atau NNFI)	0,918	*Good Fit*
Normed Fit Index (NFI)	0,879	*Poor Fit*
Relative Fit Index (RFI)	0,855	*Poor Fit*
Incremental Fit Index (IFI)	0,932	*Good Fit*
Comparative Fit Index (CFI)	0,932	*Good Fit*

Table 4 summarizes the model fit for the structural model.

Table 4: Goodness-of-fit Index - Structural Model

Goodness of fit criteria	Value	*Remark*
Relative/Normed Chi-Square (X^2/df)	2,254	*Good Fit*
Goodness of Fit Index (GFI)	0,837	*Poor Fit*
Adjusted Goodness of Fit Index (AGFI)	0,797	*Poor Fit*
Standardized *Root Mean Square Residual* (SRMR)	0,065	*Good Fit*
Root Mean Square Error of Approximation (RMSEA)	0,072	*Good Fit*
Non-Normed Fit Index (TLI atau NNFI)	0,908	*Good Fit*
Normed Fit Index (NFI)	0,867	*Poor Fit*
Relative Fit Index (RFI)	0,845	*Poor Fit*
Incremental Fit Index (IFI)	0,922	*Good Fit*
Comparative Fit Index (CFI)	0,921	*Good Fit*

Next in figure 1, the result of path analysis to examine direct influence between latent variables is shown.

Figure 1: Path Analysis

The result of the path analysis in figure 1 is summarized in Table 5 below.

Table 5: Path Analysis Summary

Hypotheses	Path	SLF	T-Value	P-Value	Remarks
H1a	*Value Driven → Brand Trust*	1,071	6,609	0,000	Supported
H1b	*Value Driven → Perceived Quality*	1,421	6,139	0,000	Supported

H8	*Brand Loyalty → Brand Advocacy*	0,674	6,860	0,000	Supported

Discussions

Based on the results in figure 1 and table 5, there are 4 paths that can be identified from the model, as listed below:

Path 1: Value driven motive - Brand Trust-Brand Loyalty
Path 2: Value driven - Brand Image - Brand Loyalty
Path 3: Egoistic driven - Brand Trust - Brand Loyalty
Path 4: Egoistic driven - Brand Image - Brand Loyalty

This result showed that out of four CSR motives (value driven, egoistic driven, stakeholder driven and strategic driven), only value driven and egoistic driven motive have impacts on brand trust or brand image of the company. In this research, the example of CSR activities performed by the company is philanthropic activities, in which Telkomsel was described as a benevolent company, donating money, health equipment, even free internet services to health and medical workers in Indonesia during covid-19 pandemic. If customers saw these acts as value-driven kindness, the kind of CSR activities that was performed because the company realized their responsibility to their environment and the society, then these activities would have positive impact on customers' trust towards the brand, which eventually would lead to brand loyalty. These activities would also be beneficial for the image of the company. Good brand image would also lead to brand loyalty.

As for the second motive, egoistic-driven, here the customers suspected that there were some ulterior motive behind the act of kindness. Customers saw the CSR activities as a performance, something that was done in order to get publicity, for instance. In the end, customers thought that all benefits would eventually go back to the company, in the forms of publicity, good image or profit. When customers think that there were some egoistic motive behind the philanthropic actions, this would affect their trust negatively towards the company, which would lead to less brand loyalty. The same thing can be applied to brand image. The suspicion of some egoistic motives behind a company's benevolent act would lead to bad brand image, which eventually would also decrease brand loyalty.

As for brand advocacy, the results showed that there were no direct path to brand advocacy. The company must build brand loyalty first before the customers are willing to advocate the brand to their relatives and friends.

Conclusions and Recommendations

The research was conducted in three areas in Indonesia where covid-19 hit the hardest, namely Jakarta, East Java and West Java. The researchers wanted to see how respondents in these area, which were also the customers of a certain company, would react to covid-19 CSR activities messages posted by the company in their official websites/social media. The researchers also wanted to examine how the customers' perception of the motives behind the covid-19 CSR activities would influence their trust and loyalty to the company, and also the impact on the brand image, which would eventually lead to brand advocacy.

Out of four CSR motives, only value-driven and egoistic-driven were proven to have impacts on brand trust and brand image, which eventually leads to brand loyalty. Brand advocacy can be achieved only after the brand loyalty is formed strongly.

The research only used one type of CSR activities (philanthropic) and only one company was used as the research object, considering that the companies must have their product throughout Indonesia and must performed covid-19 related CSR activities and also publicized them in their official website and social media. The next research should try to examine another type of activity (e.g. Corporate Social Marketing) and use more than one company as the research objects, so the results can be compared.

The next research can try to reach other areas of Indonesia which were also impacted by the covid-19 pandemic, for example Central Java and other areas in Sumatra and Kalimantan island. Respondents can also be classified into loyal and regular customers to see the differences in their perception.

Power Shortages and Changes in the Structure of Electricity Production in Poland in 2015-2019

Wioletta SKRODZKA

Częstochowa University of Technology, Częstochowa, Poland
wioletta.skrodzka@pcz.pl

Abstract

Objectives: The paper aims at emphasizing the differences between Poland and the EU-28 states with the level of security of electricity supply. **Background**: The level of energy safety is influenced by many factors: diversification of the structure of energy carriers in the domestic balance, degree of diversification of external sources of supply, technical condition and efficiency of devices and installations of the transmission and distribution systems for fuels and energy. In this context, the security of electricity supply can be considered at the level of: energy availability, power, reliability of supply and quality of supplied energy. **Expected Results**: The study is focused on the aspect of the risk of energy shortages in the Polish energy system. Two shortage incidents in Poland (August 2015 and June 2020) were analyzed in terms of the risk factor and in the context of structural changes in the energy market. The paper investigates the intensity of changes in the sector structure of energy production (using a measure of structural changes), then compares the sector structure of the primary energy production in Poland with the sector structure in the whole EU-28 using object similarity measure and finally evaluates the competition on the Polish electricity market using the Herfindahl-Hirschman Index (HHI) as an index generation concentration in power sector. **Implications:** The results of work can be used as a situational analysis for tackling security of electricity supply.

Keywords: Energy Sector, Risk Management, Power Shortfages, Security of Electricity Supply.

Introduction

Data from previous years show that the global demand for energy continues to grow (WEMO, 2019). Even though the global economy in 2020 slowed down because of the Coronavirus pandemic, which was effectively followed by a decrease in energy demand, one can speculate that once the pandemic is over, the rising trend will continue. A temporary drop in demand resulted in a reduction of wholesale energy prices (Okolnishnikova et al., 2020). According to the Polish Power Exchange, monthly prices of energy at the beginning of the year were lower by 16 - 33% compared to the first months of 2019. The average year-to-year decrease was 23,4% (TGE, 2020). Reduction in demand promotes the cheapest generation units and fuels the interest in energy transformation. This transformation is an opportunity for energy companies with a stable financial situation. Provision of energy at lower prices gives them a chance to increase their market share. At the same time, the pandemic revealed the growing risk among generation units. Because of the economic slowdown the customers reduce their energy consumption, but the energy companies are bound to ensure previously established volumes at higher prices. Hence, they suffer losses in the face of the global reduction of energy prices. An exaggerated liberalization in terms of energy consumption and deferred payments caused by the global economic slowdown is another source of risk for energy companies. It also influences the stability of the whole energy system. Disruptions in energy supplies have a negative effect on all spheres of economic and social life (Kuei-Yen et al., 2018). Stable provision of electricity supplies requires an efficient policy of managing power shortages (Danielsson et al., 2020). This stability is influenced by many factors. The increasing role of renewable energy which has feed-in priority results in reduced operation of coal units. Subsidiary sources of energy are characterized by a relatively high instability of generation (Alizadeh et al., 2016; Paterakis et al., 2017; Lund et al. 2015; Cruz et al., 2018; Aghaei &Alizadeh, 2013). Therefore, the stability of the energy system is based on conventional energy sources. Generating units of this type, however, require large investments and considerable modernization which becomes unprofitable at fluctuating energy prices. A remedy for the danger of the so called blackout, understood as the system failure resulting in the loss or significant reduction of voltage over a large area, could be the capacity market established in 2017. The act ensures safe development of renewable energy sources without a negative impact on the continuity of energy provisions to end customers. One of the expected effects of the

capacity market is investing in new power plants. The second factor influencing the stability of the power system is the occurrence of the so-called *unscheduled flows* including *loop flows*, *transit flows*). Unscheduled flows refer to power exchange between systems, which was not included in the cross-border exchange schedules. This process manifests itself, inter alia, in insufficient coordination of trade within an area whose internal balance directly affects other market areas that are not a party to the transaction. In Central and Eastern Europe, cross-border trade between Austria and Germany has a strong influence on the occurrence of unscheduled flows.

The study is focused on the aspect of the risk of energy shortages. Two power shortage incidents which occurred in August 2015 and in June 2020 were analyzed. The analysis covered the factors causing the risk and the methods of counteracting it. The Polish energy sector in the years 2015-2019 was analyzed, both in terms of the concentration of the generation sector and the production structure**.** Changes in the sectoral structure of electricity production in Poland and in the EU-28 were compared. The study also presents a comparison of the degree of intensity of changes in the years 2015-2019. The analysis was based on data from the Eurostat and the Statistical Review of World Energy 2020.

Security of Electricity Supply

The directive 2005/89/EC defines the security of electricity supply as „the ability of an electricity system to supply final customers with electricity". This definition emphasizes the security of supply as a property of the entire power system, including the generation, transmission and distribution systems, and analyzes them from the point of view of flexibility on the demand side, i.e. the end customer. The issues of security of electricity supply are also regulated in Directive 2009/72/EC of the European Parliament and of the Council of 13 July 2009 on common rules for the internal electricity market and repealing Directive 2003/54/EC. In Poland the directive 2005/89/EC was implemented in 2010 (Dz.U. 2010 nr 21 poz.104). The level of energy safety is influenced by many factors. Their significance depends on both the internal situation in a country and the situation on global markets. A few of these sectors, though, are especially important: diversification of the structure of energy carriers in the domestic balance, degree of diversification of external sources of supply, technical condition and efficiency of devices and installations of the transmission and distribution systems for fuels and energy. In this context, the security of electricity supply can be considered at the level of: energy availability, power, reliability of supply and quality of supplied energy (Sperstad, 2020). Availability refers to the ability of the system to meet the consumers' demand for electricity, taking into account the aspect of energy storage. It refers to underproduction or scarcity of primary resources (Szamrej-Baran & Baran, 2020). Energy shortages are connected with energy availability and are usually a long-term phenomenon. Production capacity shortages usually do not last as long as energy shortages. Power shortages are connected with the lack of available generation, transmission or distribution capacity. Reliability is discussed in terms of the duration of disruptions of energy supplies to end customers caused by malfunctions and pauses in the energy system due to chance events. The quality of supplied energy can be characterized in terms of frequency, voltage and distortions (Doorman, 2006). The majority of the subject literature focuses on the influence of various generation sources on the security of the energy system (Sperstad , 2019). Many studies discuss the reliability of electricity supply and analyze various types of failures in the power system and the resulting power outages (Escalera, 2018). In the subject literature there is a lot of focus on the possibilities of improving the reliability of energy systems (Yixing & Singh, 2014; Lynch, 2019). The state of knowledge on the theory and practice of the assessment of power systems reliability, including the socio-economic impact assessment, was widely presented in GARPUR Consortium (2014). Quantitative aspects of energy efficiency are discussed by Khan et al. (2018), Andersen et al. (2006), Sgouras et al. (2018), Mena et al. (2014) and Syrri & Mancarella (2016). And the quality of power supply is the main focus of the following studies: Goel et al. (2006), Safdarian et al. (2018) and Syrri & Mancarella (2016).

Power shortages in August 2015 and June 2020 - A Situation Analysis

Energy crises can be caused by many factors such as extreme weather conditions, deliberate attacks or fuel shortages. When a crisis occurs it has a devastating impact on the economy and the social life in a country. In August 2015, a combination of factors including a persistent heat wave, a difficult hydrological situation on the main rivers in the country and a resulting reduction of the available production capacity below the necessary levels forced the government to introduce restrictions in the consumption and supply of electricity. On 9 August a sudden increase in power losses reaching 1200 MW was recorded, which exceeded the values used in the criteria for assessing the sufficiency of domestic generation capacity. That led the PSE Operator SA (the operator of the electric power transmission grid in Poland) to introduce levels of restrictions for industrial customers till the end of August. Actions of this kind had not been carried out for many years in Poland.

The following measures were taken:

- the available generating units were activated, including units beyond the central control system;

- the planned repairs and maintenance of power plants were postponed;
- it was recommended to use the contracted DSR services, i.e. voluntary and temporary reduction of electricity consumption by consumers or postponing consumption at the request of PSE S.A. (electric power transmission grid operator in Poland) in return for remuneration;
- the possibilities of emergency assistance of foreign operators from the Czech Republic and Slovakia to the maximum extent possible were agreed upon;
- multilateral redispatching was widely applied in order to maintain a safe level of power flows across the Polish-German border as this border was heavily loaded with unplanned power flows.

However, the measures taken did not help to balance the demand for power which led to the introduction of restrictions in the supply and consumption of electricity. On the morning of 10 August power level 20 was announced. The restrictions helped to maintain stable functioning of the energy system. In the following days, after the elimination of failures in power plants, the power levels were being reduced and the reserves in the system were being rebuilt.

A similar situation endangering the energy system security occurred on 22 June 2020. It was accompanied by unplanned generation interruptions and failures in power units which caused the reduction in the available power by 7 GW. The power available in power plants in Bełchatów, Opole, Kozienice, Połaniec and Włocławek was reduced by 4 GW due to a number of failures. This loss constitutes over 10% of all capacity installed in Polish thermal power plants. The demand for energy at that time was 21 GW. The Polish electric power transmission grid operator PSA S.A. used inter-operator assistance. The total electricity import from Sweden, Germany, the Czech Republic, Slovakia and Lithuania reached 3 GW. It should be noted that this volume covered commercial flows and inter-operator import. These steps resulted in a sudden and temporary increase in the prices of electricity.

Comparing the situation from August 2015 with the one from June 2020 it should be emphasized that in 2020 the National Power System was better prepared for emergencies as it was equipped with new generating units. The power of photovoltaic installations which help to balance the system is growing dynamically. Installation of phase shifters on cross-border connections with Germany, as well as investments in the expansion and modernization of the transmission network increase the transmission capacity for the purposes of trade.

Data and Methods

The analysis of changes in the structure of primary energy production in Poland and the EU-28 is based on data from the Eurostat energy balance for 2015 and 2018 on an annual basis. The data for 2019 come from the Statistical Review of World Energy 2020 | 69th edition.

In order to analyze the intensity of changes in the sector structure of energy production, we use a measure determining structural changes proposed by Rutkowski (Rutkowski, 1981). It is a variability coefficient of the indexes of the analyzed aggregation's growth, which at the same time measures the irregularity of the increase of the aggregate's components (Skrodzka & Kiriliuk, 2019).

$$V_{t,t+\tau}^{i} = \left[\sum_{j=1}^{k} f_{j,t+\tau}^{i}\left(\frac{f_{j,t+\tau}^{i}}{f_{j,t}^{i}} - 1\right)^{2}\right]^{\frac{1}{2}} \tag{1}$$

where:

$f_{j,t+\tau}^{i}, f_{j,t}^{i}$ - the structure index in moments t and t+τ; j=1,2, …k – components of the structure aggregate, share of j-fuel to total primary energy production; i – object number (1- Poland, 2-European Union).

$V_{t,t+\tau}^{i} = 0$ indicates the lack of change in the structure between periods. The higher the value of the measure, the more significant the structural changes.

In the next stage of the analysis we will compare the sector structure of the primary energy production in Poland with the sector structure in the whole EU-28. Object similarity measure are used in analysis of this type (Malina, 2004). The measure is based on the value of the cosine of the α angle measured between the U_{t1}i U_{t2} vectors characterizing the state of the structure of the primary energy production in Poland and European Union in respective periods *t*1 and *t*2.

$$cos\alpha = \frac{\sum_{j=1}^{k} f_{j,t}^{1} \cdot f_{j,t}^{2}}{\sqrt{\sum_{j=1}^{k}\left(f_{j,t}^{1}\right)^{2} \cdot \sum_{j=1}^{k}\left(f_{j,t}^{2}\right)^{2}}} \tag{2}$$

where:

$f_{j,t}^{1}, f_{j,t}^{2}$- components of the structure indexes vector respectively for Poland and the European Union.

The values of the measure are normalized, but to interpret the structures similarity assessment level, we consider the angle represented by the calculated cosine. A big α spread between the U_{t1} and U_{t2} vectors means significant structure changes in period *t*2 in comparison to the structure in period *t*1. A small spread of the angle indicates slight structure changes in the discussed periods. In an exceptional case, when the compared structures are identical, the angle between the structure vectors is 0. When the cosine value tends toward 0, which means the angle tends toward 90°, the vectors represent increasingly different structures. Arbitrary ranges determining small, medium or high structure similarity were set. The values of the cosine function for the division of a 90° angle into 3 equal parts were assumed as the ends of the ranges: [0, ½]- big difference in structures;[1/2, $\sqrt{3}/2$]- moderate diversification of the structures;[$\sqrt{3}/2$, 1]- high similarity. The function is not linear with respect to the angle, so we need to take caution expressing the size of structure changes in percentage.

The assessment of the competition on the Polish electricity market was carried out using the Herfindahl-Hirschman Index (HHI) which is often used in antitrust and sector regulation activities. The HHI can be represented mathematically as,

$$HHI = \sum_{i=1}^{n} S_i^2 \tag{3}$$

where:

S_i is the market share of i-th participant, n is the number of participants in a competing market.

The higher the level of the index the lower the competitiveness of a branch. The degree of generation concentration in the power sector is determined using the most common limits: below 750 - no concentration; 750 - 1800 - moderate market concentration; 1.800 – 5.000 - high market concentration; over 5000 - very highly market concentration.

Analysis of the Polish energy sector in the years 2015-2019 in comparison to UE-28

The analysis was based on data from the Eurostat and the Statistical Review of World Energy 2020.

The global energy production in 2019 grew by 1.3% compared to 2018. Globally, coal was still the dominant energy source. Its share in the production of energy decreased by 1.5% compared to 2018 reaching 36.4%. The share of natural gas and renewable energy increased to 23.3% and 10.4% respectively. Analyzing the volume of output of the primary energy in the EU-28 in the period 20015-2019 we observe a negative trend for the majority of energy sources, except for renewables (table 1).

Table 1: Primary energy production, Share of each fuel to total production in EU-28 and in Poland, 2015–2019 (Mtoe)

Year	Area	Total production (Mtoe)	Solid fuels	Oil (total)	Natural gas	Nuclear energy	Renewable energy	Others
2015	EU-28	766.6	144.9	75.1	107.3	221.5	204.7	13.0
	PL	67.3	53.6	0.9	3.7	0.0	8.6	0.5
2016	EU-28	755.4	132.2	74.0	107.3	216.8	210.8	14.3
	PL	66.4	52.1	1.0	3.5	0.0	9.0	0.8
2017	EU-28	758,2	124,5	77,5	103,1	210,1	226,6	14,2
	PL	64	49,5	1,0	3,5	0,0	9,1	0,9
2018	EU-28	756,1	117,8	70,8	93,8	209,6	233,7	29,6
	PL	61,4	47	1	3,4	0,0	8,9	1
2019	EU-28	742,4	96,1	65,4	98,7	208	245	26,2
	PL	59,2	43,0	0,7	2,8	0,0	10,3	1,4

Source: Eurostat energy balance for 2015 and 2018 on an annual basis. The Statistical Review of World Energy 2020 | 69th edition. [online]; [Retrieved.2020-08-17],

Primary production of energy in the EU-28 in 2019 decreased by 3.2% compared to 2015. The biggest decrease was observed in the production of fossil fuels (33,3%), petroleum derived products (12,9%), gas (8%), followed by the production of nuclear energy (6%). The production of energy from renewable sources, on the other hand, increased by 19,7%. The most popular sources of renewable energy in EU-28 in 2019 were wind power plants. Wind generation increased by 14% (+54 TWh) compared to 2018. Solar generation rose by 7% (+9.5 TWh). Biomass generation rose only 1% (+1.4 TWh). Hydro generation decreased by 6% (-21.5 TWh).

Electricity production in 2019 in Poland was the lowest in five years reaching 164 TWh. The import of electricity in 2019 grew almost twice to the level of 10.6 TWh. As prosumer installations are on an increase, it is difficult to realistically estimate the domestic demand for electricity. Production in Poland in the analyzed period is based on fossil fuels which in 2019 accounted for 72,6% of the production. There seems, however, to be an upward trend in the percentage of renewable energy. In 2019 it was on the level of 17,4%, followed by gas (4,7 %), and petroleum products (1,2%). In Poland there are no nuclear power plants.

Angle measure was used to assess the similarity of the primary energy production structure in Poland and in EU-28. The results are shown in table 2.

Table 2: The Values of the Structure Similarity Measures

Years	2015	2016	2017	2018	2019
cosα	0,510951	0,491215	0,237006	0,469909	0,445086

Source: Own calculations

The analysis showed a significant difference between the structures of primary energy production in Poland and in EU-28 in 2019, the angle between the vectors is 64°. In the other years also suggests a significant difference between the structures of primary energy production. In 2017 the angle between the vectors is 77°. In the next step we determined the intensity of the structural changes in the analyzed period using the formula (1). The values of the structural change intensity measure are presented in table 3.

Table 3: The Dynamics of the Structural Change in Primary Energy Production in Poland and in EU-28 in the Period 2015-2019

Years	Change intensity measure in comparison to the previous year	
	EU-28	Poland
2016	0.042336	0.075215
2017	0.057806	0.031486
2018	0.178989	0.03897
2019	0.079111	0.279219
2019:2015	0,315197	0,926341

Source: Own calculations

Both measures have low, similar range values, which means that the intensity of the change tempo in the analyzed structures is also low. But in 2019, the measures for Poland are higher which suggests a greater intensity of the changes in Poland than in EU-28. The strongest changes in the sector structure of production in EU-28 took place in 2017, and in Poland in 2019. The last line of table 6 shows the value of the measure for the first and the last year 2019:2015. Regardless of the change path and concentrating on the two boundary years, we can say that the intensity of changes in 2019 compared to 2015 was higher in Poland.

The assessment of the competition on the Polish electricity market was carried out using the Herfindahl-Hirschman Index (HHI) which is often used in antitrust and sector regulation activities.

The higher the level of the index the lower the competitiveness of a branch. In 2019, the PGE S.A. capital group held the largest electricity generation subsector market share of 40.6%. The market share of the three largest entities, measured by energy fed into the grid, was 66.4%. Apart from PGE S.A. the dominant positions were held by: ENEA S.A. and TAURON Polska Energia S.A. The table 4 presents market shares and the concentration in the generation subsector in the years 2015-2019.

Table 4: Market shares and the concentration in the generation subsector in the years 2015-2019

Year	Number of units with over 5% share in the installed capacities	Number of units with over 5% share in the energy fed into the grid	Share of the three biggest units in installed capacities	Share of the three biggest units in the energy fed into the grid	Installed capacity - HHI	Energy fed into the grid - HHI
2015	5	6	52,2	57,4	1366,0	1762,9
2016	5	6	50,8	54,9	1309,3	1640,0
2017	4	4	63,1	69,0	17959	2281,1
2018	4	3	62,0	69,7	1740,0	2281,0
2019	3	4	62,1	66,4	1809,2	2090,5

Source: Data of the Ministry of Energy and ERO. For all entities operating in the generation sector, which are subject to an obligation of reporting statistics, including installed capacity and energy fed into the grid from wind and hydro sources. When calculating the market share ratios of the three largest entities and HHI ratios, both according to the energy fed into the grid and the installed capacity, the structure of the entity as at 31 December 2019 was taken into account. [online]; [Retrieved.2020-09-17] https://www.ure.gov.pl/en/about-us/reports/67,Reports.html

Market share ratio in 2019 measured according to the energy fed into the grid (with the consideration of energy provided by generators directly to end users) was on a high level of 66.4%. Compared to 2018 it decreased by 3 percentage points. And in comparison to 2015 it grew by 9 percentage points. The previous downward trend in HHI indices, measured according to installed capacity and the volume of energy fed into the grid, changed significantly in 2017. The HHI measured according to installed capacities grew in 2019 compared to 2018, but measured according to energy fed into the grid (with the consideration of energy provided by generators directly to end users) it decreased. In comparison to 2015, an increase in the concentration measured using the HHI was observed in both cases. The index calculated for the production in 2019 showed a moderate market concentration. However, calculated for the installed capacity, the index exceeded the upper limit of the average concentration and passed to the level of high generation market concentration. The number of units with at least 5% share in installed capacities decreased in 2019 compared to 2018. This was due to the decommissioning of the generation asset in the ZE PAK S.A. capital group, which significantly decreased the importance of this group in the sub-sector of electricity generation. The heightened importance of the PKN ORLEN S.A. capital group, resulted in the increase in the number of entities with at least 5 percent share in energy fed into the grid in 2019 compared to 2018.

Conclusions

In the context of electricity supply, energy security is understood primarily as the security of supply. It is understood as the ability of the power system to ensure security of the functioning of the power grid and to balance the supply and demand for energy. The prognoses by PSE do not indicate any dangers to the security of energy supply to Polish customers. Compared to the situation in August 2015, the National Power System is now better prepared for emergency situations. It is equipped with many countermeasures in case of various difficulties in balancing the system. The most important of them is the ability to maintain the operational reserve of generation capacity at the required level. Also inter-operator emergency assistance used by European operators in emergency situations, such as the one from 22 June 2020, constitutes significant support. Other tools include the Intervention Cold Reserve and the service of reducing the demand on the operator's request (DSR). However, as the instability of the system is growing and extreme weather conditions are becoming more common there is a need in the energy system for a bigger diversification of sources. One should also underline the special importance of photovoltaics which can be another buffer to conventional energy on one hand, but also a risk element due to its irregular supply on the other. In Poland, like in other EU-28 countries, the share of energy from renewable sources in primary production is constantly growing. The study analyzed the structure of primary energy production in sectors and the dynamics of its changes in Poland in terms of capacity risk management, and compared it with the structure in the EU-28 in the years 2015-2019. The discussed structures and the rate of changes differ much. Also the unit structure of the Polish energy sector was analyzed in terms of concentration. At a later stage of the research, the author wishes to focus on other risk factors for power shortages. In a market economy the role of the state is not to take direct actions ensuring the adequacy of generation capacity, but to create regulatory conditions for business activity which can motivate entities to build, maintain and modernize generation units, as well as motivate energy customers to limit energy consumption and gradually increase the flexibility of demand.

The Use of The Industry 4.0 Concept by Polish Enterprises of The SME Sector

Aleksandra CZUPRYNA-NOWAK

Silesian University of Technology, Gliwice, Poland, aleksandra.nowak@polsl.pl,
DOI: 0000-0001-8565-1029

Abstract

Industry 4.0 puts new enterprises against modern challenges and priorities. The Industry 4.0 concept assumes full integration of all areas of business activity. This integration should take place with the use of broadly understood information technology, both real and virtual. Polish enterprises from the SME sector are aware of the need to implement the Industry 4.0 concept. However, very often, there are barriers to organizational changes, employment, understanding the advantages of IoT, or the high cost of implementation. It is, therefore, necessary to diagnose the current state. The article aims to check the current state of Industry 4.0 solutions in selected areas of the company's activity. The theoretical discussion in the presented work was supported by research conducted among Polish enterprises from the SME sector.

Keywords: Industry 4.0, areas of implementation of the Industry 4.0 concept, SME sector.

Introduction

To survive, the enterprise adjusts its activities in a changing environment. Today's enterprises' biggest problem seems to be the need to effectively deal with the excess of data or information coming both from outside and inside. Moreover, the priority seems to be to maintain high production flexibility. The fourth revolution makes it possible to connect devices within digital ecosystems and deepen integration within horizontal and vertical value chains. The Industry 4.0 ideology pursuit is to obtain a company focused on quickly satisfying individual customer needs (Wittbrodt 2017).

Because Industry 4.0 is a new reality, there are more and more publications on this subject (Adamik 2019). M. Olszewski (Olszewski 2016) deals with the issues of transition from the stages of automation and industrial robotization to the stage of mechatronization of products. Dispersed structure. A. Zagajewski (Zagajewski 2018) presents the main directions of e-commerce development in the Industry 4.0 concept. D. Stadnicka, W. Zielecki, and J. Sęp (Stadnicka 2020) focus in their publication on the idea of Industry 4.0, assessing the possibilities of its implementation. These are just some of the authors who deal with the topic of Industry 4.0 in scientific studies. In the years 2019-20, four reports were prepared by consulting companies (Piątek 2020). According to the Autodesk report, Polish enterprises' research has shown that Industry 4.0 is an essential topic for the majority, the factor determining competitive advantage is innovation, and digitization is inevitable. On the other hand, the IDG / ABB report states that Polish companies have already started implementing Industry 4.0 solutions, but lack a strategic plan.

However, it should be remembered that the transition to Industry 4.0 is a gradual process that requires the integration of the current state with new digital technologies. Therefore, it seems necessary to analyze the current state of Polish enterprises in the SME sector and the degree of implementation of the Industry 4.0 solution. Currently, there is a lack of such studies and studies. Therefore, the article aims to check the current state of implementation of Industry 4.0 solutions in selected areas of the company's activity in the SME sector.

The article consists of two parts. The first, theoretical, concerns the very concept of Industry 4.0. However, the second part presents empirical research. The research was conducted in 2020 among Polish enterprises from the SME sector. The company's activity areas were selected: warehousing, product sales, product service, order picking, and internal transport. It seems that these are the critical areas of activity of enterprises in the SME sector. In these areas, enterprises were asked to specify to what extent they implemented Industry 4.0 solutions. The research results and their analysis are presented in the paper.

The use of the Industry 4.0 concept in enterprises

The idea of Industry 4.0 assumes full integration of the system of suppliers, customers, and producers. The concept of Industry 4.0 connects the physical and virtual world. As part of the production systems, all factory components form a unified whole, from procurement to transport. People, methods, objects, and machines are connected via the internet. Communication between them takes place in real-time and is aimed at process optimization. Industrial production can meet individual customer needs continuously. Industry 4.0 allows you to create new business models.

Such a new business model that has emerged, thanks to the 4.0 concept, is the enterprise's digital maturity model (Łobejko 2018, Nosalska 2019). This model assumes three critical pillars for the development of Industry 4.0 in manufacturing companies. The posts cover the enterprise's entire activity and are the technologies pillar, the organization pillar, and the processes pillar. Twelve modules can be distinguished within the three pillars. Modules represent the key aspects around which companies should focus their activities. Each post is assigned to appropriate modules. The technology pillar is a crucial factor driving the enterprise's changes, in line with the Industry 4.0 concept. Digital technologies (cloud computing, virtual reality, machine learning, and the Internet of Things) create an ecosystem in which physical resources (e.g., people, machines) are integrated with IT systems and enable continuous exchange and data analysis. The technology pillar includes the following modules: connectivity, automation, autonomy, and intelligent product. The organization pillar rests on two critical elements of an enterprise's operations: people, systems, and structure. The following modules can be distinguished within the post: strategy, employees, leadership, cooperation, and projects. The last pillar, the pillar of processes, the task of which is the complete integration of many areas - from production, through the supply chain, to the product life cycle. Within the processes pillar, we distinguish modules: integration with the environment, product life cycle, internal integration, and standardization.

In this study, we will focus on the internal integration module. The internal integration module is directly related to the company's production process. It is directly related to the planning and implementation of processes leading to goods and services. Internal integration aims to integrate processes vertically at all levels.

The scope of application of Industry 4.0 solutions in Polish enterprises of the SME market

The research was conducted among Polish SME enterprises. The study was carried out in December 2019 - February 2020. Five hundred sixty-nine companies participated in the part concerning the scope of application of Industry 4.0 solutions. Four levels were identified: warehousing, product sales, product service, order picking, and internal transport. The surveyed companies were asked whether they had Industry 4.0 solutions implemented in the company in the areas mentioned above. The respondents were asked to mark one answer on the scale: "no," "rather no," "hard to say," "rather yes," and "yes."

Table 1 shows the breakdown of enterprises according to the size of employment.

Table 1: The number of enterprises participating in the survey by employment size

Number of employees	Number of enterprises	%
to 9	269	47,28%
from 10 to 49	222	39,02%
from 50 to 250	78	13,71%
Sum	**569**	**100,00%**

Source: Own study

47.28% of the surveyed enterprises are micro-enterprises employing up to 9 people. 39.02% of enterprises employ from 10 to 49 employees. 13.71% are enterprises with 50 to 250 employees.

The voivodship in which the surveyed enterprises operate is the most important. As much as 42.53%, enterprises took part in the Mazowieckie voivodeship (Table 2). In terms of the number of enterprises participating in the survey, the second voivodeship was Śląskie: 15.64%. Then: Dolnośląskie Voivodeship - 7.91% and Greater Poland Voivodeship - 5.62%. The number of surveyed enterprises in other voivodeships does not differ significantly. The structure of the research reflects the design of the location of industry in Poland.

Table 2: Number of enterprises participating in the survey by voivodship

Voivodship	Number of enterprises	%
dolnośląskie	45	7,91%
kujawsko-pomorskie	13	2,28%
lubelskie	13	2,28%
lubuskie	5	0,88%
łódzkie	14	2,46%
małopolskie	27	4,75%
mazowieckie	242	42,53%
opolskie	10	1,76%
podkarpackie	19	3,34%
podlaskie	7	1,23%
pomorskie	20	3,51%
śląskie	89	15,64%
świętokrzyskie	12	2,11%
warmińsko-mazurskie	11	1,93%
wielkopolskie	32	5,62%
zachodniopomorskie	10	1,76%
Sum	**569**	**100,00%**

Source: Own study

9.31% of the surveyed enterprises conduct their activities in economic zones. The remaining 90.69% outside the economic zones.

Table 3 : The number of enterprises participating in the survey by employment size

The company operates in the economic zone	Number of enterprises	%
Yes	53	9,31%
No	516	90,69%
Sum	569	100,00%

Source: Own study

Information on the functioning of the enterprise in the economic zone is essential. Enterprises operating in industrial zones can often count on various types of facilities in the company's operations. If thanks to this, they lower operating costs, investment funds can increase. Concerning the implementation of new solutions such as Industry 4.0 solutions, it is crucial.

In the first question, the respondents answered whether their company had implemented Industry 4.0 solutions in the area of storage. 43.23% (Table 4) of the surveyed companies do not use Industry 4.0 solutions in the area of storage.

Table 4 : The number and percentage share of answers to the question regarding the scope of Industry 4.0 solutions in the warehouse area

Answers	Number of enterprises	%
no	246	43,23%
propably no	55	9,67%
hard to say	75	13,18%
rather yes	104	18,28%
yes	89	15,64%
Sum	**569**	**100,00%**

Source: Own study

33.92% of the surveyed companies declare the use of Industry 4.0 solutions. Whereas 15.64% of enterprises applied solutions, and 18.28% rather applied. Figure 1 presents the number of answers to the question graphically.

Fig. 1: The number of responses to the question regarding the application of Industry 4.0 solutions in the warehouse area.

Source: Own study

In the second question, companies answered whether their company had used Industry 4.0 solutions in internal transport. Table 5 and Figure 2 present the number of individual responses. 52.20% of enterprises replied that Industry 4.0 solutions were not used in internal transport.

Table 5: The number and percentage share of answers to the question regarding the scope of application of Industry 4.0 solutions in internal transport

Answers	Number of enterprises	%
no	297	52,20%
propably no	81	14,24%
hard to say	82	14,41%
rather yes	62	10,90%
yes	47	8,26%
Sum	**569**	**100,00%**

Source: Own study

19.16% of enterprises declare that they have implemented solutions, answering "rather yes" and "yes." Only 8.26% of enterprises implemented solutions of the Industry 4.0 idea, answering "yes." Explanations relating to internal transport are so expensive that companies do not implement them due to the cost.

Fig. 2: The number of answers to the question regarding the application of Industry 4.0 solutions in the area of internal transport.

Source: Own study

In the third question, companies answered the question about using industry 4.0 solutions in the area of order picking. In this case, only 31.99% (Table 6 and Figure 3) responded that they did not have such solutions applied.

Table 6 : The number and percentage of answers to the question regarding the scope of application of Industry 4.0 solutions in order picking

Answers	Number of enterprises	%
no	182	31,99%
propably no	33	5,80%
hard to say	84	14,76%
rather yes	144	25,31%
yes	126	22,14%
Sum	**569**	**100,00%**

Source: Own study

47.45% of enterprises have implemented Industry 4.0 solutions in the area of order completion. Complementation of orders is an area of the company's activity that each company develops. Each company aims to sell its products, which it must complete.

Fig. 3: The number of answers to the question regarding the application of Industry 4.0 solutions in order picking.

Source: Own study

Another question concerned the product service. In this case, there is also a large percentage of enterprises that do not have implemented solutions. Enterprises that answered "no" amounted to 39.54%, and "rather not" 9.49% (Table 7 and Figure 4). That answer gives a total of 49.03% of all surveyed enterprises. Implemented Industry 4.0 solutions (answer "rather yes" and "yes") 34.98%.

Table 7: The number and percentage of answers to the question regarding the scope of application of Industry 4.0 solutions in product service

Answers	Number of enterprises	%
no	225	39,54%
propably no	54	9,49%
hard to say	91	15,99%
rather yes	109	19,16%
yes	90	15,82%
Sum	**569**	**100,00%**

Source: Own study

Fig. 4: The number and percentage of answers to the question regarding the application of Industry 4.0 solutions in product service.

Source: Own study

The last question related to the areas of implementation of Industry 4.0 solutions associated with the sale of products. The results can be seen in Table 7 and Figure 5. Because sales are one of the fastest-growing areas of the company's activity, it is possible to notice many enterprises that have implemented solutions to the Industry 4.0 idea. The answers "yes" were 27.24%, while "rather yes" was 25.66%. That answerThis gives a total of 52.9% of all surveyed enterprises.

Table 7: The number and percentage share of answers to the question regarding the scope of application of Industry 4.0 solutions in product sales

Answers	Number of enterprises	%
no	145	25,48%
propably no	28	4,92%
hard to say	95	16,70%
rather yes	146	25,66%
yes	155	27,24%
Sum	**569**	**100,00%**

Source: Own study

Fig. 5: The number of answers to the question regarding the application of Industry 4.0 solutions in product sales.

Source: Own study

That is the only area of enterprise operation in which enterprises declare the use of Industry 4.0 solutions.

Based on the responses, a dendritic analysis of the reactions was also performed. The dendritic analysis was used to distinguish groups of planes for using the Industry 4.0 concept, which was internally similar.

The dendrite is obtained from the distance matrix (in the example, the Euclidean distance). The pairs of segments most identical to each other are sought. The construction of the dendrite takes place in several stages. The first stage is searching for each object most similar to it (the shortest distance between elements). The items most similar to each other are presented in the form of a non-oriented graph, i.e., one in which the vertices corresponding to these objects are connected by ligaments without indicating the connection's direction. The lengths of the references are proportional to the distance between them. After checking the consistency, the construction of the graph can be considered finished. If the chart is not consistent, its clusters are combined into larger groups. We connect the clusters assuming the criterion of the minimum distance between sets. By creating sets of order 2 in this way, it is checked whether the graph is consistent. The building process is repeated by creating higher-order clusters. Obtaining a compatible chart completes the dendrite formation process. The diagram obtained from the responses to the planes of implementing the concept Industry 4.0 has been introduced in figure 6.

Fig. 6: Classification dendrite of enterprise planer for the implementation of the Industry 4.0 concept.

Source: Own study

The levels of activity have created two bonds. One is product service, and the other is a warehouse, internal transport, order picking, and product sales. The obtained two ties form two groups of planes that can be characterized. One, which includes: warehouse, internal transport, and order picking, is a product sales group. The second one to which the product service belongs is the after-sales group.

Conclusions

The concept of Industry 4.0 is the inevitable direction of the development of any enterprise. It is crucial and essential that Polish companies also implement the vision of Industry 4.0. It also seems necessary to implement the idea in the SME sector.
The article aims to check the current state of Industry 4.0 solutions in selected areas of the company's activity.

The article consists of two parts. The first, theoretical, concerns the very concept of Industry 4.0. It presents a model of the digital maturity of an enterprise in Industry 4.0. The second part presents empirical research. The research was conducted at the turn of 2019 and 2020 among Polish enterprises from the SME sector. The company's activity areas were selected: warehousing, product sales, product service, order picking, and internal transport. It seems that these are the critical areas of activity of enterprises belonging to the SME sector. In these areas, enterprises were asked to specify to what extent they implemented Industry 4.0 solutions.

The analysis of the responses indicates the areas that Polish enterprises invest and those that are underinvested. Internal transport, order picking, warehouse, and product service are those areas in which enterprises from the SME sector do not implement Industry 4.0 solutions. Only the sale of products is the area in which Industry 4.0 solutions are implemented. The conducted dendritic analysis allowed to select two groups. One is product service, and the other is a warehouse, internal transport, order picking, and product sales. The obtained two groups of planes can be characterized, taking into account the process of selling products. One, which includes: warehouse, internal transport, and order picking, is a product sales group. The second one to which product service belongs is the after-sales group.

Abstract

The paper considers the problem of forming the network of transport and logistics centers in the territory of the Russian Federation as the foundation for transport and logistics infrastructure. Special attention is paid to the legal and regulatory framework of building this system. The authors analyze characteristics of transport and logistics centers, list the network of the existing centers located on key haulage routes. The experience of building such centers helped work out a strategy of development of transport and logistics infrastructure in the Russian Federation, which is aimed at building up other centers in all federal areas. It is noted that their location is in line with the system solutions of the "Concept of creation of terminal and logistics centers on the territory of the Russian Federation" developed by JSC RZD ("Russian railways"). Following the above-mentioned strategy, most of these centers will serve the transport and logistics systems of trade and freight movements in the international "North-South", "East-West" transport corridors, including the China-Mongolia-Naushki-Trans-Siberian trunk line. Consequently, the paper considers problems and development prospects of the transport and logistics infrastructure in the Republic of Buryatia. The authors highlight that currently the cooperation prospects between the three states in creating the integrated transport and logistics infrastructure within the program of the "Russia-Mongolia-China" economic corridor are related to formation and development of the ecosystem of the single Eurasian digital transport and logistics platform.

Keywords: Transport and Logistics System, Transport Infrastructure, Economic Corridor, Ecosystem

Introduction

In order to solve tasks, which aim to develop the unified strategy of logistics development, the Russian government passed a number of laws. Among them one of the most significant is a Comprehensive Plan for the modernization and expansion of trunk infrastructure in the Russian Federation (CP) for the period up to 2024 (the order of the Russian government dated September 30, 2018, No. 2101-p).

The foundation of the strategy of Russia's transport and logistics system in compliance with the federal project "Transport and Logistics Centers" (FPTLC) as a CP component, represents capacities of the TLC network (CP, 2018).

Cite this Article as: Nadezhda BULATOVA, Dmitriy RODIONOV, Alexey BATAEV , Alexey ALEXEEV and Darya KRYZHKO " An Issue of Formation and Development of Transport and Logistics Infrastructure in The Russian Federation " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Within 5 years the purpose of FPTLC is to set up transport and logistics centers for serving “East-West”, “North-South” transport corridors. This TLC network stipulates that transit, export-import and inland regular (scheduled) intermodal (container, piggyback) and high-speed freight linkages will be established on key routes (CP, 2018).

About Transport and Logistics Center

All TLCs which comprise the backbone network are defined as “dry ports” by the UNESCAP Intergovernmental Agreement, approved by the order of the Russian government dated October 31, 2015, No. 2209-p).

According to the current federal project a Transport and Logistics Center (hereinafter referred to as TLC) is interpreted as a multimodal technological complex network, its major elements are the following:

- intermodal terminal (container, piggyback transport),
- terminal for general, bulky and heavy cargo (optional),
- universal warehouse complex, including low-temperature storage (optional),
- customs clearance center,
- business center.

In combination of all these elements TLC represents a base element of respective freight transport and technological systems.

At present the Russian Federation has had experience in establishing TLCs, located on key freight routes (table 1).

Table 1: Existing TLC network

Name	Region	Year of launch	Investors	Characteristics
«Vorsino»	Moscow, Kaluga region	2014	«Transcontainer freight village Kaluga» (owned by Dutch Schlund Immobilien Finanzierungs undBaumanagement B.)	Terminal capacity is 350,000 TEUs per annum, planned extension to 500,000 TEUs per annum. In 2018 the TLC processed 125,100 containers.
«Khovrino»	Moscow	2014	«Logistika KS»	The terminal was constructed with the site for 7,000 containers, and access routes. The expected capacity after completion is 2.5 million tons per annum.
«Doskino»	Nizhny Novgorod region	2014	RZD (Russian raiways)	The project is partly implemented in 2012-2014: the auto transport terminal was constructed at “Doskino” station. The TLC was expected to be the backbone for construction of HSR lines.
«Vostochny»	Moscow, Moscow region	2018	«Obltransterminal»	The first phase was launched in March 2018, it is expected to handle 200,000 TEUs per annum.

** TEU (Twenty Foot Equivalent Unit) is the capacity unit of a shipping container.*
Data source: SPARK Logistics company

Additionally, the development strategy for the transport and logistics infrastructure of the Russian Federation pre-plans construction of other logistics facilities till December 31, 2024 (table 2):

Table 2: Pre-planned TLC facilities

№	Objects	Location	Goals
1 1	Two objects of the federal TLC backbone network	Central Federal District	Ensuring consumption and redistribution of freight traffic of Central Russia, servicing freight flows of the international "East-West", "North-South" transport corridors.
22	One object of the federal TLC backbone network	Northwestern Federal District	Ensuring transshipment of freight flows to/from the destination ports of the Baltic sea, servicing freight flows of the international "East-West", "North-South" transport corridors.
33	Two objects of the federal TLC backbone network	Far Eastern Federal District	Ensuring transshipment of freight flows to/from the destination ports of the Far Eastern basin, servicing freight flows of the international "East-West", "Primorye-1" transport corridors, transit of goods between China and Europe, servicing East Siberian regions.
44	One object of the federal TLC backbone network	Volga Federal District	Servicing Volga regions, freight flows of the international "East-West", "North-South" transport corridors, development of inland waterways.
55	One object of the federal TLC backbone network	Southern Federal District	Servicing freight flows of the international "North-South" transport corridor, ensuring transshipment of freight flows to/from the destination ports of the Azov and Black sea basin.
66	One object of the federal TLC backbone network	Ural Federal District	Servicing freight flows of the Ural industry and the international "East-West" transport corridor.
77	One object of the federal TLC backbone network	Siberian Federal District	Servicing Siberian regions, freight flows of the international "East-West" transport corridor.

Source: CP, 2018

Structural planning requirements for TLCs, topology of their placement and the program of their expansion to the promising testing ground for regular container trains comply with the main system solutions of the "Concept of establishment of terminal logistics centers on the territory of the Russian Federation" (2012) and the "Concept of organization of piggyback transportation (JSC RZD)" (2013).

These are the railways that underpin the TLC network. JSC RZD along with other investors implement this large-scale project of establishing hubs/ terminal logistics centers in Russia. They are components of international railway corridors, which will allow RZD to serve railway and road freight traffic along the route EU – China - Asia-Pacific region. All the objects of the network of hubs/ terminal logistics centers will be connected by regular container trains

All the TLCs of the backbone network will work by meeting the unified standards, which are the following:

- uniform terminal and warehousing technologies: handling/processing complete trainloads (71 conventional cars);
- specialized innovative rolling stock for intermodal and high-speed cargo transportation;
- uniform solutions within the framework of the Digital Platform of the Transport Complex for providing the customers (consignors and consignees) with up-to-date comprehensive logistics services, and with an opportunity to order them online;
- uniform "terminal-to-terminal" transportation technologies, permanent freight trains;
- cargo clearance, including customs clearance, on the TLC premises (Rezer, 2012).

Currently, at the first stage of the TLC network all the objects are designed technologically, i.e. development of layout solutions, evaluation of an opportunity to connect to the external transport infrastructure, determination of the need for land resources, etc.

Table 2 shows that most TLCs under construction will serve transport and logistics systems of freight and goods movements in the international "North-South", "East-West" transport corridors, which include:

1) Trans-Siberian railway with access to Vladivostok, and then other states of the Asia-Pacific region;

2) China (Manchuria) – Zabaikalsk – Chita – Trans-Siberian railway;
3) China – Mongolia – Naushki – Ulan-Ude – Trans-Siberian railway;
4) China – Kazakhstan – Russia (several railway lines with access to Orenburg, Kurgan etc.) – Central Eurasian transport corridor;
5) Indian ocean – Iran – Azerbaijan – Russia – "North-South" transport corridor.

The largest railway hubs/ terminal logistics centers for handling container cargo are to be created in the Russian territories bordered by China, Kazakhstan and Mongolia.

Such territories comprise the Republic of Buryatia, which shares a border with Mongolia in the south with further access to transport communications of China.

Currently, Russia, Mongolia and China are involved in the joint program of creating the Economic Corridor, agreed by these states at the SCO Summit in 2016 (Bulatova, 2019).

The program of the Economic Corridor

The program of the Economic Corridor became feasible after signing the following crucial intergovernmental documents:

1 The governments of Russia, Mongolia and China signed and ratified the Intergovernmental Agreement on International Road Transport. The parliament of Mongolia ratified it in April 2018.

2 At present Russian, Mongolian and Chinese experts are developing transport schemes and comprehensive feasibility studies for cross-border transportation and construction of transport infrastructure facilities throughout the Asian road network using the route AN-3: Ulan-Ude (Russia) – Ulaanbaatar (Mongolia) – Beijing (China) (fig. 1). This implies an increase in the trade between these countries, a rise in investments, development of tourism infrastructure. This transport corridor is an object of the transport infrastructure during the construction of the Northern transport corridor of the Silk Road – the "Great Tea Road" China-Mongolia-Russia. The given project will become the platform for a strategic partnership between the states.

Fig. 1: Transport schemes of the economic corridor China – Mongolia – Russia to Lake Baikal

Special attention should be paid to development of the border infrastructure in the Republic of Buryatia as an element of the transport and logistics infrastructure. Thus, in compliance with the federal project "Logistics of the International Trade"1.5 trillion rubles from the federal budget will be invested into development and reconstruction of the border

checkpoints in Naushki, Kyakhta and Mondy in the period 2019-2023. Development of this infrastructure will enable increasing the capacity of the border checkpoints and the additional income to the regional budget.

At present the daily capacity of Kyakhta checkpoint amounts to 500 vehicles, including 50 buses, 350 cars, 100 trucks, and 1,500 individuals, whereas after the reconstruction the capacity is expected to be 1,000 vehicles, i.e. 700 cars, 100 buses, 200 trucks, with a number of individuals up to 3,000 per day. Today's capacity of Naushki checkpoint amounts to 22 trains per day in both directions, whereas after the reconstruction a number of trains is expected to ride from 70 to 80 ones.

In such conditions the Republic of Buryatia has an urgent task to form the comprehensive transport and logistics infrastructure, the main elements of which are warehouses, terminals, transport and logistics centers that serve international freight traffic, representing strategic points of the regional economy growth.

However, the Republic of Buryatia does not have a comprehensive network of logistics centers, which hinders the growth of its transport and communication system.

Due to this, the Republic of Buryatia is setting up a uniform register of investment projects for the construction of transport and logistics centers on the basis of its Regional Governmental Development Fund. In accordance with this register, the Republic of Buryatia plans to build a network of logistics centers (table 3). Depending on industries, the Republic of Buryatia is going to differentiate transport and logistics centers, trading and distribution centers, customs and logistics centers, multifunctional logistics centers, which altogether will be the foundation for forming effective logistics delivery schemes for different transport and for different cargo transportation. It is more expedient to locate transport and logistics centers in accordance with territorial and regional principles.

Table 3: Planned TLC facilities in the territory of the Republic of Buryatia

No.	Title	Location	Purpose
1	Customs and logistics terminal	Naushki, Location: Khoronkhoi village 50 km	For the service of rail freight transport along the route China-Mongolia-Russia, Russia-Mongolia-China
2	Customs and logistics terminal	Kyakhta Location: in the territory of the auto-tourist cluster "Kyakhta" and adjacent border crossing "Kyakhta" within the ASEZ "Buryatia	For handling cargoes from Mongolia and China to Eurasian Economic Union states. For construction and maintenance of tourist and recreational facilities.
3	International transport and logistics center	Gusinoozersk Location: on the premises of the Industrial Park «Gusinoozersk town», Selenginsky district, Republic of Buryatia	For the organization of freight from China via Mongolia to Russia, and to Europe, including cargo transshipment for further rail transportation.
4	Multimodal transport and logistics center	Ulan-Ude Location: on the premises of the International Cargo Airport "Baikal"	For the concentration of air freight; For flight support on Trans-Siberian and Cross-Polar air routes; For creation of a Logistics center for freight traffic distribution; For creation of special economic port zone.
5	Terminal and logistics complex	Ulan-Ude Location: on the premises of the "Taltsi" Cargo Yard of the East Siberian Railway	For the service of rail freight transport along the route China-Mongolia-Russia, Russia-Mongolia-China
6	Production and logistics center	SULFAT Location: on the premises of SULFAT Station, Selenginsky district, Republic of Buryatia	For the production and processing of solid hydrocarbons, and fuel and lubricants; For the organization of assembly production of equipment and complex household appliances

7	Production and logistics industry complex	East Baikal Forestry Company	For the organization of wood processing, logging and deep processing of roundwood, sawlogs, and pulpwood, including wood waste
8	Branch branded logistics complex	Ulan-Ude Location: on the premises of JSC "Ulan-Ude Aviation Plant"	For the warehouse management within the framework of digitalization in production
9	Trading and distribution logistics centers	Ulan-Ude Location: on the premises of "Titan Company" Ltd.	Operational trading and distribution logistics centers of the wholesale trade

A number of the proposed TLCs in the territory of the Republic of Buryatia near the border between Russia and Mongolia, Kyakhta town to Ulan-Ude are being established to implement the program of the Economic Corridor "Russia-Mongolia-China" (in table 3 these TLCs are marked in points 1-5)

Currently, all objects of the first stage in the TLC network have the following technological concepts implemented:

- layout solutions have been developed;
- the possibility of the connection to the external transport infrastructure has been evaluated;
- needs for land resources have been identified;
-maximum proximity to the center of mass freight traffic emergence and/or cessation has been taken into account;
- availability of sufficient trackage, capacity resources has been determined;
-availability of free engineering capacities in the zone of the pre-planned placement of TLC facilities has been checked;
- maximum proximity to the urban agglomeration, availability of distribution capacities have been taken into account.

The Republic of Buryatia has a deficit of appropriate warehouses equipped for common logistics operations. Therefore, facilities of trade and cargo yards, located along the rail branch lines, are used as terminals and warehouses (Klimenko). Today it is the "Taltsi" cargo yard that provides opportunities for the formation of a major multimodal transport and logistics center. This cargo yard is characterized by a wide range of facilities for cargo processing, warehouses, access roads, operational work. The available facilities of the "Taltsi" cargo yard can enable creating comprehensive production structure, typical for any multimodal TLC which includes: container, piggyback, universal terminals, customs clearance point, service center, administration center, business center etc.

At present the government of the Republic of Buryatia consider the investment object of constructing a multimodal transport hub on the premises of "Baikal" airport as preferable. However, this project has some barriers to implementation. "Baikal" airport is not directly connected with the railway, the fuel depot is expected to take at least 100 ha, the international hub is expected to take 300 ha, the glide path is over residential areas and settlements.

Unlike "Baikal" airport, there are no above-mentioned barriers in the airport of the city of Chita, but the airport does not have the Clear Sky status. Nevertheless, the Trans-Baikal territory stakeholders are working on the proposal to the Federal program of the Far East development to set up a multimodal hub on the premises of the local airport.

However, it is crucial to take into account that when forming a major transport hub on the premises of the airport, "Baikal" airport is currently not competitive with the recognized leaders in cargo and passenger transportation, i.e. "Tolmachevo" airport (Novosibirsk) and "Yemelyanovo" airport (Krasnoyarsk).

As a member of the working group attending special sites for TLC location, the Chinese counterparts suggest setting up this hub near Orongoy village, taking into account the proximity of a highway and a railway line to Mongolia. This choice is rationalized by the single management of all three components. Therefore, the task to construct a multimodal transport hub that converges air routes with the road and railway connection, including development of the port free trade zone with digital transport logistics, is feasible only in this area.

The prospects of cooperation between Russia, Mongolia and China within the Economic Corridor in the transport and logistics sphere are related to formation and development of the ecosystem of the single Eurasian digital transport and logistics platform. Creation of this platform will ensure optimization of interstate commodity flows, more rapid capital turnover, synchronization of payments and documentation at the expense of concentration of commodity, information, and financial flows in combination with higher quality of logistics services. It is the platform that can

help facilitate the cargo transit throughout the territories of the above-mentioned countries, which will be an incentive for digital cooperation with other states of the Asia-Pacific region (Klimenko).

Conclusion

When it comes to digitalization, China and some other countries have great experience in dealing with it. Russia is also experienced in it. For instance, JSC RZD developed a number of digital platforms, which will have been completed by 2025. These platforms are "Freight transportation" electronic platform, digital platform of customer services of transport and logistics hubs, passenger transportation and customer services etc. Due to this, it is essential to organize joint cooperation, e.g. creation of the "joint center of competencies in IT sphere" (Development strategy of the RZD, 2013).

Thus, the formation of the transport and logistics infrastructure in the Russian Federation by developing the network of transport and logistics centers, also located in the Republic of Buryatia, will ensure centralized management of the system of international cargo and commodity movements. Besides, the usage of digital technology elements will allow creating a single digital transport and logistics environment that can provide effective interaction between all stakeholders of transport and logistics processes. Therefore, at present it is required to develop digital servers for the interaction between all stakeholders of the single transport and logistics environment, coordination of transport flows, integration into the global transport space and big data processing.

Artur WLODARCZYK
Poznan University of Technology, Faculty of Engineering Management, Poznan, Polandy, Artur.wlodarczyk@doctorate.put.poznan.pl

Abstract

The deployment of innovative solutions in enterprises is a key contributor to sustainability in a production environment. Amidst other members of the European Union, Poland comes across as a poor innovator. In a 2020 ranking, the country came in the 24th place, close to the bottom of the listing. The authors outline a range of aspects of new technology deployments in production with a focus on the ceramic sanitaryware industry. Due to the sector's high barriers to entry, additional problems may be encountered in adopting innovation and seeking to achieve sustainable production. In their paper, the authors present the cost of deploying and using an automated high-pressure casting process with specific costing figures expressed as a percentage of the costs of using the existing low-pressure-casting technology. By comparative analysis, they identify the parts of the new solution that will add extra costs. To offset such cost increases, a number of other aspects of the proposed solution (expected return on investment, improvements in working conditions, etc.) are also presented. Finally, recommendations are offered for further studies and final roll-outs of innovative solutions in manufacturing.

Keywords: Sustainable Manufacturing, Innovation, Ceramic Sanitaryware Industry.

Introduction

By designing and conducting production, humans exert a significant impact on the environment. Its implications are not only what results from sourcing the raw materials intended for use as process inputs but also the waste they generate (during and post production) and the impairment of worker health that they cause (occupational ergonomics).

Since sustainable manufacturing goes beyond innovation alone, the authors have chosen to focus on a case study that explores potential improvements in the manufacture of ceramic sanitaryware and ceramic bathroom products. The paper presents factors that make the replacement of the existing technology advisable in financial terms and outlines selected performance indicators expressed as percentages.

Innovation in the context of sustainable manufacturing

According to Encyklopedia Zarządzania (The Encyclopedia of Management), innovation (from the Latin word innovatio for renewal) is "a series of activities designed to develop new and improved products, technologies and organizational systems. The term was first used in economics by J. A. Schumpeter (...). "Innovations may apply to developing new products, new technologies, or new markets or to acquiring new raw materials or reorganizing a specific sector of the economy [mfiles…]." Innovation can be considered an outcome of a creative effort aimed at modifying an organization or society with respect to products, processes and management. Innovations are deliberate actions that are commonly intended to maximize profit, enhance development or boost prestige [Łunarski, p. 12; Manikowski A., p. 271]. According to the European Foundation for Quality Management, "innovation is a practical transformation of ideas into new products, services, processes, systems and social interactions. It produces a new revenue streams that benefit owners and sustain growth. Innovation creates jobs, improves the quality of life and supports the continuous development of communities" [European Foundation for Quality Management, 2005, p. 5].

On the down side, the promoters of innovations tend to encounter numerous barriers that hinder growth. Such barriers relate to supply (access to new technologies, raw materials, knowledge, etc.), demand (customer needs and behaviors), and environments (economic and legal/legislative environment), including internal organizational environments (people, physical resources, finance and information) [Knosala R., Deptuła A., p. 113, 2018 [as cited in:] Baruk, 2009; Saatçioğlu, Timurcanday, Özmen 2010].

Cite this Article as: Anna K. STASIUK-PIEKARSKA and Artur WLODARCZYK" Innovation in The Pursuit of Sustainable Manufacturing" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In order to become globally competitive, companies need not only to keep their costs to a minimum but also, and increasingly so, make a deliberate effort to protect the environment and ensure sustainable development and, more specifically, sustainable manufacturing.
Coined originally in the 1970s, the term "sustainable manufacturing" ties to the definition of "clean manufacturing". In the so-called Brundtland Report of 1987, "sustainable development" is defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" [https://www.parp.gov.pl/storage/publications/pdf/2011_wzp_analizadanych.pdf, p. 5 [as cited in:] Report of the World Commission for Environment and Development, 1987]. "Cleaner manufacturing, in turn, means 'environmental strategies based on continuous, integrated, preventive actions concerning processes, products and services, aimed at increasing manufacturing and service efficiency and mitigating threats to both humans and the natural environment" [https: // www. parp.gov.pl/storage/publications/pdf/2011_wzp_analizadanych.pdf, p. 30]. A set of manufacturing guidelines referred to as "sustainable manufacturing" has been developed on that basis.

The Polish Agency for Enterprise Development (an incorporated state organization which reports to the Minister of Economy and manages Polish and European Union funds supporting SMEs and human resource development) defined sustainable manufacturing as "the manufacturing of goods and the delivery of services that:

1. relies on non-polluting processes and systems (to reduce environmental contamination),
2. seeks to conserve energy and raw materials,
3. is economically viable,
4. is safe and poses no threat to human health,
5. socially and creatively benefits all workers [https://www.parp.gov.pl/storage/publications/pdf/2011_wzp_analizadanych.pdf, p. 30]. "

In embracing sustainable manufacturing, due note should be taken of the accompanying process of poly-optimization (also known as targeted vectoral optimization) in which a set of variants is defined and an acceptable and satisfactory solution is identified (by solving the so-called satisfaction problem) [Tarnowski W., 2011, pp. 11-12].

In October 2019, the United Nations Environment Program (UNEP) adopted its first strategy for engaging the private sector. The strategy guides the engagement of the UNEP with the private sector to contribute to sustained transformative changes and innovations aligned with its Medium-Term Strategy and Program of Work by 2025. The following four pillars of that strategy have been distinguished [https://www.unep.org/resources/factsheet/strategy-private-sector-engagement]:

1. Impact on Sustainable Development Goals and environmental goals (measurable and quantifiable).
2. Transformative changes of industries and sectors (cultural change and new business models).
3. Innovations leading to solutions on sustainability.
4. Resources and income to scale up and accelerate the momentum towards a sustainable future.

The above-mentioned activities appear to be vital for Polish enterprises, which tend to display a great deal of reluctance towards adopting innovations in their business. Poland is in the unfortunate position of ranking 24th out of 27 European Union member states in the European Innovation Scoreboard 2020 published by the European Commission [https://ec.europa.eu/docsroom/documents/41903]. The areas in which Poland fares best relative to the EU are the average annual change in GDP, the number of newly established undertakings and the share of manufacturing jobs in national employment. The key areas in which Poland lags behind the European Union are the share of R&D spending, per capita GDP and attributed to its top enterprises as well as the proportion of jobs contributed by high-tech and medium-tech manufacturers [https://ec.europa.eu/docsroom/documents/41886]. This demonstrates that, in pursuit of sustainable future, there is a great need for proper support for every innovative activity.

Case study

The case study concerns an enterprise that belongs to an international group of companies specializing in sanitaryware technology. The case study focuses on a large manufacturing facility dedicated to the production of ceramic sanitaryware.

The organization's industry is characterized by high barriers to entry. For the purposes of this study, the authors adopted the following premises regarding the operating conditions that are indicative of such barriers:

- immense capital expenditures,
- manual tasks accounting for a substantial share of processes,
- difficulties encountered in keeping the process stable (every unit the company produces requires a thorough quality inspection; non-compliant rejects are no longer usable and must be scrapped),
- the fact that only a minuscule proportion of school graduates qualify to work in the industry.

The study has convinced the authors that the above-mentioned features make operators from this particular industry the most representative of the general field of innovation and sustainable manufacturing.

In its classic variety, the manufacturing of ceramic products consists in thoroughly mixing the right raw materials followed by forming, drying and firing (in single or multiple cycles). The resulting compound is then sintered in a furnace at a high temperature to produce a product of desired density. The density is substantially lower than that of the raw material due to the removal of water through heat treatment. A more detailed description of the forming process is provided below.

Plaster casting is the most popular method of sanitaryware casting. A ceramic product is made by forcibly casting a water-soluble suspension of powder into a plaster mold, which removes liquid from the suspension by capillary action operating through plaster pores. The resulting product is well-suited to undergo drying, glazing and firing. Next to its advantages, the process has many drawbacks, the upmost prominent of which seems to be the fact that large-scale production requires vast production facilities and a great number of plaster molds (the molds have a short life and need to be replaced frequently). Figure 1 shows plaster molds and semi-finished products.

Fig. 1: Low-pressure-casting line in the facility in question. Source: Own research

Conventionally, ceramic production requires the manufacturers not only to frequently replace molds (which constitute waste) but also to manually produce and handle mold replacements. As a consequence, the organization in question has chosen to look into alternative solutions involving high-pressure casting. In such casting, instead of conventional plaster molds, use is made of molds made of porous resin. In this system, raw materials are injected at high pressure (in excess of 3.0 MPa). The casting cycles are shorter than in the low-pressure-casting equivalent, with capillary forces operating at pressures of 1-2 bar (0.1-0.2 MPa). High-pressure-cast products are automatically demolded and moved to dryers. They are then subjected to fully-automated working performed by robots with the use of customized cleaning tools. Figure 2 depicts a typical high-pressure casting machine.

Fig. 2: HPC machine performing high-pressure casting. Source: http://www.sacmimoscow.com/en-US/Products/Ceramics/Sanitaryware/Casting/High -pressure-casting-plants/Casting-plants-for-WCs-and bidets/AVB150.aspx?idC=62415&idO= 19748&LN=en-US

In order to lower costs and achieve a more sophisticated, efficient and sustainable process, the company examined a new High Pressure Casting (HPC) solution as a possible replacement for its existing low-pressure plaster casting technology. The flowchart in Figure 3 below shows the steps it took to deploy this innovative variant.

Fig. 4: The process of developing a new solution in the organization in question, Source: Own research based on company records

Figure 4 summarizes the main steps taken in developing and assessing a new solution in the enterprise in question. The process begins with an innovative idea (concept). This stage involves defining the prime objective and identifying the available options for accomplishing it. Next comes the stage that involves project management during which the proposed changes are assessed for business viability. At this point, one completes a costing spreadsheet in which costs are assigned to relevant cost items (such as shipping, storage and personnel). The following stage of profitability

analysis is designed to develop recommended solutions. This triggers a corporate controlling procedure designed to involve the management in a discussion of options. At this stage, data is checked for reliability followed by project approval for implementation.

To provide a specific example, the authors looked at the annual cost of producing a product called PX by the methods of both conventional and high-pressure casting (HPC). The two technologies were then compared. A conventional casting machine may comprise 14 mold sockets. In the ensuing analysis, a calculation for the HPC process performed on a machine fitted with only a single socket was compared with that of the conventional process to determine how many molds would be needed for process completion. On the assumption that 200,000 units would be produced annually, a presentation was made of all process-related costs such as personnel expenses, materials, changeover times, maintenance, and utilities. The relevant data, expressed as percentages (with the existing baseline costs representing 100% and the changes resulting from innovation constituting a share of that initial benchmark in a given category) are provided in Table 1.

The capital expenditures and one-off costs incurred in implementing the innovative solution, shown on an annual basis, amounted to 136.13% of the capital expenditures and costs of the solution that is currently in place.

Table 1: Total current cost of operating with the existing technology compared to the costs of using an HPC machine in production

Ø Annual cost of	Variant 1: Conventional casting	Variant 2: HPC	Difference
Materials	100%	35.48%	- 64.52%
Non-production workers in receiving, warehousing, purchasing	-	100%	-100%
Maintenance (internal & external)	100%	26.67%	- 73.33%
Set-Up	100%	-	- 100%
Workers in process-related jobs	100%	59.26%	- 40.74%
Waste	100%	77.78%	- 22.22%
Energy	100%	110.72%	10.72%
Total current costs	100%	73.80%	- 26.20%

Source: Own research based on company records

High-pressure casting is 36.13% more expensive than the existing technology. It is notable, however, that this difference only results from capital expenditures and one-off costs. Given below is an analysis of the costs of manufacturing finished goods.

Cost of Materials

The cost of materials required for the production of 200,000 units of the PX product includes those of 2,260 plaster molds that need to be made in one of the facility's shops. Further, the production involves preparing an appropriate plaster mixture, pouring the mixture into a mold, and waiting for the plaster to set. At a later stage, each plaster mold is subjected to an array of manual treatments and subsequently placed in a dryer for 7 days. The innovative solution (Solution 2, HPC) requires the purchase of a porous resin mold capable of withstanding the strains of high-pressure casting of ceramic sanitaryware. The cost of such a mold amounts to 35.48% of what would be spent in the conventional process on all molds needed to produce 200,000 units. Added to this are advantages of creating a more ergonomically friendly workplace that are difficult to measure in monetary terms. Working in a Form Casting unit entails a number of static and dynamic loads. Plaster molds are heavy, some reaching weights of 140 kg. Although the plant's machinery has been continuously upgraded (by, among others, purchasing new equipment to support production and handling), the two variants differ greatly in process duration, the design of the related workflows and the strains brought to bear on worker bodies.

Non-Production Workers in Receiving, Warehousing, Purchasing

The costs of non-production workers that need to be engaged to launch and run production are not included in the first variant of conventional casting. Such costs have to be factored in under the HPC variant. For the purposes of this

study, an assumption was made that automation engineers and programmers will have to work a total of 895 manhours.

Maintenance (internal and external)

In both solutions, maintenance costs include the cost of employing maintenance workers, purchasing and replacing spare parts, running preventive checks, and purchasing oils and other lubricants. Given that high-pressure casting is considerably more complex, such costs are bound to substantially exceed those incurred in the existing solution. HPC costs amount to 374.95% of the cost of the conventional process, which can only be described as a substantial difference. To properly conduct the process in both variants, it is essential to satisfy a number of process parameters such as production facility temperature and humidity as well as compound density and temperature. The HPC unit is a highly sophisticated machine that ensures greater process stability (less waste in the form of substandard products). Automatic production in a high-pressure casting process that includes drying and subsequent working by robots reduces the demand for space on the production floor. Parts of the system need to be lubricated, cleaned and replaced while the machine is running. To maintain process efficiency, each element of the system must operate perfectly. Therefore, it is vital to purchase and put on stock a large number of spare parts that will be available for immediate use if and when needed. Preventive maintenance turns out to be just as critical. The water used in the process needs to be sufficiently pure to ensure that mold micropores do not clog up and perfectly fulfill their role throughout the usable life of molds.

Set up

As mentioned above, in conventional casting, 2,260 plaster molds are required to produce 200,000 units of PX products. A casting bench contains 45 molds, which are filled with the raw material twice a day. The life of such molds spans over 80 production cycles. Thus, for the above output, the plant needs to use a total of 55.6 benches. Three workers are needed to replace a foundry bench. A single plaster mold used for the PX product weighs an average of 70 kg. A total of 174,825 kg of plaster is used to supply all benches. That makes close to 175 tons of material that requires disposal. None of these costs are shown in the study as a recycling company collects waste free of charge. However, it should also be noted that the disposal of such waste is very time-consuming (it involves removing the material from production floor, its subsequent storage, onloading, etc.). Also ignored is the environmental impact. The high-pressure casting variant requires no replacements (hence none of the above costs are incurred). A single mold, which makes up an entire section, only needs to be set up once. As mentioned earlier, the machine can accommodate 14 such molds, each capable of working independently on a different production run. This means the facility is free to make products on any mold as needed as any work section can be closed and/or opened at any time.

Production workers directly involved in process

In the conventional solution (Variant 1), the majority of the cost of production workers directly involved in the process is the cost of the labor of seven casting workers. These are the production workers who remove the product from plaster molds, work the product with high precision and prepare it for subsequent drying. The costs also include the remuneration of 1 casting bench operator tasked with precisely controlling the bench mechanism and delivering and discharging the compound to and from plaster molds under pressure in a timely manner. Meanwhile, Variant 2 (HPC) only involves 5 machine operators. A comparison of the personnel cost across both variants shows that the cost of maintenance personnel in the high-pressure process amounts to 59.26% of the wages earned by workers involved in conventional casting.

Waste

The rate of production defects that result in substandard products coming off the production line is a key process parameter in all sanitaryware ceramics manufacturing. After determining the exact defect rate on a specific model, its profitability and production viability are assessed with a high degree of accuracy. In the case in point, the current defect rate on the PX product was identified as being 9%. Accurate costing of the HPC variant showed a defect rate of no more than 7%. Scrap cost calculations demonstrated that the innovative HPC process would translate that into the savings of 4,000 units of the PX product (with costs reduced by 22.23%) relative to Variant 1.

Electrical Power

Electrical power is a key cost driver in any organization. Although power consumption levels are roughly comparable across the two variants, there is a 10.72% difference in favor of the existing process.

Total Current Costs

A comparison of the above values reveals significant differences in production costs between the existing technology and the proposed solution. Since the success of the surveyed company depends largely on the handling of product

innovation, a number of factors for project success must be considered. The roll-out of a new production process begins with commissioning and startup. A host of innovation-related organizational risks and obstacles that are largely unforeseeable frequently come into play. Despite higher upfront investment in the HPC solution and several types of annual maintenance costs that are also higher, further analysis point to Variant 2 is the one that is more advantageous to the organization. Figure 5 presents the annual rate of return.

Fig. 5: Dynamic profitability analysis (blue: HPC; red: existing solution). Source: own research based on company records

As shown in Figure 5, a full return on investment will be achieved in less than 4 years. Given the premises adopted for the analysis, this shows that the high-pressure casting variant is a more advantageous option. Moreover, Variant 2 offers the company an opportunity to restructure and upgrade its production units.

The HPC solution dispenses with many manual tasks and saves time and expenses associated with handling and environmental stresses, as described above. Work ergonomics is improved by eliminating the need for manual lifting. Improvements in the handling of ceramic products are generally a big challenge due to the brittle nature of both the semi-finished products (in process) and the finished goods. This too works to the advantage of the innovative solution. As an added benefit, the new technology requires less space for its production processes. Compared to the existing variant, the plant will save a significant amount of production floor space in a setup designed to produce 200,000 products. It is also worth noting that the analysis only considered a scenario involving the use of a single mold socket while the HPC machine may have as many as 14 of them.

Summary

Every innovations entails a certain degree of risk having to do not only with the need to modify the existing production process to match its new elements but also the related additional financial expenditures and the uncertainty of how the results will fare in a market economy. The costing analysis for high-pressure casting shows that the technology will increase the plant's production capacity. The new production technology and its new characteristics will not only boost economic performance but also reduce environmental impact. Nevertheless, one should bear in mind that by virtue of being highly sophisticated and complex, the technology adds a number of additional concerns (which include new maintenance requirements, the demand for new worker skills, etc.). By and large, it is equally vital that the nature of the production process employed in the ceramic sanitaryware industry makes it very difficult to embrace new innovative solutions. Considering the plant's current production volume, it is clearly of benefit to adopt the proposed replacement. At this stage of the study, no answers have yet been found on the best ways to integrate the new machine and technology with the existing process environment and on what savings can be achieved by launching successive

sections (sockets). While such aspects can generally impede innovative deployments, the study has shown that the solution in question will nevertheless be of benefit to the organization.

Private sector organizations need to be made aware of resource scarcity and, by the same token, of the need for sustainable production. The point is not only to refrain from generating waste (or to reduce the volume of the waste generated) but also to improve workplace ergonomics and assess the long-term impacts of the entire production system. It is also essential to note that market mechanisms are a major limiting force on innovation. New solutions will only be cost effective and advantageous if the operator finds a sufficient number of buyers for its wares. One should note that customers are increasingly concerned not only with the quality of products but also with their origins and environmental impacts. Inaccurate market research will cause the company that chose to adopt an HPC process to incur major losses.

Abstract

The present phase of capitalism rests heavily on the internationalization of economic entities. Transnational companies are spreading their activity across the world with the use of outsourcing and offshoring. Hence, transnational corporations are building dense networks of connections and fragment their chains of production across national borders. Human capital is a type of resource that attracts their attention to locate their business in a given place. Along with capital there comes a movement of people, either sent by companies to protect their interests or those who or individually initiate their employment in a given place outside their country of origin. These migrants are the most numerous, but also others move to cities and regions which provide various career opportunities. Krakow serves an interesting example of such as city, a major regional seat for provision of new business services. No doubt, the ideas of global economy materialize here leading to the emergence of a cosmopolitan hub hosting professionals of various nationalities and origin. Sadly, the present state of research on mobility and migration misses an important aspect, i.e. we do not know the extent of mobility and costs associated. The available reporting practices neglect those aspects.

This paper focuses on corporate mobility in the context of globalization; the former is materialized by outsourcing and offshoring. By referring to the situation in Krakow, the paper aims at elucidating the transnational dimensions of mobility and attempts to lay grounds for its reporting, both financial and non-financial.

Keywords: Outsourcing, Corporate Mobility, Highly Skilled Migrants, Financial Reporting.

Introduction

The modern mobility in a broad sense is inscribed in the context of globalization, modern cities, and the level of interaction between transnational corporations and the nation state. The above entities materialize globalization: they create, but also deprive individuals of opportunities to act, affecting the space of the labor market, on top of the organization of people's work and lives. It is not only human beings who move, because things, words and other forms with different significance for the people are also mobile, depending on their social position (Salazar 2016). Mobility, however, is something that brings humanity together, and it, in turn, may be linked to travel or tourism grown on the basis of travel. People participate in mobility in a heterogeneous way, through its various forms, i.e. migration, work performed abroad, business trips, tourism, or virtual movements, where strangers encounter one another (Acharya 2016, p. 38). People are becoming nomads, more and more available and reachable to others, while their physical location loses its importance (Benedikt 1991, p. 9). Today's nomadic women and men and their mobility seem to be almost limitless compared to the past (Cresswell 1996, p. 377; Polson 2011, p. 144-146).

Nowadays, mobility is connected with the growing international activity of transnational corporations, which not only produce goods but also provide services in distant places in the world creating transnational supply chains. Thanks to widely understood outsourcing processes, they build complex systems connecting manufacturers and service providers, who employ both local and foreign workforce. Foreign employees move to new locations following internal corporate strategies and the needs of their subsidiaries, but also often on their own, having decided to live and work in a particular place. Interestingly enough, while many authors tend to be inclined towards distinguishing various forms of mobility, including (corporate) labor movements, the available statistics and figures showing them are limited. This is particularly puzzling in the light of the possibility of reporting such mobility for transnational

corporations, which does not seem to be fully exploited. The goal set by the authors is to present corporate mobility against the background of globalization materialized by outsourcing, taking into special consideration the status of reporting on employee movements and indicating the possibility of such reporting.

Modern outsourcing in the global economy

Employee mobility is associated with the international activity of transnational corporations, which produce goods and services in distant parts of the world. What is important is that with the development of data transmission methods, the services have become an important element in the development of numerous economies, just as production had before. The most frequently used tool for this purpose is international outsourcing in its broadest sense.[i] The services provided within its framework belong to the branch of new business services and include (Outsourcing Portal, 2016):

- Business process outsourcing (BPO);[ii]
- Shared services centers (SSCs);
- Information technology outsourcing (ITO);
- Research & development (R&D).

As expected by the report presented by Global Industry Analytics (Adoption of Value, 2020), the global BPO market in 2020 will be worth 220 billion US dollars which means a huge increase in comparison to 2017, when it was valued at 24.6 billion. This involved commissioning additional services, conducting entire business processes for activities considered as fundamental, built on the relationships of those involved to contracts based on durability and trust.

The idea is to move abroad in order to increase innovation while lowering the costs of the operator. It refers directly to the entity as well as indirectly to the country providing and acquiring specific services and processes. As a result, it is expected to bring some benefits to both parties. This does not mean that the links between the way outsourcing is implemented and the risks, costs and competitive advantages of the company are ignored, which affects:

- costs generated by the entity,
- risk level of tasks, functions, and processes separated,
- use of resources held by an entity having an impact on building a competitive advantage (Drzewiecki, 2012, p. 29-37).

For many years, the cost factor was seen as the most important one when deciding to separate processes for external service, however, now this trend is reversing. This is no longer a decisive factor when it comes to choosing the partner with whom the project will be implemented, and the relationship between the service provider and the client is increasingly people-focused, stressing the quality of cooperation and implementation, the simplification of processes, and not just price (Stępniak, 2019).

Today, outsourcing is perceived a long-term bilateral cooperation, where both parties to an outsourcing contract strive to achieve certain benefits. Strong ties of cooperation with outsourcing service providers have become the principle on which strategic outsourcing is based (Marcinkowska 2015, p. 231), which favors the wide use of investments undertaken by external providers, their innovativeness and professional specialist capabilities that would be too expensive or impossible to reproduce in internal conditions (Quinn, Hilmer 1994, p. 45).

This is not a new phenomenon, although its current scale goes far beyond the present possibilities of influencing the generation of economic development in countries and markets. Based on years of experience, it is noted that this trend indicates that developing and transition countries have great potential to attract investment in the provision of e.g., financial and accounting services.

Nowadays, an important aspect of market transformation is the delegation of selected types of services to be provided outside the seat of the company, often, as already mentioned, abroad (Woodcock 2009, p. 334). On the other hand, the effect of such an approach is an increase in competitive pressure while improving the functioning of markets and improving the position of the consumer (Kowalski 2008, p. 8).

As Małgorzata Tyrańska (2015, p.13) points out, outsourcing is a strategic instrument which an increasing number of entities use to increase their productivity and gain a competitive advantage, which is also fostered by faster achievement of market objectives. The main strategic objectives mentioned by economic operators include continuous improvement as a key element (Zarzycka, Michalak 2013, p. 183) resulting from the evolving competitive pressure. Achieving assumed goals more and more often involves the use of resources coming from within the organization,

including human capital, and also from its environment, by means of the latest technologies. This is intended to increase the added value generated by activity (Świetla, Andrzejewski, Szmajser 2014, p. 116-128).
It is clear that customers increasingly focus on getting quality product. The spread of outsourcing is intended to respond to the risks and uncertainties inherent in the functioning of economic operators in recent years (Bauer 2013, p. 347).

One of the important trends that foster the development of global outsourcing is the automation of supported processes, which can significantly affect the change of production processes and employee mobility. Artificial intelligence and Robotic Process Automation (RPA) are increasingly supporting human beings in the performance of their activities. By utilizing the newest technology, the effectiveness of operations increases while reducing workload, minimizing possible errors in the process, and as a result, bringing measurable decrease in the cost of providing services. However, this applies to repetitive processes. The main decisions in the implementation of the processes are still in human hands and this will probably not change in the coming years, resulting in a continuous increase in employment in the industry and the acquisition of new specialized workforce, often from distant countries.

To sum up, outsourcing, which is the basis for high employee mobility, is seen as a comprehensive process aimed at increasing the dynamics and efficiency of the enterprise and achieving better financial results. This is possible by accessing the knowledge and precision tools provided by service providers. Moreover, as it is commonly believed**, for an investor in the business process outsourcing industry, access to qualified human capital resources, both local and foreign, is crucial. What matters especially is knowledge of foreign languages and high industry qualifications. Finally, it is worth mentioning the importance of location, which not only relates to a developed infrastructure, but also to a socio-economic context, such as low unemployment, friendly administration or genius loci.**

Corporate mobility against globalization and internationalization

In the case of mobility, researchers often mention its links with capital, not only in monetary terms but also in the form of human capital[iii], social capital[iv], or metacapital[v] (Jayaram 2016). However, it is worth recalling that the mobility of capital is mainly related to the investment decisions of companies and internationalization. The modern phase of capitalism is characterized by a high degree of capital mobility, and transnational corporations are free to transfer production and service processes between countries.

However, as already mentioned, understanding mobility is aided by the introduction of a category of mobility that connects the moving entities, not just people. This is how modern mobility is understood: as a category of movement and relocation. It is realized mainly in the form of travel and migration, connected with physical displacement, but also with observing, traveling, or experiencing (Urry 2007).

Physical images of mobility presented in this way do not exhaust the spectrum of its contemporary forms, especially as it is strengthened and transformed by progressive digitization. Philip Vannini (2010, p. 111) also draws attention to the so-called modern and symbolic forms of mobility; i.e., imaginary and virtual, which enriched the typology proposed by John Urry (2009), among others.

While the mobility of people is a movement that has been permanently inscribed in the framework of modern societies and economies, there is great diversity in this category: travel, tourism, migration, refuge seeking, expatriation, vagrancy, etc. A similar heterogeneity applies to the mobility of objects as "things in motion" (Urry 2009, pp. 95-97). Goods that create the context in which people live and function, they are consumed through trade, and also in connection with the activity of travelers and tourists, maintaining a link with their place of origin. This original perspective ignores the movement of goods that takes place in international trade, which should be added. Undoubtedly, this journey is macro-structural[vi], with objects moving through exports and imports, associated with transnational production processes, leading to a kind of merging meanings and hybridization of consumer tastes (Ślęzak 2019).

A particular example is imaginative mobility, which is linked to the widespread availability of television and radio sets that create images of reality. The TV set present in the social and physical space has changed the way home space and leisure time are organized. Due to television, as before that thanks to the radio receiver, the world was transformed because the prevailing monotony and apathy, about which Martin Heidegger once wrote (1919), was killed: (Urry 2009, p. 100).

The last type is the extremely fast-growing virtual mobility[vii] which is possible thanks to computers and modern technology. Individuals experience mobility at the same time as computers provide the ability to move around and

contact others without having to move physically. It is therefore reasonable to state that the dematerialization of the medium and is taking place along with the conquest of space and time (Benedikt 1991, p. 9). People's lives are full of technologies changing homes and workplaces, and the organization of human lives and behaviors.[viii] Life has merged with cyberspace, which is inhabited by virtual communities where people and machines interact; communication between man and machine takes place, which is an example of a mental marriage between man and technology (Heim 1991, p. 71). Cyberspace is a world of movement, instantaneous; everything exists in real time and you can be in many places at the same time. In this sense, the virtual journey in cyberspace results from an obvious dematerialization of the medium and the reflection of time and space (Urry 2002, p. 266). People willingly change their location switching between communities, thus becoming digital nomads. Virtual communities are seen as fragile, ephemeral entities that push out the reality of physical space.

Such a broad conceptual spectrum of mobility indicates potential analytical difficulties that materialize around the topic of corporate mobility. This is because corporate mobility is an example of a global phenomenon, typical of the present phase of capitalism and the workspace. It concerns a growing number of people for whom speed and efficiency of travel is important, which is related to their work and seen by many as time spent at work that can be used for work. The situation is slightly different for individuals who decide to stay and find a job as they travel. In this situation it is possible to expose all aspects related to tourism and the experience of new physical and socio-cultural space. It often is the experience that influences the decisions of individuals to stay and find work.

Employment abroad is a feature associated with internationalization and the expansion of transnational corporations into new markets. Foreign investors coming to a new country are not only driven by profit, but they also create jobs for different groups of employees. The game that takes place in negotiations with the nation state[ix] is to create jobs that are in line with the expectations and needs of the state. On the one hand, therefore, there are the needs of a transnational corporation to improve its international competitiveness and, on the other hand, the specific situation in the host country, which offers certain resources, including labor resources, for use. It cannot be ignored that these resources determine the investment attractiveness of a country and its competitiveness in relation to other countries. Resources, as Immanuel Wallerstein shows in the World Systems Theory, are shown by nation states as factors for improving their competitiveness, attracting foreign capital and as a result, a developmental factor. Labor resources in the form of the number of people with specific qualifications, experience, age structure, gender structure, etc. are an example of such a resource, although related factors should also be added, i.e. favorable tax and social expense, and labor market regulations.

However, this does not mean that transnational corporations—investing in countries other than their country of origin—only employ local staff on site. Local employees are usually accompanied by others coming from the head office or other branches or subsidiaries of the corporation or persons coming from abroad, who are employed by the corporation. Therefore, it is reasonable to introduce a kind of initial classification of corporate employees depending on their status in the host country. In this perspective, employees can be divided into:

- local employees from a given host country—they are employed in accordance with national regulations and the accompanying employment packages are typical for the host country;
- foreign employees who came to work in the branch from another country—the conditions of their employment vary depending on their status in the corporate hierarchy, place of recruitment and possibly relocation within the company.

Of course, both international career and mobility types are not homogeneous. Interestingly, with regard to the internationalization of companies, the literature is dominated by a discussion addressing the situation of expatriates and the mobility of highly skilled workers. It is noted that it focuses mostly on expatriates, especially managers and directors, disregarding other categories, e.g. self-selecting/self-initiated expatriates (Richardson and McKenna 2000, p. 209).

It is worth noting that the mechanisms that manage the mobility of corporate workers have a special dimension, as the constraints to which they are usually subject are different from those of typical migrants. Corporate employees are affected by attracting and pushing factors in a slightly different way than other migrants, as they do not actively seek out a new place of residence, but rather face a temporary change of residence proposal from the employer. Attractive factors are much more important for workers who are independently and actively looking for a job in their new place of residence, as their employment decisions are based on the quality of life, the typical local remuneration and the resulting acceptance of working and living conditions in the new place.

Finally, it is worth noting that migration takes place in different directions, both to highly developed and less developed countries. In the case of mobility to highly developed countries, this direction is in line with the movement

of migrants, while in the case of less developed countries, the movement is the opposite and resembles the movement of goods and capital. These can therefore be both high- and low-wage countries, and structurally this mobility is caused by the need for competence and labor resources of a subsidiary or branch of a transnational corporation in the host country. In the case of deputation to work abroad, corporate employees are subject to legal procedures related to the departure and performance of their duties as employees. Thus, in their case, legal movements are observed, which are processes coordinated by HR departments, while in the case of independent expatriates, they are usually self-organized. In general, these movements are temporary in nature due to the fact that such an employee, or the employer on his or her behalf, will apply for a temporary residence or employment permit.

Krakow as a center for outsourcing and mobility

Krakow is an example of a location where globalization is materialized in the form of internationalization, outsourcing and mobility. Compared to the rest of the country and the world, the city occupies a significant position in the global economy. According to ABSL data (ABSL 2019) in the first quarter of 2019, Poland had a total of 1,400 Polish and foreign BPOs, SSCs, ITOs, and R&D centers. These centers employ 307 thousand people. In 2019, 16 service centers launched operations, most of which (80%) were foreign entities. The increase in employment between the first quarter of 2018 and the first quarter of 2019 amounted to 10%, which translated into 28 thousand new jobs, while the overall share of foreigners in all service centers in Poland amounted to 14% (about 35 thousand people) and was showing a growing tendency.

Among the biggest investors in the BPO sector such entities as Capgemini, IBM, Nokia, Comarch, Atos, Credit Suisse, State Street, the Asseco Group, Citigrup and Sii are listed, which employ from 5,000 to 9,000 employees. Key sector jobs were arranged across 50 centers, including 19 where employment exceeded 1,000 people. The 11 largest business service centers in Poland (Krakow, Warsaw, Wrocław, Tricity, Katowice Agglomeration, Łódź, Poznań, Bydgoszcz, Lublin, Szczecin, and Rzeszów) employed 95% of all workforce in the business centers in Poland. In seven major centers, it exceeded 10 thousand people, and in the next twelve it ranged from 1 thousand to 10 thousand. people.

However, for years, Krakow has remained the clear leader in terms of employment in the sector. Approximately 70,000 people are employed in the centers, which accounts for almost 23% of employment in the whole industry. New investors in Krakow[x] include: Caspio, Danish Crown, Havi, Infinity Ward, JIVR, Kimberly-Clark, Kingfisfer, Qualtrics, TE Connectivity, Universal Investment, Varroc Lighting Systems, and Vesuvius. In addition, SpyroSoft has located a new center there as an addition to the already existing one.

Due to such strong market development, according to Tholons data (Tholons, 2019), in 2019, Krakow fell from its position in the ranking from 6th place in 2018 to 11th place (Poland was 15th in 2019 compared to 11th in 2018). Despite this, it is still on a high position in the global ranking of the best business service center locations in the world. Recently, Krakow has risen from seventh place and remains an important city for locating shared services centers in Europe, just after Dublin.

The most popular sectors represented in Krakow include:

- BPO (Business Process Outsourcing),
- ITO (IT Outsourcing),
- F&A (Finance & Accounting),
- HRO (Human Resources Outsourcing),
- RPO (Recruitment Process Outsourcing),
- R&D (Research & Development).

Krakow's high rank is also emphasized by ASPIRE, which points to its role in the provision of business services. On the basis of the information presented by ASPIRE (ASPIRE 2019), it is noted that currently there are over 350 international BPO/SSC and ITO entities operating in Krakow, employing over 80 thousand people, and further growth of their number is expected, which is also conducive to increasing the number of jobs even to 91 thousand in 2020.

This trend is derived from, among others, expansion of city office space. Krakow offers the second largest office market in Poland. Over the last decade, the growth of available office space has quadrupled, which places the capital of Małopolska as the leader regarding its volume. In 2019, the demand for office space showed an increasing trend (already in the first half of 2019 it amounted to 135,000 sq.m), of which nearly 60% was occupied by modern business service centers. (Axi immo 2019).

Moreover, the key to Krakow's success as a center of modern business services is a good communication location, IT support and especially current access to educated staff, which is guaranteed by numerous universities and colleges. The high evaluation of the city has been significantly influenced by the culture capital and the image as well as its investment attractiveness. The latter is a result of the highest number of students of science and IT faculties in the country, and, which is crucial, the innovativeness of the economy, including the market of shared services centers, which has been growing for years (PwC, 2019).

As it is widely known, the assessment of the labor market in a given region is influenced by many important factors, including its educational potential, i.e. access to educated workers. In this context, potential investors assess higher education facilities—the number of universities, the quality of education, and the professional education facilities. A key indicator is the number of students majoring in selected areas. As noted by K. Chowaniak (2019), Krakow received 8.6 out of 10 possible points. This is due to the fact that there are over 160 thousand university students in Małopolska. Krakow produces an average of 50 thousand graduates every year (Antal 2019). Most specialists are educated in the area of finance, linguistics, and IT, which is an irreplaceable database of employees for centers providing services in the field of accounting and finance using the knowledge of foreign languages and modern technologies of service and data transmission. Against other business services centers in Poland, it is best assessed in terms of **overall** satisfaction of the service centers as a place of business (average rating of 7.7 on a scale of 1 to 10). It holds this prominent position thanks to the availability of talent and qualified workforce (Rachoń 2018).

In this situation, Krakow is an analytically interesting case of considering corporate mobility in the largo sense. Unfortunately, the data are divergent, as the data from the provincial office show over 44 thousand foreigners, 26 thousand of whom declare a temporary stay. However, this is only a reference point. The largest number are Ukrainians at 23.7 thousand, followed by Russians (1.5 thousand) and Italians (1.4 thousand). In turn, the City Council estimates that there are approx. 50,000—70,000 Ukrainians residing in the city (Gazeta Wyborcza 2019). The ABSL estimates the employment of foreigners in the sector at 14%, an increase of 4 percentage points since 2018 (ABSL 2019).

Current methods of reporting mobility

However, these analytical problems are only the tip of the iceberg. It is not known from official sources what percentage of employees in the modern business services or other sectors are foreigners. This is not reported, also because citizens of EU countries need not apply for a work permit.

All issues relating to the reliability of both financial and non-financial information are subject to constant evaluation by external and internal recipients. The key to the evaluation of presented reports is their informative value presented to stakeholders. Properly prepared and presented economic information plays a key role in the entirety of the information used at various levels of management, hence the undoubtedly key role of the board of directors supervising its credibility. Information relating to the results of business activities and assets presented *ex post*, whose role is widely known, *ex ante* actions taken by the management board and presented in management and non-financial reporting on both the actions already taken and the planned directions of those actions are of great importance. Human resources policy and personnel management is undoubtedly an important area of corporate responsibility that requires reporting. It is therefore not surprising that the need to report on employee mobility issues is in line with the trend of extending financial statements towards business reports, also often referred to as annual reports (Samelak 2013, p. 115-119).

Analysis of the different dimensions of reporting brings some disappointing conclusions. Firstly, economic entities, certainly subsidiaries of transnational corporations, are obliged to use the entire financial instrumentation, i.e. international accounting standards and national regulations, e.g. American Accounting Practice (US GAAP) or Polish regulations (Accounting Act, Journal of Laws of 2018, item 395 uniform text). These regulations are mainly focused on financial issues, which poses a certain difficulty for carrying out analyses strictly devoted to corporate mobility and international movements of corporate employees.

On the other hand, International Accounting Standards (IAS) do not focus on mobility issues. The review of the 41 of them does not produce any surprising results, as it turns out that issues related to labor matters are raised in only one document. And so, the International Accounting Standard (IAS 19) Employee Benefits[xi] sets out the accounting requirements for those benefits, covering both short-term benefits (e.g. salary, annual leave), post-employment benefits (e.g. retirement benefits), other long-term benefits (e.g. long-service leave), and termination benefits. The Standard establishes principles for recognizing employee benefit costs in the period in which the benefits are received by the employee, and sets out how to measure the different categories of employee benefits (IAS19).

Going further, International Financial Reporting Standards (IFRS) do not focus on employee issues or corporate mobility (IFRS).

The analysis of the structure of the selected consolidated financial statements shows that quantitative issues related to corporate employee flows are absent from them. Issues related to employees in the strict sense of the word appear in two points of the reports, i.e. information on employees and their wages. Such information can be found at the end of financial reports, titled remuneration (e.g. HSBC) or corporate governance, accountability and salaries (e.g. UBS).

The employee section of the reports usually includes information on human resources characteristics, principles of talent acquisition and recruitment, ensuring inclusive working conditions, performance management, employee development, on top of salaries and benefits, or even total remuneration of the top management. For a large part of the entities, there is also information on the remuneration fund and the prizes awarded, as well as the shares held by employees.

One can use the provisions contained in the notes to financial statements. With regard to mobility, in part of the liabilities indirect relationships can be observed, e.g. provision for acquired companies that are usually located abroad. In turn, additional information focuses on the situation of subsidiaries and branches, parent company shares in branches and subsidiaries in different organizational and legal forms.

The non-financial information of a company, including transnational corporations, is subject to various obligations under national and transnational law, such as Directive 2014/95/EU of the European Parliament and of the Council[xii], as regards the disclosure of non-financial information and information on diversity by certain large companies and groups. The European Commission, in its Communication of 26.6.2017, indicates non-financial disclosure requirements for certain large companies with more than 500 employees in order to understand their development, performance, situation and impact (COM 2017).

Poland, like most EU Member States, has implemented the existing minimum requirements under the Accounting Directive for the disclosure of non-financial information. However, there is an increase in the importance of non-financial reporting due to market trends and voluntary decisions of companies[xiii].

Finally, it is worth mentioning at this stage the OECD Guidelines for Multinational Enterprises operating (or established) in countries that have committed themselves to the Declaration. The principles and standards for responsible business conduct in the global context, which are consistent with international laws and standards, are non-obligatory. The guidelines have been updated and extended, in particular to include changes in the chapters on topics important for mobility, i.e. employment and labor relations. There is an emphasis on the principle of equal opportunities, equal treatment and non-discrimination of workers (because of their race, color, sex, religion, political views, national/social origin, etc.). This reference to the principle of non-discrimination relates directly to the conditions of employment, but also to tasks, dismissal, salary and benefit rates, promotion, etc. Importantly, the employment of local workforce and the improvement of their professional qualifications are encouraged (OECD 2011).

A proposal for New Solutions

Corporate mobility and its growing scope clearly require some focus on its issues among various stakeholder groups, both external and internal. Management boards of business entities undoubtedly need this information and are not always willing to disclose it due to the organizational culture of the entity. Undoubtedly, the factors influencing the shape of financial statements are broadly understood cultural and social, political and legal, economic and internal factors, coming from the accounting itself and being a derivative of the system adopted by the management of a business entity. In addition, as indicated by research, e.g. by Rodney Irwin and Allan McGill (2018, p.10), the key factor for confidence in non-financial data indicated by investors was the positive perception and trust towards the company's manager. An important element of non-financial disclosures should be those relating to human capital and therefore also those relating to corporate mobility. It is most often perceived as a factor of impact on generating the value of an economic entity on the market, its relations with the environment or support for conducting a proper employment policy and creating a base of employees capable of implementing selected objectives for transnational entities.

Against this, the following operational solutions could be proposed, which could bring a number of benefits not only in terms of management but also in terms of analysis.

It can therefore be concluded that the IAS19 Employee Benefits is the right place to look for accounting regulations and to expand information related to corporate mobility and its reporting. Short-term employee benefits such as wages, social security contributions, paid annual leave and paid sick leave, profit-sharing or bonuses, and non-monetary benefits (e.g. health care, housing rental, company car and free or subsidized goods or services) for current employees shall be reported. In addition, employee benefits include those to which employees or their dependents are entitled. In this situation, they may be settled by payments (or the provision of goods or services) made directly to the staff members, their spouses, children or other dependents (IAS19). On the one hand, they will apply to all employees and some only to the management on site, on the other hand, they will consist of an employee package, e.g. renting a flat, school fees for children, etc. encouraging employees to relocate to other countries and sometimes cities. An element relating to the number and nature of the movement of employees can therefore be introduced.

