Knowing the culture of the community by the leader facilitates collaboration with others and helps to form social networks. If people are already collaborating, the leader must be a good observer of how things happen in the community. Care is required, because although the leader may be enthusiastic and wants to involve everyone, it may be difficult at first. That is why it is sometimes better to start with fewer but more convinced people than a large crowd, but some of whom are supercritical and negative. As the first members begin to create a strong community culture, more people can be integrated into community issues and this will happen with fewer disruptions.

Influencing People

Influence is the leader's ability to persuade someone to think or act the way he desire. Influencing others is an essential part of leadership.

As McBrown (2018) presented, the working definition of influencing is "everything we say or don't do or don't , is or isn't, that modifies, affects, or changes someone else's behavior, thoughts, or actions, consciously or unconsciously, for better or worse." Or more simple, influencing is the act of affecting the behaviours and actions of others. Without the ability to influence people's thinking, feeling and desires, the leader cannot achieve what he set out to do for the community.

Therefore, the leader must know how he can influence, in order to make things happen in the community.
Being able to influence without formal authority is an essential desideratum, but one that cannot be achieved without people trusting the leader, without a clear picture of the goal pursued and without the leader having highly developed communication skills to convince and persuade.

Influencing does not always mean making others accept our point of view. It is neither necessary nor a problem for community members to always agree with the leader.

According to community toolbox, influence is a combination of three elements:

- the communicator - the person who wants to influence someone;
- the message - what the communicator wants the audience to do or believe;
- audience - the recipient of the message.

The question is how do these elements intertwine, in order for the influence to appear? What helps to accept the message? What are the factors that make the influence effective?

The combination of all three elements will ultimately determine the effectiveness of the influence of the others. The auditors are the ones who, in the end, let themselves be influenced or not.
But both the communicator and the message are very important. A leader with an important message can decisively influence the auditor.

A first step in building influence can be the consolidation of ready-made ones and the formation of new networks. Helping in this regard can be members of the old network, which can act as anchors for the creation of a new network. In this way some doors are open, which maybe in other conditions, you could not open.

Trying to build influence, the image and information that those in the community have about the leader is important. Therefore, they must be positive and credible. In this sense, the credibility of the leader is highlighted when the person is competent and knows what he is saying, when he/she has charisma and attracts the public by the way he expresses himself, when he/has has a high formal status in the community, when he speaks "in the language" of the audience.

Leaders or those who want to gain access to these positions need to be aware that their public image will be important in influencing others. Therefore, they must act in accordance with what they transmit, with the values they promote, with the things they support, so as not to create cognitive dissonance.

In the way, it is clear that the leader will influence them to a greater or lesser extent, depending on how they are perceived by the public, how flexible they are, how open they are to the ideas of others, listening to them and taking into account their opinions. Do not forget that the best ideas and with the greatest chances of being accepted by the community, are those resulting from the contribution of everybody, as a result of the creativity of the group.

Changing beliefs requires a sustained effort, sometimes over a long period of time. The process of influencing does not implicitly lead to rapid change. It is important that the leader does not disarm and learn to enjoy small victories without giving up the fight.

We all must influence people sometimes. But to be a community leader, influence means more than that. It is necessary to have a distinction between influence and manipulation. Influence allows the leader to complete things and achieve the desired results.

Some suggestions for influencing are specified in the bibliographic reference mentioned above in the Community toolbox. For example, one of the suggestions is to use comparison, metaphor, and the laws of persuasion. Another one is to manifest yourself reciprocally, returning positive behavior to the other. Finally, following one of the rules of negotiation, ask the audience to say "yes" three times before answering a crucial question.

In the article “Master the 3 Ways to Influence People”, the author shows about the tactics of influence fall into 3 categories: logical, emotional, or cooperative calls. Finally, the idea is that people influence with their head, heart, or hands.

When he/she uses logic, the leader influences others with his head, because he uses the rational part of their brain. To this end, the leader can influence by referring to the beliefs of his community, the advantages of the proposal or by presenting proven facts.
When a leader's calls connect with a person's emotions, it means that he is influencing the heart. Emotional appeals are directly related to the values of those they try to influence, as well as their sense of belonging. Influence with the heart is often effective when raising funds or recruiting a nonprofit board.

If the leader uses call for cooperation, the influence of others is based on collaboration and teamwork, and then we say that the leader influences with his own hands. Collaborating to achieve a goal that benefits the entire community is a powerful influencer, especially when the leader is working to make massive and lasting changes.

Influencing others means working effectively with people you have no formal authority over. The question is what is the best way to influence? There is no standard answer, because it all depends on the audience (community members), but also on the qualities of the leader, the way, and the ease with which he communicates and transmits, encourages and motivates. As Robinson (2019) mentioned, sometimes these ways of influencing can be combined, using 2-3, depending on the leader's power of persuasion and persuasion.

Leaders have a huge desire to do something; they must do, create, and share. This desire is the force that makes them invincible. Due to their motivation, they discover how to influence the people and the culture around them.

A leader always has the absolute belief that he/she can put his vision into practice, and the influence of others always begins with their conviction. To do this, the leader must convince others to trust him, because he/she knows that uncertainty, doubt, and fear are the biggest impediments in influencing others.

But to have an influence on others, it is necessary to know what is already influencing them. In this way, the leader can make real changes. The leader must show passion, energy, and knowledge of others, and so he will know how to speak to them, to sensitize them and get them involved.

Leaders change the community and the world around it by talking about building an effective story. They show that they care about those they influence and know how to adapt their approach to certain people or groups, inspiring others with their vision and putting their plans into action.

Conclusion: the leader in pandemic time

As Martin Luther King Jr. said: “The ultimate measure of a man is not where he stands in moments of comfort and convenience, but where he stands at times of challenge and controversy.”

In times of crisis, people try to find confidence, looking at those they trust, at their leaders. Communities also need role models to follow, so they follow closely what their leaders are doing. Especially in times of pandemic, community leaders must not forget that for those who follow them, they are those models who give the desired direction and show the future, without being touched (in an observable way) by what surrounds them.

Therefore, leaders need to demonstrate several qualities that can encourage the community to move forward. These qualities are:

1. Optimism and confidence that everything you do together will be completed successfully, so that even if it is bad now, tomorrow the sun "will smile on our street too!"

2. Calm, because a calm leader allows calm to be transferred to his followers, thus building confidence that everything will be fine. Any situation will find a better solution if things are treated calmly, patiently, and perseveringly.

3. Communication, without which there can be no relationship between the community and its leader (s). Communication helps to understand reality, to fight false news, as well as gossip, conspiracy stories, etc. But this communication must be done on several levels, on different channels and with as many communication agents as possible, reliable people from the leader's team. Community members need to know that they can always find their leader, or those on the team of community leaders, that the lieder is ready to listen them and help them with their problems. Under no circumstances should community members feel abandoned, as these things have an impact on the psyche, promote fear, despair and can even lead to an altered mental state.

People in the community need to know that they can rely on their leader, in all situations, especially when they feel weak, lonely, and helpless.

4. Empathy - to understand what they feel, what they do and why they do certain things, why they react like that to certain events. In a community with low social status, modest resources or almost no resources, the leader must ask himself how he can help them survive. Empathy means being close to them in those moments, sharing their worries with them, while giving them hope that they will be able to cope. Sometimes it is enough, as a leader, to listen to them. Emotional discharge is good for those who are suffering and are overwhelmed with worries. The leader must know and be able to show compassion in these difficult times, when one or more members of the family may be affected. A community can be made up of people of different ages, sometimes many seniors, who are vulnerable to disease issues.

Young people are not safe either, the reality proving serious health problems in young and very young people, even children. Deaths can occur in some families, with a devastating effect on those left behind. The leader must be able to express his compassion, to show those affected that they are not alone, that someone is suffering near them. Such things soften pain and suffering and empower people to move on.

5. Cooperation with others, because the leader cannot work alone. Without a team behind him, not even the best leader will be able to complete what he set out to do. In addition, for many people, to be useful to someone means to prove to oneself that he is capable, that he has an existential meaning. The way they build the leader, the team of supporters, but also the way they respond to the challenges of the pandemic are the defining factors for a successful leadership. In addition, by getting involved in solving problems, people will gain a correct and clear understanding of the problems caused by the pandemic. This will lead to the closure of rumors, which occur when people do not know very well what it is about.

6. Strengthening the feeling of community. Of course, the moment of the pandemic is not the one in which the feeling of belonging to the community begins to be built, but the one in which it strengthens. People need to feel supportive, to feel that they belong to the same group and that makes them not feel vulnerable. When there are more, when they are together, individual courage increases and at the same time the feeling of pride develops, because you are part of a community in which things are resolved.
In case of a pandemic, people's morale is very fragile, so we must help them maintain their optimism and hope, to have the strength to fight the disease.

7. Control of fear. The leader is also a human, with his problems, with his vulnerabilities, which means that he too can be overwhelmed by fears, uncertainties, doubts. But this is exactly the difference from an ordinary people to a leader: the fact that he can control himself, that he can judge in a balanced way and not be overwhelmed by the problems that surround him. At the same time, those around them must see the leader as a strong person who does

not lose control of his emotional balance. If the leader expresses doubt, fears, they can prove to be contagious for the rest of the team and then even for the whole community.

In times of pandemic, when the situation is uncertain, sometimes our actions can be blocked by the fear of not making a mistake, of not doing something irreversible. But this can lead to error, because things can get out of hand and some measures can be taken too late. Therefore, the leader must be surrounded by an equally competent, reliable team, who knows when to insist so as not to make the intervention unnecessary.

As a community leader, you must accept that you can be wrong, even if it means taking contradictory measures at times. After all, the crisis does not go on a predetermined route, so it is normal for changes to occur. It is a perfectly normal human reaction to return to something already said or done when things take another turn. But you must show people why you change your mind, to let them see the logic behind the leader's behavior. Here is the role of your team to support you, and to explain, to convince them.
It goes without saying there is no leader who knows them all, who has all the information at his disposal, so the leader's team must help gather perspectives to replace and support, where the leader can no longer cope, or it is overloaded.

Finally, both the leader and the team must be able to admit when they made a mistake and together formulate the desired direction because it avoids such things happening in the future.
As Douglas Mc Arthur said:" A true leader has the confidence to stand alone, the courage to make tough decision, and the compassion to listen to the needs of others. He does not set out to be a leader but become one by the equality of his actions and integrity of his intent".

Abstract

It is now well recognized that personality traits are strongly related to job-related attitudes and behaviors, there is still lack of studies that have explored the relationship between personality traits and job involvement. We proposed such a model based on the proposition that collectivistic as the moderator of the relationship between personality traits (extraversion and agreeableness) and job involvement. According to this proposed model, the higher collectivistic more likely positive effects extraversion and agreeableness on job involvement.

Keywords: Extraversion, Agreeableness, Collectivistic Orientation, Job Involvement.

Introduction

Job involvement can be defined as the degree to which the individual psychologically identifies with his work (Kanungo, 1982). Individuals who have high levels of job involvement will certainly think about, be attached to and pay attention to their work (Paullay et al., 1994), and consider performance to be the most important part of their identity and self-esteem (Lodahl and Kejner, 1965). Research on job involvement has continued to develop and has become one of the topics of interest to researchers. Some studies have devoted to predictor of job involvement such as turnover and absenteeism (Blau and Boal, 1987); performance (Keller, 1997; Rotenberry and Moberg, 2007; Biswas, 2011), job satisfaction and organizational commitment (Singh and Pestonjee, 1990; Brown, 1996; Khan et al., 2011; Ho et al., 2012; Zopiatis et al., 2014), Burnout (Chauhan, 2009), behavior of organizational citizenship (Chugtai, 2008; Diefendorff, 2002; Zhang, 2014; Ueda, 2012); organizational justice (Tjahjono, 2011; Tjahjono et al., 2019); religiousity and spirituality (Palupi & Tjahjono, 2016; Afandi et al., 2017; Tusa'diah et al., 2017) and work attachment (Scrima et al., 2014).

Whereas other have focused on job involvement as antecedent of other variables, such as perceptions of organizational support, (O'Driscoll and Randall, 1999; Cheng, 2011), quality of work life (Permarupan et al., 2013), psychological climate (Brown and Leigh 1996), transformational leadership (Sheikh et al., 2013), work values (Ho et al., 2012), locus of control (Pisheh, 2011), leadership style and organizational climate (Omolayo and Ajila , 2012), professional commitment (Singh and Gupta, 2015), personality traits (Bozionelos, 2004; Liao and Lee, 2009; Eswaran et al., 2011).

The present study, we put more emphasis on personality traits related to job involvement. We focus on extraversion and agreeableness for two reason. First, this traits were found to be the most important predictors of job involvement in non western studies (for example, Eswaran et al., 2011; Cheng, 2011; Liao and Lee, 2009). Second,

Cite this Article as: Muhammad RUSDI, Heru Kurnianto TJAHJONO, Arif HARTONO and Wisnu PRAJOGO "The Interactive Effects of Personality Traits and Collectivistic On Job Involvement" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

in the previous studies still found the uncertainty of the relationship between the extraversion and agreeableness with job involvement so as not to show conclusive results. Some studies have reported that agreeableness has a negative effect on job involvement, while extraversion have no significant effect on job involvement (Bozionelos, 2004). In contrast, Eswaran et al. (2011) revealed that extraversion and agreeableness have a positive effect on job involvement.

Furthermore, Andreassen et al. (2010) in his empirical study found that extraversion have a positive effect on job involvement, and agreeableness has a negative relationship with job involvement. Similarly, the empirical study conducted by Liao and Lee (2009) mentions that the personality of extraversion and agreeableness have a positive effect on job involvement. Meanwhile, the results of empirical studies conducted by Burke (2006) found that extraversion has a positive effect on job involvement. Likewise, the study conducted by Cheng (2011) found that extraversion and agreeableness have a positif effect on job involvement.

In an attempt to add to the literature, especially in a non-Western culture, the purpose of this article is to demonstrate that collectivistic as the moderator of the relationship between extraversion, agreeableness and job involvement. The central tenet of the interactionist perspective is that job attitudes are shaped by both employees' personal attributes and the attributes of their work environment. Based on this premise, we predict that collectivistic an important factor will influence the frame of reference individuals use when evaluating their work environments (Williamson et al., 2009). Thus, people who have different cultural values will provide different attitudes and responses to the work environment (Chao and Moon, 2005).

In this case, collectivistic is orientation to values that emphasize the principles of togetherness and everyone will seek to maintain long-term social relationships (Wagner and Moch, 1986; Wagner, 1995). This is done because the group can provide emotional support and a sense of togetherness. Therefore, people who have high collectivism values perceive that the interests of the group are more important than personal interests. Moreover, the existence of these values asserts that the work done by everyone will have an impact on group performance. As a result people tend to identify themselves and engage in organizational work (Brown, 1996; Hackett and Hausdorf, 2001).

Several studies have also found that collectivistic orientation is an important predictor of personality (Huang et al., 1997; Triandis, 2001; Taras et al., 2010). In another example, research conducted by Williamson et al. (2009) revealed that a positive interaction between organizational rewards and collectivist orientation affects employees' commitment. Meanwhile, Fock et al. (2011) in his empirical study reported that collectivistic orientation moderates the relationship between employee psychological empowerment and job satisfaction. Similarly, the results of research Sheikh et al. (2013) finds that collectivistic orientation as moderator the influence of transformational leadership styles on job involvement.

From these result, it appears that colletivictic oritentation plays an important role in determining employee work attitude. Thus, the presence of collectivistic orientation in this study is thought to explain the influnece of extraversion and agreeableness on job involvement.

Theories

Activation Traits Theory

Activation traits theory (Tett and Gutterman, 2000) provides one possible expalanation to explain the relationship between extraversion, agreeableness, collectivistic orientation and job involvement. This theory suggest that employees will look for a work environment that allows for the easy expression of their unique personality traits. According to this theory, situation strength is related to trait relevance that can lead to the expression of one trait rather than another.

Literature Review

Relationship between extraversion and job involvement

According to Witt (2002) extraversion is a personality trait related to one's ability to interact with others. People with high extraversion levels are usually described as talking, passionate, active, and sociable (Barrick and Mount, 1991; Jhon and Srivastava, 1999). Rusting and Larsen (1997) further state that in general extravert individuals have a positive experience with work. Research shows that such a pleasant experience tends to shape positive attitudes toward work (Judge et al., 2002; Judge & Ilies, 2002; Furham et al., 1999). As a result the positive attitude

encourages a person to engage in work and earnestly in work (Watson and Clark, 1997; Ongore, 2014). Therefore, the following propositions are proposed:

P1: extraversion positive effect on job involvement

Relationship between agreeableness and job involvement

Agreeableness is described as being cooperative, trustworthy, optimistic, forgiving, friendly, avoiding conflict and easily compromising with existing issues (Graziano and Eisenberg, 1997). Organ and Lingl (1995) add that individuals who have a high degree of agreeableness tend to be affiliated and maintain good relationships with colleagues. Research shows that individuals with a high degree of agreeableness tend to exhibit higher levels of work performance and engagement (Barick and Mount 1991; Scrima *et al.,* 2014). Thus, individuals with high agreeableness have a strong level of motivation to participate in the work. On that basis, the following propositions are proposed:

P2: agreeableness positive effect on job involvement

Collectivistic As Moderator

Previous studies have suggested that differences in cultural values play an important role in shaping individual preferences (Cox et al., 1991; Coon and Kemmelmeir, 2001), since these cultural differences of values can cause a person to have a different work attitude- (Alper, 1975, Bloom and Bary, 1967, Slocum and Strawser, 1972). At the organizational level of observation, in the same cultural situation can be analyzed at the individual level because of the variation of those values at the individual level. It was found Tjahjono (2011) in the study of social capital. For example, individuals who have high collectivistic values tend to show concern for others, avoid conflicts and prioritize cooperation (Taras et al., 2010). This is because they are more oriented towards building good relationships with colleagues (Wagner, 1995; Eby and Dobbins, 1997). These attitudes and work behaviors differ from those with a low collectivist orientation that prioritizes individualistic aspects (Ramamoorthy and Flodd, , 2002, 2004). Therefore, individuals with high levels of collectivism tend to have a work attitude that prioritizes common interests rather than personal interests (Triandis, 1998, 2001).

Thus in a work environment emphasizing collectivistic values it is possible for employees with high extraversion and agreeableness leads to engaged and to more satisfaction (Hui et al., 1995; Choi et al., 2015; Templer, 2012). It is assumed that employee with high levels of extraversion tend to enjoy talking and interacting with colleagues, they are looking for jobs with high social interaction, tend to develop and maintain good interpersonal relationships is expected to lead to higher job involvement (Brown, 1996; Scrima et al., 2014). Thus, the more positive the interaction between collectivistic with extraversion and agreeablenss leads to higher the level of employee involvement. Based on this argument, the following propositions are proposed:

P3: There will be a significant interactive effect between collectivistic and extraversion on job involvement

P4: There will be a significant interactive effect between collectivistic and agreeableness on job involvement

The Model

Grounded in activation traits theory (Tett and Guterman, 2000), we develope a moderator model involving extraversion and agreeableness as antecedent, job involvement as an outcomes and collectivistic as the moderator. The model postulates that extraversion and agreeableness could help increase job involvement level and envinronment who more collectivistic orientation.

Figure 1: A moderator model on extraversion, agreeableness, collectivistic and job involvement

Conclusion

Based on some of the results of previous studies show that the relationship between the extraversion and agreeableness with the job involvement has not shown conclusive results. The uncertainty of the relationship is allegedly influenced by other factors such as collectivistic values. The presence of the collectivistic in this study has an important contribution in explaining the phenomenon of the influence of extraversion and agreeableness towards job involvement. Therefore, this study aims to proposed the following propositions: extraversion positive effect on job involvement, agreeableness positive effects on job involvement, the role of collectivistic orientation as the moderator of the relationship between extraversion, agreeableness and job involvement.

Abstract

Although handicrafts portray the Malaysian culture and heritage legacy brought forward from previous generations, over the years, due to industrial revolution and technological advancements, the handicraft industry has been severely affected. However, entrepreneurship is one of the ways forward to sustainably preserve the handicraft industry. Hence, using Azjen's theory of planned behaviour (TPB), the aim of this research is to focus on the intention of the youth to venture into handicraft entrepreneurship as a path to rejuvenate the traditional handicrafts. The current study will extend the existing TPB framework by including the digital platform as an additional construct and will be based on cross-sectional quantitative findings. The target sample for this research comprises students from the National Craft Institute, Malaysia. This research aims to discover the entrepreneurial intention among the youth to pursue their careers in a traditional handicraft business. In line with the fourth industrial revolution, the impact of the digital platform will also be emphasized.

Keywords: Handicrafts, Malaysia, Entrepreneurial Intention, Digital Platform.

Introduction

The term 'cultural heritage' has evolved throughout the years, and although initially it referred to historical buildings and monuments, in this era, the knowledge and traditions inherited from our ancestors is also referred to as 'cultural heritage' (Yang, Shafi, Song, & Yang, 2018). Malaysia is a country with diverse cultures, traditions, religions, and ethnicities, and is a place where one can find differences in culture and religion within a small geographical area. According to the study by Petronela (2016), cultural heritage contributes to the GDP of the respective country. The reason being is that tourists or people in general like attaching their emotions to symbolic or meaningful architecture. Thus, protecting the heritage culture is very important. The tourism performance report indicates that handicrafts are among the items highly purchased by tourists (Malaysia Tourism Data, n.d.).

The advent of globalisation has led to challenges in the handicraft industry, such as mass production, lack of innovation, the unwillingness of youth to be involved in handicrafts, and the lack of financial resources. The lack of interest that is shown by the youth in small businesses, particularly in the handicraft industry, makes it challenging for craft products to thrive in the market (Yang et al., 2018; Fabeil, Mahmud, Nga, Hui, & Mail, 2017). One of the viable solutions that can be applied for this situation is to entice the younger generation in Malaysia to venture into the handicraft industry. Entrepreneurship is becoming a popular career choice and various efforts have been put forward by the Malaysian government to encourage entrepreneurial activities, especially among the youth (van Gelderen et al., 2008). Majlis Amanah Rakyat (MARA) and the SME Corporation Malaysia (SME Corp.) are among the institutions that have helped and supported the entrepreneurial activities.

MIGIN, Kishamala THAMOTHARAN and Hasliza HASSAN "Crafting Entrepreneurship Behaviour among Youth to Preserve the Culture of Malaysian Handicrafts" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Although a wide range of studies has been conducted on the entrepreneurial intention among the youth in Malaysia (Ali et al., 2017; Chea, 2015), limited empirical research is available concerning the factors that impact the entrepreneurial intention of the youth in the handicraft industry. The theory of planned behaviour (TPB) is one of the frequently used models to test entrepreneurial intention and human behaviour overall. Most researchers integrated the TBP into their study of entrepreneurship to predict the intention to establish a business (Krueger et al., 2000; Van Gelderen et al., 2008; Kautonen et al., 2015). Hence, the TPB was adopted for this study to illustrate the relationship between the entrepreneurial intention and entrepreneurial attitude, subjective norms, and the digital platform. In line with the fourth industrial revolution, the digital platform is included as an additional construct to identify the determinants that affect entrepreneurial intention.

Thus, this study is conducted to address the above-mentioned gaps by focusing on the following objectives:

1. to discover the determinants that could craft the intention of youth to venture into handicraft entrepreneurship;
2. to examine the digital platform's influence on the intention of youth to venture into handicraft entrepreneurship; and,
3. to understand the relationship among attitude, subjective norms, perceived behavioural control, and the digital platform in venturing into handicraft entrepreneurship.

Literature Review

Handicrafts

Handicrafts refer to products that are handmade and that represent the culture of a community. At least 80% of the crafts are handmade using sustainable resources, such as clays, recyclable materials, and natural fibres to name a few. The handicrafts are made based upon functionality, innovation, religious affiliations, and social symbols (Garg, Mittal & Goyal, 2005; Bhawan & Marg, 2006; Rogerson, 2010). Handicrafts in Malaysia are divided into five key sectors, namely, textiles, forest-based, metal-based, earth-based, and various crafts (Amin, 2006; Fabeil, Mizal & Langgat, 2016).

Entrepreneurship

Entrepreneurship is a process of creating value by bringing together a unique package of resources to exploit an opportunity. It is a process of creating something new by putting in the requisite time and effort, taking into account the financial, psychological, and social risk. In general, entrepreneurship refers to those people who are inclined to take a risk by undertaking a new business in order to gain profit (Ferreira, 2013; Eisenmann, 2013). The contributions of entrepreneurs are significant as they create jobs, products, and process innovation. In this study, entrepreneurship is looked at from the handicraft perspective.

Theoretical Foundations, Framework, and Propositions

Numerous existing studies support the usage of the theory of planned behaviour (TPB) in predicting the intention to start a business (Krueger et al., 2000; van Gelderen et al., 2008; Kautonen et al., 2015). It is evident that TBP predicts entrepreneurial intention across different cultural backgrounds. Although most of the studies focused on the direct effect of attitude, perceived behavioural control, and subjective norms on intention, some suggested the inclusion of additional constructs. In order to increase the efficiency of TPB as a tool to predict entrepreneurial intention, another independent construct – digital platform – is included.

Attitude towards intention refers to a person's favourable or unfavourable opinion concerning the behaviour of interest. Attitude is regarded as one of the primary determinants of intention. Attitude towards entrepreneurship can be enhanced in various ways. Secondly, perceived behavioural control is one's belief that one can accomplish a task that has been undertaken, which is primarily influenced by one's involvement and insights gained through the difficulties and challenges that one has encountered (Ajzen,1991; Bandura,1997; Krueger et al., 2000). Besides that, perceived support from close relations, such as families, friends, and so on, has been shown to have a positive impact on the intention among potential entrepreneurs. One's supportive environment, especially from the people that matter, has a considerable effect on one's intention (Ajzen, 1991; Kolvereid & Isaksen, 2006). Lastly, the digital platform has a profound impact on entrepreneurial intention. The availability and ease of using the social networking sites to launch a business is preferred by young entrepreneurs (Alayis, Abdelwahed & Atteya, 2018). Social networking sites like Facebook, Twitter, Instagram, and so on play an exceptional role in inspiring people to become entrepreneurs (Fernández, Liñán, & Santos, 2009).

Based on the previous studies, the following propositions are proposed:

P1: There is a positive significant relationship between the attitude and the intention of the youth to venture into handicraft entrepreneurship.
P2: There is a positive significant relationship between the perceived behavioural control and the intention of the youth to venture into handicraft entrepreneurship.
P3: There is a positive significant relationship between the subjective norm and the intention of the youth to venture into the handicraft industry.
P4: There is a positive significant relationship between the digital platform and the intention of the youth to venture into handicraft entrepreneurship.

The conceptual framework is presented below:

Figure 1: Conceptual Framework

Methodology

Sample

The target population of this study is students from the National Craft Institute Malaysia, which is located in Rawang. A few studies, such as Ismail et al. (2009), Shook and Bratianu (2010), van Gelderan et al. (2008), and Yusof et al. (2007), have prioritized students as the subject of their study. A total of 384 survey questionnaires will be distributed among the students.

Measurement

All the items in the questionnaire are developed based on past studies. This research uses five items to capture the attitude of youth towards intention. Five items are adapted from Azjen (1991) to reflect on how a student perceives the opinion of others concerning their entrepreneurial behaviour. Five questions are adapted from Alayis et al. (2018) to measure the impact of the usage of social networking sites on entrepreneurial intention among students of the handicraft courses.

Data Analysis

The Statistical Package for the Social Sciences (SPSS) will be used for the first phase of the data analysis, to screen and obtain the descriptive statistical results. To test the hypothesized relationships and their respective indicators, SmartPLS software will be used.

Summary

A positive outlook among students towards entrepreneurship can be built by addressing the determinants that affect their intention towards establishing a handicraft business. Therefore, this paper suggests a conceptual framework to identify the factors that affect entrepreneurial intention to venture into the handicraft industry among the youth. This paper is expected to provide some insights into the determinants of entrepreneurial intention among the youth, especially towards the handicraft industry.

Acknowledgments

This research was supported by the Ministry of Higher Education, Malaysia, under the Fundamental Research Grant Scheme (FRGS) (Project ID: FRGS/1/2018/SS03/MMU/03/2) obtained through Multimedia University (MMU), Malaysia.

What Could Happen with Cities and Mining Regions During A Lifecycle of Extractive Industry? Evidence from Polish Hard Coal Mining

Abstract

This article analyses the paths of transformation of mining cities and regions within the framework of a triad including (1) mining enterprise – micro perspective, (2) regional and (3) national governments – macro perspective, together with the socio-economic effects of choosing these paths. Considerations and research are conducted on the example of the Polish hard coal mining, which for many years remains one of the key industries in the Polish economy. The analysis covered a 15-year research period - 2003-2017.There are three main paths of transforming post-mining cities and regions: (1) continuation of mining in the region, (2) gradual substitution of mining by other service or industrial branches and (3) development of post-industrial tourism. The design and implementation of a transformation strategy should take place many years before the liquidation phase of mining in a given region. This is clearly confirmed by observation of the effects of mining liquidation in the studied Polish cities of Górny Śląsk. Failure to use the transformation paths indicated above exposes cities and regions to a very severe deterioration of the socio-economic status and image. It is not possible to improve them in the short term without significant investment outlays.

Keywords: Cities Transformation; Post-Industrial Regions; Regional Policy and Strategies; Regional Management; Coal Mining in Poland.

Introduction

Extraction of natural resources is a very socially and environmentally burdensome process at virtually every stage of the mining enterprise's life cycle (Toumbourou et al., 2020; Zhi et al., 2019). This is due to the nature of the production process, and apart from abandoning mining there are no ways to completely eliminate the burdensome effects of mining (Lehotský et al., 2019). Although they can be limited, it is connected with the need to incur additional financial outlays, which ultimately increases the costs of mining enterprises and reduces the profitability of mining production (Yu et al., 2020). Therefore, mining enterprises have and will tend to avoid these additional costs and downplay the socio-ecological aspects of mining, all the more so because their activity in a given region is time-limited by the sufficiency of given deposits of natural resources. Therefore, mining companies do not have to be interested in long-term implementation of the benefits of sustainable development, and the will to implement the principles of corporate social responsibility in their case can only remain marketing tool, if it is not accompanied by deeply rooted ethical values that characterise the managers of these organisations (Tang et al., 2020; Woźniak and Jurczyk, 2020; Kochmańska, 2019; Majer, 2013; Sapna et al., 2017).

Given the above circumstances, it should be noted that local, regional and national authorities play a decisive role in limiting the adverse effects of mining operations, which by definition are required to create, implement and control the compliance with mining regulations (Alvez et al., 2020; Atienza et al., 2020; Wang et al., 2019; Spiegel et al., 2018). In addition, they are also creators of business conditions in the short-term and strategic development perspective. Therefore, they have a direct impact on what is currently happening in the region and what will happen in the future. Thus, they are active stakeholders in the activities of mining enterprises, and it is within the framework of such a triad (mining enterprise - local, regional and national governments - local, regional and

Evidence from Polish Hard Coal Mining" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

national community) that the consequences of mining activities are defined at each stage of its life cycle (Baran, 2019; Oppon et al., 2018; Cardoso, 2015; Huang et al., 2011).

In light of the above justification, this article analyses the paths of transformation of mining cities and regions in the context of the interaction of the above mentioned triad, together with the socio-economic effects of choosing these paths. Considerations and research are conducted on the example of the Polish hard coal mining, which for many years remains one of the key industries in the Polish economy (Bijańska and Wodarski, 2017; Michalak, 2016; Karbownik, 2005).

Literature Studies

In the life cycle of a mining enterprise, as in the case of other industries and enterprises, there are essentially three phases: establishment, development and liquidation. In the case of mining enterprises, the duration of this cycle is clearly limited by the size of the extracted deposits or the economic profitability of this process. Therefore, mining enterprises and industries are characterized by the temporary nature of existence in a given geographical location, which, combined with the high harmfulness of this type of activity becomes a source of many social, environmental and economic conflicts, which are primarily activated at the local and regional level (Crost and Felter, 2020; Gómez-Valenzuela et al., 2020; Rugadya, 2020; Orihuela et al., 2019; Yang and Ho, 2019; Hovards, 2019; Temper and Martinez-Alier, 2013; Avcı et al., 2010).

Nevertheless, the emergence and development of mining enterprises in a given region can be perceived as a source of economic benefits, especially in less civilised, industrialised or economically developed regions. New jobs are created and the chances of improving the economic situation of the residents and the local economy clearly increase. Local and regional authorities can also benefit from the economic benefits of starting mining enterprises by participation in fees and taxes paid by the mining industry. For this reason, they very often lobby and support mining entrepreneurs in contrast to local environmental or social organisations that fear the consequences of mining activities (Corrigan, 2019; Bainton and Jackson, 2019; Saletta and Orrman-Rossiter, 2018; Wakefield and Myers, 2018; Damigos et al., 2016; Zhang and Moffat, 2015; Söderholm and Svahn, 2015).

The establishment and development of mining enterprises is also justified by the state's resource policy. Extraction of natural resources can be a source of significant budget revenues (Siyam et al., 2020; Dai et al., 2019; Caputa, 2019; Ma et al., 2019; Rubbers, 2019; Hilson, 2000; Kumar and Amaratunga, 1994). It can become an important bargaining argument in international economic relations. It can also significantly affect the security of raw materials, including energy. The package of benefits associated with it is therefore attractive and alluring, and until there are economically and technologically viable substitutes or methods of producing natural resources, the problems associated with their extraction will be urgent and current.

If national, local government, social and ecological stakeholders come to an agreement, the emergence and development of the mining industry are inevitable. In this situation, the potential economic benefits outweigh the negative social and environmental effects. The problem of these effects appears again in the declining phase of mining enterprises in which resources are depleted or their extraction becomes economically or technically unjustified (Toumbourou et al., 2020; Molenda, 2019; Gorman and Dzombak, 2018; Krzemień et al. 2017; Bainton and Holcombe, 2018; Knierzinger and Ter-Ibinibe Sopelle, 2016). National, local and regional authorities should then consider ahead of time and by mutual agreement further regional transformation (Marais et al., 2019; Makhmudova and Matsui, 2019), which could theoretically follow the following patterns:

- starting new deposits in the region (subject to their existence and economically and technically justified possibility of extraction, and obtaining the consent of representatives of social and ecological environments),
- systematic replacement of the mining industry with other industrial and service industries,
- taking advantage of the opportunities for developing post-industrial tourism.

Defining and choosing one of the indicated options prevents social conflicts following the end of extraction due to: loss of jobs, increase in unemployment, decrease in income of residents and general pauperisation of the region (Otamonga and Poté, 2020; Kmieciak et al. 2018; George-Laurentiu et al., 2016; Rawashdeh et al., 2016). At the same time, this choice should at least take place several years in advance due to the long-term nature of liquidation of the mining enterprise and the long-term perceptibility of negative effects of this activity (Carneiro and Fourie, 2020; Everingham et al., 2018; Ober, 2020).

Misunderstanding or disregarding the consequences of mining enterprises entering the declining phase usually has disastrous consequences for local and regional communities. On the other hand, numerous cases of properly

planned, organised and implemented transformation strategies allow to state that mining regions can exist and develop in parallel with further development of the mining industry and also after the liquidation of mining plants (Veraart, 2019; Howieson et al., 2017; Harfst, 2015; Wolniak and Skotnicka-Zasadzień, 2012).

In light of the above circumstances, the main purpose of this article is to identify and characterise the socio-economic consequences and transformation pathss of cities and mining regions on the example of Polish hard coal mining. Detailed research objectives and problems related to this intention together with the research methods used are described in the next section. Then, the results of research on the transformation paths of mining regions in Poland and the socio-economic consequences of the post-mining transformation of the Śląskie Province (macro perspective) and the cities operating in it (micro perspective) are presented. At the end, conclusions regarding Poland and the studied regions were formulated. Theoretical possibilities of transformation of mining regions were also defined.

Methodology

Three research perspectives were used to identify patterns and consequences of the transformation of mining regions and cities. The first of these relates to the national level (Poland) and the three main mining basins: Lubelskie, Górnośląskie and Dolnośląskie. The second concerns the region, which is the Śląskie Province - the area of operation of the Górnośląskie Coal Basin, and the third is local and covers 19 Śląsk cities with poviat rights. This approach allows one to look at the process of changes and their consequences both synthetically and analytically.

The research is looking for answers to the following research problems:

1. At what stage is hard coal mining in three main mining regions in Poland?
2. What mining regions transformation paths have been implemented in each of the studied regions?
3. Were the cities located in the same mining region transformed in a similar or different way?
4. What influenced possible differences in urban transformation paths and their consequences?
5. What were the socio-economic consequences of selected transformation paths at regional and local level?

The analysis covered a 15-year research period - 2003-2017. In the course of the research, the following parameters were used to identify the socio-economic consequences of the transformation of regions and cities: population, budget revenues per capita, budget expenditure per capita, divided into current and investment expenditure, level of budget deficit/surplus, relation of total liabilities to total income.

For the data characterising the above parameters in the years 2003-2017, the average annual rate of change and arithmetic means were calculated, and based on them, a comparative analysis was carried out in the above mentioned research perspectives. At the end of the article, in order to group the 19 studied cities and formulate uniform management recommendations for them, Principal Components Analysis (PCA) was used to simplify the description of the studied cities from five parameters to two dimensions (Statistica Package), thus obtaining a description of the socio-economic consequences caused by choosing a specific transformation path.

Research Results

Transformation paths of post-mining regions in Poland

In Poland, hard coal mining was and is located in three basins located in different geographical regions of the country. In the southeast there is the Lubelskie Coal Basin (LZW). In the south of Poland, the Górnośląskie Coal Basin (GZW) operates, and in the south-west is the Dolnośląskie Coal Basin (DZW). Currently functioning mines only operate in GZW and LZW. In DZW, extraction was terminated in 2000 for economic reasons. Currently, the largest area of hard coal mining in Poland is GZW in which almost all Polish mines and mining companies operate: Polska Grupa Górnicza SA - 8 mines, Jastrzębska Spółka Węglowa SA - 5 mines, Tauron Wydobycie - 3 mines, Węglokoks SA - 1 mine, Przedsiębiorstwo Górnicze Silesia sp. z o.o. - 1 mine, Zakład Górniczy SILTECH sp. z o.o. – 1 mine, Zakład Górniczy Eko-Plus sp. z o.o. - 1 mine. There is one hard coal mine operating in LZG as part of the LW Bogdanka SA. enterprise. The geological characteristics of the Polish coal basins are presented in Table 1.

Table 1: General geological characteristics of Polish coal basins (as of 31/12/2018)

Basin name	Area [in km^2]	Number of deposits	Recoverable resources [in million t.]	The main types of coal
Dolnośląskie Coal Basin (DZW)	530	7	420	34-37
Górnośląskie Coal Basin (GZW)	5,600	144	49,350	31-33
Lubelskie Coal Basin (LZW)	1,200	10	11,661	31-33

Source: own study based on data of the Polish Geological Institute.

According to the data presented in Table 1, the largest and the most prospective Polish mining region is the Górnośląskie Coal Basin. However, it should be added that extraction in this area takes place in highly urbanised areas which significantly hinders operation and increases the costs of its operation. In addition, the deposits there are characterised by a high level of natural hazards, including primarily methane. In addition, most of the low-lying seams existing in the mines there have already been extracted. It is therefore necessary to deepen mining - up to 1,200 metres, which causes a significant deterioration in the working conditions of mining crews. These circumstances adversely affect health and safety at work and contribute to the deterioration of mining efficiency (Gembalska-Kwiecień, 2019).

The low and deteriorating efficiency of mining has been the reason for limiting mining activity in the Górnośląskie Coal Basin for years. In 1989 - the first year of economic transformation in Poland, 415,000 people were employed in mining with over 177 million tonnes extracted. The first period of intensive reforms began in 2001 and lasted until the end of 2003. Its effect was to reduce employment to 136,000 and decrease production to around 100 million tonnes. 29 mines were then closed. As part of this stage of the sector transformation, only the liquidation of mining plants and the system of severance pay and social protection were used for miners dismissed from mines. They rarely used the opportunity to retrain and often fell into ruin after exhausting the received funds. Due to the scale of redundancies, this phenomenon was of a collective nature and contributed to the increase in unemployment in the region and its ongoing pauperisation. Cities particularly affected by these circumstances were: Bytom, Świętochłowice and Zabrze.

After liquidation the existing mines were consolidated into several large mining enterprises, which was to ensure synergy and enable more effective management of the remaining mining plants (Wolniak, 2019). In the yearsma 2003-2012 mining plants were not liquidated on a mass scale and group redundancies were not made. In order to improve efficiency and effectiveness, individual mines were merged into existing mining enterprises to form so-called combined mines, most often with two-chain operation (Skotnicka-Zasadzień, 2013). Unfortunately, in the years 2012-2015 there was a severe economic downturn on the hard coal market, including a fall in prices and demand (Michalak and Bąk, 2018; Krawczyk-Sokołowska et al., 2019). In connection with the anti-carbon Policy of the European Union, this resulted in a deep crisis, as a result of which two large coal mining enterprises were closed, some of the permanently inefficient mines were closed and one joint mining enterprise was established - Polska Grupa Górnicza SA. Its structures also internal consolidation and the creation of three and four-chain combined mines took place. The liquidation of six mines in this phase of the sector transformation affected mostly the cities in which the closed plants operated. Among them again were: Bytom and Zabrze. They were joined by: Jastrzębie Zdrój, Żory and Ruda Śląska.

In the second of the described regions, the Lubelskie Coal Basin, mining conditions are significantly better. Mined hard coal seams are lower, characterised by a high thickness and low inclination (possibility of operating with a plough system) and serious natural hazards, including methane, are practically nonexistent. Favourable geological conditions have a positive impact on both the efficiency of extraction and the development opportunities of LW Bogdanka SA.

As already mentioned, in the last of the characterised region - the Dolnośląskie Coal Basin, operation was finally terminated in 2000 due to the very complicated tectonic conditions of the deposits located there, as well as frequent rock and gas outbursts, hindering economically profitable production. There have been several coal mines in this region since the eighteenth century, mainly near Wałbrzych and Nowa Ruda (including, among others *Bolesław Chrobry, Dawid, Herman, Julia, Mieszko, Piast, Słupiec, Segen Gottes, Teresa, Victoria, Wałbrzych)*. During the liquidation and post-liquidation phase, the closure of the mines contributed to the pauperisation of the region, the outflow of indigenous peoples and the progressive ageing of local society.

Preventive measures were only taken in the final phase of the liquidation of mining in DZW in the late 90s of the twentieth century, and they were focused on two priorities:

1. post-industrial tourism development,
2. complementing the industrial potential of the region.

Activities aimed at increasing the region's attractiveness perfectly matched the current business conducted in the region of south-western Poland, which was a certain facilitation for the development of post-mining tourism. The Dolnośląskie Coal Basin is located in the Sudetes region - an attractive mountain range with numerous rivers, lakes, caves and underground waters. And so, in 1994, the Mining Museum of Nowa Ruda was established, which was then expanded by the Tourist Coal Mine. In the facility you can learn about the mining history of the Dolnośląskie Coal Basin and visit the revitalised underground excavations of the Nowa Ruda mine (http://kopalnia-muzeum.pl/). The industrial potential of the region was supplemented in two ways. On the one hand, efforts were made to use and maintain existing industries, primarily including the ceramic industry (Wałbrzych porcelain factory) and hard coal processing (Victoria coking plant). On the other hand, new investment opportunities were sought by creating the Wałbrzych Special Economic Zone (WSEZ) offering entrepreneurs preferential tax and cost conditions for doing business. Thanks to the Zone, it was possible to strengthen and develop construction and automotive industry in the region. Nevertheless, despite the actions taken, the region of Wałbrzych and Nowa Ruda has not yet achieved full economic potential and regional significance it had prior to the liquidation of hard coal mines operating in this area.

Socio-Economic Consequences of The Transformation of Mining Regions on The Example of the Śląskie Province - A Macro Perspective

In the macro perspective, parameters are compared at the level of Poland and the Śląskie Province. The first of these is the population in the years 2003-2017, presented in Figure 1. In Poland, the population size was characterised by a slow growth trend. In the Śląskie Province, a well-adjusted trend function indicated a systematic reduction in the number of residents of this region. This is also confirmed by the average annual rate of change of this parameter indicated in Table 1. It amounted to 0.04% in the analysed period in Poland, and in the Śląskie Province -0.26% The identified regularity indicates the demographic decline of the post-mining area and the depopulation of Śląskie cities, which is largely associated with their decreasing industrial attractiveness and the increasing degree of environmental degradation.

Fig. 1: Population in Poland and in the Śląskie Province in the years 2003-2017 [in million]

Table 1: The average annual rate of population change in budget parameters for local government units in Poland and in the Śląskie Province in the years 2003-2007 [in %]

Specification	Average annual rate of change
Population in Poland	0.04%
Population in the Śląskie Province	-0.26%
Revenue of local government units in Poland per capita	7.87%
Revenue of local government units in the Śląskie Province per capita	7.35%
Expenses of local government units in Poland per capita	7.71%
Expenses of local government units in the Śląskie Province per capita	7.18%
Investment expenses of local government units in Poland per capita	6.92%
Investment expenses of local government units in the Śląskie Province per capita	5.55%

Source: own work.

The slower pace of development of the Śląskie region in comparison to Poland is also evidenced by the lower average annual growth rate of income and expenses per capita. In the case of revenues, their growth dynamics was lower by 0.52% a year in the analysed period in the Śląskie Province, and by 0.53% a year in the case of expenses. The above differences become even more pronounced at the level of investment expenses, which increased by 6.92% a year in Poland and only by 5.55% in the Śląskie Province.

However, Śląskie Province as a whole region performed slightly better compared to the national average, in the context of the level of budget deficit and debt in relation to the level of total income. The average values of these parameters for all Polish provinces and the Śląskie Province are presented in Table 2. The data contained therein show that the average annual expenses of Polish provinces exceeded the income by 1.85%, while expenses of the Śląskie Province were higher than the income by 1.36%. The debt of municipalities in all Polish provinces constituted over 23% of total revenues, and Śląskie Province's debt in relation to total revenues was 22%. Here it is worth adding that the debts of Polish municipalities, including Śląskie municipalities, has been systematically growing over time due to the need to make own contribution to development projects financed by the European Union, and increasing the scope of tasks entrusted to local governments in Poland (Spałek, 2014).

The analysis carried out for the Śląskie Province shows that this region slowly depopulated during the period studied and developed economically slower compared to the national average. However, it was not excessively indebted and the average deficit of the municipalities operating in it was lower than the national average. Nevertheless, it should be added that the Śląskie Province, apart from the Górnośląskie Coal Basin, also includes the Beskid Śląski (Bielsko-Biała) in its region and part of the Kraków-Częstochowa Upland (Częstochowa). These are tourist and agricultural areas in which mining has never been carried out. Therefore, in the next section, the analysis was narrowed to a micro perspective referring to cities with poviat rights operating in the Śląskie Province (19 government units). This approach made it possible to assess the relationships between the demographic and financial situation of the government units studied, and their main economic specialisation.

Table 2: Average values of selected budget parameters in Poland and in the Śląskie Province in the years 2003-2007 [in %]

Specification	Arithmetic mean
Budget deficit / surplus of local government units in Poland	-1.85%
Budget deficit / surplus of local government units in the Śląskie Province	-1.36%
Liabilities of local government units versus total revenues in Poland	23.39%
Liabilities of local government units versus total revenues in the Śląskie Province	22.00%

Socio-Economic Consequences of The Transformation of Mining Regions in Cities of the Śląskie Province - A Micro Perspective

Starting the analysis of social effects in the urban perspective, it is worth looking at the number of residents of the studied government units and their diversity in the studied group - Figure 2.

Fig. 2: Population in cities with poviat rights in the Sląskie Province in 2017

And so, the number of residents in all cities exceeds 50,000 in the studied group. The largest of them are: Katowice, Częstochowa and Sosnowiec (population over 200,000). Among the smallest are: Świętochłowice, Żory and Piekary Śląskie (population below 70,000).

In the case of detailed demographic parameters, presented in Figure 3, it can be concluded that In all the examined cities, a decrease in the population of 0.10% (Mysłowice) to 0.90% (Bytom) was recorded. Among the cities with the highest rate of depopulation, apart from the already indicated Bytom, there are: Częstochowa, Gliwice, Katowice, Siemianowice, Świętochłowice and Zabrze. In the given list only Częstochowa is not a post-mining city. It should also be added that Bytom, Świętochłowice and Zabrze are cities in which the liquidation of mines was carried out during both periods of mining restructuring in GZW, i.e. the cities most affected by the effects of regional transformation.

—— - average value for all local government units in Poland in the years 2003-2017

Fig. 3: Average rate of population change in the studied Śląskie cities and in Polish local government units in total in the years 2003-2017 [in %]

As part of further analysis, Figure 4 presents the average rate of change in budget revenues per capita in the studied Śląskie cities and in Polish local government units in total in the years 2003-2017. It shows that in only 9 out of 19 cities studied it was higher than the national average (Bielsko-Biała; Chorzów; Częstochowa; Jastrzębie-Zdrój; Piekary-Śląskie; Siemianowice Śląskie; Świętochłowice; Tychy; Żory). There was no mining in two of these cities (Bielsko-Biała and Częstochowa). Jastrzębie-Zdrój still has the largest European company mainly producing coking coal (Jastrzębska Spółka Węglowa SA). In Tychy, Chorzów and Siemianowice Śląskie - former mining regions, it was possible to carry out an industrial transformation (supported by the creation of special economic zones) and replace mining plants with enterprises from the automotive industry (Fiat; General Motors - Tychy; Adient - Siemianowice Śląskie), metallurgy (ArcelorMittal - Siemianowice Śląskie) and chemical (Zakłady Azotowe; Zakłady Chemiczne HAJDUKI - Chorzów). In Żory and Piekary Śląskie it was not possible to create or attract large industrial plants but many small and medium enterprises were created, and the cities changed their character from industrial to service and commercial.

In light of the above, it can therefore be stated that in almost all cities with above-average income growth the mining industry has been successfully replaced by other activities that do not expose the residents and the region to pauperisation. The exception in this respect is Świętochłowice, which, despite a significant rate of income growth, did not avoid the most serious effects of mine liquidation, which will be explained in detail later in this article.

- average value for all local government units in Poland in the years 2003-2017

Fig. 4: The average rate of change in budget revenues per capita in the studied Śląskie cities and in Polish local government units in total in the years 2003-2017 [in %]

The lowest rate of income growth was recorded in: Bytom, Dąbrowa Górnicza, Katowice, Rybnik and Zabrze. Therefore, this group again included two cities most affected by the effects of restructuring (Bytom and Zabrze). In other cities, mines were also liquidated in at least one of the restructuring periods indicated earlier. However, it should be added that Katowice being the capital of the province, could certainly deal with the changes much better than smaller and less industrialised cities, such as Rybnik or Dąbrowa Górnicza.

- average value for all local government units in Poland in the years 2003-2017

Fig. 5: Average deficit / budget surplus in the studied Śląskie cities and in Polish local government units in total in the years 2003-2017 [in %]

Figure 5 presents another of the economic parameters analysed, which is the size of the budget deficit / surplus. And so, surplus budgets occurred in: Jastrzębie Zdrój, Katowice, Piekary Śląskie and Tychy. Apart from Piekary Śląskie, all of these cities are large regional centres with a high degree of industrialisation, which either successfully continue mining traditions like Jastrzębie Zdrój or have established alternative development opportunities like Katowice and Tychy. It should also be added that these are the cities with the lowest depopulation rates and high per capita budget revenues. It can therefore be acknowledged that these cities coped well with the effects of mine liquidation.

In turn, among the cities with the highest average budget deficit were such government units as: Bytom, Dąbrowa Górnicza, Jaworzno, Ruda Śląska, Świętochłowice, Zabrze and Żory. In at least one of the identified restructuring periods mines were closed in all of these centres. In this context, the particularly difficult budgetary situation affected Ruda Śląska, Świętochłowice and Żory, where the deficit level was the highest.

The listed cities also had the highest level of debt in relation to total revenues (Figure 6) - over 30%. The record debt was in Żory, and the described group was joined by Zabrze, where the debt also exceeded 30%. These cities have therefore suffered the most severe economic consequences of the partial liquidation of hard coal mining in GZW.

- average value for all local government units in Poland in the years 2003-2017

Fig. 6: Average relation of liabilities to total revenues in the studied Śląskie cities and in Polish local government units in the years 2003-2017 [in %]

Economic consequences of the transformation of mining regions in cities of the Śląskie Province - Principal Components Analysis (PCA)

In the last stage, in the assessment of the structure of the analysed cities (cases), Principal Components Analysis (PCA) was used to simplify the process of describing data from five variables to two dimensions (Statistica Package). The results of such segregation of cities in the Śląskie Province are presented in Figure 7.

Fig. 7: Principal Components Analysis (PCA) results for the studied cities of the Śląskie Province (based on Statistica)

The first quarter of the coordinate system includes cities with high levels of budget deficits and indebtedness, in which the income growth rate rises above average over time. However, this is not a sufficient growth as these cities have unbalanced budgets and are very seriously indebted. They are therefore in a very difficult financial situation. The group of these cities includes: Częstochowa, Żory and Świętochłowice. The last two are post-mining cities in which effective transformation into other industries has not been carried out. Świętochłowice developed practically no other activity, and Żory became a commercial and service city, but in light of the data presented it did not bring the expected economic effects. In addition, it is worth emphasising that Żory, unlike Świętochłowice, was characterised by one of the lowest population decline rates which justifies the conclusion that in demographic terms, perhaps also including the attractiveness of the place of residence, they are in a much better position than Świętochłowice.

The second quarter of the coordinate system includes cities whose deficit and debt are also high, but in which the level of income (and expenses) is growing more slowly than the average in Poland. All cities located in this quarter are post-mining centres in a difficult economic situation and in most cases also characterised by high population loss (with the exception of Mysłowice and Jaworzno). Undoubtedly, in the most difficult situation are: Zabrze, Bytom and Ruda Śląska, which were most affected by the process of mine liquidation.

In the third quarter of the coordinate system there were only two cities, Gliwice and Katowice, which are the economic leaders of the region. In the context of the conducted analysis, these are government units with a relatively low deficit and debt, and a low growth rate of income and expenses (also due to their high initial level). Nevertheless, the number of residents is also falling above average in these cities. The cities in this quarter have developed the greatest potential for survival and development. They have a mining independent industry and offer their residents attractive housing conditions. They are also significant educational, cultural and sports centres. They also achieve good economic effects of transformation.

In the fourth quarter there were cities similar to Poland in terms of the parameters studied. They are characterised by lower than average indebtedness, surplus or low budget deficit, high income (and expenses) growth rate and quite a diverse population change rate. These are cities that were hardly affected by the mine liquidation, and partly also thanks to this they were able to become independent of the mining industry.