Secondly, data related to corporate employee flows can be added to consolidated financial statements. They can be included in the information on employees and their pay, or the section of the reports on employees usually contains information on human resources characteristics. Finally, the provisions contained in the notes to the financial statements can be extended.

Thirdly, it may be proposed to extend existing obligations under transnational law, such as the already mentioned Directive 2014/95/EU of the European Parliament and of the Council, with regard to the disclosure of non-financial information and information on diversity by certain large companies and groups.

Fourthly, the OECD Guidelines for Multinational Enterprises operating (or having their registered office) in the countries that have committed themselves to the Declaration appear to be a good basis for including a broad range of mobility topics, not just employment and labor relations as is currently the case.

---

[i] We do not enter into the issues of defining outsourcing and offshoring.

[ii] Sometimes, the term BPO is recognized to be an acronym for Business Process Offshoring, which is more characteristic of the American usage since the word outsourcing is often treated as selling services overseas.
[iii] Gary Becker (1975) indicates that spending on education, training or health care in their simplest form are examples of investment in human capital.
[iv] Robert Putnam (2000) stresses that social capital, i.e. standards, networks and mutual trust promote cooperation for mutual benefit. However, this approach has been criticized because of the inverse nature of the process. According to J. Urry, it is mobility that contributes to the development of social capital, not the other way around.
[v] Metacapital, according to Pierre Bourdieu (1991), is the legitimacy of the state using its monopoly and physical power to ensure control over the population, the different social areas, or other forms of capital flowing between them.
[vi] Goods are a more correct term than objects, although the term objects are used here.
[vii] In the original division the term of virtual travel was used, but mobility due to its wider conceptual range seems to be more appropriate.
[viii] This phenomenon can be compared to the experience of television decades ago.
[ix] These negotiations were later described in the triangular model of cross-border diplomacy. More in: (Stopford, Strange 1991).
[x] From the first quarter of 2018 to the first quarter of 2019.
[xi] Amended in 2011 and replacing the 1998 standard.
[xii] It replaces Directive 2013/34/EU.

Determinants of Corporate Investments In Innovativeness – Evidence From Central And Eastern European Countries

Barbara GRABINSKA

Abstract

The aim of the paper is to investigate the determinants of investment in innovativeness in the case of companies from the Central and Eastern European Countries (CEECs). To adress the problem of underreporting of R&D expenditure which seemes to be especially evident in emerging economies, we develop a proxy for the intensity investments in innovativeness. We hypothesize that financial leverage is negative and profitability and effectiveness of public support system are positive determinants of R&D. As a proxy for the effectiveness of the public policy supporting investments in innovativeness, we use a composite metric developed by OECD – implied tax subsidy rate on R&D expenditures. Our sample consists of firm-year observations from the period 2010-2018 of large and very large firms from: the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, and Slovenia. These countries besides all being the new members of the European Union from 2004, represent a similar level of economic and institutional development, share the communist heritage and a common set of cultural values. Using panel regression with robust standard errors, we provide empirical evidence supporting our hypotheses. The results of the study may be of interest to policymakers and scholars from emerging markets.

Keywords: R&D determinants, innovation policy, R&D tax subsidies , R&D intensity

Introduction

From policymakers' point of view, investments in innovativeness are considered to be of the utmost value for the economy. It is due to the widespread belief that they drive technological progress and are of crucial importance for the competitiveness of the national economy and create the most desired asset for society. On the other hand, investments in innovativeness are considered to be very risky for companies undertaking them, the outcome is very difficult to predict, and there is always a threat that potential benefits will be inequitably distributed, meaning that they will be accessible not only to the originator company incurring all expenses, but also to external entities, particularly competitors. Alternatively, a company may opt for imitating strategy. The survey studies of Levin et al. (1987) and Mansfield et al. (1981) document that the imitation process, on average, costs as much as 50–75 percent of the cost of the original invention and probably is much less risky. However, from the perspective of the economy, the incremental value is lesser than in the case of the original invention.

Understanding the logic behind the managerial decisions on R&D is of key importance for policymakers interested in increasing the innovativeness of the economy. The issue is especially important among countries ascribed to the group of emerging economies, where usually institutional and legal framework is not effective in defending the proprietary rights of the originator company. The problem is present in CEECs, which lag behind in terms of innovativeness of the economy and as recently Stojacic, Srhoj and Coad (2020) have indicated in the context of catching up economies the implementation of public support instruments needs to be adapted to the unique features of the national innovation system.

R&D is perceived to be distinct from other types of investments. Guidara and Boujelbene (2014) describe them by a high level of uncertainty and informational asymmetry.

Davis (2001) explains information asymmetry by the fact that each R&D project is unique and not repeatable. There is also no organized market for the output of R&D activity or inventions acquired from the innovation process. Finally,

Cite this Article as: Barbara GRABINSKA and Konrad GRABINSKI“ Determinants of Corporate Investments In Innovativeness – Evidence From Central And Eastern European Countries” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

accounting and reporting of R&D activity is, in most cases, discretionary, and in the case of some jurisdictions, different accounting treatments are allowed.

We hypothesize that the specificity of outlays on the company's innovativeness increases information asymmetry, and for this reason, external capital providers are not willing to provide financing. Therefore, we conjecture that a higher debt-to-equity ratio mitigates the level of investments in innovativeness. We posit also that a stable source of financing originated from the company's profitability increases the level of investments in innovativeness. As a result, our second hypothesis states that more profitable companies are more prone to invest in innovation.

We test hypotheses on the sample of yearly financial statements from the period of 2010–2018 of large and very large companies from the CEECs (Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, and Slovenia). All these countries are new members of the EU, on a similar level of economic development. They share the same experience of communist heritage and a fairly similar set of cultural values. All countries are also classified as emerging economies, althought in September 2018 Poland, as a first contry in Europe in the last decade, was upgraded to developed market status in indeces run by FTSE Russell. But they differ in the way they conduct public policy supporting business R&D and innovations. OECD has developed a composite metric – implied tax subsidy rate on R&D expenditures – which we use as a proxy for the effectiveness of the fiscal policy supporting R&D activity conducted in firms. We take this variable to test our third hypothesis stating that the effectiveness of public policy has a significant positive effect on investment in innovativeness on the corporate level.

Using panel regression with robust standard errors, we provide empirical evidence supporting our three hypotheses. We add the contribution to the existing literature by constructing a new measure of the level of investment in innovativeness and by providing evidence for its determinants for companies from emerging markets.

The paper proceeds as follows. The first section presents the literature review on determinants of investments in corporate innovativeness and hypothesis development. Next we demonstrate the research design, sample description, and results of the study. We conclude in the last section.

Literature Review

In empirical research, the innovation process can be measured by input or output measures. Neither of the group is considered to be a perfect indicator of innovativeness of the company. The former ones are usually referred to as R&D expenditures and are expressed in different proxies for R&D intensity as a ratio of R&D expenses to revenues, assets, or employees. The output measures are focused on results of research projects, mainly patent applications/grants, and their properties like a number of citations, citations lag, patent generality and originality, etc. (Koh and Reeb, 2015). The link between R&D outlays and innovation effects is not direct and depends on the effectiveness of the R&D project and the specificity of the entity. Usually, the effects of innovation processes are measured by patent grant/application, because there are probably the only observable effects from a researcher's point of view. However, in many cases, R&D processes are not ending with patent applications, and sometimes entities are not willing to apply for patents, especially in countries classified as emerging economies, where the legal system of patent protection rights is not effective. Policymakers have no influence on the success of the R&D project on the corporate level. However, they may provide some incentives to spur research activity (like tax incentives or governmental support for R&D activity). From this perspective, R&D outlays, as input measures, are more suited to reflect the result of these actions and enable investigation of determinants of research activities.

Empirical research in finance and accounting provides evidence on many determinants of investments in innovativeness. Cumming and Macintosh (2000) classify them into four main categories: legal, market, strategic and firm-specific factors.

The first category addresses the efficiency of the legal system with regard to patent protection. The theory behind postulates that the more efficient the legal system, the more a firm is able to protect benefits derived from research breakthrough, and the more a firm is inclined to invest in R&D (Ginarte and Park, 1997; Versakelis, 2001; Park, 2008).

The second category – market determinants – can be divided into three subcategories: competition, demand-pull, and consumer controversies. Competition refers to the degree of rivalry within the sector. The theory behind posits that there are two types of motivations for R&D spending. The first one refers to a monopolist firm, who wants to defend its position via gradual innovation (more frequent, however less revolutionary innovations, what is defined as efficiency effect) and the second type is characteristic for an entrant, who wants to gain a position of monopolist thanks to a breakthrough innovation (so-called replacement effect). Additionally, Czarnitzki and Toole (2013)

document that the budget of the R&D project is correlated with the level of industry's concentration (the more concentrated an industry, the larger a budget). Levin and Cohen (1985) provide evidence of a non-linear 'inverted U' relationship between R&D intensity and market concentration.

Strategic determinants refer to strategic alliances, which create a situation in which a company may gain required know-how from a partner and, because of that, it is more willing to invest in innovativeness (Vence et al., 2000). The last category od determinants – firm-specific refers to a wider array of factors. Some of them are qualitative characteristics e.g. stage of the firm's development, while others are quantitative e.g. company's size, debt-to-equity ratio, profitability. Within this category, the size of a company is one of the determinants which impact on investment on innovativeness is documented in financial research. However, the results are not unequivocal. Acs and Audretsch (1988) note that the results of many studies might be potentially biased, because usually the sample is limited to public listed companies, which consist of large and very large companies.

The context of the capital market should not be underestimated. Several studies document a positive relationship between R&D investment and market value as measured by Tobin's Q ratio (Griliches, 1981; Cockburn and Griliches, 1988; Megna and Klock, 1993; Parcharidis and Varsakelis, 2010). Investor perception can also be considered as one of the potential reasons for undertaking investments in innovativeness.

Brown and Petersen (2011) investigate another factor potentially influencing investments in innovativeness – the liquidity of the company or, more specifically, the company's cash holdings. They assume that in order to pursue the R&D project, a firm needs to provide a stable source of financing. Shocks in the financing may be potentially very troublesome. Brown and Petersen (2011) argue that especially R&D projects face the problem of so-called high adjustment costs. Workers employed in R&D projects are expensive, but eventual lay-off may cause the risk of dissemination of so far acquired knowledge. Adjustment costs in the R&D project are considered to be much higher than in the case of traditional 'physical' investments. According to Hall (2002), at least 50% of the R&D budget is allocated to the wages and salaries of highly educated scientists and engineers. A company may save substantial 'adjustment costs' by maintaining a stable, smooth path of the financing R&D project. Brown and Petersen (2011) conclude that R&D financing for small manufacturing companies is much less volatile, if companies have cash holding available to use to smooth R&D spending.

Analysis of the literature provides several theoretical reasons why higher financial leverage may limit investments in innovativeness. Several potential explanations are provided. Arrow (1962) was one of the first to note that a gap exists between the expected rate of return of the inventor's firm and the rate of return of external capital providers when innovation investments are considered. Kamien and Schwartz (1978) stated that one of the most important characteristics associated with R&D projects is the necessity for it to be financed internally, mainly from current and accumulated profits. It is especially visible in the case of high-tech companies, which assets usually are very specific. Therefore they have low liquidation value and offer lower collateral to eventual debt lenders. In the case of the R&D project's failure, the originating company is left with few tangible assets of lesser value. As a result, highly leveraged companies are not able to spend as much on investments on innovativeness as less leveraged ones and vice versa highly R&D intensive firms are not able to attract external sources of financing. Secondly, Ghosh (2012) refers to the fact that the volatility of R&D project returns negatively influences the ability of the company to meet the payment obligations of debt agreements. Thirdly, Kamien and Schwartz (1978) state that firms with important R&D projects are reluctant to reveal detailed information about the project that would attract external lenders, being afraid of disclosing too much to potential competitors. This raises the broader problem of information asymmetry and related agency costs (Lee, 2011), what is one of the key characteristics of the R&D project. Information asymmetry between the entity undertaking the R&D project and external capital provider causes the inability of the latter one to adequately evaluate the investment project (its risk and return), and for this reason, capital providers are forced to ask for a higher premium, what increases the cost of capital.

Most of the studies postulate that a higher debt-to-equity ratio negatively affects the intensity of R&D projects. Several studies (Acs and Audretsch, 1988; Himmelberg and Petersen, 1992) provide evidence that in the case of smaller companies, internal financing is a stimulus of R&D innovation. It is explained by the weaker credit position of smaller firms in comparison to larger publicly listed companies. A similar argument is provided by Hall (2002), who concluded that small and start-up firms in innovative sectors are required the higher cost of capital in comparison to the larger companies and companies from other industries. So, in consequence, the question is whether the relationship will hold in the case of larger companies. Ghosh (2012) on the sample of more than 900 Indian manufacturing companies (with the exception of state-owned firms) from the period 1995–2010 provided empirical evidence that companies that use more debt exhibit significantly lower R&D intensity. Additionally, his findings indicated that the firm's internal funds positively influences the level of investments in innovativeness.

As knowledge generated by the innovation process undertaken by companies can be difficult to appropriate and tend to spill over to other entities who did not incur costs of this activity but can reap benefits out of it, the actual level of business R&D is well below the socially optimal level. This creates the space for public policy encouraging enterprises to engage in R&D. Governments have many tools intended to stimulate innovation, among which we can distinguish: non-financial instruments (mainly aiming to strengthen I.P. protection), financial instruments (consisting of direct measures in the form of public subsidies and non-direct measures in the form of tax incentives). The problem of business underinvestment in R&D is particularly evident in the CEE region.

Each form of stimulating innovation process has advantages and disadvantages. Fiscal incentives are addressed to a broad range of recipient firms, leaving them independence on how they spend funds. By reducing the cost of investments in innovativeness, the incentives raise the net present value of undertaken projects. From the point of view of market competition, fiscal incentives, in contrast to direct public subsidies, are not seen as a source of distortion in market competition (IMF, 2016).

Worldwide there is a tendency to use R&D tax incentives as a major instrument for promoting investments in innovativeness by policymakers. As of 2017, 30 out of 35 OECD countries and 21 of 28 EU countries gave preferential tax treatment to R&D expenditures (OECD, 2018). But even countries relying on tax incentives in their research policy can adopt completely different approaches to incentives designs. The diversity of these tax arrangements is a factor hampering cross-country comparisons.

To measure and compare the "generosity" of R&D tax schemes under different jurisdictions, OECD has developed a composite indicator – implied tax subsidy rate on R&D expenditures. The tax subsidy rate is calculated as one minus B index, a measure of the before-tax income needed to break even on 1 USD of R&D outlays (Warda, 2001). Estimates are based on headline tax credit on allowance rates and differentiated by firm size and profitability scenario (https://stats.oecd.org).

Based on the above literature review, we hypothesize that a higher debt-to-equity ratio limits the level of corporate investments in innovativeness also in the case of companies from the CEE region. We argue that innovative activity increases information asymmetry and related agency costs. Therefore, external capital providers are less willing to provide financing for companies investing in innovations. For this reason, the less troublesome source of financing investments in innovativeness is the company's profit. As a result, we posit a second hypothesis that more profitable companies are able to secure a more stable source of financing for innovative activity. Thirdly, we hypothesize that public policy based on R&D tax incentives has a positive effect on the intensity of investments in innovativeness.

Research design, sample description, and results of the study

In many empirical studies, different measures of R&D intensity are used to measure the level of investments in innovativeness on the company level. Unfortunately, in the case of companies from the CEECs, only a small part of them report R&D expenses in the income statement or the balance sheet. This problem can be partly ascribed to the phenomena of underreporting of R&D activities in the financial statements. For this reason, we decided to construct a new proxy for the intensity of investment in innovativeness (INT_INNOV). We define it as the sum of R&D expenses (reported in the P&L statement) and a year-to-year change in intangibles without the goodwill and corrected by the yearly amortization scaled by the total assets from the previous period. Firstly, it is important to stress that amount of the investments measured by our proxy will be visible partly as an increase of intangible asset (without goodwill) resulting from investments, and partly in the income statement (as R&D expenses are the fraction of expenditures, which cannot be capitalized according to accounting regulations). Secondly, the year-to-year change in intangibles encompasses other elements than R&D expenditures like the cost of acquiring new software, licenses, copyrights, patents, etc. We argue that these elements also impact the innovativeness of the companies, and such a measure is a reasonably good proxy for the intensity of corporate investments in innovations in the case of companies from emerging markets.

We are using this variable to test our three hypotheses. In order to avoid the problem of endogeneity in the model, we use lagged values of all variables. In the result, we employ the following model:

$$INT_INNOV_{i,t} = POLICY_{i,t-1} + LEV_{i,t-1} + LIQ_{i,t-1} + TOBQ_{i,t-1} + SIZE_{i,t-1} + ROE_{i,t-1} + IND_{i,t}$$

Where:

$INT_INNOV_{i,t}$ – R&D expenses plus the year-to-year change in intangibles (without goodwill), corrected by amortization and scaled for total assets from the beginning of the period for *i* company in time *t*;
$POLICY_{i,t-1}$ – implied tax subsidy rate on R&D expenditures as measured by OECD in time *t-1* of the country of the origin of the company *i*;

$LEV_{i,t-1}$ – financial leverage of the company *i* in time *t-1* measured as debt to total equity & liabilities;
$LIQ_{i,t-1}$ – liquidity of the company *i* in time *t-1* measured as the current ratio (calculated as current assets to current liabilities);
$TOBQ_{i,t-1}$ – Tobin's Q ratio of the company *i* in time *t-1* calculated as a ratio of market capitalization to total assets;
$SIZE_{i,t-1}$ – the size of the company *i* in time *t-1* measured as the logarithm of total assets;
$ROE_{i,t-1}$ – profitability of the company *i* in time *t-1* measured as return on equity;
$IND_{i,t}$ – industry classification of the company *i* in time *t* (NACE code).
The initial sample consists of 7 668 firm-year observations derived from yearly financial statements of large and very large companies (Orbis database classify companies as large or very large when they match at least one of the following conditions: operating revenue >= 10 mln EU or total assets >= 20 mln EUR or no. of employees >= 150) from the CEE countries (see Table 1). We use the Orbis database to acquire the data from financial statements (firm-level) and the OECD database to collect data on the POLICY variable (country-level).

We decide to use data from large and very large companies because of the higher quality of the accounting data.

Table 1: Firm-year observations by country

Country	No. of observ.
Czech Republic	126
Estonia	153
Hungary	288
Latvia	180
Lithuania	252
Poland	6 120
Slovakia	315
Slovenia	234
Total	7 668

Source: Authors' own calculations based on the Orbis database.

However, due to the lack of data for all variables (missing data for firm-year observations), the final sample is much smaller and consists only of 1 225 firm-year observations of 347 companies. All observations related to companies from the financial and insurance sector were deleted. Additionally, all observations with negative amounts of total assets, equity, leverage, and R&D intensity were deleted. The following variables INT_INNOV, LEV, LIQ, TOBQ, and ROE, were winsorized in order to obtain more robust estimators. Descriptive statistics of variables used in the model are presented in Table 2.

Table 2: Descriptive statistics

Variable	No. of observ.	Min.	Max.	Mean	Median	St. Dev.	Variance	Skewness	Kurtosis
INT_INNOV	2 077	0.000	5.955	0.027	0.002	0.226	0.051	23.560	595.677

In order to determine interdependence between variables, we calculated the correlation matrix (see Table 3), which shows that there is no strong correlation between variables, and we conclude that they can be used in the model.

Table 3: Correlation matrix

Variable	INT_INNOV	POLICY	LEV	LIQ	TOBQ	SIZE	ROE
INT_INNOV	1.000						
POLICY	0.013	1.000

We employ panel regression with a robust option in order to neutralize potential problems with autocorrelation and heteroscedasticity. Hausmann test suggests the usage of panel regression with fixed effects. We test for multicollinearity using VIF (variance inflation factor), and results show that (all VIFs are between 1 and 10), there is no collinearity problem between variables. We also used Ramsey's RESET test for functional form misspecification of the model. The obtained result (Prob > F = 0.0517) suggests that there is no misspecification of the model.

Results of the panel regression show that a higher debt-to-equity ratio is a negative, and profitability is a positive determinant of the intensity of investment in corporate innovativeness. In both cases, the regression analysis is showing statistical significance at 1% level (p-value = 0.000 and 0.004 respectively). In the case of public policy, the results are weaker, but still, there is statistical significance at a 10% level (p-value = 0.064), and the coefficient suggests positive influence. Therefore we positively verified all three hypotheses. However, the argument supporting the last one is not so sound, as in the case of the first two.

Among control variables, there is only one statistically significant - Tobin's Q ratio, and the regression analysis suggests a negative impact on the intensity of investments in corporate innovativeness. Again, the results are supporting the anecdotal evidence that companies from the CEE region are not expected to engage in investing in innovativeness, and even the capital market more appreciate capital than intangible investments.

Conclusions

Investments in corporate innovativeness are one of the key challenges for emerging economies. The goal of the study was to determine the most important factors stimulating corporate investments in innovativeness. The study was conducted on the sample of large and very large companies from the CEE region, representing the highest quality of financial reporting, audit quality, and in consequence, the highest quality of corporate governance. Due to the inability to use one of the popular metrics of R&D intensity, we constructed a new proxy for the intensity of the investments in innovativeness. We used this proxy to test three hypotheses examining the key factors of innovativeness.

The results of the study indicate that external capital providers are not willing to provide financing for companies investing in innovativeness. The output of investments in innovativeness is characterized by increased information asymmetry, which translates into agency problems and then to a higher cost of capital required by external capital providers. In essence, it means that the returns generated by 'innovative' assets created by such investments are much more variable and difficult to predict. If companies cannot use external capital to finance investments in innovativeness, they are forced to rely on their own financing, especially internally generated profit. Therefore, such investments are undertaken mostly by profitable companies. On the other side, in times of financial stress, investments on innovativeness are the first to be cut, which is typical not only for companies from emerging economies.

The study also investigates the influence of public policy supporting investments in innovativeness. The sample consists of companies from eight different countries from the CEE region and the period of nine years. Each country adopted a different policy, which changes in the studied period. Our study uses a composite measure developed by OECD – implied tax subsidy rate on R&D expenditures, which depicts tax profits for companies engaging in investments in innovativeness. The results of the study show that public policy is an important factor influencing the level of corporate investments, and as such, may be of interest to policymakers.

Our study is not without limitations. Chiefly, we do not address a few factors in the model, which can possibly have an impact on the intensity of investments in innovativeness, e.g., ownership concentration, institutional/foreign ownership, audit quality, industry concentration/ competitiveness.

Abstract

The paper discusses the position of mechanical means of restraint in the field of securing municipal buildings and their use. The paper points out the shortcomings in the security of protected objects in the area of perimeter and mantle protection. The aim of the paper is to propose general recommendations for securing the objects of regional self-government, especially in the field of perimeter protection. The recommendations are based on experimental testing of several types of mechanical barriers, the results and methodology of which are presented in the paper. From the tested barriers, the most suitable type for securing the selected objects is then selected. The benefit of the contribution is an increase in awareness of the security of public buildings and the subsequent effective use of funds by local governments to secure their property.

Keywords: Mechanical Barriers, Fence, Testing, Regional Safety, Municipalities.

Introduction

From the legislative point of view, the municipality in the Slovak Republic is a legal entity whose statutory body is the mayor. The mayor is responsible for the administration of the municipality's property, which consists of movable property, real estate and financial resources. We can consider vehicles, mobile phones, information technology and the like as movable property (Svetlík, 2016). The category of real estate includes buildings that are firmly connected to the ground, land, apartment buildings, as well as non-residential premises and other non-residential premises under the administration of the municipality (Svetlík, 2017). The funds of the municipality are receivables and other property rights. Property rights belong to the municipalities on the basis of Act no. 138/1991 Coll. on the property of municipalities and later regulations. This Act stipulates which assets from the property of the Slovak Republic have become the property of the municipality and also regulates the property position from the point of view of property management.

Objects owned by the municipality can be considered all buildings firmly connected to the earth's surface such as the municipal office, sports hall, cultural center and warehouses intended for the technology of the municipality and the like. Most of these buildings are open to the public during opening hours, but some are only accessible to general staff. However, within publicly accessible buildings, it is necessary to control the movement of people, not only the public but also employees (Svetlík, 2016). These buildings are specific in that they store documents with personal data of residents, registry documents and need to be protected from a legislative point of view, but their market value is not high, and it is difficult to sell them (Soltes, 2016; Turecka 2017). Buildings with limited access for employees are characterized by the fact that the material and technology stored in them has a much higher market value. The municipality would suffer higher financial losses in case of property theft. In recent years, municipalities have gradually started to invest funds in the security of their facilities, the funds spent are often too high and the established security system does not provide sufficient protection (Svetlík, 2017; Lovecek, 2013). The paper generally recommends minimum requirements for securing general objects, which are based on exact data obtained by own experimental measurements according to relevant technical standards.

Object Protection System

The system of protection of objects can be understood as "the purposeful arrangement of a set of protective measures and their properties, which are to create a state of security". A protective system is a means of achieving a

Cite this Article as: Filip LENKO, Martin BOROS, Jakub DURICA and Richard JANKURA "Evaluation of Mechanical Security of Regional Self-Government Buildings" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

state of safety using protective measures that lead to the disruption or cessation of activities and events that damage property (Kubas, 2017).

The security system of a protected object is composed using a combination of four basic forms of protection. These forms of protection include:

- Mechanical means of restraint - in accordance with the required security requirements and functions, security elements are implemented in the building protection system to slow down the movement and to prevent access by unauthorized persons.

- Electric alarm systems - are among the active elements of protection. It is an electrical system that responds to manual or automatic detection of the presence of danger. Its purpose is to signal the intrusion, attempted intrusion or unwanted activity of a person in a protected area.

- Elements of physical protection - ensure timely intervention and detention of the intruder. It is the performance of protection of the building and its immediate surroundings by the physical presence of persons.

- Regime and organizational measures - are measures aimed at preparing and creating procedures that will ensure the effective and efficient application of the system of protection of buildings. These include security policies, security guidelines and the division of activities between those responsible (Mach, 2017A).

From the point of view of the financial possibilities of municipalities, it is appropriate to use the right combination of mechanical means of restraint and electric alarm systems when securing buildings. If we want to achieve effective security of property, it is necessary to realize the value of the secured property and to propose adequate security for it (Mach, 2017A; Soltes, 2017A). It is highly inefficient to secure a low value asset with a security system that is several times more expensive. Therefore, the contribution will be further taken by securing the objects of municipalities, which are accessible only to selected employees of the municipality, for whom we assume a higher value of protected interest.

One of the indicators of the need to secure a building is the development of property crime. For the purposes of the article, we will point out the overall development of burglaries in buildings in the Slovak Republic in recent years. The decline is more pronounced in 2020, due to incomplete statistics. The clarity of cases in the area of property crime and burglary into buildings has long been at the level of 30%, which is a low percentage due to the financial losses caused by this type of crime. The decrease in burglaries into buildings is caused by property protection systems, which have a deterrent effect on a potential thief. We can say that these measures have a preventive effect.

Fig. 1 : Statistics of burglary in buildings in the Slovak Republic (Ministry of interior, 2020).

Securing the Selected Object

Ensuring the protection of selected objects of the municipality can be based on several requirements. The subject of protection may be given by generally binding legal regulations (eg the Act on Municipal Property), technical standards, insurance conditions or is based on the conditions of internal organizational standards (owner, operator, legal entity, etc.). Based on these requirements, a system of protection is subsequently created.

The use of mechanical means of restraint can be divided into four basic areas of protection zones, which represent:

- Perimeter protection - ensures security in the vicinity of the protected object, its perimeter, which can be defined by natural (watercourses) or artificial boundaries (fence, wall and others).

- Shell protection - prevents damage to the shell of the building and all its hole fillings. It protects primarily the building openings of the building (doors, windows, etc.) from intrusion by the intruder.

- Spatial protection - is understood as the internal protection of buildings, which provides the internal spaces of protected interest in the building.

- Object protection - ensures the protection of objects in the protected object and objects stored in storage facilities in individual rooms. These are primarily devices designed to protect valuables, documents, cash and other important documents (Mach, 2017B).

Fig. 2: Use of mechanical means of restraint in terms of protection zones

As part of the application of zoning in securing municipal buildings where equipment is stored, it is important to pay particular attention to the perimeter and shell protection of the building. These layers represent the entrance boundary to the external spaces of the building. The task is to discourage or slow down the potential intruder as much as possible.

From the long-term development of the statistics of the Police Force of the Slovak Republic, we can state that the largest percentage of burglaries into any building was made through the front door. When overcoming the door panel, we can most often encounter two possibilities of overcoming them, which are:

- Leverage of the door frame.
- Overcoming the locking system.

In both cases, the intruder first had to overcome perimeter protection. The main benefit of perimeter protection is to clearly distinguish and delimit public space from private space and to keep intruders from overcoming it. The advantage of delaying the intruder in perimeter protection makes him vulnerable, as it is very easily detectable at this stage. After overcoming it, it comes to a shell protection, which is intended to slow it down even more, ideally to discourage it. The purpose of slowing down the intruder is a higher probability of his detection and subsequent summoning of security forces.

Requirements for perimeter and sell protection

The solution of perimeter protection is relatively simple. Most often, it is a fence in which it is necessary to take into account the nature of the surrounding environment, the value of the protected interest, the appropriate location and provision of entrances. It is important to choose the right design. In the area of mantle protection of the municipal buildings, it is especially suitable at the entrance, if it is possible to use security doors, to ensure the required level of security. If this is not possible due to other functional properties, security doors should be used at least in important rooms (Mach, 2017A; Soltes, 2017A).

If these rooms are concentrated on one floor of the building, it is possible to place a security door at the entrance to that floor. Security doors should meet the following criteria:

- all-round frame made of high-quality steel,
- longitudinal and transverse steel reinforcements, welded into a solid structure,
- single-point safety lock,
- safety cylinder,
- internal insulation filling,
- certification of the National Security Office (Mach, 2017A).

The most commonly used locking mechanism is cylindrical inserts. These are divided and certified for security doors into four security classes, according to the design, as well as additional components that increase the overall durability. The market offers a large number of cylindrical inserts with various opening options. It is recommended to use a higher security class for entrance doors to protected rooms or buildings themselves, at least 3. Window panels are often part of the opening panels of protected buildings. However, their weak part is the glass panel placed in the construction of the window frame. Two variants can be used to increase the security and durability of windows. The first is the replacement of old windows, for windows with the so-called safety glazing (Mach, 2017B).

This method is inefficient due to the need to replace entire windows with more expensive ones, along with the work of replacing them. An effective solution is to use security foils, which not only increase the resistance of the glass, but also prevent the glass pane from breaking into large parts with sharp edges. Installation of safety foils is also possible on currently used glasses. In this way, it is possible to increase the resistance of windows to breakage. Security grilles can also be used in areas that serve as warehouses for materials and tools, as only aesthetics are not considered in these places (Vel'as, 2019B).

Recommended elements of shell protection to ensure the safety of the municipality objects

During the design of protection of buildings in the municipal administration, it is possible to proceed from the international standard, which deals with urban planning and design of buildings in the context of crime prevention. This is a standard STN P CEN / TS 14 3838 - 4 Prevention of crime - Urban planning and design - Part 4: Shops and offices. The standard specifies the minimum level of protection that should be applied in the protection of administrative or commercial premises. It then divides the security level into one of five levels, according to the type of object and its activity. According to the standard, administrative buildings in the municipality administration can be included in the second level of security (STN, 2008). Based on the resulting level of security, the individual elements of object protection are recommended:

- perimeter protection, passive safety barriers of the 2nd security class
- entrance door - security door of the 3rd security class with a 4rd class for the cylindrical insert and the door frame (according to EN 1627),
- windows on the ground floor P5A or security foil (P1A) or security grilles (according to EN 1627)

Pursuant to Act no. 138/1991 Coll. on the property of the municipality, municipalities and organizations are obliged to manage the property of the municipality for the benefit of the development of the municipality and its citizens and the protection and creation of the environment. Pursuant to this Act, municipalities are obliged to protect property from damage, destruction, loss or misuse. Cities spend on average 2-4% of available funding on security solutions (Vel'as, 2019A).

As example we choose describe security of self-government building in the capital city of Australia Canberra. After the revelation of a terrorist attack that was to take in Canberra local authorities started with securing buildings. One of the element of perimeter protection is 2,5 meter high steel security fence, so in nowadays disturbers can't easily close to building. Including security fence they use serval CCTV cameras or electric security system with motion

detector too (Ward, 2017). Another Australia state, Victoria, recommends using CPTED method and focus on natural access control, natural surveillance and territorial reinforcement. The CPTED principles promote layers of defense to: deter, detect, delay, respond and recover. Main role for perimeter protection is deter and delay disturbers (Greaves, 2019). The Indian Ministry of Home Affairs issued instruction on security arrangements in government building. This security arrangements consist primarily of access control system to building or just to land of this building (Singh, 2015).

Experimental testing of passive security barriers

The term security class represents the time value of overcoming the selected security element. Security class is determines by certified company determines. This time data allows a better understand of resilience of the selected security element and this is effective for security proposal. Higher security class means higher price of security element. Price of security element needs relation in to the value of the protected interest (Soltes, 2017B; Zvakova 2018).

As part of its scientific research activities FBI UNIZA researchers also test certified and non-certified security elements. As part of their project they long time deal with passive security barriers. The purpose of testing is to verify whether the security element accomplish the requirements declared by the producer and try find out real time of overcoming security element and try find out how much effort to spend to overcoming by using appropriate tool kit to security class (Zvakova, 2018; Tun, 2018).

The tests was performed at the Faculty of security engineering. Purpose of the tests was determine breakthrough resistance according to EN 1627 standard. Specifically there was tasting fence of 2nd security class call GAMA 2D (2:BT.). Panel of fence is hot-dip galvanized and dimension of mesh's are 50 x 200 mm. Tests were performed according to the following methodology:

Fig. 3: Test methodology

There was testing mesh of 2nd security class, so they used A2 tool kit – saws, screwdriver and hammer. The expected breakthrough time of the mesh of the 2nd safety class according to EN 1627 is a minimum of 3 minutes and a maximum of 15 minutes. There were performing 10 tests and hole to the fence was made. This holes had following shapes and size:

- Circle ø 350 mm or,
- Ellipse 400 mm x 300 mm or,
- Rectangle 400 mm x 250 mm.

Fig. 4: Tool kit A2

Testing mesh were size 2500 x 830 mm. Mesh attached to test frame and results of the tests are in following table.

Table 1: Experimental testing of breakthrough time of the mesh

Number of experiment	Total test time [s]:	Test time [s]:	Shape of hole:
1	1898	514	circle, ellipse
2	1012	268	circle, ellipse
3	1227	391	circle, ellipse, rectangle
4	978	268	circle, ellipse
5	914	258	circle, ellipse, rectangle
6	919	284	circle, ellipse, rectangle
7	744	196	circle, ellipse
8	956	279	circle, ellipse
9	849	235	circle, ellipse
10	755	125*	circle, ellipse

Arithmetic of successful attempts:

$$\bar{x} = \frac{1}{N}\sum_{i=1}^{N} x_i = 299{,}22\ s$$

Standard deviation:

$$\delta = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - \bar{x})^2} = 90{,}44\ s$$

Arithmetic time of successful overcoming mesh GAMA 2D (2:BT.) 2nd security class was approximately 5 minutes.

At the Faculty of security engineering ware realization other mesh breakthrough tests. This tests ware realization as part of project VEGA and project PACITA, and there was same methodises of testing.

In the VEGA project, testing was performed on 12 mesh samples, which size of mesh was 100 mm x 50 mm and Ø vertical/horizontal was 4 mm and high of one part was 1-1,9 m and number of ripples 2-4. There were use following tools for overcoming:

- Manually - combined pliers -180 mm, lever pliers - 640 mm.

* Unsuccessful attempt

- Electric - angle grinders machine, the first with a power of 650 W and a Ø of a cutting disc for steel 115 mm (GRINDING MACHINE A) and the second with a power of 950 W and a Ø of a cutting disc for steel 150 mm (GRINDING MACHINE B).

3 tests were performed with each instrument and the resulting T_v time was determined as the arithmetic mean. The results of the test in the VEGA project can be found in the following table.

Table 2: Results of breakthrough time of fence type AXOR

Tools	T_1 [s]:	T_2 [s]:	T_3 [s]:	T_v [s]:
Combined pliers 180 mm	x	x	x	x
Lever pliers 640 mm	23,1	19,9	22,1	21,7
GRINDING MACHINE A	21,6	17,3	24	20,9
GRINDING MACHINE B	11,2	10,5	9,9	10,5

As we can see in the table in three cases, the mesh was overcoming in a relatively fast time. The fastest was overcoming with the help of an electric angle grinder with a power of 950 W and a cutting disc Ø for steel 150 mm. The angle grinder and lever pliers had comparable overcoming times.

In the PACITA project, the tests took place on complete mesh fields in which the stability and deflection of the fence were also taken into account. There were tests following meshes:

- FLUIDEX - steel wire 2.5 mm, mesh eye 55x55 mm, PVC plastic coated - similar to the VEGA project,
- BASTILLA - welded mesh, mesh eye 78x33mm, wire 3.5 mm, PVC plastic coated,
- AXIS SR - welded mesh, horizontal wire 1x6 mm, mesh eye size was 100 mm,
- AXIS DR - welded mesh, horizontal wire 2x8 mm, mesh eye size was 200 mm.

The tools used to overcoming mesh were divided into 5 groups of destructive means:

- Tools found near to mesh,
- Home tools,
- Tools with mechanical transmission,
- Cordless tools,
- External power supply.

The results of testing in the PACITA project can be found in the table.

Table 3: Results of testing in the PACITA project

Group of tools / Mesh		FLUIDEX	BASTILLA	AXIS SR	AXIS DR
1	Crowbar				
	Stone				
	Own strength				
2	Hand saw				
	Pliers				
	Hammer				
3	Lever scissors				
	Car jack				
	Dynamic straps				
4	Battery grinder				
	Battery saw				
	Circular saw				
5	Gas burner				
	230V - flexi grinder 125 mm				
	Gasoline engine cutter				

Table 4: Legend for Table 3

Legend	
Breakthrough hole wasn't made under 20 minute	
Breakthrough hole was made under 10 minute	
Breakthrough hole was made under 1 minute	

Evaluation of test

When was testing the breakthrough resistance of 2nd security class mesh fence using standard hand tools of group A2, it took approximately 5 minutes to create a transition hole according to EN 1627. Average time of overcoming non-certified mesh was 17,7 second in the VEGA project. There was used two grinding machines but each with different power and lever pliers. In the PACITA project were tests 4 type of mesh and for overcoming were use all 5 groups of tools. The shortest time for overcoming was achieve by 5th group of tools as gas burner, flexi grinder 230V and gasoline engine cutter. All this tools overcome mash under 1 minute such as lever scissors of 3rd group.

Conclusion

Properly designed and installed security of regional governments has a general benefit for township and their inhabitants. Function of designed security systems is protect secure object and also funds should be used efficiently. Object in township are mostly similar and often has similar technique and equipment. The created proposals are applicable in the all territory of the Slovak Republic and a wide range of buildings belonging to regional governments. It's important invest funds for protection this buildings because inside this buildings are expensive techniques and equipment. Trade offers a wide selection of mantle and perimeter protection elements, various security classes and prices. When customers choosing suitable security system, they can't apply rule that a higher purchase price will also provide a higher level of breakthrough resistance. This level of breakthrough resistance should be misleading for customers, so is better if customers will know time, which disturber need for overcoming by using right tools. For passive safety barriers, this time according to EN 1627 is a minimum of 3 minutes and a maximum of 15 minutes. Professional public expects that passive barrier set back disturber as long as possible, so we were testing some types of passive barriers same security class. Result of this testing is find which type of barrier has the highest resistance against attack of disturber. After the evaluation of the tests, the formulation of recommendations is based at our own findings. In the case of testing passive security barriers, the longest withstood attack GAMA 2D mesh - 5 minutes. Researchers of the Faculty of security engineering by testing various mechanical barriers create a database of time and probabilistic values, on the basis of which it is possible to make recommendations for secure various objects.

Proposed recommendations: perimeter protection - passive security barriers of the 2nd security class, entrance doors - security doors of the 3rd security class with a similar class for cylindrical insert and door frame, windows on the ground floor - security foil (P1A) or security grilles.

Abstract

Text mining models allow examination of textual data in order to find out their message, without reading them. This evaluation can be used not only to identify the main subject of the analyzed texts but can also be used for the developing of similarity patterns or for predictions. Knowing that nowadays, an increasing volume of data is recorded especially in text format, not in numerical one, text mining models have become an important and necessary tool. The main purpose of this paper is to present the Latent Dirichlet Allocation (LDA) model, mainly used for the the cluster analysis of documents, but also for the dimensionality reduction and text representation. To prove that the LDA model is a useful tool for other clustering models, we compare the performance of the k-medoids clustering algorithm using LDA representation with the one generated using TF-IDF representation. We use a self-defined corpus of news published on the Washington Post website and categorized as "policy", "business", "sport", "technology" and "entertainment". We evince that the LDA model is not only an efficient clustering model, but it is also useful for text representation cutting back the implementation costs and enhancing the quality of the further textual tasks.

Keywords: Text mining, TF-IDF index, K-medoids, Latent Dirichlet Allocation.

Introduction

Text mining is a relatively new concept of data science that has caught a lot of attention recently due to the increasing volume of non-numerical information. Precisely, it is estimated that more than 80% of our available information is unstructured and is not represented by numbers. Therefore, it is compulsory to develop new models for the retrieval of text information based on different approaches than the classic models focused only on the processing of the structured data.

Document categorization is an important and relevant process of text mining, especially because it is almost impossible and impractical to start any analysis using all amount of unsorted data, without knowing anything about the data topics. Even if the textual analysis can tackle complex tasks that exceed the problem of categorization, it is necessary to familiarize with this concept in order to control the overwhelming volume of information. As of any other text mining concept, the performance of text categorization depends on the previous preprocessing and document representation. Text preprocessing is the first step that adjusts the corpus dimensionality. This step consists of a few methods that use either a set of predefined information about textual data, like vectors of stop words and stemming algorithms, or adapted themselves to the specific features of the corpus, like the TF-IDF method. The second step is the document representation that is not only a conversion method but also can be turned into a filtering solution allowing to reduce the implementation cost.

In this paper, we focus on the LDA clustering model. According to the LDA model, one topic is a mixture of words, and one document is a mixture of topics. Additionally, the LDA model can be used for the text representation based on the generated topic-document matrix, whose size is usually lower than the initial term-document matrix. Lower-dimensional LDA representation can be employed with various categorization models, among which we choose to

present the k-medoids algorithm. Although there are more laborious and probably more efficient categorization algorithms, we choose the k-medoids algorithm to prove the efficiency of the LDA representation due to its simple approach and low implementation cost.
To prove the LDA efficiency, we consider a corpus of 140 articles published on the Washington Post website at the beginning of December 2016. The articles are separated into five topics: “policy”, “business”, “entertainment”, “technology” and “sport”.

The remaining of the paper is organized as follows. Section 2 introduces the literature review. Section 3 presents some preprocessing and representation methods. Section 4 gives an overview of the LDA model. Section 5 is dedicated to the empirical results, and the last section presents our conclusions.

Literature Review

Different from other latent variable approaches as the unigram, the mixture of unigrams, and the Probabilistic Latent Semantic Indexing (pLSI) models, the LDA model, developed by Blei et al. (2003), can generate probabilities of the new textual data (out of the training set) to a set of fixed topics. In addition, Scrivastava et Sahami (2009) proved that the LDA model does not suffer from overfitting like the pLSI and the mixture of unigram models, and overcomes the pLSI model in the field of forecast and overfitting.

An alternative model of LDA is the Correlated Topic Model (CTM). Both models belong to the topic models group, which means that both of them generate soft clustering solutions and the textual data can be represented by various topics. However, the CTM model goes further than the LDA model and assumes that the topics can be related to each other, which may lead to a better predictive performance as it was proved in the work of Lafferty et Blei (2006). On the other hand, the LDA model is closer to our natural way of thinking. Precisely, the study of Chang et al. (2009) proved that the LDA grouping solution is easier assigned to a real set of topics (word intrusion) and is closer to a human association of topics (topic intrusion).

LDA is a widely used model for the cluster analysis of the textual data, a fact that Hofmann et al. (2010) considered to be related with its high level of the analysis speed. Despite the popularity of the LDA model, its implementation keeps being a subject of debate. One source of disagreement is the method used for the initial representation of documents that might vary between the widely used term frequency weighting and TF-IDF weighting (Manning et al (2008)) or even Latent Semantic Indexing (LSI).

Besides text clustering, the LDA model works fine even as a text representation model, a fact underlined even since the model was developed in 2003. Precisely, this approach, presented already in the works of Chen et Li (2016) and Razavi et Inkpen (2014), supposes to use per topic word Dirichlet distribution output as an input matrix necessary for the accomplishment of another textual task like text clustering. In terms of efficiency, Liu et al. (2011) proved in their work that this approach works better than other common heuristic methods (like term and TF-IDF weighting) and even LSI.

The Document Preprocessing and Representation

The first step of any text mining analysis is the documents preprocessing. The main purpose of this step is to reduce the dimensionality of the considered documents. The common preprocessing steps are:

1. elimination of images, tables, charts, and links to sites,
2. elimination of punctuation marks and the numbers,
3. elimination of stop words,
4. conversion of the word families into one word, by eliminating prefixes and suffixes of those words.

The last step is the most laborious, as it requires specific algorithms for grammar. The most elaborate algorithms are made for English documents, such as Porter’s and Lovins’ algorithms. Among those algorithms, Porter’s is the most frequently used [1] and our option for the current work. Table 1 exemplifies the inner working of Porter’s algorithm.

Table 1: Porter's Algorithm examples of words transformation

Sufix	Turns into	Example	Condition
"sses"	"ss"	Addresses → address	
"ement"	-	cement	if the length of the new word is higher than 1
"is", "are", "am"	"be"		

The most simple text representations employ term frequency and binary data, as it was presented in the work of Crețulescu (2011). According to the binary data representation, elements in the term-document matrix are:

$$x_{ij} = \begin{cases} 1, & \text{if the i} - \text{th term is in the j} - \text{th document} \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

A more refined method to represents documents is based on the term frequency-inverse document frequency (TF-IDF) that assigns to the i-th term from the j-th document of the collection, a weight defined as:

$$\text{TF-IDF}_{i,j} = \text{TF}_{,j} * \text{IDF}_{i,j} = \text{TF}_{,j} * \log \frac{N}{\text{DF}_i} \quad (2)$$

where TF is the frequency of a the i-th term from the j-th document, $\text{IDF}_{i,j}$ is the inverse document frequency of the i-th term from the j-th document, DF_i is the number of documents that contain i term, and N is the collection documents number.

Unlike the simple frequencies scores, the TF-IDF index allows the selection of the most relevant words of the document collection as follows:

1. if the i-th term has a high frequency in a small number of documents from the collection, the TF-IDF index assigns him a high weight,
2. if the i-th term has a high frequency in every document of the collection or has a small frequency in the entire corpus, the TF-IDF index assigns him a small weight.

Besides the representation of documents, the TF-IDF index can be employed as a pruning method that filters out the words with a small salience score (e.g., stop words).

Latent Dirichlet Allocation

The main purpose of this paper is to present the LDA model as a solution for both text clustering and representation. The LDA model relies on a flexible approach that considers any document as a mixture of topics and any topic as a mixture of words. The output is represented by a per-document topic and a per-topic word Dirichlet distributions. Assuming that the number of topics is lower than the number of tokens, the generated topic-document matrix represents not only a method to encode the textual information, but also an efficient alternative for the high-dimensional term-document matrix.

To briefly present LDA model, we defined the following notations based on the work of Ponweiser (2012):

1. D_j is the j-th document, that has N_j words,
2. N represents the vocabulary of corpus ($N = \sum_{j=1}^{M} N_j$),
3. $C = \{D_1, ..., D_i, ...D_M\}$ represents the corpus,
4. K is the number of topics,
5. θ_j, is a K-dimensional vector that represents the per-document topic Dirichlet distribution ($\theta_j \sim \text{Dirichlet}(\alpha)$),
6. φ_k, is a N-dimensional vector that represents the per-topic word Dirichlet distribution ($\varphi_k \sim \text{Dirichlet}(\beta)$),
7. $z_{i,j}$ shows the topic of the i-th word of the j-th document,
8. $w_{i,j}$ indicates the document of the i-th word.

The purpose of the LDA model is to compute the probability of simultaneous realization of the all four matrices (W, Z, θ and φ), as:

$$P(W, Z, \theta, \varphi;\ \alpha, \beta) = \prod_{k=1}^{K} P(\varphi_k;\ \beta) \prod_{j=1}^{M} P(\theta_j; \alpha) \prod_{i=1}^{N} P(Z_{i,j}|\theta_j) P(W_{i,j}|\varphi_{Z_{i,,j}}) \quad (4)$$

Integrating out θ and φ, the equation (4) is reduced to:

$$P(W, Z;\ \alpha, \beta) = \int_{\theta} \int_{\varphi} P(W, Z, \theta, \varphi;\ \alpha, \beta)\, d\varphi\, d\theta$$

$$= \int_{\varphi} \prod_{k=1}^{K} P(\varphi_i, \beta) \prod_{j=1}^{M} \prod_{i=1}^{N_j} P\left(W_{1i,j} \middle| \varphi_{Z_{i,j}}\right) d\varphi \int_{\theta} \prod_{j=1}^{M} P(\theta_j;\ \alpha) \prod_{i=1}^{N_j} P\left(Z_{i,j} \middle| \theta_j\right) d\theta \tag{5}$$

Knowing that, the Dirichlet distribution is:

$$f(x_1, \dots, x_N;\ \alpha_1, \dots, \alpha_N) = \frac{\Gamma(\sum_{i=1}^{N} \alpha_i)}{\prod_{i=1}^{N} \Gamma(\alpha_i)} \prod_{i=1}^{N} x_i^{\alpha_i - 1} \tag{6}$$

where: $0 < x_1, \dots, x_N < 1$

Equation (5) turns into:

$$P(W, Z;\ \alpha, \beta) = \\ = \prod_{j=1}^{M} \frac{\Gamma(\sum_{k=1}^{k} \alpha_k)}{\prod_{k=1}^{k} \Gamma(\alpha_k)} \frac{\prod_{k=1}^{K} \Gamma(n_{(\cdot)j}^{k} + \alpha_k)}{\Gamma(\sum_{k=1}^{K} n_{(\cdot),j}^{k} + \alpha_k)} \prod_{k=1}^{K} \frac{\Gamma(\sum_{i=1}^{N} \beta_i)}{\prod_{i=1}^{N} \Gamma(\beta_i)} \frac{\prod_{i=1}^{N} \Gamma(n_{i(\cdot)}^{k} + \beta_i)}{\Gamma(\sum_{i=1}^{N} n_{i,(\cdot)}^{k} + \beta_i)} \tag{7}$$

The above equation is the key equation of the LDA model. The best value of the α, β parameters are obtained only when the below function is maximized:

$$\sum_{j=1}^{M} \ln\left(P\left(W_j, Z_j;\ \alpha, \beta\right)\right) \tag{8}$$

Finally, the per-document topic and per-topic word Dirichlet distributions are determined based on the newly generated α, β parameters.

Empirical Example

In this section, we provide an example of how to classify documents with an LDA-based representation implemented in R. The first step of our analysis is to generate clusters of documents using the LDA model. Then, the generated topic-document matrix is employed as a document representation for the k-medoids clustering model. We choose this model, knowing that its approach is simple, and the cost of implementation is low. To show the performance of the k-medoids model using the LDA representation, we compare its results with the ones of the k-medoids model with the TF-IDF representation.

The corpus consists of 140 articles published on the Washington Post website between December 6-10, 2016 and categorized under five topics (“business”, “policy”, “sport”, “entertainment” and “technology”).

Table 2: The structure of our corpus

Topic	Business	Policy	Sport	Entertainment	Technology
Number	21	33	29	30	27

The five topics are depicted using the TF-IDF index. This index can also be turned into a filtering method by setting a threshold of relevance. However, this extension is not necessary for this study because the dimensionality of the corpus is already low (9564 tokens). Table 3 lists the most relevant five words of the five topics indicated by the TF-IDF index

Table 3: The most relevant words per topic according to the TF-IDF index

nr.	policy	tf-idf	business	tf-idf	technology	tf-idf	ent.	tf-idf	sport	tf-idf
1	trump	0,0113	fund	0,0066	technology	0,0052	opera	0,0065	soccer	0,0127
2	republican	0,0099	retir (retirement	0,0047	devic (device)	0,0047	music	0,0061	cup	0,0102
3	democrat	0,0086	pension	0,0045	selfdriv (selfdrive)	0,0047	sing	0,0059	mls	0,0099
4	cia	0,0080	tax	0,0043	vehicl (vehicle)	0,0045	instrument	0,0057	leagu (league)	0,0085
5	donor	0,0066	index	0,0041	car	0,0043	compos (compose)	0,0052	team	0,0053

The description of topics using the above table:

1. The “policy” topic is represented by words like: “trump”, “putin” and “cia”. Those words show the interest of the political journalists for the elected president Donald Trump and the alleged Russian interference in the United States presidential election between the selected time range.
2. The “business” topic is represented by words like: “tax”, “stock” and “pension”. Those words show that during the selected interval, many business journalists paid attention not only to the classical financial subjects but also to the retirement system.
3. The “technologic” topic is represented by words like: “technology”, “vehicle” and “robot”.
4. The “entertainment” topic is represented by words like: “opera”, “concert” and “song”.
5. The “sport” topic is represented by words like: “team”, “game” and “mls”. It is also noticeable a higher interest of the sport journalists for soccer than for other sports.

Further, we classify the articles depicted above using the LDA model with the term frequency representation. The histograms presented in Figure 1 list the most representative five words for the five considered topics according to the per-topic word distribution. One should note that it is common to find topics with shareable words, fact indicated by the below histograms as well (the “year” word). Firstly, it is easy to notice that the majority of topics are properly represented, except only the “technologic” topic that is surprisingly represented by the “year” word. The word probabilities are small because the topics can be represented by thousands of words, different from the case of documents represented by only five topics. Knowing this, we notice that the “policy” and “business” topics are better represented than the other three topics.

Figure 1: Per-topic word distribution (first five most relevant words of a topic): 1: technologic, 2: policy, 3: business, 4: entertainment, 5: sport

Regarding the per-document topic output of the LDA model, only the “business” and “sport” documents are correctly classified. “Policy” and “technology” documents are rather well classified with two and three mistakes, respectively. The “entertainment” topic is the worst represented with more than a third of documents assigned to either “technology” or “business” topics. To exemplify the per-document topic analysis, we select one article from each of the five topics. Table 4 presents the per-document topic distribution, real topic, and predicted topic for the five articles.

Table 4: Topic distribution for 20 documents (four documents from each topic)

Nr	title	tech.	sport	business	ent.	policy	Real topic	Pred. topic
1	Are you smarter than a millionaire	0,0722	0,0645	0,7725	0,0410	0,0495	business	business
2	Song recital suits tenor	0,0606	0,0662	0,0568	0,7430	0,0731	ent.	ent.
3	Obama says ‘we will’ retaliate against Russia for election hacking	0,0270	0,0286	0,0459	0,0240	0,0874	policy	policy
4	Leipzig beats Hertha Berlin 2-0 to reclaim Bundesliga lead	0,1088	0,3954	0,3345	0,0805	0,0805	sport	sport
5	The Internet revolution has not reached all of us	0,7943	0,0390	0,0527	0,0437	0,0701	tech.	tech.

The LDA model provides a lower-dimensional representation by using the generated topic-document matrix. In this case, the dimensional reduction is noticeable important. Precisely, the size of the initial 9654 × 140 matrix (term-document matrix) is cut down to the actual 5 × 140 matrix. While the new representation is more efficient than the classic term-document representation (based on the TF-IDF index), we are interested to assess the effectiveness of the LDA representation in terms of text clustering by means of the k-medoids algorithm (see Tables 5 and 6). Table 7 presents the aggregated results of our comparison. The employed measures are F-measure, and Rand index whose main advantage is the penalty of the high cardinality. Besides, we also specify the recall and precision of each representation.

Table 5: The confusion matrixes of the k-medoids algorithm with TF-IDF representation

		Real Topics				
		Business	**Ent.**	**Policy**	**Sport**	**Tech.**
Predicted Topics	**Business**	27	3	0	0	0
	Ent.	0	27	0	1	6
	Policy	0	0	32	0	0
	Sport	0	0	0	28	0
	Tech.	0	0	1	0	21

Table 6: The confusion matrixes of the k-medoids algorithm with LDA representation

		Real Topics				
		Business	**Ent.**	**Policy**	**Sport**	**Tech.**
Predicted Topics	**Business**	27	0	0	0	0
	Ent.	0	30	0	0	1
	Policy	0	0	33	0	0
	Sport	0	0	0	29	0
	Tech.	0	0	0	0	26

Table 7: The comparison between the k-medoids results using the LDA and TF-IDF representations

Representation	Weighted recall	Weighted precision	Rand index	F-measure ($\beta = 1$)
LDA	0,9724	0,9695	0.9084	0,9704
TF-IDF	0,8991	0,9750	0.9438	0,9027

While the term-document matrix with TF-IDF scores leads to the incorrect prediction of 11 documents, the k-medoids algorithm with the LDA topic-document matrix assigns only one document to the wrong class. The "technologic" class records the most incorrect predictions, fact already suggested by the poor word representation at the topic-level, generated by the LDA model. We suspect that this result is caused by the broad range of subtopics associated with the "technologic". Table 7 summarises the results of the two clustering solutions provided by the k-medoids algorithm. Among all the considered indices, F-measure is deemed as the most robust given that it is a summarization score for the precision and recall, and it allows the differential weighting for the false negative and false positive errors of the clustering solution, unlike the Rand index. As a result, we mainly rely on the F-measure and the confusion matrices to conclude that the LDA model representation is not only more efficient but also more effective than the TF-IDF representation for the cluster analysis of documents.

Conclusion

The main purpose of text mining is to retrieve information from documents without reading them. Therefore, knowing that the increasing amount of data is mainly represented by unstructured data, it is natural the huge interest of researchers in this topic. In this paper, we focus on the LDA model, one of the most relevant and well-researched algorithms, used for the cluster analysis and representation of documents. According to the LDA approach, any topic is a combination of words, and any document is a combination of topics. The employed dataset is a self-defined corpus of 140 articles published on the Washington Post website at the beginning of December 2016. Using the TF-IDF representation as a baseline, we prove that the LDA model is not only an efficient clustering model, but also it is

able to improve the results of a moderate-effective model like the k-medoids algorithm, generating an almost perfect clustering solution.

As regards future work, we would like to confirm our inferences by evaluating the LDA representation on different datasets. Knowing that the number of classes specific to a dataset is often unknown, we would like to develop a validation test to indicate the correct number of classes similar to the consistency test introduced in the work of Niu et al (2007) Also, we are aware that the simple topic-document matrix generated by the LDA model might not be enough to cope with all textual variations. As a result, one might consider the topic-document matrix but also the word-topic matrix as additional features to extend the already computed document or word embeddings.

Abstract

Innovations are an effective tool for economic development, becoming a defining element of the international competitiveness of countries and regions. The assessment of the innovative activities effectiveness in the regions of Russia allows us to distinguish two groups of regions: those from which knowledge spreads, and those where it is directed and gives an innovative effect. The largest Russian generators of knowledge (in terms of R&D expenditures) show extremely low efficiency of innovation activity, while a number of other regions with a minimum of R&D expenditures demonstrate impressive results. This situation can only arise as a result of the knowledge transfer demonstrated in this article. The research could be important in terms of policy implications for the management of innovation processes and will contribute to making informed decisions on the strategic directions of the development of regional innovation systems.

Keywords: Innovation; Knowledge Spillover; Regional Innovative Activity; Spillover of Innovations.

Introduction

An innovative model for the development of a modern economy, based on the use of innovations, covers an increasing number of countries, determining the vectors of the modern development of the world economy. The trend of rapid growth in innovation indicators is becoming one of the most important prerequisites for sustainable economic growth. Innovations are an effective tool for economic development, becoming a defining element of the international competitiveness of countries and regions.

The problem of innovative development of regions poses for researchers the task of developing a model for describing the mutual development of territories. In this regard, the spatial position of the region is of great importance. In fact, we can talk about the innovative position of a region (or center) in relation to other regions (centers) of innovation activity. The most advantageous position is observed between innovatively active regions, which allow you to receive some side effects from such a neighborhood. These effects are associated primarily with the knowledge spillover and innovations.

Studying the issues of the effectiveness of innovative development is relevant for all countries. This topic is also relevant for Russian regions; their feature is a high degree of polarization of economic activity in individual large cities, while most of the regions lie in the zone of the innovation periphery. From the point of view of innovation policy, it is necessary to form a more spatial optimal configuration of regions. However, for this, at the first stage, it is necessary to assess the real configuration, the mutual position of highly innovative and less active regions. This problem can be solved by assessing the effectiveness of innovative activities in the regions and spillover effects. This article is devoted to these issues.

This study continues the scientific discussion about the effectiveness of regional economic development and contributes to the search for tools for diagnosing the effectiveness of regional innovation systems based on data from Russian regions.

Theoretical Background

The problem of knowledge spillover in modern literature is actively discussed in the example of European countries where there is a high population density, and the distances between settlements are relatively small. But even there, the geographic space limits the processes of knowledge spillover and innovations and the direct interaction of scientists and innovators, as well as the processes of financing innovation by venture capitalists. Thus, studies by Moreno et al. (2003), show that this distance is 120-180 km (up to 250 km), which is associated with the travel time to manage a business to the object in two to three hours and return home in one day. In the exchange of knowledge, the role of personal contacts, direct communication of scientists, innovators, and businessmen is important.

Modern ideas about the dissemination of knowledge are associated with the idea of proximity. The idea of proximity (see, for example, Boschma (2005)) in fact takes the geographic proximity between the actors of innovative activity to the background, bringing social, organizational, and technological proximity to the fore. As a result, it can be expected that the knowledge spillover is less and less determined by geographic space, and the spillover effects of innovations are increasing according to Kijek and Kijek (2019), Jaffe et al. (1993), Newman et al. (2015), Audretsch and Feldman (1996). Bednarz and Broekel (2019) believe that distance, however, remains a significant factor in the diffusion of knowledge and innovation. On the contrary, the Russian regions are characterized by remoteness (as an antagonist of proximity).

In a study by Preobrazhensky et al. (2020), Ogurtsova et al. (2019), Firsova et al. (2020) note, that a number of contradictions can be recorded in the innovative development of Russian regions:
- there is a high innovation potential with low demand for innovation;
- the growing importance of science as a source of innovation is recognized, but its sufficient state (federal and regional) funding is not provided;
- there is a growing need to transfer the economy to an innovative way of functioning, while the public-private mechanisms for this transfer are not sufficiently developed in the regions;
- the importance of greening technologies is increasing, but economic and legal incentives are imperfect;
- the role of sectoral management of innovation activity is decreasing, but the mechanisms of regional management of it are undeveloped (Ryapukhina, 2018).

Materials and Methods

The object of analysis is statistical indicators aggregated by regions, constituent entities of the Russian Federation for 2018. Obviously, their internal heterogeneity is great, especially for giants like the Krasnoyarsk Territory, the Tyumen Region and other large, predominantly Asian regions.

However, in many constituent entities of the Russian Federation, the actual innovation activity is localized in one or two centers - the largest cities in the region, so it would be desirable to move from a background, continuous analysis of the entire region to the analysis of innovation centers (cities), which will require a completely different approach to data collection, but will bring much more precision in research. Nevertheless, as a first approximation, we will consider precisely the mesoregional level, which sets the frame for the entire intraregional (development at the micro- and local level).

The main method of this study is the analysis of the effectiveness of innovation. It is obvious that high efficiency (above the national average) can be due to a number of factors. So, the spread in the efficiency of innovation activity can be explained by the quality of management, as well as by temporal and spatial externalities. Temporary externalities are associated with the fact that a high volume of innovative products with relatively small investments in innovations is a consequence of earlier (relative to the period under review) capital investments. Unfortunately, these statistics in the context of Russian regions are presented for a short period.

Spatial externalities are of a more complex nature. Their essence lies in the fact that the results of scientific activity are used not where they were created (or not only there), but in other regions. Their accurate assessment is a rather difficult task, but it is possible to show the main directions of the influence of some regions on others.

To assess the innovative efficiency of Russian regions and its spatial background and spillovers effects, we propose to build a 3x3 matrix, where regions are grouped in columns in accordance with the effectiveness of innovation in the region (the ratio of the volume of innovative products to the amount of research and development costs). The lines group regions according to the amount of research and development costs (low, medium, high). Thus, the following matrix is obtained (Fig. 1).

Fig. 1: The base matrix of R&D output by regions
(red arrow shows the direction of knowledge flow)

The main direction of knowledge dissemination will be directed from the group of regions with high R&D expenditures and low innovation efficiency (i.e., the cost of innovative products per ruble of R&D costs) to the group where the situation is reversed: R&D costs are close to zero, but the production of innovative products are essential.

The next step is the spatial grouping, i.e. consider the proximity of regions in two polar squares from fig. 1.

Results and Discussion

Note that the key methodological approach to assessing innovation and the impact of innovation diffusion on economic growth and regional innovation development is the comparison of the invested resources and the results of innovation processes. However, as a rule, it does not take into account externalities, primarily temporal and spatial. Spatial externalities are primarily associated with knowledge spillover, thanks to which regional actors get the opportunity to use exogenous knowledge at minimal cost (or free). There is a debate about the spatial limitations of the dissemination of knowledge. A large volume of works is devoted to this issue. The authors agree with the point of view according to which distances matter and the proximity of a region to a region with active scientific activity is an undoubted advantage.

At the same time, there is a problem of polarization of the economic space of Russia, as a result of which the favorable innovative position of the region will appear only on paper, but in reality, due to the fact that there are few innovatively active (or potentially inactive) agents in this region, this region will “Excluded” from the flows of knowledge and innovation. This situation, unfortunately, is typical for modern Russia, where cities (and, therefore, entire regions) with a population of less than 500 thousand people are actually excluded from innovation processes (this does not apply to cities in the Moscow region). The size of the region, therefore, matters (Head et al. (1995)).

As a result of the approach proposed above, we built a matrix in which Russian regions were grouped (see Table 1).

Table: The matrix of R&D costs and efficiency of innovative outcome by Russians regions

		Efficiency of innovative outcome		
		Low (less than 3 times)	Medium (between 3 and 8 times)	High (more than 8 times)
R&D costs	Low (less than 2 bln rub.)	Ivanovo Region, Oryol Region, Kaliningrad Region, Kalmykia, Crimea, Sevastopol, Astrakhan Region, Amur Region, Magadan Region, Sakhalin Krai, Republic of Dagestan, Ingush Republic, Kabardino-Balkar Republic, Karachay-Cherkess Republic, Republic of North Ossetia-Alania, Republic of Chechnya, Yamalo-Nenets Autonomous District, Altay Republic, Tyva, Khakassia, Zabaykalskiy Krai, Kamchatka	Bryansk Region, Smolensk Region, Karelia, Altay Krai, Republic of Buryatia	Kostroma Region, Lipetsk Region, Tambov Region, Archangelsk Region, Vologda Region, Pskov Region, Adygea Republic, Mari El Republic, Mordovia Republic, Orenburg Region, Kurgan Region, Kemerovo Region
	Medium (between 2 and 20 bln rub.)	Kaluga Region, Murmansk Region, Novgorod Region, **Saratov** Region**, Irkutsk** Region**, Tomsk Region,** Republic of Yakutia, **Primorskii Krai**	Vladimir Region, **Voronezh** Region, Tver Region, Komi, Leningrad Region, **Volgograd** Region**, Rostov Region**, Penza Region, Ulyanovsk Region, Khanty-Mansi Autonomous Okrug, **Omsk** Region	Belgorod Region, Kursk Region, Ryazan Region, Tula Region, Yaroslavl Region, **Krasnodar Region, Stavropol Region, Bashkortostan Region, Tatarstan Region,** Udmurt Republic, Chuvash Republic, **Perm Region**, Kirov Region, **Samara Region, Tymen Region, Chabarovsk Region**
	High (more than 20 bln rub.)	Moscow Region, Moscow City, Saint-Petersburg, Krasnoyarsk Region, Novosibirsk Region	Nizhniy Novgorod Region, Sverdlovsk, Region, Chelyabinsk Region	-

Source: compiled by authors, the initial data from Rosstat (2020)

What conclusions can be drawn from the table? First, there is an inverse relationship between R&D costs and the effectiveness of innovation. Out of the group of regions with high R&D expenditures, only in the Sverdlovsk and Chelyabinsk regions are efficiency higher than the national average, and not significantly. In Moscow, it is about five times lower than in the country as a whole.

However, if we exclude the total incompetence within the relevant institutions for transforming knowledge into innovative products, it remains to recognize the accumulation of knowledge in other regions, primarily in the third column.

Secondly, we note a number of regions in the second line, the center of which is either a millionaire city or one that is close to it in terms of population (they are in bold). In general, the regions in the second line with relatively high efficiency of innovation activity are either close to Moscow and the Moscow region, or belong to the Ural-Volga

region, this is a region that shows a fairly high volume of innovative products at relatively low research and development costs.

Third, it is rather difficult to find common features for the regions of the upper right square in the spatial aspect. All of them are relatively uncrowded.

In Russia, in the current economic situation and under the current policy of the federal center, the effectiveness of innovative activity above the average is typical for regions with a relatively high population density (see fig. 2). The presented map shows spatial differences in the effectiveness of innovation. The latter largely depends on the intensity of knowledge spillover and innovation diffusion.

Fig. 2: Differences in the effectiveness of innovative activity in Russia, 2018

The materials for compiling the map were statistics on the share of costs for innovation and the release of innovative products by region and by the country as a whole for 2018. However, aggregated regional data do not allow to fully taking into account the spatial aspect of innovation. We assumed that, in the general case, the latter is concentrated in cities, and the larger the population of a city, the presumably a larger share of the total innovative activity of the region it has. As a result, the total regional value of the indicator related to innovation was distributed by us among the cities of the region with a population of more than 100 thousand people in proportion to their population.

Within the identified zones (leading and lagging efficiency of innovation), the gradations are actually more significant. Thus, most of the “darker” territory on the map should be attributed to semi-periphery: the central regions are concentrated mainly around cities with more than a million people.

These prerequisites lead to the fact that technological development takes place in the old developed territory of Russia: the European part and the Urals. But here the territory of the so-called zone of inner periphery is also large: these are regions with “weak” regional centers, and physically and conceptually obsolete fixed assets. These entities are not capable of self-sufficient innovative development, without which we cannot talk about technological development.

We understand self-sufficiency as the ability of a system to carry out the entire chain of the innovation process: from generating knowledge to obtaining finished products, i.e. the availability of subsystems of science-innovation-industry. Of course, self-sufficiency does not mean closure. Flexible regional innovation systems combine the use of their own (intra-regional) and exogenous knowledge.

Conclusions

Thus, the assessment of the effectiveness of innovative activities in the regions of Russia allows us to distinguish two groups of regions: firstly, those from which knowledge spreads, and secondly, those where it is directed and gives an innovative effect. The largest Russian generators of knowledge (in terms of R&D expenditures) show extremely low efficiency of innovation activity, while a number of other regions with a minimum of R&D expenditures demonstrate impressive results. This situation can only arise as a result of the knowledge transfer demonstrated in this article. We note that in Russia there is a group of regions that, in terms of their population size, size of the economy and scientific potential, should claim to be innovation centers, but in reality they are far from it.

This research could be important in terms of policy implications for the management of innovation processes and will contribute to making informed decisions on the strategic directions of the development of regional innovation systems. Further research will be related to the proposal of an ideal model for the location of innovation centers in Russia, including within supraregional innovative systems (Preobrazhenskiy (2020)).

Abstract

The article systematizes the problem of economic security in industrial ecosystems. The innovation ecosystem is one of the collaboration schemes for industrial enterprises. New risks of industrial ecosystems economic security are formed in the horizontal model. The article analyzes possible risks and threats in the context of digitalization. The main threats and risks to economic security arising from the actors' collaboration in the industrial ecosystem are considered. A four-level model of ecosystem risks is presented. A method for assessing the system of economic security of industrial ecosystems is proposed. The practical significance of the research results is the possibility of using certain provisions in the practice of managing industrial enterprises, as well as in the development of program documents and strategies of organizations.

Keywords: Industrial Ecosystems, Economic Security, Actors, Threats, Risks.

Introduction

Present market conditions change the patterns and approaches of interaction between market participants. The principles of relations both inside and outside the company are changing. In order to maintain stable functionality of industrial enterprises and maintain a positive reputation in national and international markets, it is necessary to adapt to current trends and respond to current challenges in a timely manner [7,9,22,23].

A distinctive feature of the industrial ecosystem is a complex scheme of direct and feedback links (knowledge exchange), established on the principle of self-organization, supporting the self-preservation of the system within certain limits of environmental parameters [13,14,16].

Like any innovation, the industrial ecosystem entails risks and threats to the economic security of actors that have not yet been studied. The stability of an industrial ecosystem is determined by the rate at which potential threats occur when actors function in the industrial ecosystem.

Actors play a key role in the formation and functioning of the industrial ecosystem. Actors in the industrial ecosystem are participants in the economic market. They can function in the industrial ecosystem in various roles: supplier, manufacturer, researcher, developer, innovator, initiator, integrator, promoter, and investor. In the industrial ecosystem, the main functions of production, technologies and raw materials will be concentrated in

Cite this Article as: Andrey BYSTROV, Tatyana TOLSTYKH, Nadezhda SHMELEVA and Ayya AGAYEVA "The Model of Ecosystem Risks for Industrial Ecosystems Economic Security" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

actors – production enterprises. Thus, it is assumed that the backbone participants will be industrial enterprises. In this regard, the task of identifying threats and risks to economic security in the context of technological challenges is becoming more urgent.
Economic security refers to the type of basic, fundamental needs for sustainable development and protection of the functional components of an actor in an industrial ecosystem. Under the economic security of an industrial enterprise, we will understand the security and sustainable functioning of its scientific, technological, production and information functions from direct or indirect threats associated with the impact of the external environment, and the ability to develop flexibly. The goal of economic security of industrial ecosystem enterprises is to ensure the sustainable and most effective functioning of their economic activities in the conditions of collaboration, various market challenges, ensuring high potential for technological development and growth of economic indicators in the future [15]. The authors propose a study the following threats and risks of economic security:

- information
- financial-economic
- industrial-technological
- intellectual and human resources
- environmental
- marketing
- political and legal

All tasks of economic security are aimed to prevent various internal and external threats to the main divisions. Ensuring the economic security of the actor contributes to the sustainable functioning of the industrial ecosystem and prepares the ground for a certain potential to move to a new level.

Literature Review

The term risk is derived from the Latin (- resecō) [24] meaning "cut off" or "reduce". Based, The researchers [5,6,8,11,12,17,21] laid their essence in determining the risks for industrial enterprises. The definitions of researchers [5,6,8,11,12,17,21] generally do not contradict the basic concept defined in GOST-R 51897-2011 (ISO 73: 2009), but they are clarified for a specific industry. In the document GOST-R 51897-2011 (ISO 73: 2009), it is noted that risk should be understood as a consequence of the influence of uncertainty on the achievement of goals [1,2,3,4,]. As part of this study, the authors introduce a new definition of ecosystem risks to the economic security of industrial ecosystem enterprises in the context of digital challenges. Thus, the ecosystem of risk in the field of economic security we mean the event that occurs under the influence of factors external or internal environment of industrial enterprises, contributing to the deterioration of indicators reflecting the degree of economic security, which in result affects the stability in the functioning of the industrial ecosystem.

Detection of threats and hazards, not only in the material sphere, but also in the non-material one, create conditions for achieving the goals of financial and economic activity of an industrial enterprise, guarantees sustainable development and functioning in the industrial ecosystem, its economic security, which is of primary importance in the conditions of digital and technological transformation Threats to the economic security of an industrial enterprise are potential or real opportunities of the destructive impact of various factors on its development, leading to a certain damage to the economic interests of an industrial enterprise.

The globalization of digital technologies, the proactive development of competitiveness in the world, the current political situation, changes in management approaches at enterprises, mentality and foresight in the field of information technology, contribute to a change in the approach to classifying modified threats to the economic security of industrial enterprises.

In the context of digitalization, solutions based on technological innovations can act as both a driver and a generator of new threats and risks to the economic security system of industrial enterprises. Innovative technological solutions that contribute to the modification of institutional relations affect political, technological, environmental, market and legal factors. Due to the transformation of priorities in connection with digitalization, these factors affect the external and internal environment of economic security (ES) of industrial enterprises (Fig. 1).

Figure 1: Internal and external threats to ES relative to factors

The process of digitalization carried out in many sectors of the economy has led to a change in the scale of activities of economic entities and has created new threats that the world has not previously faced. The profound changes brought about by the use of digital technologies have significantly expanded problems in ensuring economic security. These threats affect the main "blocks" of economic security, creating risks for industrial enterprises (table 1).

Table 1: Threats and risks by economic security" blocks"

The blocks of economic security	Threats	Risks	Probability of damage (consequences)
Informational	• cyberwars • unauthorized access • content • cyberterrorism • cyber espionage • loss of technical identification tools • carelessness of users who write down passwords and leave these records in accessible places • use of special technical and software tools to break system protection • malicious software	• data loss • stopping production processes • destruction of information • viewing information by an unauthorized employee • hacking programs • interception of data over the network • violation of information integrity • online banking manipulation and hacking • termination of the electronic data processing system due to the destruction of the supporting infrastructure • use of video surveillance,	disclosure of trade strategy

		and electromagnetic radiation to intercept information	
Financial-economical	• insufficient data protection (passwords, keys, electronic signatures) • availability of financial resources • low administrative control	• interception of financial resources • unexpected losses of the company due to technical errors and failures, intentional and accidental errors of personnel • currency risk • lost profit • low liquidity and profitability	bankruptcy
Industrial-technological	• increasing the possibility of equipment failure due to accidental or intentional impacts of natural or artificial nature • introduction of innovations that affect production technology • phishing of technical supply devices	• defects in manufactured products • wasteful use of raw materials • the lag of technological equipment • low quality of the product • attacks on technological processes	unjustified overuse of resources, losses
Intelligent, human resources	• Creating conditions that force individual employees to perform actions related to violation of information security (blackmail, bribery, etc.) • low qualification of digitalization personnel • data processing system malfunction	• unauthorized connection to computers, communication equipment, or communication lines • destruction of information • lack of qualified personnel • staff turnover	disclosure of trade strategy
Ecological	• reduced competitiveness of products due to non-compliance with international environmental standards • outdated and environmentally inefficient technological base • export-raw material model of economic development, depletion of the resource base of fuel and raw materials industries, etc.	• environmental pollution • the exhaustion of resources • risks of accidents • ecological disaster • the increase in industrial waste	negative reputation
Market	• weak innovation activity • reduced sales volumes	• loss of market position • lower prices of products sold • reputation	leaving the market
Political and legal	• lack of necessary regulatory documents to protect information potential • lack of a strategy for creating an electronic archive	• ability to protect the rights of an industrial enterprise • raider seizure of an industrial enterprise	loss of individual protection of the enterprise

The threats and risks presented in table 1 for the blocks of economic security demonstrated that due to the proactive digital trend and current challenges, it is increasingly difficult for an industrial enterprise to stay on the international

market and protect its economic interests. Thus, new approaches to overcoming and adapting to modern realities in the world are now required.
The ecosystem approach in the development of enterprises, industries and regions provides obvious advantages that help to reduce certain risks and achieve significant effects. The decrease in overall risk is achieved by multiplying the risk between participants of the ecosystem.

In order to analyze the factors that lead to risks, we apply the Ishikawa diagram, which will help identify possible problems and threats to economic security as a result of the project implementation in the industrial innovation ecosystem.

Figure 2: Diagram of threats to the economic security of industrial enterprises in terms of interaction with other actors in the ecosystem

The industrial ecosystem is characterized by a set of relations regarding the distribution of resources, technologies, knowledge, experience, and joint tasks that are established between actors [10,18,19,20]. We identified the following internal risks that arise due to the collaboration of actors within the industrial ecosystem

Investment risks imply lost profits as a result of non-receipt of the expected return on investment, loss of invested capital. Monopolistic risks arise when one actor has a resource monopoly, and, as a result, setting high prices for them, which may be unprofitable for other actors..

Behavioral risks are associated with the typology of relationships that are established between partners as a result of interaction. Identification includes, in particular, assessing the risks of transferring key competencies, such as intellectual property rights, to other collaboration actors.

The integration risks can arise when the inclusion of actors in the value chain. This risk is associated with the probability and consequences of the fact that the actors of the industrial ecosystem did not fulfill their functional obligations on time or did not complete the task in full, which will s lead to failures for other actors in the logistics chain.

An actor's exit may suspend or slow down the project implementation process in the industrial ecosystem. If an actor who has left the ecosystem is a source of unique resources and knowledge, then this will be a threat for other businesses in the ecosystem. When interacting between actors to implement a project, such a situation may arise as "poaching employees" from other actors. The risk of headhunting can later disrupt the trust relationship between participants in the industrial ecosystem. The risk of information “leakage” is the unauthorized transfer of

confidential information, which may be intentional or accidental. Any information stored on the company's servers has its own cost.

In the context of digitalization, the key problem is the security of information data and the lack of qualified management personnel. This also leads to threats to economic security that determine the stable functioning of the actor - production, financial, and information. The most common risks include any difficulties in the activity of the actor in the process of planning and implementation. It is worth highlighting production and technological risks, since they are key to the functioning of the industrial actor. Risks associated with the production cycle are accidents, equipment breakdowns, depreciation of fixed assets and technical safety. In most cases, the actor's production, social and information risks are closely linked. So, for example, due to incorrect equipment settings the characteristics of the manufactured products deteriorate and as a result a negative impact on the reputation of the industrial enterprise.

The most important elements of the mechanism for ensuring the economic security are monitoring, analysis and forecasting of risks that determine threats to economic security. It is considered as an initial link in the system: monitoring-analysis and diagnostics-correction-achievement of the desired state of industrial enterprise safety.

The level of economic security of an enterprise is an assessment of the state of use of corporate resources according to the criteria of the level of economic security of the enterprise. Threats and risks arising in the ecosystem model can have a negative impact on the economic performance of an industrial enterprise, which will lead to a decrease of economic security. As part of this study, it is recommended to conduct a self-assessment of economic security degree at the stage of searching potential actors. If companies want to participate in an innovation ecosystem, it should to assess their degree of economic security and study the results of cross-evaluation other actors to make decision about joint project implementation in the ecosystem.

Research Methodology

The paper presents the threshold values of the degree of economic security of industrial enterprises for entering the innovative industrial ecosystem. The system for evaluating" blocks" of economic security is based on KPIs, which are assessed through qualitative and quantitative indicators. The set of indicators for assessing the degree of economic security of potential actors should be approximately the same for all, but taking into account the specifics of their functioning. In this study the potential participants of the ecosystem values were used for industrial enterprises

The assessment of the economic security of the enterprise is established based on the results of comparing the actual KPIs of the enterprise's activities. Indicators reflect the industry specifics and operating conditions of an industrial enterprise. An acceptable threshold of values that reflect the degree of economic security provides advantages and opportunities to participate in the ecosystem model.

As part of the study, the authors developed a system of KPI "blocks" of economic security and determined the threshold values using the "traffic light" method (table 3). Based on KPIs data, industrial enterprises can make decisions about their readiness to enter the innovative industrial ecosystem.

Table 3: Threshold level of economic security

Blocks ES	KPI	Indicators	Threshold level of economic security		
			(0-1)	(2-3)	(4-5)
Informational	information security of business processes	information completeness indicator	< 0,3	0,3 < Ki < 0,7	> 0,7
		information accuracy indicator			
		information accuracy indicator			
	phishing attack neutralization level	information accuracy indicator information inconsistency indicator	0-0,5	0,6-0,7	0,7-1

	flexibility of the supply chain	security SOFTWARE level logistics costs per unit of turnover	0-0,5	0,6-0,7	0,7-1
	protection level of confidential information	number of personnel who have improved their skills, per year	0-0,1	0,2-0,5	0,6-1
	security level of licensed programs	software security for employees	0-0,3	0,4-0,7	0,8-1
Financial-economical	financial stability	financial stability indicator	<0,75	0,8-0,9	>0,9
	business activity level	turnover ratio	<1	1	>1
	solvency level	coefficient of financial safety	<0,1	0,1	>0,1
	liquidity level	current liquidity ratio	<1	1-1,5	1,6-2,5
	level of financial safety margin	indicator of financial safety margin	<0,2	0,2-0,5	0,5-0,8
Human resources	staff turnover	employee turnover rate	<0,03	0,03-0,05	0,05-0,09
	level of material motivation	degree of satisfaction	<0,3	0,3-0,6	0,61-1
	level of competence of personnel in information security	training costs in total staff costs	<0,2	0,2	>0,2
	working conditions	professional diseases	>0,05	0,04-0,05	0-0,03
	the level of staff stability	staff constancy indicator	0-0,2;0,8-1	0,5-0,7	0,3-0,4
Industrial-technological	digitalization of production processes	level of automation	0-0,3	0,4-0,7	0,8-1
	level of technological security	extensive load factor	0-0,5	0,6-0,7	0,7-1
	level of innovation	labor intensity factor	0,7-1	0,6-0,4	<0,3
	level of capacity utilization	production capacity utilization rate	0-0,5	0,6-0,7	0,7-1
	level of infrastructure development	volume of software and it development expenses in production	0-0,1	0,2-0,6	0,7-1
Ecological, market, political and legal	level of responsiveness and flexibility to market changes	the level of innovation activity share of legal losses	0-0,1	0,2-0,5	0,6-1
	digitalization of business processes	the share of business in the field of digital technologies	0-0,3	0,4-0,7	0,8-1
	degree of response to challenges and trends	completeness of the analytical units of control departments	0,-0,5	0,6-0,8	0,9-1
	level of environmental friendliness	level of destructive impact	0,6-1	0,3-0,5	0-0,2
	arbitration proceeding	share of juridical expenses	0,6-1	0,3-0,5	0-0,2

For further evaluation of industrial enterprises in order to determine the level of readiness to enter the innovation ecosystem, points were determined for each zone:

from 0 to 1 – "Red zone" – critical values of economic security indicators, high risks of threats when entering the innovation ecosystem;

from 2 to 3 - "Yellow zone" - the optimal value of indicators, the probability of threats at the entrance to the ecosystem is not high, but requires constant monitoring;

from 4 to 5 - "Green zone" – the minimum probability of risks when entering the innovation ecosystem.

Discussion and Conclusion

The economic security of an industrial enterprise is the state of the most efficient use of resources, thus ensuring the sustainability of its operation. To enter an innovative industrial ecosystem it is necessary that the threshold values of economic security are in the green or yellow zone. In this way, actors must reduce risks both for each potential actor and for other participants in the ecosystem. If the value of a potential participant's EC is in the red zone, it is recommended to optimize the economic security system and develop measures to improve the indicators located in the red zone, which will lead to an increase in the degree of economic security.

The fundamental difference between the ecosystem model and others is the principles of self-organization and self-development. Detection of threats and hazards create conditions for achieving the financial and economic goals of an industrial enterprise, guarantees sustainable development the industrial ecosystem, its economic security, which is of primary importance in the conditions of digitalization and collaboration in the horizontal model.

In addition, preventive measures increase the effectiveness of the economic security system, which as a result leads to a positive reputation of the industrial enterprise. The proposed method for determining of economic security degree will allow the actors of the industrial ecosystem to identify the current weaknesses and strengths of their own economic security systems, evaluate other actors and make balanced, optimal decisions about participating in the project implementation in the industrial ecosystem.

Abstract

This paper deals with the concept of deviant workplace behavior. The paper presents the results of an empirical study on the types of deviant workplace behavior of employees in Croatian companies in the information technology sector (IT). The difference in the occurrence of deviant workplace behavior by gender and age was analyzed, after which the correlation between types of deviant behavior was examined. The results of the study showed a statistically significant difference in interpersonal deviance with respect to gender, i.e. male respondents are more prone to interpersonal deviant behavior in the workplace than women, whereas no statistically significant difference was found concerning organizational deviance. Regarding the age of the respondents, no statistically significant difference was found in any type of organizational deviance. Furthermore, statistically significant correlation was found between two main types of deviance (organizational and interpersonal), but that correlation is weak. The limitations of the research are outlined as well as recommendations for further analysis.

Keywords: Workplace Deviance, Types, Correlation, Age, Gender, Croatian IT Companies.

Introduction

In recent decades, there has been a growing interest among scholars in the topics of deviant workplace behavior. The number of studies addressing issues such as fraud, vandalism, theft, lying, spreading malicious rumors, aggressive behavior and sexual harassment in the workplace is growing rapidly. There are multiple perspectives on the concept of deviance and different understandings, interpretations and translations of the same. The causes of deviant behavior may be various, but almost always such behavior leads to adverse consequences, not only for the organization but also for the individuals. Furthermore, it can negatively influence on company stakeholders such as clients, business partners, society, etc. When work behavior breaches organizational norms, its consequences affect all levels of the organization, including the decision-making process, productivity and financial costs (Sims, 2010; Brown and Mitchell, 2010). The most common consequences are loss of motivation, stress, fear, increase in absenteeism, decrease in performance and productivity of employees, decrease in quality and service, as well as loss of reputation and performance drop of the organization. Therefore, the problem of deviant workplace behavior is important for any human capital-dependent and oriented organization aiming to create an efficient and effective work environment (Norsilan eta al, 2014).

Previous research has found that between 50% and 75% of employees are involved in some form of deviant behavior (Bennett and Robinson, 2000; Harper, 1990; Harris and Ogbonna, 2002), while more recent research shows that more than 90% of employees acknowledge engaging in some type of deviant workplace behavior (Marasi et al, 2018).

This paper provides an overview of studies related to shaping the concept of deviant workplace behavior and types of deviant workplace behavior. The following section present the basic characteristics of Croatian IT sector. The next section describes the results of an empirical study of employees in Croatian enterprises in the information technology sector (IT), which examined the correlation between types of deviant workplace behavior and differences in workplace deviance concerning gender and age. Conclusion and limitations of the research are provided at the end of the paper.

Literature Review

Defining and types of deviant workplace behavior

Deviant workplace behavior is defined as "voluntary behavior of organizational members that violates significant organizational norms, thereby jeopardizing the well-being of an organization and/or its members" and "that has a potential to cause harm to the organization, to those within, and in so doing violates significant performance-enhancing norms" (Robinson and Bennett, 1995). Organizational norms refer to grouping expected behaviors, languages, principles and postulates that allow one to work at an acceptable pace in the workplace (Awanis, 2006). Organizational norms are prescribed by formal and informal organizational policies, rules and procedures, and are related to the standards of the organization. Moreover, many unwritten rules are created by organizational culture. Hence, these rules are not the system of absolute moral standards (Kaplan, 1975). In companies that experience deviant workplace behavior, employees either lack the motivation to adhere to organizational norms or become motivated to violate those organizational expectations.

Deviant workplace behavior is also called work deviance (Appelbaum eta l, 2007), counterproductive behavior (Bennett and Robinson, 2000) organizational incivility (Miner et al, 2012), work destructive behavior etc. Hogan and Hogan (1989) view organizational deviance as a syndrome "organizational delinquency" that includes a wide variety of counterproductive acts such as theft, drug and alcohol abuse, lying, insubordination, vandalism, sabotage, absenteeism, and, according to their words, "offensive actions". These authors believe that employees who were engaged in delinquent actions are more likely to engage in others.

Hollinger and Clark (1982) categorized an employee's work deviation into a property-related deviation (acquiring or damaging property belong to the employer), and production-related deviation (violating organizational norms in terms of quantity and quality of work performed). Mangione and Quinn (1974) propose a similar categorization into: counterproductive behavior related to property (intentional damage of employer's property) and deviation related to production (poor quality or low quantity production). Often cited division (Robinson and Bennett,1995; Bennet and Robinson, 2000) divides workplace deviance into: (1) organizational that can be production-related deviance, and is a less severe form of deviance (absenteeism, delayed or early leaving work, taking longer breaks, slower pace of work, waste of resources) and property deviance that is a more severe form of deviance (demolition or alienation of property, misrepresentation of working hours, theft, counterfeiting of accounts, etc.) and (2) interpersonal, which may be political deviance that is milder form of deviance (gossip, blame shifting, favoritism, unfair competition, etc.) and personal aggression that is more severe forms of deviance (sexual harassment, verbal harassment, stealing from co-workers, sabotaging and threatening co-workers, etc.).

Two main types of workplace deviance, interpersonal and organizational are interrelated according to previous empirical studies (Benet and Robinson, 2000, Lee and Alen, 2002; Dalal, 2005). Regarding differences in main types of workplace deviance by gender, number of previous studies found that men were more often involved in deviant behavior (Santos and Eger, 2014; Anvar et al, 2011; Alsksić et al, 2019) and more often involved in aggression at work in comparison to women (Martinko, 2006; Griskevicius et al, 2009; Cross et al, 2011). In their empirical research Chernyak-Hai et al (2018) found no Mean differences in individual and organizational deviance regarding gender, but differences were find in profiles coordinates; i.e. male were more often involved in certain items of direct aggression, and in organizational deviance items of more severe form, whereby women were more often involved into indirect aggression items i.e. political deviance and in certain items of organizational deviance of less severe form.

Causes of deviant workplace behavior

Several theories, such as theory of social exchange (Blau, 1964), the norm of reciprocity (Gouldner, 1960) and theory of psychological contract (Rousseau, 1989) are often used to explain the link between responsible and undesirable organizational behavior. Theory of social exchange is a relatively old theory in social sciences that has been developed and modified over time. It covers number of models that have some common elements but also some specificities. Within theory of social exchange, basic assumption is that resources among parties are exchanged reciprocally. Social exchange refers to interdependent actions among parties based on mutual exchange of resources (economic and socioemotional) that create relationship if they are repeated. Theorists who advocate social exchange theory consider that in workplace certain kind of social exchange between the employee and the organization occurs. When one party (organization) treats the other party (employee) in a good manner, the reciprocity norm obliges the other party (employee) to reciprocate a positive treatment (Gouldner, 1960) and vice versa. Desirable initiation actions by organization are those that facilitate organizational justice, organizational support, supervisory support, trust etc. Reciprocal response by employees may include organizational citizenship behavior, commitment, trust etc. Existence of advantageous and fair reciprocal exchanges may transform economic exchange relationships into quality social exchange relationships that are closer and with longer time horizon (Cropanzano et al, 2017). Reciprocity based on

fair initiation action tends to facilitate better harmony among parties especially if repeated in cycles. It is assumed that employees receive some social benefits and rewards in exchange for their hard work and loyalty to the organization (Rhoades and Eisenberger, 2002). On the other side, negative initiation action may lead to negative reciprocating response. Consequently, unfair treatment may deter the quality of social exchange relationship and make employees prone to workplace deviance (El Akremi et al, 2010, Biron, 2010). A psychological contract refers to an individual employee's belief in mutual obligations between the individual and the organization. Such psychological contract can be relational or transactional and is seen as a strong determinant of behavior in organizations. Breach of psychological contract often results in intense negative emotions such as anger (Rousseau, 1989). Negative emotions can also be reflected in undesirable organizational behavior. In their model, Spector and Foxa (2002) explain that affect (emotions) evoke " tendencies for action " that can be constructive or destructive. The results of their research show that in a situation where a positive affect is caused, responsible organizational behavior is more likely to occur, and vice versa.

Within study of workplace deviance antecedents, scholars systematize a number of factors that are associated with the occurrence of such behavior. Alias et al (2013) categorize causes of workplace deviance into three groups: a) individual factors b) job-related factors and c) organization-related factors. Individual factors capture certain employee characteristics, feelings and cognition (including some personality traits, attitudes, values, mental health, etc.). Factors related to work include stress at work and powerlessness arising from a vague job description, work overload, lack of resources, perception of working at not respected job, while factors associated with the organization include inadequate organizational culture and climate, insufficient organizational support, low levels of trust, organizational injustice etc. (Chirasa and Mahapa, 2012).

Among the organization-related determinants, scholars emphasize the important role of organizational culture in influencing deviant workplace behavior (Vardi and Weitz, 2004). Organizational culture usually interacts with other organizational-related factors, work-related factors and individual factors of workplace deviance to create or prevent employee willingness to express deviant behavior. Formal organizational rules and procedures are in accordance with corporate culture. Schein (1985) defined organizational culture as a set of beliefs, values and assumptions that are shared by the members of organization. Sharing of certain values, norms, assumptions, and goals among employees influences the dynamics of relationships among employees, between employees and organization, and between organization and its stakeholders (Hill and Jones, 2001). Schein (2004) noted that organizational culture identifies to what things members of the organization should pay attention, how they react emotionally, and what actions they should take. Different types of values within organization culture encourage different types of social exchange that implies important role or organizational culture in distinctive type of exchange relationship (Richard et al, 2009). Corporate culture can facilitate positive or negative types of behavior by influencing on barriers to progress, reward and recognition program (Austin and Guillaume, 2016; An and Kang, 2016). There are examples of organizational culture that support aggressive behaviors as a type of employee motivation (Valentine et al., 2015). To decrease the possibility of deviant workplace behavior, organization should shape adequate value framework and other cultural artifacts that will create domain of favorable work environment.

Although deviant workplace behaviors can be analyzed at the group level (Priesmuth et al, 2014), at the business unit level (Dunlop and Lee, 2004) and at the organizational level (Ermann and Lundman, 1978), in research studies, deviant workplace behaviors have generally been examined at the individual level.

Croatian IT sector

The basic indicators of the Croatian IT sector are taken from the Survey of Croatian Chamber of Commerce (2018) related to the period from 2008 to 2017. According to this report for the year 2017, the Croatian IT sector is characterized by the following data: 1) the number of IT companies was 4.649 (9% of total number of companies in Croatia), with predominantly small-size companies - 80% of IT companies had less than 5 employees; 2) the average monthly net salary was HRK 7.722 (44% more than the average net salary in Croatia); 3) sector employs 28.347 workers (3,2% of the total number of employees in Croatia); 4) total revenue amounted to HRK 21,1 billion (3,1% of total revenue of Croatian economy), whereby IT services accounts for about 70%, trade of IT equipment for 26%, and the production of IT equipment/components about 3%; 5) the economic value added amounted to HRK 6,7 billion (4,8% of the total economic value added of Croatian economy); 6) exports amounted to HRK 6 billion (4,8% of the total Croatian export), profit margin was 7,9% (in comparison to profit margin of Croatian economy that was -1,3%). Furthermore, it is interesting to revile the movement of the basic indicators of the Croatian IT sector in the period from 2008 to 2017 (Croatian Chamber of Commerce, 2018): 1) the number of IT companies grew at an average annual rate of 8,1% (the average rate of the Croatian economy was 3,3%); 2) the net salary grew at an average rate of 2,8% (in comparison to average net salary growth in Croatia of 1,8%); 3) the number of employees grew at an average annual rate of 6% (while the average number of employees in Croatian economy decreased annually -0,6%); 4) total revenue grew on average rate of 3,8% (compared to the Croatian economy, which decreased annually by -0,5%); 5) economic value added grew annually at a rate of 6,7% (in comparison to the Croatian economic value added growth

which was 0,9% a year); 6) exports grew at an average rate of 6,7% a year (while the average growth rate of overall Croatian export was 4,4%), 7) productivity decreased by an average annual rate of -2% (in comparison to average rate of productivity growth in Croatia which was 0,1%). Concerning these data, it can be concluded that the Croatian IT sector is a propulsive sector that has been increasing faster than overall Croatian economy in the observed period. Exception is productivity (measured by total revenue per employee) that has decreased in observed period.

Empirical study of deviant workplace behavior in Croatian IT companies

Research Methodology

The aim of this paper was to investigate the occurrence of deviant workplace behavior, to examine the difference in deviant behavior by age and gender and to determine correlation between types of workplace behavior. An empirical study was conducted in which the research population consisted of employees of Croatian companies operating in the IT sector. Data were collected in 2019, and the survey was completed by 58 respondents. Participants were recruited based on a snowball technique through personal and professional contacts. This method is common in social research, especially if the research subject is connected with delicate issues (Etikan et al, 2016) such is workplace deviance. A survey questionnaire using a Google form was used as a data collection instrument. The questionnaire had 21 closed-ended questions, 2 of which covered demographics data (age and gender). The following19 questions were designed to evaluate the occurrence of deviant behavior in the workplace. In constructing questionnaire to investigate deviant behavior standardized questionnaire was considered (Bennett and Robinson, 2000). Interpersonal deviance was examined using 7 statements (items), while organizational deviance was examined using12 statements (items). Scale anchors were: 1 (never), 2 (once a year), 3 (twice a year), 4 (several times a year), 5 (monthly), 6 (weekly), 7 (each day).

Empirical research was conducted in the following stages: (1) descriptive analysis of the sample; (2) analysis of differences in types of deviant workplace behavior by age and gender; (3) analysis of the correlation between types of workplace deviance.

The analysis showed that the respondents are mostly employed in four medium-sized companies, with more than 50 employees in the IT sector. Among the respondents were 48% women and 52% men (according to the latest 2011 census, the Republic of Croatia had 48.2% men and 51.8% women). The largest share of respondents is in the 18-25 age category and accounts for 55% of the sample. Next in number is the 26-45 age category, which makes up 38% of the sample. Only 7%, or 4 respondents, are older than 45 years. None of the respondents are older than 65 years.

Research Results

At the beginning, we will present metric characteristics of measurement scales for types of workplace deviance – result of the reliability analysis.