Conclusions

In formulating the main conclusions, reference was made to the research questions posed in the methodological part. And so, hard coal mining in each of the three studied coal basins is in a different development phase. Production in the Lubelskie Coal Basin is in a development phase and due to the significant extraction potential it will be continued in the near future. It is an attractive place of employment for local communities. Also, it does not cause significant ecological and social problems due to its favourable geographical location (apart from highly urbanised, valuable landscape or tourist areas) and very good geological and mining conditions (no natural hazards, low coal seams, high thickness of seams).

In the last decade of the twentieth century hard coal mining was liquidated in the Dolnośląskie Coal Basin for economic reasons. Post-mining cities have taken two transformation paths: (1) creating special economic zones to attract investors from outside the mining industry and / or (2) developing post-industrial tourism. Their implementation was not always successful. Cities which failed to follow any of the above mentioned paths are currently characterised by high unemployment rates, low income levels of residents and systematic depopulation.

In the Górnośląskie Coal Basin, hard coal mining still exists and is a key industry in the region. Nevertheless, due to the low and decreasing profitability of mining and deteriorating geological and mining conditions some of the mines were closed during two main stages of restructuring. Therefore, it can be acknowledged that mining in this region is in the pre-liquidation phase, in which specific transformation paths should be taken and implemented, all the more so as in many cities of the region the total liquidation of mines has resulted in severe pauperisation of these cities. Based on the analysis of 19 cities, they were classified into 4 groups, described in Table 4, together with management recommendations at their addresses.

Table 4: Groups of post-mining cities in the Śląskie Province - characteristics and development recommendations

No.	Characteristics of post-mining cities in the Śląskie Province	Recommendations
I.	High debt High deficit High income and expenses growth rate No economic transformation effects	Supporting local entrepreneurship Creating a favourable climate for new investments Cooperation with more developed cities in the region The use of public-private partnerships Improving attractiveness for current and potential residents Eliminating weaknesses and overcoming threats
II.	High debt High deficit Low income and expenses growth rate Insufficient economic transformation effects Depopulation	Supporting existing enterprises and strengthening of new business ventures Development of post-industrial tourism Revitalisation of post-mining areas and facilities Debt renegotiation Searching for opportunities to increase income Improving attractiveness for current and potential residents Eliminating weaknesses and seeking opportunities
III.	Low debt and deficit Low income growth rate Quite a high depopulation rate High economic transformation effects	Increasing attractiveness for current and potential residents Strengthening existing activities for the development of entrepreneurship and enterprises Development of post-industrial tourism Revitalisation of post-mining areas and facilities Strengthening advantages and seizing opportunities
IV.	Low debt Surplus or low budget deficit High income growth rate Diversified level of population change	Maintaining good financial standing Searching for new industrial and development opportunities (education, culture, sport) Increasing attractiveness for current and potential residents Strengthening advantages and overcoming threats

Source: own work.

By synthesising the conducted considerations and research it is possible to determine the theoretical paths of transformation of enterprises and the mining industry following the establishment and development phase, together with their consequences:

- continuation of mining in the region: establishment of new mines, starting of new deposits (consequences: maintenance of the development phase, preventing severe pauperisation of the region, prevention of social and environmental conflicts by minimising negative consequences of mining, and optimisation of economic and political benefits);
- gradual substitution of mining by other service or industrial branches: supporting local entrepreneurship, creating special economic zones (consequences: maintaining the region's development, preventing severe pauperisation of the region, becoming independent of the mining industry, making the region's image more attractive),
- development of post-industrial tourism: using liquidated mining infrastructure, joining the popular creation of post-industrial tourism routes and enriching post-industrial heritage (consequences: management of technical and human resources in the region, preventing severe pauperisation of the region, maintaining development of the region while preserving the centuries-old material and non-material traditions).

The pathss outlined above do not have to be, and are not carried out separately. Many analysed cities and regions implement them in parallel, gaining in addition their synergy effect. Nevertheless, it is worth adding that their design and implementation should take place many years before the liquidation phase of mining in a given region. This is clearly confirmed by observation of the effects of mining liquidation in the studied Polish cities of Górny Śląsk. Failure to use the transformation paths indicated above exposes cities and regions to a very severe deterioration of the socio-economic status and image. It is not possible to improve them in the short term without significant investment outlays.

Modern Approaches to Assessing the Effectiveness of Social Budget Expenditures

Tatyana TKACHEVA, Southwest State University, Kursk, Russia, tat-tkacheva@yandex.ru

Lubov AFANASYEVA, Southwest State University, Kursk, Russia, lv_af@mail.ru

Alexander PIYALTSEV, Southwest State University, Kursk, Russia, pialcevaleksandr8@gmail.com

Abstract

In the contemporary fiscal practice with the methodological positions used quite a large variety of models and concepts of social policy, and social aspects of fiscal policy and taxation, which can be classified from the standpoint of social or subsidiary state and the appropriate fiscal policy: socio-loaded or liberal limited.
The article formulates two approaches to assessing the social orientation of budget policy at the regional level: process and effective. The proposed approaches are quite acceptable for the formation of the social dominant of budget policy and the allocation of budget allocations at the regional level.
As a result of the study, it is concluded that the priority direction of the budget policy at the regional level in the coming years will be to ensure social obligations. The degree of satisfaction of the population is a key indicator characterizing the effectiveness of the use of budgetary funds by state bodies, it serves as a final social indicator of the effectiveness of the use of budgetary funds.

Keywords Tax System, Budget System, Fiscal Mechanisms, Structural Parameters, Sustainable Development, Fiscal and Tax Regulation.

Introduction

Analyzing actual problems and tendencies of social orientation of fiscal policy at the regional level, it is necessary, first of all, to stop on consideration of essence of the social state. In this regard, studying the theoretical sources on this issue, it can be stated that in most of them the social state is understood as a special type of modern structure of society, which provides a high level of social protection of all citizens through an active state policy, including in the field of taxation. At the same time, the social state is characterized by the principle of social justice, the creation of ideally equal opportunities for all members of society through a system of financial, tax and social support measures, the transition from political and legal equality of citizens to their social equality, ensuring an acceptable standard of living for socially vulnerable segments of the population and individual citizens, the possibility of self-sufficiency, improving their welfare. To date, the social state as a constitutional principle is enshrined in the constitutions of countries such as Japan, Germany, Italy, Spain, Portugal, Sweden, as well as some other countries.

Applied studies of the processes of formation and development of social orientation of tax policy and evaluation of the effectiveness of tax and budget policy tools have been developed in the works Mayburov, I. A. (2012), Balatsky, E. V. (2003), Goncharenko, L. I., & Arhiptseva, L. M. (2011) Rykunova V. et al. (2017), Tsiklauri V. et al.(2019). Tciklauri V. et al. (2018), Tkacheva T, et al. (2016), Belousova L. et al. (2019). Kirilchuk, I., & Rykunova, V. (2019) Kirilchuk I. et al..(2019) Tkacheva T. et al. (2016).

In our opinion, the most important components of the assessment of the social orientation of the budget policy are, on the one hand, social standards that accumulate a level of decent and quality of life, and on the other – the effects of social action. But if the quantitative parameters of the functioning of social policy are defined and measured, the values, ideals, norms that simultaneously reflect and define the shape of social policy, themselves undergo economic and political metamorphoses.

A sign of the effectiveness of budget policy in the social aspect for the individual will be a sense of fullness of life, its qualitative manifestations, allowing to realize their needs and interests. A sign of the effectiveness of the budget policy in the social aspect for the society is the achievement of a high degree of satisfaction of the population with

Cite this Article as: Tatyana TKACHEVA Lubov AFANASYEVA and Alexander PIYALTSEV "Modern Approaches to Assessing the Effectiveness of Social Budget Expenditures" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the quality and availability of budget services, which will contribute to the optimal level of development of society and regions (figure 1).

Fig. 1: Social dominants of fiscal policy at the regional level

The main social priorities of the budget policy of the modern state are:

– unconditional fulfillment of legally established obligations to pay social benefits and compensation in the field of social protection of the population (taking into account changes in legislation aimed at improving the targeting of social assistance, the application of the principle of assessing the need for social support measures);

– ensuring the balance of the pension Fund budget and further development of the pension system;

– provision of obligations in the field of education, health, culture, taking into account the determination of the volume of guaranteed state (municipal) services in these areas and the formation of a single standard cost for their provision

It seems appropriate to identify two General approaches when assessing the social orientation of budget policy at the regional level:

1) process, which is based on the measurement and accounting of intermediate indicators. When assessing social orientation of the budgetary policy takes into account the amount of budget allocations for the implementation of a social program, social events, the number of people reached by a given program, etc. It should be noted that within the framework of the process approach it is necessary to carry out a systematic monitoring of the level of satisfaction of the population with the quality and availability of basic municipal budget services, as well as monitoring the effectiveness of the local government of municipal districts, urban districts and settlements;

2) effective, which is based on the evaluation of the final result. Its essence is to identify not only the most important values, attitudes, consequences of assistance and support, but also to assess the effectiveness of the use of budgetary funds. It is the effectiveness that determines the measure of serving the budget policy to a person.

The essence of the proposed methodology for assessing the social orientation of the budget policy of the region is the analysis and evaluation of indicators such as the effectiveness of the use of budgetary funds, cost and efficiency of the use of budgetary funds.

The effectiveness of budget expenditures is understood as the degree of satisfaction of the population with the quality and availability of budget services. This is a key indicator that characterizes the effectiveness of the use of budgetary funds by local governments of the relevant territory, it serves as a final social indicator of the effectiveness of the use of budgetary funds.

The criterion for achieving a positive result is the degree of customer satisfaction at the level of at least 70%, which corresponds to the requirement established by the Concept of administrative reform in the Russian Federation. The assessment should be carried out for 10 basic budget services: management, pre-school education, General education, additional education, improvement, housing and communal services, primary health care, culture, library services, physical education and sports, as well as the assessment as a whole.

In the social aspect of the budget policy, it is advisable to compare the average per capita expenditures of the regional budget for social needs in the dynamics for several years.

It should be noted that the average per capita social spending is directly dependent on the ratio of cash income and the subsistence minimum in the region – the richer the population, the greater the budget spending on the social sphere. There are two reasons for this. First, the higher level of income of the population is typical for regions with higher levels of budget revenues, therefore, in such regions there is an opportunity to spend more money on social policy. Secondly, higher income levels are accompanied, as a rule, and higher stratification of the population by income, so the government is relatively prosperous regions forced to spend heavily on social protection.

In our opinion, in modern conditions, it is absolutely expedient to compare the volume of financial resources spent on the social sphere of the region with the initially established amounts of budget commitments when assessing the cost (table 1).

For comparison of the amount spent budget resources to the social sector of the region initially defined volumes you can set other intervals of values to enter a six-step rating system, and a three-stage, seven-speed, etc. Can not be ignored in the calculations any costs, or, conversely, something to consider further. It is advisable to consider the costs ineffective, regardless of the result, if the non-targeted expenditure of funds related to the reporting period is revealed.

Table 1: Estimation of the budget resources spent on the social sphere of the region with the initially set amounts of budget commitments

№	Financial resources spent on the social sphere of the region	Degree of achievement	Cost-effectiveness evaluation
1	Savings of more than 15% of planned volumes	The result is achieved	Very high efficiency
2	Cost savings from 5% to 15% of planned volumes	The result is achieved	High efficiency
3	Spent budget funds with a deviation of less than 5% of the planned volumes	The result is achieved	Efficiently
4	Additional expenditure of funds in the amount of 5% to 15% of the planned volumes	The result is achieved	Low efficiency
5	Additional expenditure of funds in the amount of more than 15% of the planned volumes	The result is achieved	Ineffectively
6	Misappropriation of budgetary funds	Result not achieved	Ineffectively

In any case, to determine effectiveness is to correlate the result with the costs (or resources) that the result caused. However, the content of the performance indicator, what question it will answer, depends on what the researcher takes as a result and what as a cost.

As part of the study of the efficiency of budget expenditures of the region, it is advisable to correlate the gross value added of the region (result) with the budget expenditures of the region, which caused this result. Table 2 shows the proposed matrix of indicators of budgetary efficiency of the region.

Table 2: Matrix of indicators of budgetary efficiency of the region

Indicators	The issue of the region,	Regional budget expenditures,	Population of the region,	VDS
The issue of the region,	V	RB	H	VDS /V
V	1	RB/IN	H/IN	VDS /RB
Regional budget expenditures,	IN/RB	1	B/RB	VDS / H
RB	IN/ H	RB/ H	1	1

Depending on the objectives of the budget analysis, any detail of the budget results and budget expenditures is possible. The matrix is symmetric with respect to the main diagonal, and the values of the indicators are inversely proportional. If the values above the main diagonal rise, the values below the main diagonal fall.

Results and Discussion

Above the main diagonal, the figures are the opposite and show the capacity of our result relative to any type of cost (for example, gross value added is divided by the output of the region). Above the main diagonal are indicators of budget capacity.

In the opinion of many expert analysts, which we fully share, the criterion of the reasonableness of the allocation of budget resources should be formed on the basis of the opinion of the population about the quality and availability of budget services.

The consumer, namely his condition, needs and their priority – this is the basis for the allocation of resources.

Conclusions

As a result of the study, the following conclusions can be drawn:

1. the priority direction of the budget policy at the regional level in the coming years will be the provision of social obligations;

2. the effectiveness of budget expenditures is understood as the degree of satisfaction of the population with the quality and availability of budget services. This is a key indicator that characterizes the effectiveness of the use of budgetary funds by local governments of the relevant territory, it serves as a final social indicator of the effectiveness of the use of budgetary funds;

3. when assessing the social orientation of budget policy at the regional level, it is advisable to use two process and effective approaches. The proposed approaches are quite acceptable for the formation of the social dominant of budget policy and the allocation of budget allocations at the regional level.

Abstract

The paper is concerned with unobserved income as a limiting factor for sustainable social and economic development in the context of digitalization. The subject of the research are theoretical and methodological issues of unobserved income as a limiting factor for sustainable social and economic development in the context of digitalization. The purpose of the work is to substantiate a mathematical model reflecting regional differences in correlation between unobserved personal income and some characteristics of innovative digital development of the society on the basis of the analysis of the current state of unobserved income and factors affecting the level of digital and innovative development of the society. The paper reveals the substance of approaches to the implementation of the state policy of sustainable regional development in European countries. The study describes the key units of digital economy functioning which are closely interrelated and affect personal income and social and economic development of territories. Special attention is paid to modern research on the assessment of digitalization regarding Federal districts and economic and social effects of digitalization.

Keywords: Unobserved Economy, Unobserved Personal Income, Shadow Economy, Digital Economy, Sustainable Development.

Introduction

Research interest in unobsered personal income negatively affecting sustainable socio-economic development of regions, is growing all over the world. In the works of Russian and foreign authors, it is pointed out that a significant part of business activities is concentrated in the informal economy, and is more common to small businesses of various forms.

Unobserved personal income is in evidence in all countries including those with high socio-economic indices. It does not disappear with the development of digital economy and Internet technologies but transforms into new forms.

The constituent entities of the Russian Federation differ significantly in terms of natural and climatic conditions and the level of socio-economic development. Such regional features as significant differences in GRP per capita and average income per capita form a number of regional factors that determine the level of their informal economy, and at the same time are the result of their existence.

The subject of the research are theoretical and methodological issues of unobserved income as a limiting factor for sustainable socio-economic development in the context of digitalization. The purpose of the work is to substantiate a mathematical model reflecting regional differences of correlation between unobserved personal income and some characteristics of innovative digital development of the society on the basis of the analysis of the current state of unobserved income and specific factors affecting the level of digital and innovative development of the society.

The paper reveals the subject matter of approaches to the implementation of state policies of sustainable development of the regions in European countries. The study consideres the key units of digital economy functioning which are closely interrelated and affect the income of citizens and socio-economic regional

development. Special attention is paid to modern research on the assessment of digitalization in respect to Federal districts as well as to the economic and social effects of digitalization.

The study of scientific research works on the measurement of the unobserved economy shows a variety of approaches to this issue. To measure the unobserved (underground) economy, the volume of foreign-exchange transactions was estimated, since according to Gutmann currency is the only form of cash suitable for transactions that are not registered and are not taxed (Gutmann, 1977). It has been found out that many of the developed economies experience similar symptoms manifested as the existence of an unobserved sector (an unmeasured, tax-free, informal sector) (Feige, 1981). The "macroelectric" approach is applied to the measurement of the informal economy in Central and Eastern Europe (for measuring overall economic activity in the economy, the most informative indicator is electricity consumption) (Kaufmann and Kaliberda, 1996). The significance of the issue under study is confirmed by the fact that the Organization for Economic Cooperation and Development (OECD) issued "Measuring of the Non-Observed Economy: A Handbook" in 2002. The unobserved economy in scientific works is closely associated with the shadow economy, which has been studied in detail in (Schneider, 2009), (Schneider and Medina, 2017), systematic studies of the shadow economy are conducted by the World Bank (Schneider, 2010), (Medina and Schneider, 2018). The shadow economy is often seen as an unreported economic activity hidden from state institutions (Miller, 2006; Orviska et al., 2006; Biswas et al. 2012; Elgin and Uras, 2013; Putnins and Sauk, 2015).

The active use of digital technologies in all economic activities, formation of the digital economy using innovative tools are very important in the modern paradigm of sustainable development of economic systems and counteraction to the shadow economy and corruption (Tsepelev and Kolesnikova, 2019).

Illegal digital activities create a digital shadow economy. “The physical marketplace is rapidly transforming itself into a global electronic arena, where the multicultural consumer and its market-driven society merge and execute limitless electronic transactions at the touch of a trader's dealing screen, electronic transfers, credit and debit cards, smart cards, and so on. These are just some of the mediums which are now exploited by the money launderer without leaving paper/audit trails for law enforcement agencies and compliance communities. Advances in communications, information systems and cyber electronic innovations increasingly dispel the myth that crime stops at the border” (Haines and Johnstone, 1999).

The results of the comparative analysis of the traditional and digital shadow economies have shown that the digital shadow economy is of the same illegal nature and involves the same participants as the traditional shadow economy. The digital shadow economy is a part of the shadow economy (Gaspareniene and Remeikiene, 2015).

Based on the expert assessment of approaches to the interpretation of the digital shadow economy category the following definition is given: “digital shadow economy refers to illegal activities, such as digital service provision and sales of goods/services online, when operating exceptionally in digital space, the entities violate the existent legal norms and regulations with a pursuit of illegal mutual interest and material benefits”. The distinctive features of the digital shadow economy are described in (Remeikiene et al., 2018). The digital shadow economy is estimated using a modified simulation model, which is presented in the study (Gasparėnienė et al., 2018).

Applied studies of the processes of formation and development of social orientation of tax policy and evaluation of the effectiveness of tax and budget policy tools have been developed in the works Rykunova V. et al. (2017), Tsiklauri V. et al.(2019). Tciklauri V. et al. (2018), Tkacheva T, et al. (2016), Belousova L. et al. (2019). Kirilchuk, I., & Rykunova, V. (2019) Kirilchuk I. et al..(2019) Tkacheva T. et al. (2016).

Appreciating the contribution of scientists to the development of this area, it should be noted that there are some features of detecting unobserved income as a factor limiting sustainable socio-economic development in the context of digitalization that are specified using national statistics.

Results and Discussion

The digital economy has significant advantages over the traditional one, including reducing the risks of the expansion of shadow income due to the increase of state financial control.

The estimation of unobserved economic activities including unobserved personal income, is of great importance for the Russian statistics (Masakova, 2000). The income that is not directly observed by statistical methods has a negative impact on the development of the economy; the efficiency of the state macroeconomic policy decreases, the competitive environment for business worsens, and the social security of the working population decreases. Many researchers conclude that the income that is not directly observed by statistical methods is one of the components of the shadow economy.

Let us calculate the unobserved personal income (UPI) using formula (1). The results of calculations are shown in Figure 1:

$$UPI = PCE+CP - AMI \qquad (1)$$

PCE – personal consumption expenditures, mln. rub. CP – compulsory payments, fees and other expenditures, mln. rub.AMI - available money income, mln. rub.

The contribution of the Federal districts to the shadow (unobserved) personal income is presented in Figure 1. Note that in 2014 the Republic of Crimea and Sevastopol were included in the Southern Federal district; in 2018 the Republic of Buryatia and Zabaykalsky Krai that used to be parts of the Siberian Federal district were included into the Far Eastern Federal district.

Fig.1: Contribution of Federal districts into the dynamics of unobserved personal income, mln.rub.

Source: Developed on the basis of: (Russian Federal State Statistics Service)

Having identified the volumes and trends of unobserved income, we put forward a hypothesis about the correlation between the unobserved income (UPI) and factors reflecting the level of digital and innovative development.

Index of small businesses turnover (M) reflects the results of implementing new technologies, production efficiency, and the level of competitiveness. The number of active subscribers to mobile broadband Internet (AMBS) reflects the opportunities for GDP growth, creation of new jobs, development and quick introduction of innovative goods and services to the market, and improvement of the quality and availability of public services.

The parameters of the multiple regression equation were estimated using Statistica 10.0 software package. The results of the multiple regression are given in Table 1.

Table 1: Estimating the quality of the multiple regression equation

	Summary Statistics; DV: UPI (Spreadsheet1 UPI-AMBS-M-2018)
Statistic	Value
Multiple R	0,995899307
Multiple R?	0,991815429
Adjusted R?	0,988541601
F(2,5)	302,952791
p	0,00000606023923
Std.Err. of Estimate	98,5787982

Source: authors' own calculations using Statistica 10.0. software package.

Let us analyze the obtained results. So, the multiple correlation coefficient is Multiple R = 0.9958; the coefficient of determination is R-square = 0.9918; the coefficient of multiple determination adjusted considering loss of degrees of freedom is Adjusted R 2 = 0.98854; the Fisher Criterion is F = 302.952, the level of significance of the model is p < 0.0000; the Standard error of estimate is Std. Error of estimate = 98. Let's analyze the data of the multiple regression. The table value of the Student's criterion corresponding to the confidence probability is g = 0.95 and the degrees of freedom are v = 8-3=5; $t_{cr.}$ = t0, 05; 5 = 73. Comparing the calculated t-statistics of the equation coefficients (in Figure 2 t (5) is given) with the table value, we conclude that all the obtained coefficients are not statistically significant.

In Table 2 the results of calculating the parameters of the multiple regression equation are presented. The results of multiple regression are reflected in the following model (2):

$$UPI = -446.753 + 0.12 \times M + 5.251 \times AMBS \quad (2)$$

Table 2: Results of calculating multiple regression equation parameters

N=8	Regression Summary for Dependent Variable: UPI (Spreadsheet1 UPI-AMBS-M-2018) R= ,99589931 R?= ,99181543 Adjusted R?= ,98854160 F(2,5)=302,95 p<,00001 Std.Error of estimate: 98,579					
	b*	Std.Err. of b*	b	Std.Err. of b	t(5)	p-value
Intercept			-446,753	444,7519	-1,00450	0,361245
M	0,959272	0,055926	0,120	0,0070	17,15254	0,000012
AMBS	0,052022	0,055926	5,251	5,6450	0,93020	0,394964

Equation (2) expresses the dependence of the unobserved personal income (UPI) on the turnover of small businesses (M) and the number of active subscribers to mobile broadband Internet (AMBS). The coefficients of the equation show the quantitative impact of each factor on the resulting indicator while the others remain unchanged. In our case, the unobserved personal income increases by 0.12 monetary units with the increase in the turnover of small businesses by 1 unit, while the indicator of the number of active subscribers to mobile broadband Internet remains unchanged; the unobserved personal income increases by 5.251 monetary units with the increase in the number of active subscribers to the mobile broadband Internet (AMBS) and with a constant indicator of the turnover of small businesses.

The multiple correlation coefficient of the constructed model (Multiple R) R = 0.9958 is very close to unity, which indicates a high degree of correlation between the factors under study. The coefficient of determination (R Square) is R 2 = 0.9918, which indicates that 99.18% of the variation of the UPI variable is due to the variation of the M and AMBS variables, and only 0.82% is accounted for by other unaccounted factors. The critical (table) value of the Fisher criterion for confidence figure is g = 0.95 and the degrees of freedom are v1 = 8-3 = 5 and v2 = 2: $F_{cr.}$ = F0, 05; 5;2 = 19.03. The calculated value of the Fisher criterion F = 302.9527 is much higher than the table value of criterion F_{tb} = 19.03, which indicates a good quality of the constructed model (the model is comparable to the experimental data). The significance level p = 0.00000 indicates that the constructed regression is highly significant. Let us investigate the degree of correlation between the variables. To do this, a correlation matrix is built. The correlation matrix is presented in Table 3.

Table 3: Correlation matrix

Variable	Correlations (Spreadsheet1 UPI-AMBS-M-2018) Marked correlations are significant at p < ,05000 N=8 (Casewise deletion of missing data)				
	Means	Std.Dev.	UPI	M	AMBS
UPI	791,052	920,919	1,000000	0,995188	0,714297
M	6664,288	7389,375	0,995188	1,000000	0,690393
AMBS	84,000	9,124	0,714297	0,690393	1,000000

From the correlation matrix it follows that all the factors under study have a significant and approximately equal influence on the unobserved personal income (the correlation coefficients between UPI and M, AMBS, are 0.9951; 0.7142, respectively). The correlation matrix also shows that there is a multicollinearity between the factors (the correlation coefficients between the regressors M and AMBS are also high). Let us analyze the residuals of the regression. The residuals are the differences between the observed values and the model values, i.e. the values calculated according to the model with the estimated parameters. The observed residual variables presented in

Let us construct a graph/ illustrating the observed values of unobserved personal income (UPI) and the predicted values obtained using the multiple regression equation UPI = -446.753 +0.12×M +5.251×AMBS.

Thus, the constructed regression equation (2) is comparable to the experimental data (it has a high coefficient of determination and significant F-statistics) and can be used for practical purposes.

The mathematical model developed on the basis of the multiple regression equation can serve as a basis for forecasting and estimating the value of unobserved personal income as a factor limiting the sustainable development of the regions of the Russian Federation. The unobserved personal income is a potential resource that should be involved and estimated by official statistics tools.

The dependence we have identified shows that an increase in the turnover of small businesses and an increase in the number of active subscribers to the mobile broadband Internet lead to the increase in the amount of the unobserved personal income. Unobserved personal income is not observed by direct statistical methods for both statistical and economic reasons.

The emergence of new opportunities and their active use by the general public under the conditions of digitalization, the introduction of innovative processes by small businesses contribute to the growth of wages and business income. Current trends in minimizing cash flow and simplifying transactions make informal cash flows transparent, but at the same time, the active use of cryptocurrencies allows financial transactions to be performed beyond the control of government institutions. These new opportunities for income growth cannot be estimated and taken into account by the existing tools of official statistics. It should be noted that the obtained model reflects the regional differences in the correlation between the unobserved personal income (UPI) and factors characterizing the level of digital and innovative development of the society.

Conclusions

The state policy of sustainable development has a great potential in regulating innovative development and contains a wide list of tools to support regions targeted at the development of digital technologies.

The transition to a digital economy model is accompanied by fundamentally new, qualitative changes in social and economic relations both at the state level and at the level of economic entities. This process brings new opportunities and threats. Modern digital tools allow markets and economic sectors to develop even in the event of an economic crisis due to a quick and flexible response to changes in market conditions, and to meet consumers' needs better. It is proved that income not observed by direct statistical methods is one of the components of the shadow economy.

It is concluded that the index of small businesses turnover (M) reflects the results of the introduction of new technologies, production efficiency, the level of competitiveness; the indicator of the number of active subscribers to the mobile broadband Internet (AMBS) reflects the opportunities for GDP growth, creation of new jobs, development and quick introduction to the market of innovative goods and services, improvement of the quality and availability of public services. Unobserved personal income is not observed by direct statistical methods for both statistical and economic reasons.

Based on the analysis above, it was found out that an increase in the turnover of small businesses and an increase in the number of active subscribers to the mobile broadband Internet lead to the increase in the amount of unobserved personal income.

Abstract

This study examines the factors that influence the satisfaction of tourists visiting Trusmi, a centre for batik artisans and traders who have become a tourist village. Three predictors were chosen, including destination image, perceived value, and memorable tourism experience. Participants in this study were selected using the convenient sampling method. In total, 332 participants filled out the questionnaire completely. The data were then processed using exploratory factor analysis, confirmatory factor analysis, and structural equation models. As a result, the destination image had a significant effect on perceived value. Additionally, the perceived value affected a memorable tourism experience and tourist satisfaction.

Keywords: Batik, Trusmi, Destination Image, Memorable Tourism Experience, Textile-Based Tourism.

Introduction

Traditional textiles are one of the products of indigenous peoples which become the identity of them, which sometimes even becomes a national identity (Hani & Das, 2018). In its development, this textile is not just a piece of cloth but has been made into clothing and crafts which later becomes another expression of the artisan's identity (Sunarya, 2016). However, the issue of traditional textiles is not always related to the identity, design, benefits, and manufacturing process, but also to conservation, market acceptance, and sustainability.

Research on traditional textiles, traditional textiles as part of tourism, or traditional textile production areas has long been the focus of research. Some studies are interesting because they contain controversy. Several other studies link the role of tourism for traditional textiles. In Spain, old textile factory sites have been conjured up as part of an industrial tourist attraction (Coit, 2001). Furthermore, a study by Cohen (2001) investigated the link between tourism, traditional textiles, and the opinions of traditional textile producers. Meanwhile, Onderwater, Richards, and Stam (2000) explore the factors that influence tourists to buy souvenirs from traditional textiles. In addition, there are several other studies related to textile-based tourism. Suhud, Maulida, and Kusumawardani (2018) explore motivations and obstacles for tourists to visit a textile-based tourism destination. Besides, Suhud, Tarma, and Maulida (2019) study on authenticity of an indigenous elements including its textile. Another research from Suhud (2019) is about the personification of a destination that has a thick element of traditional textiles.

Indonesia is a country with many tribes and indigenous peoples. Almost all of them have their work products related to textiles. Some of them have modified the basic materials, colours, and workmanship techniques. Some others still maintain their authenticity. Some indigenous peoples have succeeded in making their products superior to products from other indigenous peoples. Several attempts have been made by the Indonesian government and the craftsmen to make their businesses survive and continue to grow. One of the efforts is to make traditional textile manufacturing centres as a tourism destination and this has been done for a long time.

Cite this Article as: Usep SUHUD, Heryanti UTAMI and Elena Puspita CANDRA "Tourists' Satisfaction in the Context of Traditional Textile-Based Tourism: What Factors Make Them Satisfied?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In general, research on tourism destinations will measure the internal and external factors of tourists. Internal factors include demographic, psychographic, attitudes, perceptions, and motivation. Meanwhile, external factors include the quality of services and products, prices, and promotional tools. In this case, the textile-based tourism destination is Trusmi. Trusmi is a village in Cirebon, a district in the province of West Java. This village is famous as a centre for batik craftsmen and traders. Batik is a traditional textile that has become Indonesia's identity and has been recognized by UNESCO as the Representative List of the Intangible Cultural Heritage of Humanity. Trusmi has become a destination village for national tourists who love batik. Therefore, this study aims to examine the factors that influence the satisfaction of tourists who stay in traditional textile-based tourism destinations by including destination image, perceived value, and memorable tourism experience as three predictor variables. We find research on tourist behaviour in the context of traditional textile-based tourism to be scarce. In general, research on traditional textile-based tourism has not received much attention from tourism scholars.

Literature Review

Theoretical Background

Destination Image

Destination image is formed from a tourist's experience of a tourism destination, even if the tourist has never visited it (H. Kim & Chen, 2016). According to Baloglu and McClreary (1999), the destination image consists of the cognitive, affective, and global elements of a tourist and this is influenced by personal factors and stimulus factors. Personal factors include psychological (values, motivation, and personality) and social (age, education, marital status, and others). While the stimulus factors consist of information sources, previous experience, and distribution). The tourist experience is created from the information he or she obtains, whether through other people's stories, news from the mass media, or social media. Television viewers who regularly watch foreign drama series from a foreign country can have a perception of the image of the country as the tourism destination of origin of the drama series (Suhud & Willson, 2018).

Perceived Value

Here are two prominent definitions of perceived value. Woodruff (1997, p. 142) defines perceived value as “customer’s perceived preference for an evaluation of those product attributes, attribute performances, and consequences arising from use that facilitate (or block) achieving the customer’s goals and purposes in use situations.” Zeithaml (1988, p. 14) defines perceived value as "the consumer's overall assessment of the utility of a product based on perceptions of what is received and what is given". These two definitions focus on customers and consumers who perceive the performance of the attributes and elements of a product. This perception works starting from the product before consumption, during consumption, or after consumption. Customers are different from consumers. Customers are those who buy and consume a product, while consumers are those who only consume the product. The product in these definitions refers to either goods or services. In the tourism industry, products also relate to goods and services.

Sánchez-Fernández dan Iniesta-Bonillo (2007) conduct a systematic review of studies on consumer value. According to them, those studies can be divided into two groups: unidimensional and multi-dimensional. Uni-dimensional consists of price-based studies, means-end theory, and additional research. An example of price-based studies is Monroe's research stream. Meanwhile, examples of the means-end theory are Zeithaml's approach, additional research, and the customer value hierarchy. Furthermore, multi-dimensional is divided into the customer value hierarchy and utilitarian and hedonic value. Utilitarian and hedonic value consist of axiology of value theory, Holbrook's typology of value, and consumption-value theory. The customer value hierarchy is an intersection of unidimensional and multi-dimensional. In the current study, we used a unidimensional approach of perceived value.

Prior studies have included perceived value as one of the variables that can affect visit and revisit intention, memorable tourism experience, trust, loyalty and tourist satisfaction (Jin et al., 2015; Moliner et al., 2007; Nugraha et al., 2019; Suhud et al., 2017; Thielemann et al., 2018). However, in this current study, perceived value is linked to memorable tourism experience and tourist satisfaction.

Memorable Tourism Experience

Traditional textiles are cultural products of an indigenous community. Tourists visiting a destination that has a traditional textile culture will, at one time or another, experience a certain tourism experience related to that textile, which is unforgettable. Several researchers have linked cultural elements into their memorable tourism experience. For example, Chen and Rahman (2018) state that memorable tourism experience is formed by tourist engagement and cultural contacts. Kim (2010, p. 2) defined memorable tourism experience (MTE) as “a tourism experience remembered and recalled after the event has occurred”. However, researchers are often confused by two terms that are similar but with different concepts and meanings, namely memorable tourism experiences and tourist experiences (H. Zhang et al., 2018).

Memorable tourism experience has been used to measure destination image, WOM intention, satisfaction, and revisit intention (J.-H. Kim, 2018; Song & Kim, 2017). In this current study, memorable tourism experience is linked to tourist satisfaction.

Tourist Satisfaction

When visiting a destination, a tourist has certain expectations for the attributes he will encounter in a tourism destination (Alegre & Garau, 2010). The attributes of a destination include, opportunity cost, hospitality, eating and drinking facilities, accommodation facilities, campground facilities, environment, and the extent of commercialization (Pizam et al., 1978). However, as times change and tourist behaviour changes, the attributes that tourists expect may differ. For example, tourists now hope that there will be easy internet access to how instagramable the places they visit.

There are only two possible feelings that we can find from tourists who visit a tourism destination: satisfied or dissatisfied (Alegre & Garau, 2010). The causes of contentment and dissatisfaction are the same. Many studies reveal the factors that influence this satisfaction and dissatisfaction, for example, destination image, tour quality, motivation, and perceived value (Lee et al., 2011; Som & Badarneh, 2011; M. Zhang et al., 2019).

Theoretical Framework

Destination Image and Perceived Value

Some studies examine the impact of perceived value on destination image. In contrast, in this current study, destination image examines perceived value. A study relating to island tourism is conducted by Cheng and Lu (2013). The scholars predict influencing factors of revisit intention. They link destination image of novelty, perceived value, and hedonic value. One of the results they document is that destination image significantly affects perceived value. Lin (2018) measures factors to influence environmentally responsible behaviour. In their study, destination image examines perceived value. As a result, destination image is claimed to have a significant effect on perceived value.

Some of the studies above lead us to this one hypothesis.

H_1 – Destination image will have a significant effect on perceived value.

Perceived Value and Memorable Tourism Experience

Previous studies demonstrate the impact of perceived value on memorable tourism experience. Nugraha et al. (2019) study intention of tourists to revisit a destination. They link perceived value to memorable tourism experience and revisit intention. Data were collected in seven major cities in Indonesia, including Jakarta, Bandung, Surabaya, Yogyakarta, Malang, Denpasar, and Makassar. They mention that perceived value significantly affects memorable tourism experience. Huang, Zhang, and Quan (2019) explore the impact of perceived value on memorable tourism experience and visit intention in the context of food event tourism. One of the findings they report that perceived value significantly affects memorable tourism experience.

We propose a hypothesis to be tested as follows.

H_2 – Perceived value will have a significant effect on memorable tourism experience.

Perceived Value and Tourist Satisfaction

Taking place in Mauritius, Ramseook-Munhurrun, Seebaluck, and Naidoo (2015) measure factors to influence tourist loyalty by involving international tourists. They claim that perceived value significantly affects satisfaction. Jin et al. (2015) employ perceived value to measure visit intention in the context water park destination. They compare first time visitors and repeater visitors. As a result, perceived value significantly affects satisfaction in both cases, first timers and repeaters. Furthermore, Rasoolimanesh, Dahalan, and Jaafar (2016) examine satisfaction of tourists who stay in a community-based homestay in the Lenggong Valley World Heritage Site by employing perceived value. This site is situated in Malaysia. They show a significant impact of perceived value on satisfaction.

The studies discussed above provide the basis for us to test this hypothesis.

H_3 – perceived value will have a significant effect on tourist satisfaction.

Memorable Tourism Experience and Tourist Satisfaction

Several studies examined the effect of memorable tourism experience on tourist satisfaction. In the study of Song and Kim (2017), memorable tourism experience is employed to assess memory of the trip and trip satisfaction. They say that memorable tourism experience is one of the important variables to shape tourists' satisfaction. Furthermore, Zhong, Busser, and Baloglu (2017) measure influencing factors of tourists' story telling. In this study, memorable tourism experience consists of seven dimensions including hedonism, novelty, culture, refreshment, meaningful, involvement, and knowledge. One of the findings they mention that memorable tourism experience significantly influences tourist's satisfaction.

Based on the above studies, we formulate a hypothesis as follows.

H4 – Memorable tourism experience will have a significant effect on tourist satisfaction.

Methods

Sample

This study required participants who had visited Trusmi at least once. For that, data collection was carried out in Trusmi. Participants were selected using a convenience sampling technique. They were asked one by one if they were willing to fill out the questionnaire. Once they agreed, a printed questionnaire was given to them to fill out.

Measures

There were four variables included in this current study. All variables were measured using indicators taken from previous studies. Destination image was examined by indicators adapted from Suhud and Willson (2018). Perceived value was measured using indicators adapted from Suhud and Wibowo (2016). Furthermore, memorable tourism experience was measured using indicators adapted from Kim (2018) and, Prougestaporn and Batra (2018). Lastly, revisit intention was measured using indicators from (Herstanti et al., 2014).

Data Analysis Methods

There were four phases of data processing that we conducted for this study. The data validity test is the first phase we do to analyse the data. This test uses exploratory factor analysis (EFA) with SPSS. The indicators that are considered valid are those that have factor loadings of at least 0.4 (Hair et al., 2019). EFA is also done to see the possibility of each variable having a dimension (component). The second phase is to evaluate construct reliability. Reliability of a construct is seen from its Cronbach's alpha value. If the calculated constructs have a minimum value of 0.7, then they will be deemed reliable and can be involved in testing at a later stage (Hair et al., 2019). The third phase is the calculation of confirmatory factor analysis (CFA) with AMOS software. The CFA helps us trim down indicators to truly valid ones that can survive use in hypothesis testing. The fourth phase is the final phase. In this phase, we calculate the structural equation model (SEM) with AMOS software. SEM is intended to test the research model or also known as hypothesis testing. There are four criteria selected to determine whether the model tested has achieved conformity, including probability, CMIN / DF, CFI, and RMSEA. A model is said to be fit if it has a probability value of 0.05 (Schermelleh-Engel et al., 2003) and CMIN/DF value of ≤ 2 (Tabachnick et al., 2007). Additionally, a fitted model also should have a CFI value of ≥ 0.97 (Li-tze Hu & Bentler, 1995) and RMSEA value of ≤ 0.05 (Li-tze Hu & Bentler, 1999).

Results

Participants

This study attracted 332 participants consisting of 209 females (63%) and 123 males (37%). Most participants (71.7%) were tourists domiciled in Jakarta. Talking about the level of education they had completed, 162 participants (48.8%) held undergraduate certificates. Regarding their marital status, 175 participants (52.7%) claimed to be single, and 147 participants (44.3%) claimed to be married. Furthermore, when asked about their employment status, 203 participants (61.1%) said they had a job, and 105 participants (31.6%) said they had not worked. Other information we obtain from respondents is about the frequency of tourists visiting Trusmi. Two hundred and twenty-two participants (66.9%) were first-time visitors. Furthermore, 80 participants (24.1%) had called twice, and 17 participants (5.1%) had visited three times. Meanwhile, the other 13 participants (3.9) have seen more than three times.

Table 1 : Profile of participants

Profile		Frequency	Percent
Sex	Male	123	37.0
	Female	209	63.0
	Total	332	100.0
Age	18-23	153	46.1
	24-29	28	8.4
	30-35	7	2.1
	36-41	12	3.6
	42-47	12	3.6
	48-53	78	23.5
	54-59	35	10.5
	60-65	7	2.1
Domicile	Jakarta	238	71.7
	Out of Jakarta	94	28.3
Level of education has been completed	Less than high school	5	1.5
	Highschool	83	25.0
	Diploma	26	7.8
	Undergraduate	162	48.8
	Graduate	56	16.9
Marital status	Unmarried	175	52.7
	Separated/divorced	4	1.2
	Married	147	44.3
	Widow/widower	6	1.8
Occupational status	Employed	203	61.1
	Unemployed	105	31.6
	Self-employed	19	5.7
	Retired	5	1.5

Data Validation and Reliability Tests

We conducted the data validity test on the four variables using exploratory factor analysis. With this analysis method, we proved whether a variable has dimensions or not. Besides, we also found valid indicators with a minimum loading factor of 0.4. From the calculation results, all variables have only one component, which means they have no dimensions. Furthermore, not a single variable had a factor loading of less than 0.4.

The next calculation we do is the reliability test. Destination image had an alpha value of 0.622, and perceived value had an alpha score of 0.696. Next, a memorable tourism experience had an alpha score of 0.688, and consumer satisfaction had a score of 0.787. That way, all variables could be considered reliable.

Table 2: Results of validity and reliability tests

	Variables and indicators	Factor loadings	Cronbach's alpha
	Destination image		0.622
D3	Trusmi has complete accommodation facilities	0.737	
D4	Trusmi has a good reputation as a tourist destination	0.733	
D1	Trusmi has a good quality of service for tourists	0.702	
D2	Trusmi is a great travel destination for families	0.572	
	Perceived value		**0.696**
V3	Trusmi offers good ticket prices	0.807	
V4	The overall value of batik in Trusmi is good	0.774	
V1	Doing tours in Trusmi makes me happy	0.664	
V2	The quality of batik in Trusmi extraordinary	0.641	

	Memorable tourism experience		**0.688**
M4	I could feel the local culture of Cirebon through Trusmi.	0.840	
M3	I gained a lot of new knowledge and experience after visiting Trusmi.	0.762	
M1	I have a pleasant experience from the facilities that available in Trusmi.	0.712	
M2	I rate facilities in Trusmi better than other destinations in Cirebon.	0.578	
	Tourist satisfaction		**0.787**
S2	I satisfied when visiting Trusmi.	0.818	
S1	I enjoyed to visiting Trusmi.	0.801	
S4	The experience of visiting Trusmi was exactly what I needed.	0.744	
S3	My choice to visit Trusmi was a good choice.	0.711	
S5	I have positive feelings about Trusmi.	0.617	

Hypotheses Tests

We tested the hypothesis using a structural equation model. The model tested (Fig. 1) had a probability score of 0.59, CMIN/DF score of 1.426, CFI score of 0.981, and RMSEA score of 0.36. These scores have met the criteria. Thus, this model could be said to be fit.

Fig. 1: Structural model of the hypotheses testing

Table 3 shows summary of the hypothesis testing. The first, second, and third hypotheses had critical ratio (C.R.) scores of 7.092, 7.781, and 3.321, respectively, indicating significances. However, the fourth hypothesis had a C.R. score of 1.126 showing an insignificance.

Table 3: Summary of the hypotheses testing

Hyp.	Path			C.R.	P	Results
H_1	Destination image	➔	Perceived value	7.092	***	Accepted
H_2	Perceived value	➔	Memorable tourism experience	7.781	***	Accepted
H_3	Perceived value	➔	Tourist satisfaction	3.321	***	Accepted
H_4	Memorable tourism experience	➔	Tourist satisfaction	1.126	0.260	Rejected

Discussion

Destination Image and Perceived Value

Destination image affected perceived value as reported by prior studies (Cheng & Lu, 2013; Lin, 2018). Before tourists visit a destination, they generally have expectations for that destination. When they arrive at that destination, the expectations may remain the same, or they may change. Same as the value they perceive. Value can be created before, during and after a visit to a destination. So, if the Trusmi they visit matches their expectations, and the value they feel is what they perceive, there is no reason for these tourists not to be satisfied with their visit to Trusmi.

Perceived Value and Tourist Satisfaction

Perceived value also measured tourist satisfaction (Huang et al., 2019; Nugraha et al., 2019). Destination managers, including shop owners and managers, always hope that tourists who visited their places where tourists who had values that are equivalent to their values. Mismatching values between those owned by the destination and those owned by tourists could result in gaps that lead to dissatisfaction. For this reason, destination managers need to formulate segmentation so that visiting tourists could understand if the value carried by the destination is not the same as that of tourists.

Perceived Value and Memorable Tourism Experience

Perceived value examined memorable tourism experience (Jin et al., 2015; Ramseook-Munhurrun et al., 2015; Rasoolimanesh et al., 2016). Tourists who visited Trusmi and thought that their visit had good value would tend to form an unforgettable experience. This experience formed from what they saw, felt, or heard. Indeed, this experience depended on the conditions of the destinations visited. In Trusmi, tourists saw rows of shops selling textiles and clothing made from batik, which it was a good experience for them, mainly because batik is made with a variety of motifs, colours, and materials.

Memorable Tourism Experience and Tourist Satisfaction

In general, tourists from outside the city visit the Trusmi Batik Complex in groups. There were groups of friends, family, spouses, and co-workers. In addition, not all visitors to this area shopped. Furthermore, in this area, there were not many activities that could be done by visitors, except to browse the merchandise offered and buy them. Thus, the experience experienced by tourists was very limited so that the memories created may be minimalist. Seeing this reality, textile-based tourism probably is niche tourism. It should be dedicated only for those who love traditional textile, traditional clothes, and shopping of traditional textile and traditional clothes. Those who had no interest in these things, they would feel bored. Previous research states that memorable tourism experience has a significant effect on revisit intention (Song & Kim, 2017; Zhong et al., 2017). However, this evidence was not valid in this study.

Conclusion

This study examined the effect of destination image, perceived value, and memorable tourism experience on tourist satisfaction. Participants are tourists who visit a tourism destination based on traditional textiles. As a result, the destination image had a significant effect on perceived value. Furthermore, the perceived value had a significant impact on tourist satisfaction and memorable tourism experience. Unfortunately, a memorable tourism experience did not have a substantial effect on tourist satisfaction.

This research teaches us how important it is to create a memorable tourism experience. Memorable tourism experience is considered important because it can have an impact on consumer satisfaction, also on the visit and revisit intention, as well as destination loyalty and word-of-mouth intention. Indeed, stimulating a memorable tourism experience is not an easy job for destination managers. But at least, they can pay attention to and improve the factors that can affect a memorable tourism experience.

We recognise some of the drawbacks of this study. Traditional textile tourism is part of cultural tourism. In general, this type of product is only attractive to tourists with a particular interest, especially in textiles and traditional clothing. For this reason, during participant selection, there should be screen questions about who should be involved. For example, those who visit this traditional textile-based destination because of their own will or because they want to see or buy. Thus, it is hoped that the research results will be better than the current one.

Traditional textile-based tourism destinations are found in countries with communities that are thick with textile cultures. Destinations like this can attract tourists who have a special interest in visiting. Research on the behaviour of tourists visiting such destinations is still limited. For this reason, future studies are expected to explore the same topic in different places.

Abstract

The article considers the basis of entrepreneurial activity as self-movement, which is caused by contradictions. Such contradictions include export in opposition to import, the balance of which is determined by the mode of production, international division of labor, and type of the socio-economic formation. It is possible to adequately assess the essence of the matter and the conditions for the development of entrepreneurship in the sphere of distribution, at the level of international trade, when diversity of socio-economic formations of different nations leads to identity of differences. As a result of modeling the possibilities of entrepreneurship development in Chuvashia founded on the basic Cobb-Douglas function, taking into account the dynamics of international trade turnover, the dominance of the dynamics of average per capita money incomes of the population over the index of industrial production was revealed. On the one hand, this dominance makes it possible, due to the low values of per capita money incomes to maintain identically low levels of industrial production, and on the other hand, stimulation of the growth of industrial production, above the threshold level of profitability of entrepreneurship, will cause an increase in average per capita incomes of the population and international trade turnover. The increase in the level of profitability of entrepreneurship in Chuvashia is associated with the chemical industry. The main areas of implementing possibilities of entrepreneurship development in cooperation with the chemical industry are business services in the information and communication sector, financial intermediation and administrative services provided by females, as nascent entrepreneurs in particular. Business opportunities in Chuvashia are determined by the potential and conditions for overcoming the limits of its own economic structure, which are revealed in international trade.

Keywords: Import, Modeling, Entrepreneurship, Production, Development, Export.

Introduction

The relevance of modeling opportunities for the development of regional entrepreneurship in Chuvashia is associated with the all-Russian problem of low entrepreneurial activity. Chuvashia is among the lagging regions of the Russian Federation. Minister of Industry and Trade of the Russian Federation Dmitry Manturov is authorized to

SEMENOVA "Modeling Entrepreneurship Development in Chuvashia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

supervise the development of Chuvashia. On 12 March 2020, a working meeting was held between D. Manturov and the Head of the Chuvash Republic O.N. Nikolaev, during which the details of the program of socio-economic development of Chuvashia until 2024 were discussed.

The Ministry of Industry and Trade of the Russian Federation, together with the Industrial Development Fund, decided to reduce the lower limit for loans under joint financing programs from 20 to 10 million rubles, as well as to reduce the share of co-financing from regional industrial development funds under joint loan programs from 30% to 10%. These innovations will significantly increase availability of debt financing for the modernization of enterprises.

On 4 April 2020, Minister of Economic Development of the Russian Federation Mikhail Reshetnikov spoke about measures to support subsidized regions at the President's meeting with members of the Government: "there are regions that, due to objective circumstances, do not have a developed industry, there is not enough economic potential, so it was decided to develop individual development programs for these ten regions in addition to existing measures... the republics of Adygea, Altai, Karelia, Tyva, Chuvashia, Mari-El and Kalmykia, Pskov region and Kurgan region, Altai territory. Their implementation will increase the income of their citizens in five years by 6.5 thousand rubles, or about 30%. The total amount of funding for such programs from the federal budget for the period up to 2024 will amount to an additional billion for each region per year. Co-financing from regional budgets – 1%. The main goal of all these measures is to create about 70 thousand new jobs in these regions".

To identify opportunities for the development of entrepreneurship in Chuvashia, we will use the model for determining conditions for doing business. The basis of entrepreneurship is self-movement of entrepreneurial activity, which is caused by contradictions. So, it is necessary to identify the contradictions that are the basis of entrepreneurship and affect the dynamics of entrepreneurial activity. Such contradictions should formally include export in opposition to import, which characterizes foreign trade, that in the aggregate of different countries represents international trade.

The nature, level of development and significance of foreign trade are determined by the mode of production, international division of labor and type of the socio-economic formation. Foreign trade was widely developed in the capitalist formation, at the stage of large-scale machine industry. "Capitalist production does not exist at all without foreign trade" (Marx K., Engels F., 1961), "... for its full development, the existence of credit and competition in the world market, which in general is the basis and vital atmosphere of the capitalist mode of production" (Marx K., Engels F., 1961).

The world market, being a historical prerequisite for the development of the capitalist mode of production, was at the same time its result. Foreign markets are an inseparable part of the capitalist market. "The necessity of an external market for a capitalist country is not determined by the laws of sales of the social product (and super-value in particular), ... capitalism is only the result of a widely developed commodity circulation that goes beyond the borders of the state. Therefore, it is impossible to imagine a capitalist nation without foreign trade, and there is no such nation" (Lenin V.I., 1971).

The widely developed commodity circulation in capitalism is connected with socialization of labor as a commodity. This is the basis and foundation of business activity, which is normatively fixed in the law. Article 2, paragraph 1: "The civil legislation shall regulate relations between the persons, engaged in business activities or in those performed with their participation, proceeding from the fact that the business activity shall be an independent activity, performed at one's own risk, aimed at systematically deriving a profit from the use of the property, the sale of commodities, the performance of work or the rendering of services" (Civil Code…, 2020).

Property is identified with a product that is able to create value, to a greater extent, additional. In this respect, neither Marx nor Lenin considered entrepreneurial abilities as factors of production, but used them only as part of the description of the total labor involved in the production process. According to Marx's ideas, any entrepreneur contributes to the formation of the final product value together with ordinary employees and workers, and this is not a problem. The problem does not arise in the sphere of production, but in the sphere of distribution. The compensation of an entrepreneur that he receives as a reward for his business activities in the form of profit is not proportional – it is high relative to the share in the total labor aimed at forming the total value.

The active entry of the capitalist formation into the modern social consciousness places entrepreneurial ability at the level of factors of production. It is possible to assess adequately the essence of the matter and the conditions of entrepreneurship in the sphere of distribution at the level of international trade, when diversity of socio-economic formations of different nations leads to identity of differences. Thus, it is possible to identify the environment for the development of entrepreneurship and determine methods for assessing its development. So, the dynamics

(contradictions) of international trade is the object of modeling the opportunities for entrepreneurship development in Chuvashia.

Methodology

To model the opportunities for entrepreneurship development in Chuvashia, we apply descriptive statistics methods that include processing of empirical data, systematization, visual representation in the form of graphs and tables, their quantitative description by means of basic statistical indicators (King, Eckersley, 2019). With the help of tables, charts and summary measures the behavior of each variable is described. Tables, charts and graphs are constructed using "MS Excel", "IBM SPSS Statistics Software" (Fávero, Belfiore, 2019). Descriptive statistics assesses an array of data based on statistical indicators.

Statistical analysis will serve as a method of collecting, studying and presenting large amounts of data on characteristics[1] and relationships of data, correlation relationships of spatial and time series of indicators, while maintaining the research methodology.

The use of cluster analysis is due to the fact that statistical methodologies rely on probabilistic understanding of causality (Urlacher, 2020) and require justification of the connectivity of changes in the estimated indicators.

Literature Review

To understand the possibilities of regional entrepreneurship development, it is necessary to define the business process as an objective whole. At the same time, the whole model acts as a measure of the unity of quantity and quality of the description of business activity and the real basis of its concept.

The use of mathematics and logic, as a basis and condition, serving as a model allows us to efface the boundaries between modeling tools. Mathematical modeling of entrepreneurship is carried out within the framework of its idea as an independent activity, performed at one's own risk, aimed at systematically deriving a profit from the use of the property, the sale of commodities, the performance of work or the rendering of services.

Active implementation of the idea of entrepreneurship in all countries is associated with the UN Sustainable Development Goals (SDGs). For example, Sustainable Development Goal 8 is to promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all. To ensure sustainable economic growth, it is necessary to create conditions for high-quality work that stimulates economic development without harm to the environment.

Through the created conditions and the combination of the SDGs that determine these conditions, as well as practical consequences, trust is built between the UN and social entrepreneurial enterprises (Günzel-Jensen, Siebold, Kroeger, Korsgaard, 2020), the ideas of potential entrepreneurs about entrepreneurship are expanded, and they have a positive effect on entrepreneurial activity in society.

To achieve SDG 8, it is necessary to determine the true intentions to start a business and the ability to do so, i.e. the relationship between entrepreneurial intentions and behavior. Entrepreneurial intentions include a positive relationship with entrepreneurial passion (Syed, Butler, Smith and Cao, 2020), which suggests desirability as the main determinant of entrepreneurial goal setting, followed by self-efficacy, feasibility, opportunity, attitude, and collective effectiveness (Esfandiar, Sharifi-Tehrani, Pratt and Altinay, 2019) .

For an entrepreneur, it becomes apparent that there is a movement towards a cognitive-personal social career (self-efficacy, expectation of a result and intention), which coincides with his behavior in the ratio of goals and level of determination for an entrepreneurial career (Pérez-López, González-López and Rodríguez-Ariza, 2019). This leads to entrepreneurial identification, through social identity perspectives and role conflict (Zou, Li, Guo and Guo, 2019). For example, the modern entrepreneurial decision-making process is decomposed into seven levels of engagement, ranging from "never thought about starting a business" to "gave up", "thought about it", "took steps to start", "had a young business", "had an old business", and "will no longer be an entrepreneur" (Grilo and Thurik, 2008).

The multi-source dataset of 337 Standard & Poor (S&P) 500 companies for 2007-2015 showed that entrepreneurship-oriented managers tend to focus more on value creation (such as developing a new product) than on value assignment (such as advertising), but this influence depends on at least three factors: (1) the firm's relative performance, (2) compensation strategy, and (3) capital market patience (Wang, Dass, Arnett and Yu, 2020). Thus,

business activity in a broad sense is a positive factor for economic growth (Almodóvar-González, Fernández-Portillo and Díaz-Casero, 2020), including increasing the effectiveness of the relationship between business relations and activities.

Despite positive changes in Russia's positioning in various international ratings, the country's investment and business climate is not attractive enough for foreign investors (Smirnov, Talanova, Zakharova, Dulina, Getskina, Huraskina, 2018, Zakharova A.N., Dulina G.S., Talanova T.V., 2020). The observed systemic disregard for the problems of entrepreneurial trust and corruption, against the background of general instability of the economy and its perception, causes instability of the values of society and hampers the development of entrepreneurship (Smirnov, Semenov, Zakharova, Kadyshev. Dulina, 2019, Zakharova A.N., Dulina G.S., Talanova T.V., Semenov V.L., Gubanova N. G., Getskina I.B.,2018).

The current state of the small and medium-sized enterprises (SMEs) sector in Russia is of serious concern, which is caused by the unstable dynamics of changes in their number and employees, the formation of an unbalanced territorial structure of SMEs with their concentration in certain regions and their shadowization. Most of the SMEs conduct their economic activities within the so-called "shadow" sector of the economy, which indicates the inefficiency of the economic system as a whole.

Effective support for the development of SMEs can be based on the following principles: local governments should not substitute entrepreneurial initiatives; they should provide entrepreneurs with services that the private sector is unable to develop and should proceed from the priority of the development of public services that contribute to the achievement of the goals and objectives of socio-economic development of the territory that have the greatest multiplicative economic effect (Smirnov, Zakharova, Talanova, Dulina, Gubanova and Getskina, 2019).

The authorities need to preserve the existing credit of trust through comprehensive and consistent measures that involve the promotion of financial, informational, organizational and institutional support for entrepreneurship in priority sectors.

The analysis of Russian entrepreneurial priorities according to the Global Entrepreneurship Monitor (GEM) revealed the following positions in the hierarchy of rates of gain:

1) indicators of entrepreneurial behavior (table 1):
- active gain – "Percentage of those involved in (Total Early-Stage Entrepreneurial Activity) TEA in the 'Business Services' sector – Information and Communication, Financial Intermediation and Real Estate, Professional Services or Administrative Services, as defined by the ISIC 4.0 Business Type Codebook, Business Services Sector" and "Percentage of female 18-64 population who are either a nascent entrepreneur or owner-manager of a new business, divided by the equivalent percentage for their male counterparts, Female/Male TEA Ratio";

Table 1: Hierarchy of rates of gain entrepreneurial behavior in Russia by median values (Me, %), 2007-2019

Indicator	Me, %
Percentage of those involved in TEA in the 'Business Services' sector – Information and Communication, Financial Intermediation and Real Estate, Professional Services or Administrative Services, as defined by the ISIC 4.0 Business Type Codebook, Business Services Sector	33.75
Percentage of female 18-64 population who are either a nascent entrepreneur or owner-manager of a new business, divided by the equivalent percentage for their male counterparts, Female/Male TEA Ratio	22.86
Percentage of 18-64 population who are currently an owner-manager of an established business, i.e., owning and managing a running business that has paid salaries, wages, or any other payments to the owners for more than 42 months, Established Business Ownership	6.32
Percentage of 18-64 population (individuals involved in any stage of entrepreneurial activity excluded) who see good opportunities to start a business but indicate that fear of failure would prevent them from setting up a business, Fear of Failure	3.62
Percentage of 18-64 population who agree with the statement that in their country most people consider starting a business as a desirable career choice, Entrepreneurship as a Good Career Choice	2.11
Percentage of those involved in TEA that are improvement-driven opportunity motivated, divided by the percentage of TEA that is necessity-motivated, Motivational Index	1.26
Percentage of 18-64 population who agree with the statement that in their country successful entrepreneurs receive high status, High Status to Successful Entrepreneurs	0.89
Percentage of 18-64 population (individuals involved in any stage of entrepreneurial activity excluded) who see good opportunities to start a firm in the area where they live, Perceived Opportunities	0.32

Percentage of 18-64 population (individuals involved in any stage of entrepreneurial activity excluded) who are latent entrepreneurs and who intend to start a business within three years, Entrepreneurial Intentions	-0.69
Percentage of 18-64 population (individuals involved in any stage of entrepreneurial activity excluded) who believe they have the required skills and knowledge to start a business, Perceived Capabilities	-1.14
Percentage of those females involved in TEA who (i) claim to be driven by opportunity as opposed to finding no other option for work; and (ii) who indicate the main driver for being involved in this opportunity is being independent or increasing their income, rather than just maintaining their income, divided by the equivalent percentage for their male counterparts, Female/Male Opportunity-Driven TEA Ratio	-2.15
Rate of involvement of employees in entrepreneurial activities, such as developing or launching new goods or services, or setting up a new business unit, a new establishment or subsidiary, Entrepreneurial Employee Activity	-4.29
Percentage of those involved in TEA who indicate that their product or service is new to at least some customers and that few/no businesses offer the same product, Innovation	-8.08
Percentage of those involved in TEA who expect to create 6 or more jobs in 5 years, High Job Creation Expectation	-10.80
Percentage of 18-64 population who are either a nascent entrepreneur or owner-manager of a new business, Total Early-Stage Entrepreneurial Activity (TEA)	-20.37

Source: calculated in "SPSS Statistics" based to the Global Entrepreneurship Research Association, London Business School. Entrepreneurial Behaviour and Attitudes. https://www.gemconsortium.org/data/key-aps (10 March 2020).

- active decline – "Percentage of 18-64 population who are either a nascent entrepreneur or owner-manager of a new business, Total Early-Stage Entrepreneurial Activity (TEA)" and "Percentage of those involved in TEA who expect to create 6 or more jobs in 5 years, High Job Creation Expectation";

2) indicators of entrepreneurial framework conditions (table 2):
- active gain – "Degree to which training in creating or managing SMEs is embedded in the general system of education and training at primary and secondary levels, Basic School Entrepreneurial Education and Training" and "Availability of financial resources for small and medium-sized enterprises (including grants and subsidies), Financing for Entrepreneurs";

Table 2: Hierarchy of rates of gain entrepreneurial framework conditions in Russia by median values (Me, %), 2007-2019

Indicator	Me, %
Degree to which training in creating or managing SMEs is embedded in the general system of education and training at primary and secondary levels, Basic School Entrepreneurial Education and Training	18.57
Availability of financial resources for small and medium-sized enterprises (including grants and subsidies), Financing for Entrepreneurs	5.90
Degree of freedom for new firms to enter existing markets, Internal Market Openness	4.02
Extent to which government policies support entrepreneurship – entrepreneurship as a pressing economic issue, Government Support and Policies	2.29
Extent to which national research and development will lead to new commercial opportunities and be accessible to SMEs	1.47
Level of changes in the markets from year to year, Internal Market Dynamics	0.69
Degree to which training in creating and managing SMEs is embedded in the general system of education and training in higher education institutions, such as vocational schools, colleges, business schools, etc., Post School Entrepreneurial Education and Training	-1.05
Extent to which government policies support entrepreneurship – taxes or regulations are size neutral or encourage new and SMEs, Taxes and Bureaucracy	-2.03
Availability of property rights, commercial, accounting and other legal and valuation services and institutions supporting and assisting SMEs, Commercial and Professional Infrastructure	-3.36
Availability and quality of programs of direct support for SMEs at all levels of government (national, regional, municipal), Government Programs	-3.73
Ease of access to physical resources (communications, utilities, transport, land) or space at a price that is not discriminatory to SMEs, Physical and Service Infrastructure	-6.16
Extent to which social and cultural norms encourage or allow actions leading to new business practices or activities that have the potential to increase personal wealth and income, Cultural and Social Norms	-7.40

Source: calculated in "SPSS Statistics" based to the Global Entrepreneurship Research Association, London Business School. Entrepreneurial Framework Conditions. https://www.gemconsortium.org/data/key-nes

- active decline – "Extent to which social and cultural norms encourage or allow actions leading to new business practices or activities that have the potential to increase personal wealth and income, Cultural and Social Norms" and "Ease of access to physical resources (communications, utilities, transport, land) or space at a price that is not discriminatory to SMEs, Physical and Service Infrastructure".

So, Russian entrepreneurial priorities reflect the following possibilities of entrepreneurship development: basis – business services sector – information and communication, financial intermediation and real estate, professional services or administrative services; females who are either nascent entrepreneurs or owner-managers of a new business; conditions – training in creating or managing SMEs, availability of financial resources for small and medium-sized enterprises and entrepreneurs.
The limits for Russian entrepreneurship are percentage of nascent entrepreneurs (owner-managers of a new business) and percentage of those involved in TEA who expect to create 6 or more jobs in 5 years. In turn, the conditions for this limit are social and cultural norms that encourage or allow actions leading to new business practices or activities, as well as ease of access to physical resources and space at a price that is not discriminatory to SMEs (physical and service infrastructure).

Results

Analysis

To model the possibilities of entrepreneurship development in Chuvashia, we will assess the dynamics of international trade according to the Foreign Economic Activity Commodity Nomenclature (FEACN) of import and export based on the data of the Federal customs service of the Russian Federation.

As a result of determining the significant positions according to the FEACN of import and export of Chuvashia, the following priority areas related to the chemical industry were identified:

1) import by FEACN: 2921410000; 2924299900; 2924299909; 2926909800; 2931908002; 2933399900; 2933698000; 2933998008; 2934999000; 2935909000; 2935909001; 2935909009; 3808919000; 3808925000; 3808932700; 3920995900; 7007192000-M2;
2) export by FEACN: 2933998008; 3808925000; 3808932700.
So, according to the through flow of international trade, the priority is chemical products by FEACN 2933998008; 3808925000; 3808932700.

For the target orientation (organization) of international trade by the FEACN, a cluster analysis of significant (more than one million USD) commodity groups was carried out and “contradictory” (the reason for self-movement) clusters were identified:

- FEACN 2924299900 – “China – import” and FEACN 8419818000 – “Kazakhstan-export”;
- FEACN 2924299909 – “China – import” and FEACN 1905329900 – “China-export”;
- FEACN 2926909800 – “China – import” and FEACN 1905329900 – “China-export”;
- FEACN 2933998008 – “China – import” and FEACN 3808932700 – “Kazakhstan-export”;
- FEACN 2934999000 – “China – import” and FEACN 3808932700 – “Kazakhstan-export”;
- FEACN 2935909001 – “China – import” and FEACN 8537109900 – “Kazakhstan-export”;
- FEACN 8112997001 – “Korea – import” and FEACN 0901210001 – “Belarus-export”; FEACN 2853909000 – “Italy – export”; FEACN 3812310000 – “Poland – export”.

In the above commodity group contradictory clusters, closed to China, are the main basis of international trade turnover at a value in USD FEACN 2924299909; 2926909800 at FEACN 1905329900. Excluding the trade turnover closed to China, we will determine the potential of international trade turnover, which is the function of entrepreneurship possibilities in Chuvashia.

The potential of international trade turnover in Chuvashia reflects a pronounced negative character ($y = -4E+06 \cdot x^2 + 1E+07 \cdot x + 1E+07$, $R^2 = 0.9217$), with the absolute median value $Me_{absolute}$ = 14912066.3 USD (the asymmetry of the distribution is equal to -0.5) and rates of gain $Me_{rates\ of\ gain}$ = -56.7% (the asymmetry of the distribution is equal to -1.0) (figure 1).

Fig. 1: Potential of trade turnover – function of opportunities of entrepreneurship existence in Chuvashia

(Source: calculated in "SPSS Statistics" based on the Federal customs service. Customs statistics of foreign trade of the Russian Federation. http://stat.customs.ru)

So, there is a significant acceleration of negative dynamics (rates of gain) of international trade turnover ($y = 22.351 \cdot x^2 - 196.35 \cdot x + 331.23$, $R^2 = 1$), which is a negative point (parameter) in the model of possibilities of entrepreneurship development in Chuvashia.

Modeling

To model possibilities of entrepreneurship development in Chuvashia we apply the Cobb-Douglas function as a basis, but changing it with respect to the dynamics of international trade turnover, which is presented in the formula as the base ($y = 22.351 \cdot x^2 - 196.35 \cdot x + 331.23$):

$O = (22.351 \cdot L^{\alpha} - 196.35 \cdot L^{\beta} + 331.23) \cdot (22.351 \cdot K^{\alpha} - 196.35 \cdot K^{\beta} + 331.23)$
where L – average per capita money incomes of the population (as a percentage to the previous year); K – industrial production index (as a percentage to the previous year).

As a result of applying the proposed formula, followed by a polynomial approximation, we get the function of possibilities of entrepreneurship development in Chuvashia: $y = 1.7439 \cdot x^3 - 14.873 \cdot x^2 + 38.498 \cdot x - 18.251$ (figure 2).

Fig. 2. Possibilities of existence of entrepreneurship in Chuvashia
(Source: calculated in "SPSS Statistics" based on the Federal customs service. Customs statistics of foreign trade of the Russian Federation. http://stat.customs.ru)

This function takes into account the influence of the dynamics of average per capita money incomes of the population and industrial production index on the activity of international trade turnover, as the main driver of entrepreneurial activity development in the region.

So, in Chuvashia, the determining factor of entrepreneurship is the dynamics of average per capita money incomes of the population, which makes it possible, due to its low values, to significantly reduce the need to increase the industrial production index. At the same time, stimulation of industrial production growth will cause an increase in average per capita incomes of the population and international trade turnover, thereby affecting the growth of entrepreneurship in Chuvashia.

The threshold value of profitability of entrepreneurship development possibilities in Chuvashia is x = L = K = 0.6 (figure 3).

Fig. 3: Profitability of the possibility of entrepreneurship in Chuvashia
(Source: calculated in "SPSS Statistics" according to Fig. 2)

In other words, to ensure the profitability of possibilities of entrepreneurship development in Chuvashia, the average per capita money incomes of the population and the industrial production index must exceed 60% of the maximum level. This level is estimated relative to donor regions or developing countries with high entrepreneurial activity.

Discussion of Results

As a result of modeling the possibilities of entrepreneurship development in Chuvashia founded on the basic Cobb-Douglas function, taking into account the dynamics of international trade turnover, the dominance of the dynamics of average per capita money incomes of the population over the index of industrial production was revealed. On the one hand, this dominance makes it possible, due to the low values of per capita money incomes to maintain identically low levels of industrial production, and on the other hand, stimulation of the growth of industrial production, above the threshold level of profitability of entrepreneurship, will cause an increase in average per capita incomes of the population and international trade turnover, thereby affecting the growth of entrepreneurship in Chuvashia.

The increase in the level of profitability of entrepreneurship in Chuvashia is associated with the chemical industry according to FEACN 2933998008; 3808925000; 3808932700, which is more closed to China according to FEACN 1905329900; 2924299909; 2926909800.

Business services in the information and communication sector, financial intermediation and administrative services can be identified as opportunities for developing entrepreneurship in cooperation with the chemical industry. Females, nascent entrepreneurs (owner-managers of new businesses) can act as actors of interaction. This is facilitated by the established social and cultural conditions that encourage or allow appropriate actions, as well as ease of access to physical resources and service infrastructure.

Conclusions

Possibilities of increasing entrepreneurial activity in lagging regions, which, due to objective circumstances, do not have a developed industry, where there is no sufficient economic potential (low incomes and investment, high unemployment and poverty) lie in the plane of international trade. The regions are thus able to overcome the limits not only of their own economic structure, but of the Russian economy as a whole.

Active interaction with socio-economic formations of other countries allows us to discover new opportunities for the development of entrepreneurship in Chuvashia. At the same time, contradictions in international trade become the object of modeling opportunities for entrepreneurship development in Chuvashia.

As a result of modeling founded on the basic Cobb-Douglas function, taking into account the dynamics of international trade, the interdependence of the growth of industrial production and average per capita money incomes with the chemical industry was revealed. This interdependence makes it possible to use business services of the information and communication sector, financial intermediation and administrative services, in which females, nascent entrepreneurs who are not burdened with high wage requirements, but are more responsible and diligent can act as actors of interaction.

Sectoral Structures and Regional Economic Development in European Union

Magdalena CYREK

University of Rzeszow, Poland, mcyrek@ur.edu.pl

Piotr CYREK

University of Rzeszow, Poland, piotrcyr@univ.rzeszow.pl

Abstract

The study deals with problems of sectoral structures of employment perceived as a determinant of economic results in terms of GDP per capita. The analysis is conducted for NUTS2 regions in European Union. The aim of the research is to identify clusters of regions basing on structural features of employment. To fulfill the task a Ward method is used. The paper verifies if the clusters with different sectoral labor distribution are simultaneously diversified concerning productive results of economic activity. Moreover, it is tested if the specified groups of regions are differentiated in terms of some selected indicators of human resources accessibility and labor market condition. Concerning the purpose, an analysis of variance is conducted. The results allow to conclude about positive relation between structural maturity and economic development for the EU regions. It suggests that some of regional economies may experience a middle-income trap, basing on traditional sectors and less intensive knowledge usage that limits possibilities for accelerated economic growth and improvement of quality of life. It is also found that more advanced economies in terms of sectoral structures are characterized by better human resources endowment, while sectoral labor distribution does not differentiate actual condition of a labor market. The research confirms a long-term character of the relations between sectoral structures and labor, that could be strengthen by economic policy supporting investments in human resources.

Keywords: sectoral structures, economic development, regions, European Union.

Introduction

Economic development is defined as quantitative and qualitative changes in production and consumption of goods and services. A final aim of the process of development is to improve quality of life, however, in economic terms it is usually limited to a growth of GDP per capita. Although GDP has a lot of limitation when describing welfare of society and human well-being, it is still important to specify factors influencing growth of production and finally contributing to a better life. Important part of economic development is constituted by structural transformation, and sectoral modernization is perceived as an indicator of economic maturity.

Relationships between productive results (GDP per capita) and sectoral distribution of economic activity may be analyzed at regional level. Numerous research stress that, even within converging groups of countries such as the European Union members, regional economies diverge (see e.g. Neculita and Sarpe, 2019; Longhi and Musolesi, 2007). Differences in sectoral structures and a kind of specialization may be one of the reasons. Structural features may lead some less developed regions to a middle income trap if they do not trigger their endogenic resources to innovate and modernize the economy.

It is worth noting that structural dimension of regional development is somehow neglected in economic debate (comparing to numerous research about economic development at an aggregate level), as determinants of interregional diversification of GDP per capita are found mainly in available endogenous resources, technology, infrastructure or institutions studied at an aggregate level. Meanwhile, sectoral distribution of resources and technology seems to play an important role in both a level of regional development and a process of reduction of regional disparities. Sectoral features of economy are decisive for quantity and quality of resources demanded, of which labor constitute an important part. Sectoral features determine regional productivity and its changes induced by technological progress (often sector bias technical change). Sectoral features of a region may influence its

Cite this Article as: Magdalena CYREK and Piotr CYREK " Sectoral Structures and Regional Economic Development in European Union " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

availability to take part in interregional networks as well as gain competitive advantage while competing for both resources and markets for their products. Sectoral features (especially kind of specialization) specify vulnerability of a region to shocks. Finally, sectoral features appoint general standard of living for citizens and possibility to satisfy their needs.

Concerning the relationships stated above, the aim of the study is to identify groups of regions in the European Union that are specified by economic structures with different level of advancement. It is tested if such groups are characterized by different level of economic results in terms of GDP per capita as well. It is expected that structural maturity goes along with a high production. The less advanced regional economies may thus experience a middle income trap. The paper also tests if structural differences are related to differences in human resources availability and condition of a labor market. Human resources are perceived in this context as one of important endogenic factors able to accelerate regional development in conditions of a knowledge-based economy.

The paper is structured as follows: the next section gives short review of discussion concerning problems of economic structures and regional development, the following section presents methods and data used in the research, then the main results are described and finally conclusions are drawn.

Literature Review

Economists try to explain regional differences using different models and theories, also those taking into account structural characteristics. Development economics identifies some patterns of structural modernization that seem to be universal and can allow to specify a level of advancement of an economy as well as to formulate some advice about structural policy. Theory of three sectors (early formulated by Fisher, 1935; Clark, 1940; Fourastié, 1949) points at tendencies to industrialization followed by a shift towards services. Modern studies indicate at knowledge-intensive and high-technology sectors development in the most advanced economies (see e.g. Ciriaci and Palma, 2016).

The neoclassical growth and regional development attitude explains interregional differences by resources endowment, comparative advantage and predicts existence of catching up processes (e.g. Solow, 1956; Barro and Sala-i-Martin, 1992). In contrary, model of inverted U curve proposed by Williamson (1965) suggests that regional disparities initially growth and convergence takes place at advanced stages of development, while endogenous growth theory and New Economic Geography points at divergence of regional GDP per capita connected with concentration of economic structures (e.g. Krugmann, 1991; Neculita and Sarpe, 2019). Generally a concept of structural convergence proposed by Wacziarg (2001) is empirically tested, still with ambiguous results.

Moreover, structuralists discuss problems of a middle income trap (e.g. Felipe, Abdon and Kumar, 2012; Eichengreen, Park, and Shin, 2013) that has its basis in sectoral structures of economies and pay attention to longstanding global divide connected with sectoral specialization. The division has its roots in specialization based on comparative advantage that pushes less developed economies into natural resources usage or labor-intensive branches and limit growth of wages and thus quality of life. As a solution, on the one hand, state interventionism is suggested that may help in development of domestic high-technology sectors by protection of the economy. On the other hand, liberalization and more openness for inflow of foreign investments (that allows for technology diffusion) is advised (within so called Washington Consensus). Modernly discussed New Structural Economics (see e.g. Lin and Chang, 2009; Rodrik, 2011; Lin, 2011, Lin, 2015) suggests an active role of state that should correct market externalities, provide information and coordinate investment and thus help in development of new sectors that can reveal comparative advantage. It is also pointed out (Kallioras and Petrakos, 2010) that a kind of specialization plays prevailing role for economic development and structural diversification is promoted (e.g. Longhi and Musolesi, 2007).

Summing up, both theory of regional development as well as structuralism do not provide a unique recipe for economic policy that could be able to reduce disparities and shape most favorable economic structure. The problem of regional divergence and a role of sectoral transformation in minimizing economic disparities is still a pending issue.

Research Methods

The paper adopts regional attitude to the analysis specified in the NUTS2016 classification for the European Union. It takes into account 281 regions of NUTS2 level, however, data unavailability limits the sample to 278 regions (regions FRM0, FRY5 and FI20 were excluded from the analysis).

Structural characteristics of the regional economies are specified in terms of functional groups of sections of economic activity defined in NACE Rev. 2. They cover 5 broadly specified sectors, e.g.:

- Agriculture (section A),
- Industry (sections B-F),
- Classical services – less knowledge-intensive services LKIS (sections G-I),
- Financial and business services – knowledge-intensive market services MKIS (sections J-N),
- Welfare services – knowledge-intensive non-market services OKIS (sections O-U).

The classification takes into account type of activities and their main features in terms of factors of production usage and organization of productive processes. Especially, it considers circumstances of knowledge-based economy model by including intensity of knowledge usage specified by engagement of highly educated employees.

Economic structures analyzed in the study are specified by distribution of employees across the 5 sectors of activity. A share of employment in each sector is calculated to avoid problems of comparisons of different scale regional economies. For each region the shares sum to 100%.

The EU regions are grouped with the usage of Ward method of agglomeration which is recognized as an effective hierarchical cluster analysis. In the process of agglomeration the Euclidean distance is adopted as a measure of distance between objects (regions). The agglomeration allows to specify clusters of the EU regions with similar features of sectoral distribution of employment.

An initial assumption of interrelations existing between sectoral structures of economies and other features of economic development requires to verify its validity. Thus, analysis of variance is conducted in the paper to test (assuming α=0,05) if some selected economic characteristics are essentially differentiated between the specified groups of regions. Firstly, we consider GDP per capita level as a main indicator of a general economic development and a measure of economic productive results. Then, we test some selected indicators of human resources accessibility (tertiary education, economic activity) that may be decisive for a sector existence and growth, strongly influencing a structural pattern of development. Finally, we check if actual labor market condition (specified by an unemployment rate) are diversified between regional clusters with different structural features. The existence of significant differences in any of the dimensions supports the thesis that structural features of the economy are important for an economic development in general or in its different aspects.

All data in the study are extracted from Eurostat database. They cover 2018 year as the most actual ones simultaneously for all of the indicators analyzed in the paper. Nevertheless, choice of the time seems to be reasonable considering relative stable economic condition in the EU (comparing to the preceding period of crisis and the succeeding disturbances in a time of coronavirus pandemic). Moreover, as structural changes are of a long-term character, the results presented in the study may have more long-standing implications as well.

Results

Clustering

Structural features of regional economies in the EU allows to specify two clusters. The clusters coverage is presented in Table 1.

Table 1: Results of classification of the EU regions by their sectoral structures of employment with the Ward method usage

Cluster	Regions (NUTS2)

The first group consists of 113 regions. Most of the Belgian, Danish, French, Dutch, Swedish and English regions as well as Luxembourg, Cyprus and Malta classified as a whole country at NUTS2 level are included. Only a few regions from Central and Eastern European member states are covered in the cluster (1 from Bulgaria, the Czech Republic, Hungary, Poland, Romania, Slovakia), suggesting mature structural features of the economies typical for advanced stages of developmental processes.

The second cluster is much more numerous and is created by 165 regions. The group is dominated by regions from Germany (28), however, not typical for the whole German state as most of them belongs to the former GDR (East Germany) characterized by economic structures deformations inherited from the socialist system. Numerous regions in the second cluster are also those from Italy (18), Spain (16), Poland (16), Greece (12), and France (10), suggesting that the "South" Europe countries are more similar to the "East" than "West" part of the EU. It is worth noting that the cluster covers most of the regions from Bulgaria, the Czech Republic, Germany, Ireland, Greece, Spain, Italy, Hungary, Austria, Poland, Portugal, Romania, Slovenia, Slovakia and the whole Estonia, Croatia, Latvia, Slovenia and Finland. Most of them are regions from less advanced countries and later members of the EU.

Structural characteristics of the two clusters

An average structure of employment in each of the groups reveals typical sectoral features of the regional economies. The characteristics are presented in Table 2.

Table 2: Sectoral features of regional structures of employment in the two clusters

Group of sections	A	BCDEF	GHI	JKLMN	OPQRSTU
Cluster 1					
the average share (%)	1.6	18.2	23.5	20.3	36.4
coefficient of variation (%)	79.3	21.9	14.0	29.6	14.2
minimum share (%)	0.0	7.3	15.0	10.4	21.8
maximum share (%)	5.6	25.2	33.4	45.3	51.5
Cluster 2					
the average share (%)	6.4	28.2	25.0	12.1	28.4
coefficient of variation (%)	102.0	27.7	21.6	27.4	18.3
minimum share (%)	0.4	9.7	17.7	4.2	13.5
maximum share (%)	41.8	47.7	53.2	23.3	41.0

Source: own study based on Eurostat database (Employment…).

The first cluster is characterized by significantly smaller share of agriculture and industry in employment and a slightly smaller engagement in classical services. In contrary, both kinds of knowledge-intensive services (market and non-market) appears to be of greater importance in these regions than in the second cluster. These features prove advancement of developmental processes which are transforming economies into a knowledge-based model. Moreover, as a classical theory of three sectors states, labor force outflows from agriculture and then from industry and the process is much more advanced in the first cluster.

More detailed comparisons of the regions indicate diversification of sectoral features not only between the clusters but within each of them as well. Considering agriculture in the first cluster one can find regions (usually capital cities or big metropolises) where employment has totally non-agricultural character, while in the second cluster in some regions employment in agriculture exceeds 40%. Simultaneously, the second group is characterized by more variability (with coefficient of variation of 102%) than the first cluster (79%). Industrial sector seems to be less diversified, however, minimum share of employment in the sector is about 7% in the first cluster and nearly 48% in

the second one. Once again variation is higher within regions in the second cluster. Classical services are also more important for and diversified within the second cluster. While in the first group a share of classical services range from 15% to 33% with 14% variation, in the second cluster the lowest share is nearly 18% and the highest one exceeds 53% with variation of 22%. Knowledge-intensive market services, often treated as a modern sectoral growth pole, appear to be slightly more diversified within the first cluster where they range from about 10% to 45%. However, in the second cluster their share is essentially lower at average as well as at both tails – ranging from merely about 4% to 23%. Non-market knowledge-intensive services are connected with development of a welfare state functions and to some extend their reflect institutional solutions adopted in a region. That can be found as a reason for relatively low variation of their share in both clusters. The lowest share of the non-market knowledge-intensive services are found in the second cluster and is 13,5%, while in the first cluster the highest value of 51,5% is noted.

Summing up, the structural features of the two clusters indicate more advanced process of labor sectoral reallocation in the first group of regional economies, which seems to be also less internally diversified.

Productive results in the two clusters of regions

Importance of structural features for economic development may be signalized by differences in productive results connected with different structures. This is the reason for testing significance of differences in GDP per capita between the two clusters of regions. Results of comparisons concerning economic results in terms of GDP per capita are presented in Table 3.

Table 3: Differences in GDP per capita between the two clusters

Cluster	Characteristics	GDP per capita	Results of analysis of variance
1	the average value (euro)	37926.55	F=44.5535 p=1.35E-10
	coefficient of variation (%)	55.3	
	minimum (euro)	12900	
	maximum (euro)	213400	
2	the average value (euro)	24362.42	
	coefficient of variation (%)	52.2	
	minimum (euro)	5200	
	maximum (euro)	78700	

Source: own study based on Eurostat database (Gross…).

The results support the thesis about significance of sectoral distribution of labor for general level of economic development measured by production per capita. The analysis of variance proves that an essential difference appears between the two clusters. Detailed data indicate the highest average GDP per capita in the first group of regions which was specified as a more structurally mature. Moreover, both the minimum and maximum values are higher in the first cluster. However, the economic results within the first cluster are also more diversified than within the second one. Not only is the coefficient of variation slightly higher (55.3% vs. 52.2%), but also the range is higher (200500 euro vs. 73500 euro). This observation suggests that economic structure constitutes one from numerous factors affecting productive results of regional economy, and, moreover, that the other factors may increase their importance when the structures are already advanced.

Availability of human resources as a precondition for structural maturity

Important issue is connected also with preconditions of structural maturity of a regional economy. One from many essential factors influencing creation and growth of sectors that may constitute growth poles in modern advanced economies based on knowledge is availability of human resources. It is specified by demographic factors, as well as social and economic processes inducing pursuit to economic activity and investment in human capital. Although the processes are compound and interrelated, it seems that they can be reflected in such indicators as economic activity of population and educational attainment at tertiary level. The characteristics of human resources availability in the two clusters of regions are presented in Tables 4 and 5.

The first of the indicators of labor resources availability characterizes general inclination of society to participate in market activity in a sphere of employment. It is influenced by many factors, such as situation at a labor market and thus chances for employment and high remuneration, institutional solutions connected with labor services and social care as well as social relations in families or other social groups. Nevertheless, the higher the economic

activity at a labor market, the easier is to develop any sectoral kind of entrepreneurial activity, and a barrier for growth in a form of availability of labor resources is thus limited.

Table 4: Differences in economic activity rates between the two clusters

Cluster	Characteristics	Economic activity of population	Results of analysis of variance
1	the average value (%)	66.9	F=25.23283 p=9.14E-07
	coefficient of variation (%)	7.7	
	minimum (%)	52.3	
	maximum (%)	76.7	
2	the average value (%)	63.6	
	coefficient of variation (%)	8.5	
	minimum (%)	45.7	
	maximum (%)	73.6	

Source: own study based on Eurostat database (Economic…).

Considering economic activity of population in the two clusters of regions it is possible to claim that the differences between the clusters are significant. The first cluster is characterized by more favorable indicators, as the average, as well as the minimum and the maximum values of the activity rate are higher and it is less diversified within the group. Availability of human resources may positively influence sectoral development and, simultaneously, sectoral maturity in terms of welfare services accessibility to society or higher competitiveness of advanced knowledge-based economies may stimulate economic activity. Mutual feedbacks are compound, however, the general results are favorable for the first cluster.

The second indicator of availability of human resources – share of people with tertiary education takes into consideration quality of labor and readiness to participate in a knowledge-based economy. It is a factor of growth more specific to modern knowledge-intensive sectors.

Table 5: Differences in a share of population with tertiary education between the two clusters

Cluster	Characteristics	Population with tertiary education	Results of analysis of variance
1	the average value (%)	39.1	F=140.3354 p=1.89E-26
	coefficient of variation (%)	23.7	
	minimum (%)	18.8	
	maximum (%)	71.5	
2	the average value (%)	27.1	
	coefficient of variation (%)	27.7	
	minimum (%)	12.7	
	maximum (%)	49.6	

Source: own study based on Eurostat database (Population…).

Comparisons of tertiary education rates in the two clusters once again draw a picture in favor for the first group. The average rate reaches 39% which is 12 percentage points higher than for the second cluster. Maximum value is noted in the first cluster and it exceeds 71%, while the minimum value of merely 13% is found in the second group, pointing at high concentration of educated people in few EU regions. The results of analysis of variance prove that the between clusters differences are significant. The higher share of educated people, the more structurally mature an economy is. As above in a case of economic activity, the relationships: tertiary education – structural maturity are two-sided and compound, but has been revealed in a positive form in the first cluster.

Summing up, accessibility of human resources appeared to be diversified between the two clusters of regions. General relationship between availability of high quality labor and structural maturity may be specified as a positive one. Moreover, this relationship is revealed in a long-term, as both sectoral reallocation of labor as well as changes of social behaviors and investments in education are of a long-term nature.

Actual labor market condition and structural features of economy

Short-term relations between structural features and labor market condition are specified by ability to adapt to changes such as shocks in demand-side and general susceptibility to the shocks. The features are revealed at a labor market as a phenomenon of unemployment. Question which arises may be formulated as one about economic structure that minimize the negative phenomena at a labor market such as unemployment. Differences in a labor market condition expressed by unemployment rate between the two clusters are presented in Table 6.

Table 6: Differences in an unemployment rate between the two clusters

Cluster	Characteristics	Unemployment rate	Results of analysis of variance
1	the average value (%)	6.4	F=2.327416 p=0.128258
	coefficient of variation (%)	76.3	
	minimum (%)	1.3	
	maximum (%)	29.0	
2	the average value (%)	7.4	
	coefficient of variation (%)	76.3	
	minimum (%)	1.5	
	maximum (%)	27.0	

Source: own study based on Eurostat database (Unemployment…).

Although the first cluster is characterized by a lower average value of unemployment rate, the analysis of variance does not support a thesis that the differentiation between clusters is significant. It is connected with high variation within each group and a range of the unemployment rate that appeared higher in the first cluster. The observation allows to conclude that the short-term situation at a labor market is not determined by a shape of sectoral structures. It is not possible to claim that the more mature economies are less vulnerable to shocks in terms of employment. Moreover, the economic results of economies in terms of GDP per capita are not defined by problems at a labor market that are revealed as unemployment. They may be rather influenced by productivity of the employees engaged in economic activity, which may differ across sectors.

Conclusion

The research presented in the paper allows to distinguish two groups of regions within the European Union, which differ concerning their sectoral structures of employment as well as a general level of economic development. Generally, the more advanced is the economic structure, the higher are the productive results. Thus, it is possible to conclude that a middle income trap may relate to some of the regional economies gathered within the cluster with less advanced structures of employment in terms of sectoral distribution. Endangered by the trap seem to be especially regions from the South, Central and Eastern Europe. The cluster of the regions are specified by traditional labor-intensive and technologically not-advanced sectoral features, while the cluster covering regions of "the core" EU members reveals high engagement in knowledge-intensive sectors. Moreover, the clusters are significantly diversified concerning economic results measured by GDP per capita that are in favour for the more structurally advanced regions. One of possible reason for such diversification may be found in accessibility of human resources, as the clusters differ concerning economic activity of population as well as tertiary education. The identified relation is positive and goes in line: high quality labor – structural maturity. Simultaneously, it was not confirmed that structural features influence short-term condition of a labor market characterized by an unemployment rate. Thus, the research points at a long-term character of mutual relationships in a process of development and the fact creates an essential barrier in a catching-up process. Generally, structural characteristics appear to be an important factor influencing productive results of regional economies and they cannot be neglected when shaping developmental policy. Moreover, the policy should focus on a long-term character of processes of economic development and support human capital development as one of decisive productive factors in a knowledge-based economy.

Abstract

The purpose of the research is to identify the advantages and threats of digitalization of universities, analyze the conditions and prospects for digitalization of Russian universities, as well as develop tools to overcome existing problems and limitations. The authors systematized the advantages of digitalization from development of online educational services segment, e-learning resources, use of digital technologies of electronic document circulation, involve of simulators, tools of augmented and virtual reality in the educational process, as well as digital support of students. The authors revealed the threats of digitalization of higher education institutions: the decline in the quality of education, the primitivization of competencies, the transfer of implicit knowledge, the loss of competitiveness, and threats of an informational nature. The authors analyzed the availability of Russian universities with computer equipment and specialized software, studied the growth dynamics of higher education programs implemented using electronic and distance technologies, as well as systematized the problems of implementing digital educational programs. The authors proposed a system of measures to level the existing problems and limitations of digitalization of the educational space in Russian practice.

Keywords: Digitalization, University, Internet, Digital Technologies, Threats, Staffing, Equipment of Educational Organizations

Introduction

The development of digital technologies is a process that allows to create fundamentally new conditions for generating knowledge and then sharing it. The widespread use of online platforms, online educational courses MOOCs, the introduction of modern learning technologies based on gamification, the use of virtual and augmented reality technologies and artificial intelligence to reproduce the specifics of a particular professional activity in the educational process, the introduction of electronic document management to optimize the university management process-are becoming an integral part of the development of a modern university.

However, in the process of digitalization, it is important to understand the existing potential of digital technologies for the long-term development of educational, research, and organizational and managerial activities of the university, as well as to identify and overcome the risks of digitalization.

In general, Russia is characterized by a significant digital lag behind the most developed countries. Thus, in terms of digital competitiveness, the country ranked only 38th out of 63 analyzed countries in 2019 and has certain problems

Cite this Article as: Maria E. KONOVALOVA, Zulay K.TAVBULATOVA,Alla V.BOGOMOLOVA, Svetlana A. SHAKHVATOVA and Evgeniya K. KARPUNINA "Digitalization of Russian Universities: Problems and Prospects" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

with financing R&D (34th place), spending on education (48th place), and developing digital skills (42nd place) (IMD, 2019). This cannot but affect the level of digitalization of Russian universities and their positioning in the international space.

However, in recent years, the country has had positive dynamics in the processes of Internet penetration and availability, robotization, use of big data, and technology development. This suggests that the use of the country's potential for the development of digital technologies will allow Russian universities to take a worthy place in the international digital educational space.

Methodology

The process of transforming the traditional learning model into a digital one is reflected in research by Siemens et al. (2015), Neborsky (2017), Maslova et al. (2018). The new digital model of training is focused on productivity growth, new types of work, human needs and the formation of future-oriented competencies (Dneprovskaya, 2018; Nikulina and Starichenko, 2018).

Goodfellow and Lea (2013), Sidorov (2017), Brodovskaya et al. (2019), Hazemi et al. (1998) argue that the ultimate goal of the process of digitalization of the educational environment is the formation of “digital universities” that combine mixed forms of online education, online MOOC courses, as well as ensure the digitalization of scientific and educational content through the use of online platforms that integrate information services.

Uvarov and Frumin (2019) note that digital technologies in Russian education open up unlimited opportunities for students and teachers to control the information space and share it, generate interest in learning and meaningful academic work, but methodological developments for their use in education are progressing slowly.

Brodovskaya et al. (2019) emphasize that currently there is a direct request for students to move from traditional forms of building the educational process to digital and hybrid models, but in Russian practice, there is often a formal nature of digital environments of educational institutions, when digital educational environments are replaced by their set of platforms and tools.

The purpose of the research is to identify the advantages and risks of digitalization of universities, to analyze the conditions and prospects for digitalization of Russian universities, as well as to develop tools to overcome existing problems and limitations.

Research phases:

1) Analysis of the experience of digitalization of foreign universities, systematization of the advantages of using digital technologies in educational and research activities.
2) Identification of potential threats from the introduction of digital technologies in the activities of universities.
3) Research and evaluation of the digitalization dynamics of Russian universities, as well as identifying problems and limitations.
4) Development of recommendations for overcoming the existing digitalization problems of Russian universities.

Research methods: method of theoretical analysis, economic and statistical analysis method, analysis and synthesis, systematization method, graphic method.

Information base of the research: official data of the Ministry of education and science of the Russian Federation, the Federal state statistics service of the Russian Federation, the Federal portal Russian education.

Results

Digitalization of higher education institutions is dialectical.

On the one hand, modern digital technologies are new tools for the development of universities around the world and significantly expand the opportunities for sharing accumulated experience and knowledge (table 1).

Table 1: Digitalization advantages for universities

Component of the higher education digitalization	Advantage for the university	Example from international practice
The online educational services segment	The growth in the number of courses offered and the number of students ensures an increase in the university's extra-budgetary income (Efimov and Lapteva, 2018).	US universities provide $ 7 billion in annual budget replenishment (2.7% of GDP) through the implementation of online educational programs (Beketova and Demina, 2018).
Electronic educational resources	Increased opportunities for replication and dissemination of knowledge, increased mobility and individuality of learning, flexibility of the educational process and the formation of self-development skills of students (Kentnor, 2015; Rizzotto, 2017).	The popular educational platform Coursera in collaboration with the best universities in the world (University of Pennsylvania, Stanford University, University of Michigan, etc.) presents more than 2000 online courses from 180 branches of knowledge.
Digital technologies of electronic document management	Improving the efficiency of document management and decision-making, convenience and speed of providing services for documenting students, reducing errors, leveling the corruption component.	The BlackBoard system in US universities provides access to educational content, it is a platform for interaction between students and teachers, and also collects and analyzes big data about students and the educational process (Korotaev, 2009).
Learning gamification, simulators, augmented and virtual reality tools	The introduction of virtual simulators in the educational process reduces the cost of university materials, as well as accelerates the learning process of students and improves its quality (Uvarov and Frumin, 2019).	For example, the educational process uses professional virtual simulators with game elements: from virtual medical laboratories Medical Holodeck to the simulator for training fighter pilots Pilot Training Next (Volkov, 2018).
Digital support of applicants	Universities ' notification of their applicants on their websites about special events, the specifics of admission and training is focused on an individual approach and providing the most targeted information, which ensures the growth of the number of students.	The most comprehensive and detailed information for applicants is collected on the websites of new York University, University College London, and Seoul University (Brodovskaya et al., 2019).

Source: compiled by the authors

On the other hand, digitalization as an objective process that covers almost all areas of activity carries a lot of new and unknown things, including threatening the well-being of modern universities.

Among the threats to digitalization of educational organizations, the authors identify the following (Fig. 1).

Fig. 1: The digitalization threats for educational institutions

(compiled by the authors)

The decline in the quality of educational services can be caused by such reasons as: low qualification of teachers; a high degree of information asymmetry that makes it difficult to assess the quality of students ' knowledge; unused opportunities for interactive interaction between teachers and students (Ustyuzhanina and Evsukov, 2018).

The primitivization of competencies may result from the intensive implementation of online education programs, resulting in the replacement of real human skills with digital technologies. On the one hand, it facilitates the solution of professional tasks, and, on the other hand, it turns a person into a mechanism for the formal execution of a sequence of actions (Ustyuzhanina and Evsukov, 2018).

The problem of transmitting implicit knowledge transmitted from person to person in the process of joint activities is revealed in the study of Polanyi (1966). Violation of the usual human relationships in the learning process, the termination of joint discussion of ongoing projects, the elimination of the possibility of learning from the personal experience of the teacher are the main drawbacks of the digital educational environment (Bromwich, 2015).

This is also related to the problem of socialization, which occurs when digital educational technologies are widely replaced by live human communication and interaction. The lack of psychological support for students and the termination of the educational function of the teacher lead to the undermining of a favorable social environment for the professional development of students.

As for the loss of competitiveness of an educational organization, according to Wissema (2016), digital technologies in education can be associated with “disruptive innovation, which will inevitably lead to the elimination of inefficient universities, and its benefits will be received by a relatively small number of winning universities”.

Information threats are an integral part of the digital environment in which universities operate. Exposure to information attacks, cyber espionage, software failures, and data leaks becomes a vulnerability factor for any organization (Karpunina et al., 2019; Karpunina et al., 2020).

What is the readiness of Russian universities to implement digital technologies? How well are the conditions for digitalization of the educational process in Russia formed?

In 2019, 1,279 organizations were licensed to conduct educational activities in the higher education system of the Russian Federation, which is 47% less than in 2013 (Minobrnauki, 2020).

According to a study of the state of informatization of Russian universities conducted by the Federal portal “Russian education”, almost every university (95.7 %) has computer classes. 27% of respondents rate the material and technical base of their university as “excellent”, and 40%-as “good”. 67.5% of teachers use software in the educational process, 59.9% – in distance learning, and 74.4% use it to assess the quality of education. Access to wireless Internet in higher education institutions is estimated at 62.8% (Russian education, 2018). It should be noted that the policy of universal digitalization of educational organizations set by the country's leadership is also reflected in the introduction of electronic document management systems at universities, as well as automated systems for the work of deans.

According to the Federal state statistics service of the Russian Federation, 1,279 higher education institutions in 2019 accounted for the following provision of personal computers and special software (except for general-purpose software) (table 2).

Table 2: Provision of Russian universities with personal computers and special software, 2019

Name of indicators	Availability in the organization		Also available for use by students	
	2015	**2019**	**2015**	**2019**
Personal computers – total	1075212	1052638	712437	683714
having access to the Internet	929647	931071	639340	634066
Program packages by specialty	1667	1168	1658	1641
Program computer-based testing	1637	1141	1622	1133
Virtual simulators	802	718	798	714
Electronic versions of reference books, encyclopedias, dictionaries	1713	1195	1697	1191

Electronic versions of textbooks for individual subjects or topics	1739	1213	1724	1212
Special software tools for scientific research	974	773	935	743
Electronic library systems	1760	1238	1750	1238
Electronic legal reference systems	1690	1214	1555	1147
Special software tools for solving organizational, managerial, and economic problems	1580	1149	0	0
EDM system	1362	1065	565	489
Content filtering tools for Internet access	1383	1105	1071	0
Other special software tools	1399	989	1189	846

Source: compiled by the authors according to the Federal state statistics service of the Russian Federation (2020)

Thus, the availability of personal computers in higher education institutions, including those with Internet access, as well as specialized software, remains at a low level, especially given the service life of computer equipment and the need for regular software updates.

The development of the online educational services segment in Russian universities has the following characteristics. The number of educational programs implemented using e-learning in the country's universities in 2019 was 12,133. Distance learning technologies were used to implement 6,485 bachelor's, specialist's, and master's degree programs. At the same time, the total number of educational programs implemented by Russian universities in 2019 was 46496. Thus, 26% of the total number of higher education programs were implemented in 2019 with the use of e - learning, 14% - with the use of distance technologies (Minobrnauki, 2020).

The dynamics of growth in the number of students enrolled in Russian universities in programs implemented using electronic and distance technologies is positive: in the period 2016-2019, while the total number of students enrolled in all programs decreased by 7.5%, there was an increase in the number of students enrolled in higher education programs using e-learning and distance technologies in general by 13.8%. This indicates a growing demand for this type of education. In 2019, the distribution of students in higher education programs implemented using e-learning and distance learning is as follows (Fig. 2).

Fig. 2: Distribution of students in higher education programs implemented using e-learning and distance learning technologies, 2019

(compiled by the authors according to Minobrnauki, 2020)

The effectiveness of the process of implementing and using digital technologies in universities depends on the readiness of teaching staff and their level of digital literacy. In total, in 2018, the educational process in Russian universities was provided by 236.1 thousand teachers. According to the analysis of the level of digital literacy research-pedagogical staff of Russian universities concluded that teachers of higher educational institutions demonstrate high levels of knowledge, skills and attitudes in the field of digital technologies. Thus, the digital literacy index of higher education teachers is 88 percentage points out of 100 possible (Cherkesova and Mironova, 2019). In addition, the level of digital literacy of teachers is significantly higher than the national average and higher than the level of digital literacy of young people aged 18-24 (77 p. p. out of 100).

However, there are certain difficulties in organizing the educational process using digital technologies in Russian universities (Brodovskaya et al., 2019):
- low level of development of interactive forms of online support of the educational process and work with applicants;
- lack of digital traces of the educational process, primarily video sessions;
- depersonalization in the process of digital training support;
- low quality of educational content;
- lack of practice of constant updating of educational content;
- lack of placement of educational cases as a practice-oriented technology.

It is obvious that digital technologies that provide information dominate digital technologies aimed at communication and maintaining interactive formats of interaction between applicants, students, and teaching staff.

Many of these problems are the result of the lack of effective financial motivators for teachers to improve the quality of their work using digital technologies, incentives to increase the level of digital literacy, as well as limited funding for Russian universities and imperfect institutional framework. The latter applies, first of all, to the regulatory regulation of the implementation of distance and e-learning programs, which in Russian educational practice is only fragmentally fixed. It is a key factor in restraining the development of this segment of educational services.

In the presence of these unsolved problems in higher education institutions, conditions are created for the emergence of the digitalization threats described above (decrease in the quality of education, transfer of implicit knowledge, competitiveness loss, etc.).

The solution to these problems, according to the authors, lies in providing the following measures:

1) Further large-scale investment in the digital infrastructure of universities, the development of computer networks, increasing computing power, regular software updates and the formation of a full-fledged digital educational environment. This requires additional financial resources, the source of which can be, among other things, business structures interested in training and re-profiling professional personnel, as well as in creating innovation and technology clusters as promising resources for their own development.
2) Creating motivational mechanisms in higher education institutions to increase the interest and activity of teachers in mastering new digital educational technologies and improving the quality of the educational process. In this aspect, an effective tool can be the formation of communication platforms for teachers and students to communicate with IT-specialists, internal grants to pay for foreign internships for teachers to adapt advanced experience in the field of digital educational content, as well as stimulating the remuneration of university teachers by adjusting existing effective contracts.
3) Setting new strategic goals for the long–term development of universities - increasing competitiveness to enter the international educational space. This requires overcoming language barriers, ensuring the quality and diversity of educational products, the breadth of choice, the ability to design the content of the educational program in accordance with the needs of the consumer, ease of navigation and interface, and the prestige of the diploma received.

The basis for the implementation of the proposed measures is the institutional regulation of digital educational programs at the state level, which will ensure the comparability of educational standards and levels of higher education in Russia and abroad.

Conclusions

In the article, the authors analyze the process of digitalization of higher education institutions and systematize the advantages and threats of digitalization of the educational environment.

The authors define the benefits of digitalization from development of segment of online educational services, e-learning resources, use of digital technologies of electronic document circulation, use of simulators, simulators, tools, augmented and virtual reality in the educational process, as well as digital support of students.

Among the threats to the digitalization of higher education institutions, the authors highlight the decline in the quality of education, the primitivization of competencies, the transfer of implicit knowledge, the loss of competitiveness, and information threats.

The authors analyze the availability of Russian universities with computer equipment and specialized software and conclude that there are a number of problems that limit the formation of a full-fledged digital infrastructure of Russian universities. The authors study the growth dynamics of higher education programs. implemented using electronic and remote technologies. Based on this, it is concluded that there is a growing demand from consumers for digital education programs.

The authors systematize the problems of implementing digital educational programs, and also propose a system of measures to level them.

Abstract

In paper, we consider digital tools development results for geo-information and geo-ecological support to floating nuclear power plants in Arctic. In studies, we used methods of data bases constructing, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties and risk management. As digital tools, we propose to use digital online platforms, which integrate heterogeneous hardware

and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, we demonstrate geo-information and geo-ecological system for first Russian floating nuclear power plant *Akademik Lomonosov* at Pevek. For data exchange and preliminary discussion we used platform https://www.researchgate.net/profile/Valery_Abramov2/ while research.