Interpersonal deviance was measured by 7 items: ID_1 (Made fun of someone at work); ID_2 (Said something hurtful to someone at work); ID_3 (Made an ethnic, racial, or religious remark or joke at work); ID_4 (Cursed someone at work); ID_5 (Cheated on someone at work); ID_6 (Acted rudely toward someone at work); ID_7 (Publicly embarrassed someone at work).

The results of the reliability analysis of the measurement scale for interpersonal deviance and the impact of individual items on overall reliability are shown in Table 1. It can be seen from Table 1 that the scale “Interpersonal deviance” is in the area of excellent reliability. Reliability could be improved only slightly if we remove the item INTERPER_DEV_1 "Made fun of someone at work". Hence, we will use all seven items of this measurement scale.

Table 1: Measurement scale for interpersonal deviance - impact of individual items on the Cronbach's Alpha coefficient

Item-Total Statistics: Total Cronbach's Alpha = 0,90				
Items of Interpersonal Deviance	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
INETERPER_DEV_1	10,14	39,279	0,564	0,905
INETERPER_DEV_2	10,64	37,814	0,814	0,869
INETERPER_DEV_3	10,79	39,185	0,702	0,883

INETERPER_DEV_4	10,45	35,971	0,797	0,871
INETERPER_DEV_5	11,16	44,239	0,633	0,892
INETERPER_DEV_6	10,91	38,957	0,789	0,873
INETERPER_DEV_7	11,22	43,721	0,757	0,884

Measurement scale for organizational deviance consisted of 12 statements: OD_1 (Taken property from work without authorization); OD_2 (Spent too much time fantasizing or daydreaming instead of working); OD_3 (Falsified a receipt to get reimbursed for more money than you spent on business expenses); OD_4 (Taken an additional or a longer break than is acceptable at your workplace): OD_5 (Come in late at work without permission); OD_6 (Littered your work environment); OD_7 (Neglected to follow your boss's instructions); OD_8 (Intentionally worked slower than you could have worked); OD_9 (Discussed confidential company information with an unauthorized person); OD_10 (Used an illegal drug or consumed alcohol at work); OD_11 (Put little effort into your work); OD_12 (Dragged out work in order to get overtime).

The results of the reliability analysis of the measurement scale for organizational deviance and the impact of individual items on overall reliability are shown in Table 2. It can be seen from Table 2 that the measurement scale for organizational deviance is in the area of very good reliability. Reliability could be further enhanced by deleting item ORG_DEV_12 "Dragged out work in order to get overtime." The result of the new reliability analysis without this item is shown in Table 3. After the item ORG_DEV_12 was deleted from the measurement scale for organizational deviance, a slightly higher, very good reliability was achieved and its Cronbach's Alpha coefficient is now 0.80. Since the elimination of any of the remaining eleven statements would not contribute to the increase of the Cronbach's Alpha, it will be used in this form in further analyzes.

Table 2: Measurement scale for organizational deviance - analysis of the impact of individual items on the Cronbach's Alpha coefficient

Item-Total Statistics: Total Cronbach's Alpha = 0,78				
Items of organizational deviance	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
ORG_DEV_1	20,40	45,261	0,472	0,768
ORG_DEV_2	19,36	37,217	0,622	0,744

ORG_DEV_12	20,36	48,937	0,096	0,795

Table 3: Measurement scale for organizational deviance - Impact of items on the Cronbach's Alpha coefficient after deleting ORG_DEV_12

Item-Total Statistics: Total Cronbach's Alpha = 0,80				
Items of organizational deviance	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
ORG_DEV_1	19,02	43,491	0,484	0,779
ORG_DEV_2	17,98	35,877	0,610	0,759
ORG_DEV_3	19,26	47,564	0,190	0,798
ORG_DEV_4	17,55	34,532	0,581	0,766
ORG_DEV_5	18,41	41,475	0,409	0,783
ORG_DEV_6	19,10	44,410	0,543	0,780
ORG_DEV_7	18,62	43,117	0,366	0,787

ORG_DEV_8	17,86	36,612	0,616	0,758
ORG_DEV_9	18,57	42,390	0,335	0,792
ORG_DEV_10	18,91	45,378	0,295	0,792
ORG_DEV_11	18,33	39,172	0,639	0,759

After the results of reliability analysis, the results of differences in types of deviant workplace behavior, by gender and age are presented. A t-test was used to determine the behavioral difference on the dimensions of workplace deviance by gender, taking into account the results of the Levene equality test of variance in the sub-sample distribution (Male, Female). For the purposes of this test, the individual scores of the respondents on the seven statements of the dimension of interpersonal deviance were summed up, and the individual scores of the respondents on the eleven statements of the dimension of organizational deviance were summed up. Two new variables were thus obtained: interpersonal deviance and organizational deviance. The results of the analysis are presented in Table 4.

Table 4: Difference in types of deviant workplace behavior - by gender

Types of deviant workplace behavior	Scale Mean (Male) Item-Total Statistics	Scale Mean (Female) Item-Total Statistics	t(56)	p-level
Interpersonal deviance	16,0	9,33	3,765	0,001
Organizational deviance	20,93	19,83	0,592	0,556

Table 4 shows that there is a statistically significant difference in interpersonal deviance with respect to the gender of the respondents ($p < 0.05$), i.e. male respondents are more prone to interpersonal deviant behavior in the workplace than female. No statistically significant difference in organizational deviance was found between male and female respondents ($p > 0.05$).

If the Mean of particular type of deviant workplace behavior (Item-Total Statistics) is divided by the number of items used to measure it, an average mark of deviance is calculated. For example, if we divide the Mean (Male) for interpersonal deviance by 7 (the number of items used to measure it), the average rating on these claims is 2.29. The average mark of interpersonal deviance, based on female respondents is 0.85. The average mark of organizational deviance for male respondents is 2,86, while female mark their deviance at 1,80 on average.

In the next step, t-test was used to determine the behavioral difference of the dimensions of deviance by age, taking into account the results of the Levene equality test of the variance of the sub-sample distribution (Age 18-25; Age 26+). For the purposes of this test, the individual scores of the respondents on the seven statements that make the dimension of interpersonal deviance were summed up, and the individual scores of the respondents on the eleven statements that make the dimension of organizational deviance were summed up. Two new variables were thus obtained: interpersonal deviance and organizational deviance. Given that in the analyzes of difference in behavior, the variable "age" is used as a distinguishing criteria and that the third age category in the sample is very poorly represented, the variable "age" was recoded into two categories: 18-25 years and 26 years upwards. The results of the analysis are presented in Table 5. Table 5 shows that no statistically significant difference was found in either interpersonal or organizational deviance with respect to respondents' age ($p > 0.05$), i.e. respondents were equally prone or inclined to deviant behavior in the workplace regardless of age.

Table 5: Difference in types of deviant workplace behavior by age

Type of deviant workplace behavior	Scale Mean (Age 18-25) Item-Total Statistics	Scale Mean (Age 26+) Item-Total Statistics	t(56)	p-level
Interpersonal deviance	12,09	13,12	-0,526	0,601
Organizational deviance	19,97	20,85	-0,472	0,639

If we divide the Mean of particular dimension of deviant behavior (Item-Total Statistics) by the number of items used to measure that deviance, the average mark of deviance is calculated. For example, if the Mean for interpersonal deviance of younger respondents (18-25 years) is divided by 7, the average rating on those items is 1,84. Average mark of interpersonal deviance of older respondents (age 26+) is 1,87. Concerning organizational deviance, average rate of younger respondents (18-25 years old) is 1,82, while older respondents (aged 26+) marked their organizational deviance with average score of 1,90.

Furthermore, we were interested in the proportion of respondents who, according to self-assessment, had never been deviant in the workplace (Table 6). Specifically, Table 6 shows that the highest percentages of “Never” responses relate to items such as “Falsified a receipt to get reimbursed for more money than you spent on business expenses,” “Publicly embarrassed someone at work "," Cheated on someone at work " which can be classified as a more serious workplace deviance. On the other hand, the smallest percentages of “Never” answers on items such as “Taken an additional or longer break than is acceptable at your workplace,” “Spent too much time at work fantasizing or daydreaming instead of working”, "Put little effort into your work", which can be classified as minor deviance.

Table 6: The proportion of "Never" responses in self-estimation of deviant workplace behavior (sorted from highest to lowest)

Items of workplace deviances	Proportion of „Never“ responses
Falsified a receipt to get reimbursed for more money than you spent on business expenses	93%
Publicly embarrassed someone at work	83%
Cheated on someone at work	81%
Littered your work environment	79%
Taken property from work without authorization	76%
Dragged out work in order to get overtime	76%
Used an illegal drug or consumed alcohol on the job	71%
Acted rudely toward someone at work	69%
Made an ethnic, racial, religious remark or joke at work	64%
Said something hurtful to someone at work	55%
Cursed someone at work	53%
Discussed confidential company information with an unauthorized person	53%
Neglected to follow your boss's instructions	52%
Intentionally worked slower than you could have worked	52%
Come in late to work without permission	45%
Made fun of someone at work	40%
Put little effort into your work	36%
Spent too much time at work fantasizing or daydreaming instead of working	33%
Taken an additional or longer break than is acceptable at your workplace	26%

In the next section of research, we examined the interrelationships of the main two types of deviant workplace behavior: interpersonal and organizational. A correlation analysis was performed to determine the interconnectedness of the two types of deviance. The results of the correlation analysis are shown in Table 7. Table 7 shows that analysis confirmed statistically significant correlation between the two types of deviance: interpersonal and organizational. But their correlation is weak as these two variables share only 25% of the variance.

Table 7: Matrix of correlations between the main types of workplace deviance

Types of workplace deviance	Interpersonal deviance	Organizational deviance
Interpersonal deviance	**1,000**	0,499*
Organizational deviance	0,499*	**1,000**

**statistically significant correlation*

Conclusion

Deviant workplace behavior can harm not only the organization and its employees but other stakeholders as well. Therefore, it is important to prevent its negative consequences by recognizing and demotivating deviant behavior at work. Many organizations depend on human capital, which is crucial in achieving competencies and competitiveness. Creating a supportive work environment without fertile ground for deviant behavior can help companies in their path to success. The scientific literature describes a number of factors that are associated with deviant work behavior, such as individual factors, job-related factors, and organization-related factors. Theory of social exchange implies that managers should create favorable internal environment with factors that improve organizational justice, organizational and supervisory support, adequate leadership style, adequate organizational climate and culture etc. (organization-related factors). In addition, the existence of proper work-related factors such as clear job-description and job roles, clear job objectives, sufficient resources and workload help to create work domain that reduce deviance. Moreover, individual related factors should not be neglected within the process of employee selection and development. Understanding the role of these factors can help managers to focus their attention toward identification of organizational weaknesses and improving them in order to create a desirable work environment that will diminish deviancy.

The empirical research conducted in this paper confirmed the existence of various elements of the main two types of workplace deviance in Croatian IT companies. The results showed that employees were involved in various elements of both types of workplace deviance - interpersonal and organizational, although the average level of deviance is relatively low. Regarding the proportion of respondents who, according to self-assessments, had never been deviant in their workplace, results showed that highest percentages of "Never" responses was related to items that can be classified as a more serious deviance. On the other hand, the smallest percentages of "Never" answers were on items that can be classified as minor deviance. Additionally, the paper analyzed the relationship between different types of deviant workplace behavior and the differences between deviant workplace behavior by gender and age. The results showed that there was a statistically significant correlation between two types of deviant workplace behavior (interpersonal and organizational) but these two variables share only 25% of the variance and their relationship is weak. Furthermore, there was a statistically significant difference in interpersonal deviance with respect to the gender of the respondents ($p < 0.05$). Male respondents are more prone to interpersonal deviant behavior in the workplace than female. No statistically significant difference was found between men and women concerning organizational workplace deviance, ($p > 0.05$). Average mark of interpersonal deviance for male is 2,29, and for female is 0,85 - according to scale from 1 (never) to 7 (each day). Average mark of organizational deviance for male respondents were 2,8 and for female respondents were 1,8. Additionally, no statistically significant difference was found in either interpersonal or organizational deviance with respect to respondents' age ($p > 0.05$). Respondents were equally prone or inclined to deviant behavior in the workplace regardless of age.

Relatively low level of both types of deviance, found in this study, is in accordance with the results of similar empirical research conducted in Croatian companies that indicated the same (Aleksić et al, 2019). The only difference is that the research of Aleksić et al (2019) showed that both types of deviance were slightly higher for male than for female respondents. Differences in interpersonal deviance regarding gender might have numerous reasons. The reason could be gender stereotypes that gives men "alibi" to more often express negative feelings and aggression in comparison to woman (Black, 1990), gender differences in job status, career and employment, perceived threat on employment status (Cherniak-Hai et al, 2018), differences in reward levels etc. We agree with other scholars that add additional reasons of gender differences such as level of stress, level of self-esteem, level of confidence, differences in personality traits, different social roles and other factors of broader social context.

Although this study has produced interesting results, it is certainly worth considering the limitations of the research. The limitations of this empirical research stem from two main sources of possible bias: (1) relatively small sample size - results should be understood as indicative of assessing the reliability of measurement scales and the interrelationship of the variables used; (2) respondent bias - since respondents are asked to directly evaluate their own potentially deviant behavior on given measurement scale, it must be taken into account that this is a subjective self-assessment, which may not correspond to reality. Specifically, the subject of the measurement is extremely sensitive. Thefts, misuse of resources, unjustified delays at work, insults, physical assaults or harassment behaviors that employees are reluctant to admit for fear of the negative consequences that these admissions might have on them, although the survey is anonymous. In addition, people generally have a need to portray themselves in a better light, and this is particularly reflected in the subject of measurement. Likewise, respondents may have been deliberately insincere in their self-assessment of deviant behavior, so it is likely that the incidence of deviant workplace behavior in this study is underestimated.

Recommendations for further research on this issue include: conducting empirical research on the occurrence of deviant behavior and the relationship between types of workplace deviance in other industries in Croatia or in other countries, that should include a larger number of respondents and be based on additional methodologies (such as

profile coordinate methodology etc.). Empirical research about various causes and consequences of deviant workplace behavior may be interesting to further explore the key factors of workplace deviance and their negative effects.

Abstract

More than 20 years since the Directorate General of Higher Education of the Ministry of National Education of Indonesia has encouraged the use of technology for education, very few universities have made use of online learning. With the influx of the COVID-19 pandemic, suddenly all lecturers across universities are transforming and even the digital revolution. After the issuance of the Minister of Education and Culture Circular on March 9, 2020 to university leaders to conduct learning from home, in a short time many universities switched to online learning modes. The use of online learning platform is increasingly becoming a trend in the world of education. This trend gave birth to a data explosion in Higher Education which became a new innovation for the world of education, namely Big Data. These large amounts of digital data will provide information on what students and academics see and read, student behavior and involvement, their assessment, motivation and preferences, thus providing a large amount of data that can be extracted for the learning experience. Big Data provides an opportunity to educational Institutions to use their Information Technology resources strategically to improve educational quality and guide students to higher rates of completion, and to improve student persistence and outcomes. This proposes work paper aimed at explores the attributes of big data that are relevant to educational institutions, investigates the factors influencing adoption of big data and analytics in learning institutions and seeks to establish the limiting factors hindering use of big data in Institutions of higher learning.

Introduction

With current developments, this big data can be processed and used again, even giving better results because it includes data processing in social media. The use of information technology in Indonesia has touched all areas of life, namely economy, politics, culture, law, education and healthcare. The development of information technology systems makes human activities easier and faster every day. For example, the entire transaction process is carried out with an electronic process, starting from paying for electricity, water, plane tickets, trains, online shops, student tuition fees, mobile collaborative healthcare (Syafar and Husain, 2017) and many more. Information technology has been used to carry out various main activities in higher education, starting from the payment of tuition fees, registration of lectures every semester, registration of final and comprehensive sessions, attendance and lecture minutes, even the learning process to assessment. Data on education and teaching, research, community service, and other supporting activities has also been reported using information technology. All of these activities from time to time lead to digitization of data which in turn causes a data explosion in Higher Education, thus opening up opportunities for big data analytics in universities. Drigas and Leliopoulos (2014) stated, "... Big Data can really improve the education. Can afford to shape a modern and dynamic education system, which every individual student can have the maximum benefit from that .... ". This means that the use of big data in the world of education will be able to form a modern and dynamic education system that is beneficial for lecturers and students. Large amounts of digital data leave behind what students and academics see, what they read, their engagement and behavior, judgments, as well as their interests and preferences, thus providing a large amount of data that can be mined for the learning experience.

Research Problem

Based on the background of this problem, several problems that arise in this study can be formulated, namely: 1. How does big data technology involve the world of education? 2. How is the use of big data analytics in higher education, which includes academic analytics, learning analytics and process analytics?

Research Objectives

This study aims to provide proposals for the use of big data analytics in higher education, which include, academic analytics, learning analytics and academic analytics. In addition, with the use of big data, universities are expected to be able to map their strengths and weaknesses for policy making.

Theoretical Foundations

Big data can also be defined as a problem domain where traditional technologies such as relational databases are no longer able to serve. Big data is more than just a matter of size, it is an opportunity to find insights in new and emerging types of data and content, to make your business more agile. , and answer questions that were previously considered beyond your reach. Big data can be interpreted into 9 characters (IBM) according to respondents, so it can be concluded by IBM, Big data is data that has a very large scope of information, a real-time information model, has a large volume, and is based on social media data so it can be concluded that Big data is a dataset that has a large volume and one of its contents is based on social media data, and the information from Big data is always the latest (latest data) so that the information model is real-time, and the scope of information is not focused on small industries only or large industries only but all small and large industries.

Data digitization has opened up opportunities to use big data in universities. The value of big data lies in the results of analysis and predictions or the actions taken from the results of these analyzes and predictions.

Data digitization enables effective practice to utilize big data analytics in the form of learning analytic, academic analytic and process analytic. By using big data analytics in Higher Education which is supported by the cooperation of all educational enterprise contributors, be it students, staff, lecturers, administrators, and the community, it is possible to make accountable decisions based on information and data mined carefully, so that in the end it supports increasing decision making based on data in tertiary institutions in an effort to improve the success performance of students and institutions.

Görnerup et al., imply that Big Data presents a good framework for efficiently utilizing the vast array of data in shaping the future in higher education sectors. In addition, Wagner and Ice (2012) states that the implementation of Big Data in higher education is attributed to technological innovations and developments that trigger the growth of analytics in higher education. Moreover, Drigas and Leliopoulos, (2014), found that Data Warehouses and Cloud Computing coupled with greater ownership of digital devices Higher Education stakeholders are allowing to obtain, manage and maintain big data. These Information Technologies are important resources that are useful in driving HE business strategy and decision making. According to Educase (2019), Information Technology makes available sophisticated platforms that provide computing power necessary for ploughing through big data analytic, and turning these masses into meaningful information

With the use of big data analytics in higher education, it can be obtained more insight into students, academics, and the process in higher education so that it supports predictive analysis and increases decision making based on data which in turn can help improve the success performance of students and institutions.

The use of big data analytic in higher education which includes learning analytic, academic analytic, and process analytic.

1. Learning Analytic

Big Data Analytic can be used to analyze in real time student experiences that can be generated from student activities, such as: lecture registration, payments, class participation, online learning, and assessments.

Learning Analytic is analyzing learning data in real time so that it can be used to predict successful students and students who are at academic risk. With big data analytics in higher education can provide insight into students who are at risk of dropping out so that preventive action can be taken (Syafar et al., 2019b; Syafar et al., 2017) or provide additional support to increase their success, and confidence, in the learning process before they really fail.

Learning Analytic has the potential to help students and lecturers together recognize signs of danger before threats to learning success materialize. Learning Analytics provides tools, technology, and a platform to empower educators and open doors to meaningful learning experiences that can engage, inspire, and prepare current and future students for success.

For learning analytics, you can use data sources from Student Information System data, Course Magement, Online Education, Student Assessment, and finance data.

2. Academic Analytic

The object that can be analyzed in Academic Analytic is the performance of academic staff. With academic analytic, real time analysis can be carried out on data which is a variable measurement of academic performance so that it can be seen that outstanding academic staff and academic staff are underperforming compared to other academic staff. For the academic analytic process, you can use data sources from the Outcomes Assessment data, Lecture Assessment, Staff Assessment, Faculty Assessment, and Finance Assessment data. Data captured and processed by these systems is not comprehensive and is process dependent, making it difficult to be reused for any other sources or process innovation (Syafar et al., 2015).

3. Process Analytic

Big Data Analytic can also be used to analyze real time business processes in Higher Education. The data used can be obtained from log data or activity data from students, lecturers, and units related to the processes and activities that occur in tertiary institutions to then carry out process analytics using process mining to find new business process models. However, process analytics is not limited to the process discovery of business processes but also allows for compliance checking, detecting deviations, predicting delays, supporting decision making, and recommending process redesign.

Meanwhile, process analytics can use data sources from log activity data from the Student Information System process or mobile learning system (Syafar et al., 2019a), Course Management, Online Education, Student Assessment, and log activity data from the finance process. Student Assessment, and data finance.

Data from several sources is then collected in a data warehouse to be analyzed using real time analysis and predictive technology, such as: OLAP, Analytical Reporting Tools (Business Intelligence), and Data Mining / Predictive Modeling.

The results of the analysis and predictions will be displayed in the form of a Dashboard Analytic Presentation which is expected to support the improvement of decision making in higher education in an effort to improve educational, academic performance as well as the success of students and institutions.

Research Method

This research intends to use a qualitative research design. Semi-structured interview approach will be used as the research methodology, which will provide an opportunity to triangulate as the primary source and materials from the literature review and result of Delphi study as the secondary source. The methodology intends to employ for respondents open-ended deliberations, fixing future analysis by questioning significant explanations made by the respondents. This method of qualitative research attests, and most appropriate particularly when the phenomena to be researched are not accurately understood or known, and researcher desires to get an in-debt understanding perspective from respondents experienced in the aspect. The target respondent will be the IT person of Indonesian universities.

Result Expectation

Now after one semester online learning are running on during the Covid-19 pandemic, we saw a lot of learning can be picked. The case of the spread of Covid-19 in Indonesia still not showing a significant decrease. Data on September 10, 2020, it still shows its height new cases in several provinces in Indonesia, with the number of new cases was 3861, which is much higher of the number of patients who recovered, which was only 2310 people. Thus, it seems that the situation is not quite yet under control and many regions still apply status Large-Scale Social Restrictions (PSBB).

Hence, process of online learning in higher education in the semester to become still not yet fully likely to come back "Normal" as before. Distance learning and especially learning online seems to still be coloring if it isn't dominate the lecture process at various Universities. This matter also indicated by the results of various surveys conducted, both in Indonesia and abroad. Experience one semester this should be that learning valuable so that the next online learning process can be organized in a more planned, structured, In the midst of the uncertain situation, the lecturers has demonstrated a tremendous capacity to remain running the learning wheel in various ways, make use of various learning resources exist, and with a capable spirit of serving. Plague Corona virus that came suddenly was able to revolutionize perspective, mindset, and behavior patterns of the academic community

our higher education. Uncertainty has turned into opportunities to innovate. systematic, and quality.

Conclusion

This paper will be explored Big Data Analytics and its relevance in Higher Educational systems during and after pandemic Covid-19 with a view of helping Indonesia universities adopt Big Data Analytics. The research will also explore the attributes of quality of big data and information analytic that are relevant to Indonesian HE sectors, and looked at the factors hindering the use of big data analytic.

Abstract

Dans un environnement technologique à évolution vertigineuse, l'acceptation des technologies de l'information et de la communication (TIC) est souvent un véritable goulot d'étranglement auquel se heurtent les responsables et dirigeants au sein des hôtels marocains. Pourtant l'usage des TIC est un enjeu économique mais et surtout social important pour améliorer la qualité de travail quotidien.

Depuis décembre 2019, le Coronavirus 'Covid-19' s'est propagé depuis la chine, c'est un virus qui provoque des symptômes semblables à un rhume, voire même des complications respiratoires plus graves chez les patients âgés ou souffrants de maladies chroniques.
(Source : Organisation mondiale de la santé)
Face au risque de contagion et à l'évolution non maîtrisable de la Covid-19, le Maroc décrète l'état d'urgence sanitaire, et le gouvernement impose le confinement, la fermeture des écoles, hôtels, restaurants, lieux publics et entreprises non indispensables le 16 Mars 2020.
(Source : communiqué du ministère de l'intérieur, Mars 2020)

Cette pandémie a accéléré le processus de digitalisation, et d'utilisation de la technologie pour la majorité des entités notamment dans le secteur hôtelier. Un accroissement technologique très opportun pour les entités mais pas toujours accepté par les employés.

L'objectif ultime de cet article scientifique est d'identifier l'impact d'une pandémie planétaire (Covid-19) sur le comportant humain notamment par rapport à l'acceptation et l'utilisation des technologies. Plusieurs variables affectivo-émotionelles feront l'objet d'un modèle redéfini du TAM (Technology acceptance model).

Mots-clés : Acceptation de la technologie, Covid-19, pandémie, TAM, système d'information, secteur hôtelier.

Introduction

Le Maroc est le pays africain où les technologies sont les plus développées. Selon la sixième conférence du city africa tenue à Tanger en mai 2018. Le royaume arrive en tête de la liste par le biais de son contrôle sur les exportations technologiques au moyen orient et en Afrique du nord soit 45% et par la réalisation de +10% courant les cinq dernières années dans les secteurs de la technologie de l'information et de la communication.

Selon le HCP (haut-commissariat au plan), le tourisme représente la locomotive de l'économie marocaine, le royaume se place désormais première destination africaine malgré une concurrence rude sur le continent. Une progression des visites touristiques au Maroc de 6,4% par rapport à l'an passé est notable. En 2019, Marrakech se retrouve en tête du classement national avec une hausse de 8%, suivie d'Agadir – générant à elles seules 58% des

nuitées totales. Dès lors, le secteur touristique occupe le rang de second contributeur au PIB national et créateur d'emplois de premier plan. (Source : site du Ministère du tourisme).

Afin d'être en alignement stratégique, managers et dirigeants du secteur hôtelier se disputent les dernières technologies. Malgré la valeur ajoutée qui peuvent générée, ces outils ne sont pas toujours utilisés et acceptés par les employés qui représentent généralement les keyusers. (Peypoch, 2011)

Depuis décembre 2019, la Covid-19 s'est propagée depuis la chine, c'est un virus qui provoque des symptômes semblables à un rhume, pouvant aller jusqu'à des complications respiratoires plus graves chez les patients souffrants de maladies chroniques. (Source : Organisation mondiale de la santé)

Face au risque de contagion et à l'évolution du virus, le Maroc décrète l'état d'urgence sanitaire, et après plus de cinquante cas testés positifs, le gouvernement a imposé le confinement, la fermeture des écoles, lieux publics et entreprises non indispensables le 16 Mars 2020. (Source : communiqué du ministère de l'intérieur, Mars 2020)

La majorité des hôtels marocains ont fermé leurs portes aux alentours du 18-19 mars, donnant ainsi la possibilité à leurs employés de travailler à distance sur les projets courants en télétravail par le biais de version web des logiciels, de Cloud, dossiers de partage, ESN..

Plusieurs modèles ont abordé l'acceptation de la technologie par les utilisateurs, mais la question qui se pose est : ***est ce qu'il existe un modèle qui explique ce phénomène dans un contexte de pandémie, et d'obligation environnementale ?***

L'objectif ultime de cet article scientifique est d'identifier l'impact d'une pandémie planétaire sur le comportant humain notamment par rapport à l'acceptation des technologies.

Contexte

L'acceptation des technologies de l'information et de la communication (TIC) représente souvent un véritable dilemme au sein des organisations. Pourtant l'usage des TIC est un enjeu à la fois économique et surtout social, crucial pour améliorer la qualité de travail quotidien. (Do, Thi Hai Ninh, and Wurong Shih., 2016)

Dans le but de comprendre l'usage et l'acceptation des TIC, plusieurs modèles théoriques ont été élaboré afin d'expliquer les relations entre l'attitude des utilisateurs, la satisfaction d'utilisation, l'utilité des TIC, l'intention d'utiliser une TIC, et leurs comportement interactif. (Chuttur, 2009)

Ces approches scientifiques sont nombreuses, variées, complémentaires et parfois contradictoires et capitalisent aujourd'hui de très importants travaux de recherche. (Venkatesh, 2008)

Dans la section suivante, nous allons nous intéresser au TAM, le modèle d'acceptation des technologies restructuré par Venkatesh et Bala en 2008 et à son applicabilité au sein des hôtels marocains dans un contexte de pandémie Covid-19.

Revue de littérature

Plusieurs modèles ont abordé les facteurs impactant l'acceptation des technologies, notamment le Technology acceptance Model (TAM).

À l'occasion de sa recherche doctorale, Davis (1986) a accompli une recherche pour le compte d'IBM. À partir des observations effectuées, il a abouti à la modélisation du TAM. (Chuttur, 2009)

Ce modèle se base sur la psychologie sociale et repose sur deux modèles classiques qui expliquent le comportement humain : la théorie de l'action raisonnée (TAR) développé par Fishbein et Ajzen, en 1975, et la théorie du comportement planifié (TCP) développé ensuite par Ajzen, en 1985.

La TAR implique que le comportement dépend avant tout des intentions. Des intentions déterminées à la fois par les attitudes relevant de sentiments positifs ou négatifs liés à un comportement bien spécifique et par les normes subjectives. (Venkatesh, 2008)

La TCP, est un ajustement et évolution de la TAR qui vise à éliminer certains problèmes de structure, en ajoutant un troisième élément qui est le contrôle comportemental perçu.

Ce nouveau concept introduit l'idée que les individus, ayant des attitudes positives et estimant que leur entourage approuvera le comportement en question (normes subjectives), ne développeront pas forcément une forte intention d'agir. (Taylor et Todd, 1995).

Comme ses modèles prédécesseurs (TAR et TCP), le TAM postule que l'acceptation par les utilisateurs d'une TIC dépend de l'influence de deux facteurs : l'utilité perçue et la facilité d'utilisation perçue. (Venkatesh, 2008) Le TAM implique en principe que les perceptions qu'ont les utilisateurs de l'utilité et de la facilité d'utilisation déterminent des attitudes et consécutivement des comportements d'utilisation des TIC.

Présentation du Technology acceptance model - TAM –

Le modèle d'acceptation de la technologie (MAT ou, plus fréquemment, TAM pour Technology Acceptance Model) est déployé depuis 1989 pour tenter de prévoir si un individu utilisera ou refusera d'utiliser une application informatique, en fonction de deux facteurs : la facilité d'utilisation perçue de cette application et son utilité perçue. (Venkatesh, 2008) Le modèle a fait l'objet de multiples variantes et de centaines d'applications à des domaines très variés de l'informatique et des systèmes d'information.

Figure 1 : Modèle TAM 3 (Venkatesh et Bala 2008)

En 2008, Venkatesh et Bala proposent un nouveau modèle en révision au précédent, avec un détail plus méticuleux de nombreuses variables explicatives et un regroupement de l'influence des variables modératrices en deux catégories : Expériences et Utilisation volontaire (Venkatesh et al. 2016).

Ces modèles, issus des théories de la psychologie comportementale (Dissonance cognitive et Action raisonnée) se sont perfectionnés et ont largement démontré que pour qu'une technologie soit adoptée, il faut d'abord qu'elle apparaisse utile et facilement utilisable. (Chuttur, 2009)

Problématique

Bien que le modèle de l'acceptation des technologies (TAM) mette l'accent sur plusieurs variables rentrant en jeux et impactant l'acceptation des technologies par les utilisateurs. (Dwivedi, 2010) Le modèle ne prend pas en considération les déterminantes affectivo-émotionnelles ainsi que les variables environnementales externes qui peuvent dans certains cas modifiées considérablement le comportement technologique humain.

En hôtellerie, et à fin de suivre le vent technologique, les managers optent souvent pour des outils technologiques sans pour autant prédire leur acceptation par les utilisateurs finaux.

Hors depuis la propagation de la Covid-19 au Maroc en mars 2020, les employés qui refusaient d'utiliser ces outils technologiques, étaient premiers à proposer leurs utilisations à distance à fin de se protéger et protéger leurs entourages du virus. La question qui se pose remet donc en cause l'exhaustivité des variables d'acceptation prédéfinis par le TAM.

Dans le paragraphe suivant nous proposons un modèle basé sur le TAM tout en incluant les obligations environnementales non maitrisables notamment les pandémies et leurs impacts sur le comportement humain.

Modélisation et introduction du TIAM (Technology imposed acceptance model)

Face à cette situation de confinement obligatoire imposé par le gouvernement marocain à partir du 16 mars 2020, les hôtels marocains ne pouvant laissés leurs projets en stand-by ont opté pour le télétravail. Qui dans plusieurs cas été une suggestion des employés cherchant ainsi des solutions à fin de travailler à distance. Plusieurs logiciels qui connaissaient une résistance à leurs déploiements et utilisation auparavant par les employés, étaient acceptés volontiers face à cette peur et risque de contagion imposé par la Covid19.

Le Technologie Imposed Acceptance Model 'TIAM', vient donc inclure des variables affectivo-émotionnelles jusqu'à lors non prises en compte par le TAM et qui impliquent directement l'utilisation du système comme illustré ci-dessous : (Figure 2 : Technology imposed acceptance model - TIAM - (Source : Remodélisation du TAM par l'auteur)

Il semble pertinent de consacrer une place particulière au rôle de ces variables et d'en analyser plus profondément leurs spécificités. L'ajout de ces variables affectivo-émotionnelles aux modèles de l'acceptation vise à améliorer leurs pouvoirs explicatifs et prédictifs. Ces dimensions visent à capturer des éléments du jugement utilisateur qui vont au-delà de l'évaluation rationnelle des qualités du système. (Pessoa, 2008).

Figure 2 : Technology imposed acceptance model - TIAM - (Source : Remodélisation du TAM par l'auteur)

Hypothèses de recherche

Suite à la situation de pandémie Covid-19 observée en mars 2020, et son impact sur l'utilisation et l'acceptation des technologies au sein des hôtels marocains, le TIAM introduit une variable environnementale externe, en l'occurrence l'impact de la crise sanitaire (pandémie, épidémie, virus, maladie contagieuse..).

Plusieurs facteurs apparents rentrent en jeu notamment l'obsession de contamination, la thanatophobie, l'hypocondrie ainsi que le degré d'engagement et de responsabilité professionnels de l'individu. Ceci nous mène à avancer les hypothèses suivantes :

L'obsession de contamination : ayant peur pour leurs santés et celles de leurs familles, les salariées acceptent des outils technologiques qu'ils rejetaient auparavant. (Chaumon, 2000)

H1 : La crise sanitaire liée à la Covid19 impacte l'acceptation de la technologie par les individus.

H2 : La peur de contamination impacte l'acceptation des technologies par les individus.

La thanatophobie : La pandémie de la covid19 a créé un sentiment d'angoisse, d'incertitude et de stress permanent qui a poussé les employés à vouloir quitter leur lieu du travail et à se confiner chez eux tout en utilisant les outils technologiques déployés pour le télétravail. Une angoisse principalement liée à la thanatophobie autrement dit la peur de mourir ou de perdre un proche.

H3 : La thanatophobie impacte le degré d'acceptation des technologies par les individus.

La responsabilité professionnelle : Malgré la situation stressante liée à la pandémie qui envahissait toutes les équipes, un air d'engagement professionnel était présent tout le long. Ce qui poussait les employés à accepter de continuer leurs travail en utilisant des outils technologique (Cloud, VPN, GED…)

H4 : L'acceptation des technologies dépend du degré de responsabilité et d'engagement professionnels des individus.

L'hypocondrie : La crainte de tomber malade, poussait plusieurs employés à non seulement accepter mais voir même prendre l'initiative d'utiliser les systèmes d'information mis à leur disposition et à favoriser le télétravail.

H5 : L'hypocondrie impacte le degré d'acceptation des technologies par les individus.

Conclusion & perspectives de recherche

L'utilisation des systèmes d'information tant rejetés par les mêmes individus dans deux contextes différents demeurent paradoxale. Cependant, le contexte pandémique relatif à la Covid19, a fait submerger de nouvelles variables et facteurs affectivo-émotionnels liés à l'humain dont la prise en compte est importante dans le processus de l'amélioration de l'acceptation des technologies, à savoir le degré de la responsabilité et de l'engagement professionnels et des troubles intrinsèques liés à la thanatophobie, l'hypocondrie et l'angoisse de contamination.
Le Modèle développé 'TIAM' ainsi que nos hypothèses de recherche seront testés dans le secteur hôtelier marocain par le biais de la méthode Delphi. Les résultats de notre analyse feront l'objet d'un futur article scientifique.

Remerciements

L'élaboration de cet article scientifique n'aurait pas été possible sans le soutien de notre directeur pressenti de thèse Pr Y.Lafraxo. Son enthousiasme, son savoir et son encouragement ont été une source d'inspiration et de motivation. Nous sommes également reconnaissants pour le soutien de notre famille et pour les commentaires perspicaces offerts par les pairs examinateurs anonymes. La générosité et l'expertise de tout un chacun ont amélioré cette étude d'innombrables façons.

Abstract

This pilot study aimed to identify characteristics (in self-assessment) distinguishing socially responsible students (SRS) in their relations with the university and how much these features correspond to SRU dimensions (values, relations, graduate, education, efficient organization) and depend on gender, level and year of study and type of university (public, private). In the respondents' opinions, the most important features of a socially responsible student are showing respect to lecturers, administrative staff and other students; accepting the cultural and national differences of other members of the academic community; respecting the rules of personal culture and being guided by truth and honesty while assessing lecturers and classes. These features refer to the dimension of value, being a basis for shaping other SRU dimensions and the related attributes of a responsible student. It is also a basis for building the right attitude of future graduates, aware of their responsibility for their future decisions and actions. The identified differences relating to older students, graduate studies and private universities do not distort the main conclusion. Since this is a pilot study, conclusions refer only to the studied universities. However, they indicate an interesting direction for further valuable research in this field.

Keywords: social responsibility of universities (SRU), dimensions of SRU, socially responsible student, characteristics of a socially responsible student, public, private university.

Introduction

Higher education institutions provide educational services classified as public goods, having a huge range and impact on society (Kowalska, 2009; Cybal-Michalska, 2015; Białoń & Werner 2012). Their cultural and opinion-forming role in society is crucial. Hence, it can be expected that their example will appeal to the young generation and shape them accordingly for the future. This applies, among others, to issues of corporate social responsibility. Universities should not only educate in this area, but also be socially responsible towards their stakeholders (Benedek & Takács-György, 2014; Szelągowska-Rudzka & Spodarczyk, 2018), among whom students take a special place. A pilot (qualitative) study conducted by the authors in 2017 showed that a university socially responsible towards its students should – in their opinion – be based on values, building relations, the graduate, education and efficient organization (Szelągowska-Rudzka & Spodarczyk, 2018). This will shape the graduate who meets the needs and expectations of the modern knowledge-based economy (KBE). Meeting such defined students' expectations requires that both parties, i.e. the university and students, build mutual relations in a responsible manner. Therefore, in the next stage, the authors decided to investigate how students perceive their responsibility towards the university and how much they are willing to give from themselves in order to shape these mutual, socially responsible relations. Hence, the aim of the article is to find answers to the following research questions:

- What features – in their own opinions – should socially responsible students be characterized by at a socially responsible university?
- With what areas of social responsibility of a university are the characteristics of a responsible student related?
- In what way is the perception of the characteristics of a student responsible towards the university influenced by: gender, level of study, year of study, type of university (public, private)?

In order to answer the above questions, the authors conducted a pilot study among students of selected universities in Tricity. The results, discussion and conclusions are presented later in the article.

The essence and dimensions of the university's social responsibility in relations with students

The concept of corporate social responsibility (CSR) is understood as the responsibility of an organization for its decisions and actions leading to sustainable development and taking into account economic, social and environmental aspects in contacts with stakeholders (Wytyczne ISO 26000, 2015). In turn, a socially responsible university (SRU) is a higher education institution (HEI) that serves the environment. Its responsibility towards society relates to preparing graduates to perform the functions of knowledge workers (Leja, 2013), sensitive to the natural environment (Geryk, 2008). These goals are achieved by building close relations with external stakeholders: enterprises, local (central) authorities, national and foreign universities (Cybal-Michalska, 2015), university graduates, candidates for studies and their parents, advisory bodies at the university Senate, the community of the region (country), as well as internal stakeholders: students, administrative employees, and academic staff.

Analysis of all aspects of social responsibility of a university, defining long-term goals and ensuring their implementation requires an appropriate strategy. However, before such a strategy is created, it is necessary to identify the main groups of stakeholders and analyze their needs, expectations and power of influence.

According to S. Berman, students are the most important group of university stakeholders. Shaping relations with them requires starting with building their social awareness in the educational process, including developing basic social competences, understanding the need for involvement, providing social contributions, being able to see and solve important problems (Berman, 1990). Therefore, it requires shaping a system of values, attitudes and behaviors leading to the development of their individual and social responsibility, which will complement the future professional competences desired by the market.

The authors believe that the actual implementation of socially responsible activities requires a conscious approach and commitment of all parties. Therefore, as a result of the pilot (qualitative) study conducted among students (2017), they identified key – for this group of stakeholders – dimensions of social responsibility of a university, i.e. values, relations, graduate, education and efficient organization (Szelągowska-Rudzka& Spodarczyk, 2018). In the next study (2019), they found, among others, that of these dimensions education is the most important for students. This is a process that, supported by values-based relations and efficient organization, will lead to the formation of a graduate who meets the requirements of the modern economy, ready to take responsibility for his future decisions and actions (Spodarczyk & Szelągowska-Rudzka, 2019). The features that should distinguish socially responsible students in their mutual relations with the university are the subject of this article.

University Social Responsibility and its dimensions

A socially responsible university is a HEI serving the surroundings. Its responsibility towards the society involves preparing graduates to become knowledge employees and building close relationships with economic practice and local governments (Leja, 2013). University Social Responsibility means a strategic and systems approach to managing HEIs and developing cooperation and dialogue with stakeholders, which contributes to sustainable development, building values and attitudes in the citizen society, supporting academic values and creating new ideas, keeping and developing scientific-didactic competences that influence effectiveness and innovativeness (Społeczna odpowiedzialność, 2019). So SRU, apart from classical dimensions: ecological, social and economic, takes into account also the scientific-didactic dimension. It requires development of the social responsibility strategy, whose aims are oriented towards satisfying the main stakeholders' needs and expectations and incorporating them in CSR education programs (Ławicka, 2016).

University Social Responsibility issues are becoming increasingly significant. More and more HEIs worldwide are implementing the social responsibility strategy and its good practices, which is reflected in various international organizations' reports (Cichowicz, Nowak, 2019). For instance, business universities introduce practices based on the Principles for Responsible Management Education (PRME) (within the program: Global Compact ONZ, 2007). They are based on six principles of responsible management education: purpose, values, method, research, partnership and dialogue (Koksal Arac, Madran, 2013) and enable students to understand the sustainable development subject so that in the future – as economic life members – they can balance its aims with enterprises' economic aims (PRME, 2019). Among 767 signatories worldwide Poland is represented only by a few HEIs1 (Roszkowska-Śliż, 2010; Popowska, 2016; Społeczna odpowiedzialność, 2019). Five best European universities2 have undertaken socially responsible activities focusing on the areas: education for sustainable development, responsible campus, social responsibility culture, ethical leadership, dialogue with the society, social responsibility of science. The world best universities[3]

(Społeczna odpowiedzialność, 2019) and Polish signatories[4] (Lista sygnatariuszy Deklaracji SOU, 2019) of University Social Responsibility Declaration (Deklaracja SRU) refer to the UN's Sustainable Development Goals (SDGs) stated in the 2030 Agenda. The SRU declaration was formulated in 2017 as a result of academic community cooperation with the then Ministry of Development (Społeczna odpowiedzialność, 2019). Twelve principles of SR in it refer to ethics, graduates' social and citizen attitudes, promoting social responsibility principles and sustainable development in study programs, scientific research and implementation projects within partnerships with various entities, dialogues with the surroundings, and engagement in the form of voluntary work, care for the university organisational order or its responsibility for natural environment (Deklaracja Społecznej Odpowiedzialności Uczelni, 2017).

Although Polish HEIs are nowadays more frequently implementing the socially responsible activities strategy, it is not yet common practice (Karwowska, Leja, 2019). For many universities it is still one-time action (Leoński, 2019). Few HEIs refer to University Social Responsibility Declaration or PRME. Most often examples of socially responsible universities' good practices are based on ISO 26000 and its main areas (Leoński, 2019; Mackiewicz et al., 2018), or they concern the main SRU dimensions resulting directly from its definition due to its universality, i.e.: economic, environmental, social and educational dimension (Karwowska, Leja, 2018). Universities also independently undertake initiatives to formulate cooperation principles with selected stakeholders not following indicated examples or modifying them for their own needs. The key to formulate effectively social responsibility good practices (and the strategy) is identifying the university's main stakeholders and their needs/expectations in mutual relationships (Szelągowska-Rudzka, Spodarczyk, 2018).

Research Characteristics

The study is of a pilot nature. It was conducted in the summer semester of 2019 (May-June) at three purposefully selected universities in Tricity with different academic traditions and forms of ownership. These are Gdynia Maritime University (GMU – a public, young university, building its academic competences), the University of Gdansk (UG – a public university with the longest university tradition), and WSB University (private, the youngest, dynamically developing).

The study used a survey method, a direct survey technique and an original questionnaire (data collection instrument). First, the respondents were asked to indicate the most important, in their opinion, features of a SRU in each of the identified dimensions (values, relations, graduate, education, efficient organization), and to determine the order of importance of these dimensions (by distributing 100 points among them) (Spodarczyk & Szelągowska-Rudzka, 2019). Then, they were asked to select the most important distinguishing features of a socially responsible student in mutual relations with the university. This article focuses on the results of the second part of the study.

Students of economics from the selected universities were invited to participate in the study. Ultimately, 290 persons took part in it. After dismissing defective questionnaires (48), 242 of them were used for the main analysis.

The study sample is dominated by women and students of undergraduate studies – 64% each (156). Another 32% (76 persons) are graduate students and only 4% (10) are future engineers. Most of the respondents – 48% represent GMU (116), another 30% represent WSB University (72) and 22% UG (54). First-year students account for 44% of the respondents (106), second-year ones – 38% (92), and third-year ones – 18% (44). Most of the respondents – 66% declare they know the concept of CSR.

The article presents a descriptive analysis of the obtained results (Table 1) and a statistical method (Table 1A, Appendix), in which we estimate the following models using probit and linear regressions in Stata 16:

$$Y\ level_i = B*Students'\ features + B*Gender+Level+ B*Year\ of\ study +B*University$$

The study took into account the influence of such variables as gender, level of study, year of study and type of university on the selection of the characteristics of a student socially responsible towards the university. This choice was dictated by the assumption that these variables may affect the respondents' choices, e.g. due to the knowledge of the university functioning, the prospect of taking up employment or studying conditions. This knowledge can be useful in developing a SRU strategy and its effective implementation, including building student involvement.

Results

What features – in self-assessment – should socially responsible students be distinguished by at a socially responsible university?

Table 1 summarizes the respondents' answers defining the importance of individual characteristics of a socially responsible student in relations with the university ascribed to particular dimensions of a SRU. The vast majority of respondents believe that all the listed features should characterize a responsible student. For this reason, when discussing the study results, the authors primarily focus on the answer "definitely yes", which may indicate a certain hierarchy of features characterizing the student's responsibility towards the university.

Table 1: Distribution of respondents' answers regarding the characteristics of a student who shares the principles of social responsibility in mutual relations between the university and the student, taking into account statistically significant differences resulting from the impact of selected factors

No*	Characteristics of a socially responsible student	SRU Areas	Responses (%)						Determinants			
			Definitely yes	Yes	Rather yes	Rather no	No	Definitely no	Gender	Level of study	Year of study	Type of university
1	shows respect to lecturers, administrative staff and other students	V	48	33	16	2	0	0				
2	accepts cultural and national differences of other members of the academic community	V	42	41	15	2	0	0				
3	respects the rules of personal culture	V	41	38	16	5	0	0				
4	while assessing lecturers /classes is guided by truth and honesty	V	40	36	18	6	0	0			x	x
5	acts ethically towards others	V	35	43	20	2	0	0				
6	respects and keeps the agreements concluded with the university	V	33	40	24	3	0	0				
7	prepares to the classes, tests and exams	E	32	40	21	5	1	1				
8	is punctual	O	32	38	24	4	2	0				x
9	takes care of cleanliness and the university's property	O	31	41	22	5	1	0		x	x	
10	keeps deadlines	O	30	40	26	2	2	0				
11	cares for the environment	V	30	37	28	5	0	0				
12	shapes the positive image of the university in the opinion of employers (as a student and a future graduate)	G	30	43	23	3	1	0		x	x	x
13	proudly represents the university outside (as a student and a future graduate)	G	29	43	22	5	1	0		x	x	x
14	complies with the study regulations	V	29	43	24	3	1	0				
15	respects the laws and customs of the university	R	27	43	25	4	1	0			x	x
16	honestly fulfils his/her duties included in the oath (strives to acquire knowledge, develops his/her own personality, recognizes dignity and honor of a student of his/her university)	V	26	47	22	5	0	0				
17	supports other students in the pursuit of knowledge and acquisition of new skills	R	26	40	24	9	1	0				

18	recognizes and respects the university's good reputation (as a student and a future graduate)	G	26	43	25	5	1	0			x	x
19	takes up educational opportunities offered by the university	E	26	41	28	3	1	1				x
20	attends the classes, gets involved in them	E	26	40	26	8	0	0		x		x
21	is involved in the university life	R	19	31	33	12	3	2				x
22	participates in the activities of scientific circles operating at the university	O	19	26	34	15	4	2				x
23	participates in competitions and projects organized by the university	E	18	28	37	13	3	1		x		x

The meaning of symbols: V – values, R – relations, G – graduate, E – education, O – efficient organization
* The sequence number of the characteristic corresponds to the model number in table 1A (Appendix)
x – means a statistically significant influence of a given factor

Source: based on research results.

The answers "definitely yes" to the specified features were attributed by 18% to 48% of the respondents. These were divided into 4 groups (Table 1). The respondents most often pointed out that a student responsible to the university should, above all, show respect to lecturers, administrative staff and other students; accept the cultural and national differences of other members of the academic community; respect the rules of personal culture and be guided by truth and honesty while assessing lecturers/classes (from 48% to 40% of responses).

The second group of features defining a student responsible towards the university (35%–30% of the "definitely yes" answers) include acting ethically towards others, respecting and keeping the agreements concluded with the university, preparing to the classes, tests and exams; being punctual; taking care of cleanliness and the university's property; keeping deadlines; caring for the environment; shaping the positive image of the university (as a student and a future graduate).

The least frequently, as "definitely yes", the respondents indicated the features listed in the fourth group (19% and 18% of responses), i.e. being involved in the university life, participating in the activities of scientific circles operating at the university, participating in competitions and projects organized by the university (Table 1).

To what areas of social responsibility of a university are the characteristics of a responsible student related?

The distribution of "definitely yes" answers in Table 1 shows that the characteristics of a student socially responsible in mutual relations with the university are ranked in an order that reflects their hierarchy. This shows that the most important ones (group 1 and part of group 2) belong to the dimension of values. The next ones are related to efficient organization, the graduate and relations. In turn, the least important ones for the respondents mainly belong to the dimension of education.

How is the perception of the characteristics of a student responsible towards the university influenced by gender, level of study, year of study, type of university (state, non-state)?

The results presented in Table 1 and Table 1A (Appendix) show that gender is not a variable that has a statistically significant impact on the perception of characteristics of a student responsible towards the university. The variables that differentiate the respondents' answers are the level of study, year of study, and the type of university (public, private).

Graduate students (MSc/MA) give more importance than others to the following characteristics: attending classes, getting involved in them, participating in competitions and projects organized by the university, shaping the positive image of the university (as a student and a future graduate), taking care of cleanliness and the university's property, proudly representing the university outside (as a student and a future graduate) (Models 20, 22, 17, 15, 12; Table 1A).

There are also significant differences in the second- and third-year students' responses compared to students in the first year. Thus, for older students it is more important that a socially responsible student be guided by truth and honesty while assessing lecturers and classes, be involved in the university life, recognize and respect the university's good reputation (as a student and a future graduate) as well as take care of cleanliness and the university's property,

proudly represent the university outside (as a student and a future graduate), shape a positive image of the university (as a student and a future graduate), respect the laws and customs of the university. The latter feature is more often emphasized by second-year students than students in other years (Models 12 – 17; Table 1A).

A number of significant differences in the perception of the characteristics of a student socially responsible towards the university occur depending on whether the respondents represent a public university or a private one. Students of a private HEI (WSB University) attach greater importance to such features of a responsible student as: involvement in the university life, participation in the activities of scientific circles operating at the university, participation in competitions and projects organized by the university, recognition and respect for the university's good reputation (as a student and a future graduate), taking care of cleanliness and property, shaping the positive image of the university (as a student and a future graduate), respecting the laws and customs of the university, university, proudly representing the university outside (as a student and a future graduate) and punctuality (Models 12-17; 19-23; Table 1A, Appendix).

Conclusions and Discussion

In general, it was found that, regardless of gender, all the studied characteristics are important to the respondents. They agree the most that the student responsible to the university should, above all, show respect to lecturers, administrative staff and other students, accept the cultural and national differences of other members of the academic community, respect the rules of personal culture and be guided by truth and honesty while assessing lecturers and classes. Such characteristics of a socially responsible student include, first of all, the features belonging to the dimension of values, which S. Berman (1990) recognized as the basis of students' social competences and their conscious participation in university matters. It can be concluded that the area of values is the basis for building students' social responsibility in mutual relations with the university. It indicates that these values are the starting point for shaping their attitudes and behaviors as future graduates (employees and employers), and it is them that the shaping of other areas should start with. Above all, however, these universal values should be included in the university's social responsibility strategy (Spodarczyk & Szelągowska-Rudzka, 2019) and in the ensuing actions, e.g. codes of conduct, codes of ethics, employee training, and good practices. They will then become a permanent basis for shaping mutual relations based on the principles of social responsibility between the university and students, as well as other groups of stakeholders.

The fewest definite answers regarding the characteristics of a responsible student concerned their involvement in the university life, participation in the activities of scientific circles operating at the university, and participation in competitions and projects organized by the university. These are mostly features from the area of education. On the one hand, the lower popularity of these features among the respondents may indicate that meeting them requires students' greater involvement and effort than a declaration of commitment to values. In fact, students do not want to get involved too much in the efficient organization of the educational process, considering this area to be a domain of the university's activities, of which they are beneficiaries (Spodarczyk & Szelągowska-Rudzka, 2019). On the other hand, the reason may be unattractive study programs and extra-curricular activities that do not meet students' expectations. As a result, the proclaimed (also during classes) principles of social responsibility remain more in the area of declarations than they are permanent, common activities of universities resulting from their strategy. Therefore, it may be worth involving students in submitting proposals for study programs and methods of their implementation, and (if possible) put them in practice, in order to make the educational process more attractive and more effective. This is particularly important in relation to the results of the first part of the study, in which the respondents indicated that education – as a process of shaping a socially responsible graduate expected in the contemporary labor market in knowledge based economy – is for them the most important dimension in the activities of universities building socially responsible relations with its stakeholders (Spodarczyk & Szelągowska-Rudzka, 2019).

When analyzing the respondents' answers in terms of significant differences due to gender, level of study, year of study, type of university (public, private), it can be noted that the differences in indications regarding the characteristics of a socially responsible student are primarily influenced by the year of study and the type of university. The most common differences are between the respondents of older years. The reasons can be seen in the fact that third- and second-year students have already familiarized themselves with the conditions of studying, they have relatively little time until the end of their studies and they want to benefit from this period both in terms of organization of classes, relations and education. They also understand that a positive image of the university can increase their chances as graduates on the labor market.

As mentioned above, the responses of students of public universities (GMU, UG) and private one (WSB University) significantly vary. Thus, students of a private university pay more attention to the area of education and the graduate.

The reason may be tuition for studies, and hence a desire to obtain the greatest possible benefits from studying (education and graduate), which will translate into the respondents' position on the labor market. One can also consider the question whether the higher rank of education and the prestige of the university do not prove that a private university, more than a public one, cares about an attractive offer, adapted to the labor market and students' needs.

It is also noteworthy that the area in which there are virtually no differences in respondents' answers due to the indicated characteristics (gender, level of studies, year of study, and type of university) is the area of values. This dimension was defined as the basic one, necessary for the emergence of other areas of social responsibility of a university and for building a SRU strategy. The students' unanimity as to the significance of the area of values and the individual characteristics of a socially responsible student resulting from it confirms the importance of the dimension of values in the process of building a SRU.

The authors are aware that the conducted research is of a pilot nature; therefore, the conclusions are limited only to the participating HEIs. Nevertheless, it indicates interesting conclusions and relationships that would be worth identifying in full in a study on a representative group of universities.

Abstract

Purpose – the purpose of this paper is to present the model of diffusion of technological innovation in competitive environment. The model was developed in the form of empirical model, it presents relations between identified variables. The findings revealed that the model developed is correct (the model was validated). The model can be used by decision makers disregarding the industry or enterprise size to analyze the process of diffusion of innovations in competitive environment. The model was originally developed by the authors.

Keywords: Technological Innovation, Diffusion of Innovations, Model for The Dissemination of Technological Innovation

Introduction

Innovation is one of the key concepts concerning modern technology, economics, management and sociology. The term of innovation is defined slightly differently on the grounds of each of the listed disciplines. The authors of this article are interested in the problem of technological innovations, as they refer to products and processes but within technological aspects. The definition according to the "Oslo manual" (OECD, 2015; Garcia, Calantone, 2002) seems to refer to the issue in the way that corresponds best with authors' experience. The problem considered in this article is the diffusion of technological innovation. During the analysis of the literature, the authors did not come across sources directly related to this problem. Based on the literature, it can be assumed that the same principles and models as for any other type of innovation apply to the diffusion of technological innovations. The so-called "linear model" is a commonly accepted model for the dissemination of innovations (Godin, 2006). It assumes that there are several phases in the innovation life cycle. These phases are discussed in detail in (Rogers, 2003). Authors dealing with the linear model devote little attention to the mechanism of transition between particular phases of the dissemination of innovations. They seem to assume that the transition between particular phases is natural and its pace is shaped in a spontaneous manner, according to the logistics curve (Rogers, 2003). This article accepts the hypothesis that there are factors that determine the transition between the various phases of the diffusion of innovation and affect the pace of this process. Identification of these factors is particularly important in the context of the existence of alternative scenarios of the process of diffusion of innovations. Such alternative scenarios occur in a situation where there are several competitive technological solutions, each of which potentially can be the basis for innovation. The authors accept the existence of such competing technological solutions as conditions of competition. Developing a model for the diffusion of innovations in competitive conditions may provide tools for analyzing such a situation and support decision-making processes in the field of technology development. Hence, the goal of the paper is to present the model of diffusion of technological innovations in competitive environment and validate it with an implementation example.

Cite this Article as: Agnieszka STACHOWIAK, Grzegorz PAWŁOWSKI, Marek FERTSCH and Joanna OLEŚKÓW-SZŁAPKA" The Framework of The Model of Diffusion of Technological Innovations in Competitive Environment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The paper includes five sections, it starts with introduction followed by theoretical background referring to the issues discussed, namely innovation, its definition, classification and diffusion of innovations. The next part is presentation of the original model of diffusion of technological innovations in competitive environment developed. The fourth section presents an example of the model implementation to analysis of technological innovation diffusion process. The last section is the conclusion section.

Theoretical background

The tendency that contributes to the world development has always been and is the introduction and implementation of advanced scientific and technological achievements, which are an impulse for structural changes in the economy, stimulating production of new technologically advanced products. The conditions prevailing on the market have always determined the need to intensify innovation as the most effective way to increase the economy's competitiveness and determine its further development in an intense way. The rationale for the strategic direction of development, in which innovation plays the main role, are unprecedented successes that resulted from the practical implementation of innovative solutions (Camisón, Villar-López, 2011; Cainelli, De Liso, 2005; Bradley, McMullen, Artz, Simiyu, 2012; Keupp, Palmié, Gassmann, 2012; Laforet, 2011).

Innovation is an immanent attribute of an enterprise that enables and supports doing business in a market economy. Due to increasing competition, innovations are rapidly becoming a key factor for the success and survival of businesses (Alegre, Chiva, 2008). The concept of innovation is derived from the Latin term innovatio, which means novelty, reform, and deliberately introduced change in technology, organization, economic activity or in another sphere of human life. The problems of innovation were introduced to economic considerations by Joseph Schumpeter. When refering to innovation, Schumpeter meant (Baruk, 2006):

1) introduction of a new product with which consumers are not familiar yet, or introduction of a new type of a good;
2) introduction of a new production method, not yet tested in practice in a given industry;
3) opening of a new market for which a particular branch of industry in a given country was not previously introduced, regardless of whether the market existed earlier or not;
4) acquiring a new source of raw materials or semi-finished products, again regardless of whether the source already existed or had to be created;
5) carrying out a new organization of an industry, for example creating a monopolistic situation or breaking a monopolistic position.

There is a whole range of innovation definitions in the subject literature (Yalabik, Howard, Roden, 2012; Schumpeter, 1960; Zavlin, Kazantsev, Mindeli, 1999; Damanpour, 1991). Analyzing the definitions of innovations, some of their common features that focus on the creation of a significant new value for the client and for the company through the creative change of one or several elements of the business system can be identified. Innovations can be classified due to the numerous criteria, as presented in the Table 1.

Table 1: Classification of innovations – examples of criteria

Subject of changes criterion	Scale of changes criterion	Source of cahnges criterion	Complexity level criterion	Novelty level criterion	Originality level criterion
• Product-based (technological) innovations • Proces-based innovation • Organization-based innovation • Marketing-based innovation	• Radical innovation • Upgrading innovation	• Demand-based innovation • Supply-based innovation	• Coupled innovations • Not-coupled innovations	• World-scale innovations • Country-cale innovations • Industry-scale innovations • Organization-scale innovations	• Pioneering innovations • Adapter innovations

Source: own work

From the perspective of this paper, classification of innovations according to the subject criterion is the most important. In relation to it, product, process, organizational and marketing innovations are distinguished. The subject matter of this article is technological (product) innovation, which also can be referred to as technological innovation. Changes introduced in product are consequences of construction or technology changes; hence, the term product innovation is consistent with the term technological innovation. Broughel and Thierer claim that technological innovations is a fundamental driver of economic growth and human progress, but are often lost or underappreciated in technology policy discussions today, which frequently focus on the disruptive effects associated with technological change (Broughel, Thierer, 2019). Compared to non-technological innovation, technological innovations have a crucial influence on firm success (Ryu, 2016). Moreover, technological innovation significantly positively contribute to sustainability and organization performance (Zhang, Khan, Lee, Salik, 2019).

Table 2 lists some of the definitions of the concept under consideration in the subject literature. The essence of technological innovation in this study is understood in accordance with the definition given by the OECD. In functional terms, product innovations can be defined as a deliberate replacement of previously produced products with their new versions and creating completely new products that are assessed as able to satisfy the needs and preferences of specific buyers in a unique way and thus improve the competitive position of the company on the market. In the sense of results, it can be considered that each new product form constituting a company's market offer is an innovation (Bogdanienko, 2004).

Table 2: Definitions of product technological (product) innovation

Author	Definition
Damanpour F., Evan W.	A technological innovation can be the implementation of an idea for a new product or a new service or theintroduction of new elements in an organization's production process or service operation (Damanpour, Evan, 1984).
OECD	Product innovations - new or significantly improved in relation to their previous version goods or services, taking into account technological specification, components and materials, software, ease of use for the user or other functional features (OECD, 2005).
Oslo Manual	A product technological innovation is the implementation/commercialisation of a product with improved performance characteristics such as to deliver objectively new or improved services to the consumer (Oslo Manual, 2011).
Tidd J., Bassant J., Pavitt K.	Product innovation concerns introduction of completely new products/services or significant changes in the products/services offered by the company. These changes may concern improvements in terms of their features or applications (Tidd, Bassant, Pavitt, 2005).
Reguia C.	Product innovation is the development of new products, making changes in the current product design or using new techniques and means in the current production methods(21), in other words, it focuses on existing markets for existing products, differentiating through features and functions that current offers do not have (Reguia, 2014).
Tohidi H., Jabbari M.M.	Product innovation is a process that includes: technological design, research and development, production, management and commercial activities associated with marketing a new product (Tohidi, Jabbari, 2012).

Source: own work

Three processes are inseparably connected with the concept of innovation (Niedzielski, Markiewicz, Rychlik, Rzewuski, 2007):

1) *transfer of innovation* - this is a multifaceted flow of information across the boundaries between science, technology and the practical world, contributing to the development of innovative approach;
2) *absorption of innovation* - means the process of assimilation of innovation by a specific entity (consumer, company, region or economy);
3) *diffusion of innovation* - it concerns diffusion of innovations at the place of first implementation and on other markets; this is another practical application of the same solution (information, product, technology) by the followers.

Transfer of innovations concerns the transfer of new solutions and scientific inventions from the source of their creation to potential users of innovations. Innovation buyers undertake and engage in innovative activities, thus absorbing it and implementing it in practice. The absorption process requires the involvement of appropriate resources as well as the acquisition of skills that are necessary to implement innovation. One of the most important factors determining the competitive advantage of economic entities on the market is the ability to effectively acquire knowledge and then use it in business (Pawłyszyn, 2017). Diffusion is the way in which innovations spread, through market or non-market channels, from their first worldwide implementation to different countries and regions and to

different industries/markets and firms (Oslo Manual, 2011). Without diffusion, an innovation will have no economic impact. Diffusion of innovation takes place when after the first successful application of a new technological or organizational solution; it is absorbed by other enterprises.

Diffusion of innovations is a complex and multifaceted process, the nature of which is determined by the type of innovation that is subject to diffusion, number and power of communication channels, etc. Studies show that there is a number of factors that determine the rate of diffusion of innovation (Pawłyszyn, Fertsch, Stachowiak, Pawłowski, Oleśków-Szłapka, 2020; Dearing, Cox, 2018). One the most important aspects of diffusion of innovation is the consistency of the innovator in following up with the adopter's progress throughout the adoption process. This requires a high level of psychological analysis in order to understand the instant needs and perception of the adopter (Sartipi, 2020). This issue is very important because it allows the new solution to take the dominant position in society and thus increase the economy's development. For this reason, the problem considered in a given article is the diffusion of technological innovation. During the literature analysis, the authors of the article did not come across sources directly related to this problem. Based on the literature analysis, it can be assumed that the same principles and models as for any other type of innovation apply to the dissemination of technological innovations.

The researchers noticed that the innovation diffusion process is not uniform and is characterized by a certain cycle in which a small number of individuals are initially interested in innovation, followed by a sharp increase in interest in it, which decreases at the end of the cycle. Models of diffusion of innovations, developed by scientists, help to determine the essence and course of innovation processes in time and space. Tsvetkova and Tukkel distinguished six classes of models of the process of diffusion of innovations, which are characterized by different classification features, while emphasizing that it is advisable to look for models of diffusion in the imitation class (Tsvietkova and Tukkel, 2017).

The so-called "linear model" is a widely accepted model for the dissemination of innovations (Godin, 2006). It assumes that there are several phases in the innovation life cycle. These phases are described in detail by Rogers (Rogers, 2003). He distinguished five groups of target recipients who take over innovation at the right time for them (Rogers, 1983). In addition, the Bass model should be mentioned, according to which there is a finite number of possible consumers who over time increasingly accept and buy a new product. Innovation is spreading among the participants of the socio-economic system, who interact with each other and divide into two groups (Baranovskiy, Puzyrevskaya, 2019; Figiel, 2016; Nosonov, 2015; Czubała, 2012; Zabrodskaya, Tkalich, 2009). Authors dealing with the linear model devote little attention to the mechanism of transition between particular phases of the diffusion of innovations. They seem to assume that the transition between particular phases is natural and its pace is shaped in a spontaneous manner, in accordance with the logistic curve (Rogers, 2003). In turn, Klincewicz describes the RCCTO (Relative advantage, Compatibility, low Complexity, Testability of innovation, Observability) model, which assumes that the diffusion of innovation depends on such factors as (Klincewicz, 2011):

- the *relative advantage* of innovation over previous solutions - innovation should ensure the increase of usability and efficiency over existing solutions. This is the extent to which innovation is perceived as better than existing solutions, so that the user can derive additional benefits from a product or service that previous products did not provide;
- the *compatibility* of innovation with existing standards, values and experience - is an aspect conducive to the diffusion of innovation. A given feature concerns the compatibility of innovation with the needs of potential adapters;
- the *low complexity* of innovation - it determines the level of difficulty and comprehensiveness in understanding, adopting and applying a new solution, as well as the degree of perception of innovation as difficult to understand and use;
- the *testability of innovation* - it is the ability to subject innovation to testing and testing, the ability to try and check its performance and the process of gradually introducing innovations into everyday use;
- the *observability* - the extent to which the use of innovation is visible to others, as well as the ability to observe the application of innovation by others. Observability increases the attractiveness, security and openness to the application of innovations by new users.

In other words, innovation should have certain attributes that could be perceived by the potential buyer as a benefit of its use, so that they are interested in it and express their willingness to take innovation into their reality. At the same time, the subjective perception of a given product's characteristic by the consumer is important, not the objective fact of its occurrence.

In this article, the hypothesis that there are factors that determine the transition between the various phases of the diffusion of innovation and affect the pace of this process is accepted. Identification of these factors is particularly important in the context of the existence of alternative scenarios of the process of dissemination of innovations. Such

alternative scenarios occur in a situation where there are several competitive technological solutions, each of which potentially can be the basis for innovation. The authors accept the existence of such competitive technological solutions as competition conditions. Developing a model for the diffusion of innovations in competitive conditions may provide tools for analyzing such a situation and support decision-making processes in the field of technology development.

Framework of the Model

Literature referring to factors influencing the diffusion of technological innovations and innovations in general is extensive and diverse (Rogers, 2003). There is a widespread view that the diffusion of technological innovations depends on a number of factors (Talukder, 2012). There is no single factor that determines the success of the dissemination of technological innovation. Usually, between 5 and 10 factors are mentioned, and their synergetic cooperation determines the success of the process of diffusion of innovations. In this situation, the authors do not intend to discuss the literature or analyze the degree of compatibility or similarity of views of individual authors of innovation success factors. A set of factors influencing the diffusion of technological innovation developed for the needs of this article will be presented. The selection of factors will be made by adopting the perspective of the decision-maker, whose task is to choose one of the available innovation options in a given situation.

The precondition for the occurrence of the considered situation is the existence of the "discovery". Under this concept, the emergence of a technological possibility to implement a certain process or to meet specific needs in a new way is understood. It ensures that its effect ("product") has completely new or partially new properties. The emergence of the source of innovation may be the result of the discovery (invention) or systematic work carried out in the field of basic research, research and development (R&D) or applied research.

The emergence of a source of innovation in the competitive situation under consideration in which there are several alternative innovation possibilities triggers the decision-making process of a non-random choice between the available options. The choice is based on the analysis of a number of factors that in the subjective assessment of the decision-makers in a different way affect its choice. The factors distinguished and considered in this article include:

- *usefulness of innovations* – this factor is a measure of the extent to which a new process or its effect (product) meets the needs identified by the decision maker. A positive evaluation of the usefulness of innovation from an organization's point of view can have two reasons. It may result from the compatibility of the expected effects of innovation with the organization's goals or the strategy it implements. This cause can be characterized as the primary cause. Positive evaluation of the usefulness of innovations from the point of view of the organization may also result in the observation of the pace of its dissemination, observation of the behavior of the main competitors or leaders in a given segment of activity and tendencies to imitate their behavior. This cause can be characterized as the secondary cause;
- *ease of absorption* – estimation of the effort to achieve the expected effects of innovation;
- *compatibility of innovations* – degree of compliance (fit, applicability) of the current, at the time of making the decision to implement innovation, potential (resource structure and ways to use them) to the conditions that will hypothetically exist at the moment of achieving the expected effects of innovation.

Based on the criteria presented above and the observation of economy, industries and experience of the authors, the model of diffusion of technological innovation in competitive environment can be defined as follows (Formula 1):

$$E_{t+1} = \sum_{i=1}^{n} x_{it} \times \alpha_{it} \quad (1)$$

where:

- n - the number of innovation variants available at time t, the moment t corresponds to the moment of calculations,
- E_{t+1} - the dissemination of innovations at time $t + 1$ measured in the number of innovation implementations at that moment,
- x_{it} - the dissemination of the i-variant of innovation at the moment t measured in the number of implementations of the i-variant at that moment, the moment t corresponds to the moment of calculations,
- α_{it} - attractiveness of the i-variant of innovation at the moment t, the moment t corresponds to the moment of calculations, at the moment the value of attractiveness of any available i-variant of innovation must be between 0 and m, where m is a non-negative real number (Formula 2):

$$\alpha_{it} \quad \in < 0, m > \quad (2)$$

And α_{it} - attractiveness of the i-variant of innovation at the moment t, can be calculated as follows (Formula 3):

$$\alpha_{it} = u_{it} \times a_{it} \times c_{it} \quad (3)$$

where:

- u_{it} - the evaluation of usability of the *i*-variant of innovation at the moment *t* made by the decision maker, it can take non-negative values from the interval *0 – m*, where *m* is a non-negative real number,
- a_{it} - the decision made by the decision-maker to assess the ease of absorption of the *i*-variant of innovation at the moment *t*, it can take non-negative values from the interval *0 – k*, where *k* is a non-negative real number,
- c_{it} - compatibility assessment of the *i*-variant of innovation at the moment *t* made by the decision maker, it may take non-negative values from the interval *0 – l*, where *l* is a non-negative real number,

The coefficient of relative attractiveness of the *i*-variant of innovation at the moment *t* is used as an auxiliary to the analysis of the results obtained in the model. This coefficient is not present in the model. It is calculated as the quotient of the dissemination of the *i*-variant of innovation at the moment *t* to the dissemination of innovation at the moment t (Formula 4):

$$\beta_{it} = \frac{x_{it}}{E_t} \quad (4)$$

For the moment *t*, the sum of the relative attractiveness of all innovation options available at this time must be equal to *1* (Formula 5):

$$\sum_{i=1}^{n} \beta_{it} = 1 \quad (5)$$

The structure of the model includes factors influencing future dissimination of innovation and its present status.

Validation of the Model

To prove that the model developed and presented in the above section is correct, the authors decided to validate it basing on historical data – hence referring to the situation that is already clear and the ex-post analysis of the diffusion process can be compared with the results obtained with the model.

The data used for validation are presented in the table 3.

Table 3: Data used for validation

Source: own work based on literature analysis

The data presented in the table cover the period 1880-1898. They refer to changes in the construction of warships that occurred before and during this period. A typical material, which for centuries was wood was replaced with iron and steel. This change caused the need to change the design of the warship as a whole. As a result, three concepts (innovations) have emerged:

- traditional - in the table referred to as "*a*". It consisted in building a hull made of iron or steel or reinforcing the wooden hull with these materials and placing the weaponry as on wooden ships - on its sides.
- changed - in the table referred to as "*b*". It consisted in building a hull made of iron or steel or reinforcing the wooden hull with these materials and placing weapons in armored constructions ("citadels") placed on the deck or inside the hull.
- modern – the concept is referred to as modern because it applies to the construction of warships until today. In the table it is referred to as "*c*". It involves the construction of a steel hull and placement of weapons in armored towers, placed on the deck. Its variant was the solution that had been used temporarily and referred

to as "c_m" (modern concept-modified) in the table. Basically, in that variant, the armored towers open from above were used (they were so-called "*barbets*").

The data collected in the table do not cover the whole of the war fleets existing in the analyzed period. Only the largest and heaviest armored vessels were selected, which during this period determined the strength of the fleet. The data were grouped in three intervals marked with years (1980, 1982, 1998) as they were derived from the materials published in 1880, 1882 and 1892. There was a certain problem with data regarding the year 1898. A large number of the considered warships in the source materials were described as modernized. Therefore, for them an additional category has been distinguished. It is marked in the table as a variant of "c_{zm}" (c-modernized). It applies to ships, most of which belong to the "c" category. It may contain units that were obsolete at the moment of the data collection but originating from the "c_m" option. The source (Jane, 1898) used, however, did not allow to determine the degree of modernization or the time of its implementation. The data set presented in the table comes from three sources: (Jane, 1898; Kronenfels, 1891; Kronenfels, 1893). The details of the descriptions contained in them did not always allow for a definite, unambiguous allocation to a given category. This applies mainly to the case of 1898 and the categories "c" and "c_{zm}".

The data presented in the table were analyzed with the model developed and the results of the analysis are presented in subsequent diagrams.

Diagram 1 shows the relative share of individual options in the number of applications of innovations (the number of existing ships) in the analyzed period. The curves A, B, and C refer to the identified innovations. The curve combined from the two concepts C+Cm and C+Czm shows the cumulative share of c concept in the number of applications of innovations, taking into account variants of this concept (the "c_m" variant for 1882, the "c_{zm}" variant for 1898).

Diagram 1: Relative share of innovations in total number of ships

Source: Own work

Diagram 2 shows the relative share of innovation c in relation to the number of countries implementing the innovation. The curve combined from the two concepts C+Cm and C+Czm in Diagram 2 takes into account the individual cumulative share of the application variants of this concept (the "c_m" variant for 1882, the "c_{zm}" variant for 1898).

Diagram 2: Relative share of innovation c in countries implementing it

Source: Own work

There are two curves on the Diagram 3. One of them illustrates the relative (quantity from 1880 is the reference level – assumed value 1) number of implementations of innovations (the number of existing ships) in the period analyzed. The second illustrates the relative (with the adoption of the maximum number of countries that used the analyzed innovation in the period considered as 1 [100%] – there were 19 countries) number of countries implementing innovation in analyzed years.

Diagram 3: Relative number of implementations of innovations and countries implementing innovations

Source: Own work

The results of the analysis obtained with the model are presented in the table 4.

Table 4: Interpretation of the data collected with the model of diffusion of technological innovation in competitive environment

Years	α_{it}	β_{it}	x_{it}	α_{it}	β_{it}	x_{it}	α_{it}	β_{it}	x_{it}	α_{it}	β_{it}	x_{it}	α_{it}	β_{it}	x_{it}	E_t	α_{it}

98	0	0	0	0	0	0	1.20	0.41	65	0	0		1	0.59	92	157	0.74

Source: Own work

The table presents the analysis of the diffusion of technological innovation consisting in changing the design of the warship as a whole product. The dissemination of this innovation based on the data for three consecutive periods marked as the years 1880, 1882 and 1898 was analyzed. Only the largest and heaviest armed vessels determing the strength of the fleet were considered. The three main competing variants of innovations referred to as "*a*", "*b*" and "*c*" were taken into account. Since variant *c* occurred in three versions during the analyzed period, they were considered separately, as variant "*c*" (basic) and two variants – "c_m" and "c_{zm}" variants. In the analysis of each variant for each period, the following parameters appearing in the model were taken into account:

- the emergence of a variant of innovation and its dissemination or disappearance. Actual coefficient of attractiveness of the i-variant of innovation at the moment $t + 1$ was calculated. The value of the parameter has been placed in the column "α_{it}". If the value presented is one in the row referring to a specific period that indicates the appearance of a given innovation variant for the first time. The appearance of a value different from *1* and *0* in this column in a row referring to a specific period shows the relative rate of dissimination of the considered innovation variant - the number of its implementations in a given period in relation to the number of implementations in the previous period, when the considered variant was used. The value of *0* in the "α_{it}" column shows that in the period under consideration the given variant of innovation was not implemented.
- the diffusion of innovations at the moment t measured in the number of implementations of innovations at that moment. Data about this parameter was placed in the E_t column.
- diffusion of the *i*-variant of innovation at the moment *t* measured in the number of implementations of the *i*-variant. Data about this parameter in relation to each of the considered innovation variants is placed in the x_{it} columns.

Additionally, the coefficient of relative attractiveness of the *i*-variant of innovation at the moment *t* is placed in table 2. Data about this parameter in relation to each of the considered innovation variants was placed in β_{it} columns.

The results presented are the product of implementation of the model developed. According to authors, it is possible to use the data to validate the model, as the phenomena of diffusion of changes in construction of the warships can be easily identified based on available data. Moreover, referring the facts and the data calculated to the actual condition of economy at that time enables identification of the causes of the situation and explanation of the diffusion process.

The dominance of variants "*a*" and "*b*" which is recognizable in Diagram 1 in 1880 is the result of the impact of the capacity existing at that moment (the structure of resources and methods of their use). Despite the significant share of the "*c*" option (which undoubtedly is characterized by the highest usability), the decision-makers have a low opinion of the ease of absorption and compatibility with the existing potential. The usability evaluation of variants "*a*" and "*b*" decreases gradually in 1882 and subsequent years, and their decreasing compatibility with the increasingly dominant option "*c*" leads in 1898 to the complete elimination of these variants of innovation.

On the other hand, dispersion between the "*c*" and "c_m" variants in the Diagrams 1 and 2 identifiable for the year 1882, indicates that assessment of the usability of both varieties of the basic variant of the "*c*" option was changing. However, the dispersion between the two variations presented in 1898 indicates a decreasing assessment of the ease of absorption of the basic variant "*c*". As it is known from history, the reason for the phenomena was the growing costs of building the largest and heaviest armed ships in the "*c*" variant. The trend is consistent with the decline in the overall number of ships visible in the Diagram 3. The number of countries using the analyzed innovation is growing rather slowly. It signals the changes taking place within variant "*c*" Again, as it is known from history, they resulted in the appearance of new ship classes built according to variant "*c*" - "*dreadnoughts*" and "*superdreadnots*", which took place after 1900.

Validation of the model used for the analysis of technological innovation presented in this article confirmed the assumptions adopted for the model development.

Summary

Innovation is one of the key concepts concerning modern technology, economics, management and sociology. Innovation has been described as a key factor while explaining the survival and competitive advantage of firms (Hult et al., 2004). Within this evolutionary process implying continuous change (Schumpeter, 1942), innovation is closely related to the creation of new knowledge. Therefore, scholars and practitioners agree on the positive effect that the acquisition, dissemination and utilization of new knowledge has on the innovative performance of firms (Bergman et al., 2005). Developing a model for the diffusion of innovations in competitive conditions in authors' opinion will

provide tools for analyzing diffusion process and support decision-making processes in the field of technology development. The article presents the model for the dissemination of technological innovations in competitive environment, which is the situation in which there are several alternative innovation possibilities. The assumptions of the model are presented after brief theoretical introduction. Then the authors proceed to describe the structure of the model. The model is presented and discussed, and the discussion includes validation carried out on historical data, from approximately 20 years. The validation proves correctness of the model, and gives solid grounds for its further development.

Abstract

Virtual Reality Exposure Therapy (VRET) is becoming an increasingly popular mechanism for treating a wide range of psychological disorders, such as phobias. The concept behind this therapy is to transpose the patient into a virtual environment in which he is exposed to various factors that trigger the feeling of fear at different levels. Thus, he has the guarantee of not being endangered while adapting to the conditions of the virtual environment. In this way, efficient virtual reality systems are evoked to generate in time an emotional response that contributes to reaching a final result of the treatment. However, there are a wide range of problems that prevent the adoption of large-scale virtual reality systems, such as high development costs, the depth of research on several disorders is still limited and the difficulty for patients to fully understand their relationship with the virtual system and the outcome of the treatment. This project brings in a virtual environment that exposes the user to different gradual elements in terms of claustrophobia, consulting him/her at key moments in the game in order to obtain a more detailed analysis of the anxiety index evolution in time.

Keywords: Phobia, Claustrophobia, Virtual Reality, Game.

Introduction

The context

Phobia is a type of anxiety disorder manifested through an extreme, uncontrolled and irrational fear that occurs when the subject is exposed to certain stimuli - a natural situation, the presence of people, animals or objects. There are different types of phobias, such as claustrophobia - fear of closed spaces, agoraphobia - fear of crowds or open spaces, social phobias - fear of public speaking, meeting people of higher authority and specific phobias - caused by various objects and situations (American Psychiatric Association, 2013). Social phobias affect all age groups, but the onset is usually in adolescence (95% begin before the age of 20).

Claustrophobia, a term that has its Greek origin in the word claustro, which means closed, and the word phobos, which means fear, is the fear of enclosed spaces. It can be unpleasant and scary, but most people who experience fear find ways to cope with it, usually by deliberately avoiding small or closed places. Small or closed rooms, tunnels, cellars, elevators, subway trains and crowded places are stimuli that can cause fear, and people who react to one of these situations are likely to react to all of them (Davey et al, 2000). The fears of sitting in a dentist's chair or

waiting in a long queue are also associated with the fear of not being locked up and are usually considered signs of claustrophobia.

The treatments indicated for phobias are of two types: medical (pills) or psychological, through cognitive-behavioral therapy. They help the patient to see the traumatic experience differently, by controlling thinking and behavior and by gradually exposing the subjects to the fear-generating objects, in the presence of the therapist who monitors the entire procedure and adjusts stimuli and exposure intensity. VRET allows exposure therapy in a virtual environment generated by the computer. There is no difference in terms of abandonment rate between VR exposure and in vivo exposure (Opris et al, 2012). Although virtual exposure sometimes induces motion sickness, it is estimated that over 80% of the patients prefer VRET to classical in vivo exposure.

The objectives

This paper aims to design and develop an application for people suffering from claustrophobia. Claustrophobia VRET exposes the user in a virtual environment in which he is subjected to claustrophobia stimuli. Thus, the patient is immersed in a reality generated by the computer, which presents dangerous stimuli in real-world situations. This type of therapy is called Virtual Reality Exposure Therapy (VRET) and is a behavioral treatment for disorders such as anxiety and phobias.

Claustrophobia VRET is a 3D game whose purpose is to support the users in fighting against the fear which arises from the feeling of being enclosed in a small space, without having any possibility to escape from there. The player has the mission to pass through a cave in search of a portal that teleports him to a cave whose galleries are narrower than the previous ones. Thus, the feeling of claustrophobia is accentuated depending on the level the player is at.

In order to measure the patient's progress along the route, there are checkpoints where he is asked to answer various questions. This will help us to obtain some graphical highlights regarding the user's progress, in terms of two emotion components: the anxiety generated by the objects placed in the scene and the anxiety generated by the narrow space of the pathway. Some tests have been performed with a group of people suffering from claustrophobia in order to assess the efficiency of the virtual environment. A future development of the system will be the extension of the application to allow the users to be exposed to the claustrophobic environment using HTC Vive glasses for virtual reality. Additional tests will be performed by using sensors that provide information such as skin conductivity and heart rate dynamics.

Analysis and Requirements Specification

Customers' profiles

In order to obtain the users' profiles and to extract their preferences or requirements, they were asked to fill in a questionnaire with questions that refer to the experience with virtual reality applications, the forms of claustrophobia that affect their daily lives and a table in which they assess the level of anxiety they would feel in different circumstances. The responses were received from a sample of 32 people, aged between 15 and 54. The data collected revealed the following aspects about the subjects:

25% of the respondents said that they do not suffer from any form of claustrophobia, while 53.1% said that they had small difficulties in terms of anxiety created by small spaces. They are part of a majority which, although encounters minor aspects of claustrophobia, is not affected by it in their daily lives. Instead, the remaining 21.9% encounter great difficulties in coping with claustrophobia, forcing them to change their course of activities, such as giving up using the elevator, finding other means of public transportation and avoiding crowded areas, such as concerts and festivals.

Although 37.5% of the respondents stated that they thought of visiting a specialist, only a small percentage of 6.2% did. One of them underwent 3 months of in vivo therapy, giving up due to the lack of results felt and the fear caused by the approach of each therapy session, mentioning that he wants to try other methods of therapy, such as exposure in virtual reality, which finds more attractive. A percentage of 31.3% of people intended to follow a treatment, but did not do it, because they showed a total lack of confidence in traditional methods for treating claustrophobia.

Although the trend of virtual reality systems is increasing, the patients' problems in understanding in depth their relationship with the virtual system is the main reason why people suffering from claustrophobia refuse to try exposure therapy the in virtual reality. A percentage of 62.6% of the respondents had an insufficient level of experience for finishing a therapy session in the virtual environment.

There are two situations to which the respondents attributed the highest factor of claustrophobia: to be locked in a small, dark room without windows for 15 minutes, respectively to be locked in a box of their size for 15 minutes. These two circumstances will be key elements to consider in developing the application.

By taking into account the answers of the potential customers, we obtained the necessary parameters to create a list of functionalities that the final product will have to fulfill.

System Requirements

For the application to run optimally, the computer on which it will run must meet the following minimum specifications:

- Windows 10 operating system
- Intel Cor i5-10210U processor
- 10 GB of free hard disk space
- 4GB RAM
- Dedicated MX150 2GB video card

Functional Requirements

Information menu. At any point in the game, the user can press the "I" key and the missions he has to complete to move to the next level will be presented to him, as well as the list of control elements.

Implementing player control. Similar to first-person games, the player's movement will be implemented according to the popular control elements for the WASD keyboard (W - forward, A - backward, S - left, D - right). For a good mobility, the player's point of view will be changed according to the mouse movement on the Ox and Oy axes, the sprint and squat will be accessible by pressing the LShift and LCtrl keys, and the Space key will be used for jumps.

Interaction with scene objects. Interaction with scene objects will be suggested to the player as he/she approach them. This includes pressing the "F" key to collect the crystals, or the "E" key to open the doors for the portals leading to the next level.

Randomly generated portal. To intensify the feeling of anxiety, the exit from the claustrophobic environment will be randomly generated for the user, in order for him to go through as many areas of the scenes as possible.

Game design. The environment’s design must meet the requirements obtained by configuring the customers’ profiles. Thus, the setting chosen for the project is a cave whose exit points are represented by portals inside boxes the player’s size.

Adding sound and animations. Any movement of the player will be synchronized with sounds, such as the sound of footsteps or jumping.

Adding a score system. Depending on the level of comfort that the user feels, he/she can navigate through the scene as much as possible in order to collect crystals and to obtain a score as high as possible.

Given the analysis of potential customers above, we came to the conclusion that pyrophobia is a real problem in the lives of some people. It is a phobia with which you can be born or which you can acquire. Therefore, the motivation of this paper is to create a reliable virtual environment, which can have a positive impact on people suffering from pyrophobia. We wanted to develop a functional product, based on a scenario that the users can encounter in everyday life.

Non-Functional Requirements

There must be different levels of difficulty for both novice and advanced users. At any time during the game, the player can press the "H" key and a panel will be presented in front of him/her, from where he/she can adjust his/her claustrophobia index.

There must be a smooth flow of the game without the user to get blocked.

At the end of the session, the user should have an overview of his/her evolution. Thus, he/she will receive an email that explains in detail each stage he/she went through and the accumulated score, along with a .csv file useful for making a plot of the progress.

Existing Approaches

Although in its infancy, the market for VRET applications has grown exponentially, due to better results compared to other classical methods of treating psychological disorders. Most platforms offer a wide range of environments that focus on presenting as many anxiety-provoking scenarios as possible. Next, we will analyze three platforms for phobia treatment that use VRET technology, by emphasizing the virtual environments, the scientific ideas behind them, but also a series of identified disadvantages.

C2Care (C2Care) offers the widest range of virtual reality therapeutic software solutions on the market. To date, more than 450 doctors and medical institutions in France and abroad have used the C2Care products. This platform collaborates with more than 15 university teams and many health specialists. It is designed by mental health professionals, psychiatrists, psychologists and psychotherapists. With the help of virtual reality headsets and accompanied by a therapist, the patient is gradually exposed to different levels of anxiety, depending on his pathologies. The application is composed of more than 70 exposure scenarios that help treating conditions such as acrophobia, agoraphobia, claustrophobia, ochlophobia, arachnophobia, aviophobia, school phobia, fear of speaking public, fear of dogs, fear of dentist, etc. C2Phobia allows the patients to be exposed to anxiety-related situations, while ensuring their safety and by gradually exposing them to the object of their fear. Moreover, there is the possibility to expose the patients to virtual reality at home. The therapist can monitor, expose and treat the patients even from a distance.

The Virtual Reality Medical Center (VRMC) (VRMC), based in San Diego, California, provides support to the Bureau of Naval Research, the U.S. Army and the Defense Advanced Research Projects Agency (DARPA) and the National Institutes of Health (NIH) in the field of psychological research design and training. It uses VRET in combination with biofeedback and cognitive behavioral therapy to treat phobias, anxiety, stress and chronic pain. The treated conditions include specific phobias such as fear of flying, fear of driving, fear of heights, fear of public speaking, claustrophobia, agoraphobia, panic attacks and post-traumatic stress disorder caused by road accidents. Physiological monitoring is non-invasive, with visual feedback to analyze and help patients understand when they feel anxious and when their body is relaxed. At each step, the therapist can see and hear what the patient is experiencing in the virtual world. If the level of anxiety becomes overwhelming, he/she can return to a less stressful level of treatment or simply take off the virtual reality glasses.

PsyTech (PHOBOS VR Exposure Therapy) is a virtual reality software start-up that has developed a platform for phobia and anxiety management for individuals, professionals and organizations, using Oculus Rift. Phobos (PHOBIS video) has also made games that address arachnophobia (fear of spiders), ornithophobia (fear of birds) and other animal-related phobias. In addition, they have created simulations for aerophobia (fear of flying), claustrophobia, agoraphobia (fear of open environments) and other forms of chronic or acute anxieties. In a virtual environment dedicated to claustrophobia therapy, the users are subjected to a MRI scan in which they must sit inside the device for 10 minutes or walk in small apartment. The elements present in the second scene are rooms such as a bathroom, a kitchen or a pantry, all very small-sized, with objects with which the player can interact.

Although it offers many virtual environments for treating phobias, C2Care does not present an increase on levels in terms of treating claustrophobia. The existing environments, such as using an elevator or walking on a busy street have a lower anxiety index than, for example, a cave. Another disadvantage is the price for a one-month subscription (60 euros). VRMC focuses on environments dedicated to pre-surgical anxiety. For claustrophobia, there is the MRI scan scene, similar to the one developed by PsyTech. The therapy is not remotely accessible because it involves physiological monitoring from a specialist. Even if PsyTech proposes a large number of scenes dedicated to claustrophobia, the technology used involves the Oculus Rift device only and the developed applications are 6 years old, which leads to a lack of graphical details and diminishes the impression of reality perceived by the patient.

The Proposed Solution

This chapter presents the proposed solution, from the perspective of user's interaction with the objects in the scene, as well as of the elements that create anxiety and how they are emphasized on the levels.

Claustrophobia VRET consists of 4 scenes: the first three scenes represent claustrophobic environments, in ascending order according to the index of fear caused to the patient, while the last scene contains an open environment, as a reward for the user's success to overcome his/her fears and escape from the uncomfortable environment. The ratio between the player's height and the height of the cave's galleries is different for each scene. The first (and at the same time, the easiest) level implies that the height of the player is equal to a quarter of that of the cave and in the second level it is half of it. In the last level, the player will have a height equal to that of the galleries, in some places being forced to squat to in order to pass.

The first three scenes address the theme of a cave with three clogs and are similar in terms of their construction, the difference being the ratio between the height of the player and the height of the galleries. For scene construction, we used various design elements bought from the Unity Asset Store (Bat asset, Cave asset). The player starts from the right end of the cave (Figure 1) and has the mission to collect as many crystals as possible, while finding the portal to the next level.

Figure 1: Map construction

The portal is placed randomly at one end of the cave, which accentuates the feeling of claustrophobia, by adding an element of uncertainty. This causes the user to panic when he reaches a dead end, without finding the portal to the next level. If the player finds the portal, he will have to enter a box of dimensions that will be smaller than theirs in the last scene (Figure 2). After the player enters this box, he will have to spend 15 seconds with the door closed, in order to be teleported to the next scene. The idea behind the repetitiveness of the scenes is to maintain the player's state of anxiety caused by the lack of hope in finding a final exit from the cave.

Fig. 2: Portal to the next level

After starting the application, the user is asked to fill in his personal data in order to store the information internally and to create a plot with his/her evolution during the therapy sessions he/she attends. The information is represented

by the measurements done during the game and will be saved in a .csv file. The panel contains the fields to be filled in, consisting of two text areas in which the user is given instructions - his name and the number of the therapy session which he attends, along with a save button (Figure 3).

Fig. 3: Filling in personal data

One metric designed to monitor the user's progress is to create a scoring system based on the number of crystals collected (Figure 4). The player's desire to search and collect as many crystals as possible is directly proportional to his level of comfort in the environment. If he/she develops a feeling of high anxiety, his/her main goal becomes the immediate search for a way out of the cave. Thus, those who will collect as many crystals as possible will receive a higher score. These crystals are of three colors - red, blue and white, and the player's score is updated and displayed after collecting each crystal. Also, the number of objects left to collect is displayed. To make it more difficult to gather all the crystals, they are placed in different hard-to-reach parts, such as behind groups of stalactites and stalagmites through which it is necessary to slip or on the upper parts of the cave, where the user needs to jump.

Fig. 4: Collecting the crystals

To make a more frightening environment that accentuates the state of anxiety, we added objects such as bats, skulls, skeletons or barrels in flames. In addition, we supplemented the scene with animations such as the flight of groups when the player gets near to them (Figure 5).

Fig. 5: Flight animation of a group of bats

The data that is used to analyze the evolution of the patient's anxiety level is collected in 5 control points in each of the 3 scenes available for play. The points are strategically placed in key areas: the first point is located in the middle of the first room of the cave to collect the player's initial feelings, followed by two points on each artery that starts from the intersection of the three corridors. One point is in the middle of the artery where the cave is the narrowest, and the other is before it reaches the clog. There, the level of anxiety is the highest, due to the uncertainty of finding the portal at the end of the artery. The questions are designed to obtain measurements of fear, respectively the level of anxiety produced by the environment. The questions have 5 possible answers: not at all anxious, a little anxious, moderately anxious, very anxious and extremely anxious and they are assigned an index of claustrophobia / fear of the environment from 1 to 5, inspired by (PHOBOS on Unity). Thus, we can see how the user accommodates to the virtual environment, by analyzing his profile, who resulted from the questionnaire he/she filled in before starting the game. The answers are saved on columns in a .csv file, depending on the scene in which they were collected, the control points that the player passed and the degree of fear/anxiety that he/she estimated (Figure 6).

Fig. 6: Question about the level of anxiety

If the user shows high signs of anxiety, a panel is displayed where he/she can adjust the claustrophobia index according to his/her preferences. Also, at any time on the way to the transition portal to the next scene, if the player feels the need, he/she has the option to use this panel to maintain a progressive desensitization. The panel shown in Figure 7 contains three buttons: two buttons to scale the height of the character relative to the size of the cave by 10% less or more, the extreme limits being 10% and 100% respectively and a button to close the panel.

Fig. 7: Claustrophobia level control panel

When the player finds the last portal that represents the end of the game, he/she is asked to fill in a field with his/her personal email address in order to receive the results. This feedback is divided on the evolution on the three levels and includes the answers to the questions, regarding the degree of fear in the checkpoints, respectively the degree of anxiety felt, the number of diamonds collected and the unexplored areas of the scene. The .csv file created during the game is also attached to this email (Figure 8).

Claustrofobia Virtual Reality Exposure Therapy Results

claustrophobiavret@gmail.com
către eu

Dear Marian,

Following the completion of Session Number 1 of the Therapy you received the following Feedback:

Level 1

Your average level of Claustrophobia was 2.4/5

Checkpoint 1 : Somewhat anxious (3/5)
Checkpoint 2 : Very anxious (4/5)
Checkpoint 3 : A little anxious (2/5)
Checkpoint 4 : A little anxious (2/5)
Checkpoint 5 : Not at all anxious (1/5)

Your average level of environmental fear was 3/5

Checkpoint 1 : Very frightened (4/5)
Checkpoint 2 : Very frightened (4/5)
Checkpoint 3 : A little frightened (2/5)
Checkpoint 4 : Somewhat frightened (3/5)
Checkpoint 5 : A little frightened (2/5)
Total Diamonds Collected:

Blue Diamonds:15/15
Red Diamonds:5/25
White Diamonds:4/15

Level 2

Your average level of Claustrophobia was 4/5

Checkpoint 1 : Very anxious (4/5)
Checkpoint 2 : Extremely anxious (5/5)
Checkpoint 4 : Extremely anxious (5/5)
Checkpoint 5 : A little anxious (2/5)

Your average level of environmental fear was 3.75/5

Checkpoint 1 : Very frightened (4/5)
Checkpoint 2 : Very frightened (4/5)
Checkpoint 4 : Very frightened (4/5)
Checkpoint 5 : Somewhat frightened (3/5)

Total Diamonds Collected:

Blue Diamonds:7/15
Red Diamonds:3/25
White Diamonds:1/15

Level 3

Your average level of Claustrophobia was 4.67/5

Checkpoint 1 : Extremely anxious (5/5)
Checkpoint 2 : Very anxious (4/5)
Checkpoint 3 : Extremely anxious (5/5)

Your average level of environmental fear was 3.33/5

Checkpoint 1 : Extremely frightened (5/5)
Checkpoint 2 : Somewhat frightened (3/5)
Checkpoint 3 : A little frightened (2/5)
Total Diamonds Collected:

Blue Diamonds:4/15
Red Diamonds:6/25
White Diamonds:3/15

Thank you for attending this therapy session!

We are looking forward to seeing you at the future session.

Best regards,
Claustrophobia VRET Team

AssetsTherapy_Re...

Fig. 8: Email containing the results

Case study and Results Evaluation

Out of the 32 people who filled in the initial questionnaire, in order to obtain the system's functional requirements and outline the client's profile, 16 of them agreed to participate in the game testing sessions. They downloaded the application from here (Install files). After testing, they completed another questionnaire, in which they were asked to evaluate the application from several points of view. The data analysis reveals the following:

- 87.5% of the respondents managed to finish the game and 81.3% of them considered that its duration was appropriate. The game may vary in time according to the user's desire to collect as many crystals as

possible. Thus, 6.3% considered that the route was too short, while 12.5% considered that the route was too long.