Keywords: geo-information support, floating nuclear power plants, Arctic

Introduction

Recently, the global environmental economy is within Industry 4.0 period, including floating nuclear power plants (FNPP) within energy sector. Now, many businesses are planning and implementing a wide range of information technologies (Lukyanov, 2019), (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019), (Sikarev, 2020), (Trunin, 2019). Industry 4.0 leads to serious technological changes in geo-information and geo-ecological support for FNPP within energy sector, including natural risks management NRM (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new tools, including practical learning area (Averkiev, 2020), (Korinets, 2020), (Popov, 2019).

In paper, we describe the development results of digital tools for geo-information and geo-ecological support for FNPP within geo-information management (GIM) paradigm (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). We paid significant attention to geo-information and geo-ecological support systems (GIGESS) in climate change context (Bournashov, 2014), (Gogoberidze, 2014), (Chestnov, 2020), (Chusov, 2012), (Estrin, 2020), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). Developed digital tools of GIGESS for FNPP in Arctic while climate change, considered in this article, take these factors into account.

Methods and data

In study, there are used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Tatarenko, 2020), (Vekshina, 2020). While research, there are used data bases and tools of digital online platform (DOP) EOS (Sanina, 2020) and EOS (Prostakevich, 2020).

Results

From open sources, it follows that at the end of August, the floating power plant (FTPP) *Akademik Lomonosov* was delivered to Chukotka with the help of tugs. This event was widely covered in the media https://www.reuters.com/article/us-russia-nuclear-floating-idUSKBN1VZ0CY. Soon, on December 19, 2019, it entered service in the vicinity of Pevek. This FTPP is the first of many similar ones planned for sale in the global energy market. The main technical characteristics of FTPP *Akademik Lomonosov*, as well as the history of its development and creation are given in various open sources, mainly in Russian. In figure 1, we present general view of FTPP *Akademik Lomonosov* at Pevek on computer made image while project stage, taken from open source https://bestlj.ru/151428-Vsja-pravda-pro-PATEHS-Akademik-Lomonosov.html. Commissioning of the station raised a serious question about geo-information and geo-ecological support for its operation in the Far North, as well as about similar support for next FTTPs.

Our analysis shows that there will be significant natural risks for the created natural-industrial system (FTTP itself, auxiliary structures, urbanized surrounding territories and port water areas) due to low air temperatures, strong winds, stationary and drifting ice fields, ice piles, hummocks, long waves, as well as a number of other phenomena in the atmosphere, lithosphere, hydrosphere and biosphere, including sediment movement, algae blooming, siltation, fouling of the floating hull and water intake channels. We propose to solve this problem with geo-information and geo-ecological support system (GIGESS), based on open source geo-information digital online platforms (GIDOPs) Earth (Sanina, 2020) and EOS, including its product LV (Prostakevich, 2020).

Figure 1: General view of FTPP Akademik Lomonosov at Pevek on computer made image while project stage (https://bestlj.ru/151428-Vsja-pravda-pro-PATEHS-Akademik-Lomonosov.html)

Let's move on to the example of using the proposed GIGESS for FNPP *Akademik Lomonosov* (here and after simply FNPP). A striking feature for its seasonal operation mode is formation and destruction of the ice cover around it. The greatest interest is in spring, when the solid ice field around the station begins to collapse and move, and drifting ice fields with a significant thickness of ice appear. Such fields can be piled on the protective hydraulic structure around the FNPP, and the force of the pile depends on the size of the ice field itself, as well as the strength and direction of the wind acting on it. In figure 2, we present port of Pevek space image on 12th May 2020 visualized with Atmospheric Removal Application of LV (green rectangular marks FNPP's area). You can see that the entire water area is occupied by a stationary ice field of a complex spatial structure with variable thickness and the presence of numerous cracks. It can be assumed that as this ice sheet melts, separate drift ice fields with different ice thickness will form.

Figure 2 - Port of Pevek space image on 12th May 2020 visualized with Atmospheric Removal Application of LV (green rectangular marks FNPP's area)

In figure 3, we present port of Pevek space image on 5th June 2020 visualized with Atmospheric Removal Application of LV (red hexagon marks FNPP's area). As you can see, in a short period of time the stationary ice field broke up into a set of drifting ice fields with different ice thickness. The greatest danger to FNPP is

represented by set of large drifting ice fields located above and to the left of the red hexagon. With a northwesterly wind, they can approach and attack the FNPP's protective hydraulic structures.

Figure 3 - Port of Pevek space image on 5th June 2020 visualized with Atmospheric Removal Application of LV (red hexagon marks FNPP's area)

In figure 4, we present port of Pevek space image on 15th June 2020 visualized with Atmospheric Removal Application of LV (red hexagon marks FNPP's area). As you can see, inside red hexagon that marks FNPP's area there is large drifting ice field (greenish area) which attacks the FNPP's protective hydraulic works

Figure 4: Port of Pevek space image on 15th June 2020 visualized with Atmospheric Removal Application of LV (red hexagon marks FNPP's area)

The maximum length and width of the attacking ice field measured with LV was 1.65 km and 0.658 km (figures 5 and 6) respectively.

Figure 5: Maximum length of the attacking ice field measured with LV

Figure 6: Maximum width of the attacking ice field measured with LV

Analysis of the wind field on 15th June 2020 in the vicinity of FNPP's area (figure 7) showed that the attacking field was affected by a northwesterly wind at a speed of about 7 km/h.

Figure 7: Wind field at FNPP on 15th June 2020 visualized with GIDOP Earth

Note, above mentioned data allow us to calculate the quantitative characteristics of the impact of the attacking ice field on the FNPP's protective hydraulic structures but this is not the purpose of this article.

As essential research result, we can recommend the developed GIGESS for FNPP *Akademik Lomonosov* as basement for subsequent FNPPs in the Arctic.

Discussion

Low-cost GIGESS for FNPP *Akademik Lomonosov* can be used in educational and training purposes. The essential task of university practical learning (UPL) in the field of integrated coastal zones management (Lukyanov, 2020) is to teach students the practical aspects of work with GIGESS for FNPP *Akademik Lomonosov* tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Popov, 2019), that can reduce total cost of learning process.

Conclusion

In article, we consider digital tools development results for geo-information and geo-ecological support system (GIGESS) to floating nuclear power plant (FNPP) in Arctic. In research, we used methods of data bases constructing, web-technologies and virtual reality tools. We suggest to use geo-information distributed online platforms (GIDOPs), as the main technological tools in the tasks of geo-information and geo-ecological support while FNPPs functioning. As study result, we demonstrate possibilities of GIGESS for first Russian FNPP *Akademik Lomonosov* at Pevek. As essential result, we propose to use developed GIGESS as basement for subsequent FNPPs in the Arctic, including educational and training purposes The presented in the article results of the research have a significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state environmental control bodies. They can be used in training and educational purposes, including preparation of master's programs in environmental economics.

Acknowledgment

While study, associate professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at the Russian State Hydrometeorological University (LGIS IAS RSHU), gave us very useful consulting. For preliminary discussion and data exchange while this research, we used platform https://www.researchgate.net/profile/Valery_Abramov2/.

Abstract

The paper reviews the extant literature on big data analytics capability (BDAC) and firm performance. It is indicated that research on BDAC remains at an 'infancy' stage in the tourism and hospitality industry. Therefore, future research directions are discussed, including BDAC conceptualization issue and possible moderators towards the relationship between BDAC and firm performance.

Keywords: Big Data Analytics, BDAC, Firm Performance, Typology, Moderator.

Introduction

The tourism and hospitality industry has experienced a considerable growth in the past few decades. Tourism-related sectors provided 10% of jobs and generated 8.8 trillion USD (approximately 10.4% of global GDP) in 2018 (WTTC 2019). However, the whole industry has been severely disrupted by the Covid-19 pandemic on a global scale since its initial outbreak in Wuhan, China at the end of 2019.

To curb the spread of the pandemic, many countries have been implementing strict action plans, such as closure of businesses, shutting down transport facilities and even full lockdowns. Therefore, international tourist arrivals are estimated to decline 58% to 78% (UNWTO 2020). Due to limited human mobility and decreased social activities, hotels, restaurants, travel agencies and other businesses are facing seemingly insurmountable challenges (Nicola et al. 2020).

Hotel sector has been one of the hardest-hit by the Covid-19 pandemic across the world. Specifically, China's hotel occupancy rate dropped 89% in January of 2020, and Italy's hotel occupancy rate once dropped 94% (Nicola et al. 2020). Not only have small and medium sized hotels been seriously affected, but also international hotel giants. Amid the global uncertainties induced by the unprecedented pandemic, even Hilton Worldwide made an announcement for a revolving loan of 1.75 billion USD as a precautionary measure in March of 2020 (Nicola et al. 2020).

How to survive becomes a priority for many tourism-related businesses, and necessary measures are taken to cope with the consequences of Covid-19 (Duarte Alonso et al. 2020). As a result, digital transformation has been accelerated, which is mainly driven by the changes of customers' demands. For example, customers developed a

preference in short-distance over long-haul travels and they have higher requirements on sanitation. Therefore, big data analytics is adopted to predict renewed customer preferences. By familiarizing the preferences, businesses are more likely to provide customized services for enhancing their market competitiveness and firm performance (Hao et al. 2020).

It is evident that the adoption of big data analytics is able to improve productivity, competitiveness and firm performance in a changeable market environment (Hao et al. 2020; Mikalef et al. 2019; Jeble et al. 2018). Nevertheless, it seems to be an unsolved puzzle as to what core resources are required to establish an appropriate big data analytics capability (BDAC) within an organization (Mikalef et al. 2019). In reality, many firms hold a skeptical stance towards big data analytics because their management either put more credits on personal experience over big data analytics or find the implementation of big data analytics extremely challenging (Egan & Haynes 2019; Henke et al. 2016). Besides, most of extant research focuses on big data analytics in the manufacturing sector (Gupta et al. 2018; Jeble et al. 2018). Therefore, there is very little knowledge on the key components of BDAC and its impacts on firm performance in the tourism and hospitality context.

In the present research, we discuss the conceptualization of BDAC and what core resources are needed to build an appropriate capability of big data analytics for tourism-related businesses. Besides, the conceptual paper discusses the effects of BDAC on firm performance. Based on the aforementioned discussion, future research directions are presented along with some insightful implications for the tourism and hospitality industry.

Theoretical Foundation of BDAC

With the development of information technology, the application of big data analytics has emerged as a popular topic among practitioners and researchers (George et al. 2016). As a new technological frontier, big data analytics is able to enhance a firm's competitiveness and business performance because it facilitates firms making correct strategic decisions through analysis of mass unsystematic data (Gupta et al. 2018). More precisely, appropriate application of big data analytics is an important index of a high-performing firm as it enables a firm to spot new opportunities regardless of external changes (Liu 2014).

For example, Amazon excels in transforming unsystematic mass data into competitive advantages via big data analytics. By collecting, processing and analyzing real-time data from users' browsing and searching history, Amazon develops advanced algorithms to find patterns and correlations in relation to customer and market preferences (Jeble et al. 2018). Given the benefits, more managers have gradually realized the importance of big data analytics for a firm's survival, growth and expansion, so some of them start to adopt big data analytics for strategic decision making (Grover et al. 2018). Nevertheless, the application of big data analytics is still at its 'infancy', and there are various challenges for further implementation.

Based on a joint report conducted by McKinsey and Company Global Institute in 2016, only 10%-60% of the previous forecast value of big data analytics is achieved in different industries in the US, and the achievement rate is just between 10%-20% in healthcare area (Henke et al. 2016). Besides, the same report points out that a few challenges, including talents, technology and leadership, lead to the failure of big data analytics implementation. More specifically, there is a lack of talents who are good at producing insightful analytics from mass unsystematic data; there is insufficient big data infrastructure for technical support; and there is a lack of qualified managers who are capable of transforming big data analytics into appropriate management decisions.

To gain competitive advantages in the market, a firm has to apply its internal resources in an effective and efficient way so as to improve its own capabilities (Barney 2001). Barney (1991) proposed a resource-based view (RBV) to explain the transformation mechanism from both tangible and intangible resources to capabilities within a firm. Besides, the deployed resources have to work synergistically towards firm competitiveness (Ghasemaghaei et al. 2017). Only a firm with sufficient organizational capabilities may achieve the synergistical effect in relation to

internal resources deployment (Barney, 1991). In extant literature, the RBV theory is often applied to approach the relationship between the deployment of in-house resources and the improvement of firm performance as it helps us understand a firm's competitiveness and market position (Erevelles et al. 2016).

As a static theory, RBV focuses on in-house resources within a firm, and neglects dynamic external environments. Therefore, Teece et al (1997) proposed dynamic capability view (DCV) as an extension of RBV, emphasizing environmental adaptation capability. Gupta et al (2018) argue that a firm should reconfigure both internal and external resources synergistically for maintaining and enhancing competitiveness advantages amid an increasing market complexity (Gupta et al. 2018). External environment shapes a firm's strategic goals, and the firm applies resources in accordance with its strategic goals, which transforms a firm's capabilities into corresponding competitive position (Gupta et al., 2018). Therefore, dynamic capability is referred to as an ability to strategically reconfigure both internal and external resources for fulfilling a firm's strategic goals in a dynamic market environment (Teece et al., 1997). Significantly, dynamic capability is a hierarchically layered concept with different dimensions, including management, technology and talent (Akter et al. 2016).

Both RBV and DCV are widely applied in strategic management to discuss how to maintain and enhance competitive advantages in a changeable business environment (Barney 1991; Gupta et al. 2018; Teece et al. 1997). Given the two theoretical foundations, BDAC is defined as an ability to effectively collect, process and analyze mass data to produce meaningful business insights guiding strategic decisions in the research context, and the formation of BDAC requires tangible resources, human skills and intangible resources. (Gupta et al. 2018; Jeble et al. 2018; Mikalef et al. 2019).

The Conceptualization of BDAC

BDAC is a multi-layered concept that is composed of various dimensions. Through an extensive literature review, it is found that there are different methods to conceptualize BDAC. As per Akter et al (2016), BDAC, as a hierarchical construct, consists of management capability, technology capability and talent capability. Similarly, Davenport et al (2012) argue that the conceptualization of BDAC should focus on three main aspects of big data analytics, including big data management capability, big data talents capability and tangible infrastructure capability. Meanwhile, Ransbotham et al (2015) state that BDAC contains building blocks of management culture, data infrastructure and data analytic skills. More importantly, Fosso Wamba and Akter (2019) conclude that BDAC is a third-order construct with three second-order dimensions (management capability, technology capability and talent capacity), and second-order primary dimension is composed by a few subdimensions.

Besides, Grant (1991) states that there are three core business resources within a firm, namely tangible (e.g. financial resource), human skills (e.g. staff's knowledge) and intangible (e.g. organizational culture). Furthermore, Mikalef et al (2019) refined Grant (1991)'s typology in a big data context, and they argue that tangible resources include data, technology and other basic resources; human skills contain technical and managerial skills; and intangible resources include both data-driven culture and organizational learning culture. The tangible, human and intangible resources are interrelated, and a coordination of these core resources is required to develop an appropriate BDAC (Mikalef et al. 2019).

Table 1: Typologies of BDAC

Related studies	Management capacity	Technology capacity	Talent capacity
Akter et al (2016)	Big data management capability	Big data technology capability	Big data staff capability
Mikalef et al (2019)	Data driven culture, organizational learning	Data, infrastructure and other basic resources	Technical skills, managerial skills

Jeble et al (2018)	Management skills, data driven culture, organizational learning	Tangible resources	Technical skills
Ransbotham et al (2015)	Analytics planning, sharing and coordination	Openness, compatibility and connectivity	Analytical talent, and related knowledge
Fosso Wamba et al (2017)	Planning, investment and control	Infrastructure for connectivity, compatibility, modularity	Talents with managerial, technical and business skills
Davenport et al (2012)	Analytics management capacity	Open source platforms	Data scientists

In terms of tangible resources, data-related infrastructure, equipment and technology should be deployed to develop big data solutions. Given the benefits of big data analytics, some firms make heavy financial investment in related "hardware", and match the big data initiatives with their strategic goals (Gupta & George 2016). Besides, big data itself is becoming more complex along with the development of information technology as it is generated at anytime and anywhere in various formats, which drives a firm to acquire advanced technologies and infrastructure to collect, store, process and analyze real-time big data for technological competence (Ferraris et al. 2019). In this research, we argue that basic resources, data, technology are essential tangible resources for BDAC. Although these tangible resources are the foundation to establish BDAC, they may not work unless there is a synergic mechanism with human and intangible resources (Jeble et al. 2018).

With regard to human resources, both technical and managerial skills are essential for big data talents to implement initiatives of big data analytics (Fosso Wamba et al. 2017). These skills are related to work experience, knowledge, interpersonal intelligence, problem solving ability (Barney 1991). Davenport (2014) further explains that analytical staff need to have professional technical abilities to handle big data, and managers need to obtain sufficient managerial skills to assemble, organize and manage a team in line with their firm's strategic goals. Compared to technical skills, managerial skills are relatively more difficult to acquire within a firm, and they largely determine the success rate of any big data project (Akter et al. 2016; Davenport 2014; Jeble et al. 2018).

Apart from tangible and human resources, there are some indispensable intangible resources that are important for big data analytics. Compared to tangible resources, intangible resources are not recorded in a firm's financial documents. Therefore, they may be easily ignored (Barney 2001). Nevertheless, intangible resources are crucial to firm performance (Teece 2015). Based on the extant literature, it is found that a positive organizational culture is one of the most important intangible resources within a firm because organizational culture, unlike tangible resources, is very difficult to be replicated by competitors (Barney 2001). In a changeable market environment, a firm has to regularly update its knowledge corresponding to external changes in relation to economic, social, environmental, political and legal aspects to maintain competitive advantages (Cabrera-Suárez et al. 2001). Thus, a firm needs a continuous learning culture to motivate analytical and managerial staff to keep pace with the latest knowledge.

In the big data context, a data-driven culture is a significant factor determining the implementation of big data analytics (Gupta & George 2016). An unsupportive organizational culture imposes a great challenge to implement big data analytics (Ransbotham et al. 2015). Big data analytics itself has a limited impact on strategic decision making without a data-driven workforce resulting from a data-driven culture (Grover et al. 2018). A firm with a strong data-driven culture is likely to modify its organizational process, mechanism and structure to make necessary

information accessible to all staff (Mikalef et al. 2019). Under such culture, a firm would like to invest in data-related technology and train its employees for data competency (Gupta & George 2016). Jeble et al (2018) specifically state that a data-driven culture is a key factor to realize full potential of big data. Therefore, this paper includes both organizational learning and data-driven culture as core components of intangible resources of BDAC.

Based on the aforementioned discussion, we propose that BDAC is a third-order construct with three second-order dimensions, including tangible, human and intangible resources. Tangible resources are composed of basic resources, data and technology; human resources include technical and managerial skills; intangible resources contain organizational learning and data-driven culture (Mikalef et al. 2019).

BDAC in the Tourism and Hospitality Context

There is no doubt that information technology has tremendous impacts on business operation. As an information-intensive sector, the tourism and hospitality industry consumes and produces a massive amount of data from customers, their digital devices and business operation processes (Wirtz et al. 2010). Precisely, tourists may search user generated content (UGC) before making any travel decision, and they may also share their travel experience on social media platforms; digital devices, such as smart phone, can be used to track tourists' movement patterns via GPS service; online searching, booking and other operation processes could facilitate businesses forming a better understanding of tourists' needs, wants and preferences (Buhalis & Foerste 2015; Li et al. 2018). Sheehan et al (2016) state that a firm's competitiveness and even business performance are heavily influenced by its ability in data management. Therefore, it is significant to understand BDAC and its impacts on firm performance in the context of tourism and hospitality.

However, the topic of big data is not widely discussed in the tourism and hospitality industry. According to the extant literature, a few tourism-related issues have been covered in relation to big data, including tourist behavior, Chinese tourists, event tourism, adventure tourism and tourism risk (Getz & Page 2016; Pomfret & Bramwell 2016; Yang et al. 2017; Yang et al. 2015). Most of these studies focus on data source, tourist characteristics or tourist preferences. The impact of big data analytics is under-researched in the tourism domain. Besides, practitioners do not attach enough importance on big data analytics because many managers remain relying on their personal experience over big data analytics for decision making (Egan & Haynes 2019). This is probably because of the complexity to implement big data analytics in the sector. As one of the most digitalized industries, tourism and hospitality, receives massive amounts of data that may be redundant, complex and even contradictory (Lloret-Climent et al. 2019). Thus, it is very difficult to achieve success in big data analytics within the industry. Nevertheless, it is believed that big data analytics is able to improve firm performance though its implementation is still at an "infancy" stage in tourism and hospitality (Lloret-Climent et al. 2019).

The Impacts of BDAC on Firm Performance

In the era of globalization and information technology, business competition exceeds the boundary of national borders. As a result, business competition becomes increasingly fierce among companies. Therefore, survival becomes a priority for businesses (Foster & Kaplan 2001). Apart from survival, a firm should enhance its competitiveness for more market share. Then, it may make more profits to ensure returns to stakeholders and future investment (Akter et al. 2016). Therefore, firm performance is crucial for business organizations. There is no exception for businesses in the tourism and hospitality industry.

In recent years, researchers and practitioners start to show a growing interest in BDAC and its effects on firm performance because BDAC, as a reflection of knowledge management, is one of the most critical determinants of competitiveness (Fosso Wamba et al. 2017). Specifically, BDAC allows a firm to gain a deeper and more holistic understanding of customers and the market (Ferraris 2019). Fosso Wamba et al (2017) argue that the adoption of big data analytics could facilitate a firm maintaining market competitiveness. More precisely, BDAC is likely to increase sales, revenue, profitability and productivity (Akter et al. 2016; Gupta & George 2016). Besides, BDAC is linked with higher market share as it may help a firm explore new market opportunities (Ji-Fan Ren et al. 2017). It is believed that the positive impacts of BDAC on firm performance applies to businesses in the tourism and hospitality sector as well. For example, Yadegaridehkordi et al (2020) suggest that big data adoption improves firm performance, such as profitability and revenue (Egan & Haynes 2019).

Figure 1: Conceptual framework of the research (BDAC's dimensional structure and its effect on firm performance)

With regard to the components of firm performance, we propose to include both market performance and operational performance in line with previous studies (Gupta & George 2016). According to Gupta et al (2018), market performance and operational performance are two core components of firm performance, and they are complementary to each other. Market performance measures whether a firm is able to explore new markets and launch new products/services to its existing market quickly (Gupta et al. 2018). In other words, a higher market share than competitors usually means good market performance (Ji-Fan Ren et al. 2017). Meanwhile, operational performance is reflected by productivity, profitability, return on investment and sales revenue (Akter et al. 2016). Therefore, both market performance and operational performance are considered key dimensions of firm performance in the paper.

Future BDAC Research in Tourism and Hospitality

In the ongoing industrial revolution 4.0, big data analytics becomes more important to determine a firm's overall competitiveness (Ardito et al. 2019). Majority of companies expressed their willingness to adopt big data analytics

in different industries so as to enhance their market position (Columbus 2014). Despite the willingness, only 16% of them applied big data analytics to optimize business process and strategy (Columbus 2014). What are the reasons that caused the disparity? Based on the extant literature and business reports, many companies have very limited knowledge of how to establish a sufficient capability to implement big data analytics and what core resources are needed for the capability (Henke et al. 2016; Mikalef et al. 2019).

Although the present paper proposes that BDAC is a third-order concept consisting of three second-order dimensions (i.e. tangible, human and intangible resources), and each dimension comprises sub-dimensions, there are other typologies as well (Mikalef et al. 2019). For example, Akter et al (2016) conceptualize BDAC as a third-order construct, but they propose very different first-order and second-order models of BDAC when compared to Mikalef et al (2019). Besides, BDAC may be approached as a second-order construct as well. Jeble et al (2018) argue that BDAC is composed of five dimensions, namely tangible resources, technical skills, management skills, organizational learning and data-driven culture. Therefore, future research may further examine the conceptualization issue of BDAC or the antecedents of BDAC (Rialti et al. 2019). With a clearer understanding of the core components of BDAC, businesses are more likely to form an appropriate capability to implement big data analytics.

Theoretically, BDAC is able to improve firm performance in terms of market share and other operational parameters (Barney 1991; Ferraris 2019; Gupta et al. 2018; Teece et al. 1997). The positive correlation is supported by some previous studies with empirical evidence, but these studies are mainly conducted in manufacturing sectors (Gupta et al. 2018; Jeble et al. 2018). According to Endrikat et al (2014), there are different challenges in different industries because of the variety of internal and external environment (e.g. competition intensity and market conditions). Thus, implications from manufacturing may not apply to tourism and hospitality. More importantly, big data analytics remains a marginal topic within tourism research despite its significance in the whole industry (Mariani 2019). Therefore, more studies of big data analytics and its impacts on firm performance should be conducted in a context of a given industry and country so as to fill up the research gap in literature.

Furthermore, there are important moderators influencing the relationship between BDAC and firm performance (Rialti et al. 2019). According to previous studies, organizational innovation, marketing innovation, firm size and leadership have been explored with preferable evidence (Baharuden et al. 2019; Nieves & Diaz-Meneses 2016; Raguseo et al. 2020; Ramirez et al. 2018). Nevertheless, it is suggested that future studies should explore other factors variables, such as innovativeness, growth, market share and cost leadership (Mikalef et al. 2019; Raguseo et al. 2020).

Conclusion

Based on previous research and relevant theories, the paper has suggested that BDAC has positive impacts on firm performance in terms of market share and operational parameters. Besides, possible antecedents of BDAC are discussed, which may facilitate tourism-related business, such as travel agencies and hotels, developing an appropriate BDAC by deploying the right core resources synergically so as to enhance their market competitiveness. In addition, possible research directions are provided to future studies. By addressing issues linking with future research directions, both researchers and practitioners could form a deep and holistic understanding of BDAC in the context of tourism and hospitality. Then, related businesses are more likely to improve their firm performance in the era of big data.

Abstract

China has become the largest source market for global outbound tourism. Many countries, including Malaysia, are aiming to attract more tourists from China to boost their tourism sector, and how to convince tourists to come back is a vital issue to achieve the goal. The paper intends to investigate Chinese tourists' intention to revisit Malaysia by applying the theory of reasoned action (TRA) and past travel satisfaction. PLS-SEM is used to analyze data from 276 respondents, and it is found that attitude, subjective norm and past travel satisfaction are significant factors influencing Chinese tourists' revisit intention to Malaysia. However, past travel satisfaction does not have any moderating effect. Based on the findings, national tourism organizations, marketers and operators are suggested to provide customized travel itineraries to Chinese tourists so as to make them loyal to their destination.

Keywords: Chinese tourists, Malaysia, Revisit intention, Past travel satisfaction, TRA.

Introduction

Malaysia is a well-known travel destination in Southeast Asia with its cultural diversity, beautiful natural scenery and convenient infrastructure. Since independence in 1957, Malaysia has been transforming its economy from resource-based to service-based. Its first attempt to develop tourism and hospitality dated back to the 1960s, but Malaysia didn't put too much effort into the sector until the last two decades of the 20th century (Phah et al. 2018). The promotional campaigns *Visit Malaysia* were implemented a few times, such as in 1990, 1994, 2000, 2007 and 2014, which marks Malaysia's increasing recognition of tourism's economic benefits (Mahadevan et al. 2016). Besides, the sector was identified as one key industry transforming Malaysia to a high-income nation by the Economic Transformation Programme (ETP) initiated by the Malaysian government in 2010.

In recent two decades, the tourism sector remains one of the most significant contributors to Malaysia's economy. According to WTTC (2017), the travel and tourism industry accounted for 13.7% to Malaysia's GDP in 2016, and provided 12.0% of total employment in the country. In terms of international arrivals, Malaysia received 25.83 million foreign tourists in 2018, and 70.1% of arrivals are made by tourists from other neighboring countries in Southeast Asia. Meanwhile, China was ranked the largest source market outside of Southeast Asia with 2.94 million arrivals in 2018, following Singapore's 10.62 million and Indonesia's 3.28 million (Jaafar 2019).

Due to geographic location, historic ties and amicable relations with China, Malaysia has been a popular travel destination for Chinese citizens in the last few decades. To attract more tourists from China, Malaysia grants preferential policies towards Chinese tourists, such as loosening visa requirements and providing language assistance at main transport hubs. Besides, scholars have been conducting research to investigate determinant factors influencing Chinese tourists visiting Malaysia (Phah et al. 2018). However, there are insufficient studies discussing a crucial question whether Chinese tourists are willing to revisit Malaysia.

Both researchers and practitioners agree that repeat tourists are a stable source market for travel destinations, and tourist loyalty is a key factor deciding if a destination could survive and thrive (Opperman 2000; Tasci 2017). According to Opperman (2000), it would cost more resources to attract new tourists than to convince existing tourists to come back to the same destination. Besides, repeat tourists would spend more, and they are less likely to be influenced by perceived risks (Chew & Jahari 2014). In Malaysia, local researchers have noticed the issue of tourist loyalty, but they mainly focus on Western and Muslim tourists regardless of the importance of China's outbound tourism market (Battour et al. 2012).

This study aims to examine determinants of revisit intention to a destination by applying the theory of reasoned action (TRA) and past travel satisfaction in the context of Chinese tourists visiting Malaysia (Ajzen 1991; Loi et al. 2017). The article provides some valuable insights for policy makers, industry practitioners and researchers on why tourists from China revisit Malaysia, which may help them design a feasible and efficient marketing strategy.

Literature Review

Outbound Tourism Market of China

Although China has become the largest global source market, its outbound tourism didn't really exist until the 1980s. Before the implementation of China's opening-up policy in 1979, only a handful of social elites, diplomats and athletes could have had a chance to travel abroad. Travelling abroad was strictly controlled by the Chinese government because of the ideological confrontation between socialist and capitalist camps in the world. Even during the first few years after China's reform and opening, Chinese government remained a very conservative attitude towards outbound tourism.

The development of China's outbound tourism could be categorized into 3 main stages. In 1983, ordinary Chinese citizens were allowed to visit their relatives or friends in Hong Kong, Macao and regions around border areas, which marks the 1st development stage of China's outbound tourism. However, the policy was tentative as these trips had to be fully sponsored by the Chinese citizens' relatives or friends who live in Hong Kong or Macao (Dai et al. 2017). For the vast majority of common people, they did not have much chance to travel outside of mainland China even if they could afford the trip.

In 1980, China's National Tourism Administration started to introduce "Approved Destination Status" (ADS) scheme, and China's tourism administration enlisted countries to ADS when they signed bilateral tourism cooperation agreement with China. Singapore, Malaysia and Thailand are in the 1st batch of ADS countries. In 1997, China signed a bilateral agreement with Australia and New Zealand, and Chinese tourists were also allowed to visit ADS destinations at their own expenses, which marks the 2nd development stage of China's outbound tourism (Dai et al. 2017).

China successfully organized the Beijing Olympic Games in 2008, showing a prosperous and modern China to the whole world. Meanwhile, Chinese government decided to promote its outbound tourism for displaying China's soft power, marking the 3rd development stage of China's outbound tourism. After that, China has been actively encouraging Chinese citizens to travel abroad in contrast with its previous "restrictive attitude" towards outbound tourism (Dai et al. 2017). Especially after 2010, China's outbound tourism market entered "the second wave" of rapid growth (Arlt 2013). Dai et al (2017) postulate that each stage of outbound tourism is a reflection of social, economic and political situations in China during certain periods. To clearly understand China's outbound tourism market in the past, at present and in the future, related social, economic and political factors must be considered and comprehended.

TRA

The applicability of the TRA model is supported by many empirical research. According to Armitage and Conner (2001), TRA could explain 39% of variance of behavioral intention. Moreover, Hassan et al (2016) conducted a review research by analyzing 29 journal papers using the TRA model published from 2000 to 2013, and the findings indicate that 41% of variance of behavioral intention could be explained by the model.

In the domain of tourism studies, TRA is also adopted to understand various travel behaviors across different cultural backgrounds (Meng & Choi 2018; Park 2000). Furthermore, Park (2000) argues that the relative weights of attitude and subjective norm caused by cultural differences will not change both components' ability to predict behavioral intention. Nevertheless, Hassan et al (2016) postulate that the influence of attitude and subjective norm varies in different situational and cultural contexts, and the positive relationship between subjective norm and behavioral intention may be insignificant in some cultures and situations.

For example, Ryu and Han (2010) examined tourists' intention to try local food when they visit a travel destination, but it is found that subjective norm does not have a positive effect on behavioral intention. The study was conducted in the U.S. where individualism is prevailing, which may explain why respondents consider trying food a personal matter rather than an outcome of external social pressure (Hofstede 1980). Maheswaran and Shavitt (2000) postulate that it is very difficult to have a universally applicable theory regardless of cultures. Thus, the TRA model needs to be contextualized with regard to China's outbound tourists visiting Malaysia. Based on the discussion, the following hypotheses are proposed:

H1: Subjective norm positively influences Chinese tourists' intention to revisit Malaysia.

H2: Attitude positively influences Chinese tourists' intention to revisit Malaysia.

Past Travel Satisfaction

Tourists' past travel experience and past travel satisfaction are seen as antecedents in predicting tourists' travel behavior, including intention to revisit a destination (Alegre & Janme 2010; Tasci 2017). It is argued that previous travel experience has a direct effect on destination loyalty, and satisfied tourists are inclined to recommend the travel destination to other people (Loi et al. 2017; Oppermann 2000; Tasci 2017). Huang and Hsu (2009) conducted an empirical research to examine mainland Chinese tourists' revisit intention to Hong Kong. The findings suggest that they are more likely to revisit the city in the future if they are satisfied with their previous trip to Hong Kong. In addition, findings from Cheng et al (2005) suggest that past experience has an indirect impact on behavioral intention.

However, there is very little literature investigating past travel experience or satisfaction's moderating role in tourist behaviors. According to Tosun et al (2015), past experience has a moderating effect on revisiting intention. Hsieh et al (2016) also propose that past travel experience has a moderating role on travel intention (Ajzen 1991; Kidwell & Jewell 2008). Before visiting a destination, tourists would rely on their internal attitude and external source for decision making. If they are satisfied with their previous trips to a destination, they are more likely to revisit the destination (Hsieh et al. 2016). Based on what have been discussed above, the following hypotheses are postulated:

H3: Past travel satisfaction positively influences Chinese tourists' intention to revisit Malaysia.

H4: Past travel satisfaction positively moderate the relationship between subjective norm and revisit intention to Malaysia.

H5: Past travel satisfaction positively moderate the relationship between attitude and revisit intention to Malaysia.

Figure 1: Conceptual framework of the research

Methodology

Online self-administered surveys were applied to collect data from Chinese tourists who had visited Malaysia at least once. Mafengwo.com is dubbed as the Chinese version of Lonely Planet (Wu & Pearce 2016), so invitation letters and online survey links were sent to mafengwo.com users who had posted their travel experience in Malaysia. Keyword "Malaysia" was used to search related posts, and a few thousand of posts were listed. Then a convenience sampling method was used. 1500 invitations were sent out from 28th September to 12th October, 2018, and eventually 276 usable respondents had been collected by 28th December, 2018.

The survey instrument was initially designed by referring to literature in English. Then, the questionnaire was back translated to Chinese for maximum consistency and accuracy (Brislin 1970). Besides, a small scale pretest was

conducted before the data collection stage (Sekaran 1983). Five Chinese students studying in a Malaysian public university were recruited, and all of them expressed that there were no ambiguity and complexity issues with regard to the Chinese version.

The survey has 2 parts. Part A includes items measuring independent moderating and dependent variables, and all the items were either adopted or adapted from previous literature (Huang & Hsu 2009; Loi et al. 2017; Ryu & Han 2010). In terms of measurement scales, survey items were measured by a 6-points Likert scale (Nadler et al. 2015). All Likert scales are ranged from 1 (strongly disagree) to 6 (strongly agree). Meanwhile, part B contains demographic information (i.e. gender, marital status, age, education, occupation and income).

Data Analysis and Findings

Socio-demographic Profile

Table 1: Profile of the Respondents

Characteristics		**Frequency**	**Percentage**
Gender	Male	110	39.8%
	Female	166	60.2%
Age	Below 20	4	1.4%

	3-4 Times	30	10.8%
	5 or Above Times	17	6.3%

PLS Data Analysis

The application of PLS-SEM is increasingly popular among researchers due to its advantages, such as flexibility in handling data (Hair et al. 2017). Besides, the purpose of the present research is to predict the relationships indicated by the conceptual framework. Therefore, PLS-SEM was adopted to analyze data rather than CB-SEM. Smart PLS version 3.2.8 was selected for data analysis.

There are a few standardized stages for applying SEM-PLS, including model specification, model evaluation and final result evaluation (Chin 2010). For measurement model or outer model testing, reliability and validity of latent variables were analyzed. For structural or inner model testing, the hypotheses of the present study were evaluated (Hair et al. 2017).

Table 2: Validation of the measurement scales

Construct	**Item**	**Loading**	**CR**	**AVE**
Subjective norm	SN1	0.911	0.860	0.675
	SN2	0.844		
	SN3	0.693		
Revisit Attitude	ATT1	0.919	0.966	0.876
	ATT2	0.907		
	ATT3	0.929		
	ATT4	0.929		
	ATT5	0.945		
Past Travel	PTS1	0.861	0.956	0.846
Satisfaction	PTS2	0.898		
	PTS3	0.946		
	PTS4	0.969		
Revisit Intention	IN1	0.940	0.966	0.876
	IN2	0.924		
	IN3	1.029		
	IN4	0.842		

Note: CR = Composite Reliability, AVE = Average Variance Explained

Measurement Model Assessment

Both internal consistency and validity were tested to confirm the measurement model. With regard to internal consistency, the present study measured composite reliability (CR) as an alternative of Cronbach's alpha (Hair et al

2017). As it is shown in table 2, all construct's CR values are greater than the threshold value of 0.7.

Convergent validity reflects how much a latent construct could explain the variance of its respective indicators (Hair et al. 2017). To confirm convergent validity, AVE value has to be greater than 0.5 (Hair et al. 2017). As it is shown in table 2, all AVE values range from 0.675 to 0.876. Meanwhile, discriminant validity reflects whether a latent construct is distinct from other constructs by examining correlations (Hair et al. 2017). For the present research, Heterotrait-Monotrait ratio of correlations (HTMT) was used in examining discriminant validity. According to Henseler et al (2016), discriminant validity is sufficient if HTMT value is less than 0.9. As it is indicated in table 3, all HTMT values ranged from 0.282 to 0.656, so discriminant validity was confirmed.

Table 3: Discriminant validity

	ATT	**IN**	**PTS**	**SN**
ATT				
IN	0.577			
PTS	0.656	0.282		
SN	0.469	0.547	0.308	

Note: Discriminant validity established at HTMT $_{0.90}$

Structural Model Assessment

Before moving to the structural model assessment stage, it has to be confirmed that there is no collinearity issue. According to Diamantapoulus and Sigauw (2006), VIF could be used for collinearity test, and the value should be lower than 3.3. As it is shown in table 4, no VIF value exceeds the threshold value, suggesting there is no collinearity problem for the study.

Table 4: Collinearity test

	ATT	PTS	SN
IN	2.280	2.076	1.381

Note: VIF is used to measure collinearity issue.

Then, the structural model of the research was assessed by a bootstrapping procedure. As it is shown in table 5, H1, H2 and H3 are supported. For SN -> IN, β=0.333, t=4.185, LL=0.205, UL=0.467. For ATT -> IN, β=0.502, t=5.917, LL=0.362, UL=0.642. For PTS -> IN, β=0.157, t=2.203, LL=0.037, UL=0.270. Based on these values, subjective norm, attitude and past travel satisfaction have a positive relationship with revisit intention. Path coefficient value of H2 is higher than that of H1, so attitude has a slightly more significant effect on behavioral intention when compared with subjective norm. Besides, the results of path coefficient assessment suggest that past travel satisfaction has a direct relationship with revisit intention, which meets the prerequisite of testing the moderating effect of past travel satisfaction (Hair et al. 2017).

Table 5: Results summary of hypotheses testing

Hypothesis	**Relationship**	**Path Coefficient**	**Std error**	**T Value**	**P Values**	**LL**	**UL**	**Decision**
H1	SN -> IN	0.333	0.080	4.185	0.000	0.205	0.467	Supported
H2	ATT -> IN	0.502	0.085	5.917	0.000	0.362	0.642	Supported
H3	PTS -> IN	0.157	0.071	2.203	0.028	0.037	0.270	Supported

Notes : LL (lower limit) and UL (upper limit) at 95 percent confidence interval.

Table 6: Results summary of hypotheses testing –moderating variables

Hypothesis	Relationship	Path Coefficient	Std error	T Value	P Values	LL	UL	Decision
H4	PTS moderating SN -> IN	0.056	0.112	0.738	0.461	-0.084	0.289	Not supported
H5	PTS moderating ATT -> IN	0.083	0.051	1.109	0.268	-0.141	0.024	Not supported

Notes : LL (lower limit) and UL (upper limit) at 95 percent confidence interval.

Bootstrapping analysis results of H4 and H5 are shown in table 6, For PTS moderating SN -> IN, β=0.056, t=0.738, LL=0.084, UL=0.289. For PTS moderating ATT -> IN, β=0.083, t=1.109, LL=0.141, UL=0.024. Therefore, both hypotheses are rejected as their T values are not significant.

Table 7: Assessment of coefficient

	R^2	f^2	Q^2	q^2
Construct				
ATT		0.199		0.186
SN		0.130		0.111
IN	0.417		0.349	

Table 7 above shows information on coefficients of determination (R^2), effect sizes (f^2), predictive relevance (Q^2) of exogenous variables on endogenous variables, and effect sizes for predictive validity (q^2) in this study. The value of R^2 for behavioral intention is 0.417, and this suggests that attitude, subjective norm and past travel satisfaction explain 41.7% variance of intention to revisit Malaysia among tourists from mainland China. According to Cohen (1989), the model is substantial to explain behavioral intention. With regard to f^2, attitude (0.199) has a medium effect size in producing R^2 for intention, and subjective norm (0.111) has a small effect size in producing R^2 for intention (Cohen 1988). Concerning the value of Q^2, it is greater than 0, which indicates that the model has sufficient predictive relevance, and the exogenous variables (subjective norm, attitude and past travel satisfaction) can predict the endogenous variable (intention). Besides, q^2 values are calculated by the method suggested by Hair et al (2017), and the results coincide with the f^2 values.

Figure 2: Structural Model

PTS-Past Travel Satisfaction, SN-Subjective norm, ATT-Revisit Attitude, IN- Revisit Intention

Discussion and Conclusion

The purpose of the present research is to investigate determining factors influencing revisit intention in the context of Chinese tourists visiting Malaysia. According to the findings, revisit intention is influenced by attitude, subjective norm and past travel satisfaction. There is no significant difference between subjective norm and attitude in influencing Chinese tourists' intention to revisit Malaysia, but attitude is slightly more important than subjective norm on revisit intention, which may imply that Chinese tourists are becoming more independent when it comes to choosing travel destinations (Hsieh et al 2016).

As a matter of fact, the influence of subjective norm varies in different cultural and situational settings (Hassan et al. 2016). Subjective norm may play a more important role in a collectivistic society than in an individualistic society. For example, Asian tourists would highly value opinions from their family and friends, and these opinions may outweigh their own attitude (Huang et al. 2008). It is possible that Chinese society is becoming more individualistic, and Chinese tourists start to focus on their own attitude rather than opinions from others for travel decisions (Li et al. 2011).

Besides, past travel satisfaction is positively related to revisit intention, suggesting that tourists who are satisfied with their previous trips to Malaysia are more likely to visit Malaysia again in the future (Tasci 2017). Nevertheless, past travel satisfaction is less significant than subjective norm in influencing revisit intention, which may be explained by the fact that Chinese tourists prefer to travel with family and friends, and they still value opinions from significant others (Lo & Qu 2014). Moreover, past travel satisfaction does not have any moderating effect in the research. Satisfaction may not necessarily induce loyalty to a destination, and a positive revisit attitude is not equivalent to loyalty (Yang & Lau 2015) . It is also possible that Chinese tourists, especially the younger ones, become mature as

they travel more. Thus, satisfaction may be a prerequisite of destination loyalty, but not enough to influence Chinese tourists' cognitive and affective response to a destination.

Furthermore, there are a few practical implications for destination marketing organizations and other stakeholders in Malaysia in relation to Chinese tourists. The demographic information shows that female tourists play a significant role in China's outbound tourism market. In the survey, 60.2% of respondents are female, coinciding with the fact that female tourists account for more than half of the world travel population (Li et al. 2011). Particularly in China, females are usually the ones who control the family finance (Wang 2009). Therefore, destination marketers should attach more attention on the segment of China's female tourists, and design suitable marketing strategies and travel products accordingly. The demographics also indicate that China's outbound tourists are generally young, well-educated and wealthy. However, the vast majority of them (82.9%) only visited Malaysia 1-2 times. Therefore, marketers and other stakeholders are suggested to diversify their products/services to keep repeat tourists.

As attitude, subjective norm and past travel satisfaction have significant effects on revisit intention, Malaysian tourism policy makers should take measures to improve Malaysia's destination image so as to facilitate Chinese tourists forming a positive attitude of Malaysia. However, attitude plays a more important role than subjective norm in influencing revisit intention (Hassan et al. 2016). The results of the study indicate that China remains a collectivistic society, but the influence of individualism becomes more prevailing, especially among young people. Thus, policy makers and operators need to provide more customized and individualized products to tourists from China. Moreover, they should make sure that tourists would be satisfied or even delighted with their trip in Malaysia for destination loyalty purposes.

Although the research provides insights of revisit intention in the context of Chinese tourists visiting Malaysia, there are some limitations as well. Convenience sampling method was applied for data collection via the internet. Internet users are generally young and well-educated in China, so the collected data is biased to some extent. Another limitation lies in the fact that data of all variables is from the same respondents. Future research should choose different resources for minimizing common method bias (Hulland et al. 2018).

Besides, tourists of different ages and genders may exhibit different purchase and travel behaviors (Božić & Jovanović 2017), so future studies may focus on different segments of Chinese tourists (e.g. young tourists, senior tourists and female tourists). Meanwhile, the study only applied the TRA model with past travel satisfaction to examine tourists intention to revisit Malaysia. However, some other factors are also associated with revisit intention, such as perceived constraints and travel motivation (Huang & Hsu 2009). Therefore, more factors should be considered for examining Chinese tourists' intention to revisit Malaysia.

Abstract

La toma de decisiones llevada a cabo en el consejo de administración está influida por las características y los valores de sus miembros, entre los que ha recibido gran atención la diversidad de género. En esta línea, considerando la escasa representación femenina en la cúpula directiva de las organizaciones, la Comisión Europea ha propuesto una Directiva mediante la cual se pretende promover una presencia de mujeres de al menos un 40% en los consejos de administración de las empresas cotizadas. De esta forma, además de erradicar las barreras que dificultan el ascenso de las mujeres en la escala directiva, se pretende potenciar un mejor desempeño empresarial. Debido a la importancia de esta cuestión, y tomando como referencia las empresas españolas cotizadas durante 2004-2015, se pretende conocer el efecto que la diversidad de género en el ámbito directivo tiene en la eficiencia empresarial, poniéndose el foco en el posible efecto moderador del endeudamiento en tal relación. En este estudio se constata que la diversidad de género en el consejo de administración contribuye a la obtención de una mejor eficiencia empresarial, apoyándose así la necesidad de iniciativas que contribuyan a fomentar la igualdad de género, tanto por motivos de justicia social como causas de estrategia empresarial.

Abstract

E-commerce plays an important role in today's world. Many customers shop online. The boom in e-commerce arrived mainly because today's consumers use the Internet on a daily basis, they like to try new things, discover new brands and products, but they are also modern, demanding and like convenience. The decisive criterion in this regard is access to the Internet, which is no longer a problem as people can now connect to the Internet anytime and anywhere. Life before the Internet is unimaginable for many Millennials. Generation Y uses the Internet in almost every aspect of their lives. Whether it's a search for trusted resources to write seminar papers, order food, watch online TV, or meet new people through cyberspace, the Internet has become an integral part of their lives. While widespread use of the Internet may not necessarily be a negative thing, it has lasting effects on the lives of Millennials. The aim of this paper is to identify the shopping behaviour of Millennials and their preferences when shopping online.

Keywords: electronic commerce, shopping behaviour, consumer preferences, e- commerce.

Introduction

E-commerce is a subset of e-business. Electronic commerce means the use of any information and communication technologies in order to carry out mutually beneficial transactions between the seller and the buyer (Bystrická 2013). The implementation of an information system into business processes, or the creation of an information infrastructure does not mean that it is electronic commerce (Štefko, Pollák, Gavurová 2018). The company can be included in this category only if it conducts communication with customers mainly through information and communication technologies or an implemented information system (Laudon and Traver 2016; Štefko and Šteffek 2017). According to Dorčák (2012), all business activities and services implemented through electronic data transfer tools, directly related to the implementation of business cases, can currently be included in electronic commerce (Bucko, Kakalejčík and Nastišin 2015). As for software or other information, these can also be transmitted to the end consumer electronically. At present, it is possible to carry out electronic commerce not only using personal computers, but also mobile communication platforms (Xanthidis a Nicholas 2004). Suchánek (2012) states that one of the first examples of e-commerce involving physical goods between a large number of sellers and buyers is the Boston Computer Exchange, which was set up in 1982. Manzoor (2010) states that the main elements of e-commerce are mainly online stores and related issues. However, most activities falling under online marketing are also well represented here, e.g. e-mail marketing, various affiliate programs, online advertising and all activities related to the promotion of Internet commerce (Leong and Ibrahim 2015). In a broader sense, we can also include here any websites that offer specific products or services which can be ordered via e-mail (Bhattacharyya and Bose 2020). The first e-shops in the world began to emerge around 1994 (Amazon, eBay, …). According to Tiaga and Tiaga (2012), online commerce is currently the fastest growing segment in terms of increasing business performance and productivity. E-commerce falls under direct sales, as customers can choose the goods without

having to physically visit brick-and-mortar shops or shopping centres (Gerrikagoitia 2015). E-commerce is a fast-growing segment which is now considered an integral part of today's businesses (Shim et al. 2001). Its essence is based on the use of information and communication technologies. Today, online stores make it easier and faster to do business. As e-commerce is a form of direct sales, online shopping is easier and convenient as customers to not have to leave their homes (Čorba and Nastišin 2015). E-commerce covers a range of technologies which make business relationships more effective. Typical technologies involved in e-commerce include the following (Vanhoose 2011): electronic data exchange, electronic forms, electronic catalogues, electronic mail, electronic fund transfer, fax, voice messaging, technical data exchange, workflow (Fedorko 2018). The emergence and gradual use of e-commerce brings various benefits to different organizations, businesses and social groups. The benefits of e-commerce available to customers and businesses include the following (Tondr 2002):

Benefits for customers:

- e-commerce allows customers to compare prices and reviews through comparison websites (heureka.sk),
- e-shops are not limited by regional or national borders, the only things needed are a desktop computer, laptop, tablet or smartphone with the Internet connection,
- e-shops offer a wide range of options when it comes to choosing goods that are systematically categorized,
- opening hours on the Internet, unlike those in brick-and-mortar stores, are not limited (e-shops operate 24/7); online stores are not limited by any days off or holidays. Therefore, the customer can choose and buy products and services at any time convenient.

Kotler et al. (2007) lists these benefits for businesses:

- e-shops provide the opportunity to acquire new customers, as well as various opportunities to identify the needs and requirements of potential customers and consumers,
- e-shops are not as costly, companies connect directly with their distributors, suppliers and customers via the Internet, thus reducing not only their costs but also costs of their customers as customers already deal directly with sellers,
- e-shops provide companies with greater flexibility and allow them to make ongoing adjustments to offers and programs, online catalogues can be adapted and changed at any time - this is not possible with traditional catalogues that are already printed and sent to customers,
- e-shops ensure higher efficiency of distribution lines and logistics functions (sales support, order processing, etc.),
- customers provide feedback via the Internet - manufacturers can improve their products or services and increase the satisfaction of their customers.

Methodology

Based on the analysis of the current state of shopping behaviour, the aim of this paper is to identify the shopping behaviour of Millennials and their preferences in terms of e-commerce.

Scientific methods such as analysis, synthesis, comparison method and selected statistical methods will be used to fulfil the goal of the presented paper. A questionnaire method was used to obtain primary data. The link to the electronic questionnaire was placed on the relevant Facebook pages, it was also distributed, evenly within the regions of the Slovak Republic, by e-mail (the author's private database). A total of 962 respondents filled in the questionnaire, but the research focused only on the new generation of customers (Generation Y), ie respondents from 20 to 36 years inclusive (Young 2017). After removing inappropriate observations, a total sample of 824 respondents was used for the purposes of this paper. The obtained data were processed using Microsoft Excel. The results of individual analyses were obtained through Gretl and Statistica 13.

Inputs to the analysis were obtained by implementing the CAWI (Computer Assisted Web Interview) method. To obtain the necessary primary sources of information and data for the purposes of the paper, an exploratory method

is used, through questionnaires, the principle of which is based on obtaining data based on subjective answers of respondents, which in this case will represent representatives of the new generation of customers (Generation Y) who shop online. The questionnaire submitted by the respondents consisted of 30 questions, of which the first five questions are used to classify the analysed sample for subsequent statistical analysis. The questionnaire focused on demographic information and data related to the consumer behavior of millennials and their perception of uncertainty when shopping online.

The research focuses on a new generation of customers – the Millennials (Generation Y). Regarding the definition of the age group, we relied on the methodology of Young (2017) from the company Ogilvy & Mather. Millennials are referred to as "Generation Y" - people aged 20-36.

Table 1: Age distribution of consumers by generations

C	Centennials (2001-2009)
Y	Millennials (1984-2000)
X	Generation X (1964-1983)
S	Generation S (1963 and earlier)

The research sample consisted of 824 respondents, of which 180 (21.84%) were men and 644 (78.16%) were women. The average age for the whole sample was 24.73 years, for men it was 25.01 years and for women 24.64 years. The reason for this disparity is the fact that women take part in research more frequently than men. Given that the selection was based on availability and voluntariness, the disparity was not “corrected”.

Results

In Table 2 it can be seen that respondents aged 20 to 36 shop online rarely - based on the median value (several times every six months).

Table 2: Descriptive statistics for the item "How often do you shop online?“

Variable	Mean	Median	Modus	Standard deviation	Minimum	Maximum
Frequency of shopping	2,75	3	3	0,674	1	4

Respondents were also asked about the frequency of shopping for selected items. The following Table 3 shows the absolute and relative numbers of replies to the items concerning the purchase of these items.

Table 3: Frequency of shopping for selected items

Variable	Very often		Seldom		Rarely		Never	
Auto-moto	3	0.36%	31	3.76%	151	18.33%	**639**	**77.55%**
Travel tickets	162	19.66%	**239**	**29.00%**	231	28.03%	192	23.30%
Electronics	19	2.31%	249	30.22%	**394**	**47.82%**	162	19.66%
Music (CD / DVD)	25	3.03%	71	8.62%	171	20.75%	**557**	**67.60%**
Food/ groceries	64	7.77%	101	12.26%	144	17.48%	**515**	**62.50%**
Cosmetics / perfumes	78	9.47%	**309**	**37.50%**	252	30.58%	185	22.45%
Books	57	6.92%	**295**	**35.80%**	277	33.62%	195	23.67%
Medicine	23	2.79%	150	18.20%	165	20.02%	**486**	**58.98%**

Lottery / betting	17	2.06%	32	3.88%	90	10.92%	**685**	**83.13%**
Clothing / jewellery	155	18.81%	**372**	**45.15%**	200	24.27%	97	11.77%
PC (hardware / software	15	1.82%	76	9.22%	223	27.06%	**510**	**61.89%**
Insurance	7	0.85%	76	9.22%	257	31.19%	**484**	**58.74%**
Services (cinema, vacation, ...)	118	14.32%	**330**	**40.05%**	274	33.25%	102	12.38%
Sports equipment	39	4.73%	187	22.69%	282	34.22%	**316**	**38.35%**
Furnishings of an apartment / house	45	5.46%	223	27.06%	**345**	**41.87%**	211	25.61%

This item is further described in Table 4. It was found that none of the listed items is bought by respondents at least once every 2 days (very often). Based on the average value, the median, it can be stated that the least frequently purchased items are lottery, auto-moto, music, PC and insurance. On the other hand, the most frequently bought items are clothes and jewellery, services such as cinema tickets, holidays or cultural events tickets, travel tickets and cosmetics and perfumes. The lowest variability, i.e. the difference in responses, was found for the items auto-moto, lottery and betting. On the contrary, we recorded the highest variability in items like travel tickets, food and groceries, cosmetics and perfumes.

Table 4: Descriptive statistics on the frequency of shopping for selected items

Variable	Mean	Median	Modus	Standard deviation	Minimum	Maximum
Auto-moto	4,73	5	5	0,542	2	5
Travel tickets	3,55	4	3	1,050	2	5
Electronics	3,85	4	4	0,754	2	5
Music (CD / DVD)	4,53	5	5	0,777	2	5
Food/ groceries	4,35	5	5	0,969	2	5
Cosmetics / perfumes	3,66	4	3	0,929	2	5
Books	3,74	4	3	0,897	2	5
Medicine	4,35	5	5	0,872	2	5
Lottery / betting	4,75	5	5	0,624	2	5
Clothing / jewellery	3,29	3	3	0,905	2	5
PC (hardware / software	4,49	5	5	0,738	2	5
Insurance	4,48	5	5	0,697	2	5
Services (cinema, vacation, ...)	3,44	3	3	0,884	2	5
Sports equipment	4,06	4	5	0,893	2	5
Furnishings of an apartment / house	3,88	4	4	0,855	2	5

With regard to the selected items, the mutual relations of items were calculated using Spearman's coefficient. The values in Table 5 marked in red were statistically insignificant at the significance level $\alpha = 0.05$. On the other hand, the darker the colour of the cell, the higher the relationship. It can be seen that the items “Electronics” and “PC (hardware / software)” (rs = 0.42); “Sports equipment” and “apartment and house furnishings” (rs = 0.33); “Cosmetics / perfumes” and “clothing / jewellery” (rs = 0.31); “PC (hardware / software)” and “insurance” (rs = 0,31) matched the most.

Table 5: Matches with regard to the frequency of shopping for selected items

Conclusion

E-commerce is a fast-growing segment that is a common part of today's businesses with information and communication technologies in its core. Today, online stores make it easier and faster to do business. As e-commerce allows for direct sales to customers, it is easier to buy goods from the comfort of home. E-commerce covers a range of technologies, the use of which leads to increased efficiency of business relationships.

Based on our research, it can be stated that the least frequently purchased items are lottery, auto-moto, music, PC and insurance. On the other hand, the most frequently bought are clothes and jewellery, services such as cinema tickets, holidays or cultural events tickets, travel tickets and cosmetics and perfumes. The lowest variability, i.e. the difference in the partial responses, was found for the items auto-moto, lottery and betting. On the contrary, we recorded the highest variability in items travel tickets, food and groceries, cosmetics and perfumes. The items "Electronics" and "PC (hardware / software)" (rs = 0.42); "Sports equipment" and "apartment and house furnishings" (rs = 0.33); "Cosmetics / perfumes" and "clothing / jewellery" (rs = 0.31); "PC (hardware / software)" and "insurance" (rs = 0,31) matched the most.

Acknowledgment

This paper is one of the partial outcomes of the current research under the research grant 1/0609/19 - VEGA "Research on the development of e-commerce and mobile commerce and the impact of modern technologies and mobile communication platforms on consumer behaviour and consumer preferences"

Abstract

In parallel to our growing online presence in recent years, zero-day cyberthreats have also become more commonplace and causing a considerable amount of financial damage each year. To protect the end-users from zero-day cyberthreats, it is imperative to provide them with the timely and actionable cyberthreat information. In this work, our approach is building a model to identify cyberthreats for zero-day attacks using heterogeneous information sources, including the dark web. For model building, we investigated three different feature extraction techniques to evaluate their effect on classifying zero-day cyberthreat information using different classifiers. Experimental results reveal that the use of relevant dark web data in model training significantly improves its performance to identify zero-day threats irrespective of the feature extraction technique used while TF-IDF based extraction yields better results than word or sentence based feature extraction in our case. We demonstrated that this approach is equally benefiting for extracting threat intelligence from multilingual surface web data. Our results are validated using two different performance metrics using four different classifiers.

Keywords: zero-day attack, cyberthreat identification, dark web, surface web.

Introduction

Over recent years, cyberthreats have become the most challenging aspect of our IT infrastructure surrounded life-style. Especially so when our online presence is growing due to various reasons including COVID-19 pandemic situation and businesses are becoming increasingly dependent on cloud computing. Recent technological advancements have enabled malicious hackers to commit cybercrimes on an immense scale. The sheer volume of cybercrimes in recent years has made it prohibitively difficult to prevent them with traditional measures. Zero-day attacks, in particular, are some of the most challenging cyberattacks to tackle due to their nature of the attack. Zero-day attacks are defined as the attacks that exploit publicly unknown vulnerabilities of a system, and no signature of the attack exists. Since the exploited vulnerabilities are unknown and the exposed systems have almost no way of knowing that the attack is underway, traditional measures including anti-virus programs and network security devices fall short of preventing such attacks. Therefore, there has been a shift in zero-day and related cyberthreat research in recent years toward proactive cyberthreat intelligence (CTI) gathering from various sources, including the dark web (Almukaynizi et al., 2017, Du et al., 2018, Nunes et al., 2018).

The dark web is defined as the hidden portion of the whole web only accessible through special means such as The Onion Router (TOR) network. Because it is challenging for law enforcement to track down dark web users, especially the darknet marketplaces (DNMs), it fosters a multitude of illegal activities such as buying and selling illegal products including hacking services, drugs, pornography, weapons. The darknet forums (DNFs) and internet relay chats (IRCs) on the other hand are the places where the malicious actors share information, which often includes sharing vulnerability information and elaborate hacking tutorials for hacker newbies.

It is imperative to understand and analyse the threat landscape from both the dark web and the surface web (i.e., regular web) to protect end-users from the growing risk of cyberthreats from zero-day attacks by providing timely and actionable cyberthreat intelligence. However, gathering practical and actionable cyberthreat intelligence from heterogeneous sources is a non-trivial task. Classifying whether the content is security-sensitive or not is imperative for further processing of the said content for extracting cyberthreat intelligence from them.

Techniques in the literature for zero-day identification use either surface web, or dark web information hence has limited success. The efficacy of using both surface and dark web information for zero-day identification has been hardly explored. In this work, we propose a technique to identify such attacks by leveraging the information from the dark web in addition to the surface web. Figure 1 presents a schematic diagram of our proposed approach. We acquired several datasets from both dark web and surface web for cyberthreat identification related to zero-day attacks. Since feature extraction from textual data is the most dominant step for any text classification problem which ultimately impacts our threat identification method, we compare three different feature extraction techniques, namely, word embedding, sentence embedding, and term frequency-inverse frequency (TF-IDF) techniques to assess the most effective one. We used the extracted features to train four machine learning-based text classification models, including two deep learning models. Finally, we compared the trained models' ability to classify zero-day events temporally separated from the training datasets. Moreover, we analysed the performance of each model for their ability to classifying from multilingual contents.

Specifically, the contributions of this work include,

1. For identifying zero-day and non-English cyberthreats, enhancing model performance using both dark and surface web data during training,
2. Investigating the performance of word embedding and sentence embedding techniques for textual feature extraction, along with deep learning models, for zero-days related cyberthreat identification,
3. The efficacy of the proposed approach has been validated with extensive experiments.

Related Works

Since cyberthreats appear as text excerpt, cyberthreat identification from external sources is characteristically a text classification problem. In recent years, there have been considerable improvements in text classification, primarily because of the latest advancements of deep learning algorithms in natural language processing areas. Nowadays, text classification is extensively used in many different areas, including sentiment analysis, spam filtering, and topic detection. However, it is inherently more challenging than other classification domains because of the difficulties in semantic interpretation of text content. For this reason, different approaches for text feature extraction have been evolved, such as Bag of Words (BoW), Term Frequency-Inverse Document Frequency (TF-IDF), word embedding, and sentence embedding. BoW and TF-IDF (Jones, 1972, Salton and Buckley, 1988, Zhang et al., 2011) are two of the most prominent traditional approaches for feature extraction. However, these techniques do not fully consider the semantic information from the text. Moreover, they usually produce a huge vector representation from the text with very sparse information. Word embedding technique (Bengio et al., 2003, Mikolov et al., 2013), on the other hand, preserves semantic meanings of textual words and produces reasonably short and dense vector representation. However, word embedding can not represent the semantic meaning of the words in terms of the sentence structure, which has driven the invention of sentence embedding (Cer et al., 2018), another short and dense text feature extraction technique. There exist some techniques that have used BoW (Al Nabki et al., 2017, Almukaynizi et al., 2017), TF-IDF (Al Nabki et al., 2017, He et al., 2019, Nunes et al., 2018) for at-risk system identification and illegal activities classification from the dark web. However, to our knowledge, word and sentence embedding has not been exhaustively investigated for external cyberthreat.

Applying textual features, machine learning approaches such as Support Vector Machine (SVM), Naive Bayes (NB), Logistic Regression (Log-Reg), Random Forest (RF), and Decision Trees (DT) have been extensively used for text

classification (Joachims, 1998, Manevitz and Yousef, 2001, McCallum and Nigam, 1998). Despite their simplicity, they often demonstrate superior performance for many text classification problems. These classification models also have been used extensively in dark web content classification (Al Nabki et al., 2017, Almukaynizi et al., 2017, Ghosh et al., 2017, He et al., 2019, Nunes et al., 2018, Sabbah et al., 2016). Since text classification is a difficult problem, recently, deep neural networks based models such as long short term memory (LSTM) networks (Li et al., 2018, Liu and Guo, 2019) and convolution neural networks (CNNs) (Kim, 2014, LeCun et al., 1998, Zhang et al., 2015) have gained much attention in this area. Moreover, it requires further study to evaluate the performance of these deep learning algorithms in external threat identification.

Since the dark web is a good source of cyberthreat information, there have been several studies for cyberthreat identification using dark web dataset only (Al Nabki et al., 2017, Ghosh et al., 2017, He et al., 2019, Nunes et al., 2018, Sabbah et al., 2016). Since the dark web dataset is not sufficient to identify all types of cyberthreats, Almukaynizi et al. (Almukaynizi et al., 2017) used several datasets including data from National Vulnerability Database (NVD), Zero Day Initiative (ZDI), and ExploitDB in addition to the data from the dark web. Even though NVD, ZDI, and ExploitDB are collected from the surface web, the researchers did not consider all sources of surface web information.

To bridge the research gaps identified in this literature review, the effective zero-day and multilingual threat identification requires the consideration of all relevant footprints left in cyberspace, which demands to build learning models using both surface web and dark web datasets and evaluate the performance of these models for multilingual threats such as Chinese, Farsi, French, German, Hebrew, Russian, as well as zero-day events.

Feature Extraction and Model Building

To address the research issues identified in Sec. 2, we need to leverage the features extracted from different techniques and build learning models considering the state-of-the-art machine learning algorithms. The popular and emerging feature extraction techniques and machine learning models we investigated are described in Secs. 3.1 and 3.2, respectively.

Feature Extraction Techniques

Term Frequency-Inverse Document Frequency (TF-IDF): TF-IDF is the combination of counting frequency of each term in a single document, and inverse document frequency which is calculated by counting the appearance of that term in other documents of the whole corpus (Jones, 1972). TF-IDF provides higher scores to terms which are significant in a single document but not very common in the whole corpus. For example, the term "news" could be found many times in a single document which indicates that it is a significant term for that document. However, it is quite likely that the same term will appear in all of the documents, which makes it very common, thus not providing any value for classification. Therefore, the TD-IDF score will be very low for this term.

No semantic information is preserved in the TF-IDF process (Kowsari et al., 2019); however, it prioritizes unique and vital terms which makes TF-IDF very efficient in document classification problems (Zhang et al., 2015). One limitation of DF-IDF is that the resultant vector is very sparse, and hence the method is not a very good fit for the deep neural network which prefers dense information.

Word Embedding: Word embedding techniques provide a distributed representation of words in a document while maintaining the relationship with semantically neighbouring words (Bengio et al., 2003, Mikolov et al., 2013). The embedding model used in feature extraction, which is a neural network model with several hidden layers, is trained on an extensive corpus in an unsupervised setting to represent semantically similar words closer to each other. The pre-trained embedders can be used for transfer learning settings as well, a significant strength of this technique over TF-IDF feature extraction. For our study, we have used a pre-trained neural-net language model (NNLM) (Bengio et al., 2003) with three hidden layers originally trained on English Google News 200B corpus, which provides a 128-dimensional vector for each of the words. For the given sentence or paragraph, the resultant representation vector is the weighted sum divided by the square root of the sum of the squares of the weights.

Sentence Embedding: Although word embedding techniques preserve semantic information of the words, the representation of a sentence in word embedding is not straightforward. Sentence embedding techniques try to solve this issue by embedding the whole sentence. Although sentence embedding techniques are a very recent addition to feature extraction arsenals, it has proved to be effective in various text classification problems. In this study, we have used pre-trained universal sentence encoder based on deep averaging network (DAN) (Cer et al., 2018) for sentence embedding, which provides a 512-dimensional vector for each of the entries.

Model Building

In our literature review, we found that the most popular and effective classification models for text classification are SVM, RF, LSTM, and CNN, which we decided to investigate further for zero-day cyberthreat identification. These models are described in this section.

Support Vector Machine (SVM): SVM models try to maximize the margin, which is defined as the smallest perpendicular difference between the decision boundary and the data points, where the decision boundary is placed between the negative and positive samples. For this reason, SVM performs better for binary classification problems (Manevitz and Yousef, 2001). We have used radial basis function (RBF) as our kernel function. The regularization parameter C is set to 1.0 and gamma (of RBF function) is set to scale where it calculates the value based on the number of the features and variance of the training samples.

Random Forest (RF): Random forest classifiers use ensemble technique by training several decision-tree classifiers on different sub-sample of the whole training dataset. The final classification outcome is provided as the average of the outcomes of all decision trees (Ho, 1995). Since they use ensemble technique and decision trees, they usually provide better performance for a small and medium-size dataset. In this work, we have used 100 decision trees to build our random forest classifier.

Long Short Term Memory (LSTM): LSTM (Hochreiter and Schmidhuber, 1997) networks have proved to be very efficient in learning temporal dependencies in sequential data, which made them useful in text classification problems as well because the words in a sentence have a temporal relationship with each other. In contrast to recurrent neural networks (RNN) for time series analysis where the network suffers from vanishing gradients problem for longer sequences, the LSTM networks apply long term short memory technique by using forget gates along with input and output gates to solve the issue. In this work, we have used one bidirectional layer with 64 LSTM cells for text classification.

Convolution Neural Network (CNN): Although 2-D and 3-D CNN networks are the most efficient algorithm for image processing tasks, especially for object recognition (Krizhevsky et al., 2017), 1-D CNN architectures, on the other hand, appear to be effective for text classification problems (LeCun et al., 1998). In 1-D CNN architecture, the convolution layers can learn local features from the text. In this research project, we have used two convolution layers with filter-size of 256 and 128 respectively along with 1x3 kernel size for each filter.

Experimental Setup

Datasets

Dark Web (DW) Dataset: Finding a proper DW dataset for zero-day attack related CTI analysis is extremely difficult due to lack of publicly available dataset. Furthermore, the datasets that are available on request from other DW research groups often lack relevance because of misaligned research interest between groups. On the other hand, collecting DW data directly from the dark web provides better control over the relevance and quality of the data. However, it is often not feasible since it takes a considerable amount of resources both in terms of time and computation power. Moreover, the inherent risks associated with traversing dark web often outweighs the gains acquired.

For our purpose, we used the dataset collected by Po-Yi Du et al. (Du et al., 2018) which has been shared to the research community through AZSecure Hacker Access Portal (http://www.azsecure-hap.com). The dataset contains i) DNFs, ii) IRCs, iii) DNMs, and iv) Carding Shops data scraped from various sites on the dark web using automated HTML crawlers. In this work, we have used DNF and DNM datasets which includes 1,749,572 DNF entries from 8 forums spanning Jun 1, 2002, to Apr 12, 2020, and 253,353 DNM entries from 12 marketplaces spanning Apr 1, 2015, to Jan 1, 2018. In line with the observation of Po-Yi Du et al., we found that most of the entries are drugs-related. However, since this dataset does not include the ground truths, we had to define our ground truth for the dataset. For this work, we set labels based on the mention of common vulnerabilities and exposures (CVE) ids in an entry. MITRE Corporation (MITRE) assigns the CVE ids for the publicly known vulnerabilities as they emerge. Since the mention of CVE id in a specific format on the dark web is an excellent indicator that the entry is related to that particular vulnerability exploitation in some way most of the time, we decided to use this information as the positive/negative indicator. We dropped the CVE mentions from both training and testing dataset to discourage the models from making predictions based on the presence of this information. After data pre-processing and cleaning, we got 6,177 positive entries for cyberattacks from the total 2,002,925 entries, which is 0.31\% of the whole dataset.

The final balanced dataset for our experiment included all of the 6,177 positive entries and randomly selected 6,177 negative entries from the whole dataset.

Surface Web (SW) Dataset: In addition to DW dataset, we also trained our classification models on SW dataset. The resources to collect information from the surface web for cyberthreat identification information is very much non-exhaustive. However, we focused specifically on the dataset collected from Reddit, a community based online discussion forum for almost all of the topics found on the internet, for our SW dataset. There are several subreddit communities in which the discussion is limited on cybersecurity and zero-day attacks (e.g. r/cybersecurity). We searched Reddit submissions from 1st Jan 2015 to 10th Sep 2020 for specific keywords and subsequently labelled them based on CVE mentions. From the timeline, as mentioned earlier, we extracted 1,525 positive entries and randomly selected 1,525 negative entries found using different non-security-relevant keywords from the same timeline. *Table 1* describes both DW and SW datasets.

Table 1: Training and Test Dataset Description

	Training (80%)	Test (20%)	Total
Dark Web	9,171	2,293	11,464
Surface Web	2,440	610	3,050
Combined	11,611	2,903	14,514

Multilingual and Zero-day Events Test Data: Although several non-English entries can be found in our DW dataset from Russian and French languages, positive entries from the DW dataset did not include any non-English content, that is why we decided to discard non-English contents from the negative samples as well. However, to evaluate the robustness of trained models, we decided to collect and evaluate performance on zero-days events and multilingual information from Chinese, Farsi, French, German, Hebrew and Russian language. We used Google News API for searching non-English entries on the surface web, especially from the news article published around the world and translated them to English using Google Translate API. The translation is required since the classification models were trained exclusively on English language contents. In addition to multilingual test data, we collected several zero-day events form the same data source. We defined zero-day events based on the publication date of the data. In this work, we have used 9th September 2020 as the cut-off date, since our SW training dataset does not include anything after the date and the DW dataset cut-off date is further back in time. Our multilingual test data contains a total of 933 entries, and the zero-days test set has 377 entries.

Data Preprocessing

We have applied several standard and situation-specific text pre-processing routines which includes removing any non-ASCII characters, lowercase conversion, removing URLs, removing PGP key blocks from DW entries, expanding contraptions, removing stopwords based on English lexicon, and removing CVE-ids. For sentence embedding, we did not remove stopwords to retain sentence structures as much as possible.

We have used three different feature extraction techniques to compare their effectiveness for our use-case. For TF-IDF feature extraction, we have used TF-IDF vectorization with a max features of 10K, which returned 10,000-dimensional vectors for each of the entries. We utilized transfer learning approach for our word embedding and sentence embedding techniques for feature extraction. Tensorflow Hub is used for accessing trained and ready to use models. For word embedding, we have used the neural-net language model (NNLM) (Bengio et al., 2003) with three hidden layers originally trained on English Google News 200B corpus, which provides a 128-dimensional vector for each of the entries. The universal sentence encoder based on deep averaging network (DAN) (Cer et al., 2018) is used for sentence embedding, which provides a 512-dimensional vector for each of the entries.

Performance Matrices

The following metrics have been used to evaluate the efficacy of our proposed approach.

$$\text{F1} - \text{score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \times 100\%$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \times 100\%$$

$$\text{G} - \text{mean} = \sqrt{\text{Specificity} \times \text{Sensitivity}}$$

$$\text{Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}}$$

$$\text{Sensitivity} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

where TP is the number of positive entries identified as positive, TN is the number of negative entries identified as negative, FP is the number of negative entries identified as positive, and FN is the number of positive entries identified as negative. We have used both F1-score and G-mean for reporting performance.

Result Analysis

The most intriguing insight we found from our F1-score and G-mean score analysis is that the addition of dark-web training dataset dramatically influences the performance of almost all of the classification models, which can be seen in *Table 2* and *Table 3* where models trained on DW dataset and Combined dataset always outperformed the models trained on SW dataset.

Table 2: Effect of using Dark Web dataset for classification models: Zero-days test set

	F1 Score			G-mean Score		
	SW Model	**DW Model**	**Combined Model**	**SW Model**	**DW Model**	**Combined Model**
Word	0.7145	0.6847	0.7588	0.7746	0.7320	0.8126
Sentence	0.9449	0.7617	0.9050	0.9517	0.7923	0.9367
TF-IDF	0.9686	0.8779	0.9878	0.9726	0.8953	0.9930

Table 3: Effect of using Dark Web dataset for classification models: Multilingual test set

	F1 Score			G-mean Score		
	SW Model	**DW Model**	**Combined Model**	**SW Model**	**DW Model**	**Combined Model**
Word	0.8145	0.7439	0.8315	0.8041	0.6787	0.8208
Sentence	0.9521	0.8085	0.8841	0.9569	0.7496	0.8854
TF-IDF	0.9491	0.8826	0.9561	0.9577	0.8734	0.9647

Table 4: Performance comparison of classification models over all feature extraction techniques

	F1 Score				G-mean Score			
Test Data	**LSTM**	**CNN**	**RF**	**SVM**	**LSTM**	**CNN**	**RF**	**SVM**
Zero-days	0.8374	0.8174	0.8782	0.8465	0.8547	0.8525	0.9109	0.8756
Multilingual	0.8488	0.8489	0.9064	0.8724	0.8182	0.8294	0.9106	0.8601

Note that, the DW model in *Table 2* and *Table 3* was trained on dark web dataset only, but tested on assessing identification of zero-day attacks on surface web data. The idea here is that, since more cyber criminal activities are noticed and planned in the dark web much ahead than their actual executions on the surface web targeting everyday and corporate users, a model built on the information extracted from the dark web will be equipped with the required knowledge to predict any impending zero-day attack on real users. This is demonstrated through the much better performance by the models trained with DW and combined datasets, irrespective of the text feature extraction methods used, namely, word, sentence and TF-IDF based methods. Although there is a particular bias regarding the size of our dark web and surface web training dataset, the fact that the performance was solely reported on data collected from the surface web should overcome the bias.

Figure 2: Performance evaluation on Zero-days test data (F1-score)

Figure 3: Performance evaluation on multilingual test data (F1-score)

Figure *2* and **Figure *3*** demonstrate the at-a-glance performance of the trained models on zero-day test data and multilingual test data, respectively, using three different extraction techniques mentioned in Section 3.1. The DW models, SW models and Combined models are trained on dark web dataset, surface web dataset, and their combined dataset respectively. From three different feature extraction techniques we employed, it is evident that the TF-IDF features helped the models best to learn the data distribution, which is also demonstrated in *Table 2* and *Table 3* where TF-IDF showed better performance in almost all of the cases for both zero-day test set and multilingual test set for both F1-score and G-mean score analysis. The TF-IDF feature extraction technique uses the current dataset to extract the most relevant features for the classifiers, enabling it to capture the context and characteristics of the dataset it deals. On the other hand, word embedding and sentence embedding techniques are pre-trained on a much larger global corpus which however fails to perform as expected on a smaller dataset of specialized nature which in this case is CTI.

Additionally, sentence embedding performed much better than word embedding for most of the cases both in G-mean score analysis and F1-score analysis. One of the major limitation in word and sentence embedding techniques are representing and retaining semantic information over the whole paragraph and for the whole document (Kowsari et al., 2019). The average number of words in each of the entries for the training dataset, multilingual test set, and zero-days test set are 171.86, 244.32, and 233.09 words respectively. The word embedding technique averages them as described in Sec. 3.1.2 to produce a 128-dimensional vector. On the other hand, the average number of sentences in each of the entries for the training dataset, multilingual test set, and zero-days test set are 27.41, 52.55, and 54.98 sentences respectively. Therefore, it appears that, in this specific case, word embedding techniques lose more information than sentence embedding techniques for representing and maintaining the semantic meaning of the words and sentences for each entry.

Our investigation on classification models' performance on cyberthreat identification problem reveals that the traditional statistical approaches such as RF and SVM, despite their simplicity, perform better than deep neural network models in most of the cases as shown in *Table 4*. Since both LSTM and CNN has proved to be very efficient in text classification problems over the traditional statistical approaches in various reports over time (Kim, 2014, LeCun et al., 1998, Li et al., 2018, Liu and Guo, 2019, Zhang et al., 2015), we think that they are not as effective in

our case mostly since the dataset used for training and testing these models are small compared to what is expected by them. Although it was possible to carefully tune the hyper-parameters for the neural network models for better performance, the statistical approaches could easily attain better performance with our datasets.

Conclusion

In this study, we investigated the influence of feature extraction techniques and text classification models for cyberthreat identification using the dark web and surface web data. We conclude that the TF-IDF feature extraction technique works better than the latest word embedding and sentence embedding techniques for our case, which features a small and situation-specific dataset. Additionally, despite their simplicity, statistical approaches such as SVM and RF works better than neural network models on problems where the size of the available dataset is much smaller such as cyberthreat identification problem.

Moreover, the dark web training dataset has the potential to add valuable insight for cyberthreat identification problems, especially for zero-day events. In some cases, the models trained on the dark web dataset alone outperformed the surface web trained models, especially for the case of multilingual test data. Particularly, we believe that the addition of dark web training dataset in cyberthreat identification problem could help build more robust models for zero-day attack identification since the zero-day attacks are discussed on the dark web long before the attacks become commonplace in the surface web.

There are some limitations in this study too. We did not collect the dark web dataset by ourself, which limited our ability to collect cyberthreat-specific contents from suitable dark web locations. The problem is evident in our dark web dataset, which has more than 2 million negative samples while only 6 thousand positive samples. In addition to that, our training dataset size for the surface web is smaller compared to our dark web training dataset. Gathering quality data from the dark web is extremely challenging because of the security concerns and resource limitation. Therefore, our current focus is on collecting a better and larger surface web dataset from various locations, including multilingual contents. We also would like to point out that increasing the dataset size could potentially alter the outcome of this study in favour of word and sentence embedding. We would like to experiment on a larger dataset to explore this point in near future.

Despite its limitations, this study provides some valuable insights, as discussed above. Considering the fact that the cyberthreat related research, especially zero-day threat identification using heterogeneous information sources, is a less explored area, we hope that this work would help the broader research community.

Acknowledgment

The authors would like to thank Du P. Y. et al. and especially Mr. Benjamin Ampel for sharing their valuable dark web dataset with our research group.

Abstract

This paper presents a load flow algorithm based on power summation principle, for meshed and radial low and medium voltage distribution networks, based on adaptation of the power summation approach for an on-line use, flexible with network topology reconfiguration. The proposed load flow analysis is based on the use of only linear formulation, based on power summation principle, the proposed load flow algorithm is easy to implement for passive and active distribution networks.

Keywords: Meshed distribution system; Radial distribution system; Load Flow; Power flow summation; Distributed generation; Voltage control; renewable energy.

Introduction

Distribution systems are usually designed as mesh networks, but operate as radial networks, it consists of two switches known as sectionalize switches and tie switches, due to system load balancing, service restoration, real power loss reduction, maintenance activities or voltage profile improvement, the network topology may be changed for several times in the same day.

Power flow is an important tool used in transmission network for power generating planning, the most important load flow methods existing in transmission system are: Gauss-Siedel method, Newton-Raphson method and Fast Decoupled method, for an optimum scheduling between generation plant and exchange of power.

Existing distribution networks load flow algorithms are based on the backward/forward sweep method obtained from the development of two matrices: Bus Injection to Bus Current (BIBC) and Bus Current to Bus Voltage (BCBV), from the topological structure of the network, and from the improvement of the Jacobien-based methods, such as Newton-Raphson, Gauss-Seidel and fast-decoupled methods, however, the computational time of the Jacobien-based methods is large [1][2].

Exiting load flow algorithms for distribution systems are developed from the conductors network characteristics, however, they does not take in consideration the changes in the network topology.

In this paper, we contribute a improvement of power summation based load flow methods, by ensuring an online use, and get flexible with networks topology changes. The proposed method is an iterative procedure based on power summation approach with the only use of Kirchhoff's formulation. From a dynamic data of system, a preliminary calculation is made to organize the radial distribution information. After the organization of the system data information into a suitable model. Voltages of all other nodes are set to the nominal voltage, and an iterative process start by calculating currents of branches using the Kirchhoff's current law, and the node voltages are updating using the voltage drop calculation, this backward and forward sweep are repeated until voltage magnitudes at each node in present iteration and previous iteration is lower than a tolerance limit. An IEEE 33-bus radial distribution system is taken as a study system for performing the test of the proposed method, the results shown are compared with three existing load flow methods presented in [3]: Primitive Impedance based Distribution Load Flow (PIDLF), Current Injections based Distribution Load Flow (CIM) and Fast Decoupled Single Matrix Model Distribution Load Flow (SMM).

Cite this Article as: Yassine MALIARI and Ahmed ABBOU "A Flexible Load Flow Algorithm with Network Topology Reconfiguration for Radial and Meshed Distribution Systems Based on Power Summation Approach" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The main contributions of this paper is presenting a simple load flow method to implement, flexible with the network topology changes, the reducing flow calculation is obtained by ensuring an only use of simple algebraic expressions without any trigonometric functions or matrix calculation. The proposed load flow method is valid for meshed and radial distribution system with or without distributed generations, and it's flexible for the network reconfiguration.

In what follows, we present an overview of the existing load flow algorithms in section II. Next in Section III we provide existing control systems in the current medium distribution networks, for smart metering and supervisory control and data acquisition of the network, in section IV we discuss the results obtained from a 33-bus test system, and the comparison of the results with other existing load flow methods. Section V concludes this paper.

Overview of existing load flow algorithms

The most used power flow methods are: Gauss-Siedel method, Newton-Raphson method and Fast Decoupled method. The first step in performing those load flow analysis is the construction of the Y-bus admittance matrix using the transmission line and transformer input data.

The Gauss-Seidel load flow uses an iterative method based on Gauss equation, the Newton-Raphson is based on the expanding in Taylor's series about the initial estimate the active and reactive power formulation, the terms are limited to the first approximation of the equations. The Fast Decoupled Power Flow Method is one of the improved methods, which is based on a simplification of the Newton-Raphson method, the convergence is geometric.

A common procedure of the three methods, adopted for analysing power flow in a power system is discussed in the pseudo-code shown in Fig.1 [3].

```
# Start
# Construction of the Ybus Matrix
# Make an estimate of the voltage plan
# Substitute the old values into power equations for the next iteration
# Obtain the new value
# compare the new value with Old value
# If (New value – Old value) < specified tolerance; then end otherwise go to step 4.
```

Fig. 1: Pseudo-code procedure for analyzing load flow in a power system

But distribution system in North Africa are characterized by a high R/X rations and a strongly radial structure, which leads to ill-conditioned matrices and poor convergence characteristics of those load flow methods.

The problems have been revealed in a number of papers, where the classic transmission methods were not appropriate to solve practical problems presented when analysing distribution systems [4].

Several works had been presented in the scientific literature; the methods used can be divided into two principal categories: Methods based on the amelioration and adaptation of transmission methods such as fast-decoupled, and others are based on power summation method.

In what follow we constrate on the devellopement based on the power summation and the exploration of the radial structure of distribution network in North Africa.

The power summation method may be described in the following steps [5]:

Calculate the current injection at each busbar x using Eq 1:

$$I_x^{(k)} = \left(S_x / V_x^{(k)} \right)^* \quad x = 1,2,\ldots,n \tag{1}$$

Where Si is the power injection at node i, V(k)I is the voltage of node i calculated from iteration k.

- Start from an estimate of the voltage plan: 1 p.u.

- Go from the last busbar of each branch to the HV/MV substation busbar of each branch (backward path), use the estimated voltage values to estimate the branch current : Starting from the last ordered branch, with a direct application of Kirchhoff's Current Law (KCL) and Kirchhoff's Voltage Law (KVL) [6], current Jx,x+1 in branch from the node x to the node "x+1" is calculated using Eq 2:

$$J_{x,x+1}^{(k)} = -I_x + \sum J_x \tag{2}$$

Where Ix is the current injection of node i calculated from step1, $\sum J_x$are the currents in branches emanating from node "x".

- Go from the leaves to the HV/MV substation busbar to the last busbar of each branch (Forward path), use the branch current values to evaluate a new voltage magnitude using equ3:

$$V_x^{(k)} = V_{x-1}^{(k)} - Z_x J_x^{(k)} \ , x = 2,3 \ldots., n \tag{3}$$

Where Z_x is the series impedance of branch 'x-1,x"

- Go back to step3.

The algorithms converge when all voltage magnitudes calculated in present iteration and previous iteration remain between a pre-established tolerance.

$$\max\left(\left[V^{(k+1)}\right] - \left[V^{(k)}\right]\right) < \varepsilon \tag{4}$$

Advantages of the power summation method: based on the exploration of the network tree structure to calculate the desired variables, it is not necessary, as newton-raphson or Fact Decoupled algorithms, to store and factorize any matrix.

The power summation method needs two principal information:

- The active and reactive power of each network node, which can be provided by digital meter, and be collected by the smart metering infrastructure.
- Electrical characteristics between the sending and the receiving node of each branches, which can be provided by the technical characteristics of each cables and lines used, the topology modification can be detected by the medium voltage remote control or manually by the operator who applied the modification.

Existing Control Systems Used in the Current Distribution Networks

The needed information for power summation method can be provided by digital meter installed at consumers, utilities should equip the public busbar with digital meter to provide the active and reactive of all the network nodes

Those measurements could be collected by an advanced meter infrastructure, already exiting in several medium voltage networks and reassembled in a Load-Data table:

TABLE 1: LOAD-DATA TABLE

Node	KVA	KVAr
…	…	…
…	…	…
…	…	…

From a table with all electrical characteristics of each network, obtained from the electrical characteristics of each conductors used, and organized as shown in table 2.

TABLE 2: Line-Data table

Sending node	Receiving node	R (Ohm)	X (Ohm)
…	…	…	…
…	…	…	…
…	…	…	…

The network topology is not constant, the network topology may be changed for several several reasons, as discussed in the introduction section, however, any change in the topology structure can be detected manually or by the existing SCADA, installed at HV/MV substations, and used as medium voltage network remote control system.

A flexible load flow algorithm with network topology reconfigurations, can be obtained as shown in fig 2.

Fig. 2: Schematic of the flexible load flow principale

Algorithm Development

Let's take a simple network as shown in fig-3 to illustrate the methodology chosen to develop a network analysis method.

Current injections and relationship between the bus current injections and branch current can be obtained by applying Kirchhoff's current law (KCL) to the distribution network. The branch currents can then be formulated as functions of equivalent current injections.

Fig. 3: Single line diagram of the proposed distribution network

For example the currents branch 1; 2; 3 and x can be expressed as:

$$J_{x,x+1}^{(k)} = I_x + \sum J_x \tag{5.1}$$

$$J_1 = I_2 + I_3 + I_4 + I_5 + I_6 + I_7 \tag{5.2}$$

$$J_3 = I_5 + I_6 \tag{5.3}$$

$$J_5 = I_6 \tag{5.4}$$

Therefore the relationship between the branch current and injections or consumptions currents can be expressed as:

$$\begin{bmatrix} J_1 \\ J_2 \\ J_3 \\ J_4 \\ J_5 \\ J_6 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} I_2 \\ I_3 \\ I_4 \\ I_5 \\ I_6 \\ I_7 \end{bmatrix} \tag{6.1}$$

$$[J] = [BIBC] \times [I] \tag{6.2}$$

The voltage magnitude of each node can be obtained as follows:

$$V_2 = V_1 - J_1 Z_{12} \tag{7.1}$$

$$V_3 = V_2 - J_2 Z_{23} \tag{7.2}$$

$$V_7 = V_2 - J_6 Z_{26} \tag{7.3}$$

Zxy are the line impedance between node x and node y. From the equations (6) and (7), we can obtain:

$$V_7 = V_1 - J_1Z_{12} - J_2Z_{23} - J_6Z_{26} \tag{8}$$

The equation (8) shows that the voltage magnitude of each node can be expressed as a function of injections or consumptions currents, line parameters and the root busbar voltage. therefore the relationship between branch currents and bus voltages can be expressed as:

$$\begin{bmatrix} V_1 \\ V_1 \\ V_1 \\ V_1 \\ V_1 \\ V_1 \end{bmatrix} - \begin{bmatrix} V_2 \\ V_3 \\ V_4 \\ V_5 \\ V_6 \\ V_7 \end{bmatrix} = \begin{bmatrix} Z_{12} & 0_{00} & 0_{00} & 0_{00} & 0_{00} & 0_{00} \\ Z_{12} & Z_{23} & 0_{00} & 0_{00} & 0_{00} & 0_{00} \\ Z_{12} & 0_{00} & Z_{34} & 0_{00} & 0_{00} & 0_{00} \\ Z_{12} & 0_{00} & Z_{34} & Z_{45} & 0_{00} & 0_{00} \\ Z_{12} & 0_{00} & Z_{34} & 0_{00} & Z_{56} & 0_{00} \\ Z_{12} & 0_{00} & 0_{00} & 0_{00} & 0_{00} & Z_{67} \end{bmatrix} \begin{bmatrix} J_1 \\ J_2 \\ J_3 \\ J_4 \\ J_5 \\ J_6 \end{bmatrix}$$

$$[\Delta V] = [BCBV] \times [J] \tag{9.2}$$

The two matrices BIBC and BCBV depend on the topological structure of the network. Combining equation (6.2) and (9.2), the relationship between injections or consumptions current injections and bus voltages magnitudes can be expressed as:

$$[\Delta V] = [BCBV][BIBC][I] = [DLF][I] \tag{10}$$

DLF is a multiplication matrix of BCBV and BIBC matrices

After preparing the BIBC and BCBV matrices, the voltages of all nodes are set to the nominal voltage "1p.u", as an initial value, an iterative procedure based start:

After the calculation of a [V(k)]
The new value of current injection is calculated by :

$$I_i^{(k)} = \left(S_i / V_i^{(k)} \right)^* \tag{11}$$

The $\Delta V^{(k+1)}$ is:

$$\left[\Delta V^{(k+1)}\right] = [DLF] \times \left[I^{(k)}\right] \tag{12}$$

And the new value of voltage is obtained by equ 13:

$$\left[V^{(k+1)}\right] = [V^0] + \left[\Delta V^{(k+1)}\right] \tag{13}$$

These two steps of computing the current injection, and updating voltage value are repeated until voltage magnitudes at each node in present iteration and previous iteration is lower than a tolerance limit ε.

$$\max\left(\left[V^{(k+1)}\right] - \left[V^{(k)}\right]\right) < \varepsilon \tag{14}$$

Case Study

The proposed mathematic method is tested in this section with a medium voltage network of 33 bus, as shown in fig 4, the topology characteristics of the network is presented in table 1 [4], the topology structure of the IEEE 33-bus is shown in fig 4

Fig. 4: Single phase diagram of IEEE 33-bus distribution system

From a Line Data, that indicates the resistance and reactance of each branches and the topology structure of the network, the iterative steps as shown in section 3.

Conclusions

In this paper, a load flow program based on power summation concept, is used to solve load flow problems in meshed and radial distribution systems, flexible with network topology reconfiguration.

The proposed Load flow method is easy to implement in passif and actif distribution networks, a Load-Data can be obtained and updated by the Advanced Metering Infrastructure (AMI), already existing and used for conusmers connected to the medium voltage distribution network, the needed Data of others loads can be obtained by eqquipping MV/LV substation by digital meters, and connect them to the Advanced Metering Infrastructure network. The Line-Data can be established by collecting the impedance of all the branches constituting the network, any change in the topology structure can be detected manually or by the existing SCADA, at HV/MV substations, and used as medium voltage network remote control system.

The proposed method can be exploited in several distribution network applications: Voltage control, demand side management, energy demand management.

Abstract

The purpose of this article is to develop new and improve existing theoretical foundations and practical measures to implement the tax planning system at the enterprise, taking into account the analysis of its efficiency. The problems of taxation and the direction of its influence on the efficiency of financial and economic activity of enterprises are one of the most actual issues of modern Ukrainian financial management. From the point of view of taxation, the whole process of activity of business entities is characterized by the emergence and change of tax relations. It is necessary to predict the appearance of such tax relations in order to influence them, even before carrying out the respective business operations. Tax planning reduces the uncertainty of the future tax expenditures of economic entities and the degree of their adaptation to an aggressive environment. That is why the peculiarities of the taxation process, its importance for the economy of the country as a whole and for each taxpayer in particular, make it necessary to distinguish the tax payment management system into an independent branch of financial management and a separate scientific and practical direction of economic thought in Ukraine.

Keywords: Tax Planning, Enterprise, Tax Management.

Introduction

Issues tax and taxation have a significant place in the research of economists, philosophers and politicians. From the first definitions of the place and role of the state in taxation, made by the founders of the classical school of political economy (William Petty (1623-1687) - "Treatise of Taxes and Contributions", Adam Smith (1723-1790) - section "The four basic rules of tax" from "An Inquiry into the Nature and Causes of the Wealth of Nations", David Ricardo

VOVK "Tax Planning of The Enterprise and Analysis of Its Efficiency in The Context of Tax Management" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(1772-1823) - "On the Principles of Political Economy and Taxation" and others), attempts were made to define the principles of effective and just taxation.

According to Atamanenko and Shurpenkova (2010), Nepesov (2011) the modern organization of tax planning at Ukrainian enterprises, in addition to its narrow-minded focus on reducing tax revenues, differs from the adopted standards by the excessively high role of enterprise accounting in the field of planning and some indifference of economic and financial services. The last one either do not participate in the planning of tax payments, or collect statistical information, moreover, after the fact.

Thus, the planning of tax payments by enterprises in the modern period of development can become one of the most important and useful functions of enterprise management, which, unfortunately, does not yet have the proper theoretical validity, and in practice is applied purely for the purpose of reducing tax payments to the budget, without taking into account the existing functional relationships in the internal organizational structure of the enterprise, it is haphazard in nature, designates Apressova (2008). All of the above again emphasizes the relevance of the topic of this work.

Encyclopedic Banking Dictionary Fedorov (1995) provides the following definition of tax planning: "minimizing the tax burden through financial planning, including deferred investments, the purchase of non-taxable securities, and the use of various tax warehouses". Dictionary of Business and Economics Terms by Friedman (2012) defines tax planning as a systematic analysis of different tax alternatives aimed at minimizing tax liabilities in the current and future periods. How (together or separately) to report when to sell assets and pay retirement benefits, when to receive income and pay expenses, when and to what extent to make gifts and buy real estate are all examples of tax planning.

Thus, both foreign and domestic researchers under tax planning understand, above all, activities aimed at reducing tax payments. The proposed definitions consider the meaning of tax planning from a purely limited perspective, perceiving it through the prism of confrontation of the taxpayer on the one hand, and the fiscal authorities on the other. At the same time, tax planning aims not only and not so much to reduce the tax deductions of the enterprise, although the optimization of the tax portfolio is its most important function, how much to become a regulator, together with the planning of marketing and production, the process of enterprise management.

The theoretical and practical aspects of tax planning at the enterprise are devoted to the work of many economists. Thus, the article on Armstrong et al (2019) is devoted to studying the strategic response of tax planning the authors of this work note that firms respond to changes in their industry-competitors' tax planning by changing their own tax planning in the same direction.

Chen et al (2019) research how does quasi-indexer ownership affect corporate tax planning. Authors conclude that higher quasi-indexer ownership leads to greater tax saving. So, Cooper and Nguyen, (2019) developed a new theoretical framework that analyses the interactions of motivations and opportunities in multinational enterprises' tax planning strategy. This study provides new insights detailing why and how companies plan their tax. Work of Niu et al (2019) is dedicated the study of the features of tax planning when selling to a competitor in a low-tax developing market.

Bradshaw et al (2019) investigates tax planning issues in enterprises where the state is the main shareholder. Scientists note that tax evasion at such enterprises is much lower. In the article by Ylönen and Laine (2015) discusses tax planning mechanisms for a multinational company that uses transfer pricing to achieve significant tax savings. Höglund, and Sundvik (2016) in their study conclude that outsourcing accounting tasks improves the corporate quality of tax reporting. According to scientists, firms with an internalized accounting function are more active tax planners.

The issues of global cooperation of the largest world states in the field of tax administration were studied by Lips (2018). The role of tax planning in market assessments of corporate social responsibility has been studied by Ling. and Wahab (2018). This study examines tax planning activities for their direct, mediating and moderating roles. The authors conclude that tax planning to moderate the companies' market valuations of social corporate responsibility positively.

Wahab and Holland (2012) notes that tax planning services are the largest source of fee and commission income for UK accounting firms. Authors suggest to use the Effective Tax Rate reconciliations to examine sub-categories of tax planning activities. The influence of the uncertain tax system on the application of the principle of "Aggressive tax planning" in an article by Alm (2014). Main conclusion is that there is much in theory to suggest that uncertainty leads to more use of "Aggressive tax planning", especially when both individual and group motivations are considered. Yaroshevych et al (2019) investigated the scheme of legal reduction of tax payments of companies through the use of a simplified system of taxation of small businesses.

Shevlin et al (2019) consider the impact of corporate tax policy on future macroeconomic growth. *Scientist*s propose an alternative tax rate measure that aggregates cash effective tax rates of researched firms, which reflect not only statutory tax rates, but also other features of the tax code, enforcement, and firms' tax planning. Blaufus, Möhlmann and Schwäbe (2019) explores the state-owned corporate tax strategy news stock exchange.

Laplante, et al (2019) investigate a tax avoidance strategy where firms use the ambiguity inherent in tax reporting to classify indirect costs as research and development (R&D) expenditures to take advantage of the R&D tax credit. Chaudhry et al (2017) examined the effect of the funding status of defined benefit pension plans on company tax avoidance behavior. The article by Kern (2012) examined the tax planning, research, policy and financial statement implications of tax credits via financial reporting income tax disclosures. The work of Marques et al (2011) is devoted to the study of the features of tax planning in Portugal in the context of enterprise profit management.

Thomas Neubig and Sacha (2018) investigate the strategy for tax evasion related to intellectual property and claim that it had resulted in biased measures of trade, GDP, and productivity. Gerasimova and Redin (2015) offer a system of indicators for analyzing the financial stability of the company. The system includes indicators of the quality of management, including tax management.

Summarizing the consideration of different classifications of tax planning, it should be noted that different authors, appealing to approximately the same concepts, interpret them differently. Moreover, the analysis of the economic literature has shown that the types, forms, methods and functions of management are generally defined in the same way, and in tax planning research, which is part of financial management, the same concept is given a different meaning. Obviously, this provision is due to the fact that in the study of general issues of tax planning, the authors abstracted from the basic conceptual concepts of management and planning theory.

Regulation

The main sphere of tax regulation is the economic sphere of society: the incentives and sanctions that attract the inflow of capital and labor to one or another type of economic activity, or, on the contrary, create obstacles to the development of unwanted economic trends. However, must be considered, that the impact of the size of the tax burden and tax rules are also being tested by the political and social spheres.

In all cases, the levying of a tax is considered by each individual as an "encroachment" on its welfare by the state. It is natural that taxpayers of all countries and at all times have been concerned and continue to be concerned about the reduction of fiscal obligations. People have long tried to reduce unnecessary, in their view, fiscal obligations). The psychological basis for law abiding citizens (taxpayers) is their justice - if a person thinks that the law is fair, then he or she respects it, if he / she believes that the law is unjust, then he / she looks for ways of circumventing norms avoid sanctions for its non-compliance.

The microeconomic aspect of calculating the "burden of taxation" involves the problem of the distribution of the tax burden between different social groups and between individual enterprises or groups of homogeneous enterprises, that is, industries (Shurpenkova, 2020). In turn, the distribution of the tax burden by social groups and industries are considered through the lens of the idea of fairness in taxation (Zakharov, 2010). Modern tax researchers believe that the tax system of the state is the most striking manifestation of the correlation of class and group interests, social forces, their struggles and compromises.

Tax Planning and Tax Optimization

Tax planning

Tax planning should be considered as one of the main functions of financial management. Tax expenditures are not intended to generate profit by definition.Taxes are withdrawn by irrevocably and are individually gratuitous, i.e. the organization, in a narrow sense, will not receive on these payments any counter benefits. In other words, it can be argued that the tax planning is one of the basic tools of generating performance indicators of functioning of the enterprise, since the calculation of the performance indicators of functioning of the enterprise without taking into account the tax consequences seems very reckless and irrational (Babanin, 2004). In addition, tax planning is able to become not only one of the most valuable and promising tools that are in the manager's arsenal, it already has a

profound impact on investment policy, on both macro and microeconomic level. Formation of tax planning is shown in figure (Fig. 1).

Tax Planning:

- Search of the most expedient variant of economic activity in terms of its tax consequences;

A pproving of optimized tax plan in the system of general economic planning and appointment of responsible persons for its observance;

- Permanent monitoring of external factors that may affect the results of the enterprise (change of tax legislation, new interpretation of certain norms of tax legislation by state authorities, court practice, economic and political situation in the country and in the world);

Calculation of current tax payments:

- To determine the amounts of tax liabilities based on the results of economic activity for the current tax period;

- Preparing a schedule of repayment of certain current tax payments;

- Monitoring the correctness of amounts of tax liabilities and the timeliness of their repayment.

Budgeting of tax payments:

- Determination of tax liabilities for future tax periods on the basis of interrelated budgets and business plans;

- Control over the implementation of the planned calculations. If the actual results of taxation are rejected from the planned, identifying the reasons for such deviations and adjustment of plans or economic transactions for the future;

Fig.1: Formation of tax planning

Notes: compiled on the basis (Ivanov et al, 2006)

It is worth noting that the budgeting of tax payments includes the calculation of current tax payments, and tax planning includes budgeting of tax payments. That is, there is accumulation of functions carried out by employees of the company from the basic and mandatory calculation of taxes to the special, in order to optimize taxation.

It should be noted that tax planning could be viewed as an element of the controlling system. Practical experience in business management in various areas confirms the effectiveness of the controlling system (Kalaitan, 2018; Kalaitan et al, 2019). According to Barulin and Barulina (2015), the implementation of tax controlling is due to the fact that the efficiency of tax management requires a coordinating system for managing the tax flows of firms. Unfortunately, the tax controlling methodology has not yet received the proper level of development both abroad and in Ukrainian practice.

Tax Optimization

Typically, the term «tax optimization» means the activities implemented by the taxpayer in order to reduce tax payments. There is a widespread belief, that the optimization is carried out only for the purpose of maximizing legal tax cuts. In this case, it is often called «tax minimization». At the same time, in practice, the minimum payments are not always optimal. For example, a company allocated from a general mass by too small tax payments is risking to draw the attention of the relevant authorities, and it is fraught with additional costs for this company (Gavrilenko et al, 2013).

The purpose of tax optimization is not to reduce any tax as such, but to increase all financial resources of the enterprise. Optimization of the tax policy of the enterprise allows to avoid tax overpayments at any given moment of time. In the conditions of high tax rates, improper or insufficient consideration of the tax factor may lead to very

unfavorable consequences or even cause the bankruptcy of the enterprise. The situation when the enterprise pays taxes formally following the letter of law, without binding to the peculiarities of its own business, is occurring less often in Ukraine (Zherebylo et al, 2019).

Reduction of tax payments only at first glance leads to an increase in the size of profit of the enterprise. It is possible that the reduction of one tax will lead to an increase in others, as well as to financial sanctions by regulatory authorities. Therefore, the most effective way to increase profitability is not the mechanical reduction of taxes, but the construction of an effective enterprise management system (Grachev, 2010).

There are three ways to reduce tax payments in international economic practice: 1) tax evasion, 2) tax avoidance and 3) tax planning (Bryzgalin et al, 2006; Ivashko, 2013). Tax evasion is an illegal way of reducing tax liabilities for tax payments. There is no legal option to evade taxes. Tax avoidance – it is minimizing tax liability by lawful use of conflicts and shortcomings in regulatory legislation; the taxpayer fully discloses his accounting and reporting information to the tax authorities. Both of these latter methods (2-d and 3-d), from a legal point of view, do not imply a violation of the legitimate interests of the budget. However, tax avoidance carries additional risks associated with the enormous difficulty of litigation with tax authorities. According to Dubrovsky and Cherkashin (2017) Ukrainian practice at the present stage is characterized by the following main features of the use of tax avoidance tools: 1) the structure of the economy, 2) the specifics of large "oligarchic" business, 3) attractive for small businesses simplified taxation system.

There is no clear line in the literature that separates tax planning from tax evasion. Therefore, it would be appropriate to apply the following criteria by which tax planning can be distinguished from tax avoidance (Kabanov, 2009):

- Tax planning operates in well-known categories, when the expected result can be determined with varying degrees of certainty.
- Tax planning is related to compliance with payment schedules, ensuring future tax payments with sufficient cash resources
- The concept of tax avoidance applies only to individual transactions or their related groups.