- The opinions about the route's difficulty are divided, due to the different profiles of each user, as their degree of anxiety differs. One of the obstacles encountered along the way was the difficulty of collecting crystals from hard-to-reach areas. In addition, most respondents stated that the virtual environment is very realistic, which confirms that the choice of the Unity graphics engine was a good one.
- 87.5% of the respondents considered that the questions about the emotional state were intuitive, which gives a high degree of credibility to the analysis made based on the answers given. 93.8% of the users stated that the journey in the virtual environment helped them somehow to get rid of the anxiety.

As the application is dedicated to the treatment of patients suffering from claustrophobia, we asked a person whose answers in the first questionnaire revealed that he/she is the one who is most affected claustrophobia, to perform several sessions in order to plot his/her evolution. Thus, he/she played 4 sessions and obtained the following scores: in the first session an average degree of anxiety in the 5 control points equal to 4 (out of a maximum of 5), in the second session 3.2 / 5, in the third session 2.4 / 5 and in the last session, 1.2 / 5. As it can be seen in Figure 9, his/her evolution in the 4 sessions progressively improved.

	1	2	3	4	5
Session 1	3	3	5	4	5
Session 2	2	3	4	3	4
Session 3	2	2	4	2	2
Session 4	1	1	2	1	1

Fig. 9: Plot of the anxiety level evolution of the most claustrophobic user

Conclusions

Claustrophobia VRET is an application that proposes a new challenge for people suffering from claustrophobia, in order to treat the anxiety perceived in small and enclosed spaces. This application emerged as a result of the market expansion of virtual reality therapy software solutions. By considering the analysis and requirements specification, Claustrophobia VRET aims to address all the needs of the target audience: availability on the most used gaming platform, best fit into the most appropriate navigation duration, optimal graphics quality, in-game activities and interaction with the objects from the virtual environment.

The setting in which the game takes place is one which has not been addressed by the existing virtual reality environments and has as theme the galleries of a cave in search for an exit portal. Considering the questionnaire completed by the people who tested the application, the construction and organization of the scenes, the effects of interaction and animation, the choice of the checkpoints and the intuitive questions that helped analyze the evolution of anxiety, all these proved to be key elements in creating a virtual reality environment that can treat patients suffering from claustrophobia.

Because the implementation stage of the presented application is an incipient one, there are various important functionalities that can be developed to ensure a place in the elite of virtual environments for treating claustrophobia: the development of the system, in order to allow the patients to be exposed in VR using the HTC Vive glasses, performing additional tests using a physiological monitoring system, designing more scenes in which the player will be subjected to a longer journey inside the cave, by adding other branches of galleries.

Human-Influenced Critical Success Factors in Enterprise Resource Planning System Implementation

Brenda-Leah HERNANDEZ-ROVIRA

Colorado Technical University, Denver, Colorado, USA
brenda.hernandez177@alumni.ctuonline.edu

Abstract

Identifying critical success factors can aid decision-makers in preventing human-influenced failures to enterprise resource planning implementations. The purpose of this exploratory qualitative study was to explore the human-influenced critical success factors for an enterprise resource planning system implementation. The study was accomplished through interviews with 12 mid-level to senior-level project and IT managers with experience in enterprise resource planning system implementations. The researcher looked to illuminate those human-centered factors that cause failure so managers can better avoid or mitigate issues caused by the factors. The results of this study will assist management in reducing factors that often result in the loss of revenue, resources, and market share. The need for enterprise resource planning systems to remain competitive means organizations regularly seek to ensure project success and system acceptance. Eliminating threats yields a system that realizes requirements, reduces resource waste, and increases overall task efficiency. Results from the study close the gap between known critical success factors and the behavior modifications needed to ensure successful implementation and usage. The transcribed interviews demonstrated that communication was the most frequently experienced factor in enterprise resource planning system implementations, followed by planning, readiness, expectation, lens, resistance to change, skill, and culture. Two unique findings in the study were the appearance of requirements in the top factors and that the resistance to change factor was not as prominent as expected.

Introduction

Critical success factors (CSFs) can negatively affect Enterprise Resource Planning (ERP) system implementation and subsequent system usage (Jenko and Roblek, 2016). Some CSFs may be directly attributed to human interference. Preventing negative human influence on project activities could mean the difference between a successful implementation and system adoption or the curtailment of project activities.

Providing managers with factors that warrant extra attention and mediation may ensure successful project completion and system adoption. Highly competitive and volatile markets mean that organizations employ technology to make informed strategic business decisions, exploit resources, or increase efficiency (Payne and Frow, 2005). The technology used takes the form of an enterprise information system (EIS). Systems are implemented that assist in resource deployment, supply chain management, human resources, and analytics. Of the available solutions, ERP is the most comprehensive (Alok et al., 2018). The most substantial advantages ERPs provide is the real-time tracking and deploying of resources, along with the intelligence that drives critical strategic business decisions. Markets are volatile, so the ability to shift resources, limit resource expenditure, or expand in markets can make or break an organization (Pearlson et al., 2016). ERP implementation is only made possible by expert level computer engineers and developers, so any alterations needed to ease end-user assimilation are developed and configured by these experts (Al-Jabri, 2015). As such, knowledge distributed to managers that mediate human-influenced issues with system implementation or usage is also vital to the experts developing and installing the solutions.

ERP system implementations are highly disruptive and expensive endeavors for organizations to pursue, regardless of the benefits expected (De Toni et al., 2015). High failure rates are experienced in both project completion and system acceptance leading to attempts to discover the core reasons for these failures (Jenko and Roblek, 2016). Though end-user adoption of technology was explored in Davis (1989) Technology Acceptance Framework, initial research into ERP implementation failures was first documented in the early 2000s, as evidenced by Al-Mashari and Al-Mudimigh (2003) article focused on the postmortem of a troubled implementation. The exploration into ERP issues coincides with the adoption trend at the time. ERP implementations increased as the system started to gain the attention of larger organizations. From that point, studies emerged by Chakravorty et al (2016); Etoz and Dugenci (2015); and Pabst et al (2016) documenting issues and potential mediation efforts addressing both project failure rates and system acceptance.

Even though the issues surrounding ERP implementation and system adoption are frequently researched, the human ability to derail the project and subsequent acceptance appear to remain neglected.

The study into human-influenced CSFs is of vital importance to managers and end-users in organizations planning an ERP implementation (Al-Jabri, 2015). Project post mortems and research into ERP failures have not improved the percentage of successful implementation and system acceptance (Gollner and Baumane-Vitolina, 2016). The lack of improvement in the success rate may be because research into the human influence on these factors does not appear to exist.

Research into human-influenced CSFs in ERP implementation is essential to information technology (IT) and organizational management due to the cost of sunk resources and the benefits that ERP provides when the project is successful (Amoatey and Mawuena Vincent, 2017). According to De Toni et al (2015), organizations lose between two and six percent of an organization's yearly profit in failed enterprise information system implementations. With ERP being the most popular and function integrating of the solutions available, it is here that the loss of spent resources is experienced most acutely (De Toni et al., 2015). Not only is there a loss of funds, but also a considerable loss of confidence in the organization by staff and customers, lost work hours and production from disruptions caused by the implementation, and loss of the benefits from the implemented system like greater efficiency or quality (Amoatey and Mawuena Vincent, 2017). End-user refusal to use new or different technologies was initially captured in the Technology Acceptance Framework (Davis, 1989). The research by Davis was expanded on by Abdinnour and Saeed (2015), and Davis's (1989) constructs are used in many other studies. The results of recent investigations by Campbell et al (2017); Dumpit and Fernandez (2017); Lai (2017); and Wang et al (2018) validate Davis's initial discoveries; that end-users demand technology to make their tasks more manageable and that the technology be easy to use. Any deviation from expectations will result in end-user refusal. By examining the human aspect of CSFs, managers may be able to develop more targeted mediation plans to ease fears and frustrations that end-users experience, preventing push back during the implementation phase and system usage refusal.

The problem addressed in the subject research study was that ERP implementations do not realize the potential expected, consume more resources than initially projected, or the implementation fails (Irvine and Hall, 2015). The research study was to explore the human-influenced CSFs for an ERP implementation. The researcher illuminated those human-centered factors that cause failure so managers can better avoid or mitigate issues caused by the factors. Identifying CSFs can aid decision-makers in preventing human-influenced failures to ERP implementations, both during the implementation phase and during initial use, which may result in loss of revenue, resources, and market share (Irvine and Hall, 2015).

Literature Review

The Literature Review provided background on the central research question of "What are the factors that top and mid-level management experience as being human-influenced critical success factors on an ERP implementation?" Studies into ERP system implementation failures usually center on project critical success factors (CSFs), those common factors linked to success or failure of any project. Studies are commonly done that list CSFs for ERP implementation, but few tying the CSFs to actual project success (Ram and Corkindale, 2014). Most studies conducted on ERP implementation CSFs are based on failed or ailing projects. Studies to reexamine the effect of using previously discovered CSFs to mediate or eliminate issues in another project have not been conducted (Ram and Corkindale, 2014). Organizations must recognize that compiling lists of CSFs alone is not enough to provide a complete guide to successful implementations. There needs to be guidance that provides practical instruction on how to manage each factor (Irvine and Hall, 2015).

ERP implementations are lengthy, complex, and risky (Alhakimi and Alzahary, 2015; Jenko and Roblek, 2016). Implementation costs for ERP generally range between two and six percent of an organization's profit (De Toni et al., 2015). Research into ERP implementations discloses that more than half end as failures, and of those failures, 20% terminate before the project finishes. Experts also state that 90% of ERP implementations are over budget and cost, while 67% fail to achieve the requirements (Alhakimi and Alzahary, 2015). Often the volume of issues and the enormous expense of implementation outweigh the benefits of ERP (Shaul and Tauber, 2013). A waste of benefits and investment with ERP systems is encountered if users do not utilize, or outright avoid the new system (Abdinnour and Saeed, 2015). Studies into ERP failures usually center on project CSFs, those common factors linked to the success or failure of any project. As previously mentioned, only recently have CSFs for ERP listed human components, but only revealing these factors as more of a secondary intent rather than the focus of the research (Jenko and Roblek, 2016). Close examination of many CSFs seem to indicate a strong human influence at the root. Examining previous studies have revealed CSFs in three overarching categories, human-centered, organization-centered, and project-centered. These same major categories

are featured in the conceptual framework. The combination and interaction of the seminal works of the Concept of Critical Success Factors (Rockart, 1978), System's Theory (Bertalanffy, 1972), and Technology Acceptance Framework Model (Davis, 1989) create the relationships to concepts, constructs, and variables used to develop the study (Stebbins, 2001).

Human-Centered CSFs

Regardless of how successful the project side of ERP implementations is, consideration of how organizational staff reacts to the new system is vital; there is no pay off for a system implementation if the staff refuse the system (Al-Jabri, 2015). Resistance to change presents itself in many forms during project implementations (Ronningstad, 2018). Human-centered CSFs include those that indicate acceptance, satisfaction, and preconceived impressions.

Acceptance and satisfaction.

Fred Davis first investigated user acceptance and satisfaction with information technology (IT) in 1989. Davis (1989) posited that staff would use a system if they believe it will enhance their job performance, under a construct he labeled perceived usefulness (PU). A user that feels a system is too hard to use will reject it even if it enhances their job performance was labeled Perceived Ease of Use (PEoU). Between PU and PEoU, PU is more linked to system rejection. Even if a system is easy to use, if the user believes the system provides no benefit, they will reject it. These behaviors were confirmed by Al-Jabri (2015), who added that satisfaction boosts ease of use on a system. Al-Jabri's (2015) examination confirmed that satisfaction is directly linked to system use and increases on the cumulative experience users have on the system.

Abdinnour and Saeed (2015) reported that employees make assumptions on how roles and tasks will change based on what they perceive management values most, and where an employee sits in the hierarchical structure of an organization will influence their perception of the benefits and value of an ERP implementation. Beijsterveld and Groenendaal's (2016) concluded that a common cause of ERP discontent by end-users is that the system fails to live up to the promise of specific features they assumed were to be included. Whether there was any intent by leadership to provide those features does not factor into the end-users perception that the feature should be available (Beijsterveld and Groenendaal, 2016).

Perceptions and expectations.

Staff will often negatively formulate the events and consequences of change in the absence of a clear vision. These early perceptions carry on through to the implementation of the change creating resistance (Rafferty and Jimmieson, 2016). EU and EoU are not the only system reception indicators by staff (Pierce et al., 2014). Influence for acceptance and satisfaction on system implementations occurs through communication, competency, usage intent, change resistance, subjective norm, and organizational relationships (Al-Jabri, 2015). Factors that influence acceptance and satisfaction can cause dissent through the neglect of even one factor (Brock and Khan, 2017). According to Rafferty and Jimmieson (2016), change fatigue creates negative perceptions. Rafferty and Jimmieson (2016) stated that user perceptions were greatly influenced by the amount of change in a specific. Ronningstad's (2018) study agreed that change fatigue contributes to system resistance, even when other factors are favorable. Altering daily tasks to accommodate system implementation processes creates tedium and discontent fairly quickly (Ronningstad, 2018).

ERP implementations may take considerably more time than many staff realize. Poor communication of the time needed for ERP implementations results in unmanaged expectations (Cresswell et al., 2013). Unmanaged expectations cause stakeholders to develop a negative attitude and pull away from implementation activities. Losing the support of stakeholders may mean losing the resources they bring to the table, effectively ending the project (Rafferty and Jimmieson, 2016).

Communication effect on satisfaction

Al-Jabri (2015) conducted a study that revealed communication as one of the key factors in ensuring satisfaction. Communication tasks include documenting the use case, issuing of the change management plan, and the announcement of the system changes to users to include the benefits, scope, schedule, and progress. Organizations must gain the staff's trust to see a successful change initiative. Communication is vital in order to gain trust. Communication works by acknowledging and nurturing spirit, motivation, participation, and dispensing job security assurance (Husain, 2013).

Staff competency effect on satisfaction

Jenko and Roblek (2016) revealed that constant and open communication does affect satisfaction, but the need for competent staff is just as crucial. Al-Jabri (2015) reported that intensive training is required to increase the competency of staff and ensure system satisfaction. Without training, staff may feel the system is too complicated and challenging to use. The staff may also feel too much time is required to attend to simple tasks.

Intent to use the system

Pierce et al (2014) extended the EoU and PU findings by adding attitude and intent. Intent is the primary key in what drives a user to accept and use a system. Many organizational forces influence intent; one such force is from management. Managerial pressure directly affects user intent. Pressure by management alone might enact acceptance of any object. Instruction on repetitive tasks might influence intention. The more education staff receive on specific tasks, the more willing they are to engage in them, even in instances of innovative technology (Esteves, 2014). Organizations that provide training to their employees find more staff acceptance and system usage after ERP implementation (Esteves, 2014). Staff performs better in organizations where management endorses training.

Resistance to change

Resistance to change is a symptom of fearing the unknown (Fernandez and Rainey, 2017). Combating resistance to change is achieved by making sure the staff actively participate in change activities (Fernandez and Rainey, 2017). Changes occur that may make staff feel powerless and ineffective. Completing tasks that directly affect the end goal of a successful implementation, restores confidence, and a sense of ownership in the implementation (Lin, Huang, and Chiang, 2018). Ronningstad (2018) concluded that managers are the key to deterring resistance to change. Additionally, Ronningstad (2018) indicated that project managers are the buffer between passing on changes from upper management and getting staff to adhere to unpleasant changes.

Subjective norm and organizational relationships.

Group dynamics, like subjective norms and departmental relationships, may connect to acceptance and satisfaction of a system's implementation. Alok et al (2018) revealed that subjective norms play a crucial part in the perceived usefulness and intention to use the system as peer pressure determines what is and is not useful in an organizational context. Subjective norm is the assumption that everyone behaves the same way that they do (Alok et al., 2018). In groups, staff will relate to those that think the same.

Organization-Centered CSFs

CSFs centered specifically on an organization are those that bring to front group dynamics and how those dynamics influence the success or failure of system implementations (Ballaro and Washington, 2016). Often the individual will concede personal perceptions to those of the group. The staff members going against the group face alienation (Newham and Midjord, 2018). These clique-type CSFs include group mentality, culture, readiness, assimilation, readiness, lens, size, training, and skill level.

Organizational Group Mentality

Humans are instinctively driven to collect in groups (Tsvetkova et al., 2017). Group herd behavior serves to protect from harm and make the best use of available resources (Campbell and Grimshaw, 2016). Individuals in the group observe behaviors and are then compelled to behave in the same manner (Newham and Midjord, 2018). In organizations, group collective or social behavior could result in group behaviors that propel change or collectively resist change (Tsvetkova et al., 2017).

Culture

Alhirz and Sajeev (2015) conveyed that organizations must realize that culture plays an integral part in the success of implementations. Use intention, positive or negative, can be moderated by the hierarchical influence of management. Organizational culture has a considerable influence on the acceptance of technology. Bharati and Chaudhury (2012) reported that support by top-level management is crucial to the success of any technology adoption. ERP system implementation benefits from an organizational change culture and willingness to allow assimilation. In an organizational sense, assimilation is the act of when system usage is routine and seamlessly integrated into each process (Mehta et al., 2014). User resistance to change based on organizational culture is the primary reason for the lack of assimilation in ERP implementations (Mehta et al., 2014).

Readiness

Lohe and Legner (2013) found that some of the main difficulties in implementation are the diverse stakeholders, organizational complexity, and the enormous scope of the project. Jagoda and Samaranayake (2017) advised that before beginning efforts to implement an ERP, organizations must be realistic in what the ERP implementation will accomplish and embrace those activities ERP can do better.

ERP implementations are an organization-wide disruptive initiative. Many organizations find that there was not enough time placed to completely understand how disruptive (De Toni et al., 2015). Prepping the organization for a highly disruptive implementation like ERP is the best way to ensure project success (Peci and Vazan, 2014). Planning, infrastructure preparations, management, training, communication, competence, and system exposure by the whole organization are keys to readiness.

Planning

Planning before the implementation is critical to prevent issues with the implementation. De Toni et al (2015) found that failed initial implementations can have adverse effects on perceived usefulness and ease of use of the final implementation. Holm et al (2012) discovered that the selection of the architecture to be used needs to fit the organization. Organizations achieve fit by making sure the infrastructure has been prepared by analyzing the quality of the data. Shaul and Tauber (2013) contended that evidence of poor planning shows in underperforming or failed ERP implementations. The most common cause of ERP failure is inadequate planning leading to unmanaged expectations (Cresswell et al., 2013). Failure to conduct proper planning means the organization does not have a full understanding of each process needing improvement (Peci and Vazan, 2014). Pabst et al (2016) contended that pre-implementation planning not only includes a review of failure points and robust requirements but the commitment of management as well. Successful implementation comes through the combination of organizational and management commitment so, a clear indicator that an organization is not ready for ERP is if the need for ERP is not crystal clear to stakeholders (Pabst et al., 2016). Stanciu and Tinca (2013) agreed. Their analysis revealed that success in ERP implementation hinged on top management collaborating with stakeholders during planning and implementation (Stanciu and Tinca, 2013). Stanciu and Tinca (2013) also revealed was that management commitment was essential; specifically, there is no buy-in at the bottom when there is no buy-in at the top.

Assimilation

Getting a successful implementation must include the ability for the integration of the system and the organization. Mu, Kirsch, and Butler (2015) stated that ERP is more than just the integration of hardware and software. The enterprise, as a whole, must embrace the solution. Assimilation is possible if the organization can act on the new technology and the architectural needs of the infrastructure. Nixon (2014) added that assimilation is rarely the focus when change occurs. The negative focus on assimilation places the implementation on fragile ground.

Departmental lens

The lack of consideration of assimilation could be from the way the various departments view the change. Tsiga et al (2016) reported that the success of a project depends on the viewed lens. Participants will not view project success in the same way stakeholders do. Leadership and stakeholders may view the need for ERP implementation as crucial to the

growth of the organization, yet staff may view the implementation as additional duties layered on normal daily activities (Kunert and Weth, 2018).

Organizational size.

Failures for ERP implementation do not only affect large organizations. Wachnik (2017) conducted a study that revealed successful implementations for large organizations versus small organizations were nearly the same. Wachnik observed there was a slight increase in failures for implementation in smaller organizations because of the limit on resources experienced by smaller organizations. Larger organizations can divert resources to failing implementations, improving the chance the implementation succeeds, even if over budget (Reascos and Carvalho, 2018).

Training and skill level.

Implementation success occurs in organizations that invest in training, yet many organizations do not place enough emphasis on training. Esteves (2014) reported that training regimes are not developed with cyclical retraining in mind even though the disruptive forces of ERP continue through many implementation phases. Hsieh and Hsu (2015) found that training is key to system acceptance and proved that end-user training for new information systems implementation is not sufficient. Training must occur at regular intervals throughout the project cycle and has been demonstrated to be more effective with mentoring (Hsieh and Hsu, 2015).

Project-Centered CSFs

Projects consume the most significant portion of an organization's growth strategy and focus. Ignoring the factors that signify possible issues can directly affect the outcome of any project, especially in the case of long-term projects (Irvine and Hall, 2015). Noted by Ha and Ahn (2014), ERP is considered one of the most important long-term projects organizations undertake to improve processes. Managing CSFs in long-term projects, like ERP implementations, makes sure growth dependent on a successful project goes according to strategy (Akhavan and Zahedi, 2014). Successful project outcomes rely on superior project management. Project management depends on project managers acting in the position of organizational change agents and project planners (May, 2013).

Project Management

Several studies have identified CSFs directly linked to the management of the project itself (Irvine and Hall, 2015). These project-oriented CSFs indicate possible problems with solution alignment to the organization, lack of understanding of solution implementation, or lack in project management expertise (Ram and Corkindale, 2014).

Akhavan and Zahedi (2014) went on to say that management needs to be present in each phase of implementation and visible to business units (May, 2013). Alhakimi and Alzahary (2015) found that most ERP implementations fail due to organizational management factors. Organizations must engage top management to counter employee resistance. Al-Hadi and Al-Shaibany (2017) showed that when managers agree on the present course of action, their presence is enough to quell resistance (Al-Hadi and Al-Shaibany, 2017).

Project managers are change agents.

Project implementation success occurs when organizations choose the right agents who provide the oversight, the resources, and the plan. The best agents during implementations are experienced project managers (May, 2013). Joslin and Muller (2015) stated that successful project implementations hinge on the skills and experience of the project manager. Ram et al (2013) added that effective project managers do more than manage projects. During project phases, project managers serve as management, peer, and mentor. Project managers minimize resistance to change and implementation failure by being attentive to how teams are selected, the scope of the project, and establishing tight monitoring and control routines (Ram et al., 2013).

Project managers are Project Planners.

Project managers must be included in each phase of implementation, from selection to finish, to be effective (Ram et al., 2013). A project manager's input is most critical in the planning phase. The article by Barros et al (2015) mentioned planning as the most crucial element in any integration process and mostly affects the quality of data and process improvement. Etoz and Dugenci (2015) agreed that planning is essential, and implementations fail due to poor cost estimating, scheduling, and project risk assessments. Within the planning phase is the selection of which solution best fits the organization's needs and the selection of the vendor providing the solution. Jinno et al (2017) reported that ERP packages must be scrutinized to meet expectations. Vendors will often suggest features that do not fit the organizational need or play down features creating a gap in function (Ram et al., 2013).

Research Methodology or Approach

The research method and design selected was a qualitative tradition using an exploratory approach. The exploratory design under the qualitative tradition looks to examine phenomena centered on a specific subject (Stebbins, 2001). For research centered on discovering how humans can alter the success of project implementations as with the subject research study, exploratory design for the qualitative methodology was the best choice (Stebbins, 2001).

Population and Sample

The target population for the exploratory study contained IT or project mid to senior-level managers from any industry or corporation size in the United States that experienced an ERP implementation effort. The success or failure of the implementation was not relevant as CSFs can be seen in successful implementations but are more prevalent in failed implementations (Ha and Ahn, 2014). As ERP implementations take years to complete, the inclusion of ERP implementations in progress was appropriate. CSFs for ERP implementations can appear as early as the first phase of development (Chakravorty et al., 2016). Overseas locations were not accepted as the process to implement ERP, along with success rates, differ than the US (Chakravorty et al., 2016). The consideration of the language barrier and time zones impacting interviews was also a reason to keep the selection of participants to the continental US. Of the population identified, a sample of 12 mid and senior-level managers took part in the study.

Participants of the study were obtained through a flyer posted on the professional social media site LinkedIn in two professional groups that permitted the solicitation of members, as evidenced by Site Permission Emails. Further solicitation took place using the flyer on the PI's LinkedIn account and through direct messaging after searching for IT management and project management in the LinkedIn search box. Respondents with a relationship with the PI were not selected. Participants that volunteered were put through an initial validation process to verify that the prospective participant was able to answer the questions that need to be asked in support of the study.

Data Collection Instrumentation and Procedures

Exploratory methods in a qualitative study mainly use interviews for data collection, making the researcher the data collection instrument (Stebbins, 2001). The data collection for the subject research study was used to explore human-influenced critical success factors in ERP system implementation utilizing interviews. Interviews can come in many forms, but for this study, the main form of the interview was open-ended and semi-structured. Each participant was asked the same main research questions. As the interviews progressed, more targeted questions followed to clarify answers or provide better detail. Tools used in the interview process was the voice-enabled computer applications Go To Meeting. NVivo transcription service was used to create transcripts from the interviews as well as for data analysis.

When participants accepted the invitation, they were required to verify they were able to answer the questions that need to be asked in support of the study (Derry et al., 2010). For the subject research study, the participants needed to verify they were in management at the time an ERP implementation was underway. The participants needed to have been personally engaged in the ERP implementation. After validation, the interview session was scheduled and confirmed. Main interview questions were asked of participants; however, probing questions were used to clarify or deepen participant answers during the session. Transcribed interviews and raw recorded files were stored on removable flash drives protected by a password and locked in a safe along with any physical notes and documents. Stored files will remain in the locked safe for seven years.

Data Analysis Procedures

The analysis of data collected was under the Thematic Analysis method by Braun and Clarke (2006), indicating a six-phase process. The first phase of thematic analysis began by exposing key words tagged with codes (Braun and Clarke, 2006). The study had a mixture of pre-set (priori) and newly developed (emerging) codes (Braun and Clarke, 2006). The data collected from the interviews was coded initially through a list of priori codes established from the central research question. Codes matched the categories of CSF with human factors as HF, project factors as PF, and organizational factor as OFs. Within the categories, the individual factor matched to previously known factors was noted with a category and abbreviated factor. For example, human factors were perception, expectation, intent, resistance to change, and subjective norm. These factors translated to the code as HFp, HFe, HFi, HFr, and HFs. Data analysis occurred immediately after completion of the interviews and receipt of the transcribed sessions from the transcribers. Transcribed data were uploaded to NVivo for scrutiny. The patterns and words revealed themes used to answer the central research question (Stebbins, 2001).

Data analysis began with the uploading of participant approved transcribed interview sessions after the data was identity segregated from the interviewee by a predetermined interview number (Study Participant [SP] 1; Braun and Clarke, 2006). Data analysis completed when the conclusions for the study were drawn from the rated words, phrases, and quotes. The consolidated results were used to answer the central research question on human-influenced CSFs on ERP implementation and initial usage. Data reporting turned the analysis into a comprehensive understanding of the themes revealed in the study (Braun and Clarke, 2006).

Findings

Each transcribed interview was scrutinized for experiences relayed in response to the interview questions. Passages were given codes aligned with CSFs discovered in the literature review. Most of the coding was consistent with the priori codes; however, some passages revealed CSFs that needed to be added to the existing code book. Table I depicts the raw collection of codes discovered during data collection that covers codes established for: (a) human-centered – how the individual reacted to implementations, (b) organization-centered - CSFs that highlight group dynamics and how those dynamics influence the success or failure of system implementations, and (c) project-centered – CSFs that revolve around the managers, stakeholders, staff, and teams directing and involved in the implementations project. Two codes were added that appeared in responses often but were not previously identified as a singular CSF. These two codes were added under Project Factor\management (PFm). One added code was communication (PFmC); the other was change management (PFmCM).

Table I: ***CSFs in order of Frequency from Transcript Coding***

Name	Interview Files	References
Project Factor	12	157
Organizational Factor	12	133
Project Factor\management (PFm)	12	105
Human Factor	12	78
Project Factor\planning (PFp)	12	44
Organizational Factor\readiness (OFr)	12	42
Human Factor\expectation (HFe)	12	35

Organizational Factor\lens (OFl)	8	24
Organizational Factor\skill (OFsk)	8	22
Organizational Factor\culture (OFc)	8	19
Organizational Factor\group mentality (OFg)	7	13
Organizational Factor\training (OFt)	7	12
Human Factor\resistance to change (HFr)	6	21

Human Factor\intent (HFi)	6	11
Project Factor\fit (PFf)	5	9
Project Factor\management (PFm)\Change Management (PFmCM)	5	9
Human Factor\subjective norm (HFs)	5	5
Organizational Factor\assimilation (OFa)	3	3
Human Factor\perception (HFp)	2	7
Organizational Factor\size (OFs)	2	2

Child categories had references aggregated into the overarching categories. In identifying top factors, the counts of frequency were noted; however, overarching factors were not considered in the top experienced factors. Removing the overarching factors left management (PFm), communication (PFmC), planning (PFp), and readiness (OFr). The most experienced factors were best summed up by the participants. For the factor planning (PFp), SP1 relayed:

> …When you're putting your project charter together …here is what I want to do. In order for us to be more productive, more effective, and make decisions in a quicker way, here is the process I want to follow. And asking our client how they want to do this, who do you want to involve in what kind of meeting, and who you want to involve in decision making versus status meetings.

For the factor management (PFm), SP2 conveyed:

> One of the first things I do when I start a project is a stakeholder analysis. So, identify all of the people who have a vested interest in this project. I want to know what their thoughts are on the project. …And I want to make sure I got the right people with the right skill sets. If I don't, I will do what I can to swap them out before the project starts.

For the factor communication (PFmC), SP5 revealed:

> …in the beginning of the project, the business leadership of the company made very clear why the change was being implemented. There was business rational and generally it had to do with customers and customer satisfaction and serving customers better. That translated to the project sponsor and the steering committee, the steering team and they were totally bought in on the change and why it was necessary.

For the factor readiness (OFr): SP2 exposed:

> …Dirty data is kiss a of death for some of these. And that happens way too often that they go live with dirty data and that causes problems…The vendor doesn't know the customer's data so they can't cleanse it. The only one that could do that is the business. The vendor can help them understand what they need to be looking at. They can't do it.

Discussion

The subject research study explored the human-influenced CSFs for an ERP implementation. The study illuminated those human-centered factors that cause failure so managers can better avoid or mitigate issues caused by the factors. The results of the study provided human-influenced CSFs that aid decision-makers in preventing human-influenced failures to ERP implementations, both during the implementation phase and during initial use.

The intersections of foundational theories established overarching categories of CSFs as defined in the conceptual framework (see Appendix A). The three overarching categories of human-influence, organizational-influence, and project-influence CSFs were further populated by subcategories established by previous studies. Analyzed data captured from the experiences of project and IT managers revealed that interviews expressed factors in three overarching categories. The transcribed interviews further demonstrated consistent mention of eight specific factors: communication (PFmC), planning (PFp), readiness (OFr), expectation (HFe), lens (OFl), resistance to change (HFr), skill (OFsk), and culture (OFc).

CSFs under the subcategory communication (PFmC), included common phrases of stakeholders, committee, Chief Information Officer (CIO), decisions, issues, benefits, changes, requirements, applications, and customers as depicted in the communication portion of the word frequency query results (see Appendix B). The communication factor was

determined to be mentioned more than any other in the transcribed interviews. Communication is linked to human influence as the decision to use the tools at hand to elicit clear and frequent communication is up to the individual (Al-Jabri, 2015). Comparing the common words, many of the experiences recorded were with the implementation's managers. The participants specifically mention the project manager as the hub where communication begins and ends. Al-Hadi and Al-Shaibany (2017) attribute many implementation failures due to management factors, of which communication is a key part. Customer communication was also frequently expressed by participants as a communication factor.

Factors in the planning (PFp) subcategory had resources, requirements, stakeholders, members, projects, changes, internal, systems, perspective, and responsible as the most frequently used common phrases as depicted in the planning portion of the word frequency query results (see Appendix B). As with communication, project managers are the key to successful planning, as observed by Gollner and Baumane-Vitolina (2016). Observations made in the study revealed that the project manager ensures the receiving environment is ready, each detail is covered, and the implementation goes as expected (Gollner and Baumane-Vitolina, 2016).

Factors in the Readiness (OFr) subcategory had requirements, stakeholders, resources, internal, changes, vendor, managing, projects, systems, and ability as the most frequently used common phrases as depicted in the readiness portion of the word frequency query results (see Appendix B). Readiness entails that the management of the organization prepares stakeholders, customers, and staff to the changes and disruptions coming (Jagoda and Samaranayake, 2017). Choices must be made so that the changes planned are the changes needed, and nothing more (Lohe and Legner, 2013). The infrastructure also needs to be prepared so that the changes expected run as smoothly as possible (Jagoda and Samaranayake, 2017).

Expectation (HFe) revealed the most frequently used common phrases, as depicted in the expectation portion of the word frequency query results (see Appendix B), as requirements, accounts, changes, decisions, terms, issues, stakeholders, talking, culture, and customers. Expectations are a mix of communication and perception and are easily mitigated through the conveyance of a clear vision with realistic timelines, goals, and gains (Rafferty and Jimmieson, 2016).

The word frequency query results (see Appendix B) for Lens (OFl) had the most common words as requirements, customers, employees, roles, stakeholders, teams, vendor, benefits, committee, and decisions. Each individual envisions task importance and change differently (Kunert and Weth, 2018). Staff may view changes in the infrastructure as an impediment, where stakeholders may be more focused on the increased competitiveness or profit margin (Kunert and Weth, 2018). Managers are key in helping to shape a unified lens bridging organizational growth and staff daily workflow (Kunert and Weth, 2018).

Resistance to Change (HFr) has issues, culture, accountable, changing, benefits, complain, focusing, older, partners, and receptive as the most frequently used common phrases as depicted in the readiness portion of the word frequency query results (see Appendix B). As noted by Fernandez and Rainey, (2017), resistance to change is a reaction to a fear of the unknown. Lack of communication is a big trigger, so here again, managers are key in relaying precisely what the implementation will do and how long the implementation will take (Ronningstad, 2018). Lack of clarity and communication creates mistrust by staff to management (Ronningstad, 2018).

The word frequency query results (see Appendix B) for Skill (OFsk) had resources, skills, vendor, confidence, leaders, managers, members, onboarding, perspective, and requirements as the most common words. Jenko and Roblek (2016) found staff competence was an essential element in an ERP implementation. Staff skill was not only important in the implementation team but with the ability to relearn tasks under an emerging system (Ajami and Bagheri-Tadi, 2018).

Factors in the Culture (OFc) category had culture, customers, stakeholders, champions, entity, adaptable, autonomous, benefits, committee, and communications as the most frequently used common phrases as depicted in the factors portion of the word frequency query results (see Appendix B). An organization's culture is formed through the actions, values, and belief systems of management, stakeholders, staff, and customers. ERP implementations may have any of these groups believe the changes go against a standing culture. Communication and direction by managers, along with a strong change control process, are the primary forces to inhibit feelings that the organization is abandoning hard held values (Alhirz and Sajeev, 2015).

Exploring the factors did reveal some unique findings. The first is the appearance of the word "requirements" in the top factors. Requirements are a tangible item, not a behavior, but requirements seem to drive many of the factors most influenced by human interaction or intervention. Another finding was that most of the factors captured through the

interviews were as anticipated according to the literature review, except for resistance to change and end-user refusal. Though resistance to change did feature in the top eight factors, it did not appear as prominent as expected. In the experiences relayed by the participants, outright system refusal was a rare occurrence even in cases where there was significant change resistance among staff.

Implications for Theory and Practice

Factors identified through the experiences of the participants were collected as the core reasons ERP implementations succeeded or failed. Prior research acknowledged the theories behind CSFs but mostly on how those factors interacted with project management processes. The study focused on those factors most likely to be influenced by human interaction, intervention, or refusal. Human interaction was acknowledged by Davis (1989), but only as it pertained to end-user acceptance or resistance. As Bertalanffy (1972) stated in Systems Theory, any element interacting with another is an essential part of the entire system. With ERP, humans are an essential element in the operation of the mechanical parts. Ignoring or overlooking the human component through overly focusing on the project components were revealed to be one major reason for project failure by the participants. Acknowledging the existence of human-influence in CSFs, in general, could better assist management with project plans that could lead to generating a more solid implementation process. Participants conveyed that communication, planning, readiness, expectation, lens, resistance to change, skill, and culture were areas where the most human influence is experienced. Each of the top factors hinges on the need for clear, consistent, and open communication from the bottom to the top, and from the top to the bottom of the organizational hierarchy. Communication is especially critical in the early phases, where requirements and workflow are being collected (Peci and Vazan, 2014). According to the participants, the project managers were the key to opening and maintaining those lines of communication. The participants relayed that inept or inexperienced project managers often led to confusion and unmet requirements, so organizations should take extra care in the selection of project managers both on the organization side and the vendor side.

Limitations and Future Research

The research study examined the CSFs of multiple company sizes and industry types. Therefore, a major limitation in the study is the size of the participant pool and the inclusion of differing industries. ERP implementations are conducted by manufacturing industries and service industries, demonstrating staff differences in technical aptitude and sensitivity to task change. The limitation of this study is also due to the restriction of implementations done only in the contiguous US. Culture changes, language barriers, and customs may produce an entirely different set of CSFs not explored. Finally, the exclusive use of ERP implementations to examine CSFs limits more common types of CSFs found in other large-scale IT project deployments.

Future research into human-influenced CSFs could include expanding the study internationally, noting influences linked to local area customs or company cultures. Future research is also suggested by comparing factors noted in technically proficient industries against common factors noted in manufacturing. Finally, expanding the study of human-influenced CSFs to more forms of IT project implementations.

Conclusions

The researcher sought to determine CSFs in ERP system implementations that were the most influenced by human interaction or intervention. The analysis of 12 interviews revealed communication as the number one human-influenced CSF. The finding confirms studies by Ram and et al (2013), Tsiga and et al (2016), Shaul and Tauber (2013), and Shatat (2015) who reported communication as a common project CSF. A particular finding during the study was the appearance of requirements in many of the reported factors, but a finding in line with communication. Requirements are communicated from stakeholders to the vendors and project managers. Misunderstanding or outright neglecting of communicated requirements is another often discovered project CSF (Amoatey and Mawuena Vincent, 2017; Rafferty and Jimmieson, 2016).

Issues with the implementation efforts often spring from insufficient planning at the beginning (Amoatey and Mawuena Vincent, 2017; Peci and Vazan, 2014). Requirements gathering is done in the planning phase; therefore, constant, open, and clear communication must be present from the very onset of project planning (Peci and Vazan, 2014). Technology has matured to the point team collaboration and communication are present in most project planning programs available, yet these programs are still just a tool. Managers, stakeholders, and staff have to create those lines of communication and

continue to make use of those lines throughout the entire implementation. Once communication is cut or subdued, suspicion, assumption, and groupthink take over (Amoatey and Mawuena Vincent, 2017). The cost of poor communication may cause up to 90% of ERP implementations to fail (Shatat, 2015; Stanciu and Tinca, 2013). Failure with implementation leads to the waste of resources valued at approximately 6% of the organization's net profit (De Toni et al., 2015).

Many of the collected responses mention that project managers are essential in the flow of communication. Ram et al (2013) agree with a study that revealed that competent and experienced project managers know how to communicate with vendors, staff, stakeholders, and upper management in order to keep the implementation on track and running with the least amount of friction and resistance possible. The participants emphasized communication as the factor having a significant impact on ERP implementation. Technology makes the process of communication much easier, yet it is the human that initiates, consumes, and acts on that communication regardless of the medium used (Husain, 2013). Many of the participants insisted that it is the project manager that is the hub where communication starts and ends aiding in the spread of information and the collection of requirements.

Financial Support for Older Parents in The Opinion of Poles

Sylwia PIENKOWSKA-KAMIENIECKA

University of Warmia and Mazury in Olsztyn, Olsztyn, Poland
sylwia.pienkowska@uwm.edu.pl

Abstract

Financial security during retirement depends on individual choices. The households may rely only on public pensions, additional private pension programs or/and on family and intergenerational transfers from their children. The purpose of the study is to establish whether Poles are willing to financially support their elderly parents during retirement. The analyses in the article are based on a data obtained from the quantitative survey Social Insurance Institution conducted on a representative random group of 1,030 respondents aged 15-75. According to the results, a vast majority of the Polish society claims that parents should receive financial support from their children in old age. Moreover, people who claim that the disadvantaged members of society require financial support from others are also more willing to support their elderly parents.

Keywords: Parents, Children, Old Age, Financial Support.

Introduction and Theoretical Background

In pre-industrial times, care and financial support to elderly parents was provided by children (Chybalski, 2018; Wunder, 2005). Extended family played the role of economic and care giving institution (Szweda-Lewandowska, 2008). In exchange for help with raising grandchildren and expected inheritance, younger generation provided care to the oldest members of the family (Olejnik, 2016). Introduction of state public pension schemes and development of welfare state institutions worldwide has absolved families from this informal responsibility and transferred it to the state. The first common insurance pension scheme was established by Otto von Bismarck in Germany in 1889. State old age systems were further introduced in, among others, Denmark (1891), New Zealand (1898), Belgium (1900) and Australia (1909) (Baldwin, 1910). Also William Beveridge in his report of 1942 set up a system of social security in Great Britain. It was supposed to be a welfare state based on the principle of universalism (Benassi, 2010), where "social insurance should aim at guaranteeing the minimum income needed for subsistence" (Beveridge, 1942). It was a significant difference in relation to Bismarck's model; its aim was something more, i.e. facilitating maintenance of current socio-economic status after retiring. In 1910 Baldwin (1910, p. 728) stated directly that the German pension system "[…] is unquestionably the most effective and successful scheme of old age support now in existence". Nonetheless, unfavourable demographic tendencies and persistently high unemployment rates in many European countries and worldwide over the years have put pressure on institutionalised pension security. This concerns Poland as well. As Góra (2003) claims, "What used to be an excellent solution - by this I mean the Bismarck system - became a burden to societies". Pension scheme currently functioning in Poland was introduced in 1999. It was not a parametric reform, but a complete change of the system for a new one-to-one link between contributions and pensions (Buchholtz, Chłoń-Domińczak and Góra, 2019), with additional pension security created from the ground up (Chłoń-Domińczak et al., 2020). Over the years many modifications have been implement, resulting in a subsequent changes to the three-pillar pension system in Poland (Jedynak 2019). Currently, the issue of additional pension saving is vitally important in the context of lowering replacement rates and the level of benefits provided within the base pension system. According to the last projections European Commission (European Commission, 2018) in the EU-27 countries average replacement rate for the public pension system (total benefits) will decline from 42.8% in 2016 to 35.2% in 2070. The decline in the rate, after for Spain (-31 pps), will be the largest for Poland (-29 pps). In order to assure adequacy of pension benefits, additional saving for old age is necessary (Rutecka-Góra, 2019), however, knowledge and understanding of this issue as well as the scale of additional savings for old age in the Polish society are poor and insufficient (Pieńkowska-Kamieniecka, 2020). It may be stated that the market of additional and voluntary pension schemes in Poland is still in the "preliminary phase of development" (Šebo et al., 2020). This market concludes of employee pension plans – pl. PPE (since 1999), individual retirement accounts – pl. IKE (since 2004), individual retirement protection accounts - pl. IKZE (since 2012) and employee capital plans – pl. PPK (introduced gradually since mid-

Cite this Article as: Sylwia PIENKOWSKA-KAMIENIECKA "Financial Support for Older Parents in The Opinion of Poles" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2019). In 2018, participation index in individual pension plans reached 5.8% for IKE and for IKZE 4.3% (KNF, 2019a), whereas in group PPE it was barely 2.6% (KNF, 2019b). Estimated participation index in automatic PPK schemes (also called auto-enrolment), where employers are obliged to create and enrol their workers to such scheme, and employees are entitled to contract out of it, in the fourth quarter of 2019 reached 40% (Wojewódka and Kolek, 2019).

As Olejnik (2016) points out, in the case of failure of public pension schemes as well as low level of saving participation in additional pension schemes, the role of family transfers may increase. Bengtson (2001) directly points to the fact that the twentieth century is the period when the role of intergenerational transfers has increased. The main reasons of this include: longer life expectancy of different generation members at the same time (the so-called shared life), increasing role of grandparents in the family and growing strength and stability of intergenerational solidarity. Intergenerational transfers may have various background (motives), such as: altruism, mutuality of exchange or the wish to bequeath (Cigno, 1993; Lee and Donehower, 2011; Michoń, 2012; Szukalski, 2002; Kohara and Ohtake, 2006; Becker, 1991; Kohli and Künemund, 2003) Undoubtedly, transfers within a family play a significant role in planning the future of currently owned and expected financial resources by households. In the case of retirement security, such decisions may include resignation from present-day consumption for the benefit of saving for old age or financing the needs of parents in old age (Szumlicz, 2016; Szumlicz 2018). At this point it is significant to study the general social attitude to support elderly parents.

Therefore, the aim of the study is to establish whether respondents are willing to financially support their elderly parents during retirement. The following two hypotheses were assumed:

Hypothesis 1: Majority of Poles claim that parents should be supported financially by their children during retirement.

Hypothesis 2: Those who claim that the disadvantaged members of society require financial support from others are also more willing to support their elderly parents.

Methodology and Data

This article uses data obtained from the study ordered by the Social Insurance Institution (as the author of the research) and conducted in Poland by the Millward Brown Company in Poland in July-August 2016.. It was a quantitative (non-reactive) and representative nationwide study conducted with the use of CAPI (Computer-Assisted Personal Interviewing) research technique. 1,030 participants aged 15-75 took part in the study.

So as to realize the research objective, a logistic regression model was applied. While constructing the model, the following dichotomous dependent variable was used:

Y – Should elderly parents be financially supported by their children?

This variable took on the following form:

$$Y = \begin{cases} 1 \text{ if the respondent states „Yes”} \\ 0 \text{ it the respondent states “No"} \end{cases}$$

Independent variables, both qualitative and quantitative, are presented in Table 1 and 2. Within particular qualitative independent variables reference group (as ref. group) to which the interpretation of model results refers to was specified. Significance level to stay in the model was 0.05.

Also, in order to investigate whether subjects who claim that lower social insurance contributions allow to save more and enhance individual saving for old age do save more, chi-square independence test was performed. Appropriate calculations were performed using the IBM program SPSS Statistics 26.0.

The results of the analyses indicate that subjects who took part in the study were: mainly women, aged 40-59, living in the rural areas, with vocational and secondary education, employed, not having children or parents and not living with parents in a joint household (Table 1).

Table 1: Descriptive statistics for the independent qualitative variables and characteristics of the groups

Variable	Variant of variable	N	%
Gender	Women (ref. group)	533	51.7
	Men	497	48.3

Mean income per one household member for the respondents was 1.8 thousand PLN (middle exchange rate of November 5, 2020 according to National Bank of Poland is 1 Euro = 4.52 PLN).

Analysed in the study households had approximately 2.4 members (Table 2).

Table 2: Descriptive statistics for the independent quantitative variables

Variable	N	Characteristic
Number of persons in the household	1.030	Min. 1; Max. 7; Mean 2.4
Income in the household (in thous. PLN/1 person)	1.030	Min. 0.08; Max. 7.5; Mean 1.8

Results and Discussion

The results of the study indicate that a vast majority of the Polish society (79.6%) claims that parents should be supported financially in old age by their children (Fig. 1).

Fig. 1: The share of subjects declaring whether parents should be supported financially in old age

Source: own elaboration based on the research of the Social Insurance Institution, 2016

Among these people who claim that children should financially help older parents, are mainly women (51.1%), people aged 40-59 (32.4%), living in the countryside (38.2%), with vocational education (37.4%) and employed (56.7%).

The results of the analysis indicate that not all independent variables have impact on the analysed dependent variable, i.e. whether elderly parents should be supported financially in old age by their children. Table 3 presents the results of the logistic regression model, however, only those variables which are statistically significant. High p-value in Hosmer-Lemeshow test (>.05) allows us to conclude that the choice of variables for the model was appropriate and the model is correct.

Table 3: Estimates of logistic regression model for dependent variable: Adult children should support financially elderly parents

Variable	Variant of variable	S.E.	p-value	Exp(B)
Income in the household	In thous. PLN/1 person	.079	.013	.822

Source: own elaboration based on the research of the Social Insurance Institution, 2016

The above data show that such demographic variables as gender, age, place of residence, level of education and current professional status of the subjects do not have a significant impact on their attitude to provide financial support for elderly parents in the face of lower income after retiring. This means that no significant differences in this respect were observed between, for instance, women and men or subjects with different education level. Nonetheless, the research has found that income turned to be statistically significant. Subjects from wealthier households have smaller odds of claiming that elderly parents should be financially supported in old age by their children. These odds decrease by approximately 18% as the household income increases by 1 thousand PLN (per 1 person). Consequently, it may be concluded that less wealthy subjects are more willing to help others, also family. Yet, it is also evidently more common among those who have parents. Among the subjects who do not have parents, the odds for stating that elderly parents should be supported financially in old age by their children are 34% lower. As a result, experiencing poverty in a household or having parents are those factors which significantly increase the odds for supporting family in old age.

Moreover, after analysing how the attitude to claiming that lower social insurance contributions allow greater savings and enhance individual saving for old age is reflected in the willingness to financially support elderly parents, one may arrive at interesting conclusions. Firstly, the share of subjects who agree with the aforementioned statement and whether these people actually save more often outside the public pension scheme were analysed. The results indicate that 52.4% of the society state that if the rates of social insurance contributions were lower, it would be possible to save additionally for old age. Based on the conducted chi-square test, these are people who actually do more often participate in the market of voluntary additional pension savings (Table 4).

Table 4: The willingness to save for retirement according to the opinion on "lower social insurance contributions allow to save more"

Specification		**Lower social insurance contributions allow to save more and enhance individual saving for old age**				
		Definitely not	**Rather not**	**Rather yes**	**Definitely yes**	**It is difficult to say**
Saving for old age	Yes	10.0	19.5	39.0	23.1	8.4
	No	5.6	19.5	35.0	14.2	25.5
Chi-square=41.420; p-value =.000; V-Cramer=.201						

Source: own elaboration based on the research of the Social Insurance Institution, 2016

Nonetheless, conducted analysis of logistic regression clearly indicates that for those who definitely agree with the statement that lower social insurance contributions allow to save more and enhance individual saving for old age, the odds for financial support of elderly parents are nearly two times lower (by 48.7%) than for those who do not have an opinion or who disagree with this statement. It may indicate that these people believe one should save for their own retirement in order to improve one's financial status in old age instead of counting on support from family (children). On the other hand, of different opinion are those who are willing to support the disadvantaged members of society. Respondents who claim that the disadvantaged (i.e. the poor, unemployed, homeless) should receive support from the state budget (taxes), have two times greater odds of claiming that also parents should be financially supported in old age, respectively by 130.2% ("I strongly agree") and by 109.0% ("I rather agree") than those who do not have an opinion or disagree with this statement.

Conclusion

The study shows, as other research, that Poles declare the willingness to share their resources with others if the need arises, i.e. they are willing to redistribute (Pieńkowska-Kamieniecka, Rutecka-Góra and Walczak, 2019). It is a significant conclusion in the context of the first hypothesis assumed in the present article.

However, the results of the research support the two assumed hypotheses. Firstly, a vast majority of the Polish society claims that parents should receive financial support from their children in old age, i.e. the period when their income decreases after retiring. Nonetheless, it needs to be noted that not all analysed independent variables have a statistically significant impact on the dependent variable. Regardless of gender, age, place of residence, level of education or professional status, all subjects have similar odds of claiming that elderly parents should receive financial support from their children. The second hypothesis was also supported. The results of the conducted research prove that those who claim that the disadvantaged members of society require financial support from others are also more willing to support their elderly parents. It may result from their general view that the disadvantaged need to be financially supported. Surprisingly, subjects from wealthier households and those who claim that lower social insurance contributions do not increase the willingness to save additionally for old age are less likely to claim that children should support financially their parents. This may indicate that in their opinion one should save individually for old age outside the public pension scheme rather than expect financial support from their children.

The present study undoubtedly leads to a certain conclusion. In material, as in many other spheres of life, in the face of lowering replacement rates from the public system of retirement security - Poles declare that they may count on their family in old age. However, when it comes to voluntary (natural) retirement security, individual decisions of the households will determine to what degree financing of the changing needs in old age will be based on one's own savings and to what degree they will require financial support received from children (Szumlicz, 2016; Szumlicz, 2018).

Filip LENKO
University of Zilina, Zilina, Slovakia, filip.lenko@fbi.uniza.sk

Abstract

According to the European Transport Safety Council, pedestrians, cyclists and motorcyclists make up 70% of road deaths in European cities. This is according to the European Transport Safety Council. Road safety is an essential part in sustainable urban mobility. With the constant development of new technologies in road transport, the level of safety and fluidity of road transport is increasing. On the other hand, with the increase in the number of vehicles, there is an increasing pressure on overall throughput and hence road safety. Critical nodes, junctions, low-pass routes, etc. are at risk. Continuous traffic accidents or congestion at critical times - rush hour traffic results in reduced safety levels. Properly selected methods and procedures with new technologies help to reduce this problem. In this paper we analyze the use of analytical tools in road transport to increase the safety and fluency of the population in the selected region. In city Žilina is the first one preferring public transport vehicles in Slovakia.

Keywords: Video Surveillance, Analytical Tools, Traffic, Safety, Citizen, Region.

Introduction

Traffic design and traffic monitoring is an inseparable situation of modern society. Traffic monitoring and management is of economic, safety and environmental importance. There is no doubt that modern technologies used in the field of transport increase the permeability of intersections and to increase safety. One of the main purposes for providing real-time public transport information to individuals is to reduce the levels of frustration they feel with public transport (Kalasova 2013; Caulfield 2007). Currently, passengers have access to a lot of information when planning their trip by public transport. They can use a lot of applications, which are not compatible with each other (Velas 2016; Dolinayova 2018). Road safety is an active area of research for the automotive industry, and certainly one of ongoing interest to governments around the world. The intelligent transportation system (ITS) is one of several viable solutions with which to improve road safety, where the communication medium (e.g., among vehicles and between vehicles and the other components in an ITS environment, such as roadside infrastructure) is typically wireless (Velas 2016; Arena 2020). Current assessment of road safety performance of a country, or of the EU, is mainly based on analysis and compilation of police recordings of injury accidents (Velas 2016; Erso 2018).

Public Transport Preferences

The main goal is to ensure the preference of public transport vehicles, especially so as to ensure the smooth passage of the city of public transport through the intersections, i.e. to eliminate cases where the vehicle receives a red signal "Stop!" Shortly before entering the intersection (Velas 2016; Stoller 2018).

Vehicle preference has three basic benefits:

1. shortening the delay of the vehicle at the intersection in case the vehicle has a delay (shortening the travel time between stops),

2. minimization of the number of departures, i.e. reduction of diesel consumption (vehicle passes the intersection smoothly without stopping or braking),

Cite this Article as: Ladislav MARIŠ and Filip LENKO "Design Traffic Surveillance with Analytical Tools in Regions on Citizens´ Safety" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

3. longer boarding time for passengers (the vehicle waits at the stop until the on-board computer instructs the driver to leave the stop).

The system of transport preferences should be applicable at light-controlled intersections, for its functionality it is necessary to connect the vehicle information system with controllers at light-intersections. Where conditions allow, the most appropriate solution is to build a preference using dedicated lanes. The purpose is to reduce travel times and provide passengers with an advantage over public passenger transport over individual transport. However, such lanes can be built where local conditions allow, especially regarding the width of the roads (Luskova 2018, Boros 2019, Bo-ros 2019).

The detection of public transport vehicles for preference purposes should be carried out by means of magnetometers located directly in the roadway. These should be complemented by cameras to ensure smooth traffic and fast operational management. Overall, this type of preference, even with the use of monitoring cameras, should apply to nine light-controlled intersections in the city of Žilina (Lovecek 2017; Figuli 2018).

Since the introduction of the preference, the transport company should to increase the attractiveness of public transport in the eyes of passengers compared to other types of transport, especially individual transport by car. Provid-ing a time advantage to public transport passengers has a major impact on modal shift decisions and gives public transport a strong trump card in the fight against individual transport. Another indisputable benefit is the saving of fuel and emissions from buses (Ballay 2017; Kampova 2010).

Methods

These transport preferences is mathematical simulation and visualization for a specific area (crossroads). Simulation results (Kalasova 2013; Boros 2019) for a specific area predict significant improvements in the preferred mode of transport (66% reduction in delay time for urban public transport), while the quality of the non-preferred mode of transport (urban public transport) has only partially deteriorated (10.5% increase in delay time).

However, there are also sections where the monitored parameters have also improved for the non-preferred mode of transport - these are mainly sections where the interval of passage of public transport vehicles is high. On the contrary, the deterioration of the monitored parameters was recorded mainly at the entrances through which public transport vehicles do not drive, or the passage interval of these vehicles is low. From the point of view of urban public transport, this phenomenon is not desirable, but it follows from the nature of the preference for urban public transport (Kampova 2010; Lovecek 2013).

Therefore, the proposal for the preference for urban public transport requires thorough preparation, where it is necessary to consider all risks and then minimize or eliminate them by appropriate steps (Kalasova 2013; Boros 2019; Boros 2019).

The one of these modern actions was a regional policy project in the Integrated Regional Operational Program 2014-2020, in the call Increasing the attractiveness and competitiveness of public passenger transport. Co-funded pro-ject by European Union names Preference of urban public transport at traffic lights in the city of Žilina in Slovakia.

In September 2019, the project launched. Žilina thus became the first city in Slovakia to have a comprehensive system of active preference for public transport (Kampova 2010). The project of preference of public transport vehicles at light-controlled intersections was financed by the city of Žilina through the Integrated Regional Operational Pro-gram for 2014-2020. The total cost of the project climbed to almost 1,955,000 €.

A Case Study of Public Transport Preferences Application

The aim of the preference for public transport vehicles is to ensure that Žilina trolleybuses and buses follow the timetable as much as possible and walk at the prescribed intervals. In practice, the system works in such a way that on-board units in public transport vehicles actively communicate with the road traffic signal controller at the intersection, which controls their passage through the intersection according to the current position. The controller evaluates whether the connection is running on time or late and accordingly either keeps the green signal to pass, or the driver is informed that he has to wait at a stop, otherwise he would start and brake unnecessarily and then stand at the intersection on red (Stop).

If two public transport vehicles enter the intersection at the same time, the intersection controller prefers a de-layed connection or a vehicle that has a defined passage priority. The smoothness of the passage of public transport vehicles through traffic lights will bring not only the optimization of the timetable but also fuel savings, as the vehicles do not have to start as often and unnecessarily. Not only time and money sources, but also the environment will be saved.
The project involves all traffic lights in the city of Žilina. There are a total of 9 intersections, where traffic is controlled by traffic lights. In addition, the intersections within this project were equipped with traffic cameras, thanks to which dispatchers have a secure overview of the situation of individual intersections in real time.

The project also includes the Invipo integration platform, which can be used not only by dispatchers, but also by residents. The platform is available via the smart.zilina.sk website or via mobile application. Thanks to the Invipo ap-plication, residents will find all the information about the current traffic in the city, about closures, accidents or detour routes in one place.

In the next pictures Fig. 1, Fig. 2, Fig 3 are printscreens from application (Incinity 2020).

Fig. 1: Application Invipo in Žilina – City Dashboard (Incinity 2020)

It contributes to improving mobility in the city, reducing traffic congestion, improving traffic management, reducing accidents and the negative impact of traffic on the environment. This makes it easier and more efficient to plan their journey through the city.

In addition, users will also find real-time views of traffic via traffic cameras (Misik 2015; Mitasova 2017; Re-hak 2018; Siser 2016). Passengers by public transport will provide information about public transport connections, their current location, the nearest departure or the location of stops.

Fig. 2: Application Invipo in Žilina – example of Traffic lights cameras in real time (Incinity 2020)

Fig. 3: Application Invipo in Žilina – Public transport in real time (Incinity 2020)

Fig. 4: Application Invipo in Žilina – Traffic level in real time (Incinity 2020)

In the terms of video management software (VMS), it is important to pay attention to traffic management (Soltes 2017; Soltes 2017) with the next requirements: VMS should does analyzing data for traffic management, such as:

- 24/7 monitoring,
- analyzing traffic data (density, direction, etc.),
- intelligent modules to react or make decision in case of hazards (visual verification of incidents),
- notifying or alert road users (traffic jam, hazards (Stofkova 2015), weather, e.g.),
- notifying control unit (VSS control center (Svetlik 2015), traffic authorities, emergency services, etc.),
- access to smart road signs or traffic lights,
- regulation of timing of traffic lights in real-time,
- taking in to account the variation in traffic demand with future (e.g. hours, days, vacation) estimation (e.g. Mondays, Fridays, Week Days, mornings, afternoons, etc.),
- assistance in providing an appropriate response in a timely manner to alleviate traffic congestion to minimize delays to motorists (Velas 2017, Velas 2016).

Conclusions

If cities really want to create the right conditions for preferring public transport on their transport networks, they will need to point out the possible problems associated with this preference. It may happen that the solution of one part of the transport network will worsen the conditions in another territory, or the preference for one mode of transport may have disproportionately large negative consequences for another mode of transport. For this reason, it is necessary to use appropriate traffic modeling programs that can visualize the transport network and thus provide better informa-tive value, especially for those who are not so close to this issue.

Traffic design and traffic monitoring is an inseparable situation of modern society. There is no doubt that mod-ern technologies used in the field of transport increase the permeability of intersections, increase safety protection and we can continue. Light control system is one of the useful modern systems, which are implemented in crowded cites, to provide better traffic wax, especially for city public transport such as buses etc.

In our case, the Žilina crossroads is hardly tests in each-day traffic. Traffic management applications are usual-ly implemented in such a way as to allow multiple video streams and traffic controllers to be monitored centrally in a network operations center. Consequently, these types of applications require high capacity remote or subscriber units with robust and reliable uplink capabilities. To provide the utmost safety and security, data from network video surveil-lance cameras and controllers needs to be streamed constantly and therefore any system needs to be supported by a high-capacity, high-reliability solution.

In city Žilina is the first one preferring public transport vehicles in Slovakia. This example is very nice and useful example also for other cities.

We think that preferring city public transport is one of the possible solutions for crowded cities. On other hand, exists other solutions: preferring bicycles system, preferring no go one for type of vehicles or only for residents etc.

Migrations as A Challenge for Dispositional Groups In Polish And European Comparative Perspective

Aleksandra SKRABACZ

Pomeranian University, Slupsk, Poland
aleksandraskrabacz@interia.pl

Abstract

The article provides a discourse on the essence of the functioning of dispositional groups in the perspective of contemporary migration processes and new procedures that have been implemented to make public decisions in the official social forum. It contributes two new perspectives to the development of social sciences. The first perspective relates to the migration movements characteristic of the second decade of the 21st century and on a number of challenges for Europe and Poland. The second perspective analyses the preparation of services in response to new threats in the area of security. In the implementation of the adopted research assumptions, a certain methodological eclecticism was employed, allowing the combination of methods from various scientific disciplines, which is characteristic of the methodology of security research, thus ensuring cognitive and pragmatic efficiency. Using theoretical methods, including the analysis and synthesis of knowledge available in compact and continuous sources (traditional and electronic), the essence of the functioning of dispositional groups was discussed, typologically and characterizing the specificity of operation. Using the comparative method, the problems encountered by the dispositional groups of European countries were indicated. Using exemplification, specific examples of threats to the security of the host society and for themselves are discussed. The article primarily uses the results of qualitative research by Polish and foreign scientists on disposable groups, while quantitative methods were used to analyze migration problems.

Keywords: Dispositional Groups, Migrations, Threats, European Union, Poland

Introduction

Migration is a process that has always been observed around the world. Throughout history, populations have moved for a wide range of reasons, either voluntarily or forced by external circumstances. Migration flows that follow the events across the world take on various intensities, and their direction is determined by the current political, economic and social trends. From a European perspective, the last significant wave of migration in 2011, initiated by the Arab Spring, caused significant impact on the population of Europe. Data from the International Organization for Migration, indicates that over 390,000 people moved to the European continent in 2016. The data also evidences that in 2017 there were over 180,000 illegal immigrants, and by November 2018, almost 130,000 had arrived, of which over 106,000 were by sea with the remainder by land (IOM 2019).

In 2019, 714,200 applications for international protection were submitted in the EU (plus Norway and Switzerland), which is 13% more then in compared to 2018. In addition, the data shows protection was granted to almost 295,800 asylum seekers, a decrease from 333,400 in 2018 and 533,000 in 2017. Almost a third (27%) asylum seekers were from Syria, with the three highest including Afghanistan (14%) and Venezuela (13%). The number of migrants from Venezuela increased by almost 40% in 2019 compared to 2018. Of the 78,600 Syrians granted international protection in the EU, almost 71% received it in Germany (European Parlament 2020).

Overall, more than 82 million international migrants resided in Europe in 2019, an increase of almost 10% from 2015, when 75 million international migrants lived in the region. Between 2015 and 2019, the non-European immigrant population increased from just over 35 million to approximately 38 million (World Migration Report 2020).

Migrants arriving in Europe brought with them psychological issues relating to traumatic events and this fueled high expectations of the gains they hoped to make in, with regard to aspects such as work, housing, living

Cite this Article as: Aleksandra SKRABACZ“ Migrations as A Challenge for Dispositional Groups In Polish And European Comparative Perspective” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

conditions, as well as social, cultural or education. The reality that presented to them generally across the European countries often fell short of the expectations and on occasion would lead to tensions and frustration. In many regions the reaction to the migrants was a lack of welcome or even one of hostility. Antagonisms occurring between the host community and new arrivals have become a significant challenge for many local services. Often local service are scarce, under resourced and the additional demand has caused tensions between migrants and the native population. Dispositional groups, therefore face a dilemma regarding which actions will both ensure the safety of native communities, and simultaneously assist immigrants in adapting to new living conditions, whilst respecting their inalienable and inherent human rights.

Hence, the main research inquiries focus on the following thesis: migration, understood both in the context of emigration and immigration, has a significant impact on the functioning of dispositional groups. This implies the needs and expectations visible in two areas: firstly, inside the milieu of uniformed services, which may be caused by language, cultural or social barriers as well as staff shortages, and even a direct threat to the life and health of officers. Secondly, formulated by the authorities and society in relation to the efficiency and effectiveness of these groups, even in terms of ensuring the safety of local communities, as well as breaking the law and violating social norms by immigrants.

The results of the analysis undertaken in the article are of a utilitarian nature both in the present and perspective dimensions. The experiences of European countries may provide useful direction for other countries of Central and Eastern Europe enabling them to prepare for any future large scale migration.

The specificity of dispositional groups

The term "dispositional group" has appeared not only in the language of sociology, but also in the terminology of security sciences, and is the object and subject of research of various scientific environments, including sociological, political, pedagogical and security issues. This increase in use is unsurprising and is linked directly to the is a very extensive and increasing area of research, just like the entire milieu of uniformed formations. Therefore, although they are discussed and interpreted differently in literature, they share a common goal of action, which is a direct, immediate protection and defense of society against all threats, regardless of whether they are military, paramilitary, civil or volunteer groups (Bogdalski et al 2014).

When it comes to the concept of a dispositional group, it is worth considering Maciejewski's definition (2012), considered to be one of the precursors of research on dispositional groups. In the author's opinion, dispositional groups are "such social structures, whose availability we can speak of in a narrow sense due to their specialized and specific nature of activities in a relatively limited scope". What does disposition mean? Well, it is about the general and specific ability of the above mentioned groups to carry out team activities in a planned and fixed manner, in accordance with the tasks assigned to a given dispositional group.

Morawski (2005) looks at dispositional groups from a different perspective. Morawski believes this is "a special kind of group with a state-shaped structure and hierarchy, in which smaller groups make up larger ones. The groups are entirely subordinated to the administrator". The view corresponds with Zagórski's definition (2000), who, defining the purpose of the groups' activity, states that "they are intended to stabilize the system of state power and protect it against internal as well as external threats and catastrophes of various nature". It can therefore be generalized that the dispositional group is a special social group, characterized by specific readiness to act, the so-called availability, operating in a planned and organized manner, having a specific structure within which its members function in a hierarchical manner, and the purpose of its activities are areas related to securing the life and health of citizens, stable functioning of the state and protection of property and the environment.

Why is there a need to separate dispositional groups from many other social groups? It arises from two basic issues. The first one is related to the specific characteristics of the members of these groups, who are usually distinguished by dedication and commitment to the implementation of tasks in difficult situations that require courage, dedication and availability. Due to the difficult operating conditions, they require specific procedures, staff selection and preparation methods (Bogdalski et al 2014). Therefore, it is worth emphasizing the requirement of high professional qualifications and the ability to act efficiently in various situations and conditions of members of dispositional groups, but it is also important to add here high social competences, i.e. specific psychophysical features and social skills, focusing on human behavior, attitudes, way of living, teamwork, acting under time pressure, motivation or communication and interpersonal skills. It is only a combination of these so-called hard and soft competences that determines the professional and social value of dispositional groups.

The second issue, according to M. Bsoul-Kopowska (2017) results from "functioning in larger structures, such as military or paramilitary organizational units, in which there is a specific attitude to work referred to as" service "and

a militarized organization and command-based order. In this kind of units, e.g. divisions or police garrisons, there are teams of selected and specially trained people, capable of taking rapid actions arising from special circumstances, such as the need for immediate intervention in connection with a terrorist attack, resulting riots and similar events. The very word "service" carries a certain emotional load that significantly distinguishes the nature of the activities performed. Polish dictionary defines service as "work for a community, done with dedication". This community should be understood both in the context of individual and social groups in relation to which there is a legal obligation to provide assistance, regardless of the circumstances in which it is provided.

Hence, Zalewski (2014), while listing such features of dispositional groups as hierarchy and formal subordination to the state and its authorities, draws attention to another attribute of dispositional groups, namely the disposition of administrative resources for citizens. However, as he explains: "In this context, it is worth paying attention to the differences in position and function (resulting from the scope of tasks and powers) in terms of a decision-maker, as well as the diversity of social roles of group members (citizens assign a different role to soldiers, another to policemen or firemen; completely different from those listed the role of intelligence and counterintelligence officers - mainly because it is power-oriented, not citizen-oriented)". This thesis is confirmed by surveys of the ranking of professions enjoying the greatest social recognition, in which for many years among the uniformed services the first place is occupied by a firefighter (87% of declarations of high respect), followed by a policeman (68% of positive grades) and a soldier (59% of good grades) (COBOS 2013). Therefore, in the opinion of the society, these professions are the epitome of the idea of commitment and unconditional service of the community along with personal risk of a direct threat to life and health. On the one hand, this is high social recognition, but at the same time the expectation of an impeccable ethical and moral attitude along with respect for legal and social norms. There is another significant difficulty connected with this idea. In a democratic state in which the people are the sovereign - or more specifically civil society - there may be a level of conflict between the expectations of civil liberties and freedom, and satisfying the requirements for security. In Zalewski's opinion (2014), "In a democratic state we are talking about civil society as an object of protection, but also the basic determinant of the political community of free people, i.e. those who have as wide a range of personal, political as well as economic, social and nowadays cultural rights as possible and the right to information. This community can function only in conditions of relative security, which is generally the task of these dispositional groups. [...]. Therefore, the key issue is to recognize the dynamics of mutual relations between hierarchically organized security structures and civil society, which today takes the form of information (network) one. This society quite freely uses more and more information resources, let us add, largely outside the control of national authorities. Ensuring security under these conditions is a major challenge for national governments. States are trying to "keep up" with the expanding sphere of people's activity, embracing it with ever-widening control", and this is often perceived as overt and unwelcome state control. If we impose the problem of international migration against such a background of functioning of dispositional groups in a democratic country, and such as the European Union, it is clear to recognize the complexity of the situation.

Considering the problem from the perspective of the availability of dispositional groups, it is clear to see the complexity of the dual role they are required to play. Not only do they have to protect and support the native population, but simultaneously and within the same arena, they are required to integrate a migrant group, often with different cultural beliefs and aspirations. This challenge is further compounded by language difficulties, the possible presence of psychological trauma and the and in some extreme cases, conflict with the host community. As a result of migration, therefore, often completely new security requirements are created, especially in the cultural, economic, public, social, health and universal dimensions.

Maciejewski (2012) categorized the dispositional groups into military, paramilitary, civil and voluntary groups. The military includes those that operate in the military social system, whose main purpose is to defend the sovereignty of the state. The second group - paramilitary, includes all those formations that are organized on a military pattern, including the Police, State Fire Service, Border Guard, the State Protection Service, the Foreign Intelligence Agency, and the Internal Security Agency. Civilian dispositional groups are represented by institutions functioning both in the structures of government and self-government administration as well as private enterprises. And although they have one goal in common, which is ensuring broadly understood security, they can discharge it through public and private funds. Among the voluntary dispositional groups , i.e. those whose members generally operate on a voluntary basis, those worthy of mention include Mountain Volunteer Rescue Service, Water Volunteer Rescue Service and many other organizational and legal types, including volunteer fire brigades. Due to the subject of scientific research discussed in this article, which are migration processes, the research attention will focus primarily on paramilitary dispositional groups, taking as a starting point the thesis that members of these formations are primarily dealing with migration movements taking place in Europe and they should effectively deal with the migration challenges posed by the second decade of the 21st century.

Another significant factor relating to dispositional groups is that democratic societies expect members of these groups to have special predispositions not only psychophysical, but also ethical and moral. Dispositional groups have the opportunity to act efficiently only when they receive a level of trust from the society they serve, confirming the need for their existence through the prism of social acceptance. For this to happen, communities and the media, especially at the local level, are closely monitoring the actions of members of these formations, loudly condemning all violations of legal and customary norms.

An interesting study of selected social patterns of individual dispositional groups was presented by Maciejewski (2012), pointing to specific physical, psychosocial, cultural, moral and professional characteristics of members of individual uniformed formations. Focusing on soft competences, it is worth paying attention to the special predispositions of policemen whose "moral attitude towards citizens is manifested in respect for human dignity, courage and self-sacrifice, observance and protection of human rights, kindness, courtesy, tactfulness, impartiality, responsibility, high personal culture, discretion, integrity, respect for others or caring for the image of the police". Similar expectations are formulated in relation to Border Guard officers, except that in this area special emphasis is placed on respecting the dignity of persons subjected to inspections, and in particular personal searches, which in contact with people with a different worldview or cultural custom is of special importance.

Slightly different requirements are imposed on members of the fire brigade and paramedics. For both these professions, full professionalism and readiness to help victims in all conditions, even those in which their own life and health are at risk, is required, as is often the case with rescue operations conducted by firefighters. The work of paramedics looks a little different, who - in addition to the above-mentioned features - should also be characterized by resistance to stress, the ability to make quick decisions, often under time pressure and anticipating the effects of these decisions. The factor regarding what environment paramedics find themselves is not without significance. They can find themselves being required to assist citizens under the influence of alcohol or intoxicants, aggressive both physically and verbally, possessing weapons or other dangerous tools. Hence, there are situations in which paramedics, going to specific pathogenic environments, ask for support from the police, in order to protect their own lives and health. Therefore, it is necessary to properly prepare the members of the dispositional groups to work in, often challenging environment, and not only in the physical sense, but often in the social, cultural or moral one.

Migration challenges of the 21st century

The first decades of the 21st century brought great migration movements to Europe, which impacted in many ways, affecting both the host countries and those from which the population flows away en masse. In Matis' opinion (2016), such a large influx of foreigners is one of the main problems of European countries, and mass migration has acquired the features of an epic crisis. It cannot be equated with escape, because migrants leave their land not because of fear for their own lives, but for purely economic reasons. Mass illegal migration prevents the process of cultural assimilation with the host society because countries do not have time to thoroughly check the details of arriving persons and regulate their inflow. According to this author, European countries are divided into optimists and pessimists when it comes to the view on multi-culturalism of modern Europe. Optimists say migration will help build a "new European nation" that will be devoid of nationalism. In turn, pessimists believe that multi-culturalism in the clash with radical Islam is a poses significant risks for further integration of the European Union.

Both positions hold elements of truth and it is indisputable that large scale migration into Europe will present many challenges, especially in political, social, economic, demographic and cultural terms, as Janicka (2018) indicates when analyzing the effects of migration processes. Looking from the perspective of EU countries, it is worth adding one more area that is of fundamental importance for the peaceful coexistence of various social groups, namely ensuring security that must be faced by societies and national and EU governments.

When it comes to shaping security, political scientists point out that: "Security issues have traditionally been considered in the light of national security. As a result, relatively few researchers have attempted to theoretically capture the complex of a phenomena that can be described as a tangle of links between migration and security. And yet, the issue of security has a much broader scope and also includes population security. Lack of security is a frequent experience of international migrants. In fact, it is their insecurity that should become the most important problem in security research" (Castles and Miller 2011).

Castles and Miller (2011) emphasize that "before September 11, 2001, researchers dealing with international relations and international security paid very little attention to international migration. And vice versa - researchers dealing with international migration have rarely analyzed its implications for security or understanding international relations or the world politics". This situation has now changed radically. Migrants have become a significant challenge for EU countries, contrasting significantly with migration as recently as 50 years previously, which was

often regarded as both economically and socially positive . Uncontrolled migration, however, has quickly become one of the biggest problems facing European countries, especially those centered around the Mediterranean Sea.

The specificity of the current migration crisis results from the demographic aspect, particularly evident in the large disproportion of young men to women, and difficulties in integrating immigrants into the host society, especially in the social and cultural area (Bazan 2017). The basic push and pull factors include, first and foremost, financial aspects resulting from high rates of social benefits granted to immigrants and other aspects of social care provided to large families. For example, in Germany, in 2015, the immigrant, in addition to accommodation, meals and clothes, received money for his own expenses in the amount of 352 EUR per month, of which 143 EUR in cash. In the case of a family, the sum of all benefits could be up to EUR 1,000 per month (TVN 2018).

However, material benefits are not the only reason for the popularity of Western European countries among immigrants who, when choosing the direction of migration, consider such factors as rule of law, lack of corruption, good career prospects, education for children and a sense of security, and, one very important factor – the presence of people of the same origin who have already emigrated and are a point of reference in the first months of their stay abroad in a given country. It is also worth noting that among immigrants, a large percentage are applying for asylum or refugee status, justifying their arrival in the host country with political factors such as persecution, fear of life and health or warfare. Not without significance for the wave of migrants is also the fact that Germany, as well as Great Britain and France enjoy great popularity among immigrants, spread through social media, television or simply the word of mouth. These programs - presenting European countries as immigrants- friendly - received in refugee camps, additionally motivate them to enter them whatever the personal cost. This draw has resulted in, hundreds of victims in the Mediterranean Sea, attempting to cross the ocean in unsafe craft and conditions routinely resulting in loss of life. The International Organization for Migration calls this sea "the deadliest frontier in the world," since more than 33,000 people have drowned in Mediterranean waters since 2000.

Another factor that activates migration is the war with the so-called Islamic State and other terrorist organizations. As Świderski (2016) notes, it caused "the influx of hundreds of thousands of refugees to Europe to a large extent of Islamic religion. Terrorists say that among these people there are several thousand of their fighters, whose aim is to introduce permanent unrest in Europe. (...) moreover, we are probably also on the eve of the cultural war, which for many observers of social reality is inevitable. This claim is prompted by the behavior of existing Islamic minorities in Europe, which do not want to assimilate, do not recognize European values and do not intend to comply with existing law. The dissatisfaction of European communities is growing. They express their dislike of refugees and the way the political elites conduct their policy towards them more and more clearly. Various restrictions on civil liberties are being introduced more and more often to increase security".

When it comes to Poland, although are present in our social reality yet, we also have to deal with a significant increase in the number of foreigners in Poland. Since 2014, we have been constantly recording an increase in the number of foreigners applying for residence permits in Poland. Temporary migrations prevail - 88% of applications in 2017 concerned temporary residence permits (up to 3 years), 10% permanent residence, and 2% long-term resident's EU stay. Almost 65 % of all applications were submitted by persons aged 20-39. Most often, citizens of Ukraine wanted to live in Poland, who submitted 125,000 applications in 2017 - by 30% more than in 2016. Belarusians (9,500), Hindu (8,000), Vietnamese (6,400) and Chinese (6,000) also applied for residence permits. As early as in 2005, 858 people had the right of permanent residence in Poland, and in 2014 it was already 18.9 thousand, of which most Chinese, Vietnamese and Ukrainians (Office for Foreigners 2018).

Polish migration issues are not only the challenges associated with immigration, but also the emigration of Poles abroad. After our country's accession to the European Union, most migration was on economic grounds , but the fact is that between 2010 and 2015 between 2 and 2.39 million people left Poland, of which the largest group went to the United Kingdom - 720 thousand and to Germany - 655 thousand (Central Statistical Office 2016). It is also worth adding that among this group, over 50% of people on the islands and almost 40% in Germany declared their will to stay permanently in these countries. This trend remains stable, which is confirmed by the data from the end of 2018, according to which around 2,455,000 people stayed temporarily outside Poland. permanent residents of the country. In Europe alone, there were about 2 155 thousand people, most of them - about 2 031 thousand. - stayed in the EU member states. Among the EU countries, the greatest number of Polish emigrants stayed in Germany (706 thousand), Great Britain (695 thousand), the Netherlands (123 thousand) and in Ireland (113 thousand) (Central Statistical Office 2020).

Resulting problems have been felt in the economic dimension due to the shortage of workers, or in the social area, resulting from the increased number of divorces, leaving children without due care, the so-called Euro-orphanage, and retirement benefits. The discussed processes - immigration and emigration also have a significant impact on the

functioning of dispositional groups, because officers of these formations are most often the first to have direct contact with the incoming population who is attempting to enter the host country through legal or illegal means. Hence, the issues raised in advance with the migration movements can contribute to understanding the essence of the case and to developing mechanisms and solutions that will positively influence the alleviation of difficult migration processes that have been taking place in Europe for several years.

Impact of migration on operational efficiency of dispositional groups

Considerations on the impact of migration on dispositional groups should begin with an analysis of the functioning of the environment of the groups themselves, especially in the context of problems that have been observed in uniformed services for some time. An issue worthy of mention first is personnel problems, which have been visible in many uniformed services for several years. An example would be the Polish Police, in which, due to the significant lack of officers, one might describe it as personnel crisis. The head of Independent Self-Governing Trade Union of Policemen R. Jankowski states that "there are already nearly 6,000 vacancies, and fewer and fewer willing to join the police" (2019).

According to the data of the National Police Headquarters, 3.2 thousand officers left the forces in 2019, and 1.8 thousand were taken on. This depletion of numbers is reflected in the quality of "services" provided by policemen, manifested in the time of patrols undertaking intervention. So it is where the local society most needs support and help in maintaining security and public order. The low attractiveness of pay in the police, the hardships of service, and above all the outflow of young people at working age abroad - these are the main reasons for the staff deficit in this formation. And this has a direct negative impact on ensuring security and public order, already a formidable challenge.. The influx of immigrants only compounded this challenge. An excellent native example is the area near Warsaw, where the center of wholesale trade of Asian goods is located. There are several thousand companies, gastronomic and service establishments, financial institutions and the area has developed its own security agency. The nature of this security results in all services facing difficulties with entering, from the police to the sanitary and tax and customs departments.

In some other European cities the challenges are even greater. A extremely worrying manifestation of this is the acts of terror committed in recent years, or the harassment of women on New Year's Eve in Cologne in 2015. It is also worth noting the increased activity of mafia criminal groups or the increase in common and criminal offences, which gives rise to very serious consequences for the safety of the inhabitants of the region. An example in this regard may be Germany, in which 181 thousand acts of violence were reported in 2014, and two years later their level increased to 193.5 thousand. As for the indicators for one of the German Lands - Lower Saxony, the increase in crime was even more visible. From the level of 17,500 crimes in 2014 in the next two years their number increased to 19.2 thousand. And most importantly, migrants account for 92 percent of them (Polityka 2018). It may also be the case that the number of crimes committed is not entirely accurate as many crimes not reported to the police, especially in those districts where it is difficult or dangerous for government agencies to enter. This problem appears to becoming more regular in its reporting.

The emergence of so-called *no go zone* or *no go area* is characteristic of Swedish cities, where walking in some parts of the city can threaten the life and health of not only citizens, but also uniformed services, especially the police. The term itself means areas where the level of violence and crime is so high that it prevents people from functioning normally and forces them to live in constant fear. No-go area can also mean an area that is controlled by a group of people who, by force and intimidation, prevent others (strangers) from crossing the border of "their" territory. At the end of 2014, the Swedish police published a report for the first time detailing areas that are problematic from the point of view of the work of uniformed services. At that time there were 55 such places on the Swedish map. However, in three years their number increased. In July 2017, the police published another document: "Utsatta områden - Social ordning, kriminell Konstrukcji och utmaningar för polisen" ("Sensitive places - social order, criminal structures and challenges for the police"), including a list of 61 problem areas in Sweden, among which the largest concentration is located on the outskirts of the three largest cities: Stockholm, Malmö and Gothenburg. The police admit that they are powerless in the face of the situation, and one of the Swedish National Defense Academy's terrorist analysts M. Ranstorp said in his report: "In some areas, extremists have taken control. Basic standards of justice and social peace are at stake. The police are falling apart and it's getting worse. We're dealing with a disaster in Sweden" (TVP 2019).

A further point relevant to the issue of staff deficit, is an issue the British police are facing. The issue is regarding the traditional clothing worn by Muslim women which covers the face, a traditional Muslim burqa. According to one West Midlands police commissioner, it is worth considering the service of burqa policemen to increase the "ethnic diversity of police officers" (Rzeczpospolita 2019). This is also associated with staffing problems, and such

a solution might attract new recruits. However, this is contrary to the increasingly sharper trend visible in European countries, such as Denmark, France or Belgium, where it is forbidden to wear the burqas in public places, including the streets. In the Netherlands, however, women's rights to wear face veils have been restricted in places such as schools, hospitals, public transport, and government buildings. In 2014, the European Court of Human Rights ruled that such bans do not constitute a violation of religious freedoms.

Staffing difficulties are visible not only in the police, but also in the German armed forces. In 2011, in connection with the Bundeswehr reform, compulsory conscription was abolished, at the same time assuming an increase in its number to 200,000 professional soldiers. Unfortunately, the army appears to have lost its popularity as an employer, and currently there is a shortage not only of volunteers for professional service, but also technical staff (Military Magazine 2019). This has resulted in German planners recruiting Poles, Italians and Romanians living in the Federal Republic between the ages of 18 and 40. The choice of these nationalities is the result of a simple numerical factor. 255,000 Poles, 185 thousand Italians and 155,000 Romanian at conscript age live in Germany permanently. Altogether, they constitute about half of foreigners from European Union countries in the Federal Republic. If the willingness to take up service in the Bundeswehr structures was expressed by at least 10%, this would result in 50,000 recruits (Military Magazine 2019).

In addition, the option of recruiting EU citizens for military service is also being considered, as it is done in other EU countries such as Belgium, Denmark, France, Spain, Luxembourg and the United Kingdom. What could the implications of this, for example, for the Polish armed forces? Namely, the fact that the German employer will be more attractive than the Polish Ministry of National Defense, offering better wage conditions and services, and due to the close proximity it may be a significant incentive for Polish citizens to join the German army. Of course, there are ethical, loyal and patriotic problems, and there are some with the opinion that such personnel policy will lead to the appearance of an army of mercenaries, not soldiers ready to fight for their homeland.

Another example of a different approach to immigrants can seen within the German Fire Brigade Association (Deutscher Feuerwehr Verband). They assumed that the fire brigade was perceived as a traditional organization associated with the uniform, command structures, hierarchies, service levels and regulations. Therefore, they considered it to be an important challenge to be open to groups previously under-represented in their ranks, positively recruiting people with a migration background. The organization formulated its mission as follows: enabling migrants to participate in fire brigades and to increase the intercultural competence of professional firefighters and volunteers (Feuerwehrband 2019). The justification for such actions is the assumption that "people with a migration background are needed because: 1. they are part of society and enrich fire departments culturally, linguistically, tactically-operationally as well as in HR way; 2. their experience makes it possible to help with language barriers and possible cultural and behavioral differences; 3. they broaden the horizons of existing guard members; 4. they have a positive effect on operational efficiency. Fire brigades perceive themselves as a reflection of the image of society and thus want to include all sections of the population in their ranks, and their special experience is needed in fire departments ". Thus, in the future the fire department will reflect a broad cross-section of society, enriched by the special qualifications and experience of people with a migration background.

The use of immigrants in the ranks of the fire brigade in order to overcome cultural and language barriers, among others, is another challenge for officers of dispositional groups. Entering the socio-cultural area of contemporary migrations, it is worth noting that this is a complex issue, conditioned by many factors.

First, we are dealing with a completely different family model in Muslim communities. Most often they are families with many children, patriarchal, with a privileged position of a man and a much weaker role of a woman, who often due to lack of education and language skills have difficulties interacting with the external environment, and in extreme cases may become a victim of domestic violence. Standard behaviors in female-male relationships developed in European civilization are completely unsuitable for Muslim populations, and have on occasion been be a reason for misunderstandings and violence. In Islam, the prohibition on marriage between a Muslim and a non-Muslim is widely known, and in some cases this has resulted in severe physical punishment towards the women. Therefore, dispositional groups that are strongly dominated by men, even if they are tasked with saving lives or nurturing health should be particularly careful and thoughtful, so as not to violate the cultural and moral principles in force in the community.

Secondly, the language barrier. The challenge of this problem can be seen in the situation in Sicily, where there were people in the refugee camp who taught English in their own countries. Due to the inability to communicate with city guards who spoke only Italian, immigrant teachers came up with the initiative to teach Italians English, in return for learning Italian. It transpired that knowledge of English is of enormous benefit in the city guard on the

island, whose representatives have daily contact with immigrants and refugees, who often know only this foreign language (Interia 2019).

An issue that is worth paying particular attention to is the availability of uniformed formations to detect and counteract terrorist attacks. Based on the data presented by Europol Executive Director Catherine De Bolle in the 'Report on the situation and trends in the field of terrorism' summarizing 2018 before the Committee on Civil Liberties, Justice and Home Affairs (LIBE) (European Parliament 2019), it can be concluded that the number of victims of religious / jihadist terrorism in the EU fell. In 2018, 13 people were killed in the terrorist attacks in Trèbes, Paris, Liege and Strasbourg, compared to 62 people in 2017. However, it should be emphasized that the number of thwarted attacks has increased, which indicates that the threat to internal security is still high. In 2018, one jihadist attack failed in Spain, and 16 incidents were reported as thwarted jihadist terrorist conspiracies, compared with 12 and 11 cases respectively in 2017. Jihadist attacks that were carried out and unsuccessful mostly took place using knives and firearms and were aimed mainly at civilians. All planned attacks using explosives were thwarted and most of the perpetrators acted or planned to act alone. As for the number of detained persons, a total of 511 suspects were arrested in 2018, mainly in France, Great Britain and Belgium, while in 2017 - 705. What caused a decrease in the number of terrorist attacks or their attempts in Europe? According to Catherine De Bolle, "efforts by law enforcement, security services, public authorities, private companies and civil society organizations to counter terrorism have significantly contributed to reducing violence in Europe".

When comparing the experience of Polish and other European countries in this area, Poland is not a priority target for extremist organizations, however, due to participation in the anti-terrorist campaign or NATO and EU operations, it must take into account the possibility of such activities on its territory. Confirmation of this thesis may be one of the last operations of the Internal Security Agency, as a result of which, in December 2019, a Ukrainian citizen was detained. He is suspected of preparing to carry out an explosion of explosives using a trap car under one of the shopping malls, which could have seriously threatened life , health and property.

Conclusion

Creating and maintaining an acceptable level of security in the micro-, mezzo- and macro-social dimension has become a fundamental challenge today. The etymology of the word 'security' in many languages underlines the primordial sense of danger in relation to the sense of security certainty. An example would be the Polish language, in which the old Polish word "without care" meant to remain without sufficient and adequate protection. Hence, since the appearance of man on Earth, he has taken actions to ensure the protection and defense of life and health, and over the time of property and the environment against threats typical of a given age.

The capacity of the word security, both in terms of subject (personal, local, national, international) and object (political, cultural, economic, social, military, other) means that in a democratic state virtually every public institution or social entity has statutory provisioned specific tasks to be performed as part of creating security in many dimensions. These institutions are nowadays referred to as dispositional groups, and the attributes assigned to them, such as professionalism, rule of law, professional and social competences, and readiness to act, particularly predispose them to counteract threats, among which the migration crisis is the most important characteristic of the 21st century.

Due to the universality of this phenomenon, which has affected all European countries, on the basis of the comparative studies conducted, it can be concluded that the problems faced by Western European countries can be extended to all countries of Central and Eastern Europe. Migration movements are a natural and irreversible process taking place in all types of society, bringing with them both opportunities and threats. Among the greatest advantages of migration, it is worth mentioning the economic, cultural, economic and demographic aspects, as well as social progress and the acquisition of labor, without which the economy of many countries would not function at a high level of development. The threats that arise in connection with migration, especially uncontrolled immigration, include all those factors that affect the sense of multidimensional security. This applies in particular to public safety and order, social and health security, cultural security and national identity, as well as violations of human rights and freedoms resulting from human trafficking or forced labor. Hence, these areas should be under special control and protection of the state and disposable groups acting on its behalf. Therefore, the officers working in them should have special competences to perform tasks that differ from the schemes used so far.

Currently, in the functioning of the disposition groups, problems of a personnel and image-related nature can be noticed, which creates the necessity to adopt a long-term strategy enabling service in these formations of foreigners of different religion and customs. Intercultural education and language courses are essential, especially among officers at the operational level, where there is real contact between the migrant and the representative of the

uniformed formation. This will make it possible to overcome language and cultural barriers and prepare the personnel of uniformed formations to perform statutory tasks.

The presented analysis of the experiences of European countries in solving problems in the officer-immigrant relationship is of a utilitarian nature, especially from the perspective of Central and Eastern European countries. They are the border states of the European Union, which in the first place take on the responsibility of solving migration problems. It is also them that, despite the fact that so far treated as transit countries, more and more often - like Poland - are becoming places of permanent emigration, therefore the migration policy should be adapted to new challenges.

Abstract

Farming, like every other livelihood is not without its challenges. 21st century Africa has witnessed an increasing theft of farm produce and in some cases, the murder of farmers. The reality of farm theft in rural communities poses several questions about its prevalence, consequences, and farmers' responses. Through a qualitative lens, this study investigates how and why rural crop farmers have remained interested in farming despite recurring farm theft. Eighteen (18) crop farmers were engaged in a semi-structured interview session. Through the discourse analysis approach, result showed five (5) major factors responsible for farmers' livelihood resilience in the study locale; Tradition, Income, Health, Poverty, and Prestige. As such it is recommended that focus should be on improving such factors.

Keywords: Crop Farming, Livelihood Resilience, Farm theft

Introduction

Farming in most parts of the word, especially in rural communities serves as an important livelihood for people that reside in these areas (Ajani & Igbokwe, 2013). This is to say that the occupational option in the rural regions is primarily farming, and agro-allied occupations that draw its essence from farming. It is the most prevalent socio-economic activity in rural Nigeria where up to 50% of the population resides and actively engages in the cultivation of crops and rearing of animals (Odekina, 2004). Farming goes beyond an occupation for many rural settlers, it is a lifestyle, a lifelong activity that has been passed down from many generations. In Nigeria, farming is majorly characterized as subsistence (Apata, Sanusi, & Olajorin, 2016). For instance, farmers engage in the cultivation of crops to provide food for themselves and their households. In some cases, they cultivate to fulfill other needs. In this sense, farming does not only provide food for farmers, but it also provides them with the means to meet other necessities of life (African Agriculture Review 2012).

Livelihood in all societies, including rural, is more than surviving hunger, it also involves the provision of material assets that make life enjoyable. Livelihood has two major dimensions; assets/capitals, and activities required to make a living (Morse & McNamara, 2013; Kamaruddin & Samsudin, 2014). According to Scoones (1998), there are five (5) assets of livelihood; natural assets (natural resource stocks and environmental services; soil, water, air, land, seeds, fertilizers, etc), human assets (skills, knowledge, and labour; good health, physical capability, etc), financial assets (capital base; cash, credit/debt, savings, and other economic assets), physical assets (infrastructure; buildings, roads, production equipment, and technologies), and social assets (social resources; networks, social claims, social relations, affiliations, and

associations). For farmers, the asset dimension of livelihood may then involve access to land for farming; farming experience and skills; access to farming capitals or loans; material gains from farming, farm location or proximity to roads, homesteads, and local markets; affiliations with agro-allied firms.

The second dimension involves a variety of activities. According to Tesfamariam (2014), all crops require adequate water, appropriate landscape, fertile soil, and a favorable climate. Hence the farmer needs to get a suitable land for farming. Thereafter, pre-planting operations commence, where the farmers will have to prepare the land, through the application of manure, tilling or plowing, as the case may be. During planting, farmers engage in various agronomic activities such as sowing, weeding (removal of unwanted plants), thinning (reducing seedlings per plant stand), and application of insecticides and pesticide among others. Harvesting farm produce occurs at crop maturity. It is the process of gathering ripe crops from the farm. Harvested crops are further processed to become consumable. Processing a crop may include, drying, winnowing, and threshing as applicable. Processed crops are then made ready for consumption, storage or sales in a local market.

Farming, like every other livelihood, is not without its challenges. Fierce global competition, creeping climate change, insurgent pest, prolific herbs, globalization, diminishing land, soil infertility and increasing cost of inputs have all been identified as challenges farmers have little or no control over (Bunei, 2016). However, 21st century Africa has witnessed an increasing theft of farm produce and in some cases, the murder of farmers (Bunei 2014; Chiwona-Karltun, Lemenih, Berisso & Karltun 2009; Clack 2013; Foeken & Mwangi 2000; Gichamo 2011). Criminals are descending upon farmlands to take advantage of rich pickings, a discrete environment, relatively low risk, and rural '*hot products'*(Bunei, 2017). The reality of farm theft in rural communities, therefore, poses several questions about its prevalence, consequences, farmers' responses and more importantly for this study; farmers' livelihood resilience despite recurring farm theft.

According to Luthar & Cicchetti (2000), Resilience has two major constructs: (i) *exposure to adversity*, and (ii) *positive adaptation*. Resilience has been conceptualized as a process wherein an individual, such as a farmer displays positive adjustment such as mental well-being or the absence of emotional distress despite experiencing a crisis (Greenhill, King, Lane, & MacDougall, 2009). According to Ungar (2004, p.341), resilience is the result of negotiations between an individual and the situation to maintain a self-definition as healthy. It becomes important, therefore, to identify the factors that help to moderate the negative effects that produce emotional distress caused by exposure to the crisis. A study identified some major factors responsible for farmer's livelihood resilience despite drought. Some of those factors include pre-existing viability of the business, income security, managing risk, and decision-making abilities, seeing themselves as more than a farmer, opportunities to disengage due to the seasonality of the livelihood, etc (Greenhill et al., 2009). It is with these findings that this research explores rural crop farmer's resilience if the crisis was the theft of farm produce.

Research on rural crop farmers' resilience in farming irrespective of farm theft has not been subjected to rigorous study. Existing research on the subject matter is extremely limited. One of the best-related studies that can be referred to is that of Viira, Poder & Värnik (2009), which adopted a postal survey to inquire from Estonian farmers about their intentions of quitting farming as a result of age, the share of family labor in the total farm labor, and the share of farm produce in total farm revenues. This study did not consider farm theft as a factor that may discourage farmers. It was discovered that farmers who are resilient in farming are those who have diversified into non-farming activities. Development literature on agrarian transitions concentrated mostly on the collective changes of farmers from farming to non-farming livelihood, rather than on farmers' resilience. Most rural settlers are confined to farming not out of choice but from a lack of options (Agarwal & Agrawal, 2017). International reports like that of The International Crime Victim Survey (ICVS) in collaboration with the United Nations (UN) will be difficult and unauthentic to apply to local communities. It, therefore, becomes necessary to have an in-depth knowledge of local realities that are not available in official reports to avoid falling back on ready-made broad narratives and solutions that may not be appropriate.

Theoretical Framework

Lyon and Parkins' Social Theory of Resilience

This theory builds on the Archer's cultural morphology map theory, based on a model of transition found in the theory of social ecological resilience. This overlay offers a partial response to the issue under discussion in resilience theory, community and organization. In addition, it offers a context to explain what happens in the changing cultures at the

cultural level. It illustrates how culture can support adaptive responses of changing communities. In two cultures, based ethnography advances the hypothesis that local cultural backgrounds play an important role in community response to closure challenges. The theory review also provides an alternative to functionalistic approaches to research on resilience with a focus on institutional capabilities, functional engagement and social indicators. In comparison, Lyon and Parkins (2013) research provides insights into the human organization and social change, which lead to adaptation by placing culture as a dynamic structure, distinct from a social system which is static or changeable as part of social transition processes and which can remain static (resilient or adaptive). The scientists conclude that the economic upheaval alone is not a motive for concerted action. Collective action coincided with a strong pre-existing activist community and a collective immediate reaction. Instead of offering fast and simple perspectives, this interpretive approach to resilience evaluation seeks to cross various theoretical and empirically divisive theory and the empirical divisions between biophysical and social science approaches for resilience studies in the society.

Methodology

This study employs survey design, using the qualitative methodology. An in-depth interview is used to probe for the research question, using a face-to-face semi-structured interview technique. The selected study locale is Oke-Ero Local Government Area (LGA), located in the Kwara South senatorial zone of Kwara State Nigeria. The locale was selected purposively due to perceived cases of farm theft which offers a unique opportunity to investigate the variable fundamental to this study. Oke-Ero covers an area of 445 Square Kilometers and had a population of 56,970 at the 2006 census. Using a Mathematical projection formula developed by Abubakar, Audu, & Aisha, (2017), Oke-Ero is expected to have a population of 79,465.6 in 2019. There are three political districts in the LGA; Ekan Meje, Idofin, and Iloffa / Odo-Owa. The residents are mainly Yoruba. They specialize in crop production such as cassava, maize, yam, kola nut, banana, plantain, cocoa, cashew, and palm oil. (Animasawun & Aremu, 2015).

The main respondents in this research are crop farmers residing in the study locale. This research employed the multi-stage cluster sampling technique. Stratifying Oke-Ero by districts, we have Ekan Meje, Idofin, and Ilofaa/Odo-Owa. Within each district, 3 farming communities were selected at random giving a total of nine (9) communities altogether sampled for the study. The randomly sampled towns are Aiyedun, Eken, Erinmope, Aiyekale, Odo-Ashe, Igbana, Iloffa, Imode, and Odo-Owa. For each of these randomly sampled communities, the researchers approached crop farmers and then snowball to get other contacts. Once a fixed number of respondents has been interviewed in a farming community/village, the researcher moved to another one. This process is repeated until 18 farmers from all 9 farming communities have been surveyed.

The collected data were recorded, transcribed, interpreted and analyzed. Following the guidelines for research practices, some ethical considerations had to be considered. The consent of all participants informed was considered before carrying out the study. Potential respondents were informed of the processes and essence of carrying out the study. Most significantly respondents were guaranteed that the study was conducted under the conjecture that study findings would be used for research only and kept under the condition of confidentiality. The questions were less structured and took an inductive (bottom-up) approach. Hence, they were open-ended which allowed informants' freedom of expression. Language or formal education barriers was resolved as the instrument for data collection was interpreted in the indigenous (Yoruba) language. The data were analyzed through the discourse analysis approach which involves the study of naturally occurring language in any social context; categorizing quotes into major themes, considering the actual words used, and the way the words were expressed. Since the codes were generated from raw data, the thematic analysis approach was adopted. (Shanthi, Wah, & Lajium, 2015). It involves seven major steps; Open coding/ Indexing: (one or two word summary for each discourse); Categorization of codes: (a list of all codes; both similar and redundant codes); Iterative process: (the reduction of the long list of codes to a smaller, manageable number); Matching codes: (constant comparison of codes); Close coding: (identification of overarching themes or categories); Merging themes: (find the relation between themes); Write up: (discussion of the interrelation, or a narrative from the themes, sub-themes, and codes).

Table 1: Interviewee Profile

F_n	Age Grade	Farming Experience	Sex	District of Resident	Religion

Results

All participants responded that they have been a victim of farm theft and this have not caused them to disengage from farming activities. The reasons they gave are presented as themes, which are described in Table 2 below. Virtually all farmers narrated more than one factor for their resilience, however, the most emphasized factor by each farmer was presented. The 5 major themes observed were; tradition, health, income, poverty, and prestige.

Table 2 : Themes and Coded Descriptions of the factors that sustained Farmers' interest in farming despite recurring farm theft

Theme	Code Description
Tradition	Farming is an age-long activity. Farming is a routine activity in rural societies. Farming for some household is a traditional household occupation.
Health	Farming could serve as a way to escape boredom through physical exercise.
Income	Farming is a reliable source of income.
Poverty	Some farmers engage in farming due to the dearth of other options. The inability of some individuals to be gainfully employed. The need for survival.
Prestige	Many farmers see the occupation as a prestigious occupation Some farmers appear to be resilient to save their social image

Source: Author's Fieldwork, 2020

Tradition

Tradition as a theme has 3 major sub-themes; an age-long activity, a routine activity in rural societies, a traditional household occupation for some rural households. Table 3 presents the narratives of participants who are influenced by this factor.

Table 3: Theme 1: Tradition

Participants	**Comments**
F_1	"Farming is what we wake up to do. We are not like those who live in the city, dashing out every morning to a far place in search of daily bread. They do have their challenges, and it does not stop them from going to work. Farming is our source of daily bread, we have to do it irrespective of any challenge, including farm theft"
F_6	"I was born by a farmer, my grandfather was also a farmer. It is an occupation that was handed over to me, so not even farm theft can disengage me"
F_{15}	"Before we were born, our fathers went to the farm. It is what has sustained this community, even before other kinds of jobs exist. It is an age-long activity"
F_{18}	"It is my family occupation, I am obliged to farm, and if there is a challenge, I am expected to resolve it"

Source: Author's Fieldwork, 2020

Health

This factor has the lowest contribution to resilience among the participants. Table 4 presents the narratives of the only participant influenced by the 'health' factor.

Table 4 : Theme 2: Health

Participant	Comment
F_4	"I need to keep myself busy in order not to get bored. Boredom is a terrible thing, it kills slowly. Farming also help me exercise to keep fit"

Source: Author's Fieldwork, 2020

Income

Although, the 'income' theme has only one major description; "Farming is a reliable source of income", it is, however, the most common and major narrative of all participants across all surveyed districts. See Table 5 below.

Table 5: Theme 4: Income

Participants	Comments
F_3	"With farming, you can confidently provide for your household. When you work and make money from the work you do, you are excused from thinking of stealing another man's thing"
F_5	"Farming is good business, it feeds you and takes care of other needs"
F_9	"You are sure of having something at the end of the day"
F_{11}	"You won't need to depend on others to survive"
F_{12}	"With farming, you won't have to turn to a thief yourself"
F_{14}	"Income from farming is overwhelming. It is an occupation that helped me build my house, send my children to school and have a comfortable life"

Source: Author's Fieldwork, 2020

Poverty

Poverty is a feature of most of most African country. Many have devised many means to cope with the problem (Adebisi, Alabi, Arisukwu & Asamu, 2020). The 'poverty' theme has 3 major descriptions; the dearth of other options, unavailability of jobs, and the need for survival. Table 6 presents the narratives of participants who are influenced by this factor

Table 6: *Theme 3: Poverty*

Participants	**Comments**
F_2	"We have to survive, we can't disengage from farming because of farm theft, if we do, hunger will have a free day with us"
F_7	"There's nothing else to do. I have been farming since the days of my youth, I live here, it is what this community is known for "
F_8	"I wanted to study engineering, but my parents could not afford my education. I settled into farming as a result. Now, this is all I have to make a living. It doesn't matter the challenge, I must just survive"
F_{16}	"I started assisting my husband on his farm due to lack of job. It is better than nothing"

Source: Author's Fieldwork, 2020

Prestige

Prestige was observed as a factor that influences farmers' sustained interest in farming despite the theft of their produce. This theme has two sub-themes; "Many farmers see the occupation as a prestigious occupation" and "Some farmers appear resilient to save their social image". Table 7 is a presentation of the narratives on prestige.

Table 7: *Theme 5: Prestige*

Participants	Comments
F_{10}	"I love to experiment with my charms, the failure of one charm will encourage me to prepare another one"
F_{13}	"The popular saying that says farmers are kings is true. Without us, people won't be able to buy food. I see myself as really important to society"
F_{17}	"People reverend me as a farmer and I'm enjoying the spotlight"

Source: Author's Fieldwork, 2020

Table 8 provides a summary of the total supporting cases for each of the themes. Four farmers were influenced by traditional factors; a farmer reported livelihood resilience as a result of the health factor; poverty also served as a reason why 4 farmers will not give up farming; income is the most prevalent factor as it influences 6 farmers; three farmers were influenced by prestige.

Table 8 : Summary of total supporting cases for factors that influences farmers' sustained interest in farming despite recurring farm theft

Theme	Total Supporting Cases	
Tradition	F_1 F_6 F_{15} F_{18}	4/18
Health	F_4	1/18
Poverty	F_2 F_7 F_8 F_{16}	4/18
Income	F_3 F_5 F_9 F_{11} F_{12} F_{14}	6/18
Prestige	F_{10} F_{13} F_{17}	3/18

Source: Author's Fieldwork, 2020

Discussion of Findings

The average mean age of farmers in the study locale is 54 years. This is in agreement with Bunei (2014) that argued that the majority of farmers are aged individuals. According to Greenhill et al. (2009), livelihood resilience exists if concerned individuals (in this case, farmers) have pre-existing viability of the occupation, income security, risk, and decision-making management abilities, seeing themselves as more than a farmer, opportunities to disengage due to the seasonality of the livelihood. In the study locale, it was discovered that all of the aforementioned cases are responsible for farmers' livelihood resilience. Put succinctly; tradition, health, poverty, income, and prestige are the five major factors responsible for farmers' sustained interest in farming.

The consensus among the surveyed population reveals that income is the most prevailing factor that motivates farming despite recurring farm theft. According to the participants, farming is self-sustaining. This study also reveals that farming is a lifelong activity that has been passed down from many generations. Many individuals engage in farming because they inherited the occupation from their parents. Rural poverty has also contributed to farmers' livelihood resilience. Although earlier studies in Kenya presented poverty has a motivation for farm theft (Anderson 1986), this study, however, linked poverty with livelihood resilience. Despite recurring farm theft, many farmers engage in farming due to the dearth of other options, the inability of individuals to be gainfully employed and the need for survival. It happens that the same factor that is responsible for motivating offenders to steal from farmlands also motivates other individuals to farm. Poverty has remained a constant in many rural societies, however, residents possess the ability to choose how the factor influences them.

Some farmers are resilient in farming activities as a way of escaping boredom; others engage to exercise their bodies. Prestige also serves a motivation for farmers, as some see the occupation as a prestigious, and it appears that they want to save their social image. (Ayanda, Olooto, Motunrayo, Abolaji, Yusuf & Subair, 2012).

Recommendations

There should be a focus on improving the factors identified as responsible for rural crop farmers' livelihood resilience in the study locale. This is important because what has sustained their interest in farming can be used to further proffer solutions to the various challenges of farm theft.

Abstract

In article, we consider results of decision support development for geopolitical risks management within Arctic maritime activity while Covid-19 pandemic and climate change. In studies, we used methods of data bases constructing, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties, risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space. As digital tools for managerial decision support systems, we propose to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, we proposed a structural model, that combines the investment objectives with cost of adequate managerial support, adapted to Covid-19 pandemic and climate change conditions. We used platform https://www.researchgate.net/profile/Valery_Abramov2/ for data exchange and preliminary discussion while study. Research was performed at the Russian State Hydrometeorological University within State Task of the Ministry of

Keywords: decision support, geo-political risks, Arctic maritime activity, Covid-19 pandemic

Introduction

Now, Covid-19 pandemic shook the global economy, that required major changes in management decision-making technologies, including geopolitical risks management (GPRM) technologies, especially within maritime activity (MA) in Arctic and Subarctic. Note, this pandemic shock matched the time with Industry 4.0 period, during which a lot of enterprises plan and implement wide spectrum of information technologies (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019), (Lukyanov, 2019), (Sikarev, 2020), (Trunin, 2019). Industry 4.0 leads to serious technological changes in natural risk management (NRM) (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new training and educational technologies, especially for UL (Averkiev, 2020), (Estrin, 2020), (Korinets, 2020), (Popov, 2019).

In the article, the authors present the development results for managerial decision support (MDS) during GPRM within MA in Arctic and Subarctic while Covid-19 pandemic and climate change in geo-information management area (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), within environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). Significant attention should be paid to geo-information support systems (GISS) within NRM in climate change context (Bidenko, 2019), (Bournashov, 2014), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). The digital tools for GPRM within MA in Arctic and Subarctic while climate change and Covid-19 pandemic, discussed in this article, take these factors into account.

Methods and Data

In research, we used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. Also, we used big data technologies (Popova, 2019), (Yaily, 2019) From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Bidenko, 2019). While study, we used data bases and tools of geo-information digital online platforms (GIDOPs) Earth (Sanina, 2020) and EOS, including its Land Viewer (LV) product (Bolshakov, 2020), (Vekshina, 2020).

Results

Currently, maritime activity in the Arctic (MAA) is a hot place in global environmental economy. Authors made statement, that the best way to involve the Arctic into global economy is sustainable development paradigm with adequate decision aids tools developed on geo-information management (GIM) basement. From GIM point of view, MAA while climate change and Covid-19 pandemic is to be carried out as related set of large natural-industrial projects (NIPs) within common space area and time period. In Figure1, we present a block model of investment structure for such NIPs, which combines the investment objectives (blocks 1-5) with cost of adequate geo-information and geo-ecological support (blocks 6-8), including GPRM and natural risk management (NRM) within NIPs in MAA (block 7). For MAA, there are greats GPRMs because of different sanctions and ecological restrictions in territorial waters of different states. Situation with NordStream-2 marine pipeline can be excellent example.

Figure 1: Block model for investment structure while territory development: 1 – block of distribution of resources; 2 – block of formation of resources; 3 - block of formation of private income; 4 - block of formation of total income; 5 – block of formation of the investment share of resources; 6 - block of comparison with the permissible level of risk; 7-block of formation changing in time set of GPRM and NRM, including Covid-19 pandemic and climate change; 8 – block of environmental monitoring corresponding to block 7

Authors' analysis shows that the largest part of the cost of managerial support is the environmental monitoring (block 8), the essence of which is determined by the content of block 7. Significant part of the cost in block 8 is hardware and software, the cost of which varies significantly. Now, in Covid-19 pandemic conditions, cost of GPMR and NRM for MAA can arise greatly because of general economic situation, when every country have to implement limitations for boards crossing and suffer from economic slowdown.

While research, one of the co-authors (Valery M. Abramov) hypothesized that the main factor of geopolitical risks for marine activities in the Arctic during the Covid-19 pandemic is the restrictions imposed by various states at the level of national legislation aimed at combating the Covid-19 pandemic. In this article, the main focus of the fight against this group of geopolitical risks proposed the use of international cooperation within the framework of the Arctic Council, initially focused on the development of the Arctic within the framework of the sustainable development paradigm. It should be noted that in 2021-2023, Russia will the Chairman in the Arctic Council and is currently developing a program for such a chairmanship. The main working mechanism could be the creation of a working group on Covid-19 within the Arctic Council, following the example of a similar working group on climate change in the Arctic. As tools for preparing and supporting decision-making in the framework of such a working group, it is advisable to use innovative digital technologies and tools, the structure of which is discussed below.

In research, we proposed a structural model of a geo-information distributed platform (GIDP), which contains heterogeneous databases under multi-level architecture. Proposing GIDP contains three levels of data representation DATA - PROCESSING - INTERFACE. Such representation guaranties system independence from the number of software components. We propose flow model (Figure 2).

Figure 2 - Flow model of a GIDP with heterogeneous databases

To avoid the difficulties of multi-user access to data, we suggest to use a mechanism for pre-processing heterogeneous data, which includes a virtual data processor (VDP) and a data preparation unit (DPU). A VDP is a software module that allows uniform access to all system data via standard interfaces (protocols), while hiding the features of data placement, data structures and formats. A DPU aims at collecting and first processing the data requested by the user from the system. When using this mechanism, there is no need to convert data to the format used by the system, they remain in the original view and can be used locally by their applications.

In more detail, VDP is a virtual data bank (VDB), which consists of a set of non-specified virtual databases (Figure 3). Information sources of actual state databases are the actual cycle of functioning of organizational subsystems of a complex management object, when considering the geo-information system as a system for making managerial decisions. The information sources of the databases of planned States and regulatory States can be input documents, virtual results of management decision-making, as well as the results of solving regulated tasks

Figure 3 - General diagram of dependencies between data subsystem modules in VDP

On basement of above mentioned model (figure 1) and GIDP conception (figures 2 and 3), the authors propose to develop the geo-information and geo-ecological support system (GIGESS) with combined structure for access, storage and analysis of information from geo-spatial data sources, including archives and operative mode web tools.

As a result of the research, performed using foresight technologies, the authors suggest to use geo-information distributed online platforms (GIDOP) with cloud technologies (CT) as the main technological solutions for GIGESS. We gave preference to open platforms such as Google Earth https://earth.google.com/web/. In this article, we recommend to use GIDOP EOS eos.com, including its product LandViewer (LV) https://eos.com/lv/.

Let's go to examples. In figures 4 and 5, we show the results of sequential operations performed online with LV for the Svalbard. In figure 4, there is space image on 21th June 2020 visualized with Natural Colors Application of LV.

Figure 4: Svalbard space image on 21th June 2020 visualized with Natural Colors Application of LV

In figure 5, there is the same as in figure 4, space image, visualized with Atmospheric Removal Application of Land Viewer.

Figure 5 - Svalbard space image on 21th June 2020 visualized with Agriculture Application of LV

Obviously, that figure 5 is more informative for space decoding. Note, space decoding of figure 4 and figure 5 was not task of this paper. As essential research result, authors propose to use GIDOP EOS eos.com, including its product LV https://eos.com/lv/, as basement of low-cost GIGESS for GPRM and NRM within MAA while Covid-19 pandemic and climate change.

Discussion

It is worth noting, GIDOP EOS can be used in and training and educational purposes for decision support within GPRM and NRM while Covid-19 pandemic and climate change. The essential task of university practical learning (UPL) will be to teach students the practical aspects of work with GIDOP EOS tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies, that can reduce total cost of training and learning processes while Covid-19 pandemic.

Conclusion

Here are described results of digital technologies development for GPRM and NRM within MAA, adapted to Covid-19 pandemic. In studies, there are used methods of data bases constructing within digital online platforms, web-technologies and virtual reality tools. Also, there are used Foresight technologies, theory of decision making under uncertainties, risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space. As digital tools, there is proposed to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, there is proposed a structural model, that combines the investment objectives with cost of adequate managerial support, adapted to Covid-19 pandemic conditions. As essential result, there is proposed to use GIDOP EOS eos.com, including its product LV https://eos.com/lv/, as basement for low-cost GIGESS for GPRM and NRM within MAA while Covid-19 pandemic and climate change. The research results presented in this article has significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state

environmental control bodies. They can be used in the preparation of master's programs in environmental economics.

Abstract

The theoretical aim of this article is to organize the hypothetical aspects of catering services and promotion, with particular emphasis on promotion on the Internet, and in the empirical area, presenting the scope of e-promotional activities of the catering industry during the first wave of the coronavirus pandemic on the example of the social media Facebook. The article consists of three substantive parts, as well as introduction and summary. The first and second parts of the article mainly cover theoretical considerations regarding the essence of catering services and the basic aspects of promotion in the traditional and modern approach, with particular emphasis being put on social media. The third part of the study discusses the results of qualitative research conducted using the method of observation on the type of undertaken activity of the catering industry in the field of e-promotion based on social media, namely Facebook. The time scope of the qualitative research was the lockdown period in Poland (March - May 2020), whereas the subjective scope encompassed establishments providing catering services in Poland.

Keywords: Catering Services, Promotion, Social Media, Coronavirus

Introduction

A condition for the functioning of modern catering companies is not only offering an attractive service product, but above all, using modern promotional tools. On March 12, 2020, the World Health Organization reported that a significant increase in SARS-CoV-2 coronavirus cases, causing a disease known as COVID-19, was high enough to call it a pandemic (WHO, 2020). In view of this situation, most governments in the world obliged catering companies to stop providing their services in their current form, i.e. on-site service. The introduced regulations have allowed for the provision of catering services, however only in the form of delivery to the customer, personal collection by the customer (the so-called take-out) and drive-thru. In the current situation, the importance of the Internet in the context of access to information has increased even more. Moreover, e-promotion has become the only way catering companies (Kotler, Bowen, Makens & Baloglu, 2017) can reach customers, which in turn provided an opportunity for providing any kind of business and surviving on the market until restrictions on the provision of on-site catering services are lifted.

The theoretical aim of this article is to organize the hypothetical aspects of catering services and promotion, with particular emphasis on promotion on the Internet, and in the empirical area, presenting the scope of e-promotional activities of the catering industry during the first wave of the coronavirus pandemic on the example of the social media Facebook.

The theoretical part of the article is the result of literature studies in the field of marketing and tourism economics, as well as industry reports on the coronavirus pandemic. To meet the empirical goal of the article, qualitative research was conducted using the method of observation on the type of undertaken activity of the gastronomic industry in the field of e-promotion based on social media during the pandemic (analysis of content of fan pages run by catering service providers shared on Facebook). The time scope of the qualitative research was the lockdown period in Poland (March - May 2020), whereas the subjective scope encompassed establishments providing catering services in Poland. Furthermore, methods of logical operations (primarily deduction and induction).

Theoretical and Analytical Considerations on The Example of Facebook” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Selected aspects of catering services and restrictions in the scope of their provision during the coronavirus pandemic

One of the oldest forms of economic activity in human history is gastronomy (Hjalager & Richards, 2003), as its origins started with the first family (Santich, 2004; Chossat & Gergaud, 2003; Dalby, 2013). Catering services (Scarpato, 2002) are understood as satisfying human nutritional needs in the form of production-service activities carried out in open catering establishments such as restaurants, bars, cafés, etc. In addition to performing economic and nutritional functions, the provision of catering services includes creating conditions for the creation of specific social relationships, upbringing and educating the consumer, organization entertainment or interpersonal integration.

Based on the literature on the subject, three basic functions of gastronomy can be distinguished (Sidorkiewicz & Pawlicz, 2015):

1. production (applies to the processing of raw materials into finished products),
2. service (consists of the provision of services such as serving drinks and meals),
3. commercial (consists of sale of finished products).

According to W. W. Gaworecki (2000), the types of catering facilities can be classified based on the criterion of the scope of conducted activity, with the division as follows:

- food facilities, which include, among others: restaurants, universal bars, eateries and fast food outlets, bistros and snack bars,
- complementary facilities, which include, among others: cafés and tea rooms, pastry cafés, wineries and wine bars, breweries and beer pubs, and entertainment bars,
- catering outlets, which include, among others: buffets, fish and chip shops, drinking rooms, ice cream parlours.

A relatively higher use of use of catering services can be observed in Polish households, in particular those with higher income. Every year, Poles are spending more and more on food services provided outside their homes. It has become popular to celebrate special occasions at catering establishments, or travel, which is inextricably linked to eating out (Gutkowska & Piekut, 2016). Unfortunately, it seems that the use of such services will be limited in the near future, as due to the information issued by the World Health Organization on the global pandemic, on March 13, 2020, the Polish government for the first time decided to suspend the operation of restaurants and other catering outlets in their current form, i.e. service on the spot. The introduced regulations have allowed the provision of catering services, however only in the form of delivery to the customer, personal collection by the customer (the so-called take-out) and drive-thru. In reference to the theory and classification of catering functions, it can be stated that during the first wave of the pandemic of the coronavirus pandemic, the scope of catering functions has been reduced from three to two, i.e. the production and commercial functions.

According to data provided by Statistics Poland (GUS, 2020), there were 69.8 thousand catering establishments in 2018, of which 27.6% were bars and 28.2% restaurants. Only some of them could switch into the scope of business activity proposed by the government, whereas the remaining facilities had to be closed. A survey conducted by Briefly (a website providing brokerage services in finding the right establishment for a party or a special event) states that as many as 67% of companies and establishments from the catering and event industry have completely stopped their business activity. The analysis of data prepared for Business Insider Polska (Wąsowski, 2020) by the Nomee company, which provides a sales system for catering outlets, shows that the daily turnover (23-26.03.2020) decreased by 70-80% as compared to the days of the last, so-called "Normal", week (02/08/03/2020). The data covered over 200 establishments from several cities from all over Poland, including Warszawa, Trójmiasto, Bydgoszcz, Kraków, Toruń, Płock or Mikołajki. Similar calculations were presented in the industry website https://www.horecatrends.pl/ (2020), according to which in the first days of quarantine the majority of catering establishments recorded a decrease in turnover by approx. 60%.

With the “defrosting” of the economy in Poland, the existing restrictions on the provision of catering services were lifted. The Polish government has decided to divide the plan to "thaw" the economy into four stages. The first one entered into force on Monday 20 April 2020, the second one entered into force on 4 May 2020, while the third one, which allows to conduct stationary catering activities under a sanitary regime, was introduced on 18 May 2020.

Since the reopening of the restaurants, the restrictions have changed, however, as a rule the owners of the restaurants have to ensure safe distances and hygiene measures for guests and regularly disinfect the areas used by consumers.

Social media as a tool of promotion on the Internet

In literature on marketing, the concept of promotion can be interpreted differently and evolves dynamically together with the changing society. Promotion (Kotler, 2006) can also be defined in two perspectives: narrow and wide. The former includes a set of activities and means through which an entity transfers product information to the market, shapes the needs of potential buyers, stimulating and directing demand with a view to reducing its price elasticity (Wiktor, 2001). This approach is characterized by market connectivity and impact on the market. On the other hand, the broad approach is often synonymously referred to as "marketing communication" or "enterprise communication policy with the market".

Still unlimited consumer needs force market entities to use more and more modern forms of communication with the market. These relations are currently based on modern media, mainly the Internet. As a marketing communication channel, it is a great tool for reaching consumers on several levels of perception. The variety of forms, speed of communication and the ability to precisely measure the effectiveness of all campaigns, significantly affect the high dynamics of the increase in the allocation of advertising budgets in this channel (Raport: Polska branża hotelarska na Facebooku 2012, 2012).

Based on the definition of the concept of promotion and the channel, i.e. the Internet, it is possible to define online promotion, i.e. e-promotion. E-promotion is a set of activities carried out on the Internet, through which the supplier sends a message to the market, which results in an increased interest of the recipients of the message in the product, brand (Schivinski & Dabrowski, 2016) or enterprise. This is a way used by the seller of products to communicate with the potential buyer via the Internet, i.e. the process of transferring information between entities. Today, communication is not only the transfer of information, but also the creation of relationships (Tiago & Veríssimo, 2014), community (Perenc, 2006).

The composition of such promotion has not been clearly classified in the literature. The tools and instruments belonging to it vary depending on the author. In general, the promotional mix includes advertising, sales promotion, public relations, personal selling, and direct marketing (Żurawik, 2009). In this set of promotional tools, some authors additionally distinguish sponsorship (Berndt & Hermanns, 2013). K. Orfin, A. Sawińska and M. Sidorkiewicz attempted to combine tools of classical promotion and e-promotion with examples of their means (Orfin, Sawińska & Sidorkiewicz, 2012). The examples listed in Table 1 are not a summary of all possible actions, but present only a general picture.

Table 1: List of promotional tools in traditional and modern terms (e-promotion)

Tools	
Classic promotion	***e*-promotion**
Advertisement	
• direct response advertising - television (advertising spot), radio (audio spot) and press (advertisements, visual advertising, etc.) • leaflets, advertising brochures, folders, posters	• banner forms • pop forms • floating ads • sent advertising and other formats
Sales promotion	
• samples, testers, discounts at the point of sale	• shopping platforms • auctions • online stores (e.g. special offers, discounts)
Public relations	
• Press releases • custom publishing houses • articles and papers • business cases • conferences, symposia, seminars, conventions • speeches • interviews • press conferences • media patronage	• cooperation with media • presence on online news websites • response to criticism posted on websites • participation and activity of the entity in discussion groups • online sponsoring • usage of interactive forms • viral marketing
Personal selling	

• direct contact with the seller "face to face" • contact by phone	• contact with the seller via: messengers such as Gadu-Gadu and Skype, interactive websites, social networks, chat, telephone
Direct marketing	
• advertising mail (with and without address) • telemarketing • catalogue sales • direct response advertising (TV, radio and press) • advertisement with feedback channel (e.g. advertisement with the phone number and address where the purchase can be made, press advertisement containing the ordering coupon)	• e-mailing • newsletter
Sponsoring	
• organizational support of the event • charity activities • sponsorship of promotional materials for printing, food, etc.	• sponsorship of a website • sponsorship of a website section • sponsored article • sponsorship of interactive elements • sponsorship of email newsletter

Modern marketing is more and more often using social media (Mangold & Faulds, 2009). Social media marketing involves generating traffic on the organization's website and promoting brands through the use of social networking sites (Sidorkiewicz, 2013), with the best known being Facebook, Instagram, Twitter, LinkedIn, and Snapchat. The potential for these activities is significant, considering the growing number of people who own smartphones and actively use the Internet (Mazurkiewicz-Pizło & Pizło, 2017).

In summary, it can be stated that e-promotion is a response to changes taking place in society in the area of attitudes, needs or preferences. During the first wave of the world coronavirus pandemic, it seems that e-promotion, and especially social media, were the perfect meeting place for catering service providers and potential consumers locked up in homes.

E-promotional tools used by catering service providers. Analysis of fan page content on Facebook

For the purposes of the empirical purpose of the article, qualitative research was conducted by means of observation method on the type of activity undertaken in the catering industry during the first wave of the pandemic in the field of e-promotion based on the social media Facebook. The time scope of the qualitative research concerned the lockdown period in Poland (March - May 2020), whereas the subjective scope encompassed establishments providing catering services in Poland. Furthermore, the content of Facebook fan pages run by catering service providers were analysed.

Facebook (2000) is a social networking service that allows people contact friends and potential friends from their professional and private environment. With it, it is possible to stay in touch with people, post an unlimited number of photos, links or videos, and get to know encountered people better.

The number of Facebook users in Poland is constantly growing. In December 2018, it was used by almost 21.5 million people, which represented nearly 76.5% of all Polish Internet users (Wojtas, 2019). Facebook is still the most popular social networking platform in Poland. However, there can be observed an increasing interest in other social media (Górska, 2018), such as Instagram (especially among young people), TikTok (especially among children) or Pinterest.

By analysing the development of Facebook, it can be observed that more and more market suppliers are trying to find their space there, hoping to increase the scope of their target group. Marketing strategies are being constantly expanded with new elements, and advertising agencies are trying to create even more creative and effective campaigns. Although the involvement of potential clients (referred to as "fans" or followers in social media) looks different in each business industry, every contact with them today should not be underestimated. That is why more and more companies are deciding to become involved in this website (Sidorkiewicz, 2013).

With its great reach, Facebook can be successfully used to promote catering services. Using attractive posts allows notifying a large number of users about the offer. Table 2 presents practical solutions in the field of e-promotion on the Facebook platform, used by selected entities offering catering services. Examples refer to such promotion instruments as: advertising, sales promotion, public relations, personal selling and direct marketing.

Table 2: List of activities to promote conducted on social media by selected entities offering catering services

Promotional mix tools	Tool characteristics	Example of activities in the field of promotion on social media
Advertisement	any type of paid form of non-personal presentation of an entity's offer	The action of publishing sponsored posts regarding the offer of establishment available during the period of restrictions regarding the provision of catering services. This offer has changed due to the pandemic. In addition to the possibility of ordering dishes from the menu (delivery and take-out), more and more establishments offer the so-called “dishes of the day”, consisting in the selection of dishes from a narrow offer available on a specific day of the week (an example is the "Europa Restaurant & Café" in Szczecin (post of 21.03.2020) and the restaurant of the "Park" hotel in Szczecin (post of 26.04.2020)). There can also be observed activity of catering establishments in the area of creating a special offer related to e.g. Easter holidays (an example is "CityWine" in Szczecin (post of 02.04.2020) and the restaurant "Farina" in Kraków (post of 03.04.2020) or the long May weekend (Poles spend free time between 1 and 3 May barbecuing) (an example is the establishment "Spotkanie", post of 24.04.2020 and "Steak House Villa Patrick" in Poznań (post of 28.04.2020)).
Sales promotion	all kinds of activities encouraging consumers to immediately buy a product due to short-term stimuli	The activity of publishing posts informing about promotional incentives encouraging to place an order. An example is the premises "Wyszak - Browar Rodzinny" in Szczecin (post of 07.04.2020), which introduced the following incentives regarding its offer for delivery and takeaway: • on Mondays - a promotion called "Home office", offering a children’s dish for PLN 1 with the purchase of every two regular dishes, • on Tuesdays - a promotion called "Konkurs" (Contest) encouraging to take part in a contest, where one can win a dish for two with home delivery, • on Wednesdays - a promotion called "5-te urodziny” (5th birthday), where for every four pints of beer, the fifth can be bought for only 1 PLN (it should be emphasized that the analysed establishment makes craft beer), • on Thursdays - a promotion called "Słodki czwartek” (Sweet Thursday), where you can buy a dessert for only 1 PLN, • on Fridays - the "Kino domowe” (Home Cinema) promotion, as a part of which popcorn or nachos is added for free to every order, • on Saturdays - the winners of the Tuesday contest are announced, • on Sundays - a promotion called “Słodka niedziela” (Sweet Sunday), as a part of which a free cake is added to each order. An action of announcing a contest for clients. An example is the cafe "Café 22" in Szczecin (post of 22.04.2020), which announced a competition for the most original and tastiest cake. The task is to bake a cake, take a photo and post it on the fan page of the establishment. The winning cake will become a part of the "Café 22" menu throughout the month, and its author will receive an excellent fruitcake with home delivery.
Public relations	all activities related to creating the company's	An action regarding informing about activity in the area of Corporate Social Responsibility (CSR). An example is the "Europa Restaurant &

	image as part of bilateral relations (with the environment)	Café" in Szczecin (post of 03.04.2020), which joined #GastroDlaLekarzy and provided meals and desserts to doctors, medical staff and patients of the local hospital. An action, also in the area of CSR, involving the initiation of a local charity event. An example is the restaurant "Byczyn Vegan" in Poznań, which encourages its customers to pay any amount for the so-called "postponed" meal for the homeless and needy (post of 29.04.2020). The restaurant will prepare meals for people in need for the funds raised. An action of participating in a Facebook chain letter, which began during the pandemic and consisted of publishing old childhood photos with the note "challenge accepted". The restaurant of the "Park" Hotel in Szczecin (post of 23.03.2020) also decided to participate in the initiative and published photos of the establishment from before the war. The action consisting in informing customers about the opening of premises in a stationary mode and new rules of functioning in the sanitary regime (posts from the second week of May 2020 of all restaurants planning to reopen).
Personal selling	all activities related to the direct contacts of the supplier with the client (personal communication of the company with the market)	An action based on direct contact with clients using the "Messenger" application on Facebook. An example is the correspondence on 27.03.2020 with the restaurant "U Kelnerów" in Szczecin. An action of using the chatbot in the "Messenger" application on Facebook. It is about using intelligent technology that automates answering repetitive questions from customers. An example is the restaurant "Limonka" in Warszawa (attempted contact made on 22.04.2020), where this technical solution automatically sends answers to the following questions: "What dishes do you serve?", "Can I see the menu?", "What is the location?" and "Is delivery possible?"
Direct marketing	all actions involving contact between the supplier and the client, during which the message is dedicated to a specific and usually a single recipient	An action of publishing posts on the fan page run by the establishment, dedicated to people "following" a given establishment. An example would be the restaurant "Brasileirinho" in Szczecin (post of 09.04.2020), which offered its customers the sale of the so-called "Vouchers for the future" for catering services to be used by the end of 2020. For the purchase of a voucher over PLN 200, the customer receives a bottle of red, white or sparkling wine.

Source: own elaboration based on fan page on Facebook of the following catering service providers: "Brasileirinho", "Byczyn Vegan", "Café 22", "CityWine", "Europa Restaurant & Café", "Farina", "Limonka", "Park Hotel", "Spotkanie", "Steak House Villa Patrick", "Wyszak - Browar Rodzinny".

The content of the analysed fan pages of catering service providers proves that Facebook gives entrepreneurs the opportunity to use virtually all promotional mix tools (except sponsorship). Moreover, the activity of the analysed entities compared to the period before the pandemic can be assessed as definitely greater, which is not surprising. An analysis of the online actions clearly shows that they are aimed at achieving specific behaviour of recipients. The identifiable goals of Facebook e-promotion of catering service providers that can be identified include, first of all, providing information on the catering offer, stimulating, encouraging and persuading potential consumers to buy the products, but also breaking the barriers regarding ordering dishes at home or picking them up (takeaway or drive thru).

To sum up the issue of the promotion of catering services in social media, the national initiative of the catering industry, which began on April 22, 2020, should be mentioned. The goal of the campaign was to support catering businesses by encouraging as many customers as possible to order meals in restaurants through currently available sales channels: take-out, delivery and drive thru (Kaszuba-Janus, 2020). The patronage over the event was taken by Związek Pracodawców Hoteli, Restauracji i Cateringu Pracodawców HoReCa (Association of Employers HoReCa),

which is an industry organization representing catering companies operating on the Polish market and abroad. The campaign to promote the catering services of Polish suppliers was planned to consist of four steps: firstly, publicizing the campaign on the Internet by the online community taking part in the event #smacznewsparcie#środynazamówienie (#tastysupport#Wednesday'sorder); secondly, having the message reach others by sharing details about the action on social media; thirdly, ordering a take-out meal on Wednesdays, by delivery or via the drive thru window, and publishing a photo of the ordered meal as well as tagging it #tastysupport#Wednesday'sorder; and fourthly, repeating of the third step.

Summary

The analysis of Facebook fan page content of catering service providers allows drawing the conclusion that the activity of the catering industry during the first wave of the pandemic in terms of e-promotion was varied and multidimensional. During the first wave of the coronavirus pandemic, conducting e-promotional activities on Facebook on a large scale provides a greater chance of being presented to potential clients, which was one of the main opportunities to reach the client and the chance of functioning and survival on the market until restrictions on the provision of on-site catering services are lifted.

In conclusion, it should be emphasized that this study presents only a fragment of the issue regarding the use of e-promotion by the catering industry in relation to the coronavirus pandemic. The subject matter requires further exploration based on theoretical considerations and empirical research. An interesting aspect of future research would be the verification of a relation between the activity of entities providing catering services in the field of e-promotion and their economic situation, determining their survival on the market after the pandemic.

Abstract

We measured the economic activity and stock exchanges of Germany and Austria as developed countries, and compared it with Croatia, the newest EU country, in order to demonstrate the level and direction of economic integration and historical connections. Economic integration has been researched by ARCH models in which dependent variables are stock market indices and undependent variables main macroeconomic indicators. Traditionally, Croatia has been dependent on the German and Austrian economies, due to good economic and political connections in the past. The empirical findings obtained in application of ARCH method from 2000 to 2018 provide evidence of economic integration of Croatia with Germany and Austria, but in a somewhat lesser extent. Austria has strong economic connections with Germany, while the process of economic integration of the Republic of Croatia has not yet been completed. The slower economic integration of the Republic of Croatia demonstrates still insufficient economic development, the exigency to continue reforming and to achieve effective economic growth.

Keywords: Economic integration, stock market volatility, EU entry, ARCH methodology.

Introduction

As a small, open transition economy, Croatia has strong trade links, especially with nearby Germany and Austria. According to Sadecki (2013) and Eurostat data base (2018) Croatia's one of the most important trading partners are Germany and Austria. Those links are due to historical facts and regional connectivity, which is also obvious in the significant presence of German and Austrian banks in Croatia in the form of banking affiliates, as well as the presence of companies such as the major German shareholder Deutsche Telecom (operating Hrvatski Telekom) on the Croatian market.

The authors analyze the level and direction of economic integration e.g. the dependence of the Croatian financial market in comparison to the Austrian and German markets. One of the signs for the closer economic integration are their mutual stock market trends while Geambasu et al. (2014) state that there is a significant number of papers and studies focused on examining financial momentum transfer from developed to less developed financial markets by using macroeconomic variables. Dewandaru et al. (2018) emphasize that financial integration is a desirable goal, because it eliminates national risks and provides more secure portfolio investments across various countries. Prettner and Kunst (2012) have found that large countries have often a strong impact on the economic performance of their small neighbours. Some financial integration indicators among these countries can be regarded as the result of significant economic relations (Jagric et al. 2006).

This paper deals with the stock markets of Germany and Austria, representing developed countries, and Croatia, a less developed country, to discover and compare their levels and interrelations. This was done using the Autoregressive Conditional Heteroskedasticity (ARCH) method, by applying the main economic indicators in Germany, Austria and Croatia to monthly base data compiled from 2000 to 2018.

The Theoretical Background of Economic Integration

Financial market integration in the European Union is one of the necessary conditions for the efficient allocation of capital (Kučerova 2009). Fratzscher (2002) and Cappiello et al. (2006) found that new EU member states rapidly develop their financial markets but with different degrees of financial integration. However, nearby countries have stronger trade and financial ties which has been refracted on better economic integration.

The world's capital markets have definitely become increasingly integrated in the last thirty years, although some exceptions and dispersion across countries and sectors must be acknowledged (Carrieri et al. 2007). The aim of accelerating European financial integration is to eliminate specific country risks and decrease costs, providing better opportunities for international investors to diversify their portfolios (Erdogan 2008). Stock markets diversify risk, create liquidity, mobilize savings, improve dissemination of information and contribute in other ways to economic growth. As these stock market functions become more efficient and effective, we can expect better incentives for economic growth (Sawhney et al. 2006). It is important to emphasize that New Member States become increasingly financially integrated and more vulnerable to external shocks when they are part of a common financial market. As a main factors of new EU member states in convergence and growth process are overall growth of productivity factors and significant capital inflows (Abrham, 2012). Economic integration and cooperation of the European countries makes Europe far more competitive on the global market while concept of economic governance within the Union is of critical importance (Bartušková and Vrňáková, 2014).

Croatia is undergoing the transformation from an, old autocratic socialist system towards a market economy. Over the past fifteen years, several Central European countries have made great progress towards integration with the world economy (Stavarek and Heryan 2012). Some Southern European countries have made good progress towards European and global financial integration while others have shown weak financial integration. There is also strong financial integration between Central and Eastern Europe through western European banks (Herrmann and Mihaljek 2013).

Many authors deal with the impact of macroeconomic factors on stock market indices, and Table 1 presents the most important outcomes of these studies, based on the inference that macroeconomic variables have a significant impact on stock market indices.

Comparison and Connection of German, Austrian and Croatian Economy

Reforms launched by the German government in 1998 were deemed necessary to address previously chronically high unemployment and low average growth, and contributed to strong growth and falling unemployment until the world crisis of 2008. Owing to its high dependence on exports, Germany was among the economies hit hardest by the financial crisis. Unlike most other countries, Germany emerged from the crisis quickly to become stronger than before (Storm and Naasterpad 2014). The flexibility of German industrial relations is the main element in its success and recovery from the crisis, since it allowed an appropriate, reaction according to the global demands (Dustmann et al. 2014). Germany is a European and world economic leader whose growth has been generated by strong exports.

Austria has a high-performing, wealthy economy which is closely tied to other EU economies, especially Germany's (Prettner and Kunst 2011). Before the crisis Austria recorded strong exports and employment growth, while after the crisis, growth should continue to be underpinned by strong investment and private consumption, thanks to a supportive monetary policy and stabilizing labour market, but the outlook remains vulnerable to uncertainty in the external environment (Focus Economics 2017).

Croatia is a small economy with strong connections with foreign markets. Between 1994 and 2008, the Croatian economy showed relatively high rates of economic growth. One of the main drivers of growth in the national economy was domestic demand, which between 2001 and 2008 grew by more than six percent per year (faster than the growth of GDP). One of the signs of progress in the region was the inflow of direct foreign investments, especially before the crisis of 2008 started. Less encouraging was the fact that investments were directed more to real estate and financial services, which meant a lower probability of realizing export income than if they had been

directed towards production. Between 2009 and 2010, actual household consumption fell by nearly 10%, while domestic demand increased due to private consumption based on borrowing (Benolić 2012).

Generally, we can state that the German and Austrian economies are highly integrated (Prettner and Kunst 2012). As a small, open economy, Austria is characterized by strong links with Germany, its largest neighbour. The ties between the two countries are the result of geographical proximity, a common language, and several cultural and institutional similarities, along with their turbulent common history. Germany has always been a major influence on Austria's economic development (Fenz and Schneider 2008). In Table 2 we can see the percentage of exports and imports for these countries and their interrelations, from 2000 to 2018.

As expected, Austria is one of Germany's most important trading partners. During the observation period, Austria was consistently Germany's third most important exporter and importer. From the Austrian point of view, Germany is Austria's most important trading partner, ranking in first place as Austria's most significant exporter and importer. Thus, we can conclude that the Austrian economy depends a great deal on the German economy.

In observing the structure of Croatian exports and imports, we discovered that during the observation period, Germany took third and Austria fifth place among Croatia's most important exporters. Germany was the second and Austria the fifth largest importer (on average).

When we compare Croatian export value from 2008. with 2018., export to Germany had been increased for 86% which is an increase about 18% of all exports. It is important to emphasize that there is a certain correlation of the German GDP increase, movement of goods exports to Germany and overnight stays of german tourists which came to Croatia (Croatian Chamber of Commerce, 2019).

As Sadecki (2013) states, Croatia has depended on the German and Austrian economies as a result of historical and economic relations. Šonje and Vrbanc (2000) point out that there are significant relationships between the German, Austrian and Croatian economies which are reflected in business cycles. In 2015, the Croatian financial market consisted of 14 banks in private domestic ownership and 16 banks in foreign private ownership – most banks were in Austrian ownership and their assets accounted for 60.5% of all bank assets. From 2000 to 2014, foreign Austrian capital prevailed in the Croatian banking system, while German ownership was insignificant (Croatian Central Bank 2014).

From 2000 to 2008, Croatia had a higher increase in GDP in contrast to Germany and Austria, mostly due to the transition process, often characterized by higher growth rates. Up to 2008, the primary source of Croatian economic growth was the accumulation of physical capital, followed by the growth of multifactor productivity (Dombi 2013). After 2008, the situation changed due to the financial crisis, impacting all three countries. As a transition country, Croatia has had the highest levels of unemployment and inflation. All three had similar levels of investments, regardless of their level of economic development. It is also important to emphasize that although the German and Austrian economies were far stronger than the Croatian one, they were marked by significantly higher government debt during the observation period (see Table 3 in appendices). Governments and enterprises should innovate their governance toward social responsible behaviour (Duh and Štrukelj 2011; Dankova et al. 2015).

However, the performance of the economy in any country depends on monetary policies, such as the money supply, exchange rate and interest rate, and fiscal policies such as government revenue and expenditure. These policies have a mutual effect on each other.

The German, Austrian and Croatian stock markets

The DAX Index is the benchmark index for the German equity market. It tracks the performance of 30 selected German blue chip stocks traded on the Frankfurt Stock Exchange, which represent around 80 percent of the market capitalization listed in Germany. More than 50 percent of the total trades on the Frankfurt Stock Exchange are from investors located in countries outside of Germany (Frankfurt Stock Exchange 2018). Since the mid-1990s, the disclosure and enforcement regulation of the German capital market has taken a new form. Regulators have increased requirements on disclosures, and expanded enforcement mechanisms, most notably by introducing a new supervisory regime (Meser et al. 2015).

The Vienna Stock Exchange is one of the longest-established exchanges in Eastern and South East Europe, but over the last decade, its strength has waned due to its Warsaw counterpart (Wu 2013). The Austrian Traded Index (ATX) is a major stock market index which tracks the performance of all companies listed in Austria.

The Croatian Zagreb Stock Exchange Index CROBEX is a major stock market index which tracks the performance of 25 large companies listed on the Zagreb Stock Exchange. In order to be included in the CROBEX Index, stocks have to be traded in more than 90 percent of the total number of trade days in the selected time period.

The Croatian stock market has tried to adapt its standards to international ones by improving the disclosure practices of firms, order execution, ownership rights, and reducing limitations on international capital flows (Syllignakis and Kouretas 2006). However, it still remains small, fragmented and underdeveloped in comparison with the capital markets of developed countries.

Data and Methodology

Based on studies investigating the correlation of stock market indices and macroeconomic variables in the empirical literature, we constructed a data set of explanatory variables that are usually included in models according to the literature: capital inflows expressed as percentage points of GDP, the consumer price index, the exchange rate expressed as the price of one unit of foreign currency in units of domestic currency, the industrial production index, interest rates (p.a), unemployment rate (expressed as a percentage of the total work force) while for the Austrian model we also used the DAX index and for the Croatian model the DAX and ATX indices due to the spillover effect. The equations can be written as follows:

$$CROBEX = \alpha 0 + \alpha 1CAPt + \alpha 2EXRt + \alpha 3GODt + \alpha 4INPt + \alpha 5INRt + \alpha 6CPIt + \alpha 7UNEt + \alpha 8DAXt + \alpha 9ATXt + \varepsilon t$$
(Eq. 1)

$$ATX = \alpha 0 + \alpha 1CAPt + \alpha 2EXRt + \alpha 3GODt + \alpha 4INPt + \alpha 5INRt + \alpha 6CPIt + \alpha 7UNEt + \alpha 8DAXt + \varepsilon t$$
(Eq. 2)

$$DAX = \alpha 0 + \alpha 1CAPt + \alpha 2EXRt + \alpha 3GODt + \alpha 4INPt + \alpha 5INRt + \alpha 6CPIt + \alpha 7UNEt + \varepsilon t \quad (3)$$
(Eq. 3)

Description:

CPI: Consumer price index
EXR: Exchange rate
INP: Industrial production index
INR: Interest rates (p.a)
UNR: Unemployment rate
DAX: German stock index
ATX: Austrian stock index
CROBEX: Croatian stock index
εt : error for the t period
σ_t^2: conditional variance

Eq. 1: Croatian model
Eq. 2: Austrian model
Eq. 3: German model

We relied on the database of the European Commission (2018) and those of national statistical bureaus. A monthly time series was used for the period from January 2000 to December 2018, in selected countries. Local stock price indices (closing prices) were used for each of the stock markets examined: DAX (Germany), ATX (Austria) and CROBEX (Croatia).

In different estimations of the empirical evidence of a relationship between stock exchange indices and main (macro) economic indicators, we used the Autoregressive Conditional Heteroskedasticity (ARCH) methodology. Many studies use ARCH models for analyzing the behaviour of financial time series, due to their ability to capture non-linearity and volatility clustering in stock data (Al-Zararee and Ananzeh, 2014).

Engle (1982) first introduced an ARCH model appropriate for stock markets characterized by time-varying volatility, while Bollersev (1986) proposed the GARCH model, in which the explanation of conditional variance could be captured parsimoniously. It has been used as a variance equation to be estimated simultaneously with the normal regression model in the mean equation. The GARCH (1,1) model is stated as follows:

$$Y_t = \emptyset_0 + \sum_{i=1}^{k} \emptyset_i Y_{t-i} + u_t \qquad u_t \sim N(0, \delta_t^2) \quad \text{(Eq. 3)}$$

$$\delta_t^2 = \omega + \sum_{i=1}^{k} \alpha_i u_{t-1}^2 + \sum_{j=1}^{p} \beta_i \delta_{t=j}^2 \qquad \text{(Eq. 4)}$$

The estimation of GARCH model involves the joint estimation of a mean and conditional variance equation. Equation (3) is the conditional mean equation, autoregressive process of order k (AR(k)) while the parameter $\emptyset_0$ is the constant, k lag length, ut is the heteroskedastic error term with its conditional variance. Equation (4) is the conditional variance equation specified as the GARCH (p,q) model where p is the number of ARCH terms, and q is the number of GARCH terms. This method eliminates conditional heteroscedastics problems and makes the results in the mean equation more valid (Al-Zararee and Ananzeh 2014).

GARCH modeling reguires several stages of data testing to determine data are significant to the model. We used ARCH effects test, descriptive statistics, Jarque-Bera normality test, stationarity test, autocorrelation test, heteroscedasticity test, model selection criteria, and Value of SC and AIC test for each model.

Before we initiated modelling the ARCH/GARCH model, we tested the heteroscedasticity of the residual dependence variables to prove the presence of the ARCH effect, thus verifying the validity of the ARCH/GARCH model (Table 4).

Results of the implemented ARCH tests indicate the presence of ARCH effect, hence we can use ARCH methodology because the p value of Chi square is less than 0.05. Table 5 shows descriptive statistics for the stock market indices of countries under study that contains; mean, median, max, min, skewness, kurtosis and Jargue-Bera results.

The average value indicates the loss of the stock market index during the observed period for Austria and Germany, while in the case of Croatia it recorded a rise in value. However, the most common value in Croatia example is negative and significantly higher than Germany. High variability in price is visible in all countries based on difference between maximum and minimum yields. All countries have extremely high volatility in accordance with standard deviation values. The Croatian market had a standard deviation of 0.999719, Austria 0.998641 and Germany 0.996721, which indicates that they are almost equal in volatility. The high volatility indicates that there is a greater chance of achieving high rates of return on investment, but certainly at higher risk. The Croatian stock exchange index is significantly asymmetrical, right as opposed to the Austrian and German stock indices that are skewed to the left, whereby all stock indices have excess kurtosis. This respective indicates that yield distribution is not normal. High levels of kurtosis (exceeds normal value of 3) indicate that returns are leptokurtic. In addition to the descriptive part of the statistics, the Jarque-Bera test is significant at 1%, meaning that stocks are not normally distributed and skewed. Therefore, it is an additional evidence of the suitability of ARCH/GARCH models.

All variables were seasonally adjusted (Eviews 10) on the basis of monthly data from 2000 to 2018 for individual regressions. We used the Augmented Dickey-Fuller (1979) to test a series for the presence of a unit root. According to the test results given in Table 6, all variables are stationary in the form dlog (x) i.e. integrated of order 1.

To determine the lag length, we used the Schwarz Information Criterion and Akaike and Hannan-Quinn Information Criterion because, they perform better over a longer period of research (Ashgar and Abid 2007; Akaike 1987). A maximum of twelve lags was considered for each variable when determining the lag length.

We verified the suitability of the ARCH/GARCH model by first performing GARCH (1,1) models for each individual country. GARCH (1,1) is used for Croatia and Germany, because the lagged square error term is significant - satisfies the specification requirement of the model, while for Austria ARCH (1,0) is used, since the coefficient of GARCH (1,1) lagged residual variance is insignificant and accordingly the coefficient of the lagged squared residual is significant.

The validity of the displayed models is additionally confirmed by Breusch-Godfrey test, known as the Langrage Multiplier test, which indicates that there is no autocorrelation in residuals. Breusch-Godfrey test produced Obs * R-squared probability value greater than 5% for Croatia (0.1292), Austria (0.5734) and Germany (0.5218), so H0 hypothesis can be rejected, which means that our models do not actually contain the problem of autocorrelation. We have also tested our ARCH/GARCH models on heteroscedasticity (Table 7).

Results of the ARCH LM test indicate that we have resolved the heteroscedasticity problem through our models. The obtained coefficients are greater than 5% and H0 is not rejected: There is no heteroscedasticity of the residuals.

Results and Discussion

Significant determinants of the Croatian stock exchange index movement in the observed period are capital inflows (1.24) and Austrian stock exchange index (0.12) and German too (0.12), while variable interest rates (-0.01) and inflation (0.85) are significant at the level of 10% (Table 8). In the observed period, Croatia recorded significant capital inflows due to foreign direct investment, mainly related to the non-producing banking sector and insurance companies (Kersan-Škabić and Tijanić 2014). This indicates a limited increase in economic activity that is not accompanied by strong industrial development and in our case it is obvious that industrial production has no impact on the movement of the stock market index.

The transition from planned to market economies in the South East European region has led to rapid financial developments. The strong presence of foreign banks in these countries (in the case of Croatia, Italian and Austrian banks feature the most) has not seriously helped reduce interest rates, but has broadened the supply of financial products and services to the government, companies and households (Poghossian 2008; Festić et al. 2009). Croatia has witnessed increased financial integration that accelerated its EU accession, but it is still relatively weakly financially linked to the German index. Croatia achieves better financial connection with the US market than European market (Halilović and Ergun 2015).

The Austrian and German stock indices have almost equal impact on CROBEX movement. Germany as the economic power of Europe represents a financial centre and it is logical that there is an impact on CROBEX, since by accession to the EU Croatia became economically integrated. However, DAX influence on CROBEX is not as powerful as its ATX impact is strong, indicating a strong interconnection between DAX and ATX.

The influence of DAX and ATX stock indices on CROBEX varies in time, and their strongest correlation is mainly related to global effects such as the global economic crisis in 2008 (Dajčman 2013). With the accession of the Republic of Croatia to the EU, financial integration of Croatia with European capital markets has somewhat increased, but not significantly. There is no significant contagion effect between major European and Croatian stock markets (Dajčman 2014).

Equally strong influence on CROBEX, other than DAX, has ATX, which can be explained by the fact that foreign ownership (especially Austrian) in the banking sector is extremely prominent in Croatia (Botrić and Slijepčević 2008).

Significant influence on DAX has industrial production and interest rates. Germany is world economic power and it is no surprise that industrial production (0.61) has strong influence on the movement of its stock index. Industrial production has always been linked to economic growth, while the stronger influence of industrial production in Germany was the result of higher economic growth (Krchnivá 2016).

The interest rate had a negative impact on all three markets, in line with the theory of financial integration. The German and Austrian economies had generally low interest rates during entire observed period while Croatia started with rather high interest rates which gradually decreased over the last few years, due to integration with the EU and financial integration in general.

On examples of Croatia and Germany, the coefficients both the lagged squared residuals (α) and lagged conditional variance (β) in the Variance equation are significant (probability less than 5%). Sum of ARCH (α) and GARCH (β) coefficients is very close to one which indicates that volatility shocks are quite relentless in both cases and that unconditional variance is stationary. The impact of shock leaves longer consequences on the capital market, which indicates high risk of the capital market. The past volatility in cases of Croatia and Germany ($\beta > \alpha$) means that the stock markets were more affected by past volatility than economic news, which is particularly evident in the example of the Republic of Croatia. Greater volatility brings higher risk in the financial capital market. Also, we can see on example of Austria that lagged squared residuals (α) are significant, which means that volatility clustering exists in the present moment.

Concluding Remarks

The research has shown that the smaller impact of the German and Austrian stock market indices on the Croatian CROBEX is evident, which indicates a financial integration of lesser extent despite good economic relations. In line

with the expected, the German stock exchange index has a strong influence on Austrian stock exchange index, as a result of strong social and economic ties, financial integration and the strength of the Austrian economy.

We can also conclude that there are different impacts of macroeconomic variables on stock indices, suggesting that the observed countries do not have any more significant common links in this regard. Only the rise in interest rates in all observed countries has a significant negative effect on the movement of the stock market index. The similarity of stock indices is reflected in their high volatility. In the examples of Croatia and Germany, past information has a stronger impact on future returns than current information, which is the result of higher risk.

Namely, each country has its own specific characteristics reflecting the movement of the stock market index. The capital inflows for Croatia as a small open country play a significant role in the movement of the stock market index, while on the other hand for Germany as the world economic power, the industrial production growth significantly influences the movement of the stock market index.

The process of integration of the capital market of the Republic of Croatia has not been completed yet. The slower financial integration of the Republic of Croatia indicates still insufficient economic development, the exigence to continue reforming and achieve effective economic growth. Also, it is important to emphasize that further financial integration of Croatia will be enhanced when Croatia joins the EU monetary union, which is expected to occur in 2022.

Appendices

Table 1: Overview of the empirical literature on macro-economic factors influencing stock market indices

Explanatory variable(s)	Reference	Explanation of theoretical background
Capital inflow	Keong et al. (2010) Tang (2015) Bayar (2017)	Capital inflow has a positive impact on stock market indices and promotes economic growth. Larger capital inflows lead to increased productivity or higher output growth, while stock markets are significant channels through which capital inflow affects economic growth.
Exchange rate	Chun (2012) Walid et al. (2011)	The exchange rate has a significant impact and is an important explanatory variable for studing the volatility of stock exchange indices. Recent studies reveal there is no consensus about the positive/negative

		impact of the exchange rate on stock market indices.
Government debt	Kimathy et al. (2016)	In the case of rising government debt, investors may fear that the government will not be able to repay the debt. This could lead to financial instability and investors may place their investments in more secure countries. Therefore, there is a negative impact of government debt on stock market indices.
Industrial production	Erdogan and Ceylan (2017) Peiro (2016)	GDP growth goes with a rise in industrial production that affects stock market indices positively. Industrial production, which represents output growth, is significantly related to stock market prices.
Interest rate	Knif et al. (2008)	Higher interest rates mean higher costs of borrowing, which have a negative impact on future expected returns. This makes investments more costly and reduces demand for stocks.
Inflation	Benbouziane and Benamar (2009) Al-Sharkas and Al-Zoubi (2014)	There is no consensus in theories and empirical evidence about the influence of inflation on stock exchanges. The influence of inflation on stock exchange volatility may correlate negatively or positively to the stock exchange. The Fisher hypothesis (1930) states that positive correlation can be explained by the expected real rate of interest and expected inflation.
Unemployment rate	Arestis et al. (2007) Feldman (2011)	There is a significant negative relationship between capital accumulation and unemployment, which is reflected in capital market as a negative correlation. Also, higher stock market activity is associated with a lower unemployment rate, meaning it will also have greater impact on stock volatility.

Abstract

To date, numerous studies have been conducted regarding Small and Medium Enterprises (SMEs) performance and sustainability. It is notable that in the global business competitiveness, SMEs are facing various challenges in surviving and sustaining their operations. Thus, SMEs need to exploit all of their available resources including good leadership styles and innovative initiatives to ensure the sustainability of organization's growth. The current study aims at identifying the relationship between leadership style and innovation capital towards the SMEs sustainability. It is always a major academic issue in determining whether a successful leader share similar experiences, attributes and leadership patterns. A good leadership styles can reshape and redefine the direction of SMEs performance. This paper describes the pattern of self-perception of leadership styles among SMEs top management team. Data were collected from 111 SMEs. The results from this study indicate that all leadership styles; directing, coaching, facilitating and delegating have significant relationships on sustainable competitive advantage of SMEs. The Delegating approach shows the highest score as it is indicating that good leadership should be able to delegate responsibilities to others. The results also show that innovation capital is significantly positive towards the sustainability of SMEs performance. This would be the main strategy for leaders in strategizing the appropriate leadership approaches which concentrate on innovation capital as key capabilities of the organization to achieve sustainable competitive advantage. This is very important for the SMEs not only to withstand the competition and strive, but to continue improving their performance with a dynamic market in Malaysia.

Keywords: Leadership styles, Innovation Capital, SMEs and Sustainability.

Introduction

Small and medium enterprises (SMEs) are the backbone of Malaysian economy. According to SME Corporation Malaysia (2019), in 2018, SMEs contribute toward 38.3% of Malaysia's overall gross domestic product (GDP). This indicates that the overall SME sector will be having ~~a~~ growth in performance in a later year depending on external developments. Nevertheless, unpredictable markets could have a negative impact on SME's performance. Challenging business environments demand effective leaders within an organization to ensure of its survival. Akbari et al. (2017) specifically stated that many organizations are having difficulty in handling organizational issues and problems. These issues could include employee loyalty, productivity level, lack of innovation, and many more. The management teams in every organizations need to be well equipped with necessary leadership knowledge for them to be able to steer their "ship" towards the desired course. Leaders need to constantly monitor the changes happening to the organization and make necessary adjustments and adapting their leadership styles that best fits~~s~~ the current business environment (Seah & Hsieh, 2015).

Apart from effective leadership, this study also focuses on the effect of innovation capital towards SMEs sustainability. Innovation can be important resources for SMEs that will generate wealth and drive the expansion of the business (Alrowwad et al., 2020). With innovation, SMEs can a gain competitive advantage and perform better than their competitors. However, in today's competitive environment, large corporations are able to exert pressure on SMEs in terms of their aptitude for innovation (Taneja et al., 2016). This is because they have more expertise and resources (financial, human, physical, etc.) due to greater economies of scale.

In modern times, the issue of sustainability has become more prominent. Eriksson & Svensson (2016) stated that ~~a~~ sustainable development within the organization can be understood as development which meets the economic,

Cite this Article as: Hazlina HASSAN, Shukriah SAAD, Amrizah KAMALUDDIN and Nurhayati AB SAMAD "Leadership Styles and Innovation Capital towards SMEs Performance Sustainability" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

environmental and social obligations of the present, without compromising the capability of future generations to meet their own needs. The increase of public scrutiny and legislative changes force SMEs to re-evaluate their business activities related to sustainability issues (Das et al., 2020). Failure to meet the expectation of the public towards a sustainable goal could potentially lead to resentment from every stakeholders and negatively affect the image of the organization.

There has been little or no research done to determine the effect of situational leadership and innovation capital on corporate performance sustainability especially for SMEs. The results reported in this study would be a value added to SMEs business advisor and SMEs owners. This would be the main strategy needed by SMEs owner to improve their management skills and emphasize high quality products or services to ensure SME survival. Therefore, this study examines important factors of leadership styles and innovation capital for SMEs in terms of performance sustainability. This is very important for the SMEs not only to withstand the competition and strive, but to continue improving their performance with a dynamic market in Malaysia.

Literature Review

Leadership Style

Leadership styles have evolved and changed over the past century. Effective leadership style should be adaptable and flexible which manifested with varying leadership behaviours in different scenarios. Each leader has their styles in managing the organization. The most popular leadership styles often mentioned in academic writings was the Situational Leadership Theory (SLT) introduced by Hersey and Blanchard in 1969 (Thompson & Glaso, 2018). Four key leadership styles that were stated within the theory were Directing, Coaching, Facilitating, and Delegating (Bharti, 2018). Table 1 below shows the basic description for each leadership styles for better understanding:

Table 1: 4 Basic Leadership Styles

Directing	Coaching	Facilitating	Delegating
-Very direct behaviour -Low supporting behaviours -Gives detailed procedures to achieve specific goals and objectives	-High directing and supporting behaviours -Motivates subordinates to make decisions -Provides feedback to subordinates	-Low directing behaviour, high supporting behaviours -Proactive leaders participating with their subordinates -Open minded	-Low directing and supporting behaviours -Delegate responsibilities to subordinates -Expect subordinates to handle the tasks given independently

Suriyadi et al. (2020) stated that effective leaders need to change their leadership styles depending on the competency and commitment level of their followers. Graeff (1983) highlighted the need for behavioural flexibility in leaders towards goal attainment. Flexible leaders are able to think more critical in solving organizational problems. Blanchard et al. (2017) explains that there are 4 development stages for subordinates to master certain task. These are called "The Development Continuum". Figure 1 shows an overview of the stages.

Figure 1: The Development Continuum

Based on Figure 1, each stage have different levels of competency and commitment. Situational leaders must have the ability to give suitable guidance and task support for their subordinates based on their level of development

(Ghazzawi et al., 2017). Blanchard et al. (2017) later explains how each leadership styles can best fit~~s~~ the subordinate's development level as shown below:

- D1 (*enthusiastic beginner*) - with low competence and high commitment, the subordinate will need a Directing leader
- D2 (*disillusioned leaner*) - with low to somewhat competence and low commitment, the subordinate will need a Coaching leader
- D3 (*capable but cautious*) - with moderate to high competence and variable commitment, the subordinate will need a Facilitating leader
- D4 (*self-reliant achiever*) - with high competence and high commitment, the subordinate will need a Delegating leader

Keeping this concept in mind, leaders need to change their leadership styles appropriately in pursuing the organizational objectives and goals. This is important because leadership styles are one of the important contributors towards employee~~'s~~ and organizational performance (Arham, 2014; Fazli & Sam, 2012; Maamari & Saheb, 2018; Mohd Adnan & Valliappan, 2019). Blanchard & Johnson (2015) summarise that an effective leader plans their goals thoroughly, ask for feedbacks, encourage people, and make necessary adjustments based on changing environments.

Innovation Capital

Innovation can be understood as the procedure of creating something new which is crucial to the entrepreneurial process (Barringer & Ireland, 2016). Most of the time they hold specific characteristics which include uniqueness, inimitable, and irreplaceable (Alrowwad et al., 2020). Many different types of innovation that can be produced by a company. Previous literatures has extensively discussed the specifications of innovation and how they can be identified. For example, Knight (1967) categorized innovation into organizational structure, production process, people, and product or service. Oke (2007) has his ~~own~~ idea to categorized innovations which are product (including radical and incremental) and business processes (including administrative, service and production). In recent literature, Baregheh et al. (2012) classify innovations into position, process, product, and paradigm innovation.

Kamaluddin et al. (2016) explains innovation capital in two stages. The First stage involves decisions and activities that take place by pinpointing a problem through research and development (R&D) and the commercialisation of an invention. The second stage involves processes in creating a new product or significantly improving the existing products, services, and any other operations within the organization. The Generation of innovation capital can be important in every company as it will improve the overall effectiveness and efficiency of its operations and thus give a competitive edge in the market (Kamaluddin et al., 2016). Regardless of how innovation can be generated, past studies agreed that innovation capital can have a significant impact on organizational performance (Alt et al., 2020; Kamaluddin et al., 2016; Lichtenthaler, 2016; Prima Lita et al., 2020).

Organizational Performance Sustainability

Teh & Corbitt (2015) describe sustainability as the organization's ability to meet the current needs of both the organization and its stakeholders while ensuring the future needs of stakeholders were not abandoned. In 1987, the World Commission on Environment and Development (WCED) popularized the concept of sustainable development in organizations (Laskar & Maji, 2016). As time goes, sustainability has become one of the primary concerns discussed among politicians, academics and members of communities (Poveda, 2017). This has caused organizations to shift their focus on sustainable practices and reporting from the traditional ways of doing business. Current stakeholders demand that companies conduct their business in an environmentally friendly manner and nurture a healthy work environment. Opebiyi (2020) stated that sustainable development practices include the reduction of pollutions from operations, cost savings, and better management of the human resource.

Mandatory sustainability reporting is considered as recent trends as more stakeholders are becoming aware of the negative impacts of business activities toward the environment and society (Fitriasari & Kawahara, 2018). In Malaysia, the requirement for sustainability reporting includes the disclosure of corporate social responsibility (CSR) within the company's annual report (Bursa Malaysia, 2015). However, this requirement only applies to listed companies, this means that not all SMEs are required to follow the reporting guideline. Not to mention, SMEs might not have the financial and technological advantage to support sustainable development (Das et al., 2020).

Nevertheless, SMEs should take the issue of sustainability seriously. This is because sustainability within an organization is crucial in constructing a good image for the company (Hogan & Lodhia, 2011). Past studies also indicate that sustainability potentially have a significant impact on organization performance (Bodhanwala & Bodhanwala, 2018; Das et al., 2019; Wu et al., 2017). Bad reputation due to environmental scandals could tarnish the company's brand and thus making hard for them to sustain longer in the market (Dekhili et al., 2019). Companies

that have better image gain higher chance of attracting customers to buy their products or services. Nonetheless, sustainability should not be at the expense of economic development (Mauri, 2020). Thomas et al. (2016) emphasize the need to balance (or overcome assumed trade-offs among) economic, environmental, and social responsibilities.

Methodology

A survey was carried out through a questionnaire on a sample of 400 SMEs. The sample of this study was randomly selected from the SMEs database. Total of 400 questionnaires were distributed to SMEs via an online survey of which only 111 (28%) responses were responded. The questionnaire used in this study adopted from Kamaluddin.A et. al (2016), Abernethy (2001) and Crowe (2013). The questionnaire used in this study contained demographic and three other~~s~~ dimensions which are leadership style, innovation capital and organizational performance sustainability. The survey collected measures that would facilitate validating the leadership style with 24 items. Participants could respond from 1(Not Agree) to 5 (Highly Agreed). It also contained 9 items measuring innovation capital. The response set ranged from 1 (Not Agree) to 5 (Highly Agreed). The organizational performance sustainability included 13 items on a scale of 1 (Not Agree) to 5 (Highly Agreed). Data is also checked for normality and reliability. Regression analysis is employed to analyse the data. The Cronbach's alpha values are above 0.70, ranging from 0.917 (Organizational performance sustainability) to 0.927 (Innovation Capital), implying that the data is valid (Geoge and Mallery, 2003) (refer Table 2).

Table 2: Cronbach's Alpha by Dimension

Dimension	No of statements	Cronbach's Alpha
Leadership style	24	0.924
Innovation	9	0.927
Organizational performance sustainability	13	0.917

A normality test was carried out using the Skewness and Kurtosis test on leadership style, innovation capital and performance sustainability. The summary statistics are presented in Table 3.

Table 3: Summary Statistics of Skewness and Kurtosis: Normality Test

Dimension	**Skewness**	**Kurtosis**
Leadership style	-0.756	0.578
Innovation	-0.635	-0.031
Organisation Performance sustainability	-0.205	-0.551

It can be seen that all skewness and kurtosis values are in the range -2 to 2, thus the data is assumed to be normally distributed. Thus the data can be used to further analyse variables relationship.

Results and Discussions

Descriptive Statistics

The Majority of the respondents are female (67.6%). 59.5 percent of the respondents are between the age group less than 31 years old. The Majority of the respondents are Malays (85.6%), followed by Chinese (6.3%) and Indian represents only 1.8% of the total respondents. In terms of respondents' level of education, 40.5% hold a Bachelor degree~~s~~ (40.5%) and only 9.9% hold a Professional degree. The Majority of the respondents are those from middle management (56.8%) and have below 4 years working experience. Majority of the respondents have never received any award for the organisation (76.4%). Only 23.6% have received some form of award for the organisation.

The means and standard deviation for each leadership style are presented in Table 4, Table 5, Table 6 and Table 7.

Table 4: Mean and Std. Deviation of Perception Scores on Facilitate

Statement	Mean	Std. Deviation
I provide staff with the time and resources to pursue their own developmental objectives.	3.81	0.879
I avoid making judgments or premature evaluation of ideas or suggestions.	3.79	1.001
I discuss any organisational or policy changes with staff prior to taking action.	3.78	0.948
I appoint staff into task groups to action policies affecting them.	3.63	0.962
I rotate of team briefer among the staff.	3.56	1.015
I avoid evaluating problems and concerns as they are discussed.	3.52	1.052
Leadership style: Facilitate	3.68	0.695

Table 3 presents the means and standard deviations of perception scores on facilitate. Among the 6 statements, the respondents react most with *I provide staff with the time and resources to pursue their developmental objectives* (Mean=3.81). and the least *I avoid evaluating problems and concerns as they are discussed* (Mean=3.52). It can be concluded that on average, the respondents perceived the leadership facilitate style is to a great extent.

Table 5: Mean and Std. Deviation of Perception Scores on Coach

Statement	Mean	Std. Deviation
I recognise staff's achievements with encouragement and support.	4.00	0.963
I explain the benefits of achieving their work goals to staff.	3.81	0.889
I meet with staff regularly to discuss their needs.	3.75	1.049
I focus on opportunities and not problems.	3.75	1.022
I hold regular meetings to discuss work status.	3.55	1.077
I hold periodic meetings to show support for organisation policy and mission.	3.49	1.026
Leadership style: Coach	3.72	0.726

Table 5 presents the responses on coach leadership style. It shows that the respondents agree most with *I recognise staff's achievements with encouragement and support* (Mean=4.00). These are followed, in descending order, by elements contained in the statements, *I explain the benefits of achieving their work goals to staff* (Mean=3.81), *I meet with staff regularly to discuss their needs* and *I focus on opportunities and not problems* (Mean=3.75), *I hold regular meetings to discuss work status* (Mean=3.55*)* and lastly *I hold periodic meetings to show support for organisation policy and mission* (Mean=3.49). The mean score of 3.72 indicates that the respondents viewed the leadership coach style is relevant.

Table 6: Mean and Std. Deviation of Perception Scores on Delegate

Statement	**Mean**	**Std. Deviation**
I discuss the organisation's strategic mission with staff.	4.13	2.948
I provide staff with clear responsibilities and allow them to decide how to accomplish them.	4.10	0.842
I ask staff to think ahead and develop long-term plans for their areas.	3.94	0.937

I emphasise the importance of quality but I allow my staff to establish the control standards.	3.85	0.926
I ensure that information systems are timely and accurate and that information is fed directly to staff.	3.84	1.075
I expect staff to create their own goals and objectives and submit them to me in finished form.	3.61	1.037
Leadership style: Delegate	3.91	0.838

Table 6 above shows that on average, respondent perceived *I discuss the organisation's strategic mission with staff and I provide staff with clear responsibilities and allow them to decide how to accomplish them as more important (*Mean=4.13 and 4.10 respectively) and least react towards *I expect staff to create their own goals and objectives and submit them to me in finished form* (Mean=3.61). This indicates that good leadership should be able to delegate responsibilities to others.

Table 7: Mean and Std. Deviation of Perception Scores on Direct

Statement	Mean	Std. Deviation
I make sure staffs are aware of, and understand, all organisation policies and procedures.	4.05	0.999
I have staff report back to me after completing each step of their work.	3.93	1.042
I demonstrate each task involved in doing the job.	3.86	0.968
I set down performance standards for each aspect	3.84	0.910
I check staff's work on a regular basis to assess their progress and learning.	3.84	0.920
I try to assign work in small, easily controlled units.	3.72	1.028
Leadership style: Direct	3.87	0.765

For Direct leadership style, it is found that respondent are more concerned about *I make sure staff are aware of, and understand, all organisation policies and procedures* (Mean=4.05) as compared to other statements (Table 7). This indicates that direct leadership will enhance intended task to be completed.

Table 8 presents the mean scores of statements to measure the perception of respondents on innovation capital. Based on all the 9 statements, the mean score of 5.06 implies that, on the average, the respondents agreed with the elements of innovation as manifest in the statements. From the Table 7, it can be seen that *My organization success depends on the management support towards innovation* (Mean=5.44) is the most statement viewed by respondents for the company to sustain their business in current environment.

Table 8: Mean and Std. Deviation of Perception Scores on Innovation Capital

Statement	**Mean**	**Std. Deviation**
My organization success depends on the management support towards innovation.	5.44	1.457
My organisational innovation may include new processes or strategy.	5.34	1.462
Innovation has a positive influence on my organization turnover profitability and employment.	5.25	1.598
My organization make product/service innovation such as improvement of an existing product/service or developing a new product/service.	5.24	1.630
My organization developed numerous ways to become innovative.	5.22	1.455
Productivity in my organization will be enhanced through innovation.	5.16	1.474
My organization is interested in promoting innovation activity.	5.14	1.420

The survival of my organization in the long run depends on innovation.	4.80	1.512
My organization receives R&D grant.	3.92	1.912
Innovation	5.06	1.234

Table 9 presents the mean scores and standard deviation on organization performance sustainability. The respondents were asked to indicate their agreement the extent of their agreements with the statements given. Based on the mean score, the respondents agreed most on *Quality of products and services* (Mean=5.66) followed with *overall business performance* (Mean=5.41) as a second highest mean score. *New product development* (Mean=5.14) is the lowest scored. The respondents consider the elements of organisation performance sustainability as manifest in the statements are relevant.

Table 9: The Mean Scores and Std. Deviation of Perception Scores on Organisational Performance Sustainability

Statement	Mean Score	Std. Deviation
Quality of products and services	5.66	1.066
Overall Business Performance	5.41	1.022
Sales Growth	5.29	1.021
Employees Contentment	5.28	1.089
Profit Growth / Return on Assets	5.22	1.074
New product development	5.14	1.187
Organisational Performance	5.33	0.919

Regression Analysis

A regression equation was estimated with organisation performance sustainability as the dependent variable, and leadership style and innovation as the independent variables. Table 10 presents the summary statistics of the estimated regression equation.

Table 10: Estimated Regression Equation

Variable	Coefficient	*t*-value	*p*-value
Leadership style	0.451	4.089	0.000**
Innovation	0.441	7.217	0.000**
F	68.956		0.000**
R^2	0.561		

*** Significant at 0.01*

The regression equation is statistically significant at 0.01 ($p<0.01$), implying that there is an association between organisation performance sustainability and any or all of the independent variables which are leadership style and innovation capital. The adjusted R square for the ,model used in this study is 0.561 and the F-value is 68.956 ($p<0.000$). It means that about 56.1% of the variation in the SMEs performance sustainability can be explained by the model.

Table 10 indicates that both the coefficient of leadership style and innovation are statistically significant at 0.01 ($p<0.01$). The coefficient of leadership style (0.451) and innovation (0.441) means that an increase in leadership style and innovation increases the organisation performance sustainability. This result is consistent with the previous studies by Arham, A.F (2014), Cristopher M. McDermott & Daniel (2014) .

Mediating Effect: Performance Sustainability

Table 14: Estimated Regression Equation

Path	Criterion Variable (Y)	Predicting Variable (X)	Coefficient	*t*-value	*p*-value	*F-value*	R^2
C	Organisation performance	Leadership style	0.869	7.654	0.000**	58.446 (0.000**)	0.349
A	Innovation	Leadership style	0.947	6.450	0.000**	41.596 (0.000**)	0.276
B	Organisation performance	Innovation	0.573	10.291	0.000**	105.913 (0.000**)	0.493
B,C	Organisation performance	Leadership style	0.451	4.089	0.000**	68.956 (0.000**)	0.561
		Innovation	0.441	7.217	0.000*		

*** Significant at 0.01*

From the table above the model shows a significant positive relationship between leadership styles (X) and organization performance (Y) (p<0.01). Path A model shows that leadership styles (X) is also positively related to innovation (M) (p<0.01). Path B model then shows that innovation (M) positively predicts organization performance (Y) (p<0.01). Finally, leadership styles (X) predict organization performance (Y) when controlling for innovation (M). It can be seen that, both leadership styles (X) (p<0.01) and innovation (M) (p<0.01) are statistically significant. The finding support that there is partial mediation in this model.

Conclusion

The findings of this study suggest that leadership style is one of the most important elements for organisational success. The leaders of organisations must first understand that the leadership styles they display and practise such as coaching, delegating, directing and facilitating have significant contributions to organisational performance. This study also found that innovation capital is significantly positive towards sustainability of SMEs performance. The research framework, the research questions and the methodological approach of this study contribute to the existing body of knowledge in leadership, innovation and sustainability literature. The theoretical contributions and managerial implications are also significant findings for leaders of SMEs development in the country. Some limitations are acknowledged that indicate future research directions. Finally, the timing of this study is particularly important as Malaysia is moving from being a developing country towards having developed country status, and sustainability of SMEs are considered as one of the engines for the growth of the country's economy. Hence, Malaysian SMEs need to take a deeper thought and understand the concept of leadership styles and innovation capital to be able to attain sustainability and achieve business goals.

Acknowledgement

We would like to thank Institute of Research Management and Innovation (IRMI) , Universiti Teknologi MARA, in collaboration with the Ministry of Higher Education Malaysia (MOHE) in providing the financial support for this research project (600-IRMI/Dana KCM 5/3/LESTARI (146/2017). We are indeed very grateful for the grant, without it we would not be able to carry out the research.

Abstract

A problem not often discussed or recognized is represented by noise injury in agriculture. The recommended level of noise is not respected thus many workers, farmers or family members are exposed to it. Thus, these people experience hearing losses more often than people with other types of jobs. Just lately, an interest in the subject is mentioned also in the Occupational Health and Safety regulations. The main objective of this study was to review negative effects of noise pollution in agriculture in regard to the farmers interests toward protecting their workers and the safety measures they have taken to prevent health problems. The paper focuses on agriculture noise pollution since it is a very important sector in Europe that should be investigated and developed more and more. The findings are expected to enhance the understanding of noise pollution in agriculture and review different ways to prevent it.

Keywords: Noise Pollution, Agriculture, Protection Measures.

Introduction

Technological evolution in all industries, including agriculture, is constantly adopted by the private sector, leading to increased productivity rates, and lowered physical working load for employees. (A. Gray and M.D. Boehlje, 2007). Acquisition of new and modern equipment types have also lowered the required number of operators, but given this fact, the employees will be exposed in a higher amount of time to high noise levels produced by the equipment.

Multiple studies have shown that more than 20% of the world population is living in unacceptable noise levels, while 60% from Europeans are also exposed to concerning levels of sounds during the day (Rivas et.al. 2003).

A second study, that is in agreement with Rivas et al. 2003, is the AEM - "Ambiental noise in Europe 2020", stating that approximately 20% of the population is exposed to high levels of noise that affects negatively affects health every day.
The concern for workers welfare started to be of interest when the companies started to be affected by the health issues of employees, thus affecting business as well. (Sampaio, C. A. P.et. al 2007).

Acoustic noise is one of the most prevailing risk factors on the operators of construction, mining and agricultural machinery. As data gathered by the EU countries, noise pollution leads to one of the most common occupational diseases, hearing loss. (European Environmental Agency, 2017).

Agricultural noise was studied and analyzed by scientists and some concluded that the mid to long term exposure to noise coming from machines were harmful for the operator (Cunha, J. P. A. R. et. al 2006).

found that tractor cabins can help reduce the noise level by 3dB. Also, sound levels were registered for the tractor cabin with its window open or closed, showing significant differences (Mofrad F.E. et al. 2012) .

It is important to mention that in agriculture, the activities are in close connection to different processes that involve many equipment types; thus the vibrations and the noise analysis has to be considered as a complex issue that doesn't have to be simplified.

(Junoh et al. 2011) concluded that discomfort levels for the machinery operators depend on the magnitude, direction, and frequency, but also the duration of the exposure to the noise pollutant.

In Romania, noise level monitoring falls under the activities of the Romanian Ministry of Environment, which, following their studies, outlined a rise of the average noise levels, from 50 dB in the 80's to 70 dB in 1999. Being part of the European Union, and aligned with the common principles, Romania is applying European Directives and Standards with the purpose to limit the rise of noise levels, and to protect hearing health through certifying new equipment types by sound level testing (CECE).

Agricultural equipment in Romania is tested for sound levels following the instructions of Directive 2000/14/EC [2000/14], and the instructions from Standard SR EN ISO 3744/2011, for determining acoustic level power levels and acoustic energy of noise sources using acoustic pressure (SREN3744).

The main objective of this study was to review the farmers interests toward protecting their workers, to present the noise levels of some machines and present the safety measures they have taken to prevent health problems.

General aspects of sound

In 2015, it was estimated that 10000 people died annually, around the world due to factors associated to noise pollution (Environmental Agency, Ministry of Agriculture, Regional Development and Environment, 2019). The most common noise effect is it influence on neuro-vegetative balance that can happen at around 60 db.

The negative effects of noise pollution on humans are known for a long time now, and are still constantly studied. According to the specialty literature, there are three main effects of noise exposure (González, A.E., 2012): acoustic trauma that leads to an immediate and permanent effect following acute exposure, temporary shift of hearing leading to an immediate effect after exposure that could be reverted by hearing rest, and permanent shift of hearing leading to a permanent damage caused by chronic exposure.

The Final Report which shows an analysis on the health effects of noise exposure based on the WHO Large Analysis and Review of European housing and health Status,

There is also a direct linkage between noise exposure, migraines and aggression, based on the biochemical processes of hormones and neurotransmitters (Ramírez, J.M., 2006)).

Acoustic oscillations are met when machines and equipment types are used and can be harmful for the humans. Considering the way that the acoustic oscillations are perceived by the human hearing organ, it can be classified as it follows:

- Infrasound with frequencies under 16 Hz;
- Sounds with frequencies between 16 and 16000 HZ;
- Ultrasounds with frequencies above 16000 HZ.

Sound is represented by a particle vibration in the environment, capable to produce a hearing sensation. The sound is propagated as elastic waves but only in air, liquids, and solids. The propagation speed is different due to the propagation environment properties. In the air, the propagation speed is 340 m/s (TriteanA and Arghir M, 2013). The sound frequency is measured in Hertz (Hz), and the human ear sensibility is between 2000 – 5000 Hz.

The universal measuring unit for sound is decibel (db). The human ear perceives sounds with a frequency between 16 – 20000 vibrations/second and an intensity between 0 and 120 db.

Noise is defined as being a complex mixture of sounds without a repetitive pattern which affects the psychological and biological state of people and also other organisms in nature. It's characteristics, physical or objective, refer to the sound's strength and intensity, the frequency, and the duration on noise. The most important feature is represented by the noise intensity and it depends on different factors. The noise represents a health and environment problem.

According to World Health Organization (WHO) noise represents a threat that is underestimated. WHO says that the noise pollution generated by traffic is considered the second environmental factor that affects human health.

The number of diseases that can occur due to noise exposure have an effect on the long or short term, for example it can affect the hearing up until hearing loss, can provoke cardiovascular problems, sleep disorder, can have a huge influence on work performance, etc (World Health Organization).

According to WHO the level of noise during nighttime should be less than 30 db(A) and for pupils and students the level of noise in classes should be less than 35 db(A) for good learning conditions.

European Union data presents that most of the time, whether is day or night, the level of noise in above 55 db(A). Sound levels for different general examples and agriculture machines are presented in the table below:

Table 1: Sound levels examples

No.	General situations	Agriculture	Sound levels (db(A))
1	Normal conversation		50 – 60
2	Pupils classroom		74
3	Night clubs		Up to 100
4	Rock concert		110 – 130
5	Library		40
6	Dishwasher		55 – 70
7	Jet plane at ramp		125
8	Tractor		74 – 112
9		Chainsaw	77 – 120
10		Combine	80 – 105
11		Garden tractor	88 – 94
12		Grain grinding	93 – 97
13		Pig squeals	85 – 115
14		Crop dusting aircraft	83 – 116

If the problem of noise pollution has been identified, it is necessary to see how it can be acted upon, trying to remove it, but not without making an analysis, or a noise assessment. Considering that studies have shown what are the levels of noise that can cause damage, the assessment needs to concentrate on the current state and present the findings.

If we consider the specific equipment in agriculture and its noise levels, we can mention the following:

Tractors – are the most common machines used in agriculture both by big and small farmers. The evolution in construction of tractors implied also sound-reducing cabins. The level of sound inside the cabin with its windows closed showed a lower level of noise. Older models presented noise levels as much as 100 dB(A).

Chainsaws – are an equipment used often that does not offer protection if you are not wearing additional hearing protection gear. The noise level registered by scientists for the chainsaw was about 110 dB(A).

Shed and process machinery – considering the renewable energy is used from more that a decade ago, the biomass that is one of the main materials for obtaining biogas or pellets, needs to pass through a series of production processes such as shredding. Thus, this process is part of an entire production process and just milling and shredding emits noise levels of about 95 db (A).

Researchers (Retta Zewdie and Pavel Kic, 2017). measured the noise levels for a harvester Claas 450 and three tractors Case IH, tractor Zetor Z7045 and Tractor Zetor Z7711. The authors analyzed the noise level in the operator's cabin.

Table 2: Noise level measurement of farm machine driving cabin (Retta Zewdie and Pavel Kic, 2017).

Cabin of machine	LA, dB(A)
Claas 450	81,6
Case IH	72,8
Zetor 7045	83,2
Zetor 7711	84,3

For example, the noise level measurement for the harvester was presented as follows:

Fig.1: Noise level measurement for harvester Class 450 (Retta Zewdie and Pavel Kic, 2017)

Another researcher evaluated the following machines: agricultural tractor, agricultural chainsaw, brush cutter and portable harvester (Tadayuki Y. et. al. 2012).

The analysis of noise levels was done by using sound pressure meter in the slow response circuit and of equalization "A", expressed in dB (A), and the draft shield of decibelimeters was used in all measurements. When presenting the information, the authors chose to represent is as maximum, minimum, average level to better express which the range for the sound that can affect human hearing. Also, similar to the study presented above, the level of noise pollution for the maximum level is close to 90 dB even higher, thus affecting the workers productivity (Tadayuki Y. et. al. 2012).

Table 3: Noise levels (Tadayuki Y. et. al. 2012)

Equipment	Noise Level (dB(A))				
	Minimum	Average	Maximum	Average	Standard Error
Harvester	53,49	65,94	81,85	64,29	0,41
Chainsaw	73,85	85,18	102,28	84,13	0,39
Brushcutter	71,64	84,45	99,31	83,40	0,38
Tractor	70,93	83,43	93,75	82,71	0,57

Results and Discussion

The results presented by the authors (Retta Zewdie and Pavel Kic, 2017). showed high noise levels for every equipment type, and most of the time around 90 dB, a value that is not recommended for the workers. The recommendations of the authors expressed the need for wearing ear protection and also the importance of sealing elements like rubber seals for the driving cabins

The conclusion drawn for all equipment analyzed by (Tadayuki Y. et. al. 2012)., protective equipment is needed, activity monitoring is very important and also the companies need to have a work plan for every equipment since they are different but the sound levels are similar and the effects on workers can be harmful.

To better express the distribution of noise levels, the authors also conducted a spatial distribution for every equipment.

Fig. 2: Spatial distribution of noise level for tractor (Tadayuki Y. et. al. 2012).

Chainsaws noise levels were found to be similar to that found by Dennis and May (1995). Chainsaws and other small motors, such as augers and pumps, also have high noise levels and are significant noise hazards on farms, even when used for a short period of time (Dennis and May - 1995). There are also machines with comparatively low levels of noise that present a significant noise hazard because they are used regularly or for extended periods of time, such as tractors without cabs.

Also, scientists (M. Vallone et. al, 2016) analyzed the vibration and noise level in agricultural track-laying tractors by evaluating the influence of tractor age and soil characteristics on whole body vibration and also by evaluating the noise risk. They used six tractors with different ages and three different sites which led to three different soil types. One of the data obtained presents the results for the three axes, where the vibration levels increase from T1 – T6.

Fig. 3: Predicted vibration levels for tractors (M. Vallone et. al, 2016).

Researchers applied ANOVA analysis that resulted in showing a higher influence of the tractors age than the type of soil on which the tractor is working. Also, another conclusion of the authors refer to the fact that there were identified three risk classes according to the working hours, from a low risk for 3000 working hours to high risk for 6000 working hours. (M. Vallone et. al, 2016).

To protect the people the equipment that are noisy need to be replaced with quieter equipment. To manage the noise exposure, it is preferable to make sure that the equipment is properly maintained before considering new noise controls. In agriculture it is difficult to upgrade the machines yearly, thus for old equipment needs proper control. Although, hearing protection is recommended if the noise level requires it, there are times when the hearing protection should not be the focus of farmers, their focus should be noise control using other methods.

Noise control measures outlined at an Australian field day hearing (Williams et al., 2002; Clark 2002), which include machinery substitution and engineering controls, are appropriate for reducing exposure to noise. Some of these practices included:

- Replacing old machinery with new technology that is quieter.
- Modifying the design of operator work areas;
- Using tractors or other machines with a cab;
- Using insulating materials around motors and equipment.
- Modifying operator work practices to avoid noise where possible.
- Performing regular maintenance on machines.
- Rotating farm tasks in order to reduce individual noise exposures.

The most common way of reducing noise level is ensuring that the cabin of the machine respects the levels needed for the protection of workers. The noise inside a cabin can come from the engine, the material used to build the cabin, the use of noise controls. Also the cabins design can affect the noise levels. Since the early 70s scientists found that the sound can be absorbed by materials such as polyurethane foam or fiberglass (Walker, D. E, 1970).

Agricultural noise control in Romania is an issue that is being addressed but it still needs improvement. The environmental report done by the Romanian Ministry of European Funds present the frequency of symptoms that occur because of noise.

Fig.4: Symptom frequency (%) (Ministry of European Funds, POIM report)

Conclusions

Noise pollution in agriculture is an ongoing problem that needs to be addressed at an increased level. Constant noise exposure can lead to severe problems for human hearing, and other neurological issues Ramírez, J.M. (2006).

Studying the effects of long term exposure on human hearing is a challenge for any study, given the issues with gathering relevant data. A significantly higher level of research papers on the subject of noise pollution must be realized, in order to better understand this process and the ways to address the issue of negative effects on human health.

Employers have the legal obligation to ensure health and security for their employees through the implementation of a noise management system which must contain the following: noise source identification, noise level measurements, employee health assessment, applying technical measures to reduce noise levels, proper signaling of work spaces, and instructing employees of the risk of exposure.

Additionally, a series of organizational measures can be applied: if the risk of long term exposure can't be contained, employees must be provided with individual measures of hearing protection.

Based on the European Union Directive 2000/14/EC, and the EU standard SR EN 3744/2011, in Romania, all agricultural equipment types must undergo tests for sound emission determination. But given the amount of new data

gathered by research papers on the subject of noise emission health issues, new and updated methods for testing and protection can be applied.

Abstract

Given the growing proliferation of online shopping and review sites over the last decade, online customer reviews have become an ever-more-common part of nearly every consumer's buying decisions. Reviews have also proven to help businesses gain valuable insights on how customers perceive their products and services. Thus, this feedback provides companies with a cost-effective way to monitor their performance and to increase exposure. Despite all these potentials, it has been revealed that a considerable number of these reviews is fake. Our purpose in this work is, therefore, to explore the threats that fake reviews present to both shoppers and businesses. In this context, it was noted that since deceptive reviews are primarily meant to mislead potential consumers and to manipulate their purchasing decisions, these reviews have devastating effects on businesses regardless of whether the review is positive or negative. In fact, these unauthentic reviews do not only harm a business reputation, credibility and profitability but also demolish the foundations of the trust economy.

Keywords: Online reviews, customer feedback, deceptive reviews, business, reputation

Introduction

Due to the rising proliferation of social media and review sites over the past decade, these online platforms have become an open environment where individuals can express their views on different topics. They have also developed into a virtual space in which consumers can voice their opinions and sentiments towards various brands and businesses (Faizi & El Fkihi 2019a, Faizi & El Fkihi 2019b). Thanks to their ease of use and effectiveness, they are currently the *de facto* means for consumers to share feedback or reviews on different products and services they bought or used.

With the voluminous amounts of feedback that are increasingly being generated by consumers on social media, e-commerce platforms (e.g. Amazon, Walmart and Ebay) as well as on review sites (e.g. Yelp and TripAdvior), customer reviews have become ubiquitous and more accessible. With the rise of online shopping, these reviews are part and parcel of most 21st century consumers' purchasing decisions (Schwichtenberg 2015, Faizi et al. 2017a). In this respect, it has been reported that the average consumer consults 10 reviews before feeling able to trust a particular business (Murphy 2019). As such, this valuable customer feedback serves as much as personal recommendation for many consumers, thus, constituting a new type of word-of-mouth information (Chen & Xie 2008). The prevalence of online reviews also provides businesses with a valuable source of feedback that they can use to enhance their reputation and influence potential consumers (El Fkihi & Faizi 2018, Faizi et al. 2017b). Despite all these potential benefits, many studies have confirmed that online reviews are not always reliable. In fact, a significant portion of this 'customer' feedback is fake (Barbado et al. 2019, Dellarocas 2006, Belton 2015, Luca & Zervas 2013, Khalid 2019). In a local consumer review survey conducted by BrightLocal in 2019, 82% of consumers claimed to have spotted a fake review (Murphy 2019). It is also estimated that one in seven reviews in TripAdvisor might be fake and that more than 55,000 unauthentic reviews are generated each month on Facebook (Pitman 2019a).

Therefore, our objective in this paper is to explore the threats that fake reviews present to shoppers and businesses. The remainder of this work is structured as follows. Section Two examines the major types of fake reviews and

their distinctive features. Section Three is concerned with the devastating impact of deceptive reviews on both consumers and businesses. Finally, Section Four summarizes the main findings of this paper.

Fake Reviews: Major Types and Distinctive Features

As opposed to authentic customer feedback, fake reviews are written by people who have not really used the product or service that is reviewed. Since they are written with hidden motives, they do in no way reflect the reality of the reviewed product or service (Liu 2015, Jindal & Liu 2018). These reviews are specifically designed to give consumers false impression on a given product or service that they intend to purchase.

Deceptive reviews usually fall into two major categories, namely biased positive reviews and biased negative reviews. Biased positive reviews, the more common of the two categories, usually show up when a business owner incites employees, friends or relatives or even hires other companies or individuals to post favorable reviews about his brand (Lappas et al. 2016). Such reviews are, thus, a glowing report which bears no resemblance to reality. Henceforth, they are unlikely to provide an objective or fair view of what the customer experience is, actually, like given the personal relationship or stake of the person who has written the review with that business.

By contrast, biased negative reviews are deliberately malicious massages that are submitted about a given brand in an attempt to unfairly lower its ranking position or rudely discredit the brand in some way. Just like biased positive reviews, negative fake reviews are not based on reality, but at best on shared misunderstandings or out-and-out lies. The objective of such untruthful reviews is, therefore, to persuade potential customers not to take action on the products or services that are reviewed. Often times, these reviews would rather recommend other products from a competitor.

Whether the intent is to embellish or devastate a brand, both positive and negative fake reviews aim to deliberately manipulate one's choices, thus, obscuring the real facts about a product or service we aspire to buy. Since these deceptive reviews are deliberately written to sound genuine, the lines between real consumer reviews and fake ones can often be blurred. Consequently, distinguishing between both categories of reviews is not always an easy task. However, it has been found out that untruthful reviews have a variety of linguistic and psychological characteristics or cues that make them distinguishable from authentic ones (Banerjee & Chua 2014, Fitzpatrick et al. 2015).

The first difference that makes fake reviews different from real ones is that the former are less specific as they lack details. In fact, in contrast to authentic reviews which are more specific given that they are hinged on real experiences, untruthful reviews are totally based on imagination (Ott et al. 2011). Hence, describing an event that did not take place or voicing an opinion about an experience that has not occurred might be lacking specificity (Newman et al. 2003). Rather than focusing on the specificities of a customer experience, a fake review usually offers general praise. An authentic review about a hotel, for instance, is likely to focus on details and, thus, use concrete words such as 'check-in', 'check-out', 'bathroom' or 'room service'. Nevertheless, a deceitful review would describe less the physical space of a hotel and write more about elements that set the scene. As such, words such as 'holiday', 'trip' or 'my wife' would rather be used**.**

Another feature that characterizes fake reviews is that they have an exaggerated and hyped tone (Banerjee & Chua 2019). Indeed, while a truthful review is typically more moderate in its praise, a deceptive review is overly positive or negative as it uses an attention seeking entry that is meant to convince the reader (Maurer & Schaich 2011). Many studies have shown that the presence of an exaggerated sentiment is a general cue to a deceptive review. Therefore, if a review is extremely positive or negative, or if it is a five or a one-star review, it is more likely to be a fake review, which is primarily written to dramatically embellish or ruin the quality of a product or service. This is particularly true for reviews that are extremely positive but fail to provide enough information about why they are good or extremely negative but unable to mention what is wrong with the product. Therefore, such reviews tend to include more sentiment-related words namely verbs and adverbs (Rayson et al. 2001), Moreover, in an attempt to make themselves sincere and more credible, they frequently use the personal pronouns 'I' and 'me' (Yoo & Gretzel 2009).