However, due to the ambiguity of the legal provisions, the line between planning and evasion can sometimes be blurred. Keeping of this limit while remaining within the law is a must-have task for effective tax planning.

Organization Analysis of Efficiency Tax Planning

The tax planning system envisages the development of a tax plan that covers a set of measures of operational, tactical and strategic levels of tax optimization. Assessing the effectiveness of the tax planning system is the final stage of tax planning. And it is an indicator of the effectiveness of all measures taken to optimize taxation. Elements of this stage are:

- comparison of actual data with planned indicators, determination of the magnitudes of deviations, identification and analysis of their causes, establishment of maximum permissible amounts of deviations (determination of the accuracy of tax planning);
- development of a system of indicators that allow to determine the effectiveness of the applied methods and ways of tax planning, as well as their degree of effect on the effective financial characteristics of the organization (determining the effectiveness of tax planning);
- adjusting the current tax planning system, making decisions on abandoning ineffective methods and developing new ones.

One of the common causes of deviation from the plan in practice is making an unplanned decision or abandoning an earlier one. The task of tax planning in this case is to minimize decisions that are not processed from the point of view of taxation, prompt analysis of changes and adjustments to the plan.

Analysis of the reasons for deviations of actual indicators from the planned ones makes it possible to:

- adjust medium- and long-term plans;
- take into account the identified internal shortcomings in the preparation of new plans;
- improve the planning and management system in the organization;

- to create a database of statistics characterizing the degree of influence of objective external factors on the magnitude of deviations.

Therefore, in order to check the effectiveness of the tax optimization measures, it is necessary to analyze the effectiveness of tax planning. Organizational forms of analysis of the effectiveness of tax planning at the enterprise are determined by its size and branch affiliation, Small businesses with a small number of employees and an industry-wide structure can involve a CFO, a chief accountant, or use the services of a specialist audit or consulting firm to perform the analysis. At large enterprises with an extensive structure, the analysis of the effectiveness of tax planning can be carried out by a special unit that is engaged in economic analysis.

The quality of the analysis of the effectiveness of tax planning depends on the systematic conduct of it. In this regard, all the economic analysis work should be planned at each enterprise. Comprehensive and thematic plans are drawn up for this. A comprehensive plan for analyzing the effectiveness of tax planning is compiled annually and includes a list of individual case studies and a calendar schedule for their implementation. When conducting an analysis of the effectiveness of tax planning, there are steps that are presented in table 1.

Table 1: Stages of tax planning effectiveness analysis*

Stage	Stage content
I stage	Identify the objects, goals and objectives of the analysis
II stage	Development of synthetic and analytical indicators
III stage	Collection and preparation of necessary information, verification of its accuracy, completeness and quality
IV stage	Metering and comparing results with current year target, past year data, and industry average
V stage	The calculation of the influence of factors on the overall indicators
VI stage	Identifying unused reserves to improve tax optimization efficiency.
VII stage	Summarizing the results of the analysis, assessing the effectiveness of tax planning, developing proposals and recommendations

**Notes: compiled on the basis (Pashenko, 2013; Kovalchuk. 2012)*

Particularly important in the analysis is a system of indicators that allows to comprehensively characterize the effectiveness of tax planning at the enterprise. The effectiveness of tax planning is determined by a series of coefficients, the general scheme of which calculates the ratio of the aggregate tax costs or their individual components to sales, cost or profit. Indicators can be calculated both in part of the unit and in percent.

The performance of tax planning can be divided into the following groups (Adamyk, O. V., 2005). Group I - indicators that allow you to get a general characterization of the effectiveness of methods and schemes selected by the company. Group II - indicators that characterize the part of tax payment groups, for example, in product prices and profits. Group III - indicators of the effectiveness of the use of tax benefits. The formulas for calculating the coefficients of each group are presented in Table 2.

Table 2: The coefficient of efficiency of tax planning at the enterprise*

Indicators	Formula for calculation
I group	
The coefficient of tax burden	$C_{tb}=\frac{The\ amount\ of\ taxes\ and\ contributions\ accrued}{Net\ profit\ calculated\ according\ to\ accounting}\times 100\%$
The coefficient of the tax effect	$C_{te}=\frac{Net\ profit}{Accrued\ taxes\ without\ PIT}\times 100\%$
The coefficient of efficiency of taxation	$C_{et}=\frac{Planned\ net\ profit}{The\ total\ amount\ of\ tax\ payments}\times 100\%$
The coefficient of the rationality of the tax policy	$C_{rtp}=\frac{The\ cost\ of\ forming\ and\ implementing\ tax\ policy}{The\ size\ of\ the\ economic\ effect}\times 100\%$
II group	
The coefficient of taxation sold products	

	$C_{tsp}=\frac{The\ amount\ of\ tax\ payments}{Volume\ of\ sold\ products}\times 100\%$
The coefficient of taxation of prices	$C_{tp}=\frac{The\ amount\ of\ taxes\ included\ in\ the\ price}{The\ price\ of\ products}\times 100\%$
The coefficient of taxation of profit	$C_{top}=\frac{The\ amount\ of\ taxes\ paid\ on\ gross\ income}{The\ amount\ of\ gross\ profit}\times 100\%$
The coefficient of taxation of income	$C_{ti}=\frac{Taxes\ included\ in\ the\ price\ of\ products}{Sales\ revenue\ (excluding\ indirect\ taxes)}\times 100\%$
The coefficient of taxation of expenses	$C_{te}=\frac{Taxes\ included\ in\ the\ cost\ of\ production}{Cost\ of\ products\ sold}\times 100\%$
III group	
The coefficient of preferential taxation	$C_{pt}=\frac{Tax\ savings\ resulting\ from\ the\ use\ of\ tax\ benefits}{The\ amount\ of\ tax\ liabilities\ excluding\ benefits}\times 100\%$
The coefficient of effectiveness application of privileges	$C_{eap}=\frac{Tax\ savings\ resulting\ from\ the\ use\ of\ tax\ benefits}{Total\ sales\ volume}\times 100\%$

* *Notes: compiled on the basis (Dolgikh, 2013; Samsonov, 2014)*

The amount of taxes accrued over the period should include not only self-calculated amounts, but also amounts accrued during that period by the tax inspection (including penalties and fines).

Indicators that directly characterize the efficiency of the tax policy of the organization include:

The coefficient of the tax effect indicates how net income is related to each other, which is the main indicator that characterizes the efficiency of financial and economic activity and the total amount of tax payments made by an organization (Dolgikh, 2013). An increase in the indicator, compared to the values of this indicator in the previous periods, will indicate the advantage of the profit received by the enterprise in comparison with the tax expenses, which will indicate the improvement of the effectiveness of the tax policy.

An indicator of the rationality of the tax policy of the organization. This indicator can be calculated both for all tax payments and separately for each tax. However, as economists-practitioners testify the costs associated with implementing the tax burden of the organization should not exceed 50% of the economic impact of the activity.

The tax rate of the products sold is one of the indicators that characterize the effectiveness of the tax policy of the organization. This indicator allows you to determine the amount of tax payments that are per unit volume sales, its decrease indicates a decrease in tax burden and increase the efficiency of tax policy.

Some of the tax burdens that characterize the effectiveness of the tax policy of the organization include:

Coefficient of taxation of income characterizes the share of tax payments levied on receipts (included in price of product) in sales revenue, it indicates raising the tax policy is not effective towards rationalization of tax payments paid from the proceeds (Samsonov, 2014).

Coefficient of taxation of expenses escribes the proportion of tax payments related to cost. It speaks the increase of insufficient effectiveness of tax policy in the direction of rationalization of tax payments related to cost. Coefficient of taxation of profit characterizes the proportion of taxes paid on profit in the balance sheet profit, its increase indicates the lack of efficiency of tax policy in the direction of rationalization of tax payments paid for profit and related to the financial result (Dolgikh, 2013; Samsonov, 2014).

Indicators of the effectiveness of direct and indirect tax benefits include:

The coefficient of preferential taxation allows the organization to determine the degree of influence of one or another privilege on the value of a given tax, as well as the sum of all privileges on the value of taxes paid as a whole. Describes the efficiency and performance of both individual benefits and all used in the organization of benefits. This coefficient must be greater than 0, and the higher its value, the higher the effectiveness of the benefits.

The coefficient of efficiency of application of the privilege allows the organization to determine the share of participation of this or that privilege in the increase of financial resources by the amount of total revenue (Dolgikh,

2013). Allows you to determine the proportion of additional revenue received. Describes the efficiency and performance of both individual benefits and all used in the organization of benefits. At $C_{eap} > 0$, the use of benefits (privileges) brings profit, at $C_{eap} < 0$ - a loss.

The results of the tax planning effectiveness analysis allow us to evaluate the positive effect achieved from tax optimization and to check whether the costs incurred in implementing the tax planning system are less than the benefits obtained by the enterprise through tax planning.

Conclusions and Directions for Further Research

Tax planning - is a special organization of the taxpayers' activity using a variety of methods, techniques and tools provided by the law and do not violate it in order to minimize tax liability of the taxpayer over time. The justified system of tax planning of the enterprise is able to sufficiently minimize the risks arising from the taxation of economic activity. In the systematization of tax planning, the rationale for its principles and methods, the creation of methods for planning the taxation of the enterprise should come to the fore.

Regarding the place of tax planning in the financial management system, the following should be noted. First, as part of the financial management system, tax planning occupies a specific place in it, due to the fact that the tax aspect is present in any segment of financial management of economic entities. Second, since tax relations, as an integral part of financial relations, arise at the redistributive stage of the reproduction process and are the final link in any entrepreneurial decision, tax planning as an integral part of financial management is characterized by limited autonomy. Thirdly, tax savings increase the enterprise's own financial resources, so the ultimate goal of tax planning is not only and not so much tax optimization, but of increasing its financial soundness and importance.

In today's Ukrainian conditions, we can distinguish the following main groups of businesses that are most in need of applying tax planning for their activities. First, these are complex corporate structures that have an extensive network of subsidiaries, where there are a number of additional optimization tasks that are traditionally involved in tax planning and have the most extensive developments in the field. Secondly, it is a newly created private company. The process of capital accumulation leads to the expansion and complication of the activities of many of these firms, as well as to the emergence of other factors that create the need for planning forms adequate to the modern market economy. Third, planning is objectively needed by state-owned and those that were state-owned and now privatized enterprises. For them, the scheduling function is traditional. However, their planning experience relates mainly to the period of a centralized managed economy. Hence the planning at these enterprises was secondary, reflected the planned activities at the central and sectoral levels, and therefore did not imply a serious ability to analyze and predict, determine their own development goals. This group of business entities can no longer live the old way, so forced to learn new methods of tax planning. Despite the fact that this group is the most inertial and conservative, the changed economic conditions make it actively seek out new methods of financial decision-making and engage not only in traditional financial planning but also in tax planning as a financial management subsystem. Fourth, small businesses also need tax planning that use both traditional and simplified taxation systems, or when choosing them, because of their limited resources and other complexities.

The increasing role of tax planning in today's market economy is determined by a number of factors. The need for tax planning is dictated primarily by two main factors: 1) a high level of tax burden for a particular business entity; 2) complexity and variability of tax legislation (Gribnau, 2020). Other factors include increasing the size of the firm and complicating its forms of activity.

Currently, the value of tax planning is growing as a factor of economic growth of economic entities, which is due primarily to the following circumstances:

- political and economic instability and the changes often made to tax law make some organizations more competitive. These are organizations that respond promptly to changes that are being made. As a rule, only business entities engaged in multivariate tax optimization calculations can do this;
- tax saving is a reserve for increasing the firm's net profit;
- maximizing net profit creates the conditions for dividend payments to increase and, accordingly, the value of the stock and the increase in the capitalization (price) of the enterprise.

Tax planning effectiveness analysis is conducted to determine the results of tax optimization measures. Organizational forms of analysis of the effectiveness of tax planning at the enterprise may be different and are determined by its size, organizational and legal form, industry specificity. Successful implementation of this analysis depends on carefully planned work on its implementation. In addition, the information base of the analysis plays an important role, so its completeness, quality and reliability must be checked before beginning the analysis. The results of the tax planning

effectiveness analysis allow us to compare the costs incurred in implementing the tax planning system and the financial savings resulting from tax optimization.

Abstract

Even when Blended Learning is a model that has been developed and studied for at least fifteen years, it is still little used in classrooms and schools in Mexico. The COVID-19 pandemic has brought less up the need to implement teaching-learning processes that incorporate online choices. In Mexico's case, the education in all levels was interrupted in the middle of March 2020; professors had to face the challenge to conclude the courses on distance. At Universidad Nacional Autónoma de México, the Dean declared Blended Learning as the choice to follow the teaching-learning processes during this emergency. In that sense, Blended Learning offers, not only an alternative to online learning, but also to incorporate Information and Communication Technologies into Education daily practice. In this paper it is presented a brief state of the art of Blended learning, concept and main models; as some bibliometric indicators of scientific community interest on the topic. Then a review of university efforts to encourage Blended Learning among a community with thousands of professors and students; and the emergency of training programs from each school to follow courses even with the COVID-19 Pandemic. Finally, it is presented the methodology to develop a Blended Learning session, exemplifying with the Macroeconomy lesson developed for teaching during autumn-winter semester at Engineering Faculty of UNAM.

Palabras clave: Blended Learning, Mexico, University, Teaching-Learning Process.

Introducción

At the end of December 2019, in China, was reported for the first time the detection of coronavirus disease (WHO, 2020) which was later named COVID-19. With a very fast spread around the World, on March 11th of 2020, the World Health Organization (WHO) decided to declare the epidemic to pandemic (WHO2020a). Each country with COVID-19 menace decided measures as growing sanitary infrastructure capacities, teaching populations healthy practices and arriving into lock down, that stop face-to-face schools' attendance (OECD, 2020).

Blended Learning

Blended Learning has multiple denominations as mentioned Driscoll (in Graham, 2006); among them, it is possible to find Flexible Education or Flexible Learning (Salinas, 1999; Li & Wong, 2018); Mixed Formation or Education (Pascual, 2003; García, Cerda, Fernández, Riera, Amat & Higueras, 2020); Hybrid Learning (Bartolomé, 2004; Marsh, 2003; Raes, Detienne, Windey, & Depaepe, 2019; Goodyear, 2020); Learning semipresencial (Bartolomé, 2001; Leão y Bartolomé, 2003; Gamis, 2016); Technology-Mediated Instruction (Bullock et al, 2008; Henrie, Halverson & Graham, 2015); Mixed Mode (Llorente, 2008, Picciano, 2014); Combined Learning (Moran, 2012); Web-Enhanced Instruction (Alghazo, 2006; Wingard, 2004; Walker, G., & Johnson, N., 2008). Denominations vary with definitions; some of them focus on the technologies to deliver materials; others to the pedagogical perspective and, finally, the proportions of face-to-face teachers with the use of online choices. In other words, there are multiple

A methodology proposal to face COVID-19 pandemic situation in Mexico" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

denominations with similar concepts: the integration of Information and Communication Technologies (ICT) into the teaching-learning process without losing the professor's presence.

Graham, Allen, and Ure (2005) identified the Blended Learning as:

a. The combination of instructional media such as audio, streaming video, live virtual classroom, videotape, CD ROM and collaborative learning (Smith &McGregor, 1993; Bersin & Associates, 2003; Orey, 2002a, 2002b; Singh & Reed, 2001; Bishnoi, 2017).

b. The combination of different kinds of pedagogical approaches such as constructivism, behaviorism and cognitivism (Driscoll, 2002; House, 2002; Rossett, 2002).

c. The combination of offline traditional Face-to-Face (F2F) learning with online learning (delivery method) (Reay, 2001; Rooney, 2003; Sands, 2002; Ward & LaBranche, 2003; Young, 2002).

In sum, Blended Learning can be understanded from different perspectives: as a combination of technologies, pedagogical models and intervention modality of the teacher. And as a consequence, the knowledge scope necessary to design BL sessions has been increased and requires to acquiree more abilities and skills. For instance, technological competences required are identified by Vargas (2014) as:

1) Basic Information and Communication Technology (it includes terminology and operating system),

2) Basic ICT applications (Word processor, Spreadsheet and basic databases);

3) Multimedia applications;

4) Multimedia presentations;

5) Educational software as platforms and others;

6) Internet use (for instance: seeking information, Webpages use or edition among others).

Blended Learning Models

Blended Learning is associated with some instructional models that vary according to the type of interaction among teachers-students and students-students; if there is considered to use ICT media or face to face mode; classrooms, labs, computers room, on-line work at home, structured studies program or only specific concepts. Considering all of them, the teacher should choose an appropriate model and include didactic tools into the design to its specific teaching-learning process. As figure 1 shows, the BL Models are divided in two main categories:

- Rotation Models. Education activities take place at school, and are divided in on-line, F2F and collaborative work; usually there are some stations in the classroom or even at the whole school, where students are able to interact with teachers, using computers or making work teams with other students.
- Flexible Models. Education activities are adapted for each student attending its own learning target; it is possible to study at home or in school, on-line or F2F, specific topic or concept or a long studies program. The teaching-learning process is adapted into student requirements and learning objectives.

Figure 1: Blended Learning Models

Source: Adapted from Ayob, Abd Halim, Zulkifli, Zaid & Mokhtar (2019).

The most common are rotation models, however Pandemic situations and next future could represent the inclusion of other options. The models, in very simple way are:

a. Class Rotation Model. It is effectuated at school, where there is infrastructure disposal to facilitate station students' work. The activities are schedule to rotate among workstations, including traditional F2F sessions, on-line sessions, and teamwork; as a consequence, a group is divided in three subgroups, and each of them are assigned into a workstation activity.

b. Lab Rotation. It is very similar to the rotation class; but on-line activities are laboratory practices. It is a very common activity for learning languages or to practice chirurgic procedures.

c. Flipped Classroom. Main tasks are inverted; students learn basic concepts on-line and the session with teachers are for clarifying concepts and to solve problems with other students. In other words, the homework is solved in the classroom while theory is studied at home.

d. Individual Rotation. Rotation is programmed individually, considering each student requirement. The schedules are adapted differentiating students but, following times and general curricula.

e. Flexible. Teachers and students agree on places of study: at home or at school. Each student has its own rhythm and defines how deep their knowledge wants to reach. Teacher interventions depend on the student requirement.

f. Self-Blended Model. Students define the topic or assignment to study; usually activities are designed to reinforce knowledge or learn something additional of the curricula. A teacher can help if a student requires it.

g. Enriched Virtual Model. At home or at school; mainly designed to be on-line, but teacher intervention enriches the learning once or twice a week; it can include other students F2F.

All BL models incorporate on-line and F2F work, adapting activities according to curricula assignments, studies level and students' profiles; in consequence, the execution of each model usually differs from one school to another.

Blended Learning in scientific literature

Blended Learning is a topic that has been growing in published papers, reflecting increasing interest from scientist. To situate this phenomenon, a Scopus searching was made using as a keyword: "Blended learning". The keyword could appear in the title, the abstract or the keywords of the document, any other searching restriction was established. The search was made in the beginning October 2020, finding 8,242 documents, distributed as table 1 shows.

Table 1: Blended Learning documents by type

Document Type	Documents
Article	3,773
Conference Paper	3,219
Book Chapter	707
Review	220
Conference Review	194
Book	57
Other documents	22
Total	8,242

Source: Scopus searching (Scopus, 2020)

The table 1 shows that more than 80% of the documents are articles: published in journals representing 45.7%, while conference papers are 39%. On the other side, book chapters and books represent 9.26% and reviews of conferences and books are another 5% of the total. In other documents category there has been included editorials (22), notes (22), erratum (9) Letter (6), short survey (5), retracted (2) and undefined (6). Meanwhile, Figure 2 reports the growing interest of scientific community for almost 20 years, publishing each year more about Blended Learning problematic and solutions. In 2019 it is recorded a marked decline of publications in Scopus; however, it is probable that in 2020 the numbers growth as a consequence of Pandemic and the encourage for use this modality of education.

Figure 2: Scientific documents about Blended Learning published in Scopus

Source: Scopus searching (Scopus, 2020)

Blended Learning at UNAM

UNAM is the oldest and biggest University in Mexico; it is a Public institution with 360,883 students distributed by studies levels as table 2 shows; most of them in face to face programs with 41,332 professors (EstadisticaUNAM, 2020). The enormous university community represents a challenge to incorporate ICT in current activities, but specially, in the middle of the COVID-19 Pandemic that demands professors and students teaching, learning and interacting on-line without any pre-design of these kind of activities.

Table 2: Students at UNAM

Study level	***Students***
Postgraduate	30,634
Undergraduate	217,808
High School	111,569
Music propaedeutic	872

Source. (EstadisticaUNAM, 2020).

As in all the country and every educational level, the COVID-19 Pandemic interrupted the UNAM activities, suspending all traditional attendance into classrooms; as consequence Dr. Enrique Graue, the Dean of UNAM, the 1st of July of 2020 declared Blended Learning as the education target of the teaching-learning process at the institution (DGCS, 2020).

The Pandemic seems to be an important trigger to encourage the Blended Learning modality; however, for the size of the university and the tradition of F2F lessons, BL is not very well known and less used. A review of UNAM efforts in that sense was made, identifying BL courses on use for students; platforms and courses for teachers, and learning repositories for open educational resources. The table 3 shows reported BL experiences of teachers that developed and use Moodle as complement of their courses.

Table 3: UNAM Blended Learning background.

School, BL course and professor	Description
Language School.	One of the most advanced using BL courses for English teaching. It offers a course structured in 6 on-line hours and 4 F2F hours in two sessions by week. A 140 hours in total and seven learning units (Enallt, 2012)
Faculty of Medicine with the Informatic Biomedicine assignment.	Informatic Biomedicine is imparted as Blended Learning modality that incorporates clinic cases analysis and theoretical discussions (Gatica et al, 2011). Since 2010 the Official Curricula of Medicine studies at the Faculty of Medicine incorporated the Informatic Biomedicine as one of the first semester assignments.
DGTIC-H@bitat platform The Direction of Information and Communications Technology and Computing (DGTIC) at UNAM is in charge of computing and ICT institutional management; and throughout its H@bitat Program promotes the use of virtual spaces to build the B-Learning Courses of UNAM schools. The H@bitat Program reported next experiences (Zamora & Muñiz, 2011), (DGTIC-Educatic, 2020):	
Net@ History by Professor Jesus Nolasco from CCH Oriente	Virtual platform designed to study History of Mexico: Conquer and Colonial consolidation period. Use Moodle Platform to distribute tasks, lectures and to receive homework.
Educational Orientation Course in charge of professor Zaira Monroy Neri from Escuela Nacional Preparatoria 5.	Professor has added documents assigned to students' activities as practice spreadsheets, readings, guides and tutorials. Platform also has spaces to store students' assignments.
Colegio de Ciencias y Humanidades Sur, the Geogebra course was developed by professor Carlos José Navarro.	This course is a complement of F2F sessions; it is possible to download tutorials, exercises and other documents, and to participate in discussion forums from Moodle platform.
Patricia Flores Hernandez from ENP 9 designed the course: Food Orientation aimed at Nutriology Studies in technical level.	The objective is to complement F2F classes. The platform contains individual and group activities, documents and forums to interact on-line.
For the teaching of Geography, History and its Lexic; specially for Sonre, the Greek writing system	Has audio visual materials, also has surveys and tests for on-line assessment.
In the Medicine Faculty, professor Victor Hugo Olmedo has developed the course: Biostatistics.	The content is focused in practice examples, statistics methods and database management. It also contains a Case study activity, that includes a multiple-choice survey and the correspondent feedback.

Source: Enallt (2012); Gatica et al (2011); Zamora & Muñiz (2011); DGTIC-Educatic (2020)

In the case of platforms and courses for teachers, the use of Moodle as the main institutional platform. There are software courses and personalized help to obtain virtual classrooms associated professors teaching the official educational programs. Some workshops and certified programs to manage Moodle, most of them free or with low cost for teachers from UNAM, are available (DGTIC-Educatic, 2020). Other teachers' programs are part of the Open and Distance Education Coordination from UNAM, because all Online Educational courses are programmed in Moodle. In this Coordination, teachers find training in software for educational online activities and other educational topics (CUAEIEED, 2020).

Further, each School and Faculty has its own training program for their teachers; that is the case of Online Training Program, from Engineering Faculty. This Program began with Pandemic suspension of F2F courses, and it is offered

by Educational Computing Services Unity (UNICA) of the Faculty (Ingenieria, 2020). For instance, this Program has official accreditation by UNAM, and is structured to cover in one month a total of 35 hours; with next topics:

- Topic1. Institutional Protocol to continue distance educational tasks, using ICT
- Topic 2. Psycho-social effects of Pandemic. Emotions strategies, personal and professional abilities and online communication.
- Topic 3. Pedagogical and educational aspects in online education. General aspects, teacher online abilities, online learning-teaching processes, online evaluation instruments, and online didactic planning.
- Topic. 4 Information Technologies. G Suite, Microsoft, and Moodle virtual environments, and security and control of online environment.

The training program was transmitted by YouTube open canals and was successful becoming followed by more than five thousand people (Unica-Youtube, 2020).

UNAM also encourages BL efforts reinforcing the development of Open Educational Resources (OER). OER, are any type of educational materials that are in the public domain or introduced with an open license. The nature of these open materials means that anyone can legally and freely copy, use, adapt and re-share them (UNESCO, 2017).

UNAM has multiple educational resources among repositories of schools, faculties, institutes and libraries. To encourage the online resources UNAM built and public: *Toda la UNAM en Línea* (all the UNAM online) that contains thousands of educational, research and cultural resources. This Websites represents an effort to accomplishes the Open Access Policy (UNAMenlinea, 2019).

The other interesting learning repository is the University Learning Network (RUA). The RUA goal is to concentrate, link and be accessible all materials related to the UNAM curricula. Materials included in the RUA are generated by the UNAM or other university authors; and are linked with official study programs and specific topics approved by academic committees (Alcantara, 2018). It has been an enormous effort, considering UNAM has 235 programs of bachelor's degree; 92 postgraduate programs, 263 specialized programs, 3 high school programs and 37 technical options (EstadísticaUNAM). Nowadays, RUA has covered most of the courses of high school level, and some OER for bachelor courses (RUA-UNAM, 2017).

Structuring Blended Learning in Social Sciences teaching at Engineering Faculty of UNAM

At UNAM there is a Support Program for Innovating and Enhancement Educational Projects (PAPIME) with the objective of encourage a constant enhancement of learning-teaching process. The methodology presented in Figure 3, is one of the products of the project called: Blended Learning: …., that is supported by PAPIME.

Figure 3: Designing BL class for teaching Macroeconomy

The methodology has been developed and applied in the design of Blended Learning session to the Macroeconomy topic, that belongs into the Economy Introduction Course of the Engineering Faculty at UNAM. In this case, the result is an OER as the main structure, involving F2F sessions

The methodology is composed by six steps:

7) Define topic and scope. This section consists of choosing and delimiting the topic(s), concepts or lessons to be developed in the structure activities considering a Blended Learning model.

8) To structure the activities that must be considered as part of the Blended Learning Model, it was developed in an Instructional Guide Format. The format contains main information to describe any instructional unit: course, assignment, concepts review, etc. each information field is auto explanatory, making it easier to develop. The filling of Instructional Guide has the intention to string a coherent structure, developing a disaggregated topic or subject (to granulate topics), in such a way that each learning goal corresponds to one or more activities aimed at achieving said goal.

Table 3 shows first part of Instructional Guide; this part refers to general information to identify the Educational Resource, the first column contains information required; second column describes the kind of data or information that describes the field; the third column is illustrating information for the Macroeconomic Topic development. In this way the topic belongs to Economy Introduction. The responsible of project, content design and development of Macroeconomy BL design are cited. In this case the course is part of Engineering program, the course is Economy Introduction, with key number: 1413, plan year: 2016 of the Engineering Faculty at UNAM

At the end of the table, it is recommended to specify the kind of license is given to the BL development material, concerning course description and OER. In this case, as the materials are encouraged to be Open Access, figure 4 presents information of Creative Commons Licenses, and the rights features established for each one. In this way, professor does not leave aside the decision of the type of permissions granted to the resource.

Table 3: Instructional Design Guide. General Information.

P • Attribution-NonCommercial CC BY-NC. • Attribution-NonCommercial-ShareAlike CC BY-NC-SA. • Attribution-NonCommercial-NoDerivs CC BY-NC-ND.	Attribution CC BY.

Note: Remember that Blended Learning requires on-line and alive activities with professor.

Licenses	Description
CC BY	This license lets others distribute, remix, adapt, and build upon your work, even commercially, as long as they credit you for the original creation. This is the most accommodating of licenses offered. Recommended for maximum dissemination and use of licensed materials.
Attribution-ShareAlike CC BY-SA	This license lets others remix, adapt, and build upon your work even for commercial purposes, as long as they credit you and license their new creations under the identical terms. This license is often compared to "copyleft" free and open source software licenses. All new works based on yours will carry the same license, so any derivatives will also allow commercial use. This is the license used by Wikipedia and is recommended for materials that would benefit from incorporating content from Wikipedia and similarly licensed projects.
Attribution-NoDerivs CC BY-ND	This license lets others reuse the work for any purpose, including commercially; however, it cannot be shared with others in adapted form, and credit must be provided to you.
Attribution-NonCommercial CC BY-NC	This license lets others remix, adapt, and build upon your work non-commercially, and although their new works must also acknowledge you and be non-commercial, they don't have to license their derivative works on the same terms.
Attribution-NonCommercial-ShareAlike CC BY-NC-SA	This license lets others remix, adapt, and build upon your work non-commercially, as long as they credit you and license their new creations under the identical terms.
Attribution-NonCommercial-NoDerivs CC BY-NC-ND	This license is the most restrictive of our six main licenses, only allowing others to download your works and share them with others as long as they credit you, but they can't change them in any way or use them commercially.

Figure 4: Common Creative Licenses

Source: Information from Creative Commons (2019)

The second part of the Instructional Guide concerns with Learning Activities. In this sense, second part of Instructional Guide contains the main fields to describe each activity. In this way, teachers can develop structured their activity.

Table 3: Instructional Design Guide. Activity Design

Activity Number and name		Learning Activity 1: Macroeconomy utility.
Target of knowledge: Basic concepts		**Time for the activity:** 10 minutes
Resources to use: Macroeconomy OER	**Evidence/Product:** OER records	**Evaluation/Feedback:** OER feedback and F2F session
Desarrollo de la actividad		
General Procedure **Objective:** To explain Macroeconomy concept and the influence of culture of students, citing reliable sources. **F2F Instructions:** Professors ask students: 1. To study and to research Macroeconomy concept from recommended bibliography references or Open Access sources. 2. Teamwork: To elaborate a conceptual map involving macroeconomy concept The Map has to be uploaded in Moodle. Teams has to be formed by maximum five students; the team is going to be identified by a given number. Suggestion: To elaborate the conceptual map teams can use a brainstorm. **OER Instructions** Conceptual Map about Macroeconomy. Once the map is ready, one of the participants of each team should upload the map into the platform; following next rules:		

- Document Name: MCM_TeamX, where X is team number
- Conceptual map has to contain the complete names of all participants of the team.
- Consulted sources must be cited with APA format.
- To upload the file in Moodle, click the locate the correspondent activity and click on. Click Add submission to view the file uploading area, drag and drop your file, and click Save changes to save your map.

Importance of Macroeconomy.

- To explain how macroeconomy is useful, next task consists: in an individual brainstorm to identify the macroeconomy impact in their life.
- Finally, in F2F session, professor promotes a discussion based in each student ideas.

9) Choosing the software.

The selection of learning platform and software for programming multimedia activities and alive sessions depend on institutional policies. Each educational institution determines if they use a private or free platform; and establishes some user policies, that have to be considered. In the UNAM case, there are Virtual Classroom System and Educational Environments available, as: Web Conference (ZOOM, Blackboard Collaborate and WebEx Meeting) and Learning Management System (LMS) –Moodle.

The purposed methodology was applied, following institutional decisions, in Moodle and for the Multimedia activities development it was decided to use H5P; that is a tool designed to generate content with mainly educational purposes and that is compatible with several digital platforms in the distance education field, such as Moodle. It was decided to use H5P because most of the browsers support it natively, both those focused on mobile devices such as tablets or cell phones or for desktop computers. It is also compatible with the most used operating systems like Android, OSx, Microsoft Windows or GNU / Linux. H5P uses JavaScript as a programming language that runs directly in the browser once the web page has been loaded. And with the help of HTML5 and CSS elements it is possible to generate interactive material with attractive and responsive aspects. Its connection with Moodle, allows to record the evaluation or progress of the student. Another aspect to consider is that each content in H5P can be exported, to other websites, through a single file that compresses and packages the resources (images, texts, sounds and URLs) and logic. Also, the creative community of H5P is active and constantly generates changes and updates that improve the interaction, appearance and experience to the end user. Being a platform based on the drag and drop concept, it is straightforward to create and add new content without knowledge of JavaScript, HTML5 nor CSS

10) Develop on-line study materials responding to activities designed

The programming of the OER was made with the help of three students: one of them in charge of the H5P programming, other in charge of pedagogical aspects, and third student in charge of technical documentation of OER. The developing of didactic activities requires a very near communication of the design team; the use of Instructional Guide has been very useful in this sense, because is not only an initial point of pedagogical discussions, but also, has been use as a requirements description for programming. In this case the participation of an interdisciplinary team has enriched the course and enhanced the pedagogical aspects for all the participants.

Figure 5: Screen sample of Macroeconomy OER (Flashcards)

11) Pilot testing and enhancement

    Th Beta version is going to be ready at the end of November 2020, and there are programmed two kind of testing: First the design team test, then the students of the group number 13 of Economy Introduction course are going to use it. The user survey is going to light the enhance opportunities from students with the right profile.

12) Class delivery under BL mode

    When all tests and modifications become approved, it is feasible and recommendable to make available OER for other teachers in the university, outside of the institutions and even for the general public. It is contemplated also, to upload this OER into de RUA repository.

Conclusions

This research project is contributing mainly with a methodology to develop an Open Educational Resource, but also with a designed BL Macroeconomy course described in an Instructional Guide and with multimedia OER developed. All these elements are going to be calibrated for the end of this year.

The BL of Macroeconomy is a course that combines the F2F activities guide for the professor, with online activities, completing in this way synchrony and asynchrony tasks. All the activities online have associated an adequate feedback, based in affirmative communication to encourage confidence interacting in a constructivist environment; where each student controls its own advances. Each activity is evaluated, and feedback is given at the end.

The research project and the related products were developed by a research team headed by a researcher with expertise in Blended Learning topics, and distance learning experience; a researcher with a wide experience in computing topics as technologies and architectures, supervising the programming of OER. The professor an economist with a wide experience in researching; she has been also professor in economy topics for more than 20 years; knowing the students characteristics and usual problems understanding some topics. The development of the BL course required also the participation of three students; all of them at the end of their bachelor's degree: informatic, pedagogical and industrial engineer. Because the COVID-19 problem was presented almost all the year 2020, each member of the research team developed the job at home, and virtual sessions for presenting advances and theoretical and operational discussions were made weekly.

In this case the participation of an interdisciplinary team has enriched the course and enhanced the pedagogical aspects for all the participants. The use of Instructional Guide has been very useful in this sense, because is not only an initial point of pedagogical discussions, but also, has been use as a requirements description for programming. Also the selection of learning platform and programming tool needs special attention to facilitate the course development.

The existence of financing programs for educational enhancement as PAPIME, guarantees the development of innovative OER, that once published in open repositories as the University Learning Network contributes with knowledge dissemination, one of the substantive functions of educational institutions. In this case, the project produced not only Macroeconomy BL course, but also the methodology that can be used to design Blended learning experiences for any course, topic, workshop or others.

The Macroeconomy BL course is going to be used as part of the current Introduction Economy course in the group 13 of the Engineering Faculty at UNAM. The user survey is going to light the enhance opportunities from students with the right profile. This information is going to be very useful to enhance not only Macroeconomy course, but also the complete methodology.

The conformation of project team has been a key piece to reach successful products. The knowledge and contribution of each members with different visions complemented with the whole vision of the leader of the project has facilitated the information fluxes, constant communication and product constructions

La conformación del equipo de trabajo del proyecto es una pieza clave de los productos generados. La visión de conjunto de la responsable del proyecto estableció no sólo la pauta de esa conformación, sino de la metodología de trabajo y del diseño idealizado de los productos, por su parte, la comunicación continua de todos los miembros del equipo facilitaron el flujo de información, despite the confinement.

Abstract

Any company, regardless of size or field of activity, can face several strategic and tactical challenges, especially when there are sudden economic changes, caused by emergencies and unexpected events. In order to adapt to ever-changing circumstances and opportunities, many companies are forced to make fundamental changes to their strategies and pay more attention to treasury management in order to achieve sustainable development. Treasury is considered a key element of the current and long-term management, ensuring the financing of the activity and the permanence of the enterprise. Its informative content is particularly important in the financial analysis, in the short term allowing the appreciation of liquidity and solvency, and in the long term measuring the need for financing. Using a case study, we show that understanding the enterprise in terms of cash flows is a way to achieve the performance of the enterprise, with simultaneous accounting, financial and investment influences and in relation to the multitude of users of financial information. We conclude that having an adequate system of budgetary control would allow companies to improve their managerial attitude and performance and provide useful information for solving financial challenges.

Keywords: Crisis, Covid 19, Cash Flows, Forecast, Budget, Decision.

Introduction

Any company, regardless of size or field of activity, can face several strategic and tactical challenges, especially when there are sudden economic changes, caused by emergencies and unexpected events. In the current context, influenced by Covid-19, most entrepreneurs focus on protecting employees, a clearer understanding of the risks that may arise in the company's business and crisis management; as a consequence, business plans, revenue and expenditure budgets and the cash flow of companies is constantly changing from day to day.

The occurrence of unpredictable events, such as Covid-19, can have an impact on expected results and profitability, but most importantly it can quickly generate cash flow tensions or even a financial liquidity crisis. Given the importance of cash flow at such times, entrepreneurs need to develop a management plan for available resources until the situation stabilizes. For this, it is essential to consider a perspective on the whole ecosystem that supports the business, as well as the implications of the decisions taken. Therefore, even in an uncertain horizon, good management is based on anticipation and planning.

Knowing that the business is essentially an integrated cash flow system driven by management decisions, the paper presents and analyzes a topic of great interest to businesses in crisis conditions and suggests the treasury budget as a cash flow planning tool, with relevance for business survival, growth and profitability.

The issue is approached in terms of the importance that the treasury budget has in making investment, operational and financing decisions in business, in order to maintain financial balance.

In this context, the first part of our paper describes the concepts that define the company's treasury and presents the general framework for managing the company's cash flows. In order to achieve this objective, the qualitative research methodology was used, as several scientific papers from the literature were analyzed. The research is based on an extensive documentation; it is scientifically based on a comprehensive and relevant bibliographic material,

highlighted in the bibliographic references. The breferences include specialized books, articles, studies, laws and standards, having as source both Romanian and foreign literature. The sources have a great variety, a multidisciplinary content and support our approach.

In the second part of the paper we performed a quantitative research, using as a research tool the case study. Through this quantitative approach we aimed to present a practical model for preparing the treasury budget, using data from a company in the field of wood processing.

The results of this research can be included in an integrated model for assisting managerial decisions. Through this model we aim to place the treasury budget in the sphere of management tools par excellence, as treasury forecasts allow both the anticipation of the company's financial difficulties and the optimization of financing solutions.

Literature Review

The impact of the crisis generated by the Covid-19 pandemic was also felt strongly by the Romanian economy, which was affected by a substantial slowdown in growth, with negative and immediate effects on the population and enterprises, targeting mainly jobs and sales volume. Among the factors that determined the decline of companies we can list: major difficulties in providing the necessary financing and liquidity, blocking credit, declining demand for products and services, high taxation, rising prices for raw materials, energy and food, exchange rate increases and inflation, the financial blockage generated by late payments, the unstable legislative framework, the low degree of absorption of community funds, insufficient measures to support enterprises during the crisis.

These problems affected all types of companies, that were suddenly faced with late payments from customers (who also had cash flow problems), increased costs for repaying loans committed in foreign currency due to the depreciation of the national currency, the decrease in revenue caused by a decrease in demand for products and services offered, etc.

Numerous researches in the field show the importance of traditional budgeting, which was practically proven in periods of stability. According to Berland (2000), in a predictable environment, budgeting allows production optimization, prolongs internal predictability and simplifies resource allocation mechanisms. But in the context of a crisis, budgets have a reduced capacity to play the roles traditionally assigned: goal setting, resource allocation and motivation. This is mainly explained by the high degree of uncertainty, which forces budgets to deviate from their objectives.

In the conception of several authors, in a turbulent environment, the budget is used as a reflection tool to understand the environment (Gervais, 2009). This turbulent environment results from "the uncertainty of the actors' behavior (unpredictability of their actions) and from the dynamic complexity of the environment in which they operate" (Gervais, 2009). Despite the turbulent context, organizations pay continuous attention to the dynamic relationship between objectives and resources, not only during the budget preparation period, but throughout the budget year. Instability requires flexibility, and in the context of the crisis, budgets play a new economic role: to meet the demands of investors (Bescos, 2011).

One of the characteristics of contemporary organizations is their concern to develop efficient management systems and practices, which requires the concentration of efforts in the direction of treasury management. According to Ross et al. (2016), organizations with different sizes face problems that require distinct approaches and appropriate tools, depending on the nature and complexity of the projects undertaken. Therefore, a fast and efficient approach to cash flow prediction is highly desirable. On the other hand, Scott (2007) states that, in terms of the financial decision-making process, a careful analysis of cash flow assesses the decisions made by managers regarding the allocation of financial resources based on the impact on the company's ability to generate future cash flows.

Starting from the distinction between cash flow and cash, in the opinion of Sherman (2010) treasury management (cash flow) refers to the process of anticipation and planning of receipts and payments, while cash management refers to the processes of managing short-term liquidity of the enterprise in order to optimize its results. According to Ekanem (2010), managers need to consider several key elements for effective cash flow management. These elements include people and their mood (business executives, managers and employees), support network (business professionals), key performance indicators, along with appropriate management tools and techniques. For successful implementation, they must operate in an environment that encourages continuous learning and improvement, but always paying attention to the workload and working hours of their employees: bad time management and heavy workload can lead to burnout, that can affect employees' health and performance (Lie & Mihaita, 2015). On the other hand, inaccurate cash flow prediction and inadequate cash management lead to financial problems and negative cash flows (Kaka, Price, 1993).

Anthony (1988) considers that effectiveness and efficiency are the criteria for evaluating the actions of managers, and the role of the budget in achieving them is important, as it allows the translation of medium and long term strategic plans into short-term action programs, ensures budget control, coordinates the decision-making process and ensures the convergence of the strategic objectives of the enterprise.

Often, in small and medium enterprises there are no independent financial departments and because of this the manager is forced to manage both the practical aspects and the financial aspects of the sector he is leading. This situation involves making decisions whose consequences are difficult to quantify and which can shorten the life of the company in question. Consequently, it is necessary to have a clear separation of financial activity, regardless of the type of company, and if this is not possible, the manager must have a thorough knowledge of financial management (Nicolae, 2009).

Although it is recognized that uncertainty management is a necessary condition for effective project management, it can be assumed that it should become more sophisticated before practical results can be observed (Atkinson et al., 2006).

Methodology

Field research is the main part of the paper, this being directed towards current phenomena, analyzed in the real context of the company that is the object of the study. Regarding the method of data collection, for the case study we used data provided by the company under study. In order to complete the research, some data was collected by interview.

The building of the case study is explained by a step-by-step approach. The stages to be covered in the budget process are as follows: (1) gathering the necessary information; (2) preparation of partial treasury budgets; (3) elaboration and adjustment of the treasury budget.

Gathering information is the first step in the budgeting process and is the basis for the next steps. Here the resources available to the company are identified - they are reflected in the balance sheet; the costs related to certain activities carried out are also identified in this stage. Due to the impact of each activity on the cash flow of the enterprise, it is important to identify all the factors that may have an influence on it.

The following steps are developed for the preparation of the partial treasury budgets, the elaboration and adjustment of the final treasury budget. It is necessary from the beginning, as an important step, to establish the prediction horizon of the treasury budget, because in the case of short-term prediction, many parameters are known deterministically. Therefore, the budgets must describe the general lines of the financial evolution, to ensure a margin of maneuver within their own provisions and the possibility to be revised.

Crisis management measures, based on the treasury budget, strengthen our belief that non-specific cash flow forecasting instruments are valid in a highly regulated world, without major dangers or in the absence of essential trade-offs to overcome certain events. But in a more uncertain context, marked by the acceleration of competition or the emergence of a crisis such as Covid-19, it becomes essential for the company to adopt a dedicated cash forecasting tool, according to its business model. Without cash flow forecasts, the company risks running out of cash unexpectedly and therefore going into insolvency or even bankruptcy. We use our experience and also other research in this area to suggest some measures to guide a company to this end.

Use of the treasury budget for forecasting cash flows. Case study

The Treasury registers the cash flows of the various decisions taken by the enterprise; these decisions, depending on the settlement term considered, can be long-term decisions (concerning investments and their financing) and short-term decisions (related to the operation of the enterprise and of its operation). Each of these decisions, regardless of the branch in which it takes place, ultimately materializes in a flow of income and expenditure, which generates receipts and payments, which will be administered in the short term to maintain the balance of the treasury.

Through the budget, it will be possible to highlight the treasury surpluses or deficits from time to time and, implicitly, it will be possible to take decisions regarding the treasury management that aim at:

- ensuring the availability of financing (capital increase, long, medium- and short-term loans) at their lowest cost;

- increasing the efficiency of collecting the company's receivables without affecting the policy towards customers; balanced staggering of the maturity of the company's payment obligations;
- ensuring the treasury at zero level, in order to avoid financing or opportunity costs;
- investing the treasury surplus as profitable and as little risky as possible, etc.

In addition to the theoretical considerations presented above, we will further present, in a case study, a practical model for preparing the treasury budget for a company in the field of wood processing. Due to privacy reasons, the company's name used in the study will be anonymized and referred to as Company X.

Gathering Information

The treasury budget gathers the budgetary information of different financial years, hence the obligation to collect the necessary information. The information necessary for the elaboration of the treasury budget for the current year is collected from the balance sheet of the previous year and from the other approved budgets of the current year. Therefore, for the preparation of the budget three records and forecast documents are used: *the opening balance sheet* (balance sheet for the year ended - Table 1), *the forecast income statement* and *the forecast balance sheet*.

The treasury is based on the financial flows of a certain management period, determined by the income and expenses of the period (income statement) and by the change in receivables and payables at the beginning and end of the period (opening balance sheet and forecast balance sheet), according to relations:

Receipts of the period	**=**	**Initial receivables**	**+**	**Projected income for the period**	**-**	**Final receivables**
Payments for the period	**=**	**Initial debts**	**+**	**Estimated expenses for the period**	**-**	**Final debts**
Treasury budget		***Opening balance***		***Forecast income statement***		***Forecast balance***

Table 1: Annual financial situation Balance sheet at 31.12. 2019 (simplified)

A. Fixed assets		**535617**
Technical installations and machines	Gross value	584287
	- Depreciation	48670
	= Net value	535617
B. Current assets		**111447**
Inventories		2024
Raw materials		576
Final goods		1448
Miscellaneous receivables (1)		36861

Available at the bank	70538
C. Debts to be paid in a period < 1 year	**72172**
Trade debts - suppliers (2)	45120
Tax and social debts	26542
Amounts owed to credit institutions	510
D. Current assets or net current liabilities (working capital) (B-C)	**39.275**
E. Total assets less current liabilities (permanent capital)	221322
F. Debts to be paid in a period > 1 year	**20158**
Amounts owed to credit institutions	20158
G. Equity (E-F)	**191164**
Subscribed and paid-in share capital	120000
Legal reserves	71164

(1) The receivables of the clients are estimated to be collected: 60% in February and 40% in March 2020;

(2) The projected payments to the suppliers are made as follows: 55% of the debt value in the first month and 45% in the second month; of which: VAT payable 2,563 u.m.

Other information necessary for the elaboration of the treasury budget of year 2020: VAT to be paid until the 25th of the following month; VAT rate: 19%; Salaries are paid in the current month; Payment dividends are paid in June; Taxes and fees related to gross salaries due by the company to the state budget are considered 80% of the level of gross salaries; Debts to the budget regarding salaries are paid in the month following the payment of salaries; Income tax rate: 16%; Advance payment of income tax per quarter I and quarter II: in March - 4,000 u.m. and in June - 5,000 u.m.; The profit tax for the previous year is paid in April; The share of VAT generating expenses in the total expenses of the enterprise: fixed expenses 50%, variable expenses 60%, mixed expenses 40%, sales expenses 70%.

Preparation of partial treasury budgets

Cash flow is one of the key factors influencing the survival of small businesses, and the difference between the time of invoicing and the time of collection or payment influences the solvency of the business. Even if it has a profit margin, if a company does not practice good cash flow management, it operates at a significant risk. This becomes even more important for SME owners when operating in a climate of continued global economic volatility.

That is why, whaile elaborating the treasury budget, the distinction between *cash accounting* and *accrual accounting* must be taken into account, because there are situations in which an enterprise can end the financial year with profit, but at the same time it can register a negative treasury, due precisely to the gap between the moment of registering in the accounting the expenses and incomes and the moment of their maturity as receipys and payaments. The treasury budget thus becomes a management tool that translates in monetary terms (receipys and payaments) the expenses and revenues generated by the scheduled activities of the company, aiming to permanently ensure the payment capacity of the company, by synchronizing receipts with payments.

The treasury budget can be prepared for different periods of time, depending on the objectives of the company and the maturities of receipts and payments. Thus, the decision can be made to prepare annual budgets, when the maturities of receipts and payments are quarterly or greater than 90 days, budgets for several months (4-6 months), when the maturities of receipts and payments are monthly and greater than 30 days and day-to-month budgets. However, a realistic budgeting of the treasury is made for a management period of one year, with breakdown by month and breakdown by week for the first three months of the year.

In order to build the company's treasury budget, three distinct partial budgets are drawn up a priori: a revenue

budget, a payments budget, a VAT budget. The amounts related to expenditures and revenues registered in the budgets are without VAT. Receipts and payments must be expressed with VAT included, with the obligation to determine at the end of each month the amount representing "VAT payable" or "VAT recoverable", which will be settled with the state budget.

Revenue Budget

Receipts (cash inflows) refer to: settlements with customers (reflected in the sales budget), down payments received from customers, production of fixed assets (reflected in the investment budget), to which we add the financial receipts from: capital increases; obtaining a loan or selling a new issue of securities; rents, interest, dividends and other income collected.

The forecast of receipts is, in most cases, passed from the sales budget to the receipts from sales. Once the annual turnover and its monthly distribution are established, the forecast of receipts is based on a statistical record of the time staggering of the collection of monthly revenues. Furthermore, the forecast must consider the changes that may occur in the structure of sales and the degree of solvency of the company's customers, which will influence the gap between delivery and collection data, which is often 30-90 days.

The budget has two areas:

- The uppear area of the table allows the calculation of the turnover (including VAT) and the VAT collected for the current month (which is taken over in the VAT Budget)

- The lower area of the table highlights the receivables from customers and other receivables, which appear in the balance sheet of the previous year, taking into account the discrepancies on receipts, due to the agreed settlement terms.

The Revenue budget of Company X, for year 2020, is presented as follows (table 2):

Table 2: REVENUE BUDGET

Specification	Jan.	Feb.	Mar.	Apr.	May	June	Sem. I	Total year
1. Sales (excluding VAT) (according to Sales budget)	28000	30160	31200	32240	35040	35680	192320	423280
2. VAT collected	5600	6032	6240	6448	7008	7136	38464	84656
3. Turnover (including VAT) (1+2)	33600	36192	37440	38688	42048	42816	230784	507936
4. Accounts receivable from the initial balance sheet	0	22116	14744	0	0	0	36861	36861
5. Operating subsidies	0	0	0	210	0	100	310	530
6. Investment subsidies	10	0	5	0	10	6	31	50
7. Dividends receivable	0	0	0	0	0	875	875	875
8. Receipts from bank loans	0	400	0	0	0	0	0	400
9. The result of the disposal of the assets	0	0	130	0	0	140	270	460
10. Other receipts	40	35	29	31	27	25	92	279
Total receipts	**33650**	**58743**	**52348**	**38929**	**42075**	**43962**	**269223**	**547391**

Payment budget

Payments (cash outflows) refer to the payment of debts caused by purchases (reflected in the supply budget), payment of salaries and premiums, operating, administration and distribution expenses (included in the production expenditure budget, in the distribution expenditure budget, in the budget of administrative expenses, etc.), acquisitions of fixed assets (reflected in the investment budget), taxes and fees due to the state budget, to which payments of a financial nature are added: interest and dividends paid, loan repayments, purchases of financial securities, redemption of securities issued by the company.

Payments (cash outflows) refer to the payment of debts caused by purchases (reflected in the supply budget), payment of salaries and premiums, operating, administration and distribution expenses (included in the production expenditure budget, in the distribution expenditure budget, in the budget of administrative expenses, etc.), acquisitions of fixed assets (reflected in the investment budget), taxes and fees due to the state budget, to which payments of a financial nature are added: interest and dividends paid, loan repayments, purchases of financial securities, redemption of securities issued by the company.

The forecast of payments is made on the basis of projected expenditure and the planned staggering of payments and differs according to the nature of the expenditure, such as expenditure on material supplies, which is planned according to the manufacturing schedule or staff costs, which are provided taking into account the company's labor policy, etc.

The payments budget (Table 3) groups the expenditures appearing in the expenditure budgets, according to their way of regulation. The amount representing the "VAT payable" for the month, established in the VAT Budget, is also entered here.

Table 3: BUDGET OF PAYMENTS

Specification	Jan.	Feb.	Mar.	Apr.	May	June	Sem. I	Total year
1. Provider liabilities from the initial balance sheet:								
- payment in the first month 60%	27072	0	0	0	0	0	27072	27072
- payment in the second month 40%	0	18048	0	0	0	0	18048	18048

11. Interest on loans	27	34	7	7	7	7	90571	115643
Total payments	**62052**	**54568**	**42660**	**37349**	**41267**	**48885**	**286781**	**566613**

VAT budget

This budget allows the calculation of "VAT payable" according to the rule:

VAT payable for month M	**=**	**VAT collected for month M**	**-**	**Deductible VAT for month M**

The VAT payable for a given month is paid during the following month.

The construction of the treasury budget requires the determination of the corresponding amount "deductible VAT" for the month and, therefore, the restoration of purchases of any kind.

The top of the table allows you to highlight purchases with VAT included, so that you can determine the amount representing "deductible VAT" for the month.

The bottom of the table enables the establishment of the “VAT payable” for the month, using the rule stated above; it represents the main area of the VAT budget.

Based on the information collected, the VAT Budget of Company X is presented as follows (Table 4):

Table 4: VAT BUDGET

Specification	Jan.	Feb.	Mar.	Apr.	May	June	Sem. I	Total year
I. Deductible VAT for the month, of which for:	**2185**	**7061**	**2186**	**7825**	**2087**	**8372**	**29716**	**69127**
1. Supplies of raw materials	0	4882	0	5693	0	6195	16770	42896
2. General production costs	2185	2179	2186	2132	2087	2177	12946	26231

2.2 variable production costs	132	133	129	131	140	138	806	1595
2.3 mixed production costs	204	208	201	210	200	204	1230	2456
2.4 sales expenses	1478	1467	1485	1420	1376	1464	8684	177230
II. VAT collected for the month, of which for:	**5600**	**6032**	**6264**	**6448**	**7008**	**7162**	**38515**	**84743**
1. Sales of final products	5600	6032	6240	6448	7008	7136	38464	84656
2. Other sales	0	0	24	0	0	26	51	87
III. VAT payable for the month	**3415**		**4078**		**4921**			
IV. VAT recoverable for the month		**1029**		**1377**		**1210**		

Preparation of The Treasury Budget Itself

Once the partial treasury budgets have been established, **the treasury budget** is drawn up.

The treasury budget is generally presented in two succesive version and the budget work consists of:

a) establishing an initial version of the budget, which contains the gross monthly cash balances;
b) the development of an adjusted treasury budget, which takes into account the financial policy of the company.
a) **Initial version of the budget.** In this perspective, month by month, the revenues are compared with the payments, so that they are taken over in the previous partial budgets; at the same time, the availabilities that appear in the balance sheet of the previous year are taken into account.
This version is set column by column because the final cash balance of a given month becomes the initial balance of the following month.
b) **The adjusted (actual) treasury budget** resumes the total receipts, the total payments and, considering the initial treasury, will release the final treasury balance every month. These final cash balances may be deficits or surpluses. Only the financial manager can balance this treasury, so that the adjusted treasury budget must present zero or positive cash balances, as it will consider the financing policy adopted by the enterprise to balance its treasury. Preventive negotiation of short-term financing is generally less costly and safer than resorting to possible short-term loans in the event of a negative treasury.

The following rules are taken into account for the construction of the treasury budget:

- the initial balance in January corresponds to the treasury in the initial balance sheet;
- the final cash balance of one month is the initial balance of the following month;
- the final balance of December, after applying financing solutions, corresponds to the treasury from the forecast balance.

Final balance = Initial balance + Receipts – Payments

When the final balance is positive, the company has a cash surplus, which in the short term should be deposited in the bank to avoid the opportunity cost.
If this balance is negative, the company has a cash deficit, which must be absorbed by short-term financing, usually in the form of short-term bank loans, etc.
After adjusting the balances, the treasury budget (adjusted) or the cash flow plan (table 5) is drawn up.

Table 5: TREASURY BUDGET

	Jan.	Feb.	Mar.	Apr.	May	June	Sem. I	Dec.
Initial balance	72562	44160	48335	58023	59603	60411	72562	72562
Receipts	33650	58743	52348	38929	42075	43962	269707	547391
Payments	62052	54568	42660	37349	41267	48885	286781	566613
Final balance	**44160**	**48335**	**58023**	**59603**	**60411**	**55488**	**55488**	**53340**

The treasury budget is not flexible but needs to be reviewed frequently. Resulting from all the other budgets that make up the company's budget network, it bears all the effects of their changes: slowing or accelerating sales, rising wages, changes in commodity prices, changes in fiscal policy, etc. All these reasons show the need for frequent adjustments in order to have a budget as realistic as possible.

The company will need to test financial plans under stress in several scenarios, to understand the potential impact on financial performance and to assess its duration. When the business is significantly affected and previous budget assumptions and business plans are no longer relevant, the company must consider minimum operational requirements, including essential dependencies on manpower, suppliers, location and technology. Thus, a detailed analysis of the nature of receipts and payments is required, and the cash flow forecasting instrument should therefore be constructed according to the typology of receipts and payments, and not according to budgetary elements.

During the process of elaborating the treasury budgets, in a crisis situation, such as the crisis generated by COVID-19, the company must pay attention to the communication it has with different actors on the market:

- in relationship with customers, during the Covid-19 crisis, the company risks facing the absence of new orders or the collection of advance payments, with possible difficulty in fulfilling orders due to interruption of production process or suppliers, difficulties in recovery the value of goods and services in case of customers' inability to pay. In this situation, it is important to have direct communication between business partners in order to extend the deadlines or to invoke "force majeure" or "fortuitous event". These proactive actions will help mitigate damages or liability for non-performance of obligations towards customers.

- in its relationship with suppliers, the company must maintain regular contact with regard to their ability to deliver goods and provide services, as well as with regard to their plans to recover their value, thus enabling them to consider alternative options for receiving supply in a timely manner.
- in relation to creditors and investors, the company must analyze the terms and conditions of loan agreements, to identify debts and avoid breaches of contracts. These analyses will also have the benefit of giving the company the opportunity to proactively manage dialogue and communication with creditors on any necessary changes to existing conditions or refinancing agreements.
- in relation to government and regulatory authorities, the company should consult with their legal teams for advice on possible obligations, as well as with the business units, to see how to manage the communication of ongoing infringements and the collection of evidence, if any.

Pilotage measures in crisis situations based on the treasury budget

The companies' performances are the result of mobilizing all the resources they have, and in crisis situations the managers explore all the methods of flexibility and adaptation to the internal and external requirements of the organization. Having permanently as reference the treasury budget, the enterprises can resort to a series of measures that would allow them to pilot the enterprise in these unfavorable conditions:

- *Monitoring and updating the treasury budget as often as possible*. In times of crisis, the treasury budget becomes an extremely important tool, which provides a clear picture of receipts and payments. A correct planning and a permanent monitoring of them allows detailed analyses regarding the past financial results, the cash flow registered in a certain time interval, the activity of the cost and profit centers and taking the required corrective measures in order to remedy some unfavorable situations, which negatively affect the profitability of the business.
- *Avoid liquidity blockages*. During this period when many companies are likely to have fluctuations in sales or will face problems caused by very large increases in expenses, late collection of invoices from customers or discontinuity in the supply of stocks (because the supplier is blocked due to an outbreak of infection, because the supplier requires prepayment or reduces the payment term, due to stockouts, because in one period sales are very slow and in another orders are very high. All these negative shocks can be anticipated by simulating the impact on cash flow and working on the basis of several stress scenarios to avoid liquidity blockages, which inevitably increase the risk of going into insolvency.
- *Ensuring a cash reserve for crisis situations* can be achieved mainly by opening a short-term credit line, in order to cover the immediate need for cash caused by the gap between receipts and payments, the purchase of stocks, the payment of invoices or the payment of unexpected expenses. If necessary, the sale of assets that are not essential for the core business may also be used. Another possibility is to resort to factoring (financing of receivables), a method that does not require material guarantees and does not affect the degree of indebtedness or other financial indicators.
- *Choosing quality partners.* The company must always take into account the quality of the partners it collaborates with, whether they are a customer, a supplier, a bank or a strategic business partner. It is very important to know which partner can be trusted when it is necessary to request the postponement of payment terms or credit restructuring or renegotiation of contracts with customers and suppliers, to reduce the average duration of receivables collection and to extend suppliers' payment terms.
- *Adapting the business to the emergency situation (resilience strategy*). Given the rapidly changing context in which it operates, the company must be flexible, ready to take new measures in terms of business strategy, such as changing the product, accelerating sales and revenue, accelerating the liquidation of stocks, materialization of gains from the liquidation of stocks, changes of the client portfolio, ensuring the cash available for situations of crisis, etc.
- *Detailed analysis of expenses*. In order to maintain the activity going, it is important to reduce variable costs as much as possible and to keep fixed costs under control. The company must analyze operating costs and must consider reducing or discarding all non-essential expenses. Rational management of expenses, adapted to the level of monthly receipts, can be a very good resource (action) for maintaining a constant positive cash flow.
- *Reviewing investment plans*. The company must assess the possibilities for short-term capital raising, debt refinancing or additional support from banks or investors, as well as political support from the government. At the same time, taking into account the cash flow forecasts, you have to answer a series of questions such as: Which investments can be postponed until the situation improves? Which of them should be reconsidered? What investments are needed to return to positions and create a competitive advantage?
- *Staff motivation*. Another aspect that must be controlled in moments of uncertainty is the level of motivation of the team. Permanent communication regarding the existing situation, involvement in projects

that ensure the survival of the company, showing appreciation for the work done, offering empathic help for personal issues are elements that strengthen staff motivation. Encouraging work from home and mutual support are the best ways to deal with this time of crisis.

Conclusions

To conclude, we can say with conviction that the treasury budget is a very useful tool for the company's financial strategy and management decision-making, because detailed knowledge of cash flows helps the long-term development of the company. The policies of an enterprise can only be conceived from the cash flow, which is the key element of any business plan, and the movement of flows is the "great art" in the decision-making process.

Companies around the world are trying to accept the effects that current events have had on cash flows and their business. Although the risks are considerable, the crisis also reveals areas where companies can develop resilience and where they can reshape in the post-crisis period.

Acting in an uncertain horizon, with an unstable cash flow, it is essential for companies to follow the cash flow forecasts throughout the year, at least at monthly intervals and in case of atypical events. Good control of the projected cash flow, either in the “isolation” phase or a fortiori during takeover, can be a decisive competitive advantage for organizations' management and their ability to recover. Thus, financial managers can determine approximately the periods during which the treasury will have a surplus or a deficit, provisions that are found in the treasury budget.

Efficient management of the cash flow generated by the activities carried out can help the company in controlling and managing resources, reducing costs, maintaining financial stability, anticipating problems and maximizing the results obtained, while incorrect management of the treasury is often the main cause of bankruptcies.

In order to maintain the financial balance, it becomes necessary to use the treasury budget, which predicts the ratios between receipts and payments and identifies possible credit needs. Therefore, we can say that the treasury budget is a forecast dashboard of the company's liquidity supply and demand, which allows financial managers to optimize the company's financial results.

The cash flow statement has been integrated for more than fifteen years in the financial reporting system of Romanian enterprises, but it is not regularly taken into account by managers in the decision-making process. This statement is consistent with the findings of other researchers, including Mautz and Angell (2009), regarding the confusion and difficulties of understanding that the cash flow situation still raises for users of financial statements. We hope that our approach has succeeded in presenting, theoretically and applicatively, the importance of using the treasury budget in managing cash flows and that it will determine more and more managers to add it to the other performance management tools used in the management process.

The issues addressed in this paper create the premises for expanding research through an approach that allows budgetary control of the treasury and optimizing the company's cash flow, as well as identifying other methods and tools for managing the company's treasury. Having an adequate system of budgetary control would allow companies to improve their managerial attitude and performance and provide useful information for solving financial challenges.

Abstract

As a rule, the problem of improving the operational effectiveness of the enterprise is in the responsibility of its key managers. The concepts of Lean manufacturing and Six Sigma (Lean Six Sigma) transpose these tasks on all the processes and areas of the creation of the product's value. The positive experience of Honeywell demonstrates how the operational effectiveness of the enterprise can be increased by incorporating the methods of Lean Six Sigma into the production system. This article discusses the main elements of the Honeywell operating system that may influence its operation efficiency. The specific examples of the use of Lean and Six Sigma methods at a Russian enterprise are given. The method of Tier meetings, which enables to increase the operational effectiveness by means of timely identification of production problems, is described. The conclusion highlights the possibility of spreading this experience to other Russian enterprises.

Keywords: lean manufacturing, six sigma, operational effectiveness, Tier meetings, Honeywell operating system (HOS).

Introduction

In the era of digitization, the task of increasing the operational efficiency of an enterprise, achieving the best ratio between attracted resources and the final results of its performance remains to be no less relevant [1, 2]. The practice shows that the best companies seek using all modern managerial methods to complete this task. Among these, Lean and Six Sigma are the most widely used methods [3,4]. In this regard, it would be particularly informative to consider the successful practice of applying the above methods by the example of Honeywell.

Honeywell is a diversified corporation that is concentrated on industrial technology & software and is among the world's 100 leading companied according to the Fortune magazine. The corporation's approximate annual turnover is 35 billion USD. The corporation serves customers all over the world, offering products and services in such industries aerospace engineering, special materials and the control systems for industrial enterprises and buildings [5].

On the territory of the Russian Federation, Honeywell owns three production plants on Lipetsk, Moscow and Arzamas (Nizhniy Novgorod region). They produce the components for automation systems, control, protection and security of safety of facilities as well as personnel, devices and systems for electricity and gas metering [5].

The Methods

This study of Honeywell's experience was completed by using the methods of systematical, logical and comparative analysis. The achieved findings will be implemented in the management of the company.

The Results

The production system that is created by the company (HOS – Honeywell Operating Systems) allows to standardize and improve business processes of the company, as well as to create a specific work culture. It is based on the principles of Lean and Six Sigma and the employees' behavioral models. This system is implemented at all levels of the company, from business planning to manufacturing, and is focused on the level of personnel's involvement and continuous process improvement. It is needless to say, that the management support is needed for its successful performance. Much attention is paid to the production sectors where the product's value is created. The structure of HOS is demonstrated in Figure 1.

We believe, that for improving the company's operational efficiency, the following elements of HOS have significant potential: 5S, Visual Management, Tier Meetings, Rapid Problem Solving, The Suggestions on Improvements (Kaizen).

Figure 1: The structure of HOS

The developed by the company Tier Meetings system is characterized by short meetings of workers of production sites, managers and the employees of functional services. During these meetings, the results of the past day and the plans for the current day (or a week) are discussed, the main difficulties are identified, and priorities of the working day are set. The principle of conducting Tier Meetings is the same for all levels. In Honeywell, the meetings are hierarchically structured and arranged. It is worth mentioning, that duration of workshop meetings is strictly limited to a maximum of 15 minutes.

Tier 1 Meetings are held every morning at the beginning of a working day at the workplace. The meeting is dedicated to discussion of the elements of labor protection, quality indicators, and production efficiency. A shift foreman or an engineer of the quality control department tells about the implemented changes at the workplace. The worker, in turn, briefly describe the problems that occurred.

Then, Tier 2 Meetings of all company's departments (logistics, procurement, quality department, engineering department, warehouse, etc) take place. Tier 3 Meeting is arranged for the purpose of production planning and is attended by the heads of the departments. Thus, in the morning all the managers are aware of the results of the previous day and make changes, if needed, to the plans of the present day.

Let's have a look at the experience of Lean and Six Sigma for improving a company's operational efficiency given by three specific examples of the production activities of Honeywell enterprise in Lipetsk.

Example 1. 'Wrong thread number'.

White threads are used in the production process of the leash. A strictly defined number must be used for each seam. In case of using wrong thread, the entire product is rejected. As the threads do not differ from each other by their appearance, they can be identified only by the color of the coils and there are no any numerical designations.

During the final inspection, it turned out that several products had been made with the wrong thread numbers and these produces were rejected.

At the daily meeting of Tier 1, the engineer of quality control department (hereinafter – QC) explained the problem to the seamstresses and enquired for a possible solution. During the day, the shift foreman and the QC engineer discussed the possible options of eliminating this problem with seamstresses. They came to an agreement to mark the thread number on the holders above each sewing machine (which was done right away). In addition, the QC engineer prepared an information table for quick determining of the thread number by the color of the coil.

The next day, all the changes and innovations were told in detail to all employees at the meeting (thus, a training was conducted for the operator of two shifts). The conclusion of this example is obvious: by implementing 5S elements and visualization into HOS, the defect was eliminated, and it never appeared again.

Example 2. 'Bad cut'.

The harness tape arrives at the enterprise in reels of 100 meters each. Before sewing the product, the workers cut the pieces to required length. For this purpose, a special equipment is used – an automatic hot knife. After adjusting it to specific technological parameters (the knife temperature and cut time), the defect of the final product in the form of a bad cut appeared. The ends of the tape had not been sealed as they should be, and therefore could not meet the requirements on quality. Moreover, in a short period of time, the percentage of defective goods increased sharply (see figures 2 and 3).

Figure 2: The structure of defected goods in October 2018.

Figure 3: The structure of defected goods in November 2018.

As follows from Figure 2 and Figure 3, in October 2018 this type of defect accounted for 36% of all defected goods, but in November – 61% already.

After discovering this situation, the QC manager discussed the problem with the engineer responsible for the equipment and outlined possible solution to the problem. At the Tier Meeting, the production workers were shown this type of defect and were warned of the necessity of additional inspection at this production stage.

The engineers contacted the equipment manufacturer and had been adjusting the parameters of the hot knife, achieving the required quality of the cut. The seamstresses and the QC engineer had been monitoring the results of the changes and the amount of defects in order to identify the optimal parameters of the knife. As a result, in December 2018 the above defect had been eliminated entirely (see Figure 4).

Figure 4: The dynamics of finished goods featuring 'bad cut' defect (October 2018 – January 2019).

Considering this example, we come to the conclusion that the company's engineers and managers have used such Lean manufacturing methods as 'Rapid Problem Solving' and 5S (in terms of forming the habit of accurate following the established rules, procedures and technological operations) as well as Six Sigma (reducing the percentage of defective goods).

Example 3. 'Falling out of the needle during sewing'.

During the production process, there were several identical cases when the needle was poorly secured in the needle bar and fell out during the sewing. As a result, the equipment was damaged, and the production entirely stopped for repair. Due to the frequent repetition of this situation, there was a potential threat of stopping production because of the amount of spare parts for sewing machines. Apart from that, the increased consumption of materials (needles) resulted in the increase of production costs.

According to the company's records, in February 2019 alone, equipment downtime at the production site due to needle falling out amounted for 20% of total downtime.

Since at the Tier 2 Meetings in the engineering department there is a daily analysis of production downtime due to the breakdowns of the equipment, the initial cause of the breakdown of the equipment was identified quickly. Then, at the Tier 2 Meeting, the engineers explained to the production workers (in this case – seamstresses) the causes of the equipment breakdowns. After that, an additional clause to the local regulatory act of the enterprise – the regulations for servicing sewing machines for operators, obliging them to check the needle attachment before working – has been added. These regulatory changes were introduced to the operators. In a week period, they were conducting appropriate training with the seamstresses. In the process of completion, the special screwdrivers were selected and placed at every workplace.

The technical audit of the failed spare parts identified exactly those parts that were necessary to have to be always available at the enterprise in order to avoid equipment downtime for organizational and technical reasons. It allowed to order the necessary parts to be delivered to the warehouse of the enterprise in advance (as the delivery may normally take several months). As a result of taken measures, the noted malfunction no longer appeared.

Conclusions

Honeywell's existing HOS manufacturing system combines all business processes for sustainable development, that is constantly developing the best products and is using the best experience, while increasing the productivity and efficiency of production processes, as well as reducing the costs [2, 3].

This system is based on the principles of Lean Manufacturing as well as the concepts of Six Sigma and 8 models of employees' behavior. The considered examples of practical implementation of the methodologies of Lean and Six Sigma inro the practice a Russian enterprise lead to the conclusion about its successful applicability for increasing operational efficiency. The experience of Honeywell can be extended to other Russian enterprises as well [6], [7].

Abstract

The aim of the study is to examine household preference toward financial inclusion in the coastal area of Aceh Besar District, Aceh Province, by using a logistic model. Primary data of households are collected from the coastal area with total respondents of 400 households. The results reveal that income has a positive and significant effect on household preference toward financial inclusion and the magnitude of the variable is the biggest compared to other variables. Furthermore, the educational level has a second bigger effect on household preference toward financial inclusion, whereas age has a negative and significant effect on household preference toward financial inclusion. To increase financial inclusion in this area, the local and provincial governments should promote household income.

Introduction

The development of banking services continues from conventional banking to digital banking. With digital banking, banking services are not only limited to the availability of bank offices. Still, they can reach a wider area as long as there is an internet network of sufficient quality to support digital banking. Although digital banking has developed very rapidly, many people do not have access to banking services. Bank Indonesia Banda Aceh finds that banking services in Aceh Besar District are still deficient at only 2.56 percent (BI Aceh, 2019). The position of Aceh Besar District, which borders the City of Banda Aceh, does not yet have good banking services, so that financial inclusion also faces obstacles. The imbalance in banking services is enormous because Banda Aceh has banking services of 11.19 percent and is the highest banking services in Aceh Province (BI Aceh, 2019). As an inland area of Banda Aceh, Aceh Besar District has an economy that does not follow the pattern of Banda Aceh as the center of economic growth in Aceh. For example, the poverty rate in Aceh Besar is still high, namely 13.92 percent, much higher than Banda Aceh, which reached 7.22 percent in 2019 (BPS Aceh, 2020). Meanwhile, the economic structure of Aceh Besar is still primarily dominated by the primary sector with a contribution of 28.12 percent, followed by the secondary sector at 17.32 percent and the tertiary sector at 54.56 percent (BPS Aceh Besar, 2019).

The workforce usually follows the pattern of economic structure in each sector. Figure 1 shows that the people's primary occupation in Aceh Besar District was in the tertiary sector from 2006 to 2017. This condition is the same as the distribution pattern of GRDP in Aceh Besar District. When viewed from the distribution of GRDP and the

DAWOOD and Nanda RAHMI "Household Preference Toward Financial Inclusion in the Coastal Area of Aceh Besar District, Aceh Province" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

dominant occupation in the tertiary sector, the utilization of banking services should be more generous because activities in the tertiary sector are usually more modern and use a lot of banking services. However, banking services are available, which is still at 2.56 percent (BI Aceh, 2019). The result describes a situation that is not in line with the economy and workforce's distribution pattern—perhaps related to the tsunami disaster in 2004, which hampered the development of banking services in Aceh Besar District's coastal area.

The 2004 Aceh tsunami natural disaster caused financial inclusion to experience delays because several studies found that natural disasters harmed the regional economy, including financial inclusion (Keerthiratne & Tol, 2018). Aceh Besar District, which experienced the 2004 tsunami natural disaster, faced the problem of inequality. Aceh Besar District, which experienced the 2004 tsunami natural disaster, faced inequality of financial inclusion and delays in developing financial inclusion coupled with deficient availability of banking services.

Figure 1: Employment by Main Sectors in Aceh Besar, 2006–2017 (percent)

Financial inclusion differences can also be caused by other factors such as income level, education, gender, region, and other factors (Ains & Weill, 2016). The same thing is documented by research conducted by Zins & Weill (2016) that several factors that determine financial inclusion are poverty level, education, and gender. Many studies have also analyzed the role of financial inclusion in poverty reduction. The study results prove that financial inclusion has a positive effect on economic growth in 55 OIC countries (Kim, Yu, & Hassan, 2018). The study shows that financial inclusion has an essential role in driving economic growth.

Furthermore, a study conducted by Li (2018) found that financial inclusion can reduce the amount of poverty in China. However, other studies find that financial inclusion cannot mitigate the poor (Neaime & Gaysset, 2018). This situation can occur due to various factors. For example, some people have not used banking services for productive activities, so financial inclusion has not been optimal.

Most of the studies conducted in many countries have focused more on financial inclusion on poverty and economic growth. Still, there is a minimal study of how households prefer financial inclusion. There are very few studies on this, and even for the 2004 Aceh tsunami, it has never been conducted. Based on these considerations, this study discusses household preferences for financial inclusion in the area after the 2004 Aceh tsunami, so this study is specifically for coastal areas in Aceh Besar District.

Literature Review

Aceh Besar District has many beaches used as tourist attractions, so that the coastal area became the center of economic growth before the 2004 Aceh tsunami. Thus, people are concentrated in this area to provide services for tourism activities in the coastal zone. Many victims of natural disasters in this area are caused by the concentration of residents in coastal areas. Many studies conducted in various countries prove that disasters cause damage and poverty in the area. Ramalanjaona (2011) found that the 2004 Aceh tsunami had a considerable impact. At least 250,000 people died in 18 countries, and 1.7 million people were left homeless.

Another study in Nigeria found that natural disasters significantly affect life, property, education, and people's lives (Ademola et al., 2016). Furthermore, research in India shows the impact of flooding on people's loss of life and property (Mahanta & Das, 2017). The same thing was found by Karim (2018) in Bangladesh, where floods harmed agricultural income. These various studies show that natural disasters affect people's lives, assets, and livelihoods, including financial and banking developments.

The rehabilitation and reconstruction of Aceh after the 2004 tsunami had a positive impact on people's lives in coastal areas, including in Aceh Besar District. However, the development of the financial and banking sectors was still relatively low, as evidenced by a study conducted by the Bank. Indonesia, whose banking services in Aceh Besar District, are still deficient (BI Aceh, 2019). The development of the financial and banking sectors is significant to encourage regional economic growth and improve people's welfare. Kim et al. (2018) found that financial inclusion substantially affects economic growth in OIC countries.

Furthermore, their research results show that there is a causality relationship between economic growth and financial inclusion. This result indicates that the development of financial inclusion is significant in improving people's welfare. A higher level of welfare will increase financial inclusion owned by the people.

Li (2018) proves that financial inclusion has a significant effect on reducing the poor in China. This research is the same as the results of previous research conducted by Boukhatem (2016). The study documents that financial inclusion impacts the reduction of the poor in low- and middle-income countries. However, different results were found by Neaime & Gaysset (2018) that financial inclusion does not have a significant effect on improving welfare in MALEA countries. That is, financial inclusion may not be notable under certain conditions in the country.

The study of financial inclusion plays a role in improving welfare, but there are also several studies on the development of financial inclusion and the factors that influence it. The result of financial inclusion cannot be separated from the internet's progress today because with the presence of the internet, digital banking is increasingly developing and able to serve customers in a broader range. Ozili (2018) states that digital banking's progress is an essential factor in the development of financial inclusion. Digital banking provides more comprehensive access to people, including those with low incomes.

Tchamyou et al. (2019) found that the development of ICT affects financial inclusion and will ultimately reduce inequality in people's income. In this case, digital banking's role is a significant factor in the development of financial inclusion (Iqbal & Sami, 2017).

Zins & Weill (2016) found that several factors determine the choice of financial inclusion by individuals. These factors are gender, wealth, education, and age. But especially for age, young people prefer digital banking compared to senior citizens because of using digital banking applications that make it easier for young people. Furthermore, confirmation of the study results was carried out by Ains & Weill (2016). Apart from these factors, there are still regional factors that determine financial inclusion by households. The result is closely related to the availability of useful internet to support digital banking.

Lyons et al. (2018) found that education, age, income, and gender are essential variables in society's financial inclusion preferences. This study's results are in line with previous research conducted by Zins & Weill (2016) and Ains & Weill (2016). Furthermore, previous research conducted by Swamy (2014) found that females are more receptive to financial inclusion than males.

This study of household preferences for financial inclusion is essential to fill empirical evidence gaps, especially in the post-2004 Aceh tsunami and particularly Aceh Besar District. This preference is expected to be one of the vital information in developing financial inclusion in Aceh Province, hoping that increasing financial inclusion can impact people's welfare.

Research Method

Population and Samples

This research was conducted in the coastal area of Aceh Besar District, selecting sample sub-districts carried out deliberately because of the aftermath of the tsunami in Aceh in 2004. There are six sub-districts sampled in this study. These districts are Lhoong, Leupong, Lhoknga, Peukan Bada, Baitussalam, and Masjid Raya. Tejada & Punzola (2012) state that a tolerable error of 5 percent determines the ideal number of samples represented by the Slovin formula. Determination of this ideal sample with the formula (Tejada & Punzola, 2012):

$$n = \frac{N}{1+Ne^2} \quad (1)$$

where *n* is the sample, *N* is the number of populations, and e is the error tolerance. Following equation (1) and the population in Table 1, the ideal sample size is:

$$n = \frac{24,771}{1+24,771(0.05)^2} = 393 \quad (2)$$

Fortunately, the number of samples in this study was 400, even though there was a Covid-19 pandemic. Still, the sampling method using simple random sampling carried out in households was only found due to the Covid-19 pandemic problem. The sample distribution for each sub-district is shown in Table 1.

Table 1: Subdistricts, Households, and Samples

No	Subdistrict	Households	Ideal Samples
1	Lhoong	3145	56
2	Leupung	879	16
3	Lhoknga	4176	74
4	Peukan Bada	4752	84
5	Baitussalam	5606	100
6	Masjid Raya	6213	110
Total		**24771**	**400**

Model

The analytical model commonly used in determining preferences is a logistic model. This logistic model's choice is due to the limited number of samples, and the dependent variable is dichotomous, so it is very suitable for this study. The estimation model in this study is stated as follows:

$$FI = \beta_1 + \beta_2 Y + \beta_3 EL + \beta_4 A + \varepsilon \quad (3)$$

Theoretical coefficients: $\beta_2, \beta_3 > 0$, and $\beta_4 < 0$

FI is financial inclusion. A dummy variable represents the variable, *1* for households with financial inclusion, and *0* otherwise. Income is measured in rupiah and transformed into a natural logarithm (in Indonesian rupiahs). Simultaneously, the education level is expressed in a dummy variable, *1* if the household has high education and *0* otherwise. Finally, *A* is the age in years. Increasing age will impact reducing the desire for financial inclusion because the advancement of digital banking affects the ability of senior citizens to use various digital financial applications.

The model used in this study is limited to only a few variables to get a parsimony model. The parsimony model usually gives more reliable results than an over parameterized model. The cross-tabulation was performed on the selected variables.

The logistic model in equation (3) is very suitable for use in this study because the sample size is 400 households. Following the large sample properties, the logistic model will be more reliable if the number of samples used. According to Tejada & Punzola (2012), the minimum sample size is 393, while this study used a sample of 400 households. Based on these considerations, this logistic model is very suitable for use in this study.

Findings and Discussion

Statistics of Variables

The findings and discussion section discusses several subsections that can complement this study. The first part is the statistics of variables that can be used to measure the distribution of data used in this study. The variables selected in this section are only age, family size, income, expenditure, and years of schooling.

The variables' statistics show that the lowest household sample age was 35 years, and the highest was 70 years, with an average of 45.52 years and a standard deviation of 9.14 years. When viewed from that age, most of the household samples are of productive age. Furthermore, the lowest number of dependent respondents is one person, and the maximum number of respondents is eight people with an average of three people. The average family size is almost the same as the average family size in Aceh Province, four.

Respondents in this study experienced enormous inequality because the smallest income was IDR 200,000, and the maximum was IDR 30,000,000. The lowest amount of income is far below the average income of Rp. 2,943,810. This condition indicates that some households are impoverished, and some are very rich. The same thing can be seen from the lowest total expenditure of IDR 30,000 and the highest IDR 8,000,000 with an average of IDR 1,910,048.

The last variable is the average years of schooling are 11 years, the lowest has never attended school, and the highest is 16 years. The average years of schooling are two years, where this achievement is higher than the national compulsory nine-year education program. Regarding income, there is a correlation that low-income households have a low level of education. More detailed data shows that only 30 households or 14.3 percent of respondents have high education, and 180 respondents or 85.7 percent have insufficient education. The variable statistics are presented in more detail in Table 2.

Table 2: Statistics of Variables

Variable	Minimum	Maximum	Mean	Std. Deviation
Age	35	70	45.52	9.14
Family Size	1	8	2.86	1.58
Income (IDR)	200,000	30,000,000	2,943,810	3,446,066
Expenditure (IDR)	30,000	8,000,000	1,910,048	1,147,548
Years of Schooling	0	16	11	3.48

Source: Estimated Results, 2020.

Estimated Logistic Model

Estimation of equation (3) is conducted to analyze household preferences for financial inclusion with independent variables, namely income, education, and age. The estimation results are presented in Table 3, where income is a variable that significantly influences household preferences for financial inclusion. This coefficient is positive, which indicates that an increase in income has a very significant effect on household desire for financial inclusion. This coefficient also has the most considerable magnitude compared to other variables. Increased income will have an impact on increasing the possibility of choosing financial inclusion. If income rises one time, the probability of selecting financial inclusion increases 13.42 times, assuming ceteris paribus.

The results of this study are in line with research conducted by Ains & Weill (2016), Zins & Weill (2016), and Lyons et al. (2018), who found that income is a significant variable in determining financial inclusion. This result implies that economic developments that result in increased income are very substantial in determining household preferences in choosing financial inclusion. Equality in economic development must be better and more equitable so that all society levels can access banking services, including digital banking.

Besides, education is also significant, indicating that education has a positive effect on financial inclusion choices. If one year of education increases, the probability of choosing financial inclusion will increase 1.12 times by the assumption that other variables are held constant. This is according to the statistical variables in Table 2, which provide information that there are still many respondents who have low education but are willing to use banking services to fulfill daily household transactions. This result is perfect for increasing the selection of financial inclusion so that more people use banking services. By increasing financial inclusion, it is hoped that it will reduce poverty and inequality in living standards and social welfare.

Research by Ains & Weill (2016), Zins & Weill (2016), and Lyons et al. (2018) stated that education is essential in financial inclusion. Thus, this study is in line with their research. Efforts to improve knowledge are a crucial factor so that people have a higher level of education. Better education will encourage households to use financial inclusion, which will increase the standard of living and welfare of the people.

The last variable is the respondent's age, which is negative and significant, which indicates that the older the respondent is, the lower the chances of choosing financial inclusion. This result is very rational because with the development of digital banking today, various banking service applications will not be easy for elderly households. An increase in age for one year resulted in a decrease in choosing financial inclusion by 0.96 times.

The effect of this age has a smaller magnitude than other independent variables. Table 3 shows the results of the logistic model estimation from equation (3) in this study. This study's results are in line with research by Swamy (2014), which found that the elderly have a lower tendency to have financial inclusion, especially digital banking.

Table 3: Estimated Logistic Model

Variable	Coefficient	SE	p-value	Odds Ratio
Income	2.597	0.304	0.000	13.42
Education	0.111	0.051	0.029	1.12
Age	-0.044	0.016	0.006	0.96
Constant	-37.126	4.307	0.000	0.00

Source: Estimated Results, 2020.

Cross-Tabulation

Several variables were tested individually to determine their effect on financial inclusion, with the control variable being gender—first, the impact of education on financial inclusion between males and females. The test results prove that education is very influential in financial inclusion in both males and females. This study demonstrates that education is critical in financial inclusion. Better education will influence people's desire to access banking services. This situation is very rational because, with better education, households' ability will be better and more open to various facilities provided by financial institutions, including digital banking. These results support the previous works that education is an essential variable in financial inclusion. These results can be seen in more detail in Table 4.

Table 4: Financial Inclusion, Educational Level, dan Gender

Gender	Pearson Chi-Square	df	p-value (2-sided)	p-value (1-sided)
Female	18.63	1	0.000	0.000
Male	16.41	1	0.000	0.000
Total	34.60	1	0.000	0.000

Source: Estimated Results, 2020.

Second, the effect of the level of welfare on financial inclusion between males and females. Low and non-poor households still have a desire for financial inclusion, both male and female. The result reveals that the advancement of banking services has been put to fair use by households. These results are also under the effects of previous estimates. For more details, the test results can be seen in Table 5.

Table 5: Financial Inclusion, Welfare, dan Gender

Gender	Pearson Chi-Square	df	p-value (2-sided)	p-value (1-sided)
Female	28.29	1	0.000	0.000
Male	26.17	1	0.000	0.000
Total	57.12	1	0.000	0.000

Source: Estimated Results, 2020.

Table 5 shows that the welfare variable is significant, as evidenced by the very significant Pearson Chi-Square coefficient on both 2 and 1 sides. This result is significant to emphasize that welfare is an essential factor for households in choosing financial inclusion. From all income levels, all walks of life can accept financial inclusion in the current transaction process. This development is an indicator of increasing public acceptance of financial inclusion. Financial institutions can utilize these developments to increase penetration of the financial market for all levels of society.

The last variable is the effect of job status on financial inclusion between males and females. The results of the latest variable statistical test are presented in Table 6. The table shows that female's employment status does not affect determining financial inclusion. Working and unemployed females still have a relatively low desire for financial inclusion. Meanwhile, for males, the work contract or long term is a significant variable so that every man in this study still wants access to financial inclusion. Financial inclusion is substantial for the male to support daily transactions in financing household needs. However, for females, the desire for financial inclusion from permanent and casual employment has not yet influenced financial inclusion choices.

Table 6: Financial Inclusion, Working Status, dan Gender

Gender	Pearson Chi-Square	Df	p-value (2-sided)	p-value (1-sided)
Female	0.46	1	0.570	0.310
Male	9.09	1	0.003	0.002
Total	8.96	1	0.004	0.002

Source: Estimated Results, 2020.

Conclusions

Based on variable statistics, logistic model estimation, and cross-tabulation, several things can be concluded. First, the respondents' average age in this study was at a productive age, even though some were 70 years old. Second, the number of household dependents is still below the Aceh Province average, so the dependency burden is relatively lower. Third, household income is unequal because some are very high, and some are very low, and the same condition is shown by expenditure. Fourth, the average years of schooling for sample households are higher than the national compulsory education program. Fifth, income is a significant variable in household preferences for financial inclusion, while the effects of education and age are also significant. Sixth, cross-tabulation shows that education is critical in financial inclusion for both males and females. The level of welfare indicates the same. Meanwhile, the types of work have different results between males and females, where females who have permanent jobs will have more influence on financial inclusion than males.

There are several recommendations according to the results of this study. First, banks must increase service coverage to villages to have complete access to banking services. Second, an increase in people's income, followed by better distribution, should be the government’s attention in any development policy to benefit from the regional development process. Third, it is necessary to encourage society's tendency towards education so that education plays a role in improving welfare and financial literacy. This situation will affect financial inclusion.

Abstract

The paper deals with constructive solutions for a feed system used at a hybrid process for miniature material removal, ultrasonically aided micro-electrical discharge machining µEDM+US. Some aspects on the state of the art of feed system for EDM are presented, e.g. types of control loops and corresponding control systems, used to improve the EDM and micro-EDM technological performances. The general and main functions are formulated, based on conceptual design approach, which were substantiated by block diagrams for displacements execution and structure of feed system. These are associated with several methods for quality improvements applied for identification of design solutions, like QFD, FMEA, relation, affinity, and tree diagrams. Finally, some constructive solutions resulted that were implemented in the design of the feed system dedicated to µEDM+US machining.

Keywords: micro-EDM, ultrasonic vibration assisted micro-EDM, feed system.

Introduction

In the current trend of miniaturization, the demand for precise components, with small dimensions and micro-scale features, is growing. Many of these components are demanded by important industries, such as automotive, aerospace and biomedical. These industries, and many others, are using components made of alloys with increasingly high toughness and less heat sensitivity, essentially difficult to machine through conventional (cutting) methods. Nonconventional processes like Micro Electrical Discharge Machining (µEDM) can be an excellent popular technological solution to machine materials with enhanced mechanical properties as discussed by Prakash et al. (2017).

Micro Electrical Discharge Machining becomes an important fabrication process to be used in manufacturing components at micro scale. However, the process is limited by a narrow working gap (1 to 5 µm) which facilitates the accumulation of debris. The debris need to be removed as soon as possible from the gap to prevent accumulation, otherwise the process becomes unstable, due to abnormal discharges. This ineffective flushing of particles out of the working gap leads to extensive machining time. Because the tool diameter is less than 1 mm, often in the order of µm, flushing techniques like: pressure flushing, jet flushing and suction flushing are very difficult to implement and they usually lead to breaking or shattering the electrode. Therefore alternative flushing techniques need to be used, one of which is ultrasonic aiding.

Ultrasonically aided Micro Electrical Discharge Machining (µEDM+US) is a hybrid nonconventional process. The vibrations of the tool or workpiece, improves the stability and the productivity of the process by flushing out the debris from the working gap as concluded by Khatri et al.(2015). Ghiculescu (2015) found out that the surface quality is also improved by reducing the roughness and the thickness of molted and resolidified material with often has microcracks, the so-called white layer.

The working gap remains narrow in case of µEDM+US and moreover it varies with ultrasonic frequency, which requires a more precise feed system to be used than in case of classic microEDM. Quick response, high speed and high acceleration of the feed system, i.e. high dynamics, prevents short-circuit between electrode and workpiece and also idle working of EDM process.

Aspects of state of the art of feed system for EDM

Feed systems are used to adjust the work gap throughout the machining process. If the work gap is too big, no discharges take place, and if the gap is too narrow, short-circuits could happen. Therefore, the work gap has to be maintained at an optimal distance throughout the machining process. Consequently, a feed system is required, the *servo* one is the most common used, providing a loop for feedback reaction. One of the simplest variant is based on controlling the work gap by measuring the voltage in it, as stated in the book written by Elman (2001), and shown in figure 1. Other variants are based on other analogic parameters like: delay time at discharge ignition, number of normal discharges within a sampling period etc.

Fig. 1: The principle of EDM servo system based on voltage within the working gap

The system works as follows: a value in the machining voltage is selected as reference (A) with margins of ± e [V] for controlling the servo system. This reference voltage is compared to the real machining voltage (B), measured between the tool-electrode and workpiece. This difference between the reference voltage and the actual machining voltage between tool and workpiece is used to command the servo system to advance, retract or hold position.

Feed systems are built around a control loop, which is used to measure and adjust a certain variable to control a process. The most common ones are presented in figure 2 and 3, but there are also combinations of them (hybrid):

A. Open control loop – the output data has no influence on the input data. These type of systems do not measure the output data in order to check if the command has been properly executed (figure 2);

Fig. 2: Open control system

B. Closed control loop – the output data is fed back to the input data (feedback), in order to check that the command has been properly executed, and correct any errors (figure 3).

Fig. 3: Closed control system

On the basis of these control loops, a number of more sophisticated feed control systems emerged:

1. Adaptive Control System (ACS) – which is utilized to detect changes in process and automatically adjust the input parameters in order to optimize the result – the servo system works as an ACS;

2. Adaptive Control Optimization (ACO) – works just like ACS, but can adjust the input parameters before the process degrades, by tracking certain trends in the process;
3. Fuzzy logic – is a method that mimics the human mind in decision making. It analyzes all possibilities between 0 and 1, and takes the best decision possible.

These systems were adapted by various authors for EDM and µEDM machining, as shown in table 1.

Table 1: Published papers on feed systems

Control type	Title	Characteristics
ACO	An Adaptive Speed Control System for Micro Electro Discharge Machining	Yeo et al. (2009) developed an *adaptive* speed control for µEDM machining which demands a higher level of accuracy. The system enhanced the productivity by 50% in comparison with the classic servo system.
ACO	In-situ process monitoring and adaptive control for precision micro-EDM cavity milling	Jun et al. (2017) developed a new monitoring system in order to compensate for tool wear and achieve high machining accuracy. The system counts *normal discharges* and correlates it to the volumetric tool wear and compensates for it. The system reduced the work cycles by 18%, while maintaining accuracy.
FUZZY	Optimization of EDM Process with Fuzzy Logic Technique	*Taguchi method and fuzzy logic* are used by Biswas et al. (2012) to optimize EDM machining. The process parameters were optimized by performance parameters (productivity and surface roughness). Experiments identified a number of variable process parameters that achieved the best productivity and roughness.
FUZZY	Controlling of EDM Servo System using Fuzzy logic Controller	Shuruq et al. (2016) attached a *fuzzy logic* controller to a servo control system. The fuzzy controller can alter the motor's speed and acceleration, resulting in smoother curves of speed and acceleration. Therefore it reduces the excessive tool retraction, resulting in a less time consuming operation.

The papers published on feed systems focus on *speed control and process monitor*, showing that control over these can significantly improve the stability of EDM machining.

Some solutions for feed system

Several solutions for feed systems were developed by various authors:

1) Modification of the process dynamics in µEDM by means of an additional piezo-control system – Schulze et al. (2017) discussed that a chance to increase precision and productivity in EDM is to reduce the amount of inefficient process conditions. An approach is based on increasing the feed system dynamics and to achieve smaller increments;

2) A New Pulse Discriminating System for µEDM – Yeo et al. (2009) proposed a system that employs current pulse as the main detecting parameter, and classifies them into normal discharge, delayed discharge, arcing and short circuit. Experimental results show that machining time was reduced by more than 50% and the accuracy of resulting features is increased;
3) Digital Gap Monitor and Adaptive Integral Control for Auto-Jumping in EDM – Wang et al. (1995) uses an adaptive control strategy that regulates the periodical retraction of the tool electrode based on the working gap condition. The system ensures quick retraction (jumping) of the electrode.

Response time is crucial in µEDM. The faster the tool retraction happens the more short-circuits and arcing between tool and workpiece are avoided, resulting in improved working condition and stability. The faster the tool advances the more time is used machining, resulting in increased productivity.

Aspects of conceptual design

The general function of a feed system for microEDM is to position the tool electrode relative to machined surface under conditions of up to 5 µm, work gap. A series of main functions are deducted from the general function:
1. Ability to advance, hold and retract the electrode – the feed system must be capable of executing these types of movement throughout the operation length within a response time appropriate for microEDM;

2. Continually measure and indicate current position – system needs to constantly monitor its position with an accuracy of 10^{-1} µm order;
3. Execute movements with minimum delay – the feed system must execute technological movements – used while machining, and rapid movements – used in case of short-circuit and arcing. In both cases minimum delay is desired.

The PhD thesis of Ghiculescu (1999) revealed that there is a maximum response time of $\Delta T = 10$ ms, a threshold needed for small gaps, e.g. finishing or super finishing working modes (relation 1):

$$\Delta T = \Delta t_{MPP} + \Delta t_j + \Delta t_f + \Delta t_e \text{ [s]} \quad (1)$$

where: Δt_{MPP} – delay caused by a stepping motor [s]; Δt_j – delay caused by switching from advance command to retract command, clearance taking over [s]; Δt_f – delay caused by friction between moving elements [s]; Δt_e – delay caused by the elasticity of the system elements [s].

The study concluded that in 5 ms, there is a movement of 2 to 5 µm. Therefore it is recommended that the response time do not exceed 10 ms, otherwise the process becomes unstable for an usual 10 µm gap for the mentions above types of gaps. Since the study has been conducted in the case of EDM+US finishing, the value must be much lower for µEDM+US, where the gap varies with amplitude due to oscillation movement of tool or workpiece.

4. Execute movements after a profile of speed and acceleration – the feed system must be capable of adopting a speed and acceleration curve (*S shape* is one of the most appropriate) compatible with the precision imposed by µEDM+US machining.
5. Transform the rotation movement in translational movement – The component of the system that moves the electrode must execute only translational movement.

6. The system must be perpendicular on the work table – the feed system's precision depends on the perpendicularity on the machine's table;
7. Angle adjustment for use in angled holes – the system must be capable of executing a manner of sophisticated holes, inclined holes included;

8. Minimizing the transmission of ultrasonic vibrations within the technological system – Ultrasonically aiding µEDM consists of attaching an ultrasonic chain to the feed system. The horn, from the ultrasonic chain, has a node

where the vibration's amplitude is zero; the catching surface of US chain, the nodal flange is recommended to be as close as possible to the nodal plane.
Based on the functions detailed above, the block diagrams of the execution system of displacements (figure 4) and of the feed system structure were built (figure 5).

Fig. 4: Block diagram of displacements execution system

Fig. 5: Block diagram of feed system for ultrasonically aided microEDM

The main functions are used in the following chapter to improve the performance of the feed system of the ultrasonically aided µEDM through various performance improvement methods.

Methods for design improvement

In order to improve the performance of the feed system, a series of quality improvement methods are used from the book by Ghiculescu (2016): QFD (Quality Function Deployment) method, FMEA (Failure Mode and Effects Analysis) method, Affinity diagram, Relation diagram and Tree diagram:

Quality Function Deployment Method

Based on the main functions of the feed system and a requirements list from clients, several technical objectives resulted (figure 6), satisfying their needs in that order of priority: 1) Attach an encoder for position monitoring or output linear transducer; 2) Use "S" shape speed and acceleration curve – to make sure no shocks are induced in the system; 3) Motor native step split by a digital driver – the driver allows the motor to effectuate a so-called micro-step, the precision being increased; 4) In order to evaluate the minimum response times, certain tests are needed previously; 5) Use an adjustable contact roll to make the nut execute only translational movement; 6) Assemble the horn with minimal contact around the nodal plane; 7) Use a mounting plate with circular slots – to allow tilting; 8) Use blocks to align and orient components.

Clients requirements And priority \ Technical characteristics		Advance and retraction movements	Continuous monitoring position	Execution of movements with minimum response time	Execution of movements with correct profile of speed and acceleration	Transforming rotational movement in translational movement	Perpendicularity on work table	Adjustable tilt of the feed system	Minimize US vibration transmission in system	Competition assessment according to customer requirements*

Technical objectives		Motor step split through digital driver	Attach an encoder /linear transducer for position monitoring	Validation of minimum response time	Use an "S" speed and acceleration curve	Use an adjustable contact roll to make the nut only execute translational movement	Use of blocks to align components	Mounting plate with circular slot	Reduced contact with the horn, and placement near the zero amplitude zone				

Fig. 6: Quality Function Deployment Diagram

*Each competitor (1, 2, 3, 4) is assessed with a mark, as follows: A – High mark; B – Average mark and X – Low mark based on clients requirements and technical characteristics. Afterwards the designed feed system uses the competitors as benchmarks to be exceeded one by one, starting with number 4.

Failure Mode and Effects Analysis method

The method identified a series of high RPN, Risk Priority Number, calculated as product of appearance, criticality, and detection error, as shown in table 2, and discussed below:

Table 2: Errors found with FMEA method

Component	Error	Cause	A	B	C	RPN*	Prevention methods
Motor	Bearing failure	Lifespan was exceeded	7	10	8	560	Motor change and run precision tests
Encoder	Faulty motion detection	Low resolution	3	10	8	240	Driver change, check resolution beforehand
Screw nut	Loose fits	Design error	5	10	10	500	Check calculations
Screw nut	Improper pitch	Design error	4	10	9	360	Check calculations
Screw nut	Bearing failure	Lifespan was exceeded	4	10	9	360	Bearing change
Shaft Coupling	High flexibility	Improper selection	4	10	10	400	Check documents and run tests
Shaft Coupling	Low flexibility	Improper selection	4	10	10	400	Check documents and run tests
Guide column	The contact pressure of the roller is excessive	Improper adjustment	4	10	10	400	Eliminate the improper adjustment by adding an eccentric spindle
Ultrasonic chain	Induces vibrations in system	Contact zone is too big	4	10	10	400	Check calculations for nodal positioning and reduce contact zone by using prisms

** The Risk Priority number is calculated as a product of occurrence (A), importance (B) and detection (C). They are rated on a scale of 1 – 10, where: 1 – very rare occurrence/very low importance/very easy detection and 10 – very frequent occurrence/ utmost importance/very hard detection.*

Motor bearing failures are very hard to detect (justifies the highest RPN) without proper laboratory testing, usually because there is no precision test on the ordered part. If the tested motor does not conform to the specified requirements, the motor will be replaced. The faulty motion detection of the encoder happens when the resolution of the encoder and the motor doesn't match. In order to prevent such errors, the motor's resolution needs to be checked (in all running modes) and an appropriate encoder needs to be ordered. The screw nut mechanism has loose fits between screw and nut, this happens due to design errors (improper dimensions), where the nut doesn't take full contact with the screw, leading to precision errors. Checking the mechanism's calculations is recommended, in order to avoid this error and the improper pitch error. The shaft coupling can be too flexible or too rigid, however in both cases testing needs to be done in order to know the impact it has on the feed system's precision. The contact pressure of the roller is excessive, this error can cause delays in motion execution. In order to prevent this error, an eccentric spindle is designed that lowers the roller on the guide column and ensures that subsequent adjustments retain the same contact pressure. The ultrasonic chain produces vibrations, however the horn has a zone where the amplitude of the vibration is zero. Contact has to be near this zone on a small zone, therefore prisms are used in order to assembly the horn with the feed systems. Finite element simulation needs to be used to bring the ultrasonic chain under resonance condition.

Affinity Diagram

The affinity diagram (figure 7) identified the most important ideas for enhancement of feed system precision:

Fig. 7: Affinity diagram

1) Testing the ultrasonic chain – the ultrasonic chain is composed from the horn and transducer, assembled through a threaded pin. The horn and the transducer need to have the same natural frequency, otherwise the ultrasonic chain won't function optimally. Therefore it is necessary for the horn to be tested and adjusted in order to have the same natural frequency as the transducer; 2) Ensure that the contact surface with the horn is small, to avoid vibration propagation in the system; 3) Screw nut type – is one of the mechanisms that directly affects precision and needs to be designed accordingly; 4) Screw pitch – directly influences the screw nut mechanism, and needs to be taken in account when designing the nut screw system; 5) Guide column – makes possible for the nut to execute only translational movement; 6) Coupling flexibility – if it is too high it induces delays in execution, it it's too rigid it introduces deformations of coupled parts when they are not coaxially - in both ways it affects precision. However a flexible coupling is chosen, because the deformations of parts affects precision primarily; 7) Motor type – the most influential component that affects precision. The motor needs to be chosen on the account of precision and cost; 8) Motor driver – can allow the motor to function in different modes, one of which is of particular interest – microstepping – where the natural step of the motor can be split, enhancing the motor's precision; 9) Encoder for constant position monitoring.

Relationship Diagram

Fig. 8: Relationship diagram

Relation diagram identified the three main components responsible for precision enhancing (figure 8): The most important component is the motor, which directly influences precision. However the motor's precision is directly influenced by the screw-nut mechanism and motor type. Also, indirectly the speed and acceleration curve is important, because it can induce errors due to sudden acceleration and deceleration.

Tree diagram

Fig. 9: Tree diagram

Tree diagram (figure 9) has identified the following ideas to enhance precision:

1) Choosing a high precision type motor; 2) Implementation of an "S" acceleration and speed curve; 3) Use an open loop control system for low cost benefits; 4) Use an encoder, for constant position monitoring; 5) Design a screw nut mechanism with high precision; 6) Design a column with a plane surface in contact with a roll, mounted on eccentric spindle, able to adjust the contact pressure by its rotation; that blocks the rotation of the nut and column, allowing only smooth translational movement, with reduced response time; 7) Simulate by finite element modeling and test the horn before use; 8) Have a small contact zone for the horn, when it is assembled with the feed system.

Feed system for µEDM+US

The designed feed system, appropriate to requirements of µEDM+US is presented in figure 10, incorporating the solutions and ideas found using the methods presented above.

The feed system is powered by an electric stepper motor which is used in microstep mode, and divided in 32 000 parts by a digital driver to ensure maximum precision. The motor's precision is continually monitored in terms of position, speed and acceleration by an encoder mounted above the motor, and assembled with a flexible coupling to prevent any coaxial deviations. The screw nut mechanism also uses a flexible coupling to connect with the motor. The screw nut mechanism is a roller type screw, recommended for high precision operations and low friction. The nut is locked from rotational movement by a roll, which has contact with a plane surface of a column guided by ball bushing with low friction. The contact pressure between the roller and column is adjusted by an eccentric spindle, which lowers or raises the roll. A pressure test is needed to see how much pressure is needed to completely stop the rotational movement of the nut without increasing the feed system's response time. The ultrasonic chain is mounted on the feed system using a set of prisms to ensure minimum contact, in the very proximity of nodal point, to minimize vibration transmission in the whole system. Finally the entire feed system is mounted on a plate that allows tilts up to 30º.