Impact of Fake Reviews on Consumers and Businesses

Thanks to the valuable information that they usually host, online reviews have become a critical resource to which people increasingly resort to before making a purchasing decision. From restaurants to hotels, consumers visit

review sites such as Yelp, TripAdvisor and Foursquare so as to get advice. However, despite their importance in helping consumers make wise buying decisions, a huge number of these reviews is fake. This means that such reviews, be they positive or negative, will have severe repercussions on customers' purchasing decisions. In fact, since the main objective of a deceptive review is to mislead readers by giving them false information about the items that they need to buy, consumers end up making the wrong purchase decision. However, this manipulation of online reviews does not only have a negative impact on consumers' choices but it has severe repercussions on businesses as well.

Just like bad customer reviews, negatively biased reviews have numerous detrimental effects on a business as they harm its reputation, trustworthiness, profitability (Lappas 2016). Indeed, one single negative review can immediately drive away around 22% of prospects (McCambridge 2019). Accordingly, negative reviews seem to be every business owner's nightmare. However, when such reviews are fake, that nightmare becomes even worse (Pitman 2019b). In fact, when a business gets negative reviews from its real customers, their feedback can allow the business to detect difficulties that clients are having, identify prime issues of concern about the brand and can, thus, help the company spot areas for improvement (Faizi et al. 2018a, 2018b). Nonetheless, when a malicious review that is full of lies comes from a person who has not even been a customer, and he has written that fake review simply as revenge for something that is unrelated to the business, it really becomes a serious problem. The purpose of such reviews is not to constructively criticize the brand but solely to mislead potential customers and unfairly hurt the business. Since these reviews come from some unscrupulous business owners or competitors seeking to get a leg up, they will surely cause significant damage to the brand and to its reputation.

In an attempt to boost their ratings and overtake their competitors in terms of visibility in Web searches, some businesses also adopt the strategy of self-injecting positive reviews. For businesses with not enough positive reviews, it may be tempting to opt for shortcuts in trying to build their online reputation (O'Connor, 2010). Thus, paying for good or 5 star reviews with cash, coupons and promotions may sound a cost-effective solution. However, even if such positive ratings or reviews are a small image boost and certainly make for a first good impression as they can quickly bury negative feedback and propel the business to the top of online search results, they are deceptive, unethical and illegal (Bagley 2018, Bassig 2019). These positive reviews do not apparently seem to cause direct harm to anyone. Yet, they do mislead potential consumers and cause problems for competitors. Companies resorting to deceptive reviews might get some benefits in the short term. But in the long run, they are harming themselves and abolishing the foundations of the trust economy. When a customer does not trust your reviews, he will not trust your business either (Nallapaneni 2020).

Due to the growing concerns of the increasing proliferation of deceptive reviews, many online businesses claimed to have started taking a variety of measures to block the generation of this malicious content on their sites. It has also been reported that the Federal Trade Commission has recently made its first key decision aimed at cracking down on untruthful online reviews (Fair 2019). However, despite the actions or attempts that have individually been taken by some e-commerce platforms, organizations or governments to combat fake reviews, the fight may seem unending at least in the short-term. More efficient strategies and/or practices are, therefore, required.

Conclusion

The objective of this paper was to explore the threats that fake reviews present to both customers and businesses. In this vein, it was shown that since these deceptive reviews aim to mislead customers and persuade them to make bad purchasing decisions, this untruthfulness and manipulation have severe repercussions on businesses. In fact, regardless of whether these reviews are positively or negatively biased, they do have damaging effects on businesses as they harm their credibility, reputation as well as profitability.

digital online platforms, which integrate heterogeneous hardware and software resources within web-technologies in distributed networks and wide application of cloud services. As study result, structural model is proposed, which combines the investment objectives with cost of adequate geo-information support, adapted to climate change and Covid-19 pandemic. For data exchange and preliminary discussion, platform https://www.researchgate.net/profile/Valery_Abramov2/ there was used while study. Research was performed at the Russian State Hydrometeorological University within State Task of the Ministry of Science and Higher education of the Russian Federation, project FSZU-2020-0009.

Keywords: geo-information support, air quality management, climate change, Covid-19

Introduction

Recent time, the Covid-19 pandemic negatively impressed the global economy, that required major changes in management decision-making technologies, including air quality management (AQM) technologies, especially in large cities, industrial zones, wildfires areas. Serious attention is to be saved for black carbon influence on climate change in Arctic. Note, Covid-19 pandemic matched the time with Industry 4.0 period, during which a lot of enterprises plan and implement wide spectrum of information technologies (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019), (Lukyanov, 2019), (Sikarev, 2020), (Trunin, 2019). Industry 4.0 leads to serious technological changes in AQM, as part of natural risks management (NRM) (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new digital tools, including practical learning area (Abramov, 2020), (Popov, 2019).

Below are described the development results of digital tools for AQM while Covid-19 pandemic wthin geo-information management area (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) in environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). Significant attention is paid to geo-information support systems (GISS) within NRM in climate change context (Bournashov, 2014), (Gogoberidze, 2014), (Chestnov, 2020), (Chusov, 2012), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). Developed geo-information support technologies for AQM, considered in this article, take these factors into account.

Methods and data

In study, there are used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Bolshakov, 2020), (Vekshina, 2020). While research, there are used data bases and tools of digital online platform (DOP) Earth (Prostakevich, 2020).

Results

Recently, AQM is a hot place in global environmental economy while climate change, including black carbon problem (Isaev, 2015). Note, particulate matter (PM), which is essential air carrier for black carbon, can be the same carrier for Covid-19, also. Authors made statement, that black carbon and Covid-19 have to be investigated together within sustainable development paradigm by means of adequate decision aids tools developed on geo-information management (GIM) basement.

From GIM point of view, AQM is to be carried out within related set of natural-industrial projects (NIPs) in common space area and time period while climate change and Covid-19 pandemic. In Figure1, it is presented a block model of investment structure for such NIPs, which combines the investment objectives (blocks 1-5) with cost of adequate geo-information and geo-ecological support (blocks 6-8), including AQM within NIPs (block 7).

Figure 1 : Block model for investment structure while territory development: 1 – block of distribution of resources; 2 – block of formation of resources; 3 - block of formation of private income; 4 - block of formation of total income; 5 – block of formation of the investment share of resources; 6 - block of comparison with the permissible level of risk; 7-block of formation changing in time set of NRM, including Covid-19 and black carbon; 8 – block of environmental monitoring corresponding to block 7

Authors' analysis shows that the largest part of the cost of managerial support is the environmental monitoring (block 8), the essence of which is determined by the content of block 7. Significant part of the cost in block 8 is hardware and software, the cost of which varies significantly. Now, in Covid-19 pandemic conditions, cost of AQM can arise greatly because of general economic situation, when every country have to implement limitations for boards crossing and suffer from economic slowdown.

On basement of above mentioned model (figure 1), authors propose to develop the geo-information and geo-ecological support system (GIGESS) with combined structure for access, storage and analysis of information from open geo-spatial data sources, including archives and operative mode web tools.

As a result of the research, performed using foresight technologies, the authors suggest to use geo-information distributed online platforms (GIDOP) with cloud technologies (CT) as the main technological solutions for GIGESS. In this article, the authors recommend to use GIDOP Earth https://earth.nullschool.net/ru/, which allows to get digital color interactive maps of horizontal flows PM10, PM2.5 and PM1 in the ground air layer for the entire planet.

Let's go to examples. In figures 2-4, there are maps of horizontal flows PM10, PM2.5 and PM1 in the ground air layer for Arctic ocean and surrounding territories on 8th April 2020.

Figure 2: PM10 flow map for Arctic ocean and surrounding territories on 8th April 2020

Figure 3 : General diagram of dependencies between data subsystem modules in VDP

Figure 4: PM1 flow map for Arctic ocean and surrounding territories on 8th April 2020

For arbitrarily selected point on an interactive map (green circle in figures 2-4) in the lower left corner of the map displays interactive data: coordinates, direction and speed of the wind, numeric value of characteristic displayed on the map. Note, map's decoding on figures 2-4 was not task of this paper. As essential research result, authors propose to use GIDOP Earth, as basement of low-cost GIGESS for AQM while Covid-19 pandemic and climate change.

Discussion

It is worth noting, GIDOP Earth can be used in educational and training purposes for AQM while Covid-19 pandemic and climate change. The essential task of university practical learning (UPL) will be to teach students the practical aspects of work with GIDOP Earth tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies, that can reduce total cost of training and learning processes while Covid-19 pandemic.

Conclusion

Here In paper, authors described results of digital technologies development for AQM, adapted to Covid-19 pandemic. In studies, there are used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing within digital educational platforms, web-technologies and virtual reality tools. As digital tools, authors propose to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, there are proposed a structural model, that combines the investment objectives with cost of adequate managerial support, adapted to Covid-19 pandemic conditions and climate change. As essential result, GIDOP Earth is proposed to usage, as basement for low-cost GIGESS for AQM while Covid-19 pandemic and climate change. The presented in the article results of the research have a significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state

environmental control bodies. They can be used in the preparation of master's programs in environmental economics and health research while Covid-19 pandemic and climate change.

Acknowledgment

While study, platform https://www.researchgate.net/profile/Valery_Abramov2/ was used for preliminary discussion and data exchange. Research was performed at the Russian State Hydrometeorological University within State Task of the Ministry of Science and Higher education of the Russian Federation, project FSZU-2020-0009.

Analysing the Industrial Real Estate Market

Izabela RĄCKA
Calisia University – Kalisz, Poland
i.racka@akademiakaliska.edu.pl

Abstract

The industrial real estate market is a growing and dynamic market and there is a big difference between submarkets in terms of type of property or geographic area. As a rule, modern industrial properties are being leased, and they are the most often located in large cities, but for older properties, located in subregional areas, turnover is more common. There is a clear research gap in the analysis of sales transactions on the non-residential and non-agricultural market, especially in the segment of industrial real estate. Industrial are atypical properties, which means that when looking for similar properties in order to analyse the market, the spatial scope of the research should be extended. For this reason, the industrial submarket should be viewed more broadly and its analysis should cover the area of several neighbouring towns, districts or counties. The market analysis procedure was carried out starting from the observation of the market reality. Next we tried to find the coexistence of phenomena and establishing cause-effect relationships, after that we built a regression model. We built a database of nearly 100 records containing all transactions where the land was built-up with industrial plants in the southern part of Wielkopolskie Province in 2015-2019. The research showed that the prices of industrial real estate are influenced by: location, land area, type of space, date (year) of sale, type of buyer, type of seller, type of property rights. The study can help making investment decisions may be important for active participants of the industrial market.

Keywords: commercial real estate, market analysis, valuation.

Introduction

The industrial real estate market is one of the most dynamic and strategically important sectors in global economies. The availability of products which we buy in shops and online is because of the presence of manufacturers, suppliers, retailers, 3PLs, distributors, storage and supply chain companies. Functioning in an intensely changing environment is difficult for investors and entrepreneurs. The broadly understood environment changes very quickly, which creates a difficult situation for real estate, which stability in place, durability and inability to adapt to market changes hinders development. In case of commercial real estate, especially owned by enterprises, changes are required by different market participants. The attractiveness of commercial real estate becomes important the moment it appears on the market – as the object of rent or sale. However, the assessment of this attractiveness is possible only after the analysis of the similar real estate market and comparing the real estate to the competition.

The number of real estate purchase/sale transactions in Poland exceeds 500 thousand every year and rises. The transactions are being recorded in the Registers of Real Estates Prices and Values which constitutes about 90% of the total number of notarial deeds related to real estate sales and recorded by the Ministry of Justice. The majority of real estate transactions takes place in urban areas. More than 60% of the total number of transactions are being concluded in the cities. The majority of transactions were related to premises (almost 50% of all real estate purchase/sale transactions). Non-residential and non-agricultural built-up properties (including commercial, office, production real estate and garages) constituted almost 20% of the number and about 30% of the value of the registered transactions. The average price of a single production premise in 2018 was PLN 1,448 and the average price per 1 m2 of production premises was PLN 1,660 – which is low compared to residential premises (about PLN 5.500 on the primary and about PLN 4,500 on the secondary market) [Statistics Poland 2019]. The share of industrial real estate in business in Poland is therefore small and industrial real estate is very diverse, which makes it difficult to analyse this market segment. Actually, many researchers question the existence of one national real estate market [Hoag 1980].

Some public institutions as well as private agencies and consulting companies conduct analysis of the commercial real estate market. Quarterly information on real estate prices and the situation on the residential and commercial real estate market in Poland since 2010 have been published by the National Bank of Poland. However, in the part devoted to commercial real estate, NBP analyses only the rents of the office space and the profitability of investment in rental housing [NBP 2020]. Research on the commercial real estate market in large cities is conducted

Cite this Article as: Izabela RĄCKA "Analysing the Industrial Real Estate Market" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

by real estate agencies such as Colliers International, Cushman & Wakefield, Deloitte, Emmerson, Jones Lang LaSalle, Knight Frank and others. Range is limited to large cities and up to date spaces meeting modern production and logistics standards. Such properties are the most often located in large cities: Warsaw (zone I, zone II, zone III), Poznań, Krakow, Wrocław, Tricity, Bydgoszcz/Toruń, Szczecin, and in region along motorways: Central Poland, Upper Silesia, East and West. Warsaw, Upper Silesia and Central Poland markets maintain leading position in terms of industrial real estate supply [Colliers 2020]. As a rule, these properties are being leased, so they are not the turnover, but lease agreements which are usually under analysis.

Though growing interest among developers in smaller markets such as Lublin, Olsztyn and Rzeszow has been observed [Colliers 2020], the real estate agencies do not analyse local industrial markets. Thus, there is a clear research gap in the analysis of sales transactions on the non-residential and non-agricultural market, especially in the segment of industrial real estate. Importantly, this submarket should be analysed in a broader sense, because investment real estate is not as closely related to the location as, for example, housing. When making an investment decision, investors often go beyond the local market, i.e. beyond a given city or its suburbs [Rącka, Palicki and Kostov 2015]. For this reason, the submarket should be viewed more broadly and its analysis should cover the area of several neighbouring towns, districts or counties. Industrial are atypical properties, which means that when looking for similar properties in order to analyse the market, the spatial scope of the research should be extended [Dolman 1979]. Early work in the US provided evidence that regional factors had an important impact on prices and yields, however that was limited to broad regions or sub-markets within given urban areas. In their research [Grissom, Hartzell and Liu 1987] they investigate if a segmented market exists for industrial real estate. The results support the existence of regional markets for industrial real estate. The authors note that geographic regions of the country vary in terms of their economies and cause differences in industrial real estate returns and prices. Moreover, there are some studies that examine the clustering effect of local industrial real estate markets [Benjamin, Zietz and Sirmans 2003]. The companies often locate within close proximity, frequently encouraged by government's incentives and availability of infrastructure to form "industrial districts". The companies can be more profitable in locations where there is an agglomeration of complementary activities.

Therefore, in this paper the analysis of industrial real estate prices and factors influencing them in the selected regional market was adopted as the research problem. The aim of the study was to verify the impact of the location of industrial real estate on their prices. The research hypothesis was: the industrial real estate market is supralocal and the location of the industrial property on regional market does affect its price. In order to prove the hypothesis, we collected data on the prices and characteristics of sold industrial properties in 2015-2019 in the southern part of Wielkopolskie Province in Poland. Then, the role of industrial real estate characteristics in determining prices was demonstrated. Data analysis allowed to determine whether the location of the properties on the regional market in the studied region influenced their prices. This is a contribution to the development of science, but also information that can be used by investors, property owners or property appraisers in the real estate valuation process.

The novelty of the paper is to indicate the factors affecting industrial real estate prices on the regional market. Most of the research concerns housing market, whilst industrial submarket is neglected. So far, the majority of authors have focused mainly on the analysis of factors influencing real estate prices in large cities, which were considered to represent the entire states. Few studies have examined the phenomenon on regional submarkets. However, the research we conducted showed that the industrial market in subregions is different from big cities, prices are lower, and properties are less modern. Hence, we decided to show what types of factors affect the industrial real estate prices in subregions.

In the article we subsequently review the literature on the methods of the industrial real estate market analysis, then characterise the research procedure and data sources, and finally discuss the obtained results in relation to the contemporary research achievements in this field.

2. Literature Review

2.1. Real Estate Market Analysis Methods

Real estate market analysis is a part of market research. From the marketing point of view, market research is a systematic planning, collection, analysis and presentation of data and conclusions related to a specific problem and purpose of the research. Market analysis is a part of this research, providing diagnostic data on the phenomena occurring on the market [Kotler and Keller 2012]. In strategic terms, market analysis is based on customer and competition analysis aimed at determining the attractiveness of the market (or its part) for current or future participants. This attractiveness is manifested in the possibility of making profits, measured by return on capital in the long run [Aaker and McLoughlin 2010].

The deepening of the meaning of "market research" and "market analysis" leads to the conclusion that the market analysis is placed in the market research process. Research is a planned, purposeful and systematic activity, and also leads to decision-making and activities as a result of obtaining information in the research process. Market analysis, preceded by the collection of relevant data, may be conducted *ad hoc*. It can also constitute the basis for issuing recommendations, but it does not have to lead to taking action.

Choosing a research strategy requires not only defining a research goal, but also identifying a possibility of obtaining data and available sources of information, which include [Rącka 2017]: censuses, public statistics, notarial deeds, the Registers of Real Estates Prices and Values, rent and lease agreements, real estate portals (sales and rentals), MLS, land and mortgage registers, records of the land-use network, geoportals, local spatial development plans, zoning, taxation of property (taxation tables and taxonomic maps), register of monuments and municipal register of monuments, reports, scientific and popular publications, sets of unit price indices in construction, valuation reports, technical and design documentation and other.

Market research analyses buyers and sellers (owners and tenants; lessors and lessees) for a particular type of property right or geographic area. It allows to determine what type of real estate, the structure of sellers and buyers, or the form of real estate ownership dominate in a given area. The elements of market analysis include the determination of [Carr, Lawson and Schultz 2003, Thrall 2002, Greer and Kolbe 2003, Fanning 2014]:
- the spatial range of the market,
- leading parts of the market (submarkets),
- current and future market size (supply and demand, market situation, vacancy rate, market absorption),
- the pace of development of the market and its parts (development factors: demographic data, fluctuations in sales, price policy; economic base: the level of income and professional activity of the population, etc.),
- profitability of the market and its parts (profitability level, average potential profit),
- industry cost structure (important in building a competitive advantage),
- distribution channels (existing, emerging and trends),
- market trends (changes in the demand and supply price elasticity, changes in buyer preferences, time on the market, regional trends),
- key success factors (elements necessary to achieve the company's marketing goals).

The market analysis procedure can be carried out starting from the observation: the behaviour of buyers and sellers, and the overall exchange relationship, which should be carried out continuously. It is important to subordinate observation to a previously formulated goal. The collected data should be described and explained, which makes it possible to identify the co-occurrence of phenomena and establish cause-effect relationships. This can be done using popular statistical programs. The next step is to build a model on the basis of which you can quantify the reality and predict the future (Fig. 1). The collected data can be analysed in terms of structure, intensity, variability, dynamics, development tendency, seasonality, as well as interdependence [Mruk 2003].

Fig. 1. Market Analysis Process

This article uses the above research procedure. We collected data on the prices and characteristics of sold industrial properties in 2015-2019 in the southern part of Wielkopolskie Province (counties: Kalisz, Ostrow Wielkopolski, Kepno, Krotoszyn, Ostrzeszow, Pleszew) in Poland (Fig. 2). Then, we showed the role of industrial real estate characteristics in determining prices. We analysed the data and determined whether the location of the properties on the regional market in the studied region influenced their prices.

2.2. Results of the analysis of the industrial real estate market

Literature rarely discusses industrial real estate market. This is due to the limited access to information as well as the large variety of this type of property [Bieda 2018; Wang, Kazak, Han and de Vries 2019]. The problem of low commercial real estate market transparency was raised in a study conducted to empirically investigate the extent to which appraisal-based information production complements or substitutes for transactions-based information production [Downs & Güner 2011]. The researchers tested the substitution hypothesis by constructing a market activity measure based on commercial real estate data for over 100,000 transactions from 2001 through 2009 across US 51 markets. The findings indicate that the market participants derive transactions-based information in case of relatively transparent markets. Appraisal-based information is potentially most critical in markets or conditions where the information environment is incomplete (i.e., transactions are scarce or the information regarding transactions is not public). Due to the low transparency of the industrial real estate market, it is difficult to rely on transaction data.

Some authors note the problem of heterogeneity of industrial real estate market, which is an aggregate market consisting of at least two submarkets: manufacturing and distribution [Black et al. 1997]. A sample of 331 industrial property sales from the south-eastern region of the United States in the period of 1987-1995. These studies show that there is no difference in prices of most industrial properties, some property-characteristic differ. The following factors were considered to differentiate industrial real estate: building volume, below-average building condition, site area, and dock-high doors.

Research on factors influencing the prices of industrial real estate is carried out much more often than analyses of prices in regional or national markets. Some authors [Jackson 2002] have studied the effect of environmental contamination on the sales prices of industrial properties. They examined to what extent sales prices may be impacted by contamination and whether sales price effects due to contamination persist subsequent to the remediation of previously contaminated industrial properties. To answer the research question, they estimated sales price models using data on industrial property sales in Southern California. The results show that there are statistically significant impacts on property values in the period before and during remediation, but that these effects dissipate subsequent to clean-up. Other authors focused on the possibility of reusing industrial real estate after removing contaminants from previous industrial activities [Tonin and Turvani 2014]. The research was conducted on the case of Porto Marghera in the Lagoon of Venice, a large and complex contaminated site listed on the Italian National Priority List. Using a hedonic price method, they explored the effect of contamination and alternative remediation schemes on the industrial real estate prices. As a result, industrial real estate with a complete and certified clean-up scheme are more expensive than properties remediated with the 'permanent safety containment measures'. The market for industrial real estate is influenced by a variety of factors, ranging from the specific characteristics of the properties (size, location, accessibility) to local demand factors and to macro variables.

Research on the impact of external factors on industrial real estate prices includes relationship between the selling price (per square foot) and property tax rate, property characteristics and location in one of the analysed counties [McDonald and Yurova 2006]. The authors analysed the industrial real estate market in O'Hare Airport area in metropolitan Chicago for 2001–2004. They found out that comparable properties located in two different suburban counties were sold for different prices. Previous studies found that industrial real estate prices are a function of distance from airports and freeways, property characteristics (size of building, size of land, parcel, age, ceiling height, office space in the building), and contamination prior to clean up.

3. Materials and Methods

In order to verify the research hypothesis, it was checked whether the location on the regional market had an impact on the industrial real estate prices. We used regression modelling (OLS). The analysis was based on the prices of sold production properties, derived from notarial deeds. We expanded the information from the notarial acts with data from geoportals kept by the County Geodetic and Cartographic Documentation Centres.

The impact of industrial real estate location on the regional market on their prices was verified by regression modelling. For this purpose, we have built a database containing all transactions on the real estate market in the

analysed submarket of the southern part of Wielkopolskie Province in 2015-2019, and selected transactions where the land was built-up with industrial plants. As there were no transactions on the primary market, we only analysed the secondary market. We built a database of nearly 100 records. Records containing incomplete information, e.g. where the property characteristics could not be determined, were removed from the original database. Finally, a set of 19 production properties from the secondary market was a subject of regression analysis. The transaction price was assumed as the dependent (endogenous) variable. On the other hand, the set of explanatory (exogenous) variables includes a wide range of real estate market characteristics (information about the date of sale, location (county), land area, building usable area, land development factor, type of space, type of buyer, type of seller, type of property rights). Initially, the largest possible number of potential explanatory variables was selected, gradually reducing it after verifying the significance of individual variables for the further procedure. The final acceptance or rejection of potential explanatory variables was determined by statistical and formal criteria.

Fig. 2. Research Area. (a) Territory of Poland, (b) Wielkopolskie Province with analysed area marked

The analysed area covers mainly Kalisz-Ostrow Agglomeration, especially Kalisz, Kepno, Krotoszyn, Ostrow Wielkopolski, Ostrzeszow and Pleszew counties, located in southern part of Wielkopolskie Province. We analysed the market turnover on the area of 520 ha, which is almost 20% of the Province area. The following industries dominate there: electrotechnical, electronic, precision, machine, metal, food, chemical, textile and clothing, building materials. The subregion does not arouse such spectacular interest of investors as the capital city or regional cities, however, investments in the analysed area are both local and regional. Investment properties are largely purchased by external companies operating throughout the country and abroad.

A regression model was estimated by taking into account the regional market location and other property characteristics. The full list of potential explanatory variables is presented in Table 1.

Table 1: Potential variables explaining the price of industrial real estate

Explanatory variable	Type of variable	Description and variants of the variable
YEAR	quantitative	Year of transaction
AREA	quantitative	Area of county
LOKA	qualitative	Location in a county: (Kalisz = 1 and 0 otherwise)
LOKE	qualitative	Location in a county: (Kepno = 1 and 0 otherwise)
LOKR	qualitative	Location in a county: (Krotoszyn = 1 and 0 otherwise)
LOOS	qualitative	Location in a county: (Ostrow Wielkopolski = 1 and 0 otherwise)
LOOT	qualitative	Location in a county: (Ostrzeszow = 1 and 0 otherwise)
LOPL	qualitative	Location in a county: (Pleszew = 1 and 0 otherwise)
BLDA	quantitative	Building usable area [m2]
LNDA	quantitative	Land area [ha]
LDVF	quantitative	Land development factor [%]
USIN	qualitative	Use: industrial (industrial = 1 and 0 otherwise)
USWA	qualitative	Use: warehouse (warehouse = 1 and 0 otherwise)

USCO	qualitative	Use: commercial (commercial = 1 and 0 otherwise)
USOF	qualitative	Use: office (office = 1 and 0 otherwise)
TSEL	qualitative	Type of seller (enterprise = 1 and 0 otherwise)
TBUY	qualitative	Type of buyer (enterprise = 1 and 0 otherwise)
TPRR	qualitative	Type of property rights (ownership = 1 and 0 otherwise)

In regression modelling, we used a linear approach to estimate the model described by the equation:

$$y=\alpha_0 + \alpha_1 x_1+\alpha_2 x_2+...+\alpha_k x_k.$$

where y stands for the dependent variable (transaction price of industrial real estate), x_1, x_2, ..., x_k are the explanatory variables (the market characteristics of the property), while α_0, α_1, ..., α_k are the structural parameters of the model. Then we estimated OLS model and assessed its quality.

4. Results

The level of industrial real estate prices in recent years has been rather stable, although the condition of the industrial real estate market in southern part of Wielkopolskie Province (few transactions, properties differ significantly) makes it risky to assess the trend or forecast price changes. There were no significant changes in the industrial sector. There is an extension of the period of negotiating the terms of the transaction, the number of transactions is lower than in the period of the peak sales and price levels, while the relative balance of the positions of sellers and buyers is noticeable. The outlook for the regional industrial real estate market is optimistic. After the 2014-2016 period, which was very good for all market segments, we can still see increased activity on the part of investors, mainly in the logistics and warehouse sector, but also strictly in production. Demand in the broadly understood industry submarket remains at an optimal level, rental rates are stable, with a visible increase in the case of modern space, and the vacancy rate, despite new investments, does not increase. The investors' positive sentiment is mainly caused by the improvement in economic indicators, including the decline in unemployment, increase in employment and wages, and increase in private consumption.

The observation of the market participants' behaviour shows that for industrial real estate market, the following factors are of the greatest importance in determining value: real estate supply and real estate demand, real estate turnover, population size, unemployment rate, per capita income, property location, the amount of the rent, building exploitation costs, land use and zoning, type of property rights, technical infrastructure, distance from technical utility facilities, distance form main routes, accessibility, and anticipated changes. Most of the industrial properties are located in urban areas, with good access and infrastructure. In Kalisz county, the largest number (over 55%) of industrial properties are located in industrial districts, there are both older and modern facilities, built mainly in a special economic zone. Modern industrial plants are located mainly on the outskirts of the city, on the national road.

The supply of industrial properties on the regional market is small, there are currently over a dozen properties offered, most of them are located in Kalisz. The asking prices range from PLN 0.16 to PLN 3.5 million with the average PLN 1.5 million and the median PLN 1.3 million. Unit offer prices, on the other hand, oscillate around PLN 1,500 per m2. Most of the facilities are characterized by a dominant warehouse function, in a few the production function prevails.

Industrial real estate demand is limited. External investors (nationwide and international companies) with significant financial resources are interested primarily in the purchase of undeveloped real estate and the foundation of a facility that meets the requirements of the planned business activity. Local and regional investors pay attention to older and cheaper facilities. Industrial real estate is not of a universal nature and therefore it is difficult to sell – the level of turnover in this real estate submarket is small.

The estimated regression equation shows that the explained part of the variability of industrial real estate prices was shaped by a linear combination of variables characterizing properties in terms of their location, land area, type of space, date of sale, type of buyer, type of seller, type of property rights. Moreover, the upward trend in prices on the regional market in the analysed years was statistically significant (Table 2).

Table 2: Modelling prices on the industrial real estate market

USWA	-0,06334	0,034641	-1103736	603601	-1,8286	0,110174
TSEL	0,26069	0,056198	5563291	1199314	4,6387	0,002373
TBUY	-0,49016	0,042446	-8540898	739603	-11,5479	0,000008
TPRR	-0,06853	0,037417	-1353927	739278	-1,8314	0,109717

The estimated model showed that the location of industrial real estate on the regional market had a statistically significant influence on their prices. The probability of making a mistake in the assessment of statistical significance was close to zero (p-Value<0.000). As expected, properties located close to the agglomeration centre were more expensive. The value of the model determination coefficient was 99%. The high statistical significance of the F test indicates that the estimated model is satisfactory, and its cognitive value is high.

5. Conclusions

Market analysis is carried out for specific purposes, specifying the segment and spatial scope of the market, as well as the time scope. The analysis should be based on transactional data, which is the most important set of data, but in the event of a problem with their availability, offer data can be used as more recent, constituting an "early detection of changes" system. However, the offer data are not the resultant of the forces of supply and demand, therefore they are not a fully reliable indicator of the market situation, but mainly a reflection of the expectations of the supply side of the market [Widłak 2013]. In this view, this paper analyses the industrial real estate market based on the provisions of real estate sale agreements (notarial deeds) in terms of real estate prices and characteristics, as did other authors [Krajewska and Pawłowski 2019].

The conducted study showed that the prices of industrial real estate are influenced by: location, land area, type of space, date (year) of sale, type of buyer, type of seller, type of property rights. Thus, the previously formulated hypothesis about the location impact on prices was confirmed.

Some studies show similar results. An example is the 1987-1991 study of productive property prices in the Dallas-Fort Worth, Texas metropolitan region [Lockwood and Rutherford 1996], in which authors employ a multivariate analysis of industrial property values designed specifically to address the measurement problems associated with current tests of the sources of industrial property value. They used a linear structural relations model to examine relationships between industrial property prices and hypothesized determinants of value. One of the features of industrial real estate is location in the local market. The authors proved that the property's value is positively related to its location (understood as the distance (in miles, calculated by the most direct route) to the Central Business District, distance to the Dallas/Fort Worth Airport, distance to a major road, access to rail, and in Dallas or in Fort Worth, as the location variables. It is worth noting, however, that these studies show there was a noticeable difference in the location between the two cities of the metropolitan area. Our research, however, concerns less urbanized areas, located outside metropolitan areas at a distance at least 100 km.

Investors often choose between purchasing an undeveloped or developed land. Making decisions about the location of industrial investments by enterprises is conditioned by their financial capabilities, but also various macroeconomic factors, and at least real estate prices and characteristics. Our research showed that industrial real estate prices are influenced by their location in the region, but also by other characteristics, such as the date of sale, land area, type of entities concluding the transaction or the type of property rights. As for the location, it is perceived on many levels – as the possibility of easy access, the availability of infrastructure, the proximity of sources of supply and sales markets, but also the condition of the real estate surroundings and the level of development of the local economy. The conducted research may be important for active participants of the industrial market, but also for brokers and valuers, providing better opportunities for modelling the price levels.

Abstract

The terms diaspora and migration have obtained a broad semantic domain and encompass a diverse array of groups. A lot of people migrate to other geographical spheres in search of job and for better living. The paper probes into the linguistic effect of migration on the lives of people who move from India. An attempt is levied to analyze the relationship between linguistic factor and social, economic, and educational/ professional factors among 60 migrant respondents. Karl Pearson's Correlation Analysis is used for data analysis. As literature is the mirror of life, the paper also analyses diasporic drawings in literary works, both at national and international levels. To trace the essence of diasporic cartography in the works of Indian-English writers, literary work titled *A House for Mr. Biswas* by V.S. Naipaul is critically analyzed. Besides, it analyses the theme of migration in *Inside Out and Back Again* by Thanhha Lai and explores the impact of migration on international subjects. In short, the paper examines the power of language on the lives of migrant society.

Keywords: Diaspora, Economic, Educational, Linguistic, Migration, Social.

Introduction

In referring to modern diasporas, Sheffer (1986, p.3) has defined modern diasporas as cultural minority groups of migrant derivations inhabiting in host countries though upholding strong sentimental and material associations with their homelands. The diaspora endures a lot of difficulties in the struggle towards identity formation. The term refers to people who get displaced or dislocated, voluntarily or not, from their homeland as an aftereffect of colonialism, and is done through the process of migration, exile, immigration, and so on. The displaced retains a secret desire to come back to the homeland at times when such land exists in its true spirit. Diaspora implies a dislocation from the motherland or the place of origin and relocation in another country or region (Brah, 1996). It includes diverse groups of displaced who move across the globe. As a social construct, the term is in flux and attains new resonance over time. While the traditional pattern relate it with uprooting and resettlement, the post modern reading relate it to hybrid consciousness (Hall, 1990).It is a broad domain at present and includes a diverse range of cluster such as alien residents, guest workers, migrants, overseas communities, etc.

Writing is considered as a weapon by the diaspora community to bring out the inner thoughts and nostalgic feelings about the homeland. There is a remarkable difference between the first generation and second generation diasporic writers. While the former tries to withstand the heritage of their homeland through their food, clothing, and so on; the latter takes freedom of choice to remove the cultural indicators thereby making it easy to assimilate with the culture of the host country. A diasporic writer is always occupied twice within a luminous space as an outsider to the new culture and an outsider to the homeland mourning about the bygone past. In short, all such people go through the

Cite this Article as: Shibina K.M. and P.P. Vijayalakshmi "Linguistic Cartography of Migration and Its Impact on The Social and Economic Spheres" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

same types of nostalgic feelings, alienation, displacement, and so on. Hybridity and heterogeneity are the essential features of such subjects as the displaced takes in the elements of the dominant culture or language, and place it in flux through creolisation (Bhabha, 1994, p.120). A multi-dimensional approach including varied variables is quite essential in diasporic cartography. It creates nostalgia as it takes one through the process of "re-rooting" and intensifies the effect of displacement by accelerating the connection or memories with the homeland. The diasporic subject who undergoes various layers of identification attains a hybrid nature at times. In short, they have a physical life at the host country but maintain eternal bondage with their motherland, its cultural heritage, and so on. The endless love towards the homeland acts as an energizing factor to defy the process of isolation and assimilation in the new cultural setting.

Migration as a mode of diaspora has its significance as a social process from human civilization onwards. It is considered as the predominant course of action nowadays. Salman Rushdie (2010, pp. 278-280) suggests that similarly as the word metaphor suggests the movement of thoughts into pictures migrants are additionally "metaphorical beings' as they leave one culture and country to enter another. As the migrant undergoes social and linguistic dislocation in the very process of migration, he realizes that "reality is an artifact" and so resists all "absolute form of knowledge". It reinstates that a migrant who has been to various cultures is just sure of the relativity of things. Migration differs from immigration in such a sense that the former implies a permanent change of residence that need not be a shift from one state to another where the latter implies a shift from one state to another that too far from the homeland. It is a condition of human life rather than being an act and its effect on social relationships demands careful and systematic assessment. In the past, the tension between the native people and immigrants in ideologies reflected in their relations. However, immigration, communication means, and technological advancements accelerate the relationship between distinct linguistic groups. Good income and better living opportunities are the driving forces of migration in the post-modern era as it triggers the development of the multilingual community in the world. Technology also makes it possible for the immigrant to maintain regular contact with the native country.

Materials and Methods

The study is carried out using Primary and Secondary Data. For primary data collection, the researcher selected a sample of 60 including migrants from India to various countries and collected details using an open-ended questionnaire. Karl Pearson Correlation analysis is employed to analyze the relation between variables in the Primary Data. Secondary Data includes two novels and are analysed on linguistic and literary grounds using the theories of language and literature.

Research Discussion

The tables show the calculated correlation between four variables and focus on the interrelationship between Linguistic factor with Social, Economic, and Educational/Professional factors. Table 1 shows the correlation between two variables namely Linguistic and Economic factors.

On the basis of Correlation value (Table 1), it is inferred that there is a positive relationship exists between linguistic and economic factors with a correlation of .586. It shows a high positive correlation. It demonstrates that the rise of linguistic ability results in the rise of economic factors and vice-versa.

Correlations			
		Linguistic Factor	Economic Factor
Linguistic	Pearson Correlation	1	.586
	Sig. (2-tailed)		.001
	N	60	60
Economic	Pearson Correlation	.586	1
	Sig. (2-tailed)	.001	
	N	60	60

Table: 1

The key point of Marschak (1965) is that there is a warm relationship between the investigations of language improvement and financial matters, and as a fundamental device in human monetary exercises, language has financial qualities, for example, esteem, utility, expenses, and advantages. The way that a few qualities of a language have been saved or disposed of as time went on for the most part relies upon the capacity of that language to move the greatest measure of data with the base exertion. Knowing a language can be viewed as ability. To learn at least one

other dialects is an interest in human capital that brings monetary advantages. In the United States for instance, the loss of wages and the distinction in the joblessness rate brought about by the absence of English capability were assessed to be separately somewhere in the range of 3.8% and 38.6% and somewhere in the range of 1% and 6.5% (Gonzalez, 2005). Likewise, explicit language skills such as listening, speaking, reading, and writing definitely affect salary (Chiswick, 1991; Carnevale et al., 2001). Subsequently, from the point of view of human capital, the longing and inspiration of individuals' learning a language are performed under pure monetary motivating forces (Zhang, 2008a).

Table 2 demonstrates the correlation between two variables namely linguistic and educational factors and its result is as follows:

Correlations		Linguistic Factor	Educational Factor
Linguistic	Pearson Correlation	1	.666
	Sig. (2-tailed)		.000
	N	60	60
Education	Pearson Correlation	.666	1
	Sig. (2-tailed)	.000	
	N	60	60

Table 2

Correlations			
		Linguistic Factor	Social Factor
Linguistic	Pearson Correlation	1	.195
	Sig. (2-tailed)		.136
	N	60	60
Social	Pearson Correlation	.195	1
	Sig. (2-tailed)	.136	
	N	60	60

Based on the correlation value.666 (Table 2), it is asserted that there is a progressive relation between linguistic and educational factors. Language is used as a medium to impart education. As recommended by M. A. K. Halliday, the connection among language and education can be partitioned into three namely learning language, learning through language, and learning about language. Instructive projects for little youngsters regularly stress educational program and guidance to encourage language learning because the gradual learning of various realms of subjects can accomplish only through the medium of language. Early English learning in schools help students to get great direction over the language to get better educational outcome and thereby to contend in the worldwide situation (Enever& Moon, 2009).

Table 3 demonstrates the correlation between two variables namely linguistic and social factors as follows:

Table 3

It is shown in Table 3 that there is a correlation value of .195 between linguistic and social factors. The study shows that there is no significant relationship between these factors while compared to other factors. It is due to the cultural diversity of migrants and the language variations. It is inferred from the study that lack of proficiency in language hinders the social relationship between the migrants. English as a global language acts as a medium to strengthen the relationship between people and linguistic ability thereby results in better social interaction. In addition, it is through acculturation, the disparities are evaded to a certain level. Acculturation results in the cultural transmission of people when people of varied cultural settings have continuous contact between them and it is essential for adaptation in a foreign setting. As Agha (2006) asserts language is firmly connected to our social connections and is the medium through which we partake in an assortment of social exercises. Language is not only a type of social activity but also a compelling device with which we define models of public activity. In short, a connection exists between language, culture, and society.

A critical analysis of the secondary data helps us to trace the diasporic cartography in selected works. It helps us to understand about the factors that hinder the association between migrants and the host country. Being a Trinidad colonial, an English metropolitan, and a man of Indian ancestry, Naipaul has a unique personality and his fictions to

a great extent are a kind of self-exploration. *A House for Mr. Biswas* by V.S. Naipaul also deals with the theme of displacement. The protagonist Mohan Biswas is a man of Indian origin in rural Trinidad and so resembles Naipaul's father. His feeling of displacement and his firm desire to set up own identity by having a house of him move the novel forward. His dual perspective as a modern man without any orthodox Hindu practices and his attitude when he didn't get dowry throws light on the theme of displacement. Though none of the characters have paid any visit to India, they appear as close to being an India. They are offspring of Indian manual workers who left India in the 19th century.

Mohan's revelation of the world dictum that education is a prerequisite for survival in the world urges him to give the best of education to his son. The house where he lived is like a nation with many people (1961, I, ch.3). The novel throws light on the fact that educational aspect strengthens one's economic and social mobility. The protagonist understands that education is the only protector that assist one to survive in the new world (1961, p.393). It is this insight that urged him to provide the best education to his son Anand and thereby to light the life.

As a representation of human flexibility, *Inside Out and Back Again*(2011) by Thanhha Lai, a Vietnamese-American essayist, outlines the life of a little youngster named Kim Ha' and her family's relocation from Vietnam to Alabama because of Vietnam War. Different types of deterritorialization, removal, estrangement, and personality emergency that the focal character experiences inferable from the demonstration of being put out from the country. Here the uprooted experience a procedure of change and restoration that includes refashioning of character. At this point, undue accentuation is given to the battles that Kim Ha' suffered because of language obstructions and her counter endeavors for endurance. It is written in refrain structure to think about the hints of Vietnamese thus to give a sound to the way of life to which she has a place with. The language highlights tangible perplexity of social varieties and complex feelings of an evacuee. The readers get a cross breed experience where Vietnamese and American characters jump to life through the ten years of age hero.

The core problems that displace the central characters in the above mentioned literary pieces can be illustrated as follows:-

Title of the Work	Protagonist	Problem	Level of Displacement	Solution
A House for Mr. Biswas	Mohan Biswas	Identity Crisis	Emotional and Physical	Providing education to his son is considered as a key to enhance the economic and social mobility.
Inside Out and Back Again	Kim Ha'	Communication Barrier	Cultural	Language Acquisition

Stephen Krashen (1998, p.146) proposed the concept of "comprehensible input" to explain how the learners acquires a second language and it is defined as the "language input that can be understood by the listeners despite their not understanding all the words and structures in it". In both the works, the input is provided through education and self-motivated training respectively. The will and determination to overcome both emotional and physical obstructions are also conveyed in a deliberate manner.

It highlights the importance of mastering English language for global survival. It is through education and the medium of language, the central characters withstands the strong currents of social, economic, and institutional pressures. In Language and Culture, Kramsch (1998, p.10) affirms that the chronicled and abstract nature of culture are co-developed , thus individuals have a place with a specific network shares a typical social space and hold a typical arrangement of standard. Absence of education and learning about a language particularly in another land is depicted distinctively and it symbolizes the social antagonism. It underscores that by learning a language, one absorbs the social properties of the land too.

Conclusions

The study of the Primary Data establishes that there is a positive correlation between the selected variables. While correlations between linguistic and economic, educational show a significant increase, there is no significant correlation between linguistic and social factors. It throws light on the fact that the migrant gets displaced in a migrant world due to cultural variations. The migrants try to withstand in the host country through the processes of acculturation and assimilation. The diasporic community always tries to withstand their cultural heritage for the future generation and at the same time tries to amalgamate with the culture of the host country, and it eventually results in a dual culture. Any kind of discrimination leads to a categorization between the host and the guest communities and it adversely affects the guest community as a minority group and results in the conception of a broken identity.

Literature written by the migrated persona reflects their longing for cultural traits and the past glory of their homeland. As Rushdie (1991) asserts, the diasporic writers try to recreate their cultural memory through their works. In the process of negotiation, they confront with the process of acculturation. The dominant culture of the country takes its position forefront in the process. It is through the process, the migrant and the host develops a cultural adjustment and it results in overcoming the barriers. It is high time to evade the cultural confinements and to strengthen cultural integrity (Krishner, 2012).

Migration is a social process that eludes geographical boundaries, and social collaboration and technological advancements play a major role in it. People migrate from their homeland in search of a better opportunity and their income play a major role in the development of their country. Migration result in either positive or negative outcome to both origin and destination countries and balancing of the same lead to a pervasive effect. If the process gives positive outcome to both, the possible drawback of the process itself can be limited. Migration results in social, economic, political, and linguistic effects. By employing an equilibrium strategy, the adverse effects can be erased and a better social network can be formed. As Indians are accustomed with the practice of "unity in diversity", through cooperation and combination, we can implant unity and collaboration with people at any parts of the world.

Researchers have shown that migration results in the welfare and better conditioning of the families especially of migrants from poor countries to developed ones. It results in enhancing the economical, social, and educational standards of migrants and their families. In order to withstand in a new land, migrants make use of their linguistic skills. It is drawn from the analysis that linguistic factors assist in the gradual development of economic and professional factors. It is through the development of these three factors, social factors can be enhanced.

Abstract

In paper, we considered results of digital tools development for water resources management within natural-industrial systems, adapted to climate change. In studies, we used methods of data bases constructing, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties and risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space. As digital tools, we propose to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, we proposed a structural model, that combines the investment objectives with cost of adequate geo-information support for water resources management within natural-industrial systems, adapted to climate change. We consider examples of

developed tools usage for water resources management within different natural-industrial systems including Neva bay area. While research, we used platform https://www.researchgate.net/profile/Valery_Abramov2/ for data exchange and preliminary discussion.

Keywords: Digital Tools, Water Resources, Natural-Industrial Systems, Climate Change.

Introduction

Currently, the global environmental economy, including water resources management (WRM), is within Industry 4.0 period, when many businesses are planning and implementing a wide range of information technologies (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019), (Lukyanov, 2019), (Sikarev, 2020), (Trunin, 2019). Industry 4.0 leads to serious technological changes in WRM, including natural risks management (NRM) (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new digital tools, including practical learning area (Averkiev, 2020), (Estrin, 2020), (Korinets, 2020), (Popov, 2019) (Prostakevich, 2020),

Below we describe the development results of digital tools for WRM while climate change within geo-information management area (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) in environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). Significant attention is paid to geo-information support systems (GISS) within NRM in climate change context (Bournashov, 2014), (Gogoberidze, 2014), (Chestnov, 2020), (Chusov, 2012), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). Considered in this article developed geo-information support technologies for WRM while climate change take these factors into account.

Methods and data

In study, there are used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Bolshakov, 2020), (Vekshina, 2020). While research, there are used data bases and tools of digital online platform (DOP) EOS (Sanina, 2020).

Results

Currently, WRM has important value for global environmental economy while climate change. We have made a statement that VRM should be implemented within environmental economics paradigm with the help of adequate decision support tools developed on geo- information management (GIM) basement.

From GIM point of view, WRM is to be carried out within related set of natural-industrial projects (NIPs) in common space area and time period while climate change. In Figure1, it is presented a block model of investment structure for such NIPs with water resources involving or polluting and distorting, which combines the investment objectives (blocks 1-5) with cost of adequate geo-information and geo-ecological support (blocks 6-8), including WRM within NIPs (block 7).

Figure 1 - - Block model for investment structure while territory development: 1 – block of distribution of resources; 2 – block of formation of resources; 3 - block of formation of private income; 4 - block of formation of total income; 5 – block of formation of the investment share of resources; 6 - block of comparison with the permissible level of risk; 7-block of formation changing in time set of natural risks within WRM, including climate change; 8 – block of environmental monitoring corresponding to block 7

Made in study analysis shows that largest part of the cost of managerial support is the environmental monitoring (block 8), the essence of which is determined by the content of block 7. Significant part of the cost in block 8 is hardware and software, the cost of which varies significantly.

On basement of above mentioned model (figure 1), we propose to develop the geo-information and geo-ecological support system (GIGESS) with combined structure for access, storage and analysis of information from open geo-spatial data sources, including archives and operative mode web tools.

As a result of the research, performed using foresight technologies, we suggest to use geo-information distributed online platforms (GIDOP) with cloud technologies (CT) as the main technological solutions for GIGESS. We gave preference to open platforms such as Google Earth https://earth.google.com/web/. In this article, we recommend to use GIDOP EOS eos.com, including its product LandViewer (LV) https://eos.com/lv/, which provides efficient open source tools for searching, processing, and analyzing large amounts of satellite data from the Landsat-8 and Sentinel-2 satellite systems. Usage of LV allows to find and use satellite images of chosen areas with WRM objects, to determine the location of these areas and to assess their main spatial characteristics (linear and area dimensions).

Let's go to examples. Neva Bay is prominent large water-terrestrial NIS, where WRM is very important strategical task. Here, WRM includes and operational monitoring for different coastal objects. On Neva bay coast there are Saint-Petersburg city with around five million people, some large ports, recreational zones, some particularly guarded natural zones. There is a need of a tool, which allows decision makers to see the Neva Bay as an integral object of WRM in the operational mode at strategic time intervals. As essential result of study, we propose to use LV, as such tool with conditionally open access to satellite data from the Landsat-8 and Sentinel-2 satellite systems for the Neva Bay area. In figure 2-4, there are presented satellite images of the Neva Bay area which era visualized with different LV's applications.

Figure 2 - Space image of Neva Bay on 27/06/2020 visualized with Natural Colors Application of LV

Figure 3 - General diagram of dependencies between data subsystem modules in VDP

Figure 4 - Space image of Neva Bay on 7/05/17 visualized with agriculture colour combination of LV

We propose to use GIDOP EOS for long-period monitoring within WRM. As example, there is space image for about 28 years' period ago for Neva Bay, which can be visible through GIDOP EOS (Figure 5).

Figure 5 - Space image of Neva Bay on 14/06/1992 (Landsat 5) visualized with Natural Colors Application of LV

Note, decoding of space images in figures 2-5 was not task of this paper.

Discussion

We propose to use GIDOP EOS in educational and training purposes for WRM at University level. The essential task of university practical learning (UPL) will be to teach students the practical aspects of work with GIDOP EOS tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies, that can reduce total cost of learning process.

Conclusion

We consider results of digital tools development for WRM within natural-industrial systems (NIS), adapted to climate change. In studies, we used methods of data bases constructing, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties, risk management approach. From the point of view of geo-information management, we structured geo-space to allocate the interconnected components of the solution space. As digital tools, we propose to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, we proposed the block model of investment structure into NIPs with water resources involving or polluting and distorting, which combines the investment objectives with cost of adequate geo-information and geo-ecological support for WRM within NIPs while climate change. As essential result, we propose to use GIDOP EOS eos.com, including its product LV https://eos.com/lv/, as basement for low-cost GIGESS for WRM within NIPs while climate change. The presented in the article results of the research have a significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state environmental control bodies. They can be used in training and educational purposes, including preparation of master's programs in environmental economics.

Acknowledgment

While study, platform https://www.researchgate.net/profile/Valery_Abramov2/ was used for preliminary discussion and data exchange. Research was performed at the Russian State Hydrometeorological University within State Task of the Ministry of Science and Higher education of the Russian Federation, project FSZU-2020-0009.

Abstract

The purpose of the study is to reveal the nature and consequences of the economic and social impact of the coronavirus pandemic on the dynamics of Russian regions development. The authors described the economic consequences of the pandemic for the regions of the Russian Federation by analyzing key indicators of their socio-economic development. The top 10 regions that are most stable to the impact of the pandemic and the top 10 outsider regions for each analyzed indicator by economic sector are presented. The focus is on studying the structure of regional economies, identifying the most resistant to a decline in economic activity during the pandemic, and determining regions that have internal potential to deal with risks. The authors analyzed the most effective state support measures implemented by European countries and the United States in comparison with those proposed by the Russian Government.

Keywords: region, COVID-19 pandemic, Russia, economic damage, social consequences, economic barrier

Introduction

The problem of viral disease epidemics is not new. According to the world health organization, up to 5 million people get sick every year and up to 500 thousand die. Epidemics of "Spanish flu", "Asian flu", "Hong Kong flu", avian flu, SARS not only undermined the health and physical well-being of people, but also caused huge damage to the economy (for example, the economic damage from the SARS epidemic alone amounted to 59 billion dollars).

The impact of the 2019 coronavirus epidemic was a shock to the global economy, resulting in a halt to the usual socio-economic process and a devastating impact on entire regions and industries (for example, the almost complete shutdown of world tourism, world trade and the airline industry). Experts compare the current situation with an economic "barrier" to the development of the world economy, which will have a very negative impact on both the economies of countries and the entire global community. The economic impact of the coronavirus epidemic was superimposed on the prepared ground for the global crisis-the loosening of the established "globalization" model of the world economy, the tightening of global competition due to trade wars and the launch of reshoring processes, as well as the beginning of the destroying the European Union due to the initiation of "Brexit" in the UK.

Russia has not remained aloof from global problems. According to experts, the current situation certainly threatens the well-being of the country and its regions (Newsru, 2020). In the first four months of 2020, a third of Russia's regions experienced a reduction in budget revenues, and the drop in tax and non-tax revenues amounted to more than 200 billion rubles. The coronavirus pandemic is projected to reduce the country's gross domestic product (GDP) by

Cite this Article as: Ekaterina V. LISOVA, Igor V. PETROV, Tatyana V. KORYAKINA, Victoria I. KALOMBO MULAMBA and Evgeniya K. KARPUNINA "The Well-Being of Russian Regions under Threat: Economic and Social Impact Assessment of COVID-19" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

10 to 20 percent (Tirskikh et al., 2020a). The situation is further aggravated by the strong impact on the Russian economy of the global energy market panic - the decline in energy prices on the world market at the height of the pandemic, and, consequently, a significant increase in inefficient reserves in the oil and gas sector (Profinance, 2020).

What are the economic and social consequences of the pandemic for Russian regions? How effective are state policy measures in maintaining the well-being of the country's regions? What is the potential of Russian regions to offset the negative impact of the pandemic? These questions are relevant for the study.

Methodology

The purpose of the study is to identify the nature and consequences of the economic and social impact of the coronavirus pandemic on the situation in Russian regions.

Research problem:

1) disclosure of the economic consequences of the pandemic for the regions of Russia;

2) identification of effective regions of the country and regions that have internal potential to deal with the risks of economic decline;

3) analysis of the structure of the regional economy in terms of their resistance to the negative impact of the coronavirus pandemic.

According to scientists, the coronavirus pandemic is not only a new “plague” of the 21st century (Bryndin et al., 2020; Rinaldi and Paradisi, 2020; Plushikov, 2020; Savinov et al., 2020; Maksimova and Morozov, 2020), but also a global destructive impact on the foundations of the world economy and the principles of functioning of modern society (Zhiltsov, 2020; Pazdnikova et al., 2020; Shaginyan, 2020; Howick and Ongaro, 2020; Soldatova and Soldatova, 2020; Yaikbaeva, 2020; Antropova, 2020; Khlopov, 2020; Maksimov, 2020; Koltsova et al., 2020; Dolgov and Savinov, 2020). The researchers emphasize that the erosion of state sovereignty of many countries will take place in the conditions of an even more active transfer of the influence of state policy towards the largest corporations, as well as the strengthening of modern methods of conducting hybrid wars.

The transition to a post-global world, triggered by the coronavirus pandemic, creates conditions for deepening uneven development both between different regions and between countries (Altayeva, 2020).

A number of relevant scientific studies are devoted to assessing the impact of the coronavirus pandemic on the Russian economy, forming forecasts of socio-economic development in the short and medium term, as well as analyzing the negative consequences of the pandemic in Russian regions and of the national economy sectors (Tirskikh et al., 2020a; Karpunina et al., 2020; Pazdnikova, 2020; Yaikbaeva, 2020; Buldakova, 2020). Special attention is paid to the analysis of implemented measures of state support for citizens and enterprises. Thus, the Russian Government is ready to allocate about 2-2. 5% of GDP to support citizens and entrepreneurs, while in the United States the government has allocated 20% of GDP for these purposes, in the European Union from 8 to 10%, and in Japan -10% (Soldatova and Soldatova, 2020).

However, the study of the mechanisms of state assistance to Russian regions in a difficult situation remains fragmentary (Tirskikh et al., 2020a), and the search for flexible models for getting out of it is open to research due to the lack of previous experience in overcoming such phenomena.

The information base of the research is represented by official statistical data of the Federal state statistics service of the Russian Federation (Rosstat), the Ministry of Finance of the Russian Federation, expert analytical agencies, including Expert, and materials of scientific publications.

Research methods: method of economic analysis, graphic method, method of systematization, analysis and synthesis, system approach.

Results

The introduction of quarantine, mass transfer of workers to a remote work system, mobilization of medical institutions, and institutional restrictions on international and domestic movements have led to some stabilization of the level of coronavirus infection among the population, which, however, is not provided in all regions of Russia. Regions with the highest incidence of coronavirus as of 11.09.2020 these are: Yamalo-Nenets Autonomous district, Republic of Tuva, Moscow, Murmansk region, Republic of Kalmykia, Magadan region (Fig. 1).

Fig. 1: Top-10 and Outsiders-10 among the Russian regions by the number of cases of the coronavirus in the 1000 population of the RF subject, a person (as 11.09.2020)
(compiled by the authors according Infotable, 2020)

We will analyze the impact of the coronavirus pandemic on the Russian economy to identify effective regions and regions that have internal potential to deal with the risks of economic decline. The overall negative impact of the coronavirus epidemic on the Russian economy was manifested in a decrease in the country's GDP by 11.82% (Fig. 2).

Fig. 2: GDP dynamics in current prices in 2019-2020, billion rubles
(compiled by the authors according to Rosstat, 2020)

According to the Ministry of Finance of the Russian Federation, as of August 1, 2020, tax and non-tax revenues decreased by 8% (-515 billion rubles), amounting to 6,041 billion rubles, while income tax receipts decreased by 18% (-387 billion rubles) compared to 2019 (Minfin, 2020). Repayable receipts from the federal budget amounted to 1,743 billion rubles, with an increase of 62% (+667 billion rubles). Expenses were financed in the amount of 7,867 billion rubles, with an increase of 19% (+1,240 billion rubles). The consolidated budget deficit was 4 billion rubles (in 2019, there was a surplus of 1,075 billion rubles). With a total deficit of 264 billion rubles, the budgets of 36 regions were executed (against 14 in 2019), and the budgets of 49 regions were executed with a surplus of 259 billion rubles (against 71 in 2019). Moreover, the

financing of budget deficits in the regions of the Russian Federation was carried out by attracting credit funds in the amount of 493 billion rubles.

Figure 3 shows the top-10 and outsiders-10 among the regions of the Russian Federation in terms of the dynamics of the budget surplus/deficit.

Fig. 3. Top-10 and outsiders-10 among the regions of the Russian Federation in terms of the dynamics of the budget surplus/deficit (comparison of August 2020 to December 2019, %)
(compiled by the authors according to the Minfin, 2020).

The state debt of the regions of the Russian Federation is 2,171 billion rubles, and it has grown by 2.7% (58 billion rubles) since the beginning of the year. Moreover, the growth of the debt of the Russian regions is actually offset by a sharp decrease in the efficiency of budget execution, caused by a reduction in regional economies and a "shock" scenario for the development of problem regions. So, figure 4 shows the top-10 and outsiders-10 among the regions of the Russian Federation in terms of the dynamics of state and municipal debt.

Fig. 4: Top-10 and outsiders-10 among the regions of the Russian Federation on the dynamics of state and municipal debt (comparison of data from August 2020 to December 2019, %)

(compiled by the authors according to Minfin, 2020).

The impact of the coronavirus epidemic on the industrial production index for January-July 2020 compared to the same period last year was manifested in a decrease in this indicator by 4.2% in the country as a whole, and the most negative situation in the industry was in the Republic of Tuva and Sevastopol (a decrease of about 40% from last year's level). The maximum growth was recorded in the Tyumen region, which can be explained by the presence in the structure of the regional economy of the Tyumen region of the main "locomotive" of regional growth - the mining sector, which occupies more than 60% in the structure of the regional economy. Significant growth is observed in the Republic of North Ossetia–Alania (+27.3%), the Republic of Karelia (+21.8%), the main sectors in the structure of the economy of which are the manufacturing sector (20%), the mining sector (17.1%), and the transport sector (11%). Industrial growth occurred in the Kabardino-Balkar Republic (+20%) and the Altai Republic (+18.9%), which have a rather weak industrial potential. In this case, the positive dynamics is explained by the presence of individual regional growth points in the industry. Industrial growth in the Tula region for 7 months of 2020 compared to the same period last year amounted to more than 20.3%, due to the presence of a strong manufacturing sector – enterprises of the regional military-industrial complex (Fig. 5).

Fig. 5: Top-10 and outsiders-10 among the regions of the Russian Federation on the industrial production index for January-July 2020 to January-July 2019, %

(compiled by the authors according to Rosstat, 2020)

In the country as a whole, the regional manufacturing sector also did not withstand the negative impact of the coronavirus epidemic and in January-July 2020, by the same period of 2019, it decreased by 2.5%. By region, the situation is as follows (Fig. 6).

Fig. 6: Top-10 and outsiders-10 among the regions of the Russian Federation according to the index of production "Manufacturing sector" for January-July 2020 to January-July 2019,%

(compiled by the authors according to Rosstat, 2020)

Thus, among the outsiders in reducing this indicator, we can distinguish a group of regions with a low share of the manufacturing sector in the structure of the regional economy - Sevastopol (the share of manufacturing industry is 8.7%), Khabarovsk territory (9.9%), Primorsky Krai (9.5%), Chukotka Autonomous region (0.3%), Zabaykalsky Krai (2.8%), the Republic of Kalmykia (0.8%), the Republic of Ingushetia (5.5%). Here, the decline in the manufacturing industry is stronger than in the regions with a higher share of manufacturing in the structure of the regional product (Kaliningrad region (22.7%), Krasnoyarsk territory (31.8%), Nizhny Novgorod region (31.9%)). The exception is the Kaliningrad region, where the manufacturing index fell by 13%. The maximum index of the manufacturing industry in Sakhalin industry (the share of manufacturing in the structure of regional economy 2.4%), Tyumen region without Autonomous districts (18,2%), Altai Republic (4.6 per cent), Kabardino-Balkarian Republic (10,8%), Tula region (45,1), the Jewish Autonomous region (5,5%), Arkhangelsk region (17,4%), Nenets AO (0,2%), Tyumen region with districts (4.3 percent) and the Irkutsk region (10,9%). Thus, it can be noted that growth in the manufacturing sector, despite the negative impact of the coronavirus epidemic, does not depend on the share of manufacturing in the structure of the regional economy.

It should be noted that the construction sector of the Russian Federation as a whole withstood the negative impact of the coronavirus and decreased by only 0.4% in January-July 2020 compared to the same period in 2019. The strongest decline in the construction sector for 7 months of 2020 compared to the same period last year occurred in the following regions: the Republic of North Ossetia-Alania (the share of the construction sector in the economy of the subject is 8.6%), the Republic of Sakha (Yakutia) (9.6%), the Chukotka Autonomous region (7.3%). As the share of the construction sector in the regional economy decreases, the rate of decline in the sector reduces: Ivanovo region (6.2%), Ryazan region (4.9%), Pskov region (6.5%), Irkutsk region (6%), Vologda region (6.5%) and Kamchatka territory (4.1%). The regions with a lower share of the construction sector in the regional economy are the leaders in the growth of the construction sector for the first 7 months of 2020: Kostroma region (4.8%), Astrakhan region (4.9%), Tver region (6.3%), Yamalo-Nenets Autonomous district (12.4%), Kaliningrad region (8.1%), the Republic of Ingushetia (11.9%), Oryol region (7.1%), Zabaykalsky Krai (4.7%), Murmansk region (7%) and the Republic of Mari El (3.7%) (Fig. 7).

Fig. 7: Top-10 and outsiders-10 among the regions of the Russian Federation in terms of the volume of work performed by the type of activity "Construction", January-July 2020 to January-July 2019, %
(compiled by the authors according to Rosstat, 2020)

The agricultural sector showed growth of 3% in the country as a whole for the first half of 2020 compared to the same period last year. The largest growth was observed in the Tver region (the share of the agriculture sector in the regional economy of 6.8%), Kaliningrad oblast (6,3%), Jewish Autonomous region (7,4%), Kaluga region (5,7%), the Komi Republic (1,5%), Orel region (19,9%), the Republic of North Ossetia – Alania (12%), Tambov region (24,7%), Tula

region (6%), Penza region (12.2 per cent). As you can see, not all regions that have shown an increase in agricultural production have an agricultural specialization. The maximum reduction in agricultural production has occurred in the Magadan region (the share of agriculture in the structure of the regional economy is 6.3%), Novgorod region (7.8 per cent), the Republic of Kalmykia (25,9%), Stavropol region (14.7 per cent), the Republic of Crimea (6,7%), Kemerovo region (1.9 per cent), Rostov region (10,2%), Moscow (0,1%), Chukotka Autonomous district (2.5 percent), Volgograd region (10,5%) (Fig. 8).

Fig. 8: Top-10 and outsiders-10 among the regions of the Russian Federation according to the index of agricultural production, I half of 2020 to I half of 2019, %

(compiled by the authors according to Rosstat, 2020)

For 7 months of 2020 to the same period of 2019, in terms of a general decline in business activity in the country caused by the coronavirus pandemic, the production index for the type of economic activity "providing electricity, gas and steam; air conditioning" decreased by 3%, and the production index for the mining sector - by 6.6%.

The pandemic also affected the state of retail trade - for 7 months of 2020, compared to the same period last year, its turnover in the whole country decreased by 5.8%, and the following situation was observed in the context of Russian regions (Fig. 9).

Fig. 9: Top-10 and outsiders-10 among Russian regions by retail trade turnover, January-July 2020 to January-July 2019, %

(compiled by the authors according to Rosstat, 2020)

The largest drop in retail trade turnover for 7 months of 2020 compared to the same period in 2019 occurred in regions with a high share of this sector in the structure of the regional economy (which can be explained by serious measures to prevent coronavirus diseases, including the introduction of quarantine in the regions): Stavropol territory (the share of retail trade in the regional economy is 15.9%), Primorye territory (19.3%), Bryansk region (17%), Tambov region (16%), Omsk region (11.5%), the Republic of Dagestan (23.2%), the Republic of North Ossetia – Alania (18.9%), Kabardino-Balkar Republic (16.3%), Karachay–Cherkess Republic (8.7%). The Republic of Sakha (Yakutia), which has a 5.7% share of retail trade in the structure of the regional economy, was an exception.

The introduction of quarantine also affected the sector of paid services to the population, the decrease in the volume of paid services to the population for 7 months of 2020 was 20.3% compared to the same period last year. The negative impact was maximum for Moscow, the Yamalo-Nenets Autonomous district, the Republic of North Ossetia-Alania, the Arkhangelsk region, and the Primorsky territory.

Rapid growth in the consumer price index in the country in the second quarter of 2020 compared with the same period last year declined by 4.8% per capita incomes, which also were not uniform in different regions of the country (Fig.10).

Fig. 10: Top-10 and outsiders-10 among the regions of the Russian Federation by average per capita monetary income of the population, II quarter of 2020 to II quarter of 2019, %

(compiled by the authors according to Rosstat, 2020)

And, of course, the negative consequences of the pandemic were manifested in the form of increased unemployment. According to the Ministry of labor and employment of the Russian Federation, in April the unemployment rate was 4.7%, in September 2020 - 6.4% (Rbc, 2020) . The highest growth in unemployment was observed in the Republic of Ingushetia (30.6% for May-July 2020), the Republic of Tuva (21%), the Chechen Republic (18.6%), and the Republic of North Ossetia-Alania (17.3%). The most stable regions in terms of maintaining employment were Moscow, Yamalo-Nenets Autonomous district, Khanty-Mansi Autonomous district, and Saint Petersburg (Fig. 11).

Fig. 11: Top-10 and outsiders-10 among the regions of the Russian Federation in terms of unemployment in the labor force aged 15-72 years, for May-July 2020 (average for the period), %

(compiled by the authors according to Rosstat, 2020)

A detailed analysis of the impact of the coronavirus epidemic on various aspects of the functioning of regional economies allows us to conclude that the most prosperous region of Russia during the pandemic is the Tyumen region, and the region that is in the most difficult socio-economic situation is the Republic of Sakha (Yakutia).

What ensures this level of stability in the Tyumen region? In the structure of economy of the Tyumen region a high proportion of sector mining of minerals (20,3%), manufacturing sector (18.2 per cent), the sector of wholesale and retail trade (11.3 per cent), transport sector (9.5%), the sector of scientific and professional activities (9,4%), construction sector (7,6%) (Fedstat, 2020). This structure of the Russian Federation's economy allows it to recover quickly after the Government's restrictive measures have been completed, not to disperse financial resources across many sectors, but to allocate narrowly targeted assistance to specific affected sectors of the region.

On the contrary, the Republic of Sakha (Yakutia) has a "weak" regional structure that has not actually coped with the crisis caused by the coronavirus epidemic. The Republic of Sakha (Yakutia) has a very well-developed mining sector (more than 50% in the structure of the economy of the subject), and, of course, in a region rich in natural resources, the development of other industries is weakened. The well-being of such a region depends to a greater extent on the development of one sector of the regional economy. This did not allow us to quickly reallocate resources to other "pain" points in the development of the coronavirus epidemic.

Thus, the more diversified structure of the region's economy was more resilient to the impact of the pandemic.

The Federal government plays an important role in overcoming the impact of the pandemic in the country's regions. For example, in most European countries and the United States, effective measures have been: the introduction of civil liability and penalties for violations of quarantine measures, the creation of centralized channels for informing citizens, state support for the medical care sector and pharmaceutical companies, direct financial support for citizens (for example, in the United States in the first weeks of the crisis, the President allocated $1,200 for each American; Every unemployed person received $400 a week, the tax burden of citizens was eased), support for large and small businesses (in the UK, 15% of GDP was allocated to support economic sectors; every entrepreneur registered in the United Kingdom could expect to receive 10,000 pounds from the state), salary increases for workers affected by the

coronavirus pandemic (a program implemented in Germany and extended for the period 2020-2021), and so on (Baranovsky, 2020).

The anti-crisis measures introduced in Russia slowed down the fall in revenues and stopped the growth of budget deficits, but only for a while. Tax breaks for business, which, however, led to an increase in the budget deficit of the Russian Federation's constituent entities. To make up for the increased costs of the state, the government proposed raising the tax rate on mining, reducing benefits in the oil and gas sector, increasing excise rates on tobacco products, updating agreements to avoid double taxation, and raising the tax rate on personal income to 15% for citizens earning more than 5 million rubles a year. In our opinion, the revision of these tax rates will not radically change the current situation, since most of them make up the revenue part of the Federal budget and can be redirected to national needs, for example, to increase the country's defense capability. At the same time, the increasing rate of income tax on "wealthy" individuals can provide growth of incomes of subjects of the Russian Federation to stabilize the financial situation in the country.

At the same time, the experience of the "full lockdown" experienced by the Russian economy and the possible adjustment of the structure of the economy of the affected regions in terms of their resistance to the pandemic will help to avoid serious imbalances in regional development, as well as take prompt measures to correct the situation.

Conclusion

The article analyzes the impact of the coronavirus pandemic on the socio-economic development of Russian regions. The authors studied the structure of the economy of Russian regions from the point of view of their resistance to a decrease in economic activity during the pandemic.

Using open statistical data, the authors showed which sectors of the economy and which regions were most and least affected by the pandemic. The authors formed the top 10 regions that are most successful in overcoming the crisis situation, as well as the top 10 outsider regions that have the weakest economic structure.

The article analyzes the measures of support to regions by the Russian government, as well as systematizes the most effective methods implemented by developed countries to normalize the economy during the pandemic.

Abstract

The study assessed the development of integration in the Eurasian space, on the basis of which the hypothesis was substantiated that the processes taking place within the EAEU are aimed at maintaining sustainable economic growth and creating equal competitive conditions for its members. The study showed that the "four freedoms" within the EAEU contribute to the improvement of key indicators characterizing the integration processes. It was confirmed that the use of restrictive and the inconsistency of leaders have a serious impact on the implementation of agreements on the creation of common markets of production factors and is one of the obstacles in solving problems of using the economic and integration potential.

Keywords: EAEU, key indicators of integration, "four freedoms", economic and integration potential.

Introduction

In constantly changing world the integration provides the states participating in this process with additional opportunities to expand trade and economic interaction not only within the created association, but also with third countries, which, in turn, contributes to the achievement of competitive advantages for its participants, as well as an increase in the level of innovative economic activity as one of the main factors in increasing the competitiveness. The Eurasian Economic Union (EAEU) is considered a young integration association and its economic model is constantly being improved taking into account global trends in order to achieve deeper integration and maximize economic benefits for its members (Podbiralina, G., 2018).

As noted in the report of the Eurasian Economic Commission (EEC), "currently there is a growing tendency to reformat the existing architecture of the world economy. <…> International organizations regulating world trade, in particular the WTO, are not always able to respond to new risks and threats. The EAEU, in accordance with the norms and principles of the WTO, creates a network of regional integration groups. Such effective trade interaction with foreign partners and the development of integration within the Union itself make it an attractive, reliable partner" and contributes to the deepening of integration processes in the Eurasian space (Annual report. EEC, 2019).

In this regard, it seems appropriate to assess the results achieved within the EAEU integration project framework on the basis of the main indicators of foreign economic activity, which will identify problems in the development of integration in the Eurasian space and propose ways to solve them, as well as determine how economic integration contributes to the economic development of countries. This study also aims to confirm the conclusion that one of

" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the key areas and the main factor of integration is the interaction of the participating countries in the field of trade and the implementation of large (including cross-border) infrastructure projects.

Review of relevant studies and problem statement

A significant number of theoretical and analytical studies are devoted to the development of economic integration, assessment of the strengths and weaknesses of this process in different regions of the world, as well as the relationship between economic integration and socio-economic development. For example, it was shown, that the conceptual foundations, the classification of five types (stages) of economic integration and the strategy of European economic integration (Balassa B., 1961), as well as the structures and instruments of foreign policy and European economic relations were laid down in the Schumann Declaration, at the same time their author in fact was a famous French economist and politician Jean Monnet (Schumann R., 2002; The European Union in Search of a Global Role: Politics, Economics, Security, 2015).

The development of common approaches to the internal and external problems faced by the European Community, as well as the formation of the institutional system of economic integration and its structure are reflected in the works (Lindberg, L., 1963; Pollack, M., 2009; Peterson J., Shackleton M., 2012; Parsons, C., Matthijs, M., 2015) and other authors.

The research of the Institute of Europe of the Russian Academy of Sciences are devoted to the most successful integration union and its interaction with the world (The European Union in Search of a Global Role: Politics, Economics, Security, 2015).

The experience of the EU in the formation and development of integration is in many ways valuable for other countries, including from the point of view of a comparative assessment of integration processes in the European and post-Soviet space.

The work (Apostolakis, S., Margaritou, K., 2018) assess not only the effectiveness of "Eurasian governance in its institutional dimension", but also emphasizes the role of entrepreneurship and innovation as a basis for economic integration and growth of member states. Based on use of Balassa's method, problems of achieving competitive advantages by individual countries participating in the Eurasian Economic Union are identified (Falkowski, K., 2017).

However, only a few of them present an analysis of the potential of the entire association. A number of works identify internal and external factors that impede the development of trade and economic relations (Podbiralina, G., 2018; Sopilko et al., 2019).

Nevertheless, most authors agree that the participants of regional integration associations “are linked not only by economic and political, but also by socio-cultural interests,” therefore their historical interdependence and existing interests contribute to the desire to intensify interaction between the post-Soviet countries in various fields, including science and education (Eurasian integration: origins, problems, prospects, 2017).

By becoming members of one or another integration association, countries strive to obtain certain economic benefits, so the main purpose of this article was to analyze the trade and economic interaction of the EAEU countries and, on its basis, to determine the directions of integration potential in the Eurasian space.

Research Methodology

The research methodology is based on assessing the trade and economic interaction of the member states of the Eurasian Economic Union and identifying areas for realizing the integration potential of the EAEU. The theoretical and methodological framework is characterized by a combination of theoretical and quantitative analysis, systematization, comparison, descriptive statistics, which makes it possible to identify modern trends in the development of Eurasian integration.

As a result of the analysis of the structure of the EAEU intra-zonal and foreign trade, other areas of foreign economic cooperation in the context of maintaining low growth rates of the world economy, caused by the recent impacts of the Covid-19 coronavirus infection and the strengthening existing trade and economic relations between countries, but also the development of new ones, especially with third countries (including through the conclusion of regional trade agreements (RTS). As a result, the participating countries of the integration association receive additional benefits: improving the well-being and quality of life of people; ensuring maximum efficiency of the common market for business and consumers, etc. And for the association itself (in this case, for the EAEU) it is

building new formats of interaction with external partners and, as a result, obtaining maximum efficiency from participation in the integration process.

The study (L.L. Razumnova, T.E. Migaleva, G.V. Podbiralina, N.P. Savina, 2020) considered the problems of integration cooperation between the EAEU countries during the COVID-19 pandemic.

The theoretical basis for studying this issue was the work of Russian and foreign scientists and experts in the field of regional integration, especially in the post-Soviet space, and analytical reports and reports of the Eurasian Economic Commission (EEC) and materials of the EAEU Department of Statistics.

The statistical basis for the study was the reports of the Eurasian Economic Commission (EEC) and data from the EAEU Department of Statistics.

Results

Let's highlight the key indicators in the strengthening of integration processes in the post-Soviet space, one of which can be considered changes in the volume of mutual (intra-union) and EAEU foreign trade.

Assessment of intra-union and foreign trade in goods of the EAEU countries

Based on the EAEU Department of Statistics data, it should be noted that from 2017 to the present, there has been an increase in the value of mutual trade in goods (Table 1).

Table 1: Mutual (intra-union) trade in goods of the EAEU 2015 - 2020, USD million

	2015	**2016**	**2017**	**2018**	**2019**	**January – July 2020**
Export						
to the countries of the Union (mutual trade)	45 615,7	42 960,3	54 711,6	60 261,5	61 634,0	29 326,3
including:						
Armenia	256,2	393,9	571,0	688,5	769,2	340,8
Belarus	11 007,8	11 384,8	13 651,0	13 932,2	14 569,7	7 632,5
Kazakhstan	5 120,3	3 930,2	5 262,5	6 046,8	6 406,2	2 842,1
Kyrgyzstan	410,2	447,1	541,5	640,6	641,7	279,4
Russia	28 821,2	26 804,3	34 685,6	38 953,4	39 247,2	18 231,5
Import						
from countries of the Union (mutual trade)	45 654,2	42 427,2	53 812,5	59 732,4	61 861,1	28 437,1
including:						
Armenia	988,8	1 062,6	1 314,2	1 440,7	1 707,0	929,4
Belarus	17 207,6	15 381,2	19 715,8	22 760,5	22 205,9	8 723,5
Kazakhstan	11 211,6	9 863,5	12 518,1	14 097,4	15 297,4	7 553,8
Kyrgyzstan	2 065,1	1 626,0	1 863,7	2 161,3	2 100,8	1 009,3
Russia	14 181,1	14 493,9	18 400,7	19 272,5	20 550,0	10 221,1

Source: Department of Statistics of the EAEU.

At the same time, from the moment of the formation of the EAEU (2015) and up to the present day, almost all EAEU member states (except Russia) had a negative balance in mutual trade in goods (Table 2). An increase in the trade deficit is observed annually for Armenia and Kazakhstan, while in the Republic of Belarus and Kyrgyzstan this indicator decreased in 2019. The only country that has a positive balance in mutual trade in goods with other member countries of the association is Russia (however, this indicator decreased in 2019). It should be noted that a negative trade balance has a negative impact on national economies, considering the low diversification of the trade structure (both domestic and foreign) (Kofner Y., 2020; Eurasian Economic Commission Analytical review, 2020).

Table 2: The balance of intra-union trade of the EAEU member states, 2015-2019, USD million

	2015	2016	2017	2018	2019	Average (2015-2019)	Change between 2015 and 2019,%
Armenia	-732,6	-668,7	-743,2	-752,2	-937,8	-579,34	-28,0
Belarus	-6199,8	-3996,4	-6064,8	-8828,3	-7636,2	-6545,1	-23,2
Kazakhstan	-6091,3	-5933,3	-7255,6	-8050,6	-8891,2	-7244,4	-46,0
Kyrgyzstan	-1654,9	-1178,9	-1322,2	-1520,7	-1459,9	-1427,32	11,8

Source: EAEU Statistics Department and authors' calculations.

The increase in the value of intra-union trade by 2019 can be assessed as good results compared to the decline in 2014 and 2015 against the backdrop of Western sanctions against Russia. In addition, there was a slight change in the status of the dollar as a payment unit: according to statistics, from 2013 to 2018 Russia reduced the share of settlements in dollars in foreign trade by 12.6%, increasing the share in euros and rubles by 26.6% and 14%, respectively. At the same time, the role of the Russian ruble as a settlement means within the EAEU in 2013 - 2017 increased from 61% to 74% (Eurasian Development Bank, 2019). Nevertheless, in 2019 in mutual settlements for the export and import of goods and services the share of national currencies payments decreased slightly, and settlements in Russian rubles amounted to 72.4% (72.7% in 2018), in other national currencies - 1.5% (against 1.2% in 2018). In the payments structure between the EAEU member states (taking into account mutual settlements) and all countries of the world, US dollars still prevailed. Their share in payments for exports was 60.6%, for imports - 36.5%. Other foreign currencies (except US dollar and euro) in settlements with third countries accounted for 1.9% in exports and 3.6% in imports (Eurasian Economic Commission. Express Information, 2020).

It should also be noted that in the first half of 2020, food became a driver of not only internal but also foreign EAEU trade. Its sales increased in the first half of 2020 by 17.2% in monetary terms. Non-food agricultural products showed an increase of 9.1%. Export sales of sugar (12 times), poultry meat and by-products (2.7 times), sunflower (doubled), sunflower oil (42.3%) and wheat (9.3%) increased the most. At the same time, as a whole, the volume of non-resource non-energy exports of the EAEU to third countries for the six months of this year decreased by 9% compared to the same period last year (Karabut T., 2020).

As for the EAEU foreign trade, the trend continues when the intrazonal (intra-union) trade turnover is noticeably inferior to the foreign trade turnover, which is mainly due to the orientation of Russia and Kazakhstan (large economies of the grouping) to export outside the union. Table 3 shows the indicators of the EAEU foreign trade, on the basis of which it can be determined that the total volume of foreign trade in goods of the Eurasian Union member states in January- July 2019 amounted to 735.8 billion US dollars, including the export of goods - 460.8 billion US dollars. Imports is just over $ 275 billion. However, compared to the previous year, the volume of foreign trade turnover decreased by 2.4% or by $ 18 billion, including exports - by 6.1% (by $ 29.9 billion), while imports, on the contrary, increased by 4,5% (by $ 11.9 billion) (Table 3). Nevertheless, the foreign trade surplus remains at USD 185.8 billion, which is USD 41.8 billion less than in 2018 (USD 227.6 billion).

Table 3: Foreign trade in goods of the EAEU 2015 - 2020, million US dollars

	2015	2016	2017	2018	2019	January – July 2020

Source: Department of Statistics of the EAEU.

The total volume of foreign trade in goods of the EAEU with third countries in January - July 2020 amounted to 342 billion US dollars, including exports of goods - 202.9 billion US dollars, imports - 139.1 billion US dollars. However, these indicators are significantly lower than the same period of 2019: compared to January - July 2019, the volume of foreign trade turnover decreased by 17.3% or by 71.6 billion dollars, exports - by 22.7% (by 59.5 billion dollars), imports - by 8% (by 12.1 billion dollars) (Eurasian Economic Commission. Analytical review, 2020).

This dynamics is primarily due to a sharp deterioration in the situation in world markets caused by the negative impact of Covid-19, as well as the ongoing trade confrontation between the two largest economies - the United States and China.

As a result, the decrease in the value of exports of the EAEU member states to third countries compared to 2018 (by 6.1%) is due to a decrease in average prices for exported goods (by 3.1%) and the physical volume of supplies (by 3.1%). The fall in prices and the decline in physical volume equally (by 50% respectively) determined the overall decline in the value indicator. The value volume of imports increased by 4.5%, their physical volume - by 5.9%. Average prices for imported goods decreased by 1.3%. The increase in the value of imports is entirely due to the growth of the commodity volume. The price conditions of trade with third countries are characterized by an unfavorable ratio of prices for exported and imported (price conditions index - 98.2%). The EAEU demand for goods from third countries exceeds the external one produced in the EAEU (gross conditions index - 91.5%). (Eurasian Economic Commission. Analytical review, 2020).

It should also be noted the unequal contributions of the EAEU member to the aggregate indicators of foreign trade (as a percentage of the EAEU total), which were distributed as follows (Figure. 1):

Figure 1: Contributions of the EAEU member states to the aggregate indicators of foreign trade, 2019, in % of the total for the EAEU.

Source: Eurasian Economic Commission, 2020.

Thus, at present it cannot be fully asserted that the indicators of intra-union and foreign trade characterize a high degree of integration in the EAEU, however, there is a huge potential that can be realized due to export diversification, as well as a decrease of the political factor influence. In the meantime, existing forecasts (including the EEC) indicate that in 2020, due to a sharp deterioration in the foreign trade situation, exports from the EAEU

will significantly decrease, and the volume of mutual trade of the association will decrease by 24.1% (The EAEU recorded a decrease in the volume of mutual and foreign trade, 2020).

Trade in services of the EAEU countries is a driver of integration development

It should be noted that trade in services is developing at a fairly rapid pace, which was largely facilitated by the conclusion of the Treaty on the EAEU and the creation of a single market for services, which began to function on January 1, 2015. Forty-three service sectors operate within the single market of services (including construction work, rural and forestry, wholesale and retail trade, logistics, etc.). In December 2016, the Presidents of the EAEU member states approved liberalization plans for 18 service sectors; by the decision of the Supreme Eurasian Economic Council on May 14, 2018, another 9 sectors were transferred to the format of a single service market. In May 2019, the single market for EAEU services was supplemented with mapping services (5 years of the Eurasian Economic Union. Eurasian Economic Commission, 2019; Export and import of services of the member states of the Eurasian Economic Union. Express information, 2020).

The single market for services in the EAEU allows to supply and receive services without restrictions, exemptions and additional requirements on the basis of a permit obtained by a service provider in its territory (which is part of the EAEU), with recognition of the professional qualifications of personnel. As a result, approximately 55% of the volume of services produced in the countries of the Eurasian Economic Union is already provided in the single market mode. In the future, this should help reduce prices, create new jobs, give an impetus to business development (especially small and medium-sized ones), and ultimately ensure the growth of national economies, increase the competitiveness of goods and services and the investment attractiveness of the EAEU economies. Nevertheless, from 2015 to 2018 in intrazonal trade in services, only the Republic of Belarus and the Russian Federation had a positive services trade balance (Table 4).

Table 4: Balance of intra-union trade in services, 2015-2018, USD million

	2015 г.	2016 г.	2017 г.	2018 г.	Average (2015-2018)	Change between 2015 and 2018,%	In relation to GDP (on average for 2015-2018),%
Armenia	-22,4	-71,9	-77,9	-88,0	-65,1	292,3	-0,6
Belarus	505,8	516,7	685,8	550,9	564,8	8,9	1,4
Kazakhstan	50,1	-271,7	-530,4	-151,2	-225,8	-401,8	-0,1
Kyrgyzstan	9,1	-6,2	-434,8	-113,7	-136,4	-1349,5	-1,9
Russia	961,8	546,6	630,0	735,3	718,4	-23,5	0,05

Source: Kofner Y., 2020.

In 2019, compared to 2018, the export of services increased in all EAEU countries, except for Russia; imports enlarged in Armenia, Belarus and Kyrgyzstan. A positive balance of trade in services was observed in Armenia, Belarus and Kyrgyzstan; in other EAEU member states, imports exceeded exports. Figure 2 shows the growth in trade in services.

Figure 2: Growth in trade in services (2019, % of 2018).

Source: Eurasian Economic Commission, 2020

Thus, we see that intra-union trade in services is developing dynamically, which means that the existing economic and integration potential in this area can be realized. But for its implementation, it is necessary to remove existing barriers and obstacles in the internal market of the association, and the EEC is working to solve this problem.

So, at the meeting of the EEC Board in July 2020, the Minister for Internal Markets, Informatization, Information and Communication Technologies of the EEC G. Vardanyan presented a report on the results of monitoring the implementation of the roadmap for the elimination of exemptions and restrictions in the internal market of the EAEU for 2018-2019, where it was noted that currently 63% of the planned activities have been implemented. According to experts, “removing only certain obstacles included in the roadmap will reduce business transaction costs by about $ 100-120 million, and the cumulative positive effect of this removing will vary from 1.5 to 2% of the volume mutual trade "(EEC news, 2020).

Capital market as a necessary condition for the development of integration in the Eurasian space.

As noted in the EEC publications, the common financial market is currently at the stage of formation (the Agreement on its functioning should enter into force in 2025). It is assumed that the financial market will include not only the sphere of banking interaction, but also the insurance market, brokerage services, that is, the entire range of financial services (Annual report. EEC, 2019).

The concept of a EAEU common financial market formation was signed on October 1, 2019. This document defines: the main goals, principles, objectives, stages and expected results; legal basis and main directions of market functioning; the procedure for information interaction and administrative cooperation of financial market regulators; tasks and powers of the supranational body for regulating the EAEU common financial market. In addition, on December 23, 2014, an Agreement on the exchange of information (including confidential information) in order to create conditions in the financial markets to ensure the free movement of capital was signed. It entered into force on October 21, 2016 (The creation of a common labor market is one of the main priorities of the EAEU, 2016).

It is necessary to clarify that the capital market operates the main investment resources, which include not only loans and borrowings, but state and insurance funds, as well as the assets of enterprises. An important role is played by mutual investment and foreign direct investment (FDI), because their inflow allows to increase the fixed capital within the country, and an outflow increases the country's total ownership of assets in other member states. Thus, in the IV quarter of 2018, compared with the indicators of the previous period, the inflow of mutual direct investments to the EAEU member increased by 197 million US dollars. At the same time, direct investments in the EAEU from all over the world increased by USD 2,491 million (fig.3), and the predominant instruments of mutual direct investments were investments in the capital of companies, including reinvestment of income, investments in equity interest and shares of investment funds (Department of Statistics of the EAEU. Express information. Eurasian Economic Commission, 2019).

The EAEU Department of Statistics notes that during the period under review, in the structure of mutual direct investments, the largest inflow was observed in Belarus (703 million US dollars) and Kazakhstan (619 million US dollars). The main investor of mutual direct investments in the EAEU was Russia (USD 1,586 million) (Department of Statistics of the EAEU. Express information. Eurasian Economic Commission, 2019).

An important direction in the development of the integration and functioning of the capital market is the creation of the Eurasian Development Bank (EDB), which acts as a regional financial mechanism in the Eurasian space. As of September 1, 2019, the EDB's investment portfolio was approximately US $ 3.9 billion, and its balance sheet was US $ 2.6 billion (excluding provisions and discounts). Currently, the activities of this institute are aimed at financing priority projects in the field of energy, transport and infrastructure; carrying out informational, analytical and predictive research in the financial market of the EAEU, the CIS and other countries of Eurasia.

An important area contributing to the development of Eurasian integration can be considered the preparation of the annual Review of the largest investment projects of the EAEU countries, which brings together more than 600 investment projects in various sectors of the economy and is designed for a total amount of more than $ 700 billion. Its role and practical importance is to provide an opportunity to identify areas for the development of cooperation in industry, mutual attraction of investors, suppliers of equipment, raw materials, contractors to perform work and provide services for implementation of investment projects. The realization of the recommendations proposed in the Review will contribute to an increase in the volume of mutual FDI and mutual trade in investment goods and services within the EAEU (Department of Statistics of the EAEU. Express information, 2019).

Common Labor Market

The common labor market has been functioning in the EAEU since January 01, 2015. This means that, in accordance with the Treaty on the EAEU, citizens of the member states of the association have the same conditions of taxation, social insurance and medical care as citizens of the state of employment. Within the framework of the EAEU, all workers are given the opportunity to work not only under a labor contract, but also under a civil law contract. Mutual recognition of diplomas is ensured in all specialties with the exception of pharmacy, medicine, law and pedagogy. Children of labor migrants can attend preschool institutions and receive education in accordance with the legislation of the state of employment. The formation of legal conditions for workers should also contribute to the activation of migration processes within the EAEU, since "labor migration is a real resource in the development of the entire Eurasian region, and further integration will depend on how consistently the member states move in this direction" (Department of Statistics of the EAEU. Express information, 2016; Sopilko, N. et al., 2019).

Currently, a search system "Work without Borders" is being developed in the EAEU space. It will expand the opportunities for citizens of the member states of the association in the single labor market. The project is being implemented within the framework of the EAEU digital agenda. Since its launch, standard software has been created and integration work has been carried out in all five countries of the Union: Armenia, Belarus, Kazakhstan, Kyrgyzstan and Russia. The project "Unified search system" Work without borders ", if necessary," can become one of the services of the information system for recording labor migration", i.e. after the launch of the system, citizens of the EAEU countries will have additional opportunities for employment both in their own country and in the countries of the union, and for employers the list of sites for personnel search will expand (The search system "Work without Borders" is being created in the EAEU, 2020).

Nevertheless, for the existence of a single labor market to become economically feasible, it is necessary to develop and implement joint projects that are interesting (preferable) for the workers of the EAEU member states. In addition, it is important to invest in human capital and create attractive jobs for new workers, especially highly skilled workers. Only in this case the member states of the association will be able to realize the existing potential and create the necessary conditions for successful economic growth in the future.

Conclusions

Based on the study, the following results and conclusions were obtained.

During the existence of the EAEU, certain successes have been achieved. First of all, it is necessary to highlight the development and construction of an integration model of multilateral interaction, which is aimed at ensuring the strength and further development of the integration association. Since the functioning of the EAEU, one of the main conditions for its existence has been developed and adopted a huge array of supranational legislation, which is aimed at ensuring the free movement of goods, services, labor on 1/7 of the world land of the member states location. As a result, a common market for goods and services, labor and capital is functioning. In addition, as of 2019 a total of Memorandums were signed: eight - with regional integration associations, fourteen - with governments of third countries, eleven - with ministries and departments of third countries, thirty-eight - with international organizations and their subdivisions, and five - Trade agreements with other states.

Currently, a draft of the Strategic Directions for the Development of Eurasian Economic Integration until 2025 has been prepared (EAEU Closer to the people. Annual report. EEC, 2019), which indicates a new stage in the development of Eurasian integration. This document covers not only the completion of the areas provided by the Treaty on the EAEU to strengthen integration in the Eurasian space (the formation of single and common markets that ensure the implementation of the “four freedoms "; the development of basic regulatory legal acts, etc.), but also the achievement of harmonization and synchronization of the approaches of the Member States to the definition and regulation of new areas of cooperation; improvement of mechanisms of functioning and interaction of supranational and national institutions of the Union. Attention was paid to the development of new directions for the development of integration, in particular, in green technologies, renewable energy sources, in the field of health care, sports, tourism, education and science.

As noted in the Annual Report, "the new Strategy is fully consistent with national economic interests, the goals of sustainable and inclusive economic development of each EAEU member state" (Eurasian Economic Commission, 2019). In the future, in order to preserve the status of a “fast-growing integration association” for the EAEU, it is necessary to create conditions for the advanced development of the economy of all participants in this process, an increase in investment and innovation activity, in the competitiveness and scientific and production potential of the Eurasian Union as a whole. Based on the analysis of the EAEU's intra-union and foreign trade, it was determined

that since 2017, there has been an increase in the volume of mutual trade between the EAEU member states, however, this trend is largely due to an average prices rise for goods and services. In addition, the tendency of excess of foreign trade turnover over intrazonal remains. It is shown that integration within the EAEU has moved to a qualitatively new level, however, the effectiveness of the functioning of the association will largely depend on the creation of equal competitive conditions not only for its members, but also for third countries. In the meantime, we are witnessing the existing disagreements between the EAEU countries, for example, in making and agreeing decisions regarding the Draft Strategic Directions for the Development of Eurasian Economic Integration until 2025. Until now, the desire of the member states of the Union to preserve their sovereignty, as well as to independently build trade and economic cooperation with other countries, remains, which may subsequently lead to increased competition within the EAEU and negatively affects the development and strengthening of Eurasian integration.

Acknowledgment

This study was prepared with the support of the Russian University of Economics. G.V. Plekhanov, Order No. 1167 of September 25, 2020 (as amended by Order No. 1232 of October 8, 2020) on the topic: "Development of international business in the Eurasian space in the face of new global challenges."

Abstract

Trás-os-Montes region presents a range of certified products with high cultural and commercial value such as Terrincho Protected Designation of Origin (PDO) cheese, which is manufactured with milk of the Churra sheep from Terra Quente. The aim of this research was to define the consumer profile of Terrincho PDO cheese, as well as its purchasing and consumption habits. To achieve these objectives, an analytical and cross-sectional research was developed. To collect the data, a structured questionnaire was applied through personal interviews. The respondents were approached, at random, in public spaces of Bragança city between March 1th and 27th, 2019. Of the 380 interviewees, 57 were consumers of Terrincho PDO cheese. These consumers were mainly female (56%), with an average age of 58.3 years (± 16.190), married (70%), active (50%), lived in the municipality of Bragança (90%) with 2 (40% %) or 3 (28%) people in their household. Consumers of Terrincho PDO cheese differ significantly (p-value < 0.05) from non-consumers because they had a higher education degree (53%), a monthly household income above 1200 euros and were retired (47%). The frequency of consumption of the product occurred once a month (33%) or two to four times a year (26%), while the purchase frequency occurred on a monthly basis (69%). At the time of the purchase, most of the interviewees opted for the certified product (67%) due to the safety (79%) that it represents. Terrincho PDO cheese is a product capable to generate high added-value contributing to the economic development of Trás-os-Montes region given its acceptance by consumers.

Keywords: Terrincho PDO cheese, Protected Designation of Origin, Market Research, Consumer profile, Bragança.

Introduction

Traditional Portuguese products and their particular modes of production characterize unique elements with origin in the region that gives its name. The strong connection with the place of production is able to prove that the quality of the product is influenced by the animal breeds, soil, vegetation, climate and manufacturing technology. These have been assuming increasingly important roles as they represent part of the social history of a given culture (Vales, 2014; Cabo, Ribeiro, Fernandes & Matos, 2015).

Cite this Article as: Larissa Caroline PERINOTO, António José Gonçalves FERNANDES, Roberta de Souza LEONE and Maria Isabel Barreiro RIBEIRO "Purchase and Consumption Habits of Terrincho PDO Cheese: The Consumer Perspective in The Municipality of Bragança, Portugal" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The association of food products name with the place or region of origin is an ancestral practice, present in biblical passages, and was usually used among the Greeks and Romans, as they already did it as a way of differentiating products. This type of association has persisted over time and has become a form of appreciation. However, when a product reaches a reputation capable of crossing borders, there is the possibility of confrontation with products copied using the same name (Vales, 2014).

Given the potential of these products for the development of the rural environment to which they belong, policies for the valorization of traditional agro-food products were created, being the starting point for the protection of agricultural products by the European Union. Thus, there is a great interest in traditional products, where, with the reform of the Common Agricultural Policy (CAP) in 1992, the agricultural productivist model was put aside and the multifunctionality of agriculture went beyond the productive aspect, highlighting its role as facilitator of the construction of a territory in which people may live (Fiuza, Pinto & Amoedo, 2006; Tibério & Cristóvão, 2001).

A certification brand name ensures that a product from different manufactures will have particular characteristics, both in quality and in components, at a higher than normal level, this being a guarantee that it has been subjected to prior and continuous control by the producing association (Trentini & Sae. 2010). The use of a certificate of origin can, in theory, be applied to several product segments. As pointed out by Trentine and Sae (2010), any product class may be entitled to a certificate of origin. However, it is customary to have such a name for natural or elaborated products, where the geographical element has importance or even decisive influence on its quality and typicality.

The link between the product and the geographical region is due to natural and human factors. In the first case, it concerns the soil, climate, water, flora and fauna, as well as the nearby regions, namely, forests, sea, valleys or mountains. In the second case, it involves all the traditional techniques, work and practices related to production, and if these methods were transported to another region, it would not have the same effect in what concerns to the characteristics of the final product (Trentini & Sae, 2010).

According to the Comissão Europeia (2014), there is a preference on the part of consumers in relation to products of local or regional origin, as well as products of traditional specialties. The use of designations for specific products promotes the identification, the guarantee of quality and safety and the preservation of its tradition. The identification of Protected Names offers an incentive for the valorization of agricultural products and is available in the form of Protected Designation of Origin (PDO), Traditional Guaranteed Specialty (TGS) and Protected Geographical Indication (PGI) (Barros, 2014).

Among the products with Protected Names, the Terrincho PDO Cheese stands out in this research. This is a cheese obtained from the milk of the Churra da Terra Quente sheep, a breed whose manor is found, according to Ramos (2008), in the Terra Quente region of the Bragança district, including some municipalities of Vila Real and Guarda districts. The characteristics of the region favor the breeding of these animals, which makes it possible, thanks to their milk aptitude, to manufacture the only sheep cheese in the Trás-os-Montes region with a protected name.

Given the importance of the certified products for the development of the region in which it is produced, this study was carried out with the objective of knowing the buying and consuming habits of Terrincho PDO cheese consumers in the municipality of Bragança, as well as defining the consumer's profile.

Methodology

In order to achieve these objectives, an observational, quantitative, cross-sectional and analytical research was developed based on a sample constituted by 380 individuals. The anonymity of the respondent, the confidentiality of the collected data as well as the conditions relating to data protection were guaranteed to all participants.

Data was collected using a questionnaire that was applied to consumers who were circulating in the main squares and avenues of Bragança city between 11 and 27 March, 2019. The questionnaire had three sections. The first section consisted of questions regarding the consumption habits of Terrincho PDO cheese. The second section referred to the product's buying habits. Finally, the third section concerned the profile of the participant. All questions were structured, being multiple choice, single choice or dichotomous, with pre-defined alternatives, indicating whether the respondent could choose one or more alternatives, if necessary. Open questions were not used in this questionnaire, in order to facilitate the participants' cooperation. The order defined for the sections of the questionnaire aimed to create trust in the participants, leaving the personal questions to the end. In total, the questionnaire consisted of 30 questions.

A pre-test was carried out in order to highlight possible errors and allow the correction of the definitive questionnaire (Gil, 2002; Lakatos & Marconi, 2003). Only after the pre-test, the research instrument is validated. The pre-test must ensure that the questionnaire is well prepared, that is, regarding the clarity and precision of the words, the form and order of the questions and the introduction to the questionnaire (Gil, 2002; Gil, 2008). The pre-test carried out in this study took place in the municipality of Bragança on February 26, 2019, in a public square, with a sample of 15 respondents selected at random. The method of application was personal interviews. Each interview lasted, on average, 10 minutes. During the interview, the researcher could perceive the resistance of the interviewees to cooperate with the research, as well as the difficulty to answer some questions.

The sample characterization is shown in Table 1. Considering all the interviewed individuals, the distribution of the sample by gender was equitable (50%). However, most respondents had literary qualifications at the level of secondary education (12th grade) (32%) or higher education (33%), were married (53%), were employed (50%), lived in households with 2 (39%) or 3 (23%) people, had a monthly household income between 600 and 1200 euros (39 %) or 1201 and 3200 euros (33%) and lived in the municipality of Bragança (82%). The respondents' age ranged between 18 and 88 years, with an average age of 51.7 (± 18.625) years old.

Table 1: characterisation of the sample (n = 380)

Variable	Group	Frequencies	
		Absolute (n)	Relative (%)
Gender	Female	190	50
	Male	190	50
Education level	1st cycle incomplete	8	2
	1st cycle complete (4th grade)	65	17
	2nd cycle complete (6th grade)	22	6
	3rd cycle complete (9th grade)	37	10
	Secondary education (12th grade)	123	32
	Higher education	125	33
Marital status	Married	202	53
	Single	123	32
	Divorced	31	8
	Widow	24	6
Professional occupation	Employed	191	50
	Unemployed	31	8
	Student	29	8
	Retired	129	34
Monthly household income	Less than 600 euros	69	18
	Between 601 and 1200 euros	147	39
	Between 1201 and 3200 euros	123	32
	Between 3201 and 5200 euros	28	7
	More than 5200 euros	8	2
	Missing	5	1
Size of the household	1 person	74	20
	2 people	148	39
	3 people	86	23
	4 people	56	15
	> 4 people	16	4
Residence	Bragança's municipality	312	82
	Bragança's district (other municipalities)	36	10
	Other district	10	5
	Other country	13	3

The software used to edit and process the data was IBM SPSS version 26.0 (Statistical Package for Social Sciences). Descriptive statistics were calculated, namely, absolute and relative frequencies for nominal and ordinal variables and measures of central tendency and dispersion for variables of quantitative nature (Pestana & Gageiro, 2014; Maroco, 2018).

To compare the age of the interviewees was used the Man-Whitney test since the conditions to apply parametric tests were violated (data normality and variances homogeneity). In fact, the non-normality of the data was verified by using the Kolmogorov-Smirnov test with the Lilliefors correction ($n > 30$). The variances homogeneity was tested using the Levene test. The Man-Whitney test is used to teste the null hypothesis (H_0) that the medians (η) of consumers' and non-consumers age are equal (H_0: $\eta_{consumer} = \eta_{non\text{-}consumer}$) against the alternative hypothesis (H_1) that the medians of consumers' and non-consumers age are different (H_1: $\eta_{consumer} \neq \eta_{non\text{-}consumer}$).

Pearson's Chi-square test is characterized by being a non-parametric test, applied to nominal variables. It allows testing the null hypothesis of the proportions (θ) being equal (H_0: $\theta_{consumer} = \theta_{non\text{-}consumer}$), that is, the variables being independent, against the alternative hypothesis (H_1) of the proportions being different (H_1: $\theta_{consumer} \neq \theta_{non\text{-}consumer}$), that is, the variables being dependent (Sanders & Smidt, 2000). The practical rule of the Pearson Chi-square test indicates that $n > 20$ and 80% of the expected frequencies must be higher than 5 (Marroco, 2018). Pearson's Chi-square test was used to compare the profile of consumers and non-consumers of th Terrincho PDO cheese. Also, the channels of communication (media) and the types of promotion available to promote the product were compared considering the same groups. Fisher's Exact test is a non-parametric test used to compare two small independent samples, with dichotomous nominal variables grouped in 2x2 contingency tables when the practical rule of the Pearson's Chi-square test was violated (Marroco, 2018).

To carried out the analytical study, a significance level of 5% was used. According to Maroco (2018), the rule of statistical decision is to reject the null hypothesis when p-value (probability of significance) $\leq \alpha$.

Results and Discussion

Among 380 respondents, 57 were consumers of Terrincho PDO cheese (Table 2). The table shows the characteristics of the interviewees who consumed the product. It is noteworthy that the majority of consumers of the product were female (56%), had a higher education degree (53%), were married (70%), were employed (51%) or retired (47%), lived with 2 (39%) or 3 (28%) people in their household with a monthly household income between 600 and 1200 euros (23%) or between 1200 and 3200 euros (40%) and lived in the municipality of Bragança (90%).

For Wongleedee (2015), consumer behavior can be defined as actions to purchase goods and services for domestic and individual uses, in order to satisfy their basic needs, in which individuals are involved in the decision process and exchange of goods and services. According to Barroso and Madureira (2005), the cultural environment in which an individual grows determines, to a large extent, their patterns and consumption habits. Social status is a variable that influences and conditions consumer behavior, being a strong market segmentation variable. People belonging to the same social group tend to have the same opportunities, to live in the same type of houses, in the same areas, to buy similar products in the same type of stores. For this reason, to stratify populations, variables such as income, occupation, educational level or lifestyle are often used.

To analyze consumer behavior is to research consumers' patterns of purchase, consumption and use of products, or a specific product. Table 2 shows the comparison between respondents who were consumers of Terrincho PDO cheese and those who were not. There were significant differences (p-value < 0.05) in four of the characteristics evaluated, namely, educational level, marital status, professional occupation and monthly household income. There were no significant differences (p-value > 0.05) in three of the characteristics of the respondents, namely, between gender, size of the household and place of residence. It can be said with a 95% confidence level that those who consume Terrincho PDO cheese are married people, already, retired. The results in Table 2 also show that those who consume Terrincho PDO cheese are individuals with higher education qualifications and who earn a higher monthly income (between 1201 and 5200 euros per month) compared to non-consumers.

Among the non-consumers of the product, it can be concluded that the majority are people with academic qualifications concentrated between the 3rd cycle (9th grade) or secondary education. They are students or people who were unemployed, single, and with an average monthly household income between 600 and 1200 euros (Table 2).

In a study developed by by Fernandes, Ribeiro, Cabo and Matos (2017a) in the Bragança region, there were significant differences in educational level and in the household's monthly income, when comparing the profile of respondents who were consumers and non-consumers of gourmet products. The authors concluded that consumers of gourmet products in the Bragança region were people with higher education qualifications and higher income. Since gourmet products were

defined as high quality products, generally with specific origin certification and produced regionally, it was possible to confirm these characteristics obtained for consumers of Terrincho PDO cheese in the present study.

The average age of Terribcho PDO cheese consumers was 58.3 years old (± 16.190) and in non-consumers was 50.5 years old (± 18.805). When using the Mann-Whitney test to compare age between consumers and non-consumers, it was noticed that the median age of those who were consumers (62 years old) and those who were not consumers (52 years old) showed a significant difference (p-value = 0.005) at a 95% confidence level, indicating that consumers of Terrincho PDO cheese are older people. This significant difference in age was not detected in the study of consumers of gourmet products by Fernandes, Ribeiro, Cabo and Matos (2017a).

Table 2: profile of the consumer and non-consumer of Terrincho PDO cheese

[a] Results obtained with Pearson's Chi-square test.
* There are significant differences at the significance level of 5%.

One of the objectives of this research was to describe the consumption habits of the interviewees who assumed to consume Terrincho PDO cheese. According to Correia (2015), all individuals have needs, but these needs differ according to the different moments of their lives. For Zamberlan, Sparemberger, Wagner and Sartor (2006), consumption is a central resource in the formation of social and cultural identities. Regarding consumption, there are motivations, influences, habits, preferences and perceived risks, which are added and mixed making the moment of food consumption something with multiple meanings. The process of motivation for consumption begins with the recognition or activation of the need that occurs when there is disagreement between the desired state and the real state (Correia, 2015). The motivations that

lead the interviewed consumers of Terrincho PDO cheese (n = 57) to choose this product are shown in Figure 1. It is noticed that the majority of respondents choose this product because they value its sensory characteristics (68%) and few consumers associate the product with certain health benefits (2%). The sensory characteristics of a food are all the properties of the food that can be perceived by the human senses, namely, sight, touch, smell, hearing and taste, through which color, odor, taste, texture and sound of the product are detected (Teixeira, 2009).

Fig. 1: Motivation to consume Terrincho PDO cheese (n = 57)

Among the 57 respondents who consumed the product, a frequency of consumption of 33% was presented for those who consumed the product once a month and 26% for those who consumed it 2 to 4 times a month. Those who consumed the product daily represented the smallest part of the interviewees, being only 11% (Figure 2).

Fig. 2: Frequency of consumption of Terrincho PDO cheese (n = 57)

Still regarding consumption, it was found that, for most consumers, the product was eaten as an afternoon snack (75%) and as accompaniment (63%). Those who consumed it in main meals, represented 40% for dinner and 35% for lunch. About 21% consumed the product at breakfast and the smallest part of the interviewees consumed it at supper (16%). Among the ways of serving, in addition to the accompaniment, the consumers of Terrincho PDO cheese also indicated to serve the product as a dessert (35%), as a main dish (12%) or as an appetizer (5%), as can be seen in Figure 3.

Fig. 3: Meals and ways of serving of the Terrincho PDO cheese (n = 57)

Regarding the forms of consumption, the interviewees preferred to consume Terrincho PDO cheese with bread (77%) and with marmalade or jam (53%). The smallest portion of the interviewed consumers (2%) answered that they used the product incorporated in meals (Figure 4). According to the study carried out by Fernandes, Ribeiro, Cabo and Matos (2017b), regarding the consumption of PDO cheese in the Bragança region, there was a preference for the consumption of cheeses accompanied by marmalade, and this combination occurred mainly as an afternoon snack.

Fig. 4: Forms of consumption of the Terrincho PDO cheese (n = 57)

Terrincho PDO cheese is marketed in two forms, namely, the conventional Terrincho PDO cheese and Terrincho Velho PDO cheese. The Terrincho PDO cheese has a light straw yellow rind, with a slightly buttery texture and greasy aspect. The Terincho Velho PDO cheese presents reddish rind due to immersion in pepper paste mixed in olive oil, hard texture and less greasy aspect (QUEITEC, 2016). The two forms have different sensory, physical and chemical characteristics despite being produced from the same raw milk. As for the preference for Terrincho PDO cheese varieties (Figure 5), of the 57 consumers interviewed, 44% favor Terrincho PDO cheese in the conventional way, 31% give preference to Terrincho Velho PDO cheese with red and peppery rind and 25% consume both varieties.

Fig. 5: Preferences for the varieties of Terrincho PDO cheese (n = 57)

Regarding the individual of the household responsible for the purchases (Figure 6), it was found that, of the 57 interviewed consumers of the product, 61% stated that women were responsible for supermarket purchases in their household, another 23% replied that the couple made the purchases and 16% stated that the man was responsible for purchases related to food in the household.

Fig. 6: Household member responsible for the purchase (n = 57)

As for the frequency of Terrincho PDO cheese purchase (Figure 7), 69% consumers bought it monthly, 19% responded to buy it annually and 12% bought it weekly.

Fig. 7: Frequency of Terrincho PDO cheese purchase (n = 57)

Later, consumers of Terrincho PDO cheese were questioned about the seasonality of the consumption (Figure 8). Of the 57 respondents, 56% stated that they bought the product equally in every season. On the other hand, 44% (n = 25) stated there was a season of greater consumption.

Fig. 8: Seasonal consumption of Terrincho PDO cheese

For 52% of the consumers who bought the product seasonally, the Winter was the season with highest consumption of the product followed by Spring (28%), as shown in Figure 8. In the traditional grazing of the Churra da Terra Quente sheep, that occurs according to the specifications of the Terrincho PDO cheese, in Spring there is a time of great food abundance, taking advantage of the rains of the cold season and, in Summer, the food shortage, with Autumn and Winter representing intermediate situations and variable production depending on the weather (QUEITEC, 2017). Therefore, there is a greater abundance of the product on the market at the end of Winter and in the Spring, due to the greater amount of food available to the Churra da Teera Quente sheep, with the availability of the product (8% of the 25 respondents) one of the motivations to the greater consumption of the product at a particular season.

Assessing the interviewees' motivations for consuming more Terrincho PDO cheese in specific seasons (Figure 9), it was found that, of the 25 respondents that respond to this question, 40% consumed the product more in a specific season due to quality and 32% did it due to traditional parties. Winter starts on December 21st and runs until March 20th, within this period traditional festivities take place, namely Christmas and New Year's Eve. These events may represent motivations for the consumption of traditional Portuguese products.

Fig. 9: Motivations for the seasonal consumption of Terrincho PDO cheese (n = 25)

Seeking to evaluate all the components of the marketing mix, the consumption habits were studied in relation to the product, the price, the distribution and the promotion of Terrincho PDO cheese. In fact, according to Barroso and Madureira (2005), it is always necessary to take into account all elements of the marketing mix, in order to develop marketing strategies that will subsequently support decisions about the elements that compose it.

In the section of buying habits, in relation to the product, consumers' preference was evaluated regarding products' physical characteristics, such as presentation, packaging and certification. As for the presentation preferences of Terrincho PDO cheese (Figure 10), of the 57 interviewed consumers, the majority assumed that they always chose to buy the whole unpackaged product (58%), secondly, they opted to buy it whole prepackaged (40%) and in third place in prepackaged portions (2%). There were no respondents who bought it emerged in olive oil. Still in Figure 10, it can be seen that most consumers interviewed had a preference for buying the product without packaging (56%). As for the types of packaging, consumers prefer the vacuum plastic packaging (28%), paper (14%), with a minority of consumers opting for decorative packaging (2%).

Fig. 10: Presentation and packaging of the Terrincho PDO cheese (n = 57)

As for certification (Figure 11), of the 57 respondents who consumed the product, 67% said they always buy the certified product. On the other hand, 30% indicated that they opted for the non-certified product and 3% were indifferent, indicating that they opted for the product that was available at the time of the purchase. Among the 67% who purchased only the certified product (n = 38), the reasons for this preference, were safety (79%) and quality (53%).

Fig. 11: Preference for product certification

The price represents a value that will allow to buy a finite amount, weight or other measure, of a good or service. The price depends on the average cost of the company and the value that the customer knows in relation to competing products (Wongleedee, 2015). Terrincho PDO cheese, as a traditional product, both certified and non-certified, has a high added value. Among traditional cheeses, at the national level, Terrincho PDO cheese had a commercial value only lower than Azeitão PDO cheese in 2016. The Terribcho PDO cheese costs 14.50 €/Kg for the certified product and 13.75 €/Kg for the non-certified product, and the Azeitão PDO cheese costs 20.00 €/Kg for the certified product and 12.00 €/Kg for non-certified product (DGADR, 2017). The significant differences in the income of consumers and non-consumers of the product are explained by the high added value that a traditional product, such as Terrincho PDO cheese, has become a food most consumed by the upper classes of the population.

For the interviewees who assumed to opt for the non-certified product (30%) or to be indifferent as to the type of product (certified/non-certified) they purchased (3%), they were asked if they would be willing to overpay for a certified product. Of the 19 respondents who answered this question, 74% said they would not overpay for a certified product and only 26% said they would be willing to overpay (Figure 12). To the 26% who stated that they would be willing to overpay to obtain a certified product (n = 5), they were asked how much they would be willing to overpay. Figure 12 shows that 40% of the respondents that answered to this question would pay more than 0.5 to 1 euros, another 40% would be willing to pay more than 2 euros for the certified product, and 20% would pay less than 0.5 euros.

Fig. 12: Price of the Terrincho PDO cheese

Regarding distribution, that is, the means that the company has at its disposal to take the product from its origin to the final consumer (Barroso & Madureira, 2005), it can be seen in Figure 13 that 81% of the 57 interviewees, consumers of the product, prefer to buy Terrincho PDO cheese in supermarkets.

Fig. 13: Place of the purchase (n = 57)

There are still 23% of interviewed consumers who make the purchase directly from the producer. Considering that the 23% of the respondents, who prefer to purchase the product directly from the producer, prefer to obtain a certified producer, they will have to travel outside the municipality of Bragança to do so. It is known that the municipality of Bragança is not part of the region of production of Terrincho DOP cheese (QUEITEQ, 2017). The municipality of Macedo de Cavaleiros is the closest region to the municipality of Bragança where the product could be purchased directly to the producer.

Still in relation to product distribution, researching the motivation to select the place of purchase Terrincho PDO cheese, it can be observed in Figure 14, that the majority of respondents (68%) chose the place based on the proximity of the establishment to their residence. Other criteria pointed out were the quality they relate to the place and the trust in the establishment, with 11% of respondents each. The price and variety were not mentioned as very important criteria to select the place of purchase. In fact, only 5% of the interviewees considered these criteria.

Fig. 14: Criteria to select the place of purchase (n = 57)

Promotion is the element of the marketing mix that establishes the bridge between the company and the outside (Barroso & Madureira, 2005). In this research, the promotion was evaluated through the channels of communication (media) to which the interviewees had access in their daily lives and the types of promotion that they thought were more appropriate to Terrincho PDO cheese. These questions were asked both consumers and non-consumers of the product allowing to identify the channels of communication and the types of promotion to which both groups of respondents have more access and value the most.

It can be seen that the media most used by both groups of respondents (Table 3) is television, with 89% for Terrincho PDO cheese consumers and 81% for non-consumers. In sequence, the Internet is the second most used media by both groups, with 63% of consumers and 64% of non-consumers. Still with a relevant share, national newspapers came in third place among the media, with 56% of the interviewees consumers of Terrincho PDO cheese and 46% of non-consumers.

When assessing the possible differences between the two groups of respondents, namely, consumers of Terrincho PDO cheese and non-consumers, using Pearson's Chi-square test and Fisher's Exact test, Table 3 was obtained. It is observed that there were no significant differences (p-value > 0.05) in any of the media (television, local newspaper, national newspaper, local radio, national radio, local magazine, national magazine, flyers and internet) considering the two groups

of respondents. Then, it can be concluded that all respondents make use of the media in the same way. The most used are television, the internet and national newspapers.

In order to carry out marketing campaigns, the Terrincho PDO cheese management company, considering the results of this research, can make use of the same channels of communication in order to reach the two different groups with an advertising campaign. It can be said that, regardless the channels of communication the company uses to promote the product, it can reach both groups, that is, those who already consume the Terrincho PDO cheese and those who are not yet consumers. Also, considering that the media that reach a larger population are the television, the internet and the national newspapers, the Terrincho PDO cheese management company, can use the internet as the main channel to communicate with potential clients since this is an affordable and accessible media capable to shorten the distribution chain since the company can sell directly to the final consumer. Internet can, also, be used to increase the visibility of the product through the use of social media. Television, despite being the most used media by both groups, has very high costs for the dissemination of products information, in general.

Table 3: channels of communication preferred by consumers and non-consumers of Terrincho PDO cheese

Variable	Group	Consumer		p-value
		Yes (n = 57)	No (n = 323)	
Television	Yes No	51 (89%) 6 (11%)	261 (81%) 62 (19%)	0,115 [a]
Local newspaper	Yes No	6 (11%) 51 (89%)	24 (7%) 299 (93%)	0,425 [b]
National newspaper	Yes No	32 (56%) 25 (44%)	148 (46%) 175 (54%)	0,150 [a]

According to Barroso and Madureira (2005), promotion is a very relevant variable in the agro-food sector, since it encompasses techniques for stimulating demand based on product experimentation or increasing its visibility. Also, experimentation is a powerful incentive when making a purchase decision. Promotions are characterized by being short-term activities with the objective to reach specific audiences. The types of promotion can be varied, and can involve tastings, free sample offers, free gifts, discount coupons, discounts to distributors and contests (Table 4).

Table 4: types of promotion preferred by consumers and non-consumers of Terrincho PDO cheese

Variable	Group	Consumer		p-value
		Yes (n = 57)	No (n = 323)	
Tastings	Yes No	28 (49%) 29 (51%)	160 (50%) 163 (50%)	0,954 [a]
Free sample offers	Yes No	15 (26%) 42 (74%)	84 (26%) 239 (74%)	0,961 [a]
Discount coupons	Yes No	10 (18%) 47 (82%)	36 (11%) 287 (88%)	0,172 [a]

Discounts to distributors	Yes No	3 (5%) 54 (95%)	25 (8%) 298 (92%)	0,783 [b]
Contests	Yes No	3 (5%) 54 (95%)	26 (8%) 297 (92%)	0,596 [b]
Free gifts	Yes No	1 (2%) 56 (98%)	14 (4%) 309 (96%)	0,709 [b]
Fairs	Yes No	35 (63%) 22 (37%)	165 (64%) 158 (36%)	0,150 [a]

[a] *Obtained with Pearson's Chi-square test.*
[b] *Obtained with Fisher's exact test.*

Among the ways to promote the Terrincho PDO cheese (Table 4), fairs were identified as the main type of promotion in the opinion of the interviewees, with 63% of the consumers and 64% of non-consumers. Tastings were the second most chosen type of promotion by respondents in both groups, with 49% of consumers and 50% of non-consumers.

Again, the comparison of the types of promotion considering the two groups of respondents, consumers and non-consumers of Terrincho PDO cheese revealed no differences at a 95% confidence level (p-value > 0.05) in the types of promotion (tastings, free sample offers, discount coupons, discounts to distributors, contests, free gifts, fairs). Again, indicating that the company can operate with the same types of promotions to reach its customers or to reach an audience that is not yet a customer of the product. So, in promotion campaigns, the Terrincho PDO cheese producer association could bet on marketing at fairs and tastings of the product at points of sale, which were the types of promotion most valued by both groups of respondents.

Conclusion

Most Terrincho PDO cheese consumers in the municipality of Bragança was female, with an average age of 58.3 years (± 16,190), who was employed or retired, lived with 2 or 3 people of their household, earn a monthly income above 1200 euros, had a higher education degree, was married and lived in the municipality of Bragança.

The main motivation for the consumption of Terrincho PDO cheese was linked to the sensory characteristics of the cheese. The consumption of the product occurs once a month, mainly as an afternoon snack and, generally, as an accompaniment to bread. It was also noticed that the consumers who preferred to consume the product in the main meals, namely, lunch or dinner, did it as a dessert, usually accompanied by jam, marmalade or bread. In addition to these consumption preferences, it was found that the consumers gave preference to Terrincho PDO cheese over Terrincho Velho PDO cheese.

In relation to purchasing habits, it was found that, in most cases, women are responsible for the purchases in the household, with the frequency of consumption and purchasing of Terrincho PDO cheese occurring monthly, in all seasons. However, those who chose to buy the product more seasonally, did it more in the Winter, motivated by the believe in a higher quality of the product. The preferred place to do the purchase was the supermarket, motivated by the proximity to the respondents' residence. At the time of the purchase, respondents prefer to purchase the whole product and without packaging. They, also, prefer to buy a certified product, mainly for the security it presents. Among those who opted for the non-certified product or were indifferent as to the type of product they purchased, it was realized that they would not be willing to overpay for a certified product.

With regard to promotion, it was found that the most used channels of communication, in the daily routine of the consumers, were the television and the internet. As for the types of promotion, the interviewees pointed out that they consider fairs and tastings as the best ways to promote the product. As there are no significant differences in the channels of communication and the types of promotion between groups of consumers and non-consumers of the product, there are indications that, regardless of the type of promotion that the company uses, it will reach both audiences.

The cross-sectional character of the research constitutes one of the limitations of this study. In fact. This type of study portrays the profile of the consumer in just one moment, being a static study. The non-probabilistic sample also ends up representing a limitation because the interviewees were chosen at random. For this reason, the results cannot be extrapolated to the general population. These limitations can be circumvented with future researches, which should be

longitudinal and based on probabilistic samples, ensuring that the sample of respondents is representative of the population of Bragança municipality and allowing to characterize the profile of Terrincho PDO cheese consumer over time.

Abstract

The construction project, due to its complexity, often faces difficulties in the timely implementation of all activities, without interventions or modifications on them. Also, the realization of a construction involves the work of a large team of specialists and the collaboration of large categories of stakeholders. These are subject to new requirements and regulations, which have appeared periodically, related to safety conditions, quality, maintenance, etc. BIM is a concept that proactively responds to these challenges by improving the way buildings are designed, built and monitored. This paper suggests that BIM is a viable alternative to successfully implementing a complex project, due to the advantages created by the high-performance information system on which it is based. The research aimed to analyse the correlation between BIM performance factors and ensuring the success of construction projects. The analyse was performed by a survey applied on the managers in the construction sector from North-western Romania, who intend to implement, or have implemented BIM based construction projects. The study shows a positive correlation only with some of the BIM performance variables with the success of the project, suggesting the idea of a poor perception of managers in the studied area on the benefits of using BIM technology in construction projects.

Keywords: Building Information Modelling, Construction Projects, success factors

Introduction

The European construction sector is facing tough but promising economic, environmental and social challenges. This sector leads to economic growth and SMEs development. (https://ec.europa.eu/growth/sectors/construction_en). An innovative, competitive and growing construction sector is a key component of the response to the challenges of our century. Like other sectors, construction is currently going through its own "digital revolution", having previously received only modest improvements in productivity. Construction projects have a complex character which needs some additional elements from other projects to ensure their success. Companies must improve to stay ahead of their competition, but should cooperate with them. A construction project, due to its complexity, often faces difficulties in the timely implementation of all activities, without interventions or modifications. Also, a construction involves the work of a large team of specialists and the collaboration of large categories of stakeholders. (http://www3.weforum.org/). The new regulations and additional requirements make the design and the implementation of these projects more difficult. The solution is the use of BIM (Building Information Modeling); it provides an efficient flow of information throughout the design, construction and operation pahses of the construction, which in the end translates directly into a significant increase in performance.

Cite this Article as: Sanda Mărioara NAȘ, Corina RĂDULESCU, Virgil Mihai Gh.M. RĂDULESCU, Gheorghe M.T. RĂDULESCU, Mircea BONDREA and Adrian T.Gh.M "Influence of Building Information Modelling (BIM) on a Projects' Success" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Building Information Modeling or BIM represents a new approach in designing buildings, unlike traditional technology CADD (Computer-Aided Design and Drafting) in addition to graphical objects, allows the manipulation of extensive and diversified data or information . They allow automatic generation of drawings, reports, order forms, collaboration with structural analysis applications, detailing, management and performance simulation, building monitoring during operation and more (Eastman et al., 2011; Kensek & Noble, 2014).

The success of BIM resides in the possibility that all specialties involved (architecture, structure, and installations) can use a single 3D model which will extract all the images and representations required: plans, sections, and elevations, details of execution, quantity and price estimates including as-built documentation. Any changes to the unique model are automatically reflected in all drawings and documents extracted from it, which allows effective management of changes in the project. This is extremely important because customers are usually willing to pay only the final draft, not the changes which occur during its development.

Several authors (Kensek & Noble,2014; Jalaei & Jrade, 2015; Wong & Zhou, 2015) argue the role of the Building information modeling. BIM, in the authors' opinion, represents a strategic tool to achieve cost savings, to increase operations' efficiency, to improve the quality of infrastructure and enhance the performances concerning environmental issues (Cerovsek, 2011; Miettinen & Paavola, 2014). The main problems that this concept solves refer to: reducing design time, eliminating the need to redesign, improving coordination between disciplines, the opportunity to explore and creating a simulation in the model to detect design problems with lower cost, higher quality and level of trusted deliverables (two-way connection with the 3D model, while the risk of inconsistencies is practically zero).The main advantage of BIM is increasing the level of coordination and collaboration between all team members involved in the project (architects, specialized engineers, manufacturers, executors, beneficiaries) from concept, technical project, execution details, to manufacturing, construction and maintenance. These new communication possibilities give designers the opportunity to improve their products. They allow, in theory, communication analysis and simulation software that provides real-time information throughout the design process.

Contribution of BIM to the success of Projects

BIM's performance factors

As a general principle, BIM uses full integration (Rahman et al., 2013; Irizarry et al.2013; Succar, 2009). Involves the correlation of all activities that execute drawings belonging to a project, in a single electronic format model. This prevents duplication of possible corrections to the drawings and their modification in real time, allowing all teams to have instant access to design changes made and to see the effects. Adoption of this model leads to the following performance factors:

1. Reducing time:

   A. Shortening redesign - By instantly modifying the project drawings and the possibility of their immediate visualization by the project team, the number of man-hours worked in the design activity is considerably reduced.
   B. Reducing changes in construction and resumption of work - identifying design problems and substantially reducing the implementation period of new design solutions. Execution of construction is carried out without changes and without restoration work, the so the cost associated with these changes is removed.
2. Estimating costs - The inclusion of design elements as attributes of BIM data processing, such as materials used, unit costs, pre-measurements, etc. will instantly generate the price for the whole assembly or other necessary calculations (quantities of works, carpentry centralizers, finishes, structural elements, lists of materials, etc.) obtained directly from the BIM model and the actual quantity and cost control.
3. Information flow rate - The BIM model allows the use of such information in several documents and places, storing all relevant information on the design of the building, and providing complete information about the project; in addition, BIM also stores all other information related to the project, including planning and costs. The effects of increasing the flow of information are reduced errors, which helps to minimize the costs of necessary changes.
4. Enhancing productivity - the full integration of BIM has the effect of increasing productivity within the construction project team. Work is streamlined by standardizing operations, similar to CAD technology (Computer Aid Design). However, besides having a complete resource database to work with, the BIM system allows designers to instantly see the effect of their design changes (Liu et al., 2017).

5. Increasing communication - As all design specialists work on the same model, make sure everyone knows what the other is doing.
6. Satisfaction and customer retention - capturing customer requirements and needs and establishing a common understanding with them on designing and developing a partnership approach is essential and their involvement throughout the process of informing and receiving feedback from them can be achieved by adopting BIM to meet and retain the customer.

Azhar et al.(2008), refers to a report by Stanford University's Center for Integrated Facilities Engineering, which highlights the benefits of BIM based on 32 projects:

- Savings for unplanned changes (up to 40%)
- Expected expenditure estimate (deviation of only 3%)
- Faster determination of expenditures (save up to 80% time)
- Cost savings (up to 10% of contract value)
- Time savings (up to 7%).

Success factors in Project Management

The success of a project depends on many factors.

Starting from the definition of project management, we can identify three constraints that influence the success of a project: purpose, cost and time (Müller & Jugdev, 2012). The time constraint refers to the time available for the project. Cost refers to the budget available. The purpose of the project represents the solving of the problem and achieving the objectives (goals).

These three constraints are interdependent. For example, if the scope of the project is expanded (new objectives are defined), this will involve higher costs and a longer execution time. If you want to reduce the time for a project then either costs need to be increased or goals need to be reduced. Achieving a balance between these three factors is the key to achieving a successful project.

According to Turner (2016), the criteria for the success of a project are:

- The product delivered by the project achieves its declared economic and social purpose; The project fulfills the predefined objectives: these are met under the conditions of functionality and quality required and under appropriate time and cost conditions;
- Satisfies the needs of different types of stakeholders and of the beneficiary;
- Makes a profit for the owner, financier or promoter;

In large part, there is a close link between these criteria and the benefits of implementing the BIM concept.
A positive correlation between BIM's performance factors can lead to increased success of BIM based projects.

Research Methodology

The research aimed to analyze the correlation between BIM performance factors and ensuring the success of a construction project.

The study is an exploratory one that describes and analyzes human behavior in the subject matter and is based on a questionnaire applied to managers in the construction industry. In this respect, 17 companies have been selected from the construction field in the NW of Romania. Criteria for the selection of these companies was related to the fact that these companies use the BIM tools, have complex projects in their portfolio and have carried out comparative analyzes related to the traditional design vs. BIM (http://allbim.net/home/ro/Utilizatori-BIM/Infrastructura-BIM.html)

Data and Methods

Business executives were asked to check information on time and money savings after implementing BIM. The managers of the 17 companies answered the questions. They were invited to appreciate the importance of the factors on a scale from 1 to 5, respectively 5 Very important, 1 Not at all important.

The companies to which the questionnaire was applied execute design, architecture, construction, structures, installations, automation and infrastructure. These companies have implemented a number of projects assisted by BIM technology, so they can answer the questionnaire.

Depending on their size, the companies are distributed according to Table 1.

Table 1: Distribution of companies on Firm's size and field(Source: The authors)

Company size	Micro	Small	Medium	Large	Total
Architecture	1	6	0	0	7
Structural engineering	0	3	2	2	7
Installations	1	0	0	0	1
Infractructure	0	0	1	1	2
TOTAL	2	9	3	3	17

Questions in the second part of the questionnaire refer to managers' perception of the qualitative features (performance factors) of the BIM on the success of the construction project regarding the correlation of these features.

Testing the research hypothesis

Hypothesis H 1: Managers' perception of BIM performance factors is correlated to the success of the construction project.

To check this research hypothesis we will use the following questions in the questionnaire: How do you assess the relevance and performance of BIM related to project success?

Hypothesis H 2: Correlation between project success and BIM performance factors is positive and significant.

Part II of the investigation served as the basis for data collection. In this part, the questions addressed the factors contributing to BIM performance, with varying scales of favorable or unfavorable perceptions of the BIM impact on the success of the project implementation. In this way, the possibility of erroneous answers from those who only put the maximum answer for each question was avoided. Respondents' choice varied on a scale from 1 to 5 (Likert scale), from the least important to the most important, with the following options:

How do you assess the importance of BIM performance factors on a scale from 1 to 5?

not at all important	small importance	medium importance	important	very important
1	2	3	4	5

The variables introduced in the research are:
V1 Increased success of the project
V2-V7 BIM performance factors:

- V2 - Time reduction
- V3 - Estimated costs
- V4 - Speed of information
- V5 - Productivity
- V6 - Communication
- V7 - Consumer satisfaction

Results

Responses received from managers were ranked in descending order, obtaining:

Time reduction (94 Estimate costs (88%), Speed of information (86%), Productivity (80%), Comnunication (70%) and – Consumers' satisfaction (54%).

Respondents were then asked to classify BIM performance factors according to their perception, respectively the degree of improvement of BIM on a scale from 1 to 5; 5 showing the most improvements and 1 indicating that BIM does not contribute at all to improving performance factors. In order to use this information to validate the research hypothesis, scores of importance were assigned to each individual response. Then, average scores were determined for each manager and these scores were assigned according to the importance of BIM factors, resulting in the correlation with Table 2.

Table 2: Distribution of average scores for the variables used to validate hypothesis H1(Source: The authors.)

Managers` perception on the importance of a project's success factors	Managers perception on the importance of BIM performance factors				Total
	Small importance	Medium importance	Important	Very important	
(2 - 2,5)	1	0	0	0	1
(2,5 – 3)	0	1	2	0	3
(3 - 3,5)	0	0	1	1	2
(3,5 – 4)	0	0	1	4	5
(4 - 4,5)	0	0	1	3	4
(4,5 – 5)	0	0	0	2	2
Total	**1**	**2**	**3**	**11**	**17**

To verify the assumptions in the study we used the $\chi 2$ test method (Opariuc, 2009).

$\chi 2$ is a coefficient of association between two nominal variables. It is rather a statistical test than an indicator of degree of association.

The null hypothesis of $\chi 2$is is that there is no association between two variables.

The contingency coefficient $\chi 2$ only allows for the identification of a contingency between the variables. We cannot be sure, however, about its intensity. The data processing and analysis was done using the IBM-SPSS 21 program. The test results are presented in Table 3 and the values for which the zero hypothesis is rejected are shown in Table 4.

For V1,V2,V3 V4, V5,V6,V7 the hypothesis is rejected, so there is a correlation between the variables.

Further, in order to verify the H2 hypothesis, we used Spearman correlation coefficient p (rho). It is a rank-based coefficient, it is not influenced by media representativeness and is generally used when the research group has small dimensions (under 30 cases), or when at least one of the variables does not meet the administration conditions of the parametric tests. The coefficient merely transforms the original scores into ranks and analyzes the relationship between them.

Table 3: Association test(Source: The authors. Computation with IBM-SPSS21)

Hypothesis Test Summary				
	Null Hypothesis	**Test**	**Sig.**	**Decision**
1	The categories of V1 occur with equal probabilities.	One-Sample Chi-Square Test	,009	Reject the null hypothesis.
2	The categories of V2 occur with equal probabilities.	One-Sample Chi-Square Test	,023	Reject the null hypothesis.
3	The categories of V3	One-Sample Chi-Square Test	,056	Reject the null hypothesis

	occur with equal probabilities.			
4	The categories of V4 occur with equal probabilities.	One-Sample Chi-Square Test	,047	Reject the null hypothesis.
5	The categories of V5 occur with equal probabilities.	One-Sample Chi-Square Test	,023	Reject the null hypothesis.
6	The categories of V6 occur with equal probabilities.	One-Sample Chi-Square Test	,056	Reject the null hypothesis.
7	The categories of V7 occur with equal probabilities.	One-Sample Chi-Square Test	,051	Reject the null hypothesis.
Asymptotic significances are displayed. The significance level is ,05.				

Table 4: Values of the Chi Square Test by variables(Source: The authors. Computation with IBM-SPSS21)

V1	**Chi-SquareTest=11,471**	**The min expected value=4,25**
V2	Chi-Square Test=7,529	The min expected value=5,667
V4	Chi-Square Test=6,118	The min expected value=5,667
V5	Chi-Square Test=7,529	The min expected value=5,667

The calculation formula (Opariuc, 2009) is not compressed and can be summarized as:

$$\rho = \frac{n(\sum r_x r_y) - \sum r_x \times \sum r_y}{\sqrt{n\sum r_x^2 - (\sum r_x)^2}\sqrt{n\sum r_y^2 - (\sum r_y)^2}} \qquad (1)$$

The Spearman correlation coefficient ρ is a directional correlation coefficient and can be between -1 and +1. Values close to +1 indicate a direct (positive) association between the two variables, while values close to -1 indicate the existence of a negative association. The closer the values are to 1 (regardless of the sign), the stronger the association, the variables being more "linked" to each other (Opariuc, 2009).

Discussions

The strongest correlations are noted between V1 and V2 = 1, i.e. the success of the project and time reduction, which means that reducing the re-design time and reducing construction changes and resuming works due to the BIM implementation will have a direct impact on the timely implementation of the project. Also, V6 and V3 have a correlation coefficient of 0.462 at a significant level of 0.05 (Table 5). The correct cost calculation will determine the correct price.

Table 5: Spearman's correlation of variables

			V2	V3	V4	V5	V6	V7	V1

		N	17	17	17	17	17	17	17

**. Correlation is significant at the 0.01 level (1-tailed).
*. Correlation is significant at the 0.05 level (1-tailed).
(Source: The authors. Computation with IBM-SPSS21)

Customers are very sensitive to the contract price, which is one of the most powerful factors that determine purchasing decisions and satisfaction.

As for the V4, it has significant links with V3-Estimated Costs (0.416 at a significant level of 0.05) and V6-Communication (0.421416 at a significant level of 0.05), which suggests the perceived role and importance of information as the key resource for increasing performance in accounting information, and effective communication through the qualitative and quantitative flow of project-related information.

The only negative correlation occurs between V1 and V7 (-0.455 at a significant level of 0.05). This means the success of the project is not perceived as related to the productivity of BIM processes. Although this is a BIM performance factor, it is an effect of proper organization of BIM processes rather than the quality of project implementation.

Conclusions

In the context of increased competitiveness within the construction sector, numerous innovative strategies are being implemented worldwide, which will lead to increased performance. To this end, BIM represents, through its many advantages, a way to ensure an efficient information system considering that its effect is the successful implementation of the project.

The research aims to analyze the correlation between BIM performance factors, ensuring the success of a construction project. Following the analysis, the two hypotheses of the study were confirmed.

We believe that the research undertaken by us brings novelties and originality to the local research in the field of project BIM-based management in the construction industry, although it also has limitations: selecting the sample was done only at the level of a few companies that apply the BIM concept in Romania. At this level, not all managers have understood the role and importance of BIM, even if they do not currently use this technology for all construction projects.

Project implementation will continue to keep up the pace, shortening the construction cycle, and this will be the main concern over the next decade. This leads to an increase in pressure to achieve a performance management at

the construction site level and increase productivity. The overwhelming amount of information needed to create a project and the need for them to be available at the right time, leads to the need for better communication tools. Organizations that can use such solutions will get an important competitive advantage. At the same time, they also increase the ability of organizations to respond to technical training requirements.

Abstract

The last ten years have brought spectacular changes in the structure, nature and cost of geomatics systems and technologies. The decrease of the specific costs due to the increase of the service offer, makes these technologies more and more accessible, including in the conservation and enhancement activities of the cultural heritage built. The fact that in Transylvania there are more than 600 castles and mansions in different stages of degradation, because they have not yet been major themes for promotion, can be a prime example, because sooner or later, they will have to be analyzed and highlighted. The confirmation comes from the priorities of the Europe 2020 program of the European Commission and the European Council, through which the role of castles in Transylvania can be established in the context of the role of culture in local and regional development. The objective of this work is on the one hand to provide companies active in the field with information on the up-to-date status of the new geomatics technologies, thus contributing to the increase of their offer of specialized services, and on the other hand to signal to the beneficiary specialists (architects, historians, restorers, builders) the opportunities created by these systems as final results (Façade and Detail Plans, Models 2 and 3D, Sections, Relays, etc.) extremely useful in establishing strategies to restore the value of the cultural heritage built. The case study was carried out on a Bánffy Castle, from the village of Urmeniș, Bistrița Năsăud County.

Keywords: UAV, TLS, Conservation, Cultural Heritage.

Introduction and motivation

Current Geomatics Technologies (GT) offers new possibilities for visualizing and analyzing the status, geometry and appearance of cultural sites, for the purpose of analyzing and designing conservation, restoration, and finally enhancement actions. In fact, each construction belonging to or that can be assimilated to the cultural heritage, has its own characteristics, but the fact that the new technologies can be applied to each case makes them more and more available. Establishing the current state of an objective is essential in the elaboration of a conservation strategy. And the fact that the new technologies bring the objective, with all its details, on the analyst's screen, is the most important

aspect of the present analysis. There is a new form of presentation of information regarding the state of an object analyzed. We have passed in a relatively short timeframe from the traditional presentation, consisting of topographic plans, graphic sections, elevations and static elevations for 2 and 3D models to the possibility that starting from the digital background offered by geomatics means, virtually infinite information on the studied construction can be extracted. The highest expectations in this area stem from aerial photogrammetry performed with an Unmanned Aerial Vehicle (UAV) and by laser scanning performed with a Terrestrial Laser Scanner (TLS), but the information can be supplemented by data taken from the ground, through terrestrial photogrammetry, made with a digital camera or data taken from enclosed spaces with portable lasers. All this information can be subsequently integrated, depending on the purpose and scope of the restoration action, in Geographic Information System (GIS) and/or Building Information Modeling (BIM), powerful information and analysis tools. However, the biggest problems created by the newly created general context come from the lack of knowledge of the real potential of these new tools.

Literature Review

It can be said that the development of the field of Geomatics, produced in the last ten years, had several engines but surely two of them can be identified that have a direct connection with the activity of monitoring and preserving the built cultural heritage: the first is the use of sensory technologies in monitoring the evolution of the health status of the construction, in the broad process of Structural Health Monitoring, an aspect that will be analyzed in a later paper, and the second one refers to the explosion occurring in the production of increasingly efficient technologies, but at the same time increasingly more accessible in the geometric-topographic surveying of the objectives being studied. In this context, an impressive number of papers have been published that address this latter aspect, which is extremely current. In the following we present those materials that had the greatest impact, related to the number of citations or the high degree of evaluation of the magazines or the conferences in which they were published.

The use of UAV in Cultural Heritage

According to the dictionary, an UAV (unmanned aircraft (or aerial) vehicle) is "an aircraft that can navigate without a human pilot on board" [D "ICAO's circular 328 AN/190], commonly defined as Drone. With military origins, as well as many other achievements in the field of Geomatics, due to the immense knowledge potential it offers, which can exceed the tolerable one, for authorities, all states have adopted strict rules for use, registration and monitoring [Stöcker, C., Bennett, R., Nex, F., Gerke, M. and Zevenbergen, J., 2017]. Arnadi Murtiyoso and Pierre Grussenmeyer state in their work on UAV intervention in the preservation of cultural heritage [Murtiyoso, A. and Grussenmeyer. P., 2017]. The problem is also addressed in other works [Azzola, P., Cardaci, Roberti, G.M. and Nannei, V.M., 2019, Barrile, V., Gelsomino, V. and Bilotta, G., 2017], and the opportunities of the results are highlighted in the works dealing with the subject of 2 and 3D models that can be created following the interpretation of digital images taken from the air with UAV systems [Manajitprasert, S., Tripathi N.K., and Arunplod, S., 2019].

The use of the Laser Scanner in Cultural Heritage

a. Stationary laser scanners

The spectacular growth of the laser scanner market made by the American market analysis platform Marketsand Markets in 2019, is expected to occur in all areas of the world from USA, Europe to Southeast Asia. The importance of laser scans in the activities dedicated to the conservation of the built cultural heritage [Daneshmand, M., Helmi, A., Avots, E., Noroozi, F., Alisinanoglu, F., Arslan, H.S., Gorbova, J., Haamer, R.E., Ozcinar, C. and Anbarjafari, G., 2018] is just one of the arguments that explain the constant and generalized growth of this particular market. Even though the advantages offered by laser scans are significant, the difficulties concerning them come from two directions: cost, which remains very high compared to conventional technologies, terrestrial or aerial photogrammetry performed with UAV systems and the second is the difficulty of use, learning the system and processing the data taken in the field, which requires specific and long-term training. Regarding the first aspect, Caprioli, Minchilli, Scognamiglio [Caprioli, M., Minchilli, M. and Scognamiglio, A., 2011] state that "the cost of laser scanner tools and software packages is still high... in every possible survey in the cultural heritage field", and regarding the second aspect: "the great demand for laser acquisition of historical buildings, monuments and objects for documentary purposes is not followed by training the purchaser in the requirements and goals for a correct survey. Despite the great potential of these tools, they are often only used to produce plans, elevations and sections (plotted to scale!)".

b. Mobile laser scanners

The advantages of using mobile laser scanners are undeniable: they can provide the most interior details of buildings evaluated in order to establish strategies to be followed in their preservation. Choosing a route to be scanned is essential to cover all information gaps. A model is presented in the work of Andrea di Filippo (and co-authors) [Filippo, A., Jiménez, J.A.M., Aparicio, L.J.S., Barba, S., Mora R. and Aguilera, D.G., 2018] in which the authors worked with ZEB-REVO, commercialized by GeoSLAM, which consisted of a 2D time-of-flight laser scanner (Hokuyo UTM-30LX-F from Hokuyo Automatic Co., Osaka, Japan), rigidly coupled to an IMU mounted on a rotary engine. It is essential that the planning of the scanning route, doubled by the continuous geo-referencing of the device at the time of data retrieval, cover the entire building in order to provide comprehensive and complete information.

Combined use of UAV and Laser Scanner technologies in Cultural Heritage

On the market of geomatics services offered for the activities of evaluation, protection and conservation of the built cultural heritage, there is a unanimous opinion that the combination of the aerial photogrammetry realized with UAV systems with the laser scanning performed with stationary laser scanners for the exterior of buildings and with mobile scanners for interiors is the optimal solution [Hoon Jo, Y. and Hong, S., 2019, Pimentel, C.J. and Rodrigo. G., 2019]. At times, there may be situations where outdoor laser scanning (the most expensive activity of the combination mentioned) can be replaced with terrestrial photogrammetry, which is much cheaper but which produces results that do not always meet the requirements of the architect [Seker, D.Z.
and Duran, Z., 2010].

Geomatics and Geoinformatics Technologies applied in Cultural Heritage

Once the technology that will be used has been established, knowing for each of the technologies what field work is required and which office shall carry it out, we can proceed to the design of the entire integrated system, subordinate to the intended goal. In Figure 1 we presented the Workflow of the integration of Geomatics-Geoinformatics Technologies in the activities of protection and conservation of the built cultural heritage, according to the author's view. In principle, the stages of carrying out a project regarding the restoration of a national heritage objective involves the following stages:

1. Identifying the planimetric landmarks of known Stereo 70 coordinates in the area, or near it; if they do not exist, a support base can be built using GNSS technology;
2. Identification of the level markings of known RMN1975 elevations in the area, or near it;
3. Thickening the planimetric and level networks in the operating area by creating Groud Control Points (GCP) that will allow accurate mapping of the target and bring it into the system;
4. Designing the flight plan for aerial photography made with a drone, carrying out the flight and taking the images considered necessary for the proposed goal;
5. Design of fixed stations for taking images from the ground with the means of terrestrial photogrammetry, a much cheaper alternative to laser scanning, but one that implies a significantly lower quality of the data as a whole, an activity corroborated with activity 4, in order to create a complementarity of the data so as to obtain the complete image of the target;
6. Design of fixed stations for taking images from the ground by laser scanning, activity corroborated with activity 4 with the specification made in the previous point, performing scans;
7. Designing the circuit to be followed with the mobile laser scanner station in order to capture all the interesting interior details for the project, the route and carrying out the scans;
8. The combined processing of data and the formation of the products necessary for the following activities:
   a. Use of 3D photogrammetry software for drones.
   b. Using a laser scanner data processing software.

The result of the laser scan will be a very dense point cloud (called DDSM - Dense Digital Surface Model). For each point of the model the coordinates X, Y and Z and the value of the reflectivity are known. The processing of the data taken with the laser scanner consists of a set of actions necessary to obtain the correct digital model of the object,

starting from a set of point clouds. This set of actions can be divided into 2 different stages [Leandro B. and Fulvio, R., 2004]: • Preliminary data processing;

• Solid point cloud modeling.

c. Quick Terrain Modeler (Manufacturer Applied Imagery) is one of the most important 3D terrain visualization software packages for the cloud.
d. ArcGIS Pro 4. (Manufacturer Esri) is a component of the Esri Geospatial Cloud, being a GIS desktop application.
e. JRC 3D Reconstructor Software (Manufacturer Gexcel) is a processing software that can import, process and manage the data of terrestrial, portable, mobile, aerial laser scanners and integrate UAV and Laser 3D data into a single platform.

Fig. 1: The workflow of the integration of Geomatics-Geoinformatics Technologies in the activities of protection and conservation of the built cultural heritage (Source: Authors) The purpose of using laser scans in the activity of preserving the cultural heritage is generally to complete the graphic field documentation obtained through other Geospatial Technologies, to support the project with overall and detail plans, elevations and sections, as well as to study the geometrical characteristics of the vertical and horizontal structures.

9. Integration of the products obtained in the previous phase into a computer system:

a. The use of CAD design software is one of the solutions to continue the project, as these software serve as the data base for integrating different types of data obtained by a number of measurement techniques, including terrestrial, aerial, Lidar, or terrestrial photogrammetry, or aerial, fixed and mobile laser scanning. Thus, the registration and reconstruction process is replaced by a holistic approach to recording, processing and distributing information.

   b. Integration of the products obtained from UAV and Laser scanner data processing in Building Information Modeling (BIM) [Tkáč, M. and Mesároš, P., 2018].
   c. Integration of the products obtained from the processing of the UAV and Laser scanner data in the Geographic Information System (GIS). These will allow for an alternative, in the case of a project aimed at built cultural heritage, complementary to the other two mentioned in points a. and b. [Gustafsson, H. and Zuna, L., 2017].
10. The final product, the conservation, renovation, enhancement project was realized in step 9
   a. and implemented on a BIM and/or GIS platform, according to the requirements of the beneficiary of the whole process.
11. The management of the conservation, renovation and enhancement activities will be made available with the documentation and all the information provided and made available in the previous phase.
12. Alternatively, or complementary, Lidar technology can be used, either by using groundbased stations or by UAV technologies using Lidar cameras mounted on drones. The strength of this technology is that it is precise, fast and capable of obtaining a very intense cloud of points on the surface of the object in a short time, DEM (Digital Elevation Model) and DSM (Digital Surface Model) being generated automatically [Yoo, H-I., 2010].
13. 3D printing based on the three-dimensional model created following the previous steps becomes increasingly useful to make the connection between stages 9, 10 and 11[Marinos I. and Ewald, O., 2014].
14. The retrospective analysis of the entire process 1-13 will allow the issuing of extremely useful conclusions for similar future projects.

Case study

Bánffy Castle in the village of Urmeniș, overview

The paper [ONG Pont Group, Cluj Napoca, 2015] entitled The Castle Strategy in Transylvania 2016–2025, elaborated by the Pont NGO team from Cluj Napoca, makes an extremely detailed presentation of the situation and status of the castles in Transylvania. We chose as a Case Study the Bánffy Castle in the village of Urmeniș, which is in an advanced state of degradation (Figures 2, 3) but nevertheless recoverable.

The village of Urmeniş is located in Mureş County, town attested in documents from the XIV century entered in 1638 in the property of Prince György Rákóczi I, who, after having arranged here the center of the Urmeniş-Coroisânmartin domain, decided to build a new mansion. The new building was erected between 1639–1640, the architect of the building and the head of construction work being the master Mátyás Fundáló of Alba Iulia.

[https://www.castelintransilvania.ro/castelul-banffy-urmenis-.html, 2015]. During the reign of György Rákóczi II, the owner of the castle changed. It first came into the possession of the Barcsai family, and later, after a long process, it became the property of the Bánffy family, who in the years 1667–1668 modernized the castle.

Documentation works on the assessment of the state of the Bánffy Castle located in the village of Urmeniș, at the end of 2019

The works on data acquisition through UAV and Laser Scanner technologies took place in the first half of December 2019 and consisted of completing the most important stages mentioned in Figure 1. Thus, following the same phase of the documentation-acquisition stages of the field data, we performed the following operations:

1. Identifying the planimetric landmarks of known Stereo 70 coordinates in the area, or near it; if they do not exist, a support base can be built using GNSS technology; Given that the main purpose of the paper is to consider an objective, relativity being the main aspect and not accurately positioning it in the system, it was used the GNSS technology. Thus it was stationed in landmarks P1 and P2, with the antenna of the Leica GS08plus GNSS receiver, forming a support base P1P2, which was developed through the landmarks P3-P9, going through a planimetric circuit in the circuit using the total Leica TS02 7 station.

Fig. 2: Bánffy Castle in the village of Urmeniș, Mures County, exterior state in 2019

Fig. 3: Bánffy Castle, interior state in 2019

2. Identification of the level markings of known quotas RMN1975 located in the area, or near it; Starting from a known landmark in the RMN1975 system, the route P1-P9 was crossed, through a middle level geometric leveling with the Leica Sprinter 50 digital level, matching the quotas of the mentioned landmarks.
3. Thickening the planimetric and level networks in the operating area by creating Groud Control Points (GCP) that will allow accurate mapping of the target and bring it into the system. Thus, we created the support base for the georeferencing of the whole paper; for georeferencing we used 9 ground control points (GCPs) with coordinates determined by measurements taken with the total station, coordinates determined in the planimetric 1970 Stereo Projection System and the RMN 1975 Reference Plan, for elevations (Figure 4.); their coordinates are presented in Table 1.

Table 1: Ground Control point coordinates – GCP, Bánffy Castle, Urmeniș

Landmark	X(m)		Y(m)	Z(m)
		Stereo 70		RMN1975
P1	451543.288		585735.307	381.246
P2	451538.666		585753.723	382.025
P3	451539.308		585766.065	382.760
P4	451547.104		585782.078	383.937
P5	451571.142		585782.759	383.873
P6	451596.052		585773.126	382.365
P7	451595.125		585752.423	381.947
P8	451583.347		585738.462	381.865
P9	451565.593		585735.418	381.675

Fig. 4: Ground Control points –GCP, used for aerial photography of Bánffy Castle

Figure 5: The DJI Phantom 4 UAV drone used for aerial photography of Bánffy Castle, Urmeniș

4. Designing the flight plan for aerophotography performed with a drone, performing the flight and taking the images deemed necessary for the proposed goal. A DJI Phantom 4 UAV drone was used (Figure 5), with the

following features: Sensor Camera: 1" CMOS; Resolution: 20 Mpixels, Lens: FOV 84°; 8.8 mm/24 mm(35 mm equivalent format:24 mm);f/2.8 - f/11, auto focus at 1 m - ∞.

The drone was set to the automatic mode of taking pictures, on a route set by the device Drone Deploy software. (Figure 6). 120 photographs were taken during the first flight, some of them being shown in Figure 7.

Fig. 6: Airplane flight plan for Bánffy Castle, Urmeniș, on the instrument display

Fig. 7: Aerophotograms, Bánffy Castle, Urmeniș, 1st session

Following the analysis and processing of the photographs and the generation of the point cloud, unsatisfactory clarity and accuracy details were found, especially in the area below the eaves, which is due to the high altitude, thus chosen for the reasons mentioned.

Fig. 8: Print screen of the photogramobtained in the 1st session, insufficiently clear details

On the same day and in the same conditions, with the same device, a second flight was performed in manual mode, in which the aim was to supplement the images for the subsequent generation of the 3D model and of a cloud of points with greater precision and clarity, in the areas that had not been appropriately covered by the first flight. Another 28 photos were taken, added and processed together with the original ones (Figure 9).

Fig. 9: Aerophotograms, Bánffy Castle, Urmeniș, 2nd session

5. In this case, we did not use the means of terrestrial photogrammetry, considering the UAV data and laser scans to be sufficient.

6. Designing fixed stations for taking images from the ground by laser scanning, performing scans. Laser scanning was performed with a scanner from Zoller + Frochlich (Z + F) (Figure 10). Data was collected from a number of 18 stations, arranged symmetrically with the construction, in order to be able to retrieve all the data necessary for the correct generation of the point cloud and the 3D model (Figure 11.a)

Fig. 10: Zoller + Frochlich (Z + F) Laser Scanner, Bánffy Castle, Urmeniș

a. b.

Fig. 11. A: The 18 scan stations with Zoller + Frochlich (Z + F) Laser Scanner, Bánffy Castle, Urmeniș, b. Aligning the stations for georeferencing and data homogenization with UAVs

For aligning the 18 stations, the software of the Z+F Imager 5010 equipment was used (Figure 11.b), as well as targets glued to the façade with coordinates taken with the total station, to fit the points resulting in the same projection system with the points taken with UAV (Stereo 70, NMR 1975).

7. Designing the circuit to be followed with the mobile laser scanner station. The activity is scheduled for the future, depending on the opportunities for recovery that will be created following the transition to a next phase, by accessing steps 9-11.
8. The combined processing of the data and the formation of the products necessary for the following activities:
   a. Use of 3D photogrammetry software for drones. For the present case study, UAV data processing was performed with the Agisoft Photoscan software. A point cloud of 5,894,000 points was generated (Figure 12).
   b. Using laser scanner data processing software. After downloading the data taken from the field and cleaning the cloud of points from the noise points and those covering areas that were not of interest for the case study, a number of 289,000,000 points resulted.

Fig. 12: Screenshots of Bánffy Castle, UAV aerophotograms processed in Agisoft Photoscan

Z + F LaserControl® Office and Scout is the optimal solution to work efficiently and fully with Zoller + Fröhlich laser scanners. A series of filters, measuring and recording tools allow high differentiated processing of scan data and are the key to filtering, recording and coloring 3D point clouds. The first step is to segment 3D terrestrial scanning using a Limit Box. The quality of the network can be adjusted depending on the size of the files and their use. The file is saved in OBJ format, then post processing is done in Autodesk Reminder. Finally, after various operations, a polygonal mesh with texture is obtained. The final grid will still have some white areas where the texture was not properly acquired and applied. These areas can be further processed using specific 3D textures such as Surface Painter or even 2D image processing software such as Adobe Photoshop.

c. Comparison and completion of the two point clouds resulting from the UAV and 3D Scanner was performed with the CloudCompare software (Figure 13). To align the point clouds and compare the errors, the point cloud resulting from the 3D Scanner (the bottom of Figure 13) was used as reference, over which, in the first phase, the point cloud resulting from the UAV was manually aligned.

Fig. 13: Comparison of point clouds generated by processing UAV aerophotograms with laser scanner information using CloudCompare software

Fig. 14: The first matrix of errors (centimeters) generated in CloudCompare

Fig. 15: The second error matrix generated in CloudCompare: it is observed that the errors star from the areas shown with blue (0-2 mm) to the maximum ones, shown with red (11-15 mm)

It can be observed that for the studied objective the error between the points belonging to the point cloud taken with UAV and the one taken with Laser Scanner was between 1 and 15 mm. After consulting with specialists in the reconstruction of heritage monuments, their opinion is that the presented margin of error is acceptable for monuments without complex architectural details, as is the case of the Bánffy Castle in Urmeniş, so that the point cloud resulting from the UAV can be used successfully in the activity of reconstruction and restoration of the studied objective. This may represent a first response in step 14 mentioned in Figure 1. All this information can be the basis of the transition to the design stage using CAD software and/or the construction of BIM and/or GIS as well as the management of activities for its restoration and maintenance, in stages 911.

Conclusions

The case study can be successfully replicated, in the context in which there are around 600 castles in Transylvania, with mostly identical construction and architectural features, belonging to nobility from the 14-18 centuries, which included a limited number of families. (Bánffy, Rákóczi, Bethlen, Teleki, etc.). The study refers exclusively to the outside area of the monuments, but the authors intend to make similar comparisons for the heritage monuments inside, in future works, using data taken with 360° cameras, Leica BLK3D and 3D scanning equipment and introducing into discussion other modeling software and comparative results (Technodigit 3DRESHAPER, Leica Cyclone, R ...), and in the next step to use Lidar technology and 3D printing of the generated 3D model (steps 12 and 13). All these technologies for collecting points (both those used in the present case study and those proposed) use totally non-invasive, sustainable methods, which require the perfect preservation of heritage buildings, the possibility of generating reports and images that can allow them to be visited through virtual reality, virtual tours, etc. It is important to replicate a large-scale case study in the studied area, leading to a drastic reduction of the costs of preserving the monuments, by generating data acquisition costs with technology UAV at the level of 10-15% of the costs required for LIDAR technology, 3D SCANNER (note: the price comparison is valid for the Romanian market but is close as a ratio in general). We consider that the present work is part of this trend, contributing to the arrangement of the technical support that extends at the basis of the strategy of enhancing at least part of the castles existing in Transylvania, in different states of degradation.

Acknowledgment

The authors thank Professor Călin Neamțu from the Department of Design Engineering and Robotics, TUCN, for his contribution to scanning the studied objective.

Modeling the Impact of Socio-Economic Factors on European HSR Fare: The Perspective of Rail Baltica

Olga PITERINA

The Baltic International Academy, Riga, Latvia

olga@ekoair.lv

Abstract

The construction of the high-speed railway (HSR) corridor Rail Baltica with a gauge of 1435 mm is justified by the aim of achievement of greater economic cohesion of Latvia, Estonia and Lithuania with the rest of the European Union. The aim of this study is to prove the following hypothesis: HSR fares depend not only on the characteristics of individual HSR projects, but also on specific aspects of the economic environment in which the project is being implemented. The objects of study are the European States that are already operating HSR, as well as Rail Baltica Member States. To achieve the set aim of the study, the descriptive analysis, methods of multidimensional statistics and econometric methods were used. The result of the study is the grouping of research subjects by their level of development and determination of the degree of influence of significant factors on the value of the HSR fares. At the same time, it was noted that the forecast fare for passenger transportation along the Rail Baltica corridor is completely unrelated to salaries in the region, which may make it impossible for the bulk of the population of the project region to use these HSR services. It is concluded that objectively existing differences in the level of socio-economic development of European States have a significant impact on the formation of the HSR fare, which is confirmed by the results of correlation analysis, indicating different sets of influencing factors acting in the selected clusters.

Keywords: Cluster analysis; European High-Speed Railways; HSR fare; Rail Baltica.

Introduction

Developing a trans-European HSR network is a stated goal of the European Union. However, to date, the trans-European HSR network, according to the European Court of Auditors (2018) represents a few scattered national projects rather than a fully integrated pan-European network. Therefore, projects such as Rail Baltica, aimed at improving cross-border connections, were given priority status.

The main goal of the Rail Baltica project, which forms part of the Trans-European Transport Network (TEN-T) projects (European Commission (2007), declares the restoration of direct connection between the Baltic countries and the European railway network and development of regional integration based on the railway track gauge of 1435 mm. Currently, in the countries participating in the project, the railway track gauge is of 1520 mm. Estonia, Lithuania and Latvia have declared the project one of their priorities in the development of transport infrastructure. The European Commission (2015) expects that the creation of the TEN-T could create up to 10 million jobs by 2030 and increase the GDP of the European Union by 1.8%.

However, the data on an increase in EU GDP by 1.8% does not provide an understanding of the changes for each EU subject as a result of the implementation of the TEN-T. It is possible that for the countries producing rolling stock, infrastructure, services and rail control segments, GDP and jobs growth will reach even more significant values, while the peripheral regions of Europe, after the construction of HSR projects, will be forced to redirect taxpayers' funds from the implementation of social or educational programs to maintenance of the infrastructure of unprofitable HSR projects, as well as to close some of the existing enterprises due to the impossibility of competition of their products with similar products of large companies that received easier access to the peripheral markets of Europe due to the construction of the cross-border HSR.

In the case of Rail Baltica, this area of research remains controversial and requires consideration of a wide range of factors, especially those related to the territorial context. The issues of the impact of regional socio-economic processes on future fares for the carriage of goods and passengers have not yet been studied. In this regard, in this

Cite this Article as: Olga PITERINA" Modeling the Impact of Socio-Economic Factors on European HSR Fare: The Perspective of Rail Baltica " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

study, the author made an attempt to assess the degree of influence of the socio-economic characteristics of the Europeans States on HSR fares for international passengers travel, regardless of the state tariff policy of a particular country, and to determine the existing patterns in order to form a forecast of the price aspects of the Rail Baltica strategies for the future.

The formation of the initial hypothesis was influenced by the studies concerning the level of cross-country differentiation of socio-economic development indicators within the Europeans States.

The structure of the paper is as follows. The next section provides a review of the preceding literature with a focus on clustering of HSR subjects and HSR fares. The ensuing section 3 introduces the different data sets on which this analysis is based, and empirical strategies are detailed, while section 4 gives their results. The final section synthesizes and draws conclusions on the preceding analysis.

Background

When carrying out the study, the author relied on the methodological approaches to assessing regional disparities in the dynamics of socio-economic indicators described in Krugman (1991; 1999); Puga (2002). Precisely, New Economic Geography (NEG) of Krugman is a theoretical framework for understanding the economic processes that produce regional inequalities.

Puga (1999; 2002) analyzes the development of inequality within the EU countries, focusing on objective regional differences. At the same time, he notes that the improvement of transport links should be considered as two-way communication: on the one hand, less developed regions get the opportunity to quickly access highly developed transport hubs, on the other hand, companies from highly developed regions get new sales markets for their products, having a clear advantage over enterprises from these regions due to the scale of production.

As for HSR itself, in a number of paper by Thompson and Bawden (1992); Button (2012); Campos and De Rus (2009) reflect concerns about overall investment costs and real economic returns from HSR across regions. Moreover, Campos and De Rus (2009) argues that the emphasis on HSR connections is likely to favor central and end nodes of the network and is unlikely to promote the development of new activity centers in secondary nodes, thus, augmenting inequality in regions and reinforcing the core regions as transport hubs.

Clustering issues related to HSR regions have been investigated mainly to analyze passenger travel behavior and choice preference factors based on cluster membership (Jian and Zhang, 2012; Albalate, 2016; Gutierrez and Ortuño, 2017; Gutiérrez *et al*., 2018 ; Jing Yu Pan and Dothang Truong, 2018).

Li *et al*. (2016) and Jie *et al*. (2019) used analytical clustering techniques to assess the economic impact of HSR on cities along the route. Jianbo *et al*. (2020) conducted a cluster analysis of more than two hundred railway infrastructure standards in China. Moyano and Coronado (2018) used cluster scoring methods with the goal of deriving an HSR city-pair link typology.

The classification of railway stations for strategic transport and land use planning can be found in Zemp *et al*. (2011).

With regard to the spatial inequity of HSR fares, researchers note various aspects. For example, Bouf and Desmaris (2015) analyze the inequity of the French HSR pricing system (ticket prices per kilometer vary by the line and are not proportional to the distance traveled). Pagliara *et al*. (2016) show that in Italy consumers are very sensitive to the cost of high-speed train tickets, which has a strong impact on spatial equity.

Delaplace and Dobruszkes (2015) note that income levels affect the potential for leisure and long-distance mobility. When prices are high, they are more widely used by socio-professional categories that have the highest income and which are the most mobile (top managers, consultants, etc.) Thus, low-income populations may not be able to use HSR transport. Under these conditions, as Delaplace and Dobruszkes (2016) argue, considering government expenditure on HSR - taxpayers pay for the mobility of the wealthiest.

There are currently no published studies on the relationship between the pricing aspects of the Rail Baltica and the ability of the population of the project regions to pay for HSR services. The only source of information on this issue is the Cost-Benefit Analysis (CBA) of Ernst & Young Baltic (2017).

In scientific and academic databases, there were no papers available related to clustering the regions of the European HSR network, both active and under design or construction, in order to determine the impact of socio-economic factors on the price aspects of the network.

Revealing such differentiation and patterns of influence of socio-economic factors on HSR fare will increase the efficiency of planning and management decision-making process on the Rail Baltica project, which makes the choice of the author of this study relevant, both within the framework of the development of the trans-European HSR network and in the regional aspect.

Data and Methodology

Descriptive Analysis

As an initial step in investigating the relationship between socio-economic indicators and HSR fare, a table was compiled highlighting the various demographic, geographic and economic factors of the European States currently operating HSRs and the Rail Baltica Member States (RBMS) - the objects of the study clustering.

Table 1: Main socio-economic indicators

	Country	*GDP*	*POP*	D_{pop}	*URB*	*GFCF*	PRC_e	*SAL*	*TOU*	D_{rail}	*PRV*	*FARE*
	Unit	euro/person	million people	people/sq. km	%	euro/ person	euro/kWh	euro	million people	km/1000 km²	per 1000 inhabitants	euro/km

Note RB – Rail Baltica* *Source: designed by the author on the basis of European statistics*

In terms of the data gathering, a variety of sources have been used, but key sources included:

• Eurostat, UNECE, UNWTO – includes standard published data sets;
• National railway websites.

As study period 2018 was chosen, which is explained by the presence for this period of the last available complete database for all variables used in forming of the initial hypothesis.

It is necessary to take into account that the type of fare chosen for the study is for a single station to station pair, and as booking horizon (the period between booking and travel) - booking a month in advance.

The choice of variables is explained by the intention to study the impact on HSR fare of the main social and economic indicators, as well as the observance of the comparability and unity of the conditions of the objects under consideration.

The following indicators were used as indicators participating in the study:

Table 2: Defined variables

Code	*Dependent variable*	*Source*
FARE	HSR Fare determined by distance travelled irrespective of origin and destination	National railway websites; www.raileurope.com
Code	***Independent variable***	***Source***
GDP	Gross domestic product at current market prices per capita	Database of Eurostat
POP	Level of population	The United Nations Economic Commission for Europe (UNECE)
D_{pop}	Density of population	UNECE
URB	Degree of urbanization	Database of Eurostat
GFCF	Government gross fixed capital formation per capita	Database of Eurostat
PRC_e	Electricity prices (without VAT)	Database of Eurostat
SAL	Average salary (netto)	Database of Eurostat;
TOU	Amount of foreign visitors	The World Tourism Organization (UNWTO) is the United Nations
D_{rail}	Density of railway network	Database of Eurostat
PRV	Level of private vehicles ownership	Database of Eurostat

Multidimensional Statistics

The clustering task boiled down to dividing all European States with HSR, including RBMS, into an unknown number of clusters.
Nominal GDP *per capita* and population density were selected as a set of variables that best reflects the concept of similarity between clustering objects in the framework of this study.

The most commonly used methods for processing socio-analytical data are the following methods: agglomerative hierarchical, divisive and iterative grouping methods (Kaufman and Rousseeuw, 2008). The following methods of hierarchical clustering are most common: between-group linkage, Ward minimum variance method, hereinafter - Ward method (Ward, 1963). Hierarchical agglomerative methods are more suitable for solving the problem of this study. From the methods mentioned above, the Ward and single-linkage methods are appropriate. Ward method aims to optimize the minimum variance within clusters. The initial formation of similarity between objects is determined using the Euclidean distance between the distance of their centers. For our problem, the Euclidean distance is calculated as follows:

$$E = \sqrt{(X_i - X_j)^2 + (Y_i - Y_j)^2} \quad (1)$$

The distance for the similarity matrix is calculated using the formula:

$$d_{i_j} = \frac{a_i(a_j)}{a_i + a_j}\left(\left|\left|\bar{X}_i - \bar{X}_j\right|\right|^2\right) \quad (2)$$

where a_i and a_j are the amplitudes of clusters I and J. $\bar{X}_i$ and $\bar{X}_j$ are the coordinates of the centers of mass of the clusters, ‖ ... ‖ - Euclidean distance. As a result, a symmetric matrix is formed. Then two clusters are determined, the distance d_{i_j} between them is minimal. These clusters are combined, and the new center of the resulting cluster is calculated:

$$\bar{X}^{(new)} = \frac{1}{a_i + a_j}(a_i\bar{X}_i + a_j\bar{X}_j) \quad (3)$$

The distance value for the formed cluster is recalculated according to the formula (2) taking into account the new coordinates of the center and amplitude.
However, in cases of elongated clusters, the Ward method tends to divide them into many small ones, 1-3 cells in each, and therefore, in this study, the use of only the Ward method for clustering objects leads to a significant number of clusters (7) with a small sample, which does not allow solving the research problem. In addition to Ward method, the single-linkage methods were used. This approach is appropriate to be used in the analysis of relatively small data sets (Everitt *et al.,* 2011). In this task, the degree of proximity between objects is determined by the principle of the location of the coordinates of the clustered objects on the plane - nearest are adjacent objects. This paper combines the above mentioned two methods to form the desired clusters.

Econometric Methods

At first inspection there appears to be no evidence relationship between the indicators presented in Table 1 and the change in the HSR fare. Nevertheless, the characteristics of national rail networks and the economic and demographic profile of states are part of the background against which tariff policy is determined, and might affect fare levels, whether administered, regulated or set only by reference to the market. Therefore, after the procedure of clustering the research objects, author examined the relationship between HSR fare in each of the clusters and a range of characteristics, set out in Table 1 with a comment on their potential influence in each of the clusters.

This study has made use of correlation analysis in order to determine the degree of influence of the variables selected by the author on the HSR fare within each of the clusters. For this, a matrix of paired correlation coefficients was used (Table 4).

Then, after defining the reference cluster and the most significant independent variable in it, the parameters of the resulting typological regression model, characterizing the influence of the selected factor on the HSR fare in all clusters, were estimated.

Results and Discussion

The final visualization of the structure of research objects ’clusters is presented below:

Figure 1: Summary fit of cluster analysis

Source: designed by the author

In this case, three clusters were identified. The first includes 6 subjects: Belgium, Germany, Luxembourg, Netherlands, Switzerland, United Kingdom. The second cluster also includes 6 subjects: Austria, Finland, France, Italy, Spain, Sweden; the third cluster includes Poland and RBMS.

For the general characteristics of the obtained clusters, the average values of the factors selected for the study (intragroup averages) were calculated, which are presented in Table 3.

Table 3: Average value of factors in clusters

Factor	*FARE*	*GDP*	*POP*	D_{pop}	*URB*	*GFCF*	PRC_e	*SAL*	*TOU*	D_{rail}	*PRV*
Cluster 1	0.24	49,878.0	31,202.8	290.9	86.1	1,765.4	0.103	2,715.5	19.3	81	611.2
Cluster 2	0.13	38,225.5	33,119.3	90.2	77.5	1,292.9	0.088	2,210.2	45.9	40.8	636.7
Cluster 3	0.09	16,505.5	11,006.4	55.9	66.4	751.7	0.087	746.8	6.9	40.2	553.5

Source: calculated by the author

Data in Table 3 allows to draw the following conclusions:

• The first cluster is characterized mainly by the highest average values among all three clusters, significantly inferior to the second cluster only by the number of foreign tourists. As for the average of the level of wages, GDP *per capita* and GFCF *per capita*, for the subjects of the first cluster they are practically 3.5; 3 and 2.5 times higher than for the subjects of the third cluster (RBMS) accordingly.
• The results obtained in respect of the averages for the first cluster are consistent with the view that high urbanization tends to result in relatively high rates of shortened rail travel, resulting in a higher average HSR fare.
• The second cluster is characterized by lower average values of indicators of economic development, with the exception of the indicator of foreign visitors, which is the maximum in this group of subjects. The highest rate of motor vehicle ownership is associated with the propensity of residents of southern Europe to own motorcycles.
• The third cluster includes subjects with the lowest socio-economic indicators, while having an equivalent average electricity prices with the second cluster.

As a result of using a matrix of paired correlation coefficients of independent variables with HSR fare, the factors that have the greatest influence on the studied variable within each of the clusters were established.

Table 4: Matrix of correlation coefficients between *FARE (Y)* and factors $X_1..X_n$ in the context of clusters

Factor	*GDP*	*POP*	D_{pop}	*URB*	*GFCF*	PRC_e	*SAL*	*TOU*	D_{rail}	*PRV*
Cluster 1	0.774	-0.586	0.0356	-0.284	0.901	0.056	0.699	-0.441	0.542	0.492

Source: calculated by the author

It follows from Table 4 that the GFCF factor has the greatest influence on the dependent variable in the first cluster, and density population with electricity price factors in the second cluster. It is worth paying attention to the fact that in the third cluster, seven out of ten independent variables affect the HSR fare; five of them demonstrate a strong negative correlation, while the average salary in the region practically does not correlate with the projected fare for transportation along the new railway corridor. It is worth recalling that for RBMS, this study considers the rate specified in the investment justification of Ernst & Young Baltic (2017).

The relationship between population density and average HSR fare in the second and third clusters is very significant but has different signs.

Since the clustering results are represented by three groups of research subjects, to construct a typological regression of the entire set of subjects, it is needed to turn to the method of composition of regression models with the inclusion of dummy variables. Due to the fact the each cluster exhibits a different set of most influential factors, two models were evaluated. The statistical tools STATISTICA and HGROUP were utilized in this research.

The first model is a regression reflecting the influence of the GFCF variable on the HSR fare in the first cluster, since in this case it is the reference one. After checking for multicollinearity between influencing factors in Cluster 1 (Tab. 5), the resulting regression equation can be expressed as follows:

$$\tilde{y} = 0.033 + 2.21 \cdot 10^{-4} GFCF_i \tag{4}$$

Table 6: Result of regression analysis of Cluster 1

Dependent Variable: FARE				
Variable	***Coefficient***	***Std. Error***	***T-Statistic***	***Prob.***
Determinate	0.033	0.086	-0.387	0.725
GFCF	$2.21 \cdot 10^{-4}$	$6.154 \cdot 10^{-5}$	3.594	0.007
R-squared	0.812		***F-statistic***	17.916
Adjusted R-squared	0.749		***Prob (F-statistic)***	0.007

Source: calculated by the author

Since the GFCF variable has a significant effect only in the first cluster, two dummy variables were used in the typological model for all three clusters (Chatterjee and Simonoff, 2012):

$$\tilde{y} = b_0 + b_1 GFCF_i + b_2 Z_{1_i} + b_3 Z_{2_i} \tag{5}$$

where b_1, b_2, b_3 are factor coefficients (model parameters), and b_2 and b_3 show how much the free member of the model differs with the values of dummy variables equal to one from the free member of the model with the base values; b_0 is a free term that determines the value of HSR fare provided that the values of the factors are zero (intersection with the y-axis); Z_1 and Z_2 are dummy-variables with the following values:

$$Z_1 = \begin{cases} 1, the\ Subject\ is\ in\ the\ \ Cluster\ 2; \\ 0, in\ other\ cases; \end{cases} \qquad Z_2 = \begin{cases} 1, the\ Subject\ is\ in\ the\ \ Cluster\ 3; \\ 0, in\ other\ cases; \end{cases}$$

The following model is obtained as a result of the correlation - regression analysis for all clusters based on the most influential factor in the reference cluster:

$$\tilde{y} = 0.187 + 5.489 \cdot 10^{-5} GFCF_i - 0.130 Z_{1_i} - 0.146 Z_{2_i}, \quad (6)$$

Summary statistics based on the above model is provided in Table 7.

Table 7: Model's Parameter Estimates

Dependent Variable: FARE				
Variable	***Coefficient***	***Std. Error***	***T-Statistic***	***Prob.***
Determinate	0.187	0.068	1.764	0.218
GFCF	$5.489 \cdot 10^{-5}$	$4.347 \cdot 10^{-5}$	2.293	0.038
Dummy Z_1	-0.130	0.049	-2.673	0.022
Dummy Z_2	-0.146	0.059	-2.422	0.034
R-squared	0.656		***F-statistic***	6.596
Adjusted R-squared	0.575		***Prob (F-statistic)***	0.009

Source: calculated by the author

In Tables 6, 7 parameter estimates are depicted. As seen in the tables, all independent variables are significant at 0.05 level. The F- test also shows that the regression models is globally significant at a level less than 0.01. The negative values of coefficients of the dummy variables imply that the fixed capital investments factor has lower values and lesser relationship with the HSR fare in the second and third clusters. This finding is consistent with the method and result of clustering of the objects in the study.

Conclusions

Based on the findings of the study, it is concluded that objective national and rail sector characteristics are the factors that have a significant impact on the HSR fare, regardless of the characteristics of individual projects or regulation of tariff policy.

Based on the final results of clustering of research subjects, the author concludes that examples of successful implementation of HSR projects in densely populated European States with an overwhelming share of urban population, high levels of GDP per capita and fixed capital investment should not be used as an advertising justification for the urgent need to implement such projects in less developed regions that do not have their own mechanical engineering enterprises; with a low population density, while having salary twice lower than the average in Europe.

With regard to the Rail Baltica project, another result is that the projected HSR fare does not correlate with salaries in the project region and has a weak correlation with the electricity price. The consequence of this may be the economic exclusion of most of the project region's population from the potential passenger traffic of Rail Baltica.

In connection with the above, the author considers it necessary to recommend the holders of the RB project to revise the forecast fares for passenger transportation, since it is expected that the total revenue will increase, despite the lower price, as a result of elastic demand. Otherwise, due to the lack of income, the potential passenger will prefer to drive their own car, if available, which will lead to a completely opposite result of the project, in contrast to the currently declared "green" effect of Rail Baltica.

Hence, for the States participating in the Rail Baltica project, it is necessary to develop a project pricing strategy with a clear understanding of the regional specifics, based on careful planning and coordination of actions between stakeholders. Achieving such cooperation requires innovation in institutional arrangements as the basis for all infrastructure development in the Rail Baltica project region.

Abstract

The bone segmentation process is a method by which engineers can extract bone tissue using image processing algorithms such as threshold algorithm, region Growing algorithm or recursive Gaussian algorithm, on patients' MRI (Magnetic resonance imaging) or CT (Computer Tomographic) scans to obtain virtual models on which to perform virtual simulations using FEM (Finite Element Method). In biomechanics such studies represent an important step in determining the mechanical behavior of various human anatomical parts, especially for the bone joints, because the results obtained can be used to improve endoprosthesis and increase their lifespan.
This paper aims to virtually analyze the mechanical behavior of a female patient with hip joint arthritis by using CT scans in order to perform bone segmentation in dedicated software such as ScanIP Simpleware to extract the pelvis and the femur as an individual CAD (Computer Aided Design) part, and to perform virtual simulation at different loads corresponding to a certain body weight in order to observe how the patients' unhealthy hip joint is affected in the event that it would gain weight.

Keywords: Hip Joint; Arthritis; Mechanical Behavior; Virtual Simulation.

Introduction

The human hip joint, or sometimes referred as coxa in specialized medical terminology is the biggest joint of the human body. The hip joint plays an important role in the human body, without which locomotion would not have been possible. It is a synovial and spherical joint because the spherical head of the femur fits in the pelvic concave cavity, thus forming the hip joint capsule. The surface of the femoral head and the concave surface of the pelvis are covered by a layer of hyaline cartilage or articular cartilage, which has the role of reducing the friction between the two joint elements during movement, but also of absorbing shocks that may occur during more demanding activities or even in the event of an accident.

Arthritis is a pathological disease that involves articular inflammation which occurs as the acetabular labrum wears out with time. As the disease progresses the cartilage is diminished excessively until it disappears and, over time, leads to bone deformation that causes hip pain.

Nowadays exist around one hundred arthritis affections which, depending on the disease stage or progress, can lead over time to surgical interventions. The most common forms of arthritis are rheumatoid arthritis-RA (the most painful forms of arthritis, an autoimmune disease according to Harris, 1990) and osteoarthritis-OA (occurs at the appearance of acetabular labrum wear, especially with aging) according to Harris WH (1986). If arthritis affects more joints at the same time it is known as polyarthritis and it is usually associated with autoimmune diseases that can occur at any age.

The causes of arthritis may vary, depending of the heredity, medical history and predisposition of the patient, the rheumatoid arthritis arises because the patient's immune system start to produce antibodies that attack their own tissues which, at the beginning results as an inflammation, but in time the inflammation spreads to the cartilage, muscles, tendons, ligaments and finally to the bones that start to deform and wear. This autoimmune disease affects around 1% of the world population being nine times more frequent in women. Osteoarthritis / osteoarthrosis instead, occurs with aging and it is a degenerative disease that appears with time. Because of hip cartilage wear, severe hip pain and disability among elderly patients is frequently caused.

(a) (b)

Fig. 1: (a) Human hip joint assembly; (b) Human hip joint anatomical parts[Brăileanu, 2020].

Due to patients percentage who are predisposed to diseases such as arthritis the probability that they will undergo surgery to substitute the affected joints is constantly growing, thus, engineers and orthopedic surgeons are working together to optimize the current prosthetic implants in: geometry / design, material mechanical properties, the osseointegration capacity of the implant and its durability.

Methods

CT data acquisition

CT scans or Computed Tomography is one of the most revolutionary discoveries in medicine made by two researchers, Godfrey Hounsfield a British engineer and the physicist Allan Cormack with South African origin, invention who received the Nobel Prize in 1979 as noted by Brăileanu (2020) and Vladimir et al. (2006). The name of tomography comes from the Greek word "tomos" which means slice and from the word "graphia" which means writing.

The CT work on the principle of reconstructing the image of a body starting from its projection, thus realizing a two-dimensional reproduction of the patient's body. It measures the attenuation of an X-ray fascicle that crosses the patient's body and calculates its attenuation coefficient so that the radiological density of the tissues can be identified as noted by John et al. (1993). The patient exposure risk case of CT scan is minimal because of the small amount of radiation exposure during examination, presenting an optimal level of safety and a minimum exposure time.

For our particular study, we used the CT of a female patient aged 77 years old at the date of examination procedure. The patient was diagnosed with arthritis at the left hip subsequently undergoing a THR surgery to improve the patient's quality of life and eliminate the pain caused due to hip joint mechanical wear. In case of determining a problem at the hip joint level, radiologists use as ROI (Region of Interest) the patient pelvic area in order to lessen the exposed body zones, extracting only the necessary information for diagnosis and also for the procedures that help in organizing the surgery, such as THR preoperative planning.

Acquisition of DICOM (Digital Imaging and Communications in Medicine) images was made with the help of Siemens Somatom Definition AS in CT modality, the body part examined being set to the pelvic region with a nominal slice thickness called also slice thickness of 1 mm, the patient position was set to HFS (Head First Suspine), with a flat filter type, the peak kilo voltage or KVP of 140 mA·s, 34 kW generator power, data collection diameter of 500 mm and a reconstruction diameter of 474 mm, table height set up at 173.5 mm, distance source detector of 1085.6 mm and distance source to patient of 595 mm, exposure time of 1000 m·sec, rotation direction in CW (clockwise), the X-Ray tube current of 190 mA, a 0.6 mm single collimation width with a total of 12 mm collimation width, 0.55 spiral pitch factor value, with a total number of 356 DICOM image files. The table speed moves with 6.5(9) mm in one second in order to collect image data and the table feed per rotation is also about 6.5(9) mm during a complete rotation around the fixed orbit and in image collection was used an equal number of 512 rows and column in the image, being the multiples of the vertical or horizontal down sampling factor if any of them are encoded in the vertical or horizontal direction. Regarding pixel tag settings the spacing between each pixel center was set at ~0.93 mm with a 16 bits allocated for every pixel and a total of 12 bits used to store each pixel, with a number of 11 high bits which represents the most significant pixel data bit. The largest image pixel value of data acquisition is about 2251 and the smallest image pixel value is represented by 0, the rescale intercept set up to -1024, type 1 measured in HU (Hounsfield scale), the window center for display set to 40\400 and window width 350\2000, Brăileanu (2020).

2.2. Bone Segmentation Methodology

Today there are multiple dedicated software programs which realize bone segmentation in an automatic way by applying an image processing algorithm and directly extracting the bone tissue, or in a semi-manual way, requiring user's intervention, usually prepared or trained to use the specific software as noted by J. Fripp et al. (2010). In our case we had to extract the pelvis and the femur of a patient, which suffers of arthritis and because of this, an automatic bone segmentation software will extract the pelvis and femur in the same CAD file due to the hip joint wearing, the threshold algorithm couldn't identify the difference between the two bone parts. Because we are dealing with the CT scans of a patient with arthritis we chose to use the Simpleware ScanIP Version 7.0 +FE software, dedicated to the processing of medical images, having a complex basis of image processing algorithms which can be applied to obtain a better surface and a better CAD model in order to perform virtual analysis or even in preparing a 3D printing model, Brăileanu (2020).

The principle of bone tissue extraction from medical images is based on voxels (it is the equivalent of a pixel in a three-dimensional space) identification from region of interest by applying various image processing algorithms on each CT scan, slice by slice, so that the 3D anatomical model can be recreated as found by Brăileanu (2020) and Li Y et al. (2004).

The model accuracy obtained after image processing can also be influenced by the digital image quality, which are often affected by a specific phenomenon called noise. According to J.Lee (1980), noise in images occurs due to imperfections of medical capture devices, scanning systems or optical systems when transferring data and can be of several types: additive, Rician, multiplicative, Gaussian or white etc. As noted by Lei Huang et al. (2009), if the situation requires, these images can be processed with the purpose of imperfections and noise reduction, thus, the following algorithms can be applied: histogram equalization by adaptive filtering with contrast limitation or CLAHE, linear contrast adjustment, image filtering, Wavelet transform, Fourier transform, image binarization etc. All these medical image adjustments can help clinicians to better isolate and identify the patient's medical problem by increasing the visibility of the studied areas, Brăileanu (2020).

Mechanical properties of human bone tissue

As noted by Jae-Young et al. (1998) bones are not composed of a homogeneous and isotropic material, they have the characteristics of a non-uniform solid that consists of two types of bone tissue: cortical bone (hard bone or compact bone) tissue and spongy bone (trabecular bone or cancellous bone) tissue, each tissue having different mechanical properties.

The cortical bone tissue is represented by the outer part of the bone, is a hard tissue meant to support the structure of the human body, with a lamellar structure that is in a continuous transformation, developing in the areas where higher

mechanical loads appear, thus the cortical bone tissue represents most of the bone mass due to its high density. Studies performed on corpses, but also by simple CT scan analysis demonstrate that compact bone tissue has superior mechanical properties to spongy bone tissue according to Jae Young et al. (1993). However, studies have shown that cortical bone tissue mechanical properties may vary from patient to patient, so we can find an elastic modulus range between 17.9 and 3.9GPa with a Poisson coefficient between 0.62 and 0.26 determined by the patient's medical history, age and bone quality, Brăileanu (2020).

Table 1: Cortical bone tissue main mechanical properties, Morgan (2018).

Properties	Unit Measure	Value
Young Modulus	GPa	17.9
Poisson coefficient	N/A	0.3
Density	g/cm^3	0.9

Trabecular bone tissue is a porous tissue located inside the bone, having an irregular structure, with the role of giving flexibility to the bone and taking over the external loads and equally distributing them. Studies have shown that spongy bone tissue has lower mechanical characteristics than compact bone tissue, which makes it more fragile, representing a small percentage of total bone weight as noted by Jameson and Robert (2014). As in the case of cortical bone tissue, trabecular bone tissue can have a range of values depending on the patient's bone quality and age; studies showing that the young modulus of a trabecular bone can have a range between 0.76 and 10GPa.

Table 2: Trabecular bone tissue main mechanical properties, Ramin et al. (2015) and Birnbaum (2002)

Properties	Unit Measure	Value
Young Modulus	GPa	0.76
Poisson coefficient	N/A	0.3
Density	g/cm^3	0.3

As we grow older, the ability to restore bone cells slows down, our metabolism is transformed and the capacity to recover in case of complications and fractures is diminished, all these changes affects patient bone quality. Bone loss or bone demineralization occurs with aging or in case of diagnosing with disease causing this effect, which affects the population both men and women. Bruno et al. (2018) noted that although the loss of bone mass can affect regardless of gender, studies have shown that women are more exposed with aging to diseases such as osteoporosis or osteoarthritis (OA), a disease that affects bone quality, making patients more susceptible to fractures, slow healing or medical complications.

Assuming that both the femur and the pelvis contain a homogeneous and isotropic material, we have chosen to use the cortical tissue for this study, because of the better mechanical qualities. With age the cortical bone tissue loses its quality, becoming more porous and transforming into a tissue almost similar to the trabecular one. Following the cortical tissue analysis of the femur in case of females over 70 years old, studies have shown that Young's modulus can be 0.96 ± 0.19GPa, tensile strength can be 0.019 ± 0.0014GPa and compressive strength can be 0.096 ± 0.00083Gpa. The values show a significant deterioration of the bone quality compared to the average of the bone quality in case of a young and clinically healthy patient, thus in the case of our study, we used these values because the analyzed patient can be included in the age range and gender group statistic, Brăileanu (2020).

Finite Element Analysis of a female hip joint diagnosed with arthritis

Finite element analysis is a numerical method of reproducing in a simplified or complex manner a physical phenomenon helping us to describe and understand the virtual model behavior when submitted to external loads. Virtual models tend to reproduce the object, organ or cells as accurately as possible, but most of the times they are simplified, so the analysis can be reduced only to the area of interest because in the case of a complex model it takes more time and more resources to solve the equations and to give an analysis result. A biological model has a higher degree of difficulty due to its irregular shape and surface, so a mesh in this case can be more complex and the FEA study can take longer, Brăileanu (2020).

(**a**) (**b**)

Fig. 2: (a) Femur and pelvis fixture in Solidworks (green); (b) Femur and Pelvis load applied area in Solidworks (purple), Brăileanu (2020).

Even though this method has incredible potential in terms of the experimental side the results obtained from the analysis remain approximations of the CAD models mechanical behavior because they depend on the model parameters. Usually the errors that appear when solving are related to the simplification of the geometry model commonly named as discretization errors (they occur because of the element size or shape, which is in a relation of interdependence with the structure, anatomical morphology or model thickness), but also due to a displacement field called interpolation error. Although the human body is a complex "biological machine", this method allowed specialists to predict prosthesis or organs mechanical behavior and to evaluate them, in order to decide if the virtual model can pass at the ex vivo experimental test, Brăileanu (2020).

Fixing the geometry (constrains) helps maintain and support a CAD model, whether is a functional part or an assembly, and a mandatory step to perform FEM analysis. In order to fix the hip joint anatomical parts geometry, the constraints were simplified as follows: in case of the pelvis the acetabulum labrum area was fixed and in case of femur the inferior part of it was fixed, but also the margins of the femoral neck. This type of constraint helps us perform a static analysis of the anatomical parts to be able to understand how the hip joint models behaves when receiving external loads of different intensities, Brăileanu (2020).

Another mandatory condition for running a FEA study is to assign a type of material to the studied geometry. Because the study wants to recreate the mechanical behavior of a patient that has suffered bone loss due to arthritis, the material is not standardized, thus, a custom material can be created in a CAD software, for example Solidworks, Brăileanu (2020).

Table 3: Mechanical properties of the cortical bone tissue used in the FEA study, Jameson et al. (2014), Bruno et al. (2018)

Properties	Unit Measure	Value
Elastic Modulus	GPa	11.6
Poisson's Ratio	N/A	0.26
Mass Density	kg/m^{-3}	1440
Tensile Strength	MPa	21.13
Compressive Strength	MPa	97.19

In this study it was assumed that the material applied to both, pelvis and femur CAD models is homogeneous, linear, elastic and isotropic. Cortical bone tissue was used due to the superior properties and the mechanical properties data of the femoral cortical bone tissue of a female aged over 70 years were extracted from Raviraj Havaldar et al. study on effects of tensile and compressive loadings on human femur bone.

As noted by Nicola et al. (2010), the human hip joint is daily subjected to repetitive movements and external loads as a result of the activities that we perform, thus, during more demanding activities such as walking stairs or running, the human hip joint can be subject to stress up to ten times higher than during a normal gait cycle or a static position. This happens due to the high stress that can appear in the human hip joint, but also due to patient's weight, which can affect the coxofemoral articulation by increasing the load applied. In this study simulations were performed on both

pelvis and femur model by applying ten types of forces, some of them representing approximately the equivalent of the weight that a patient can have and some of them, respectively 2000 N, 2500 N and 3000 N, representing the equivalent of a shock received in the hip joint in case of accidents, Brăileanu (2020).

Table 4: Forces applied in the FEA study of a female arthritic hip joint, Brăileanu (2020)

Force	Value [N]	Equivalent in kgf
F_1	686.46	70
F_2	784.53	80
F_3	882.59	90
F_4	980.66	100
F_5	1078.73	110
F_6	1176.79	120
F_7	1274.86	130
F_8	2000	204
F_9	2500	255
F_{10}	3000	306

In this study, solid models of the pelvis and femur affected by arthritis were used, with a curvature based solid mesh type and 4 Jacobian points. The CAD pelvis model having a maximum element size of 7.62 mm and a minimum element size 7.61 mm, with a total number of 29 177 nodes and 18 608 elements, presenting a high quality mesh plot. The CAD femur model contains a 5.23 mm maximum element size and a 5.22 mm minimum element size, with a total number of 23 494 nodes and 15 298 elements, presenting a high quality mesh plot, Brăileanu (2020).

Results

Stress Analysis Results

Following the FEA study performed in each load case applied inside the acetabulum, the results have shown a minimum stress located in the node 6904 and a maximum stress located on node 8013, in the pelvis model in all FEA studies. In *Figure 4* we can identify the minimum and maximum stress values resulting from each analysis. From the analysis evolution of both minimum stress and maximum stress, the FEA study results of the patient's pelvic model who suffered bone loss due to arthritis disease show a linear increase of the load values from 686.46N to 1274.86N, however, with the application of loads greater than 2000N, stress increases considerably, Brăileanu (2020).

Figure 3 (b) contains the graphical representation of Von Mises and how it is distributed on the virtual pelvic model (N/mm^2 or MPa). Acetabulum margin is the most affected area, containing the maximum stress area that increases at the same time with the load, showing critical values especially in the case of 3000N force applied, Brăileanu (2020).

Following the FEA study performed in each load case applied to the femoral head, results have shown a minimum stress located in the node 5511 and a maximum stress located on node 4758, in the femur model, in all FEA studies. In *Figure 5* we can identify the minimum and maximum stress values resulting from each analysis. From the analysis evolution of both minimum stress and maximum stress, the FEA study results of the femur model of a patient who suffered bone loss due to arthritis disease, have shown a linear increase of the load values, Brăileanu (2020).

Figure 3 (a) contains the graphical representation of Von Mises stress on the femur virtual model. Femoral neck is the most affected area, containing the maximum stress area that increase at the same time with the load and showing higher values especially in the case of high loads applied, Brăileanu (2020).

Fig. 5: Minimum (a) and maximum (b) Von Mises Stress results [MPa] obtained in case of the femur CAD model, Brăileanu (2020).

Displacement Analysis Results

Following the FEA study performed in each load case applied inside the acetabulum, the results have shown a minimum displacement (0mm) located in the node 727 and a maximum displacement located in the node 8331, in the pelvis model in all FEA studies, Brăileanu (2020).

(**a**)

(**b**)

Fig. 6: (a) The pelvis model displacement analysis results of F_{10} in case of an older patient diagnosed with arthritis; (b) Maximum displacement results [mm] obtained in the case of the femur CAD model, Brăileanu (2020).

In *Figure 6 (b)* we can identify the minimum and maximum displacement values resulting from each analysis. Following the analysis of the minimum displacement and maximum displacement evolution results from the FEA studies of the pelvis model of a patient who suffered bone loss due to arthritis disease, we can observe a linear deformation for the first eight cases, with an increase of the deformation in the case of applying a load which exceeds

a value of 2000N. *Figure 6 (a)* contains the graphical representation of displacement results and how deformations affect the pelvis virtual model. The acetabulum part is the most affected area, especially its center, displacement values increasing at the same time with the value of the load applied. Although the deformations may appear small, in case of an elderly patient suffering from arthritis and bone loss, a simple crack can rapidly degenerate into a fracture or other medical complications that can lead to surgery, Brăileanu (2020).

(**a**)

(**b**)

Fig. 7: (a) Femur model displacement analysis results of an elderly patient in case of F_{10} load; (b) Maximum displacement results [mm] obtained in the case of the femur CAD model, Brăileanu (2020).

The FEA study performed in each load case applied on the femoral head has shown a minimum displacement located in the node 175 and a maximum displacement located node 4, in all load cases. In *Figure 7 (b)* we can identify the minimum and maximum displacement values resulting from each analysis. *Figure 7 (a)* contains the graphical representation of displacement results and how deformations affect the femur virtual model. The femoral head part is the most affected area, displacement values increasing at the same time with the value of the applied load. Such displacement results in the case of an elderly patient suffering from arthritis and bone loss, can cause fractures of the femur which can conduct to a THR surgery, Brăileanu (2020).

Conclusions

Nowadays, FEA made with dedicated software is becoming more popular in research and in companies that want to verify the virtual prototype or who want to make design changes to a product and observe how they affect its mechanical behavior. Although in the case of human-designed shapes, the studies may seem simplified due to a so-called standard geometry and most of the times, due to the assigned material that is usually homogeneous, the virtual analysis of the mechanical behavior of human organs or anatomical parts must be radically simplified because of the complexity of the human body, geometric surfaces, tissue composition, patient's degrees of freedom, patient's mobility, patient's age, numerous variables which unfortunately cannot be fully taken into account, Brăileanu (2020).

Using CT scans of an elderly female patient diagnosed with arthritis at the left hip joint, bone segmentation was perform in order to obtain CAD models, which were used to performed static FEA studies at different loads in the pelvis acetabulum and on the femoral head, where normally stress may occur due to daily activities or as a result of injuries. The results of the study have shown that both, the pelvic model and the femoral model, present high stress values, which can occur due to the poor cortical bone tissue mechanical properties corresponding to female patients over 70 years old, used in the FEA studies. Comparing the analysis results obtained from the pelvis and femur model, we conclude that the femur is more prone to cracks and fractures than the pelvis, especially in the area of the femoral neck, due to its shape and load distribution capacity. Although virtual bone FEA studies are simplified due to the complexity and uniqueness of each patient, they can still provide valuable information regarding bone failure prediction, Brăileanu (2020).

Selected Aspects of Occupational Safety (Case Study)

Kornelia POLEK-DURAJ

Opole University of Technology, Opole, Poland,
k.polek-duraj@po.edu.pl

Abstract

The article analyses selected aspects of work safety. Particular attention was paid to the accident rate, the number of employees working in hazardous conditions and harmful, nuisance and dangerous factors. The analysis was supplemented by a survey on the fields of work among employees of the wood industry.

Keyword: Work Conditions, Hazardous Condition, Wood Industry.

Introduction

Occupational safety is closely linked to the work environment organisation [In the book by Gembalska-Kwiecień (2015)], which impacts on human well-being, health, productivity and length of working age. Appropriate creation of work environment allows the organisation to develop, compete on the market and function in accordance with the applicable occupational health and safety standards. Therefore, it is a fundamental factor influencing the effective growth of every business activity. There are many factors of work environment that may have a negative impact on occupational safety (e.g. poor organisation of work, occurrence of onerous factors), which may have a destructive influence on the employee's well-being. They usually result in reduction of physical or mental performance and excessive fatigue leading to reduced productivity or accidents in the workplace. They also often have more serious health consequences, such as disabilities as a direct result of occupational accident or diseases. The work environment plays an important role in all sectors of the national economy. One of them is the furniture industry, which for many years has been one of the most dynamically developing branches of the Polish economy. Polish furniture is sold all over the world and its production is one of the most significant industries of both Polish and world economy. In 2019, the Polish furniture industry reached the value of sold production of 49 billion zloty, which accounted for over 4% of the total sold production of own products[1]. Approximately 90% of the produced furniture is exported[2], Analysing the statistical data, it can be noticed that companies that have mastered the furniture market in Poland are primarily micro and small enterprises (they account for over 98%[3] of the total number of entities on the furniture manufacturing market), a large proportion of which are family businesses. Unfortunately, the sector, in spite of significant sale successes, technological, technical and organisational progress, is characterised by numerous factors that negatively influence the quality of working conditions and non-compliance with contemporary OHS standards. It is reflected in the high level of threats and a large number of accidents at work, which weaken human capital to a large extent.

The Essence of Work Environment

The work environment is a crucial element of physical and psychosocial factors influencing the employee in the workplace. It is of relative importance as it refers to an individual, i.e. it is perceived variously by superior or subordinate. Thus, the work environment is central part of human environment. In order to properly illustrate the work environment with regard to safety, the concept of working conditions needs to be clarified. The term "working

conditions" used both in the scientific literature and the practice of economic life has not yet been precisely defined. It usually refers to " the totality of physical and psychosocial factors that originate in the work environment and affect individuals at work" [In the book by Pocztowski (2008)],. The term "working conditions" is often associated with the term "work environment" (In a research study by Gajdzik (2014)) . It is reflected in the detailed division of working conditions, which comprises organisational and technical elements (incorporating physical work environment and work organisation), economic elements (related to working conditions in terms of among others type of contract, remuneration, additional benefits for employees) and social elements (including interpersonal relations between superior - employee and employee - employee) [In the book by Dunlop and Williams (1997)]. The literature also distinguishes aesthetic factors(e.g. interior design, room equipment), sanitary and hygienic factors (e.g. social facilities), provisional factors (e.g. time spent at work,) content of work (e.g. scope of duties entrusted to employees) [In the book by Dunlop and Williams (1997)]. . Working conditions and workplace threats (e.g. caused by the specificity of production or technology used) constitute the integral part of professional functioning of an individual employee. The influence degree on the employee and its work depends on:

- type of factor, time and duration of action and severity,
- nuisance of work,
- individual resistance and sensitivity of a person to a given factor and state of health and current condition.

It is challenging to demonstrate the connection between these factors and their impact on workers. It cannot be assumed that the presence of harmful factors, burdensome or dangerous to health is equivalent in every case to potential risk of accident at work or occupational disease. Thus, they do not always determine whether or not work in given company is carried out in safe conditions. Properly implemented safety policy should be a key element in any company that aspires to be competitive on the market.

Characteristics of the wood and furniture industry in Poland

The wood and furniture industry in Poland has a long tradition. According to the Polish Classification of Activity (PKD), the sector comprises three divisions:

- Forestry and logging,
- Manufacture of articles of wood and cork, except furniture and manufacture of articles of straw and plaiting materials,
- Furniture production.

The furniture manufacturing division is the most thriving, as it dominates in terms of share of sold production, accounting for over 55% for the entire sector. It is an important indicator of sold production, which is one of the key parameters describing the state of the economy. It presents how quickly companies manage to sell their goods, i.e. what is the demand for the goods on the market. If the indicator is growing systematically, the economy is developing. If it is very high, one can speak of dynamic growth. A fall in the rate of sold production indicates a slowdown in the economic development. The statistics for 2020 will present this situation. It will be a consequence of the downfall that occurred in Poland due to COVID - 19 pandemic in the second quarter of 2020. So far, the furniture industry has been one of the fastest growing processing industry in Poland. For many years, the sales of furniture manufacturers have remained at 2% of GDP, and their share of total employment in the processing industry has been approximately 7%[4]. It is twice more than in the European Union. Poland is the sixth largest furniture producer in the world, with nearly 3% of world furniture production[5]. In terms of trade balance in international turnover, the Polish wood and furniture sector is inferior only to the Chinese and Italian sectors. At present, there are almost 31 thousand registered companies (as of 31.12.2019[6]) and according to the Central Statistical Office, more than 161 thousand people work[7].

Furniture production involves a number of various processes. Among the most important are: wood preservation, sawing, drying, wood panel production, mechanical processing, sanding, mortar, bleaching, dyeing, polishing, sandblasting, varnishing, assembling and finishing. Usually these processes occur in more than one plant. At each stage of production, workers are more or less exposed to hazardous, onerous or harmful factors. According to the

latest data of the Central Statistical Office (GUS) (dated on Dec. 2019), one in eight workers employed in the furniture industry works in dangerous conditions. Employees are most often exposed to noise, dust, chemicals, mechanical vibrations and incorrect lighting of the workplace. The degree of risk is largely determined by the technology used. At the same time, industry is characterised by a relatively high accident rate. It is most often caused by a lack of adequate protection of the workplace, defective machines (e.g. lack of a device protecting against the rejection of material) and simply inattention of employees. Interestingly, the accidents that occur are not always a consequence of poorly functioning obsolete machines, and more and more often they occur while using modern equipment. They are frequently a result of incompetence, recklessness of the employee and negligence of the employer (e.g. lack of a workplace instruction for safe work, inadequate training).

Selected aspects of occupational safety (case study)

In order to determine the level of occupational safety of persons employed in the furniture production in the Opole region, the analysis was performed to establish the number of workers exposed to hazardous conditions, the accident rate and reasons of accidents. The research was conducted in February 2020 in randomly selected plants, the representatives of small enterprises. Their selection results from the fact that small business account for over 90% of all economic entities in this sector, both in the Opole region and Poland. The study covered 80 plants with diverse market positions. The analysis used both the data provided by the Central Statistical Office and the plants. The data for analysis were adopted for the years 2010-2019. The research was complemented with the evaluation of interviews on safety awareness at workplace among randomly selected employees.

Table 1: Employment under threat of life between 2010-2019 (per 1000 employees)

Specification	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
industrial processing in total	142,9	138,2	100,6	138,1	133,1	126,1	124,1	119,9	118,7	118,6
wood and furniture industry in total	253,3	251,9	244,4	247,1	237,4	221,0	212,5	193,0	196,7	193,5
furniture industry	212,9	197,1	183,0	190,6	180,4	155,5	136,3	136,8	134,3	130,9
wood and furniture industry, opolskie voivodeship	261,3	194,6	189,0	213,1	170,2	155,2	184,6	153,2	183,6	180,1
furniture industry, opolskie voivodship	199,7	166,0	145,9	162,1	129,0	105,6	96,5	91,5	132,3	121,8
analysed plants	208,1	209,5	200,8	164,7	147,5	128,9	110,2	112,8	129,4	120,1

Source: Own study based on data obtained from the Industry Statistical Yearbooks 2009-2017 and the analysed plants.

Considering the employment rate in hazardous conditions, it can be seen that both the wood and furniture industry in general and the furniture industry itself in Poland are characterised by significantly higher values than the average for the entire industrial processing, despite a systematic decline since the beginning of the analysed period. It is particularly evident in the wood and furniture industry, which largely stems from occupational safety situation in the sawmill industry. During the investigated period, on average every sixth employee is exposed to hazardous work. The state is comparable in the Opole region, apart from the years 2013-2016, it was considerably lower then. Unfortunately, according to the latest data, it has increased again and the situation is at a comparable level to national data. However, it is worth noted that the rate of employment in hazardous conditions in furniture production in examined period has decreased, but not to a satisfactory level. It indicates that the level of occupational hazards is exceedingly high in the industry in question. Moreover, the level of risk did not change significantly during the period considered. Therefore, it can be concluded that both in the Opolskie Voivodship and in Poland, insufficient measures have been taken to eliminate or at least reduce occupational hazards.

Over a period of two five-year periods, the study was carried out in terms of the level of risk in examined establishments, detailing harmful, dangerous and burdensome factors at the workplace. On the basis of synthetic data presented in the table, it can be concluded that more than half of the employees work in hazardous conditions. Nevertheless, it can be seen that there has been a slight improvement over 5 years. The highest level of risk is caused by factors occurring in the work environment, which is largely due to the specific nature of the furniture industry. A high level of risk (more than ¼ of respondents) results from mechanical factors, using obsolete and exploited equipment in the production process. Practically all factory owners admitted that significant impact on the

situation is a consequence of extremely high costs of purchasing modern machines and tools. The relatively lowest percentage are workers who are exposed to hazards associated with the nuisance of work, which may indicate that mere operation of machines, tools or other equipment does not cause greater problems.

Table 2: Persons employed in hazardous conditions – dangerous, harmful and burdensome conditions in the factories investigated in years 2010-2014 and 2015-2019 (%)

specification	Total employment in hazardous conditions	Hazards related to working environment	Hazards related to nuisance of work	Hazards related to mechanical factors
2010-2014	62,3	58,9	14,5	26,6
2015-2019	55,8	54,2	18,7	27,1

Source: Own study based on data obtained in the analysed plants.

Considering that greatest risks to workers' health and life arise from the physical work environment, on the basis of a thorough analysis of the data, it has been established which are relevant and to what extent (table 2). Noise is the greatest threat, both in the wood and furniture industry, as well as in the furniture manufacturing sector and in the analysed plants. In all plants, it significantly excessed acceptable standards. Wood dust and chemicals contained in adhesives, varnishes, paints and preservatives correspondingly represent relatively high degree of risk. Every fifth employee is exposed to them. It is worth noting that it is only in the case of chemical substances that a higher level is recorded in relation to the wood and furniture industry in general. The lower percentage of employees in the other sections is not solely due to better working conditions in this aspect, but resumes from the fact that work with adhesives, various impregnates, etc. is an insignificant part of their duties. In addition, in some plants, workers are exposed to too high or too low temperatures, but it is more than twice as low as the industry in general. Since, unlike most other branches, furniture production is located indoors to a large extent it results in good conditions in this regard. The frequency of remaining risks is negligible and of low importance to the health of employees in the analysed factories.

Fig. 1: Structure of workers exposed to hazards related to the work environment in the examined plants in comparison with the furniture industry in general and the wood and furniture industry in the Opole region in 2010-2019 (in %)

Source: Own study based on data obtained in the analysed plants and data from WUS in Opole.

On the basis of the data presented in table 4, it can be noticed that the level of accidents in the analysed sector both in general and in the analysed plants in Opolskie Voivodship is definitely higher than the national average in industrial processing. It also exceeds the average of the wood and furniture industry. It is worth noting, however, that in both cases data presents a downward trend, although recently it has been rather symbolic. On this basis, one

can be tempted to state that working conditions, and particularly the physical work environment in the manufacture of furniture, pose a fairly high risk to health.

Table 3: Accident rate per 1000 employees in industrial processing, in the wood and furniture industry in Poland and in the analysed plants in 2010-2019

Specification	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
industrial processing in total	12,20	13,10	13,60	12,50	11,64	11,59	11,12	10,99	10,64	10,23
wood and furniture industry in total	14,10	15,20	15,70	14,30	13,74	13,39	12,78	12,40	12,32	12,31
furniture industry	14,80	15,50	16,20	14,90	13,36	12,79	12,52	12,03	11,98	11,58
wood and furniture industry, Opolskie voivodeship	16,60	15,80	15,20	15,10	14,30	13,01	12,98	12,70	12,40	12,35
furniture industry, Opolskie voivodship	16,10	15,30	15,10	14,80	13,90	13,70	13,10	12,50	12,45	12,41

Source: Own study based on data obtained from the Industry Statistical Yearbooks for the years 2009-2018, information obtained from the Informatorium of the Central Statistical Office in Opole and data obtained in the analysed plants.

Analysing the data presented in table 4, it can be concluded that most accidents in the wood and furniture industry as well as in analysed plants are caused by mistakes made by the employees themselves. Among the most common reasons resulting from the human factor, the incorrect behaviour of employees (the cause of more than half of all accidents) is mentioned. To a much lesser extent, there are: employee arbitrary behaviour, deliberate non-use of protective equipment and improper physical condition of the employee.

Table 4: Reasons for accidents at the workplace in the wood and furniture industry in general and in selected plants of the furniture sector in the Opolskie Voivodeship in 2010-2019 (%)

Human factor			Organizational factor			Technical factor		
Wood and furniture industry	furniture industry	examined plants	wood and furniture industry	furniture industry	examined plants	wood and furniture industry	furniture industry	examined plants
78,7	75,9	77,7	10,1	7,7	7,1	12,2	16,4	15,2

Source: Own study based on data obtained in the analysed plants and data from Central Statistical Office in Opole.

It is worth noticing the discrepancies between the reasons in the sector in question and the entire industry. Furniture manufacturing plants are characterised by a lower number of accidents resulting from an inappropriate technical and organisational factors thus it may indicate relatively good work organisation and properly prepared equipment. Unfortunately, considering the human factor, it is more significant for furniture manufacturing plants than for other sectors of the wood and furniture industry. It is more alarming, as technical and organisational reasons of accidents can be reduced to a minimum, while reducing human causes is complicated, since often the behaviour of employees is unpredictable. Therefore, it can be concluded that it will not be feasible to improve working conditions and work quality unless on the one hand, workers themselves deliberately ignore health and safety recommendations and, on the other hand, employers knowingly or unknowingly put their health and even their lives at risk.

The information on occupational safety is complemented by the opinions of 150 production workers who were interviewed individually. In total, 100 interviews were conducted (85 men - 15 women). The low number of women in the survey results from the nature of work (heavy and arduous), mainly men work in production sectors. Most of the respondents have secondary and vocational education and work experience longer than 5 years. Each

employee answered 5 questions. The first one referred to the issue of providing personal protective equipment by the employer.

Fig. 2: Provision of personal protective equipment by the employer (in %)

Source: Own work based on conducted surveys.

Examining the data presented in figure 1, one can notice that every tenth person surveyed responded negatively. A low percentage of respondents have not possessed any knowledge in a given subject. Therefore, it can be determined that employers have not violated health and safety regulations in this respect. The first question was supplemented with verification whether the respondents use personal protective equipment. Here, the answers were quite surprising, since as many as ¼ of the respondents admitted that they violated the regulations in this respect (table 4). It may indicate that control in this regard is inappropriate.

Table 5: Structure of respondents' use of personal protective equipment

Do you use personal protective equipment?		
Yes, always	Yes, but not always	No
73,9%	24,3%	2,3%

Source: Own work based on conducted interviews.

The distribution of responses is even more alarming as it has been presented earlier that the industry is characterised by a relatively high level of risk in the workplace. It might lead to the conclusion that employers should enforce the use of personal protective equipment more effectively. Occasionally, it will be sufficient to organise training to raise awareness of the consequences of not using personal protective equipment, or systematic control at workstations combined with consequences if irregularities are found.

The next question was aimed at examining the level of employees' awareness of the numerous occupational hazards in their workplace (Figure 2).

Fig. 3: Structure of workers' awareness of risks at work (in %)

Source: Own work based on conducted interviews.

Unfortunately, it can also be observed that a significant proportion of workers is unaware of the risks in the workplace. Interestingly, even those who responded positively, when asked to indicate the most common ones, were unable to give a clear answer. It is worth noting, however, that despite average awareness of employees of the fact that the employer provides personal protective equipment and occupational hazards, over 85% of respondents have a sense of security both at their workplace and in a company. Individuals expressing different opinion pointed out the lack of regular training in the area of occupational hazards and safety at work, which would be in line with the previous answers. Finally, the respondents were asked whether the feeling of safety at work translates into their satisfaction As it turned out, almost half of the surveyed employees (47.9%) answered negatively. The low remuneration and the lack of an indefinite work contract were primary reasons.

Summary

We are all adapting to live and work in an environment with specific characteristics. Deviations of environmental parameters from the conditions assumed to be safe may cause a number of negative disorders in human functioning and negatively influence on work and life quality. In the light of the studies carried out, it can be assumed that safety at workplace, during the analysed period, had not improved sufficiently to be considered satisfactory, particularly from the perspective of workers. There is still a high proportion of workers exposed to factors that threaten their health and relatively high accident rate. Moreover, the workers' approach to safety at work leaves much to be desired. Dismissive attitude of superiors is also alarming, as on the one hand, they are unable to motivate their subordinates adequately to use personal protective equipment and, on the other hand, they do not draw the appropriate consequences if health and safety rules are not obeyed in the workplace. Unfortunately, the analysis carried out indicates that the high position of the Polish furniture industry, both on the European and global markets, does not have a sufficient impact on work safety nor on a significant increase in the work environment quality in furniture manufacturing plants. Therefore, it can be concluded that the culture of work safety in the analysed industry requires significant changes, especially in the area of proper control of compliance with the requirements concerning procedures of behaviour at workstations and the use of personal protective clothing/equipment, as well as regular actions raising the awareness of superiors and their subordinates in the area of occupational health and safety. Measures should also be taken to increase external controls in companies, especially small ones, on compliance with health and safety rules. Only then would the employers quickly and more radical address the issue.

Abstract

The aging of the population is a long-term trend that began in Europe several decades ago. This trend is visible in the transformation of the age structure of the population and is reflected in the growing share of elderly people in the general population, combined with the corresponding decreasing share of the working-age population. As people age, they undergo general changes in their bodies in the physical, physiological, and mental spheres, which changes their market behavior. The importance of recognizing the attitudes of older people in the process of purchasing products results primarily from the fact that Poland is the fastest aging country in the European Union. Older people are perceived stereotypically as being closed to new things, with strongly shaped traditional attitudes. However, research results show that the senior segment is highly diverse. Increasingly, older consumers show interest in new products and services. The research aimed to determine the impact of subjective well-being on consumer innovativeness. This study was conducted in Poland in 2018 on a sample of 1,617 people. The respondents were selected using the quota selection method; the structure of the sample examined according to the criterion of gender and age was the same as the structure of the elderly population in the Wielkopolska region. The presented research results they indicate, that seniors are not a homogeneous group. At the analyses carried out indicate that the most important determinants of the process of acceptance of product innovations by seniors include, first of all, individual (subjective) variables. The inclusion of subjective well-being consisting of specific individual components in the analyses completed the picture of the shaping of attitudes of seniors towards new products. Older consumers may be an attractive segment for innovative companies.

Keywords: Consumer Behavior, Product Innovation, Older Consumers, Consumer Innovativeness, Subjective Well-Being, Seniors.

Introduction

Population aging is a global phenomenon deeply troubling to economists and policymakers due to its numerous economic and financial implications. In many European countries, and above all in Poland, this trend has been on the rise in recent years, and the effects are becoming increasingly noticeable.

At the end of 2018, the population of Poland was 38.4 million, including more than 9.5 million people aged 60 and over (approximately 25%). The share of people aged 60 and over in the general population increased from 14.7% in 1989 to 24.8% in 2018 (an increase of 3.9 million people). In the subpopulation of older people, the largest group (almost one-third) are 60-64-year-olds, the number of whom has increased by more than half over the last 25 years; the number of people aged over 80 has also increased (17.5% of the total population) (see Table 1). By 2050, the number of people aged 65 and over is expected to increase to 11.1 million (Population forecast for 2014-2050, 2014).

Table 1: Number of older people and structure in Poland in 2018

	Population in thousands	%
In all	38411.2	
including people aged 60 and above	9508.4	24.75
60-64	2776.0	29.20
65-69	2413.0	25.38
70-74	1595.9	16.78
75-79	1057.7	11.12
80-84	876.5	9.22
85 and above	789.3	8.30

Source: Information on older people in Poland for 2018, 2019

The growing number of older people in Poland is conducive to research in many scientific disciplines aimed at describing and understanding consumer behavior due to aging. Many researchers make the effort to acquire knowledge about the specifics of decision-making in the purchasing processes of older people (Moschis 2003; Moschis 1996; Greco and Swayne, 1997; Ong, 2008; Sudbury and Simcock, 2009). Numerous studies have shown that human aging has a radical impact on consumption and purchasing behavior (Carpenter and Yoon, 2011; Mata, Schooler, and Rieskamp, 2007).

Population aging is a global phenomenon, which is particularly prevalent in developing countries. Therefore, for economists, the role of seniors as consumers has become the subject of numerous scientific considerations; a common thread therein is the statement that the market behavior of older people is highly diverse. At the same time, as is generally believed, the frequent lack of information on how seniors behave leads to the interpretation of their behavior based on specific stereotypes (Moschis 2012; Zniva and Weitzl, 2016).

However, it should be remembered that the actions of enterprises directing their products and services to seniors based only on a false image may be ineffective; hence the need to permanently deepen knowledge about the market behavior of older people. Aging is one of the key future challenges of global life. Of particular interest is the consumption-related decision-making of older people, as a better understanding of this phenomenon would facilitate the effective influence of behavior which would help to secure the economic well-being of, and ensure a better quality of life for, this demographic cohort (Olejniczak and Olejniczak, 2020). Presently, 12.3% of the world's population is aged 60 years or older - a proportion that is expected to rise to almost 22% by 2050. In line with this increase, the annual purchasing power of older people is expected to grow from $8 trillion in 2010 to more than $15 trillion by 2020 (Kearney, 2013). Given this change, companies have an increasing interest in understanding how older people make consumption-related decisions. This interest is driven by the hope of securing a better quality of life in old age through goods that suit this population's respective needs (Moschis, 2012).

The diversity of the course of the aging process considered in three dimensions (biomedical, mental, and social changes), as well as life events and circumstances that occur in the lives of older people, make their behaviors dynamic and highly diversified (Sthienrapapayut, Moschis, and Mathur, 2018). The research results presented so far also indicate that the attitudes of seniors towards innovation are moderately positive, but at the same time difficult to interpret and ambiguous. To deepen the considerations on their attitudes towards innovation, the identification of individual factors influencing the shaping of this process was made. The main goal of the research was to determine the determinants of purchasing and acceptance of product innovations by seniors on the FMCG (*fast-moving consumer goods)* market. As part of the implementation of this goal, it was assumed that the following qualitative factors are of significant importance in the acceptance process: health status, determined by the subjective opinion of consumers; cognitive age, determined by the measure of compliance with their chronological age; and the level of optimism of seniors, expressed by determining their feelings about their independence in terms of functioning in everyday life in the future. All these factors contribute to the subjective well-being of an elderly person.

The literature currently adopts a three-dimensional approach: well-being is created by emotional, personality (psychological), and social elements (Derbis, 2005; Petrescu and Kara, 2018; Cloninger, 2012). Emotional well-being is the subjective assessment of an individual regarding the severity of positive and negative effect, sense of happiness, general satisfaction with life, and satisfaction in its various areas (Román and Toffoletto, 2017). Psychological well-being means the state of human feelings that occur along with one's actions while striving to realize one's potential and living, and social well-being takes the nature of positive experiences of an individual resulting from his belonging

to a given society and community into account (Wojciechowska, 2008; Zammit et al., 2012; Ferring and Boll, 2010; Ulloa, Moller and Sousa-Poza, 2013).

Therefore, the article adopts a broad perspective, interpreting the subjective well-being of older people as: experiencing emotions (well-being related to age identity), level of mood (looking at the future in the context of the possibility of performing daily activities), as well as the level of life satisfaction (related to a subjective sense of health). As part of the analysis of seniors' consumer behavior, an attempt was made to verify the hypothesis that the subjective well-being of older people is an important element influencing their decisions related to the purchasing of product innovations

Method

Research among older people (it was assumed that a senior / older person is a consumer aged 60 years and over) was conducted with the help of a personal interview carried out in 2018 on a sample of 1617 people in Wielkopolska (Greater Poland). Wielkopolska is one of the largest regions in Poland (the second-largest region in terms of land area in square meters (m^2)), with the third-largest population - but with the lowest rate of aging in the country (taking into account the number of people over 60). Product innovations appearing on the *fast-moving consumer goods* (FMCG) market were analyzed: food, health products - parapharmaceuticals / medical, cosmetics, and household chemicals. The selection of respondents was carried out using the quota selection method, and the structure of the research sample according to the criterion of gender and age was the same as the structure of the elderly population in Greater Poland[1].

Sample

The respondents were selected using the quota selection method; the structure of the sample (see Table 2). examined according to the criterion of gender and age was the same as the structure of the elderly population in Wielkopolska.

Table 2: Structure of the sample in 2018 (%)

Age groups	Altogether	Women	Men
60-64	36.8	57.5	42.5
65-69	27.3	58.8	41.2
70-74	16.3	55.7	44.3
75-79	9.2	61.5	38.5
Over 80	10.4	72.6	27.4

Source: Own research

Measures

As part of the analysis, descriptive statistics were used to determine the structure of the surveyed population: structure and intensity indicators (proportions, percentages), location and variability measures (mean and standard deviations). The coefficients of variation of two independent variables referred to the correlation between variables measured on a quantitative (student t-test) and qualitative (Kendall) scale (Akoglu, 2018; Croux and Dehon, 2010).

Results

One of the determinants of shaping attitudes towards innovation is the specific attitude of seniors to changes in the environment. Researchers have noted the diversified approach of seniors to changes in the environment, which are reflected in attitudes of activity or withdrawal (Stuart-Hamilton, 2006). Research results indicate that the innovation of senior consumers, measured as interest in new products, should be assessed as moderate. Among respondents, one in three respondents (34.9%) is interested in new products, but only one in 10 (12.2%) looks for additional information and finally makes a purchase. Slightly more than one-fifth (22.3%) sometimes take note of product innovations, but rarely buy them (see Table 3).

[1] Based on the statistical chi-square (x2) test, the p-value was calculated, which was 0.74 (age) and 0.99 (sex), respectively. The values indicate that the structure studied is the same as the structure (age and gender) of older people in Wielkopolska (p–value > 0.005).

Table 3: Interest in product innovations by senior consumers

How interested are you in innovative, new products?	%
I am not interested and I do not buy such innovative products	16.0%
I am not interested, but sometimes I buy such products – as and when I need them	28.2%
I know there are such products, I can see them in stores, but I rarely or never buy them	21.3%
I'm interested, sometimes I take note, but I rarely or never buy (for various reasons)	22.3%
I am interested in looking for information on and buying innovative products	12.2%

Source: Own research

A similar-sized group of respondents (21.3%) notice market novelties in stores, but rarely or never buy them. 44.2% are not interested in new products, although at the same time 28.2% of those who are not interested declare that they buy new products in certain cases.

The results of the survey indicate the existence of two groups of seniors with different attitudes towards innovation: consciously innovative consumers (engaged in seeking information about new products and active shopping) and market conservative consumers (showing a lack of interest in new products). The largest group of respondents is a group which represented the full spectrum of behaviors that can be characterized from cautiously innovative (sometimes interested but rarely or never buyers) to innovatively unaware (declaring a total lack of interest in new products, but not ruling out purchasing in specific situations).

Three elements were adopted as components of the subjective well-being of seniors: an assessment of subjective health, an assessment of the prospects for independence in performing everyday activities in the future, and the subjective perceived age. The research results show that the seniors surveyed generally assessed their health quite positively. Almost half (47.9%) of respondents say that they feel well or very well, 28.4% of respondents sometimes feel more ailments, and only 23.8% declare that they are chronically ill and are under constant medical supervision (see Table 4).

Table 4: Subjective health of seniors

	%
Very good - I don't get sick	9.3%
Quite good - I have minor ailments	38.6%
Neither good nor bad - sometimes I suffer from greater ailments	28.4%
Quite bad - I have a chronic disease, I am under medical supervision	18.5%
Very bad - I have several types of diseases, I am constantly undergoing treatment	5.3%

Source: Own research

The subjective assessment of the health condition of seniors is varied, and the decisive factors in determining it are the chronological age, cognitive age, and the optimism of older people regarding independent functioning in the future (see Table 5).

Table 5: Correlation coefficients between the selected variables and the subjective assessment of health

Variables / Features	**Health of seniors**
Age	0.355**
Cognitive age	0.322**
Life optimism	0.333**

*** Correlation significant at the level of 0.001.*
Source: based on research results, 2018.

The results of the analyses conducted show that people who are younger, both in terms of age and mindset, and those thinking about the future in a positive way, more often assess their state of health as good and very good.

Chronological age, denoting the actual age of the consumer, has always been one of the main criteria of segmentation, as the prevailing opinion is that the use of this criterion is necessary because age determines consumption needs, habits, and lifestyle, and thus may be a significant predictor of changes in consumption behavior (Amatulli, Guido and Nataraajan, 2015). However, the development of knowledge about consumer behavior means that a view about the limitations of inference based on chronological age is increasingly prevalent.

It was noted that in terms of differentiation of consumer aging processes resulting from the passage of years as a result of biological and psychological changes, the variable chronological age is characterized by ambiguity in explaining consumption phenomena. It has increasingly been noticed that a given older person feels younger than he or she actually is, and this is reflected in the decisions he or she makes (Sherman, Schiffman, and Mathur, 2001; Van Auken, Barry and Bagozzi, 2006). As a result, the hypothesis that older consumers who feel younger than their birth certificate indicates may also behave like younger people was put forward and positively verified (Szmigin and Carrigan, 2000). Therefore, in consumer research, particular attention should be paid to the psychological concept of cognitive age, which is an image of the subjective perception of the perception of old age by consumers, as it can be considered a factor that explains consumer behavior well (Mathur and Moschis, 2005).

Moreover, the literature emphasizes that consumer purchases can be better explained through the prism of cognitive rather than chronological age (Yoon et al., 2005). Similar conclusions are drawn by other authors: for example, Gwinner and Stephens (2001) argue that cognitive age provides more information about consumer behavior in comparison with chronological age. This conclusion is also supported by Moschis, who clearly emphasizes that changes in recent years have strongly differentiated the aging process of individual consumers; hence, chronological age becomes a limited variable for predicting consumer behavior (Mathur, Mathur, and Moschis, 2011).

Cognitive age has thus proven to be a construct that can explain certain consumer behavior as well or even better than some of the more commonly used variables such as income, education, health, and social activity. Nevertheless, cognitive age may be an insufficient factor to interpret consumer behavior in many areas; hence the cognitive value of analyses of standard demographic data describing consumers is still recognized (Gwinner and Stephens, 2001).

Research results indicate that older people very often feel mentally younger than their chronological age would indicate (Choi, DiNitto, and Kim, 2014). I. Rippon and A. Steptoe (2015) analyzed data from research on aging from 2004-2005, in which almost 6,500 people participated. The perceived age was measured by asking participants the question: "How old are you?" and it turned out that the average age perceived by them was 56.8 years, which is 10 years lower than their actual average chronological age (65.8 years). The 2000 analysis of senior consumers in the United States shows that those aged over 50 feel 10 to 12 years younger than their chronological age (Szmigin and Carrigan, 2000).

Research conducted among elderly people in Wielkopolska confirms the above-mentioned results of other national studies: seniors assess their age as being lower than it really is. Over 42.5% of respondents believe that they feel younger than their birth certificate indicates. A third of those surveyed (36,8%) indicate that their cognitive age is equal to their real age, whereas one in every five seniors (20,7%) declares that subjectively they feel older than they really are (see Table 6).

Table 6: Cognitive age of seniors

	%
I feel older than I actually am	8.4%
I feel slightly older than I actually am	12.3%
I feel my age	36.8%
I feel slightly younger than I actually am	30.2%
I feel much younger than I actually am	12.3%

Source: Own research

Correlation analysis allows us to determine the relationship between the assessment of one's cognitive age and the variables describing the respondents. It turns out that the subjective sense of age fundamentally determines the optimism of seniors regarding the future, subjective health condition, chronological age, and the level of education (see Table 7). The more optimistic older people are about the future (in terms of coping with everyday activities), the better they assess their health condition, the higher the level of education they have, and the more often they consider themselves younger than their date of birth would indicate.

Table 7: Correlation coefficients between the selected variables and the perceived age of seniors

Variables	**Cognitive age**
Sex	$p < 0.05$
Life optimism	-0.392^{**}
Health	-0.322^{**}
Age	-0.280^{**}
Education	0.183^{**}

Social activity	-0.180**
Financial situation	0.159**

*** Correlation significant at the level of 0.001.*
Source: based on research results, 2018.

Social activity also influences cognitive age, as seniors who maintain intense interpersonal contacts are more likely to express the opinion that they feel younger. The literature also draws attention to the fact that women are more sensitive to negative stereotypes about old age (Barak and Schiffman, 1981).
The third component of the subjective well-being of older people is the individual assessment of independence in performing daily activities. The vast majority of seniors (68.5%) declare that in the future they will be able to cope alone or with a limited amount of help from their loved ones (see Table 8). Almost one in three respondents (31.5%) is now aware of their limitations and expects constant or temporary help from the environment in performing many daily activities.

Table 8: Life optimism of seniors

In the future:	%
I can handle it on my own - I will do most of my daily activities on my own	28.8%
I can cope with a little help from my relatives - sometimes, at certain times, my relatives will help me with my activities	39.7%
I will most likely require help - I think I will most likely require more help from my loved ones	19.5%
I expect others to help me - I know I can't do it alone	12.0%

Source: Own research

As may be assumed, the assessment of the future is largely based on the assessment of the present, and in the case of seniors, the assessment of the health situation and feelings about age is essential (see Table 9). To a very large extent, older people also associate their optimism regarding their future health and mental functioning with their financial situation and level of education. It may also be noted that seniors who lead an active lifestyle based on social relationships look to the future more positively and assess that they will perform most of their daily activities independently.

Table 9: Correlation coefficients between selected variables and the life optimism of seniors

Variables	**Life optimism**
Health	0.333**
Age	0.272**
Education	-0.155**
Financial situation	-0.206**
Social activity	0.148**
Cognitive age	-0.392**

*** Correlation significant at the level of 0.001.*
Source: based on research results, 2018.

The results of the study confirm that the innovativeness of senior consumers (measured by declarations of interest and the frequency of purchasing new products) depends in a statistically significant manner on the assessment of their subjective well-being. The better the health assessment, the lower the cognitive age and the greater life optimism, the more often interest in innovative products is declared, which also translates into subsequent purchases of new FMCG products (see Table 10).

Table 10: Correlation coefficients between subjective well-being and the level of interest in new products and the frequency of their purchase

Components of the subjective well-being of seniors	How interested are you in innovative, NEW products?	How often do you buy innovative products?
Health	-0.221**	0.401**
Cognitive age	0.245**	-0.608**
Life optimism	-0.222**	0.400**

*** Correlation significant at the level of 0.001.*
Source: based on research results, 2018.

The analysis of the research results based on the correlation of Kendall's coefficients shows that the subjective well-being of seniors significantly affects their interest in innovative products on the FMCG market, and is also of fundamental importance in the process of their purchasing behavior. This is highly interesting and requires further research into significant dependencies: real consumer behavior (in the form of research results on the frequency of buying new products) is more strongly correlated than the declarative interest in purchasing innovations by seniors.

Conclusion

Summarizing the presented research results, it should be clearly stated that seniors are not a homogeneous group. Various psychological and social factors significantly determine their attitudes toward product innovations. At the same time, the analyses carried out indicate that the most important determinants of the process of acceptance of product innovations by seniors include, first of all, individual (subjective) variables. The inclusion of subjective well-being consisting of specific individual components in the analyses completed the picture of the shaping of attitudes of seniors towards new products. At the same time, research results suggest that cognitive age may be a precise criterion explaining the diverse attitudes of older people towards product innovations in the FMCG market. It complements the view found in the literature that age may be treated as a set of many variables: life satisfaction, self-confidence, physical and social activity (Sherman, Schiffman, and Mathur, 2001; Barak, et al., 2001). A wider approach to perceived age than in the case of chronological age enables the analysis of the identity of seniors, especially their belonging to many groups with differing attitudes towards innovation: reluctant conservatives (seniors not interested in innovation, and look ahead with pessimism), knowledgeable traditionalists (older people with a sober view of their lives, who do not buy new products due to traditionalism, but notice new products in the commercial offer), aspiring withdrawn/passive (seniors with a diverse approach to innovation, interested, sometimes buyers, but still withdrawn, looking at the changing reality with a sense of worry), unaware practical (elderly people with a practical approach to shopping, who are not interested in new products, looking optimistically at the present and future), rational innovators (interested in new products, very positive about the future) (Olejniczak, 2019). Thus, the cognitive age category enriches knowledge about seniors, emphasizing diverse patterns of behavior, and ultimately has a fundamental application, especially in the market segmentation process.

Analysis of The Y Generation's Advertising Perception

Jakub HORVÁTH
Faculty of Management, University of Prešov, Prešov, Slovakia
jakub.horvath@smail.unipo.sk

Abstract

The article focuses on the perception of advertising and its evaluation by the generation of the Millennials. The basic population for the purpose of the survey is the millennials of the East Slovakian region. 180 respondents were surveyed and it was possible to include 154 respondents' answers based on the criterion of completeness of completed questionnaires. Data collection was conducted through simple random sampling in January and February 2019. To verify the hypotheses, we used the StatSoft SPSS software. Due to the nature of the analysed variables we used Cronbach´s alpha and Mann Whitney U test. Based on the research findings, the respondents did not know or did not want to rate the internet advertising (banner, context, advertising on social networks, e-mail advertising). The generation of the Millennials evaluate internet advertising as more negative than the traditional advertising. This output suggests to some extent the so-called "advertising blindness". The result of the hypothesis verification is that there is a significant difference between the ranking of traditional and internet advertising in the generation of the Millennials. These results are very interesting if we confront them at the level of the global tendency of advertising perception by Y generation representatives.

Keywords: Advertising, Advertising Perception, Ad Ranking, The Millennials.

Introduction

People are hit by an enormous amount of ads trying to get their attention from various media - television, print media, radio, and now even the Internet. With this number of promotional messages, businesses that do not use marketing communication are in the shadows of those who use it (Hagyari, Bačík and Fedorko 2016). Every company that builds its promotional activities only on the recommendations of its customers does not very often achieve what we call magnetism (Turner and Shah 2014; Lizbetinová et. al. 2019). However, if the company wants to achieve it, it should focus on developing the right strategy for marketing communication (Bačík, Mihal and Fedorko 2015). Marketing is an activity, a set of institutions and processes that have been created to communicate, deliver and exchange offers that are valuable not only to customers but also to other stakeholders and the general public (Lamb, Hair and McDaniel 2012; Mura and Kljucnikov 2018). In traditional marketing theory, we should be familiar with McCarthy's 4P model, which deals with product, price, placement and promotion (Dann and Dann 2011). Marketing communication is, according to Ferencová and Butoracová Šindleryová (2009) "any form of controlled communication used by organizations to inform, persuade or influence consumers, intermediaries and even certain groups of the public". In the traditional marketing theory, marketing communication tools include advertising, public relations, personal sales, sales promotion, direct marketing and etc. (Armstrong et al. 2009). E-marketing is a form of marketing where the application of IT tools and the Internet allows marketing tools and activities to focus on the defined relationships (Molenaar 2012). Molenaar further claims that e-marketing consists of three sub-areas: marketing, information technology and Internet. E-marketing helps to create customer demand by using the power of the Internet (Mudrík and Fedorko 2010). It gives businesses the opportunity to exchange attention for value (attention economy) (Frankovský and Birknerová 2014). E-marketing tools help building a long-term customer relationship. Moreover, the e-marketing environment is very well measurable (Stokes 2013; Mura, Marchevská and Dúbravská 2018). Dorčák (2012) states that traditional forms of e-marketing communication include: website, contextual advertising, banner advertising, search engine advertising; PPC advertising, e-catalogues, e-mail marketing and public relation (Štarchoň et. al. 2018; Štefko, Bačík and Fedorko 2014). A website is a document containing hypertext, images, and other multimedia elements stored on a web server that is displayed to the user when entering a specific web address in the selected search engine (Fedorko and Kakalejčík 2015). For businesses, it is one of the proprietary media that allows it to communicate with its potential customer (Dorčák 2012). In an ideal world, any Internet user would immediately become a customer (Kovaľová, Frankovský, Birknerová and Zbihlejová

Cite this Article as: Jakub HORVÁTH "Analysis of The Y Generation's Advertising Perception" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2019). As the real world differs greatly from the ideal, businesses need to think about the steps that the customer takes before and after the purchase to offer the customer enough information transforming them to customers as soon as possible. The funnel is the best choice for defining a purchasing cycle.

Fig. 1 : Purchasing funnel

The purchasing funnel is the purchasing process that the customer is conducting during the purchase cycle. It usually consists of several phases (Halligan Shah 2014). The definitions of the funnels vary with the author. However, for the purposes of this article, we will use Carter's (2013) purchasing funnel, which is shown in chart 1. The displayed funnel consists of 3 phases and 4 types of people involved in it. We can define these people as follows: stranger – represents an internet user who has not previously visited the business website (Halligan and Shah 2014); visitor – represents the internet user who previously visited the business website (Carter, 2013); lead - represents a visitor who has expressed a deeper interest in the website by providing their contact information in exchange for the content of the website (Scott, 2013; Štefko, Bačík and Fedorko 2014).

Methodology

The main objective of this article is to find out if there are differences in the ranking of traditional and online forms of advertising. Based on this objective, a research question is formulated as to whether: “Are there any differences in the evaluation of internet and traditional Y generation advertising?” Based on this research question, a research hypothesis is formulated:

H1: We assume that there are significant differences between the ranking of traditional and internet advertising in the generation of the Millennials.

The deeper relationships of the conducted research show a portion of inference statistics and part of the analytical processing. In this section, Cronbach's alpha and Mann Whitney U test were used.

For the purpose of this research, the research sample was defined as a new generation of customers represented by the Millennials. As for the definition of the age group of the Millennials, the article follows the methodology of Young (2017) from Ogilvy & Mather. The Millennials are referred to as “Y generation” from the age 18 to 34.

- C Centennials (1995-2012),
- Y Millennials (1977-1994),
- X Generation (1966-1976),
- S Generation (1955-1965).

The inputs to the analyses were obtained through the implementation of primary research, which was carried out using CAWI (Computer Assisted Web Interview). Data collection via an electronic questionnaire was conducted in January and February 2019. It was a quota selection based on the ROD variable, where were efforts to maintain the population ratio, i.e. 52% representing women and 48% representing men. It was an electronic inquiry, where the questionnaires were distributed on the Facebook pages to the groups of the University of Prešov and to other groups of people living in the Prešov and Košice regions. E-mails (from the private address database of the authors) were subsequently sent to identify the gender characteristics. The research was conducted in January and February 2019. Thus, based on the selection, the research has a limitation and therefore it can be generalised only to Eastern Slovakia. 180 answers were collected and in case of the question identifying their generation (how old are they) 26 respondents were eliminated, i.e. the number of selection proceeding to the investigation is 154.

Results

The examined issue points to the perception of advertising and its evaluation by the generation of the Millennials. The following chart shows the gender characteristics ratio.

Fig. 2: Gender characteristics – Advertising Rank

The previous chart points to the fact that the selection consists of 55.84% women (86 respondents) and 44.16% men (68 respondents), thus we can talk about the selection approximating the actual population of Eastern Slovakia. The questionnaire for the survey variables (the ranking of individual types of ads) also offered the possibility of not filling out the items. The following table shows the actual frequencies found.

Table 1 Advertising Rank – Frequency

Advertising type	**TV Advertising**	**Banner advertising**	**Contextual Advertising**	**Advertising on Social Network**	**E-mail Advertising**
Valid	152	136	134	152	136
Not filled out	2	18	20	2	18
Advertising type	**Radio Advertising**	**Leaflet Advertising**	**Newspaper Advertising**	**Billboards**	**Posters**
Valid	152	150	154	154	154
Not filled out	2	4	0	0	0

It is noteworthy that the respondents did not know or did not want to rate the internet advertisement (banner, contextual, advertising on social networks, e-mail advertising).

Table 2: Descriptive Statistics - Advertising Rank

Advertising Type	TV Advertising	Banner Advertising	Contextual Advertising	Advertising on Social Network	E-mail Advertising
Negatively					
Rather negatively	62	36	36	34	58
Rather positively	44	42	46	44	58
Positively	32	46	36	54	8
	14	12	16	20	12
Median	2.00	2.00	2.00	2.00	2.00
Mean	1.99	2.25	2.24	2.39	1.81
Std. dev.	1.00	0.95	0.98	0.98	0.90
Advertising Type	**Radio Advertising**	**Leaflets**	**Newspaper Advertising**	**Billboards**	**Posters**
Negatively					
Rather negatively	26	12	8	16	10
Rather positively	52	32	16	30	26
Positively	56	70	88	66	74
	18	36	42	42	44
Median	2.00	3.00	3.00	3.00	3.00
Mean	2.43	2.87	3.06	2.87	2.99
Std. dev.	0.91	0.87	0.76	0.93	0.85

The previous table shows the outputs of descriptive statistics on the subject. Looking at the characteristics of the central tendency it is possible to note that the internet advertising of the generation of the Millennials is rated as more negative than the traditional one. This output suggests to some extent the so-called "advertising blindness". The following sections will be devoted to exact confirmation of the significance of the differences.

H1: We assume that there are significant differences between the ranking of traditional and internet advertising in the generation of the Millennials.

The assumption defined by the previous H1 hypothesis will be verified on average values of traditional and internet advertising. The possibility of average individual items is determined by an acceptable level of reliability. The following table illustrates this.

Table 3: Cronbach's α - Reliability

Traditional advertising		Internet advertising	
α	N	α	N
0.788	6	0.830	4

The threshold for applying the selected item adjustment procedure (arithmetic mean) in terms of reliability is 0.7 (70%), thus the condition can be considered fulfilled. Data were adjusted by arithmetic mean. The following table shows the Mann-Whitney Wilcoxon U test output, and thus the significance of the difference in ranking between traditional and internet advertising.

Table 4: Test - Difference in Ad Rank

Ad rank	
Mann Whitney U	2 949.000
Wilcoxon W	5 577.000
Z	- 5.683
Asymp. Sig. (2-tailed)	0.00

H0: there is no significant difference between the variables.
H1: there is significant difference between the variables.

Based on the p value, which is equal to zero to three decimal places, it is advisable not to reject the alternative H1 hypothesis and to adopt an opinion on the significant difference in the ranking of traditional and internet advertising. The presented output also recommends adopting the basic H1 hypothesis, that there is a significant difference between the evaluation of traditional and internet advertising in the generation of the Millennials. The following chart shows the difference.

Fig. 3: Rating of traditional and internet advertising

From the above it is clear that the Y generation (the Millennials) evaluate better the classical/traditional advertising. This fact can be a cause of advertising blindness, i.e. the given generation is ignoring the ads on the screen of their smartphones and they are somehow immune to it.

Conclusion

Until recently, businesses have implemented their marketing activities based on traditional marketing communication tools. However, since these tools often required a considerable budget, they were not available for every business. In addition, they only provided one-way communication. However, the arrival of the Internet as a network of networks and

the emergence of social media has changed the situation. Using modern marketing communication tools, even small businesses with limited budgets have the ability to reach out to their target audience, often with minimal cost. In addition, they have the option of two-way communication.

A similar research was carried out by the authors Miklošík, Štarchoň, Vokounova. Korčoková (2020), Bačík, Fedorko, Rigelský, Sroka, Turáková (2018) and Wong and Malone (2016). The research results are very similar to ours, but mentioned researches are focusd especially on TV or SMS advertising. Research carried by Bačík et al. (2018) compares the perception of advertising not on the basis of gender, but on the basis of belonging to generation Y or Z.

Based on the above analysis, we can say that the Millennials do not know or do not want to evaluate the internet advertising. Representatives of the Y generation rated the internet advertising more negatively than the traditional one. This output suggests to some extent the so-called "advertising blindness". Based on the hypothesis we have established, we note that there is a significant difference between the evaluation of traditional and internet advertising in the generation of the Millennials. The y generation (the Millennials) rated traditional advertising as better. This fact can be a cause of advertising blindness, i.e. the given generation is ignoring the ads on the screen of their smartphones and they are somehow immune to it.

Resumen

Las Tecnologías de Información y la Gestión del Conocimiento aportan de manera relevante al buen desempeño de las organizaciones. Esto es particularmente cierto en el caso de las instituciones de educación superior. Sin embargo, esta afirmación no ha sido demostrada previamente en la literatura ni tampoco se encuentran informes empíricos que la sustenten al menos parcialmente. Por ello, se realizó un estudio empírico en Instituciones de Educación Superior Tecnológica en México que considera la relación entre estas variables. Los resultados indican que las tecnologías de información influyen positivamente en la gestión del conocimiento, la cual tiene una relación positiva con las tres dimensiones medidas del desempeño organizacional: satisfacción de agentes, desempeño comparado y resultados de gestión. Con lo que mostramos por primera vez que las Tecnologías de Información y la Gestión del Conocimiento es útil para obtener un buen desempeño organizacional en las instituciones de educación superior mexicanas.

Keywords: Gestión Del Conocimiento, Desempeño Organizacional, Tecnologías De Información.

Introducción

El desempeño organizacional es uno de los constructos de mayor interés en los estudios económico administrativos. En un sentido simple, corresponde al indicador de lo bien que una organización está logrando sus objetivos dentro de un entorno cambiante donde la competencia es cada vez mayor (Arena, Arnaboldi, Azzone, & Carlucci, 2009; Li-An, 2011; Richard, Devinney, Yip, & Johnson, 2009).

En el caso de las instituciones de educación superior (IES), la importancia del desempeño organizacional se ve incrementada debido al papel vital que estas organizaciones juegan en el desarrollo del capital humano y crecimiento económico sostenible de una sociedad justa y equilibrada. Por ello es importante, en principio, encontrar métricas adecuadas para evaluar el desempeño de las IES, además de identificar los factores que contribuyen a mejorarlo.

Para contribuir a la solución de tales cuestiones, el presente documento propone utilizar la sección de resultados de excelencia administrativa del modelo EFQM como instrumento de autoevaluación del desempeño organizacional, así como estudiar la relación que tiene el uso de las tecnologías de información y comunicación (TICs) y la gestión del conocimiento con el desempeño en el contexto de las instituciones de educación superior tecnológica en México. Para ello, el escrito se compone de tres bloques. En el primero, se abordan el desempeño organizacional y la relación que las TICs y la gestión del conocimiento tienen con el mismo. En segundo lugar, se describe el método de trabajo. Finalmente, se presentan los resultados y las respectivas conclusiones.

El desempeño organizacional en las IES

El concepto de desempeño organizacional se basa en la idea de que la organización es una asociación voluntaria de recursos productivos (humanos, físicos y de capital), con un propósito compartido (Richard et al., 2009). Estas fuentes de recursos estarán comprometidas con el logro de los objetivos en la medida que estén satisfechas con el valor que reciben a cambio. La esencia del desempeño es la creación de valor que la organización genera para sus integrantes en función de los recursos que éstos aportan a la misma. De esta forma, la discusión sobre el desempeño organizacional se centra en dos temas principales: para quién debe generar valor la organización y de qué forma debe hacerlo. Tradicionalmente, se identifican como stakeholders de las IES a los estudiantes y personal (académico y no académico), exalumnos, organizaciones profesionales, empleadores, ciudadanía en general, instituciones de educación media, otras instituciones de educación superior y gobierno (Sarrico, Rosa, Teixeira, & Cardoso, 2010; Yorke, 1991).

Un problema central en la medición del desempeño de las IES es identificar los factores que influyen en el logro de los resultados, es decir, los facilitadores o agentes. En el caso del modelo de excelencia de la EFQM, los resultados en clientes, en empleados, en la sociedad y en la gestión, son consecuencia de los agentes o facilitadores (liderazgo, personas, estrategia y alianzas y recursos), pues el modelo asume una relación causal entre facilitadores y resultados. En ese sentido, la utilización del modelo EFQM presenta la ventaja de poder separar a los facilitadores de los resultados y evaluar de forma completa el impacto de la organización en distintos stakeholders.

Así, la evaluación del desempeño en las IES puede ser realizada tomando en cuenta a diversos interesados, tendiendo a modelos que capten la naturaleza multidimensional de este complejo concepto. Es por ello que para tal efecto en el presente documento se propone al instrumento del modelo EFQM (específicamente el bloque de resultados) para la autoevaluación del desempeño organizacional, en la versión de Machorro y Mercado (2015), quienes reportan tres dimensiones del desempeño organizacional en IES mexicanas: Satisfacción de Agentes, Desempeño Comparado y Resultados de Gestión.

Las TICs y la gestión del conocimiento en el desempeño

El efecto que tiene la gestión del conocimiento en el desempeño organizacional ha sido estudiado ampliamente, encontrando en su mayoría resultados positivos y significativos. Tal es el caso de Gholami, Asli, Nazari-Shirkouhi, y Noruzy (2013), quien reporta una influencia de la gestión del conocimiento (adquisición, almacenamiento, creación, intercambio e implementación) en el desempeño organizacional medido con indicadores tanto financieros como no financieros i.e. productividad, innovación y satisfacción de clientes. Por su parte Daud y Yusoff (2011) estudia el efecto moderador que tienen los componentes del capital intelectual en la relación entre la gestión del conocimiento y el desempeño organizacional, Zack, McKeen, y Singh (2009) estudia el efecto de la gestión del conocimiento en el desempeño financiero con la mediación del desempeño organizacional.

Respeto a la relación entre las TICs y la gestión del conocimiento con el desempeño organizacional, se identifican dos estudios previos: Mills y Smith (2011) quienes encuentran una relación negativa y no significativa de la infraestructura tecnológica con el desempeño organizacional, mientras que la gestión del conocimiento tiene una influencia positiva y significativa. En el caso de Kuo y Ye (2010), reportan una relación positiva entre las tecnologías de información y la gestión del conocimiento, el cual, puede predecir un mejor desempeño en la organización. Por lo tanto, las hipótesis planteadas en el presente trabajo son las siguientes:

H1: Las tecnologías de información y comunicación tienen una influencia positiva y significativa en la gestión del conocimiento.

H2: La gestión del conocimiento influye positivamente al desempeño organizacional.

Método

Para el estudio de la relación entre las TICs, la gestión del conocimiento y el desempeño organizacional se consideró a ocho institutos tecnológicos descentralizados del estado de Veracruz (México), los cuales están certificados en la norma ISO 9000 y no aplican el modelo EFQM, ni ninguna otra opción para una autoevaluación integral del desempeño. Aunque en esta entidad federativa hay 21 instituciones tecnológicas, las participantes en el estudio son aquellas que ya cuentan con egresados colocados en el campo laboral, pues el instrumento de medición considera tanto su satisfacción como la de los empleadores en cuanto a la calidad de estos profesionistas. Dichas

características las cumplen 16 institutos tecnológicos, a los cuales se solicitó autorización para la aplicación del instrumento. Finalmente se obtuvo respuesta positiva de ocho de ellos.

Dado que las variables requieren la comprensión de datos de desempeño en un nivel organizacional se han tomado en cuenta únicamente a los mandos medios y directivos. En todos los casos, la aplicación del instrumento fue realizada de manera personal en las áreas de trabajo de los mandos medios y directivos (directores generales, directores de área, subdirectores, jefes de división y jefes de departamento); obteniéndose 147 cuestionarios debidamente requisitados.

La medición del desempeño organizacional se realizó con la escala reportada en Machorro y Mercado (2015), la cual toma como base el modelo EFQM de excelencia administrativa y cuenta con las siguientes dimensiones:

a) Satisfacción de Agentes, que mide el nivel de agrado que tienen los alumnos, padres de familia y personal con los resultados de la institución, así como la confianza en ella.

b) Desempeño Comparado, evaluación del logro de los objetivos de la institución, en función de los resultados obtenidos por otras similares. Este factor es particularmente importante para instituciones que forman parte de un sistema educativo, tales como los institutos tecnológicos en México.

c) Resultados de Gestión, los cuales presentan el grado de logro en los objetivos respecto a la planeación en la institución educativa: planificación, gestión del personal y gestión económica.

En el caso de las variables gestión del conocimiento y tecnologías de información, se crearon reactivos con opciones de respuesta en una escala de diferencial semántico, propuesta por Osgood, Suci, y Tannenbaum (1957), en la cual se presenta al sujeto un par de adjetivos bipolares con dirección o intensidad de su asociación en la escala. Para el caso del cuestionario construido, a partir de palabras clave identificadas, se realizan afirmaciones y se presentan dos adjetivos: adecuado o inadecuado. Cada adjetivo se acompaña de una descripción situacional que facilita la evaluación por parte del respondiente y se solicita determinar en una escala que va del uno al diez, su percepción sobre el instituto tecnológico en el que labora. Los aspectos incluidos en la medición de estas dos variables son:

a) Tecnologías de Información y Comunicación: calidad en la conectividad a internet, equipo de cómputo (hardware y software) e infraestructura para la educación a distancia.

b) Gestión del Conocimiento: investigación y producción científica, manuales y procedimientos y cultura orientada hacia la generación de conocimiento.

La tabla 1 presenta las dimensiones utilizadas, así como sus abreviaturas y número de reactivos.

Tabla 1: Dimensiones del instrumento aplicado

Dimensión	Abreviatura	Núm. Reactivos
Tecnologías de información	TICS	3
Gestión del conocimiento	KM	4
Satisfacción de Agentes	SAT_AGE	5
Desempeño Comparado	DES_COM	5
Resultados de gestión	RES_GES	5

Para el análisis de los datos obtenidos mediante la aplicación de cuestionarios se utilizó un modelo de ecuaciones estructurales basado en mínimos cuadrados parciales (Partial Least Squares, PLS), el cual presenta ciertas ventajas frente a las técnicas basadas en la covarianza (Covariance-based Structural Equation Modeling, CBSEM), en cuanto a las exigencias de la distribución de las variables de la muestra, el tipo de variables y el tamaño de la muestra (Gefen, Ringdon, & Straub, 2011). Por tanto, el análisis de los datos se realizó con la técnica de PLS utilizando el software WarpPLS en su versión 5.0.

Resultados Y Discusión

El análisis de datos muestra que el 57.1% de los encuestados son del sexo masculino y 42.9% del sexo femenino; 46.9% tiene estudios de licenciatura mientras que el 53.1% posgrado. Respecto al área en el que se desempeñan los encuestados el 51.7% laboran en el área académica, mientras el resto (48.3%) en áreas administrativas.

Bondad De Ajuste Del Modelo

Para la evaluación del ajuste del modelo mediante la técnica de PLS, los resultados incluyen tres índices: el coeficiente de trayectoria promedio (Average Path Coefficient, APC), la R cuadrada promedio (Average R-Squared, ARS) y el factor de inflación de la varianza promedio (Average Variance Inflation Factor, AVIF). Estas medidas se basan en el procedimiento Bootstrap que consiste en dividir la muestra original en N muestras para calcular la consistencia del parámetro que se desea evaluar con el objetivo de calcular su valor promedio y la significancia. El número de submuestras a utilizar recomendable es 500 de acuerdo con Chin (Wynne W. Chin, 1998; Wynne W Chin, 2010a)

Adicionalmente, Tenenhaus, Vinzi, Chatelin y Lauro (Tenenhaus, Vinzi, Chatelin, & Lauro, 2005) plantean el uso del índice de bondad de ajuste (Goodness-of-Ft Index, GoF) como una manera de validar globalmente un modelo de mínimos cuadrados parciales. Esta medida se calcula mediante la raíz cuadrada del producto de la varianza media extraída (Average Variance Extracted, AVE) y la R2 promedio. Wetzels, Odekerken-Schröder y Van Oppen (Wetzels, Odekerken-Schröder, & Van Oppen, 2009) proponen el valor de 0.360 como umbral para asegurar un modelo con adecuado ajuste. Como puede verse en la tabla 2, las medidas de ajuste son adecuadas para proceder a la evaluación de los modelos de medida y estructural.

Tabla 2: Medidas de ajuste

Medida de ajuste	Valor obtenido	Valor recomendado
Tecnologías de información	TICS	3
Gestión del conocimiento	KM	4
Satisfacción de Agentes	SAT_AGE	5
Desempeño Comparado	DES_COM	5
Resultados de gestión	RES_GES	5

Modelo De Medida

Para la evaluación del modelo de medida mediante PLS, se calculó la confiabilidad individual por reactivo, la consistencia interna (o confiabilidad de la escala), la validez convergente y la validez divergente (Wynne W. Chin, 1998).

La confiabilidad individual del ítem es valorada examinando las cargas de las medidas con sus respectivos constructos. Para aceptar un indicador como integrante de un constructo, debe tener una carga igual o superior a 0.707 (Barclay, Higgins, & Thomson, 1995), lo que implica que más de 50% de la varianza de la variable observada es compartida por el constructo. Para el caso del modelo presentado, las cargas por variable son mayores que el valor sugerido. Como se muestra en la tabla 3, todos los reactivos tienen carga factorial mayor que 0.707, por lo que puede afirmarse que el modelo es confiable en cuanto a los reactivos de forma individual.

Tabla 3: Cargas factoriales por reactivo

Para evaluar la consistencia interna de la escala, es decir, con qué rigurosidad las variables observadas miden a las variables latentes, se utilizan dos estadísticos: la confiabilidad compuesta y el alfa de Cronbach del constructo. La primera presupone a priori que cada indicador de un constructo contribuye de la misma forma, con la ventaja de no verse influenciada por el número de ítems en la escala (Hair, Sarstedt, Ringle, & Mena, 2012). La interpretación de ambos estadísticos es similar y según Nunnally (2009), quien sugiere 0.700 es un nivel de confiabilidad modesto en etapas tempranas de la investigación. Los valores observados en la tabla 3 son indicativos de que las dimensiones medidas tienen una alta confiabilidad.

Tabla 4: Confiablidad del instrumento

Constructo	No. de Reactivos	Confiabilidad compuesta	Alfa de Cronbach
TICS	3	0.875	0.785
KM	4	0.906	0.861
SAT_AGEN	5	0.899	0.860
DES_COM	5	0.938	0.917
RES_GES	5	0.958	0.945

La validez convergente evalúa si los diferentes ítems de un constructo miden realmente lo mismo, por lo que el ajuste será significativo y estarán altamente correlacionados. Para esto, se calculó la Varianza Media Extraída (AVE), pues proporciona la cantidad de varianza que un constructo obtiene de sus indicadores con relación a la cantidad de varianza debida al error de medida. Fornell y Larcker (1981), desarrolladores de esta técnica, sugieren que la AVE sea al menos de 50%. Para el caso del modelo evaluado, el valor más bajo es para el constructo satisfacción de agentes (64.20%), lo cual indica que existe validez convergente en todas los componentes (tabla 5).

Finalmente, para la validez divergente del modelo de PLS se comparó la raíz cuadrada de la AVE con la correlación entre los constructos. Para poder afirmar que el modelo tiene validez divergente es necesario que la AVE de cada constructo sea mayor que la varianza compartida con los demás (Kock, 2012). De acuerdo con los valores presentados en la tabla 5 todos los constructos del modelo cumplen con el criterio señalado de validez divergente.

Tabla 5: Validez convergente y divergente

Constructo	TICS	KM	SAT_AGEN	DES_COM
TICS	(0.837)	0.623	0.473	0.457
KM	0.623	(0.841)	0.577	0.577
SAT_AGEN	0.473	0.577	(0.801)	0.759
DES_COM	0.457	0.577	0.759	(0.867)
RES_GES	0.517	0.636	0.788	0.776

Modelo Estructural

El poder predictivo del modelo estructural en PLS es evaluado mediante la cantidad de varianza explicada (R^2) de las variables endógenas (Wynne W Chin, 2010b). Los coeficientes de trayectoria (β), indican en qué medida las variables predictoras contribuyen a la varianza explicada de las variables endógenas. En el caso de la R^2, se obtuvieron valores por encima de 0.400 en todos los casos (figura 1).

Fig. 1: Modelo estructrural

Adicionalmente, los coeficientes β en todos los casos resultan positivos y con valores elevados, siendo el menos fuerte el que evalúa la influencia de la gestión del conocimiento en el desempeño comparado de las IES. El análisis Bootstrap ejecutado con 500 submuestras de acuerdo con la recomendación de Chin (1998), evidencia que todos los coeficientes β son significativos a un nivel de 0.01.

De acuerdo con Falk y Miller (1992) un índice razonable para un modelo estructural es el efecto total de las variables exógenas sobre las endógenas evaluadas a través de la combinación de cada coeficiente de trayectoria (β) por la correlación entre los constructos (r). De este modo, una variable exógena debe influir en al menos 1.5% de la varianza del constructo endógeno para que dicha relación puede considerarse significativa.

Tabla 6: Influencia total

Relación entre constructos	β	r	Influencia
TICS - KM	0.63	0.623	0.392
KM - SAT_AGE	0.63	0.577	0.363
KM – DES_COM	0.60	0.577	0.346
KM – RES_GES	0.66	0.636	0.419

Conclusiones

El análisis de datos muestra que el 57.1% de los encuestados son del sexo masculino y 42.9% del De acuerdo con el análisis presentado, se valida la hipótesis de que las tecnologías de información tienen una relación positiva y significativa con la gestión del conocimiento. Además, la gestión del conocimiento tiene una influencia positiva en los tres constructos medidos del desempeño organizacional en instituciones de educación superior. Lo anterior plantea la necesidad de realizar una mejor gestión de las tecnologías de información en estas instituciones, las cuales puedan fomentar una mejor generación, almacenamiento, difusión e intercambio de conocimiento. Estos procesos de gestión del conocimiento tienen un impacto positivo en el desempeño ya que mejora los procesos tanto la satisfacción de estudiantes y empleados, así como el desempeño comparativo entre las instituciones. Además, ayuda a incrementar sus resultados de gestión, tales como el logro de objetivos planteados en los planes de desarrollo y factibilidad presupuestaria y financiera.

Como posible agenda de investigación futura se puede plantear: la aplicación del instrumento a una mayor muestra de IES, tanto en número como en tipo, con lo cual pudiera garantizarse la generalización de los resultados

obtenidos; además de complementar la evaluación del desempeño organizacional con información secundaria (datos estadísticos de las IES).

Resumen

El Cuadro de Mando Integral (Balanced Scorecard) se considera una de las herramientas más eficientes en el control de gestión, además de tener la ventaja de poder adaptarse a distintos tipos de organizaciones. En esta investigación se presenta una propuesta de Cuadro de Mando Integral para una institución de educación superior tecnológica en México, para lo cual se creó un mapa estratégico de alineado con los documentos de planeación estratégica existente, así como también fueron diseñadas cédulas de indicadores útiles para la medición del desempeño. Se concluye que la herramienta es fácilmente adaptable a las características de una institución de educación superior pública y que puede resultar un instrumento adecuado de control organizacional.

Keywords: Cuadro de mando integral, mapa estratégico, educación superior, administración educativa, indicadores.

Introducción

Desde hace tres décadas los sistemas de educación a nivel internacional han estado en constantes cambios, la globalización provoca que las organizaciones tengan que competir en el mercado implementando herramientas de gestión administrativa más eficientes y eficaces orientadas hacia el logro de los objetivos para poder alcanzar el éxito. La administración estratégica en el sector educativo público en México no se queda atrás, ya que requiere de la implementación de estrategias para alcanzar los objetivos propuestos, enfocados en la misión de las instituciones, impulsados por un sistema de medición tangible (basado en indicadores) que les permitan evaluar su rendimiento. En los últimos años algunas instituciones públicas han comenzado a implementar herramientas de control de gestión provenientes del ámbito empresarial tales como el cuadro de mando integral (Balanced Scorecard).

El cuadro de mando integral es un instrumento de gestión administrativa que proporciona los elementos necesarios para poder obtener una dirección estratégica en una organización, así como controlar el cumplimento de los objetivos, fue creado para diferentes tipos de organizaciones empresariales por los autores estadounidenses Robert Kaplan y David Norton (1992). La gran flexibilidad de esta herramienta permite construir estrategias de tal manera que las organizaciones tengan acciones y resultados mediante la alineación de todos sus objetivos. Además, ha podido implantarse en organizaciones públicas y sin fines de lucro, específicamente en instituciones de educación superior.

La institución educativa objeto del presente estudio brinda educación superior tecnológica en el estado de Veracruz, México. Cuenta con un instrumento de planificación estratégica, llamado Programa Institucional de Innovación y Desarrollo (PIID), en el que se definen los objetivos, las estrategias, líneas de acción y los indicadores que la organización se ha propuesto; sin embargo, no existe un instrumento formal de control para dar seguimiento al cumplimiento de los objetivos planteados.

La problemática originada por esta circunstancia es la incertidumbre de alcanzar los objetivos y metas establecidas por el PIID en tiempo y forma, y las consecuencias en el desempeño organizacional que esto tendría. Es por eso que el objetivo de este artículo es presentar una propuesta de gestión administrativa basada en el Cuadro de Mando Integral para esta institución. Se considera que esta herramienta es la adecuada para el cumplimiento de los objetivos estratégicos que permitan llevar con éxito la misión de la institución y de esta manera darle un valor agregado a la misma.

La estructura documento se conforma de la siguiente forma: posterior a la presente sección introductoria, el marco teórico aborda la temática de la adaptación del Cuadro de Mando Integral a instituciones públicas, específicamente en educación superior; la metodología expone las estrategias ejecutadas para el logro de los objetivos. En la sección de resultados se presenta el mapa estratégico diseñado y la propuesta de cédulas de indicadores; la última sección aborda las principales conclusiones y recomendaciones.

El Cuadro De Mando Integral

El Cuadro de Mando Integral (CMI), es utilizado como instrumento en control de gestión administrativa para las empresas, organizaciones e instituciones de todo el mundo, lucrativas y no lucrativas. El CMI puede interpretar los objetivos estratégicos y la misión de la organización en un sistema de medición de manera que los objetivos estén ligados a indicadores y relación entre ellos. Fue propuesto por los norteamericanos Robert Kaplan y David Norton (1992), quienes sugieren cuatro perspectivas o ejes en las cuales desarrollar los objetivos e indicadores:

a. La perspectiva financiera. Examina los resultados económicos buscando el desempeño financiero para maximizar los beneficios, esta perspectiva para las instituciones de sector público educativo se caracteriza por tratar de tener los recursos necesarios para prestar un servicio de calidad.

b. La perspectiva del cliente. Se centra en la imagen de la institución educativa, calidad del servicio, relaciones, precio o aquellos factores que son importantes para mantener la satisfacción de éste. En el sector educativo existen clientes internos (alumnos) y clientes externos (sector industrial).

c. La perspectiva de procesos internos. Se trata del control de los procesos, en el caso de las instituciones educativas son áreas claves o departamentos necesarios para poder alcanzar el objetivo organizacional de la institución de esta manera garantizar el éxito.

d. La perspectiva de aprendizaje y crecimiento. Se basa en la habilidad y competencia de los directivos, docentes y personal en general, así como la capacidad que tiene los empleados de alcanzar los objetivos de los de los procesos de la institución.

Mapas Estratégicos

Los mapas estratégicos tienen sus inicios en la milicia, cuando planean estratégicamente cómo atacar al enemigo, posteriormente esta actividad fue llevada a las organizaciones empresariales con modificaciones para su aplicación. A finales de los años cuarenta y principios de los cincuenta, aparecieron las primeras organizaciones en la administración con estas estrategias.

Dentro de la literatura del Cuadro de Mando Integral, los mapas estratégicos fueron propuestos por Kaplan y Norton (2000), como una herramienta para la alineación de los objetivos estratégicos a la misión y visión de las organizaciones. De esta forma, considerando que la administración estratégica está orientada a los objetivos de las organizaciones a largo plazo, un mapa estratégico es una representación gráfica de los objetivos estratégicos ordenados en las cuatro perspectivas, las relaciones causa-efecto entre objetivos, los indicadores, las metas, los responsables y los proyectos que van a medir el éxito que tiene la organización en su proceso de implantación de la

estrategia. Además, permite el análisis de su misión, el propósito los valores y el cumplimiento de los objetivos estratégicos para la obtención de resultados satisfactorios para sus principales usuarios o clientes.

Implementación Del Cuadro De Mando Integral En Universidades Públicas

El cuadro de mando integral tiene una amplia aceptación su aplicación en instituciones educativas. Por ejemplo, en Reino Unido, la Universidad de Edimburgo ha sido una de las primeras en medir su desempeño institucional con esta herramienta desde 2002 (Nelson, 2006). En esta universidad se adoptaron 32 indicadores distribuidos en cuatro perspectivas: desarrollo organizacional, que considera indicadores financiera, negocios internos y de stakeholders.

En Estados Unidos, Brown (2012), propone cuatro perspectivas para la escuela de enfermería del College de St. Scholastica en Duluth, Minnesota: financiera, estudiantes y comunidad, procesos internos y aprendizaje y crecimiento, cada una de ellas con cinco indicadores para medir el desempeño de la organización. Por su parte Xing (2009), propone el uso del CMI en la medición del desempeño organizacional de siete universidades en China. Para tal efecto en la perspectiva financiera considera como indicador la proporción entre el gasto y el ingreso; en la perspectiva clientes incluye la satisfacción social, de los empleadores, de padres y estudiantes; los procesos internos evaluados fueron el desempeño de la docencia y la investigación científica; finalmente, en la perspectiva de aprendizaje y crecimiento se evaluó la satisfacción de la planta docente.

Otro ejemplo del diseño y adaptación de las perspectivas del CMI en universidades se identifica en Inglaterra donde Philbin (2011) considera en la perspectiva financiera los fondos por programa; propone una nueva perspectiva de las partes interesadas (stakeholders); la tercer perspectiva hace referencia a las capacidades de la institución (personal adscrito y equipo); y finalmente la perspectiva de aprendizaje y crecimiento considera los productos de investigación (artículos científicos y conferencias).

De igual forma en Europa, Hladchenko (2015) realizó una comparación del diseño de los CMI en tres universidades de Alemania y una en Austria, tal análisis concluyó que la herramienta es capaz de brindar una visión sistemática de la estrategia de la institución, así como traducir dicha estrategia indicadores pertinentes para la medición del desempeño organizacional. En África, Mohamad (2016) midió el desempeño de ocho facultades de la Universidad Assiut (Egipto). Para tal efecto propuso cinco perspectivas distintas: perspectiva financiera, perspectiva de los clientes y beneficiarios, perspectiva de procesos internos, perspectiva de aprendizaje y crecimiento, y perspectiva de desempeño social.

Método

Este trabajo de investigación plantea la necesidad de diseñar una propuesta de modelo que represente de manera confiable aquellas variables reales relacionadas con la gestión estratégica de una institución educativa de nivel superior. Para ello se realizó por principio un diagnóstico organizacional con el objetivo de poder diseñar el mapa estratégico y los indicadores correspondientes.

Diagnóstico de la Institución Educativa

Como primera instancia, se recopilaron documentos relacionados con nivelación de jerarquías, acreditaciones y procesos existentes. Posteriormente se analizaron exhaustivamente la estructura y gestión de la institución educativa y su plan estratégico, donde se pudieron encontrar indicadores existentes con los objetivos del plan institucional. Así mismo se empleó un conjunto de entrevistas y encuestas para realizar un análisis FODA de la institución que sirviera como base para el establecimiento de perspectivas y prioridades estratégicas.

Establecimiento De Perspectivas

Para establecer las perspectivas correctas se realizó un análisis del estado del arte donde se identificaron varios artículos relacionados con características similares a la problemática de la institución, tal es el caso de la Universidad Nacional de Loja en Ecuador (Muñoz Vizhnay, 2011), es por ello que se decidió adaptar los cuestionamientos realizados en tal investigación para el establecimiento de las perspectivas del CMI:

- ¿Cómo nos ven los estudiantes?

- ¿Podemos continuar mejorando los procesos y creando valor?
- ¿En qué debemos ser los mejores?
- ¿Cómo podemos optimizar los recursos financieros?

Una de las principales características de un Cuadro de Mando Integral es que es una herramienta que es muy sencilla y clara. De tal manera que las perspectivas deben tener una secuencia lógica en el mapa estratégico, por lo que a partir del diagnóstico organizacional se estableció un orden de prioridad de las perspectivas establecidas.

Creación Del Mapa Estratégico

Un principal objetivo del Cuadro de Mando Integral el alineamiento de las actividades con el plan estratégico de la institución. Para poder realizarlo es fundamental traducir la visión en estrategias, que de manera lógica los objetivos. Esta relación causa efecto ilustra los supuestos en las diferentes perspectivas de la organización: estudiantes, procesos internos, aprendizaje y crecimiento y financiero.

Para el diseño del mapa estratégico se consideró también un objetivo central en cada perspectiva el cual fue seleccionado tomando en cuenta las prioridades de la institución.

Establecimiento De Indicadores Para Cada Objetivo

Para poder seleccionar los indicadores se tuvieron en cuenta varios criterios. Por principio, la cantidad de objetivos a establecer por cada perspectiva, los cuales se estableció no fueran mayor a seis ya que si se tienen demasiados indicadores pueden diluir el mensaje que comunica el CMI y, como consecuencia los resultados se pueden dispersar intentado perseguir demasiados objetivos al mismo tiempo.

Para cada indicador fue establecida la unidad de medida, así como la frecuencia de medición tomando en consideración la naturaleza de cada uno de ellos. Además, en función del análisis realizado, se determinó un valor meta para el año 2018, así como un rango de valores que indiquen precaución y peligro. De esta forma se pretende que la herramienta sea pertinente para monitorear de manera práctica el desempeño de la organización.

Resultados Y Discusión

Diagnóstico Organizacional

El primer paso para poder entender el propósito de la organización fue analizar su misión y visión, las cuales son presentadas en la Figura 1. Con base en ellas se pudieron realizar entrevistas a directivos para poder identificar los elementos del análisis FODA.

Visión
Ser una institución de alto desempeño que se esfuerce por ser parte de desarrollo sostenido, sustentable y equitativo encaminado a una excelencia profesional de sus egresados, con base docentes comprometida acorde a las épocas actuales y futura.
Misión
Formar Profesionales comprometidos con la sociedad y el medio ambiente de forma pertinente y equitativa a través de una educación integral que conlleve altos valores humanos en beneficio del desarrollo sustentable de la región, estado y el país

Fig. 1: Misión y visión de la institución

De acuerdo con las entrevistas realizadas a directivos de la institución se lograron establecer las fortalezas, oportunidades, debilidades y amenazas de la institución, con lo cual se estructuró la matriz FODA que se presenta en la Figura 2.

Fig. 2: Análisis FODA de la institución

Perspectivas del CMI

De acuerdo con el análisis organizacional realizado se establecieron las perspectivas pertinentes para el CMI de acuerdo con la metodología de Muñoz Vizhnay (2011). Las cuatro perspectivas finales, así como su prioridad se visualizan en la Figura 3.

Perspectiva del Cliente/Alumno. La principal función de la institución educativa es la satisfacción de las necesidades de los alumnos que son sus clientes. Esto destaca el compromiso de calificar profesionales altamente competentes, para que ellos sean bien aceptados en el mercado de trabajo como lo marca la misión de la institución.

Perspectiva del Aprendizaje y Crecimiento. Esta perspectiva se empodera de las instituciones educativas ya que es preponderante para las instituciones de enseñanza superior público, pues será fundamental la apuesta en la capacidad de los empleados, en el conocimiento, y así como los sistemas de información, para mantenerse en el mercado, continuando con la prestación de servicios con la calidad cada vez más exigido por la población, las instituciones de educativas tienen que la obligación constante de capacitar de su cuerpo docente, las formas de competencia que actualmente se trataba son muy demandantes porque ellos son los principales agentes en la formación de los alumnos, como habíamos referido anteriormente constituyen la preocupación principal de estas instituciones. También, el autor Niven (2008), refiere que en esta perspectiva está las capacidades de los empleados, la satisfacción de los mismos, la disponibilidad de la información y los sistemas de información.

Perspectiva de Los Procesos Internos. Define los outputs, de los procesos que permitan cumplir, los objetivos definidos para la perspectiva de los Clientes/Alumnos, los cuales son:

a. Calidad
b. Planeación
c. Vinculación
d. Servicios Administrativos
e. Finanzas

Estas actividades internas de la institución están suscritas en esta perspectiva y ellas cuando bien hechas llevan beneficios al exterior de la institución y cumplen con su cometido y crea valor a todos los implicados en este proceso.

Perspectiva Financiera. Al tratarse de una institución pública, el instituto depende de la financiación del estado y de la federación, por lo que debe de ser consciente del aspecto de la reducción de las subvenciones gubernamentales que existen y que se está presente en casi todos los países. Esta perspectiva es relevante ya que representa la única forma de llevar a cabo sus actividades y principalmente poder cumplir la misión institucional.

Fig. 3: Perspectivas del CMI

Mapa Estratégico

La Figura 4 muestra el mapa estratégico diseñado de acuerdo con el análisis del diagnóstico organizacional realizado. Puede apreciarse que se plantean cuatro objetivos estratégicos centrales, los cuales describen la ruta bajo la cual se propone que la institución logre cumplir con su misión. Cada uno de esos objetivos centrales están apoyados por objetivos estratégicos que se encuentran alineados a su ejecución. De esta manera se garantiza que todas las actividades que se realicen dentro de la organización apoyen a la misión institucional.

Fig. 4: Mapa estratégico

Objetivos E Indicadores

Se establecieron un total de 16 objetivos en el mapa estratégico. Se propone que cada uno de estos objetivos sea medido con al menos un indicador.

Tabla 1: Indicadores de la perspectiva Cliente/Alumnos

Tabla 2:

Objetivo	Indicadores
Satisfacción del egresado	Nivel de satisfacción de los usuarios
	Número de quejas por año en los servicios prestados.
Garantizar la incorporación del egresado al sector industrial	% de contratación de empresas en la región.
Proporcionar al alumno estrategias para la culminación de los estudios	% de alumnos atendidos por el personal de carrera
	% de alumnos inscritos en planes tutoriales
Mayor oportunidad a los jóvenes para lograr el éxito en la culminación de proyectos	Cursos de regularización impartidos por docente
	% de alumnos que participan en proyectos de investigación

Indicadores de la perspectiva Procesos Internos

Objetivos	Indicadores
Mejorar continuamente los procesos	Juntas de planeación al año.
Implementar el Sistema de Garantía Interna de Calidad	No conformidades en el sistema de calidad existente
Establecer estrategias para concientizar el personal y a los estudiantes del uso responsable de los recursos ambientales	% de uso de energía alternas
Implementar evaluaciones de desempeño a todos los niveles	% de Docentes evaluados al semestre
	% de Administrativos evaluados al semestre
Promoción y gestión de patrocinio a proyectos de investigación y de desarrollo tecnológico	Proyectos de investigación apoyados
	Proyectos de desarrollo tecnológico apoyados

Tabla 3: Indicadores de la perspectiva Aprendizaje y Crecimiento

Objetivos	Indicadores
Potenciar y capacitar a los administrativos y docentes	% de docentes en cursos de actualización
	% de participantes en actualización administrativa
	Número de eventos de formación y capacitación realizados
Mejorar la Cultura organizacional	% de personal capacitado en motivación laboral
Mejorar la comunicación interna de los procesos	% de personal capacitado en comunicación interna
Incrementar docentes de Tiempo Completo con postgrado	% de docentes de Tiempo Completo con posgrado

Tabla 4: Indicadores de la perspectiva Financiera

Objetivos	Indicadores
Maximizar los recursos disponibles	% de disminución del costo anual promedio por estudiante
Optimizar el recurso financiero destinado a gastos administrativo	% de disminución de gastos operativos
Gestionar recursos económicos que genere fondos internos o externos o por medio de donaciones	No. de donaciones anuales gestionadas

Cuadro de Mando Integral

Para poner diseñar el Cuadro de Mando Integral es necesario confeccionar cédulas que ayuden a estructurar el tablero de control. Se establecieron además intervalos de medición para los indicadores, para tal efecto se diseñaron semáforos de tal manera que ayuden a visualizar rápidamente en donde aplicar los correctivos o ajustes necesaria para lograr su efectividad en el tiempo propuesto y la consecución de todos los objetivos inicialmente. A

continuación, a manera de ejemplo se muestran las Fichas Técnicas del Cumplimento de los Indicadores para los objetivos centrales establecidos en el mapa estratégico.

Objetivo Estratégico	**Satisfacción del Egresado**						
Indicador	**Nivel de satisfacción de los usuarios**						
Responsable de cumplimiento	**Divisiones de Carrera**						
CLASE DE INDICADOR

Conclusiones

El objetivo general de la investigación fue diseñar un modelo de Cuadro de Mando Integral para una institución pública de educación superior el cual fuera adaptado a las características particulares de dicha organización. A modo de conclusión general, se puede establecer que la herramienta utilizada (CMI) permite tener una visión y un control completo de la organización de forma alineada, y que posee una facilidad y flexibilidad en su uso, lo que permite incorporar y cambiar las perspectivas tradicionales. Debido a ello, para desarrollar el CMI, se realizó un

diagnóstico FODA con el fin de encontrar un enfoque que cumpliese con los requerimientos de la misión institucional.

De acuerdo con el diagnóstico realizado se adaptaron las cuatro perspectivas clásicas del CMI, reordenándolas para que se tuviera congruencia con misión y visión, además de transformar la perspectiva clientes a una perspectiva basada en la satifacción de los alumnos y egresados. El planteamiento de los objetivos estratégicos se formuló según las cuatro perspectivas propuestas (alumnos, procesos internos, aprendizaje y crecimiento y finanzas). Además se establecieron indicadores adecuados para cada uno de los objetivos planteados.

Podemos concluir que la presente investigación aporta evidencia de la factibilidad de la implementación de un Cuadro de Mando Integral en la institución, ya que la herramienta cuenta con la flexibilidad necesaria para adaptar las perspectivas en objetivos estratégicos e indicadores pertinentes para medir adecuadamente el desempeño organizacional de una institución pública de educación superior.

Finalmente se recomienda que la dirección general del instituto haga el seguimiento adecuado para que la herramienta propuesta pueda implementarse de tal forma que sirva como base para la mejor toma de decisiones y gestión administrativa a partir de la planeación estratégica con la que se cuenta.

Abstract

In Romanian society there is only a pale image of the existence of community leaders, who should focus on people problems and solve them, without waiting for political involvement. Community membership is based on five attributes: boundaries, emotional security, group membership and group identification, and a common system of symbols. Community engagement can be defined in a context of partnership and reciprocity as a mutual exchange of knowledge and resources. Low community engagement leads to a lack of trust in the community. In this way, the level of unemployment, poverty and in direct connection with a poor quality education and with the increase of the crime rate are accentuated. Creating local networks of community members fosters a climate in which more people are willing to work to achieve a goal. This article is about who and what such a leader should look like, about the influence and positive changes it can bring to the community. While leaders 'theories place great emphasis on emotional intelligence, current research speaks to culturally intelligent leaders who know and understand how culture acts on the individual, how specific values and beliefs direct individuals' behavior. At the same time, because in times of crisis we need leaders, the article shows how such a leader can coagulate energies, to overcome critical moments. The article is a theoretical study conducted as a documentary document for building a training program for community leaders.

Keywords: Community, Leader, Ethic, Influence, Culture.

Introduction

Through this paper we aimed to demonstrate the importance of training community leaders to increase the well-being of the community and solve its main problems.

Therefore, the objectives of the paper are:

- presentation of the main features of an effective community leader
- demonstrating the leader's need to possess cultural intelligence
- designing some characteristics of the community leader during a pandemic.

We need these answers to build a training program for community leaders, in the category of those over 50, even those who have retired, and this in two ways:

- to use the experience and knowledge of a category that can bring value to the labor market;
- to respond to the utility needs of individuals, who with retirement from active life may develop anxiety and depression, exacerbations of diseases that until then manifested only latently.

The initiative is promoted and financed by a European project Erasmus + "Model Of The Mentoring Between The Local Community Leaders", no: 2019-1-PL01-KA204-065651.

Based on the bibliographic research undertaken on the profile of community leaders, a training program for these leaders will then be built, which will have branches throughout the country.

Community is a fundamental building part of society which are realised through dynamic, diverse and interdependent interactions between and inside of groups, organizations and institutions and individuals, both internal and external to the community.

A community is a small or large social unit that has in common norms, religion, values or identity and often share a certain way of thinking and judging, specific to a certain area. The term "community" comes from the Latin "communitas" meaning community, "public spirit" (Latin-communis-shared). Communities can share intention, faith, resources, preferences, needs and risks, all of which influence the identity of members and their degree of cohesion.

Creating communities as places where people want to work and live has been a challenge for society, taking a step beyond their traditional role of providing services and ensuring the necessities of daily life. Communities can be seen as complex systems which are not only defined by boundaries such as geographical location but are open to different participants despite their location.

A definition of community was made by McMillan and Chavis (1986) throuth four dimensions: membership, influence, reinforcement and shared emotional connection. Wilkinson's theory (1991) shows that community development is a process in which local actors deliberately try to create or strengthen social networks to work together to solve community problems and express their common interest in the locality. In other words, community is defined by social interaction. In the same time, people can be parts of many communities and in this position they are able to "transfer, translate, and transform experiences from one community to another" as Dahlander and Frederiksen mentioned (2012).

Community membership is based on five attributes: boundaries, emotional security, group membership and group identification, and a common system of symbols. At the same time, influence shows, on the one hand, that a member who must be attracted to a group must have an influence on what the group does, and the cohesion of the group depends on how the group itself is able to influence the members. Community engagement can be defined in a context of partnership and reciprocity as a mutually beneficial exchange of knowledge and resources. Low community engagement leads to a lack of trust in the community. In this way there is an accentuation of the level of unemployment, poverty and in direct connection to a poor-quality education and to the increase of the crime rate. Creating local networks of community members fosters a climate where more people are willing to work to achieve a goal. Leaders who get involved in the community creates involved communities. People who accept the needs, values, and opinions of others are often the most influential members of the group, while those who force things by always wanting to influence, trying to dominate others, and ignoring the desires of others are often the least strong.

When it is decided to be organized a community, it is necessary to identify leaders and potential community leaders, because leadership is a vital element of that organizing action. In his work, Chaskin (2001) suggests that there are at least four common factors contributing to community strengthening, referring to the existence of resources (including individuals 'abilities, access to capital and resources), building a network of relationships, leadership and support for community members' participation in the action. collective and problem solving.

Leadership theory has evolved over the past decades, leaving from the idea of the leader as the main and decisive factor, to the influence of the others and more recently to the imagining of a multidimensional social process composed of complex relationships, which are based on social integration and individual skills.

In any organization, the effective leadership is based on promoting certain ideas, but to convince others, these ideas must be challenging, mobilizing. In other words, the leader is the inspiration and the engine of the action. The key elements of classical leadership are the follower, the influence, community objectives and peoples.

A follower is a person who is influenced by a leader. At the same time, a follower is not a "yes man" because he/she, in turn, influence the leader. At the same time, a follower is not a "yes man" because he/she, in turn, influence the leader. A good follower is a person who says what he thinks, gives a correct feedback, and influences the leader. An effective follower shares what he/she thinks with the leader.

The essence of leadership is influence. It involves the process by which the leader communicates the ideas and these ideas are accepted by the community, which supports the leader in their implementation.
The influence is highlighted by the leader-follower relationship. Leaders and followers often change roles in the influence process.

The community objectives can be achieved through the joint work of the leader and the other members / followers. The leader is the one who shows the direction, but together with the followers he sets the objectives.

A community cannot go forward only by preserving status quo. It`s about the vision of the leader to introduce the change and about his ability to present this change which is necessary and possible.

The greatest resource of any community is people. Being a good leader means loving people and knowing how to work with them. An effective leadership means appreciating people's capabilities and putting them at the service of achieving community goal.

Community leadership has other nuances than the classical notion of being "about" leaders "who solicit, convince and influence" followers ". According to Onyx and Leonard (2011), community leadership does not have hierarchies and is carried out through voluntary actions, which lead to the creation of social capital being a factor in promoting change.

Community leaders are, most often informal leaders, unelected but self-entitled.

The well-being of the community is built from the settings of development directions starting from the shared values of the members of the community, by building relationships based on ethics.

The community must be able to develop relations with the external environment, but at the same time it is necessary to ensure communication between its members, so that, to build relationships, connections inside the community. If there is trust in the relationships between the members of the community, they can reset the goals of the community, and in this way to set new roles and responsibilities for its members. Community development is one of the most useful way to improve the lives and livelihoods of individuals within a community as Syme and Ritterman mentioned (2009).

The Leader

Community leaders are those who cause change, those who make things progress. This implies that they are good connoisseurs of the community in which they live. Leaders have direct and indirect effects on community evolution and development.

These were widely share clearly understood and supported by all the community members. They must act to test all new developments, activities, or initiatives.

Many successful leaders start without self-confidence or skills. Leadership skills can be trained and built step by step. No matter what the skills are at the moment, anyone can become a leader if they want and accept it.

Effective leaders had a very strong and clear vision and set of values for their community which powerfully influenced their and others actions and established a clear sense of direction and purpose to it. To be a leader means to build a vision. As a community leader, you can have different visions. Vision is the starting point in any construction. It represents the way the leader understands to build for the community. Because nothing happens until it happens in someone's mind first.

To achieve the vision, the leader must follow a few steps:

1. First, develop his own vision
2. Communicate it to others
3. To share this vision with the group, and possibly improve it within the group.

To build the vision it must start from the things around you and think about how to make them better. It can find countless solutions and elements. The vision must be communicated continuously, every time you talk to people in the community, remind people where to go. The more the leader insist on the vision, the more people will be willing to commit.

The vision must be launched just before forming a group. As the leader increase the circle of those who know about it, it is created a community of people who know about his idea and who can support him. Community members must adhere to the common vision and develop a sense of ownership over it, to engage in the group. In this way they will engage in long-term community activities.

It is not necessary for people to agree with all the details of the leader's vision to follow him. But to work together, people need to share an overview and some basic goals. All of these give a detailed picture of what is happening in the community.

Based on these investigations, leaders could establish the direction, purpose, and goals of community development. In this phase, it is important for the leader to know how to communicate all these elements effectively and to start building his network. He must be able to motivate and mobilize all human resources of the community, establishing roles and building appropriate responsibilities for members. An important step here is to plan and design actions, for this purpose, the leader being able to express himself clearly and structured.

Once the planning of activities has been completed, the leader power of convincing will be decisive in creating relationships with others. The ability of a leader to establish a relationship is very important and he/she develops these relationships, using his/her reputation and resources. In this way, the leaders want to encourage community members to stay involved and continue to participate. To convince and be followed, community leaders must be characterized by a set of basic ideals and principles of community action. For this, leader must imagine innovations and solutions that have never existed before.

Leadership theories shows the leader must possess emotional intelligence. But some and more recent theories shows the leader must also possess cultural intelligence. Especially when working with and in favor of communities, leaders need to possess cultural intelligence, which means more than knowing cultures. There are multiple definitions of this cultural Intelligence, but I prefer to use this one which Butcher (2008) specified as a “key competencies, which allow us to effectively interact with people from diverse cultural backgrounds in all kinds of settings”.

Cultural intelligence requires that leaders possess more than cultural knowledge. They need to be aware of how culture works, how specific values and beliefs drive people's behavior.

Cultural intelligence has a certain dynamic, which assumes that, over time, one will continue to learn, and their cultural intelligence will expand. This is not a step-by-step process that culminates in an "end result." Due to cultural intelligence, the leader learns more about him / her, as well as about the ability to interact with different cultures. There is always enough place for improving and developing cultural intelligence.

Cultural intelligence does not speak of specific cultures. Cultural intelligence is a broad approach that considers the development of a set of skills, attitudes and knowledge that make it possible to adapt and interact with multiple cultures.

Finally, cultural intelligence is the ability to adapt successfully to unfamiliar cultural settings.

As a community leader there is a contact with a variety of characters, situations, problems. To address them, the leader must show flexibility in thinking, understand why community members behave in this way, discern where values, attitudes and behaviors relate to the culture of the group.

In this way, Marilee Adams (2004) proposes a new approach to change the judgment, starting from the way you ask your questions. She was speaking about the two types of questions: some involving judgments and some which involves learning. Usually, we ask ourselves both types of questions and choose which one to ask in any given situation. But asking questions in a different way leads to a different perspective (table 1). As a conclusion, culturally intelligent leaders create strategies that help them focus on goals and their interactions. They rely on feedback from the situation and use it to create a new image, thus creating new learning models for themselves.

Table 1: **Judger vs. learner questions**

Judger	Learner
What is wrong?	What works?
Who is to blame?	What am I responsible for?
How can I prove I am right?	Why can I prove I’m right?
How can I protect my territory?	What is the big picture?

How can I be in control?	What are my choices?
How could I lose?	What is useful about this?
How could I get hurt?	What can I learn?
Why is that person so clueless and frustrating?	What is the other person feeling, needing, and wanting?
Why bother?	What is possible?

As a conclusion, culturally intelligent leaders create strategies that help them focus on goals and their interactions. They rely on feedback from the situation and use it to create a new image, thus creating new learning models for themselves.

Community Culture

Culture is a complex, multidimensional concept. The community culture is highlighted by the way things are done in that community; it is reflected in the way people interact, make decisions, and influence others. Culture is reflected in the way people in a community live. This includes their language, religion, stereotypes, traditions, and history. It includes the fashion to which people relate and is socially accepted. Every community in the world has her own culture.

Culture is expressed through the social structure that brings people together. Social communities are created to address their formal needs (such as religious, school, and governmental), but also the informal ones (group and community activities that have various purposes: socialization, punctual problem solving, common objectives, etc.). Culture is highlighted by common and distinct values, beliefs, attitudes, assumptions that people have about themselves and others.

In the community can function formal roles (obtained through official elections) and informal ones through which people occupy a social structure: who are the leaders and followers, who has authority and who does not, who participates actively and who is less involved. Social norms are common behaviors that manifest and strengthen local culture. Thus, the norms are visible when the members of the community shake hands or not, when they meet, keep or not the cleanliness of the place where they live, respect or not, the formal and informal laws of the community, etc.

Community culture must be known and mastered by community leaders because the conscious and unconscious beliefs of community leaders materialize in decisions and behaviors, and repeated behaviors become leadership practices. These leadership practices are finally becoming patterns of leadership culture, so leaders must be aware of the responsibility in creating or changing culture.

Community culture allows people to practice how to understand other people's culture, accept involvement in relationships with others, and build strong and diverse communities. Community culture is a vivid expression of the culture of everyday life, which can be taught and practiced informally from an individual to another.

Community culture is characterized by fundamental assumptions about accepted behaviors, trends, and their daily manifestations. A fit between culture and leadership strategy is desirable because it creates added value for the community and society.

Culture is important for the vitality of the community. To create a common culture in the community the leader can start from promoting common values and accepting different ones. A balance between tolerance and sanction is desirable here. Violation of community values is sanctioned by social control. That is why the leader must make sure that community behavior is encouraged, and non-community behavior is more difficult. He must make culture visible as part of everyday life. Therefore, it is required to courageously address the fears and to the same extent to eliminate taboos.

It is the task of the leader to contribute decisively to the development of the community culture. In this regard, several questions can clarify the meaning of community culture. Thus, to clarify what are the objectives proposed for the community, the leader must start from the question of why you want to create a community, what is the purpose you propose? Here are some alternatives:

- to connect community members to share knowledge.

- to bring a series of improvements to community life (related to cleanliness, improved living conditions, leisure initiatives, etc.)

With the answers he finds, the leader understands how to streamline the strategy and promote the ideas in a way that is as meaningful as possible for the others.