Fig. 10: Feed system for ultrasonically aided micro electrical discharge machining

Conclusions

The functions derived from systematical conceptual design associated with several methods for quality improvement led to some constructive solutions for the design of a feed system appropriate for a hybrid machining, ultrasonically aided micro-electrical discharge machining (µEDM+US). The **most relevant** solutions implemented were: micro-step division by digital driver in parts that ensures axial increment of 0.2 µm, even at 2 mm pitch of roll screw-nut mechanism; monitoring the position by an encoder; speed and acceleration on *S* shape curve to assure smooth rapid movements; decrease of response time by rolling friction at all movement organs of the feed system; translational displacements assured by a roller mounted on an eccentric spindle with possibility to attain an optimum contact pressure between roll and guided column by rotation around its axis; mounting of ultrasonic chain, which includes the electrode-tool, by using a set of prisms with contact in the very proximity of nodal plane, with null amplitude, to avoid transmission of ultrasonic vibration within the feed system.

Further researches will be focused on precise execution and testing in order to validate the constructive solutions of the designed µEDM+US feed system.

Abstract

The paper deals with a search of scientific articles focused on the optimization of production planning in relation to the use of energy and natural resources, production planning using simulation models in the context of Industry 4.0 and the methodologies for the creation and use of simulation models in the context of Industry 4.0. These topics are focused on the current development of the Industry 4.0 concept in connection with simulations, planning and optimization. These are mostly articles indexed in the Web of Science (WoS) and Scopus databases. These databases were selected because the articles contained in them are recognised by Czech technical universities.

Keywords: Industry 4.0, Simulation, Discrete simulation, Optimization, Green planning, Production planning.

Optimization of production planning (or planning) with regard to the use of energy and natural resources (green production planning)

Today, there is an increasing emphasis on the life of the individual with the least possible impact on our environment. There is a visible effort to reduce the use of plastics and other materials that can be harmful to the environment. An increasing part of the population is also thinking about minimizing the unnecessary relocation of people and services, materials or products across our planet. This is no longer just a question of individuals, but production companies and service industries are also starting to think this way. This thinking then has implications for product design (design, materials, etc.) and especially for the method of production and distribution. Price, respectively financial costs, is ceasing to be the most important factor in choosing the method of production, machines used, etc., but it is decided according to the required energy and its quantity and natural resources - regardless of financial advantage, or only with reasonable regard to the cost/energy ratio and natural resources. It is therefore beginning to be considered whether a product will be produced more cheaply, but with a greater "waste" of energy (or natural resources), or more expensively but with less "waste" of energy (or natural resources).

One approach to minimizing carbon emissions is to reduce energy consumption in a particular machining system. The authors propose an integration model based on nonlinear process planning and the implementation of such a method that will lead to a reduction in the energy consumption of the machining system. Zhang et al. (2016) use a model based on Therblig. Other approach mentioned by Wu et al. (2018) is to minimize carbon emissions by solving the problem of capacity multiple dose sizing for non-identical parallel machines, where the goal is to meet demand for various items in the planning horizon to minimize costs without reducing capacity and increasing carbon emissions using Lagrangian relaxation and generating columns to improve the lower and upper bounds above linear programming relaxation. A similar problem is solved by Zandi, Ramezanian and Monplaisir, (no date), who present a mathematical formulation that solves the problem of green production on parallel machines with respect to energy consumption and production time. Due to the high computational complexity of the proposed model, they developed a heuristic algorithm to obtain the exact Pareto boundary of these two targets with polynomial complexity. Another solution mentioned by Su, Yang and Liu (2017) is to use a hybrid swarm algorithm with discrete particles based on real data collected from a pharmaceutical company. The production planning model is based on an analysis of the energy consumption of different units and equipment, and experimental results have shown that carbon emissions in a company can be reduced by an average of 6.77%, and CO2 emissions can be reduced by 610.2 tonnes per year. Another possible approach is in a research study by Shin, Suh and Stroud (2015) improve green productivity (GP) where the basic mechanism of the algorithm is the

implementation of a process improvement cycle, which measures GP performance by collecting machining data, quantifies this performance by categorical representation and predicts performance using prediction models.

Another way to minimize energy consumption, a model called ultra-flexible job shop (UFJS) is also studied by Liu, Zhang and Lu (2019). In UFJS, the order of operations between tasks can be changed within certain limits. To formulate this energy-efficient planning, a mixed-integer linearly programmed model was developed. To solve big problems, the authors then designed and implemented a genetic algorithm.

The authors Junker and Domann (2017) of the article "Towards Industry 4.0 in corporate energy management" state that more than 120 software systems are offered on the market, but according to their analysis this software can be used exclusively for monitoring and reporting. The reason is roughness of data and work of the software with them. Planning and management are not supported. Thus, they developed an energy management system which can collect data on energy consumption at the level of production facilities based on data sheets of equipment manufacturers and a modular and self-organized communication system (as a combination of hardware and software) that "reads" internal electricity data from production facilities in real time, or measures the flow of liquids or gases using sensors and provides real-time energy control.

An interesting way to minimize energy costs (in this case, it is really about costs, not about minimizing the carbon footprint or consumption) is to optimize product variants. Kruse, Uhlemann and Steinhilper (2016) see a link between the diversity of production and energy consumption. They have developed a simulation-based model that examines the effects of production diversity on energy consumption (electricity, compressed air, gas). The model was implemented in a simulation environment of discrete events and verified in a case study in the metal industry. The results show that efficient variant management makes it possible to improve energy efficiency.

Production planning using a simulation model in the context of Industry 4.0

A reasonably designed and created model and a simulation with suitable parameters running above it can be used as a tool for selecting a suitable product flow through the production process. In other words, the model and the simulation running above it can be used for production planning. As the approach to production evolves and new trends in production continue to emerge, planning methods need to be adapted accordingly. Currently, the paradigm is the concept of Industry 4.0, which builds on the transfer of constantly recurring activities, or simple activities from a human to a machine, and communication between people, people and machines, as well as the machines themselves. Therefore, the use of simulations for production planning in a company based on the Industry 4.0 concept and dedicated mainly to small series production could be suitable. In such production, it is necessary to solve the reconfiguration of production machines, suitable interchangeability for a new product and/or a new series, and to solve situations where the production of several types of products coincides, or one species in production is running out and at the same time a new one is to be produced as well. The vision is that the material can go through several paths during production, interchangeable machines report their status (settings, usage, etc.) and then the production can be planned both for a new product and theoretically for each piece when entering the system according to the state on the whole line. For this, however, it is necessary to modify one of the existing methods of production scheduling, or to create a completely new methodology. Predictive maintenance is also connected with production planning, which can include possible machine outages, etc. in the planning.

A constant trend in data collection (for simulations) or their visualization is the use of digital twins, which are supplemented by modern possibilities such as machine learning. These digital twins are used to develop intelligent algorithms for autonomous control and other cases involving optimization, mental models and decision support systems, mentioned by Atorf and Rossmann (2018). The digital twin enables the connection of the production system with its digital equivalent for the production process. According to the authors Uhlemann, Lehmann and Steinhilper (2017), in order to ensure the maximum conformity of the cybernetic process with its real model, multimodal data acquisition and evaluation must be performed. Jaensch et al. (2018) represent the possibility of extending digital twins with the possibility of machine learning of data-based models to the learning of control logic of complex systems. They show how to use machine learning in conjunction with these models to achieve shorter development time of production systems.

The topic of predictive maintenance also began to develop within the Industry 4.0 concept. This has a great impact on planning and allows production to be planned with regard to downtimes that are caused by maintenance, failures, etc. This approach pursues the goal of eliminating system failures before they occur. It prevents situations when the device enters unexpected downtime, and high costs are saved. One option is to use the generic predictive maintenance simulation in AnyLogic ™. The concept contains a description of the function and objectives of the simulation, the interface for data transfer to and from the simulation, the general structure of the simulation and the indicators used to evaluate the simulated production plans. The first case study shows how a simulation model can

be used to simulate sample data from a testbed to improve production plans how is mentioned in study by Zarte, Wunder and Pechmann (2017). According to Teufl et al. (2018) it is not uncommon today to have a predictive model of a factory, although these models are often simplified in nature. However, such models rarely reflect the current operational performance of the system, use simple and separate data streams, and do not have machine/workstation resolution. They can support production planning, but usually have limited use to optimize factory performance in response to changing external stimuli. That is why the OPTIMIZED research project is developing a holistic plant management platform that responds to unexpected factory failures. It uses the application of optimization based on simulation to support the production planning of the production process of one of the industrial demonstrators. The simulation model captures the relevant production limitations of the factory up to each machine and workstation. The simulation model reads data from enterprise information systems, live data from machines and data from retrofitted sensors in the production plant. As a result, service levels and production costs are optimized.

According to Fantini, Pinzone and Taisch (2020) with the growing cyber physical systems, there is a great consensus that work will change and different skills will be needed. However, the question remains whether the organization of work will evolve towards greater responsibility and decision-making of employees or towards higher technological control. The challenge is to manage this development and purposefully lead the process of integrating people into CPS. The authors propose a methodology to support the design and evaluation of various work configurations and consider the uniqueness of human labour and the characteristics of cyber production in a comprehensive framework. The method includes routine production as well as irregular scenarios, such as fault detection or maintenance intervention, with a particular interest in human labour. The applicability of this method is illustrated by two industrial cases, which lead to proposals for staff training and to the improvement of the whole cyber-physical-social system.

Simulation, or a digital twin, is now commonly used as a basis for decision making. Authors Denkena and Winter (2015) use a simulation of rotor blade production in the wind turbine sector as a basis for decision-making in order to reduce planning time and costs, and to estimate the mutual impact on production capacity by product, technology and factory in the planning phase. The authors Yang and Takakuwa (2017) go even further, focusing on production planning with regard to the possible ongoing communication between the manufacturer and the customer. Thanks to Industry 4.0, the manufacturer is able to respond more quickly to customer requirements, which means that manufacturers now have to control production planning more tightly. The customer order and the product processing table are imported into the simulation model. The experiments are implemented in case the system encounters unexpected conditions. The proposed approach represents a potential tool for manufacturers to make real-time decisions. Constantinescu, Francalanza and Matarazzo (2015) consider it one of the main challenges for Industry 4.0 to ensure that the right people have the right information at the right time to make the right decisions. That is why it comes with a multi-level just-in-time simulation tool to support digital race planning decisions. It uses appropriate means to capture and represent the knowledge of the production system in several types of industries and types of companies (large, small and medium-sized enterprises). To support modelling activity, the human-system interface of the simulation tool uses just-in-time information retrieval (JITIR) to proactively provide the required information at the right time based on context during modelling and simulation.

One way to use simulation and visualization to quickly verify production flow plans is by generating semi-automatic data-driven models, which is illustrated by an example of implementation using FexSim simulation software, how is mentioned by Krenczyk et al. (2018). Caggiano and Teti (2018) use digital modelling and simulation tools for short-term analysis and validation of production management strategies, or for medium-term production planning or design/redesign of a production system. They propose a Digital Factory methodology to support the expansion of an existing production cell for the production of aircraft engine turbine blades using robotic automation of its deburring station. 3D modelling and discrete simulation are used to verify the upgraded production cell in order to increase its efficiency in terms of resource utilization and transit time. The validation of the simulation model is performed by collecting real data from a physically reconfigured production cell and comparing them with the model forecast.

According to Avventuroso et al. (2017), there is currently a lack of knowledge and structured approaches regarding the transition of production systems from rapid prototyping to large-scale production. They therefore present a procedure for FMS simulation analysis supporting planning, design and performance evaluation. They developed and used a discrete simulation model for the operational evaluation of an industrial case, which includes 3D printing, automated transport and storage systems.

According to Goodall, Sharpe and West (2019), refurbishment operations in particular can benefit from the simulations to support the assessment of different strategies for real-time scenarios due to the uncertain nature of product returns. They propose a data-based simulation that consists of three elements:

- an adaptive remanufacturing simulation algorithm for modelling the complex material flow found in the remanufacturing process in a general and reusable way
- an information model for structuring and highlighting simulation data requirements
- a layer of information services for collecting and analysing sensor data for use in the simulation.

The simulation is implemented to demonstrate how to automatically reconfigure and adapt to changes in data inputs (process and factory models) using a case study of operations from an electrical and electronic waste producer.

Methodology of the approach to the creation of a simulation model in the context of Industry 4.0 and the use of simulation models

The standard approach in creating models and subsequent simulations is to create a model without a layer which would ensure communication between individual machines, or machines and workers in different positions and different hierarchical levels. At the moment, the standard "if" conditions on the given input/output are used for the transport system (conveyor, forklift, spreading, …) if is necessary to cover the decision-making. Thus, the question may be, for example, whether the flow of material/product could be evaluated not only according to the following workplace/operation, but according to a comprehensive view of the state of the production section, hall, or entire factories, including separate workplaces or plants. In the article "Industry 4.0 and the New Simulation Modelling Paradigm" by Rodic (2017), the authors present the influence of the Industry 4.0 concept on the development of a new simulation paradigm, embodied in the Digital Twin concept. The main lesson is that while the new paradigm of simulation modelling is being adopted by large companies and small and medium-sized enterprises, there are significant differences depending on the size of the company in the problems they face and the methodologies and technologies they use. While the cases examined suggest the adoption of a new model of simulation modelling in industrial and scientific communities, its adoption in academia requires close collaboration with industry partners and diversification of researchers' knowledge in order to build integrated, multilevel models of cyber systems. As the presented cases show, the lack of tools is not a problem, because the current generation of tools for modelling using discrete simulations for general use offers adequate integration possibilities.

A frequent requirement when creating simulation models is the possibility to use them as an educational platform, most often for education in simulations, communication, the concept of Industry 4.0, etc. According to Grube, Malik and Bilberg (2019) simulation and the digital twin are a way for SMEs to realize their potential. The authors emphasize the connection between virtual and physical artefacts. This in turn inspires companies to change. Uhlemann et al. (2017) also point out the lack of knowledge of the Industry 4.0 concept and the possibility of simulations with the possibility of automated data collection. They demonstrate the benefits of these solutions for SMEs on a digital twin using real-time data collection and consider it a suitable learning platform for this size of organization.

Mourtzis et al. (2019) also point out the ignorance of companies. They focus on trying to connect the academic sphere controlling the simulation with the private sector, for which it is a useful but relatively unknown tool. They consider the Teaching Factory to be a missing link aimed at bridging the gap between academia and industry. Therefore, they show the design and evaluation of a real production system using discrete simulation and, based on real data obtained from the metallurgical industry, it is presented in the context of the Teaching Factory paradigm. In contrast, Lang et al. (2018) present the concept and current state of development of modular, decentralized and digital learning factories for use by students and researchers. In addition to the presentation of industrial modules and their settings, they represent a control and communication strategy that enables the creation and operation of any preferred layout in the company. They also briefly describe the discrete simulation model and the emulation model for virtual commissioning.

Another interesting trend is the use of simulation and possibly digital twins for setting up cooperation between manufacturing companies. Kadar et al. (2018) propose using simulation to manage a network of producers who can dynamically reconfigure and share their resources within a pre-registered community, and to analyse how the cardinality of such a "community" affects both collaboration and global and local production KPIs. In contrast, Kaihara et al. (2017) present crowdsourced production, a new type of production in which companies share their production resources depending on their demand and capacity. Accordingly, companies share their resource information and can find an outsourcing company when they need specific resources. The authors developed a production simulation model which crowdsourced with a source model and an agent-based negotiation algorithm to evaluate production efficiency based on machine delivery and utilization. Depending on the combination and balance of the business style, the delivery rate varies with the saturation point, which depends on the identity of the sources. Turker et al. (2020) then use real-time data collection and simulations to decide whether or not there will

be a delay in production in the future, and the proposed system decides whether or not to outsource the production of the order.

Mentioned by Klos (2018) a frequent trend in the use of simulation is the possibility not only of predicting the necessary corrections, or downtime, but also the reorganization and implementation of a different production plan than the standard, e.g. in the event of a sudden failure. In such cases, the problem is to anticipate possible failures, and most importantly to have prepared scenarios for system behaviour. Therefore, the authors of the article propose a methodology for gaining knowledge about maintenance using computer simulation. They created their example using Tecnomatix Plant Simulation software. A similar topic is addressed by Shin, Cho and Oh (2018). who study active protection to enable the "self-repair" function. The authors proposed workshop modelling and a dynamic reconfigurable CPS scheme that can predict the occurrence of anomalies and self-protection in the model. To this end, machine learning technology has made it possible to reduce overload in the production process. The result is a proposed simulation model that autonomously detects abnormal situations and is dynamically reconfigurable using self-correction.

The articles dealing with simulations then show another direction which the simulations can take - interconnection. It is not only about interconnection with hardware, which for example enables real-time data collection, but also about connection of software for discrete simulations and software for dynamics simulation mentioned by Goncalves Laurindo, Peixoto and de Assis Rangel (2019), where the authors present an integration mechanism for online communication between these tools and also use it for verifying the logic of the programmed PLC. Another example is the connection between discrete simulation and virtual reality (VR DES) mentioned in the research paper by Turner et al. (2016). In this paper the authors identify VR DES as a new platform for scenario testing and decision making. The work addresses the necessary communication protocols, aspects of system design, model validation and VR and DES applications. According to the authors, further research is needed in the areas of lower latency image processing, DES delivery as a service, gesture recognition for VR Interactions DES, and the interconnection of DES with real-time data streams and large data files. T. Delbruegger et al. (2019) then focus on interconnecting simulation systems. According to the authors, simulation models cannot be easily combined, and therefore interdisciplinary global optimizations often cannot be achieved. In addition, the aspect of human interaction with such complex co-simulation systems is often overlooked. Therefore, they present a concept for combining different simulation models with interdisciplinary multilevel simulations of production systems. The concept includes three hierarchical levels of production systems (Process Simulation, Factory Simulation and Human Interaction) and allows human interaction with the simulation system, but the concept can be easily extended to support other levels. Within a multi-level structure, each simulation system performs multi-objective optimization. Pareto optimal solutions are passed on to simulations at higher hierarchical levels in order to combine them and meet the flexibly adaptable goals of the entire production system. The concept is tested using a simplified production system to be optimized in terms of power time and electricity consumption. The results show the potential to optimize the productivity and efficiency of production systems in this way.

Y. Lu et al. (2020) discuss the recent development of Digital Twin technologies in manufacturing systems and processes, analyse the connotations, application scenarios, and research issues of intelligent Digital Twin-controlled manufacturing in the context of Industry 4.0. In their work, they identify unresolved research problems in the development of digital twins for intelligent manufacturing:

- Standardize the architecture pattern for the digital twin by an ideal combination of the two currently used architectures
- Focus on reducing communication latency for digital twins
- Standardize the data collection mechanism (define best practices)
- Define standards for digital Twin
- Standardize/design default digital twin functions
- Focus on version management of the Twin-Twin model
- Focus on "simulating" people in Digital Twin applications

S. Kern and J. Scholz (2020) deal with a simulation approach based on modelling agents for indoor production facilities. Simulation methods are used to optimize the spatial dimension with respect to the simulation of production processes. The agent-based model developed in this paper is used to simulate a production environment using an artificial interior space and a set of test data. The results show that different levels of available spatial information affect the results of simulations of internal production environments and processes. The distances covered by labour agents can be significantly reduced as well as the unproductive movements of labour agents (excluding production assets).

Conclusion

The simulations and the idea of digital twins in the Industry 4.0 concept are shown to be a necessary tool not only for planning with regard to various requirements such as minimizing costs, increasing productivity, "green" production, but also for education. The importance of simulation and digital twins in current developments is becoming increasingly important. In addition, there is an observable trend to extend simulations and digital twins to new technologies and possibilities, such as machine learning, real-time data collection, virtual reality interconnection, discrete interconnection and dynamics simulation, or interconnection of simulations and digital twins across companies to simplify cooperation and outsourcing.

Abstract

Not only companies but also consumers are increasingly trying to minimise the negative impacts of their consumption. Accordingly, factors such as sustainability and social responsibility play an increasingly important role in consumers' purchasing decisions. Therefore, the influence of environmental and social responsibility of companies on the purchasing decisions of consumers should be analysed. An online survey among consumers in the USA (n=148) was conducted and statistically analysed. The results of the study show that for the majority of consumers, the performance and price of a product or service is the most important factor in their purchasing decisions. However, more than half of the survey respondents are concerned about the sustainability, environmental and social responsibility of companies in their purchasing decisions. Consumers seem to be more aware of product-related CSR activities than of CSR activities related to services. Interestingly, the answers do not differ significantly by age, gender or household income level. The implication is that for consumers, aspects such as environmental and corporate social responsibility are essential factors in purchasing decisions, but in their absence, they are not an exclusion criterion. Besides, companies need to communicate CSR activities in the context of services to a greater extent, as consumers hardly notice them today. Further research on the influence of CSR activities on purchasing decisions and their communication needs to be further investigated.

Keywords: CSR, Purchasing Decisions, Marketing.

Introduction

The growing globalisation outside the marketplace creates external adverse effects of economic activity, which cause significant social and ecological damage nationally and internationally and across generations. The CSR movement is widely supported and conceptually promoted by politicians. The question is how CSR affects the short and long-term profit prospects of companies and which factors play a role here. A significant influencing factor here is the purchasing behaviour of consumers. The buying behaviour of CSR significantly influences the profit situation. The duty of responsible consumption limits our previous economic goal of unlimited freedom of consumption. Increasingly, all economic entities, both companies and consumers, are being called upon to act in a socially responsible manner (Schleer, 2014).

OLDENBURG, Alfred ZECH, Azim CAUSEVIC and Kerim HRAPOVIĆ "Consideration of Corporate Environmental and Social Responsibility in Purchasing Decisions of Consumers in The U.S.: Product-Related Initiatives Are Most Likely to Be Noticed" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

It has already been found that emotions and feelings effectively shape the decision-making process of consumers. They impair logical thinking and make it difficult for people to find choices. Moral feelings about caring for other people play a central role in CSR-oriented purchasing decisions (Schleer, 2014).

CSR can provide three forms of value to consumers: emotional, social, and functional significance. Each of these enhances or diminishes the overall value proposition for consumers. Moreover, the added value created by one form of CSR can either reinforce or reduce other product attributes (Green & Peloza, 2011). The purchasing behaviour of some consumers is influenced by the perceived "CSR quality" of the companies placing the products on the market. Studies already carried outcomes to the result that it cannot be assumed that good CSR quality goes hand in hand with good product quality. The studies point to considerable potential for misleading CSR communication, which cannot be verified by consumers (Schoenheit, 2014). Other surveys show that more and more consumers want socially and environmentally responsible companies. Producers must, therefore, also meet ethical standards in their product manufacturing and take more responsibility for social concerns, such as fair working conditions. CSR demands a reorientation of the core business towards sustainability beyond the legal requirements, both at home and abroad. In its core business, CSR includes environmental protection, fair working conditions and consumer protection (Zimmermann, 2016).

From the vital relationship between CSR and consumer behaviour, this paper examines those factors that determine the influence of CSR activities on consumers' purchasing decisions. The dimensions of CSR and sustainability are increasingly in the spotlight and appear to play an increasingly important role in consumers' purchasing decisions. Today, it is not only companies that are striving to minimise their negative impact on the environment, but also consumers. There is little literature on the practical implementation of CSR activities in companies (Bhattacharya, Korschun & Sen, 2009; Castelnovo, 2020; Peloza & Shang, 2011). There is also little research on consumers' awareness for the product and non-product-related CSR activities and how consumers react to CSR activities in connection with products and services and how this influences their purchasing decisions (Chen et al., 2018; Peloza & Shang, 2011).

The main research question is, therefore: What influence does the environmental and social responsibility of companies have on the purchasing decisions of consumers? The following hypothesis can be derived from the literature review: The more visible corporate environmental and social responsibility initiatives are, the greater their influence on consumers' purchasing decisions.

The aim of the study is, therefore, to gain insights into the influence of CSR activities related to products and services on consumers' purchasing decisions. For the study, U.S. consumers were surveyed via structured online surveys. As the Western country with the highest GDP, the USA can be seen as a highly developed economy and therefore as a role model for many other nations, which allows for a specific generalisation of the results.

Literature Review

Corporate social responsibility is a model that is implemented in businesses which ensures the social accountability of companies, including the stakeholders, societies and communities. One of the essential components of CSR in business is to check the impact it is creating on the environment. Implementation of CSR aims to ensure that the effect is kept minimal and there is no degradation of the environment as a result of business functioning of the company. Furthermore, it is also essential that the business works for the betterment of the society and there is overall well being of communities. Thus, it is also the responsibility of companies to understand the needs of the customers instead of just focusing on profitability (Loureiro & Lopes, 2018).

CSR can be an element of competitive strategy. CSR activities are very valuable for product differentiation (Anselmsson & Johansson, 2007; Boehe & Cruz, 2010; Chen et al., 2018; Duarte, 2020). Especially in saturated markets, product differentiation is the most important instrument to achieve and maintain a competitive position. CSR activities that offer customer benefits can create a real competitive advantage (Oldenburg & Miethlich, 2020). In marketing, product differentiation is defined as the innovation of a product from other products so that it catches the attention of the customers. Product differentiation is an essential strategy in marketing that either focuses on the quality of the product or its price. Henceforth, marketers believe that to make the desired impact on the customers, a brand must create a new product different from the existing products in the market. Additionally, product differentiation also includes the relatively lower price of the products, which shall be another factor of creating an impact on the customers (Suki, Suki & Azman, 2016).

Customers must have adequate knowledge of the business and business-related aspects so that they can make their purchase decisions wisely. Corporate social responsibility is that essential element of marketing that helps to share

knowledge and creating awareness among the customers. The crux of CSR lies in the payment of heed to the environment, societies, communities and stakeholders. The customers shall identify themselves to be essential parts of the company with the help of corporate social responsibilities. However, the impact created on the customers must be positive, which shall be ensured with the similarity between the needs and objectives of the consumers as well as the company. The needs of the consumers must also be addressed so that the company could work towards the fulfilment of those (Alafi, 2018). One of the important factors associated with marketing is the knowledge sharing process for the customers. One central aspect that drives the decision-making process of customers is their knowledge, based on which they shall decide if they shall opt for the products and services of the concerned brand. Through CSR, they shall also develop a notion of the responsibilities and ethical sense of the company. Thus, consumers also create an idea that if the brand is paying heed to the environment, it shall also manufacture the products and design the services as per the needs of the consumers.

On the contrary, when firms do not implement CSR activities efficiently, there is a lack of information and knowledge, which also impacts the decision negatively making the process of the customers. This is because they are not sure of the activities and functions of the business (Mayorova & Lapitskaya, 2016). The significant impact that is triggered by corporate social responsibilities is the increase in sales, sponsorship, customer loyalty and profitability. Fishbein's theory of reasoned action shall be selected in this regard which focuses on the role of purchase intentions in driving the purchase behaviour of the consumers. One of the intentions of consumers' purchase intentions is satisfaction. However, the customers who are new to a company shall not have any previous experience cannot decide if they would gain satisfaction from the company. Thus, there would be no impact on their repeat purchase behaviour. Therefore, CSR plays a vital role in this regard because it creates an effect on the satisfaction level of the consumers and they shall opt for buying the products of the company (Park, Kim & Kwon, 2017). CSR activities also result incorporate evaluation which further impacts product evaluation. Whenever a consumer tries to evaluate a business for making his buying decision, he shall take into consideration the corporate social responsibility of the firm even if he has no buying experience in the past. In the process of making the business decision, the concerned individual shall use the information stored in his memory as a result of the implementation of corporate social responsibility of the firm. Thus, in this regard, it shall be understood that the CSR activities of a firm shall play a significant role in corporate evaluation by the customers by processing knowledge and information in their memory (Butt, 2016). The relationship between CSR and price has been evaluated. Therefore, it has been identified that lower price as a part of corporate social responsibility has a more significant impact on customers. The lower price shall impact the intent of the customers, and they shall be driven to buy the products of that brand. Apart from products, customers shall also be aware of the non-product related aspect of the brand by understanding that the needs of the customers are addressed well, particularly the customers who are price sensitive. Furthermore, taking into consideration the environmental aspect of CSR, it could be stated that this also impacts the buying intent of the customers. This is because they understand that the company has associated itself with activities that create well being on a broader aspect (Albus & Ro, 2017).

To gain real benefits from CSR activities, the awareness of consumers must be achieved (Du et al., 2007; Sen, Bhattacharya & Korschun, 2006). At the same time, CSR activities can only generate real competitive advantages if they manage to increase or create added value for customers (Chen et al., 2018; Peloza & Shang, 2011). Consumers are most likely to respond and prefer product-related CSR activities (Anselmsson & Johansson, 2007; Du, Bhattacharya & Sen, 2007; Chen et al., 2018; Peloza & Shang, 2011). For products, the attributes (labelling of content and origin, policy implementation, and product liability, etc.) the basis for the purchase decision. Other commitments of the manufacturer are hardly taken into account since this information is not present during the purchase decision, and the customer would have to deal with the manufacturing company in more detail. Social and work-related issues have a strong influence on a brand's CSR image but are more difficult to communicate (Anselmsson & Johansson, 2007). From the consumer's perspective, the treatment of employees plays a key role. The focus here is mainly on the people who have contact with consumers (Anselmsson et al., 2016; Rosenbaum et al., 2017). Communication for CSR activities in connection with services is difficult, and therefore the perception of consumers is comparatively low (Miethlich, 2019; Miethlich & Oldenburg, 2019). One example of CSR activities in services is the employment of disadvantaged groups, like people with disabilities (Castelnovo, 2020; Duarte, 2020; Miethlich, 2019; Miethlich & Oldenburg, 2019). Promoting the employment of disadvantaged groups creates added value through corporate social responsibility and secures the professional future of those concerned. Companies that get involved will produce a real "shared value" with increasing social prosperity, from which companies will benefit again (Miethlich & Slahor, 2018; Papula, Papulová & Papula, 2014).

Methods

To study what aspects are essential for the customers when making a purchase decision for a product or service an online survey (Table 1) has been carried out with a sample of 148 participants in Spring 2020. The survey used the SurveyMonkey (2020) panel, which includes over two million people worldwide. The invitations to participate in the

survey were dynamic and adjusted to achieve the most representative sample possible. The research question was operationalised, and the respondents have been asked questions about whether they consider environmental and social responsibilities of the companies when making decisions on the purchase of products or services, what they think about the corporate social responsibility, what issues should the companies address most urgently, etc. The Research method included an online survey among the U.S. citizens with a sample of 148 participants, among them 54 percent women, 46 percent men.

A 5-gradation Likert-scale has been used to assess the level of the respondents' agreement to the suggested statements in the following categories: not true, rather not true, neutral, rather true, true. To carry out statistical analysis, the gradations are transferred to a scale from 1 to 5, whereby 1 stands for "not true" and 5 for "true".

The quantitative analysis is then carried out using descriptive statistics and statistical tests using IBM SPSS statistical software. For the main variables, it was checked whether there are statistically significant correlations per different demographic characteristics including gender, age and household income level.

Table 1: Questionnaire of the online survey

Question	Answer options
I pay more attention to sustainability in	- Products - Services
I know a company that promotes the employment of people from disadvantaged groups	- Yes - Yes, that's why I'm a customer there. - No - No, but I'd be there to support the cause
What importance do the following aspects have for you when making a purchase decision for a product or service?	-Primarily performance and price count. -With my consumption, I want to contribute to a socially acceptable development and do not to harm the environment. -Only when I have products or services from different companies, but with identical characteristics to choose from, I consider the environmental responsibility of the company. -Only when I have products or services from different companies, but with identical characteristics to choose from, I consider the social responsibility of the company.
My opinion on corporate social responsibility	- Important and necessary - Not much - If I want to do something good, I get myself involved (voluntary work, donations, etc.) - It's not honest and just about marketing and the company's reputation
Which issues should be addressed most urgently by companies?	- environmental protection - fair and safe working conditions - promoting the employment of disadvantaged groups (social inclusion) - other
Demographics (Age, gender, household income, region)	Age, gender, household income, region

Results

The 54.1 percent of the survey respondents were female, and 45.9 percent were male. Respondents from 45 to 60 years old comprised the largest groups in the sample (35.1 percent in total), followed by the respondents from 30 to 44 years old (31.8 percent in total). Respondents from 18 to 29 years old comprised 18.9 percent of the total population, while 14.2 percent were those aged 61 and more. The income level of the respondents has been regrouped and presented through four levels. 24.1 percent of the respondents have a household income less than 24.999$. 27.8

percent have income levels between 25.000 and 49.999$, and 36.8 percent have income levels between 50.000 and 99.999$. 11.3 percent of the respondents had more than 100.000 $ household income (Table 2). 15 respondents refused to answer this question.

Table 2: Demographic Data of the Respondents

Demographic groups	Absolute numbers	%
Gender		
Female	80	54.1
Male	68	45.9
Age		
18-29	28	18.9
30-44	47	31.8
45-60	52	35.1
> 60	21	14.2
Household Income		
$0-$24,999	32	24.1
$25,000 -$49,999	37	27.8
$50,000 - $99,999	49	36.8
$100,000 +	15	11.3

As for the region of living, 18.2 percent of the respondents were from the Middle Atlantic, and 16.9 percent were from South Atlantic regions. Respondents living in East North Central and Pacific regions comprise 14.2 percent and 12.8 percent of the total population, respectively. 11.5 percent were from the West South-Central region. The rest of the respondents were from the West North Central, East South Central, New England and Mountain regions (Table 3).

Table 3: Region of Living of the Respondents

Region	Absolute numbers	%
Middle Atlantic	27	18.2
South Atlantic	25	16.9
East North Central	21	14.2
Pacific	19	12.8
West South Central	17	11.5
West North Central	14	9.5
East South Central	10	6.8
New England	8	5.4
Mountain	7	4.7

Respondents have been asked to mention whether they pay more attention to the sustainability of the product or services. 80.4% of the respondents mentioned that they pay more attention to sustainability in products, while 19.6% in services. Chi-square test did not reveal any differences for this indicator per gender, age and income groups (χ^2 (3, N = 148) = 0.74, p = .995).

In total 58.8 percent of the respondents mentioned that they know a company that promotes the employment of people from disadvantaged groups, among them 16.2 percent mentioned that that fact is the reason they are customers of these companies. This means that 27.6 percent of the respondents who are aware of the companies supporting the employment of people from disadvantaged groups are their customers intending to support their initiative. 41.3 percent of the respondents are not aware of the companies promoting work among disadvantaged groups, among them, 21.0 percent mentioned that in case they are aware of these types of companies they will support the cause. In total, 37.2 percent of the respondents are supporting or will support (if aware of) companies that promote the employment of people from disadvantaged groups.

The respondents have been asked to assess the importance of different aspects when making a purchase decision for a product or service. The following criteria have been suggested: "Primarily performance and price count", "Contribution to a socially acceptable development and not harming the environment", "Consideration of the environmental responsibility of the company", "Consideration of the social responsibility of the company". The results for each criterion are presented in the below sections.

Primarily performance and price count: 72.1 percent of the respondents mentioned that primarily performance and price count of products and services are important to them when making a purchase decision for a product or service, for 30.6 percent among them these aspects are crucial. 22.4 percent of the respondents mentioned that this aspect is neither important nor not important. 5.5 percent of the respondents mentioned that primary performance and price count is not important to them when making a purchase decision. Chi-square tests did not reveal any statistically significant differences for assessment of the importance of primarily performance and price count when making a purchase decision for a product or service per gender ($\chi2$ (4) = 0.947, p = .918), age ($\chi2$ (12) = 10.614, p = .562) and income groups ($\chi2$ (12) = 10.266, p = .593), p-value > .05.

Contribution to a socially acceptable development and not harming the environment: 61.0 percent of the respondents mentioned that they want to contribute to a socially acceptable development and do not to harm the environment when making consumption. For 32.2 percent of the respondents, this aspect is neither important nor not important. 6.9 percent do not think about contributing to a socially acceptable development and about the environment when making consumption decisions. No statistically significant differences have been found for this indicator per gender ($\chi2$ (4) = 1.744, p = .783), age ($\chi2$ (12) = 5.931, p = .920) and income groups ($\chi2$ (12) = 12.745, p = .388), p-value > .05.

Consideration of the environmental responsibility of the company when making a purchase decision: The respondents have been asked to mention to what extent they agree with the following statement: "Only when I have products or services from different companies, but with identical characteristics to choose from, I consider the environmental responsibility of the company". In total, 47.7 percent of the respondents agreed with this statement among them 18.4 percent completely agreed. 35.4 percent were neutral, and 17.0 percent did not agree with the statement. The statistical tests did not reveal any statistically significant correlation between the respondents incline to consider environmental responsibility of the company and their demographic characteristics including gender ($\chi2$ (4) = 0.695, p = .952), age ($\chi2$ (12) = 11.428, p = .493) and household income ($\chi2$ (12) = 16.417, p = .173), p-value > .05.

Consideration of the social responsibility of the company when making a purchase decision: Only 42.5 percent of the respondents consider social responsibility of the company when they have products or services from different companies, but with identical characteristics to choose from. 39.5 percent of the respondents are neutral, and 18.3 percent do not consider the social responsibility of the company when making purchase decisions. Consideration of the social responsibility of the companies when making purchase decision does not differ per gender ($\chi2$ (4) = 1.364, p = .850), age ($\chi2$ (12) = 15.642, p = .208) and income groups ($\chi2$ (12) = 11.219, p = .510).

Corporate social responsibility of the companies: Respondents have been asked to provide their opinion on corporate social responsibility (CSR). In total, 159 answers have been received. Almost half of the respondents think that corporate social responsibility is essential and necessary (53.4 percent of the respondents mentioned this option), which comprises 49.7 percent of the total answers received. 14.2 percent of the respondents (13.2 percent of total mentions) think that CSR is not much important and necessary. In comparison, 10.1 percent of the respondents believe that CRS is not honest and is just about marketing and the company's reputation (9.4 percent of the total mentions). 29.7 percent of the respondents argued that if they want to do something good, they will get themselves involved (voluntary work, donations, etc.) (27.7 percent of the total mentions).

To the question which issues the companies should address most urgently, 50.7 percent of the respondents mentioned fair and safe working conditions and 31.8 percent mentioned environmental protection. 12.2 percent of the respondents think that promotion of the employment of disadvantaged groups is the most urgent issue the companies should address. 5.4 percent of the respondents mentioned other issues, among them was the production of high-quality goods at a reasonable price (2 respondents), remaining profitable (2 respondents), both environmental and social issues (2 respondents) and provision of high wages and benefits to the employees (2 respondents).

The research question "What influence does the environmental and social responsibility of companies have on the purchasing decisions of consumers?" can be answered as follows: The environmental and social responsibility of companies plays a subordinate role in the purchasing decisions of customers and is only taken into account when the actual customer need is satisfied. Product-related initiatives seem to have the most significant influence on the purchasing decisions of consumers because of their visibility. Thus the hypothesis derived from the literature "The

more visible corporate environmental and social responsibility initiatives are, the greater their influence on consumers' purchasing decisions." can be confirmed by the results.

Conclusion

The study aimed to gain insight into which aspects are essential for the customers when making a purchase decision for a product or service. Research method included an online survey among the U.S. citizens with a sample of 148 participants, among them 54 percent women, 46 percent men. The results of the survey were statistically analysed.

Based on the discussions in the current review of literature, it could be stated that CSR activities have been indispensable in businesses. It is important that businesses pay attention to the well being of the stakeholders, customers and the environment. This is because of the increased rate of pollution in the current era, and therefore, it is crucial that firms check the pollution level and impact on the environment. Furthermore, taking into consideration the needs of the customers is equally important, and firms shall identify their needs first. Currently, consumers shall not opt for business firms which pay heed to only profitability. This is because the intent of the customers has changed. Henceforth, CSR activities impact knowledge and information of the customers, based on which they make their purchase decisions.

The findings of the online survey suggest the following:

- The vast majority of the respondents (80.4 percent) pay more attention to the sustainability of the product rather than the sustainability of the services.
- More than half of the respondents know a company that promotes the employment of people from disadvantaged groups, 27.6 percent of them are customers of these companies with an aim to support their initiative. 37.2 percent of the respondents are supporting or will support (if aware of) companies that promote the employment of people from disadvantaged groups.
- For about 70 percent of the respondents primarily performance and price count of the products and services are important when making a purchase decision for a product or service
- More than half of the respondents (about 60 percent) think about the contribution to a socially acceptable development and the environment when making consumption decisions. About 40 percent of the respondents are either neutral or do not consider socially acceptable development or the environment when making consumption decisions.
- Almost half of the respondents (47.7 percent) consider environmental responsibility and less than half of the respondents (42.5 percent) consider social responsibility of the companies when they have products or services from different companies, but with identical characteristics to choose from. The rest of the respondents are either neutral or do not consider environmental and social responsibility when making purchase decisions.
- No statistically significant differences have been found out for the different criteria of consumption preferences and per respondents' demographic characteristics including gender, age and household income level.
- More than half of the respondents think that corporate social responsibility is important and necessary. 10 percent of the respondents believe that CRS is not honest and is just about marketing and the company's reputation.
- Among the other issues, such as the provision of fair and safe working conditions and environmental protection, promotion of the employment of disadvantaged groups was mentioned less frequently as an issue that the companies should address most urgently (approximately by the 10 percent of the respondents).

For the majority of customers, the scope of services and the price of the product are important in their purchasing decisions. Customers seem more sensitive to product-related CSR activities than to CSR activities related to services. Interestingly, consumers do not seem to differ significantly in age, gender or income. The implication is that for consumers, factors such as environmental and corporate social responsibility are an important factor in purchasing decisions. Still, in their absence, they are not an exclusion criterion in the purchasing decision. Besides, companies need to communicate CSR activities in the context of services to a greater extent if consumers are to be aware of them at all.

The present study is based on a small sample only, but the results are in line with the findings of the existing literature. The study should also be conducted in other cultures and with larger samples. In particular, the communication of CSR activities in relation to services and in comparison to product-related CSR activities should be further researched.

Abstract

This qualitative study examines the development of an innovative military electronic board by a subsidiary of a high-tech multinational company (MNC). The module involved software, hardware and mechanical projects. A conflict with a traditional supplier of avionics systems in a project phase where scope changes are not permitted to vary, necessitated a change in the management approach. There were considerable technical, psychological and political challenges involved in the development of this module. This paper describes the unorthodox application of Agile methods that enabled this project to be delivered within much shorter timeframes than similar products developed by the headquarters. As a consequence of successfully completing this project, the role of the subsidiary in relation to the headquarters changed substantially. The level of confidence in the subsidiary's technical capacity increased and it now has almost a complete control of the NPD cycles for all national projects.

Keywords: Project Management, NPD, Springboard Theory, Stakeholder Analysis, Defence

Introduction

Although the relationship between headquarters and subsidiaries has been widely investigated by the international business literature over time (e.g. Gupta and Govindarajan 2000; Almeida and Phene 2004; Bouquet and Birkinshaw, 2008; Kostova et al. 2016; Stolzmann et al. 2019), there are few studies about subsidiary evolution, especially in the field of project management of NPD (e.g. Jha and Bose, 2019), whose importance has increased over time (Zwikael and Smyrk 2019). Based on springboard theory, which analyses the reasons and process of expansion of multinational companies (MNCs) in emerging countries (Luo and Tung, 2018), we aim to reduce this gap by investigating the value of project management innovation in increasing subsidiary performance and with increasing headquarters' attention (Ambos and Birkinshaw 2010).

In particular, we describe a case study about the development of a modular component for a military cargo plane by a subsidiary company that solved a major problem for the headquarters. Named X86, it is a double motherboard included in the mission computer (MC), an integrated information processing system, comprising software applications to support missions like cargo handling, in-flight refuelling, medical evacuation, search and rescue, forest fire fighting, amongst others. The headquarters had hired a traditional supplier of avionics systems to supply a mature X86 board. However, after the critical design review (CDR) of the aircraft (FAA 2000), where scope changes are not allowed, this supplier decided to increase the price and to extend the deadline beyond what had been previously agreed. From the point of view of the headquarters, extra costs could be absorbed, but delays in delivering this electronic board meant heavy fines and conflicts with the manufacturer of the aircraft (the intermediate customer) and potential commercial problems with the Air Force (the end-user customer). This situation proved to be an opportunity for the subsidiary to increase its autonomy without threatening the headquarters (Dönmez and Grote 2018) by showing its ability to develop complex projects from scratch. Our findings indicated that project management innovation can increase the performance of the subsidiary and thus, attract attention from the headquarters. For that reason, the project management approach should respect the characteristics of the project, the top manager should support this initiative and team members should have expertise and be motivated.

CLARKE "Project Management Innovations Driving Subsidiary Reputation: A Defence Industry Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The rest of this paper is organised as follows. Section 2 reviews the literature. Section 3 presents the case study focused on the approaches adopted that overcome the challenges described above. In Section 4, the authors outline the method, including the justification for choosing a case study and the procedures to collect data and the sample acquired, while Section 5 discusses the findings of this study. Sections 4 and 5 cover the criteria identified by Perks and Roberts (2013) for longitudinal studies in innovation. We conclude this paper by providing our methodological contribution of tailoring a range of project management approaches that was able to develop a complex NPD project in record time and deal with political issues.

Literature Review

In order to investigate the impact of project management innovation in increasing subsidiary performance and therefore increasing headquarters' attention, we start by reviewing six distinct project management approaches that can are applied to NPD projects, because 'one size does not fit all' (Shenhar and Dvir 2007). The role of the subsidiary in generating and disseminating knowledge across the multinational and the concept of success is undertaken the aim of which is to establish whether this can lead to an improve subsidiary's reputation.

Project Management Approaches

Created 1986, Stage-Gate is a sequential approach that aims to develop projects through five stages for managing project activities (scoping, build the business case, development, testing and validation, and launch). These five gates have acceptance criteria for moving a project from one stage to the next (Cooper et al. 2002). In Stage-Gate, costs follow a proportional inverse relation to the project uncertainty and stages. In the early stages, costs are usually low as the project uncertainty is high, but as uncertainty decreases during project development, the costs of subsequent phases increase (Summers and Scherpereel 2008). However, NPD projects have high uncertainty in the initial stages (Amaral Féris et al. 2020), conflicting with the cost constraint assumptions built into the initial stages of Stage-Gate (Van Oorschot et al. 2010).

In 1994, Microsoft created the MSF, consisting of two models: the (1) a Team Model that defines the people who will work in the project and their respective activities (Santos 2007); and a (2) Process Model that divides the project development in five project phases, including envision, planning, developing, stabilising and deploying. MSF's goal is to promote an iterative and adaptive process consisting of a set of principles (e.g. agility and learning from all the experiences), concepts (e.g. willingness to learn, motivated teams and customer-focused), as well as utilising proven practices (e.g. for multidisciplinary teams and working in teams) derived from its own experience in development products and services (Microsoft 2005).

Two years later, Rational Software created the RUP PM approach. With four project phases (inception, elaboration, construction and transition) and milestones between them. RUP aims at ensuring the development of a high-quality software that meets the customer's needs within a predictable schedule and budget through. To that end, RUP provides a comprehensive set of guidelines, templates and tools aimed at covering the development process in a more broad and deep way than other approaches (Karlsson and Wistrand 2006). It is however a 'heavy' process with more than 100 artefacts that represents an additional and often unnecessary burden for small projects (Smith 2001).

In this same year, the UK government created Projects IN Controlled Environments version 2 (PRINCE2). This approach focuses on the business case and process control that can be tailored to a specific project environment (McHugh and Hogan 2011). PRINCE2 has seven principles (e.g. learn from experience and manage by stages), seven processes (e.g. managing a stage boundary and closing a project) and seven themes (e.g. quality, risks and plans) (Kruger and Rudman 2013). However, as PRINCE2 is a legacy of the public sector, there are rigid practices that hinder its adoption in NPD projects, such as heavy documentation in almost every project step.

One year later, Eliyahu Goldratt created critical chain project management (CCPM) based on his theory of constraints (Goldratt 1997). CCPM is focused on resource management and assumes that task uncertainty is the major factor that will impact project performance. Instead of adding buffers on the duration of tasks to absorb any delays that may occur to the project, CCPM halves task estimations and distributes the remaining part into buffers that are monitored throughout the project. However, the applicability of CCPM in NPD projects is limited: it considers that the availability of resources is unlimited- this does not occur in practice; b) it views the software development process with the same logic as a manufacturing process- impossible to do in most cases; and c) it reduces estimates by imposition that can lead to a lack of commitment among team members (Raz et al. 2003).

In 2001, seventeen independent-minded software practitioners launched Agile, an approach that aimed at creating and responding to changes in order to succeed in developing software within an uncertain and turbulent environment (Howell et al. 2010). Instead of process, tools, comprehensive documentation and contract negotiation, Agile is focused on individuals, customer collaboration and incremental way of thinking, and covers project management, software development and testing through several practices. For example, Scrum to manage product

development (Sutherland, J. 2015) and Kanban to design, manage and visually improve flow systems (Dennehy and Conboy 2018). The success of Agile over recent years and its wide acceptance in the IS field, resulted in its popularity with diverse projects and industries, like construction, government, telecommunications and health care (Serrador and Pinto 2015).

The Role of the Subsidiary

Multinational companies (MNCs) play a crucial role in sharing knowledge, since mergers and acquisitions offer excellent opportunities for both the country and its subsidiaries to renew their knowledge base and to aggregate new knowledge. The main reason why MNCs exist is because of their ability to transfer and exploit knowledge more effectively and efficiently in the intra-corporate context than through external market mechanisms (Gupta and Govindarajan 2000). For MNCs, subsidiaries have two primary sources of external knowledge that can be taken advantage of: (1) other MNC units (e.g. headquarters and other subsidiaries) and (2) local organisations (e.g. customers and suppliers). The implication is that a subsidiary must be able to acquire, assimilate, and exploit the knowledge of the headquarters and their peers as a natural consequence of belonging to that global social community (Colakoglu et al. 2014).

Some subsidiaries seek to implement the headquarters approach in the local context. However, others have the incumbency to contribute to the MNC by generating and disseminating local knowledge. In this case, they need to leverage capabilities and resources across the enterprise by take initiatives that are monitored closely by the headquarters. The successful ones tend to increase their reputation and autonomy (Ambos and Birkinshaw 2010). However, there are several factors that impact these initiatives, such as skilled workforce, infrastructure (Cantwell and Mudambi 2005), competitors, suppliers, customers (Borini 2016) and the level of relation between the two units (Najafi-Tavani et al. 2015).

One of the most important actors in this process is the top manager of the subsidiary (Bouquet and Birkinshaw 2008), who has some degree of freedom to restrain formal requests from the headquarter or to submit their own proposals. For example, he or she can provide conditions to increase the absorptive capacity (i.e. the ability to recognise relevant knowledge, assimilate it and apply it commercially, see Song 2014) by promoting the transfer of knowledge to the headquarter and being the design authority of a NPD product in a reverse knowledge transfer process (Kogut and Mello 2017). Besides the potential profit from the delivery of a NPD, the subsidiary can increase its reputation within the headquarter (Blomkvist et al. 2010). Moreover, expatriates play a significant role. They are managers and specialists from the headquarters that are relocated into the subsidiary for integrating knowledge and processes between them and reducing cultural differences between team members (Kostova et al. 2016). Conversely to expatriates, inpatriates are relocated for a long-term stay abroad in the headquarter, aimed at sharing tacit knowledge that can be used to leverage knowledge generation (Chang et al. 2012). Finally, there are the local professionals that complement this rich organisational environment in the subsidiary.

Project Success Concepts

The traditional definition of project success is now five decades old. Avots (1969, p.78) suggested implicitly that project success is determined based on delivering on the scope with the quality required, on time as well as on budget. This is referred to as the Iron (or Golden) Triangle (Atkinson 1999; Zwikael and Smyrk 2011).

This concept has also been criticised by other researchers. Among others, Scott-Young and Samson (2008) claimed that satisfaction, longer-term business success and the preparation of the organisation for the future are ignored, while Bakker et al. (2010) stated that this definition is not suitable for software development, because requirements change during the project lifecycle, thereby influencing time and cost.

As a result, several researchers have proposed improvements to this definition. For example, Pinto and Slevin (1988) included the assessment of the usefulness of the project, as well as the level of satisfaction and effectiveness for its intend users. Atkinson (1999) added long-term properties, such as maintainability and evolvability factors. DeLone and McLean (2003) developed a model specific for information systems, dependent on the organisational context, aiming to synthesise different measures of effectiveness. Symons (2010) suggested measuring of the productivity of software development projects (ratio of software size to effort) and the speed of delivery (ratio of software size to duration). Zwikael and Smyrk (2011) proposed an additional dimension for assessing the unplanned effects that the project may produce, such as the degraded performance of a system after a new software release is launched (Savage et al. 2015). Lechler and Dvir (2010) published a more detailed view of project success with four distinct dimensions. These included efficiency for measuring the extent to which time and cost plans have been met, measuring the extent of benefits that the project brought to its client, customer satisfaction with the benefits provided by the project and how it was conducted as well as the business results for measuring the perceived value of the project.

The Case Study

In this section, the authors describe a set of unorthodox project management practices adopted in the development of the NPD that was able to overcome the challenges discussed previously in the Introduction. This section is organised according to what was reviewed in the literature and nine knowledge areas defined by Project Management Body of Knowledge (PMBOK) focusing on Agile practices (PMI 2017).

The role of the subsidiary. The subsidiary is located in an emerging country and part of a high-tech MNC that initially acquired it in order to provide product maintenance for local customers. In the early years, experienced managers and specialists (i.e. expatriates) were relocated to the subsidiary for implementing part of the organisational processes used by the headquarters and to start manufacturing products locally. Later, young engineers (i.e. inpatriates) were relocated to the headquarters to start the development of software projects. However, the level of subsidiary autonomy was very limited at that time, including the lack of autonomy to develop a complete NPD project. Over the years, its autonomy of the subsidiary has increased due to the quality of work it had provided to the headquarter. This led to a new context, where some projects were shared between the project managers of the headquarters and the subsidiary (Scott-Young et al. 2019). When the x86 crisis happened, the top manager of the subsidiary identified an opportunity to increase its reputation and autonomy (Blomkvist et al. 2010). He provided strong support for this challenging project (Shepherd et al. 2017), by funding it and acting politically (Kyriazis et al. 2017) to decrease the level of mistrust at the headquarters.

The concept of project success adopted. Usually, the subsidiary adopts the concept proposed by Lechler and Dvir (2010), because it includes aspects related to the outputs (like efficiency) and outcomes (including effectiveness, customer satisfaction and business results). In this project, on-time delivery was very important, because the intermediary customer expected a X86 board able to fly in the military cargo plane in five months. On the other hand, an over cost was acceptable, because the cost of developing this project could be absorbed later, during the future production of this board. This definition of success guided the approach adopted for cost and procurement management.

The project management approach adopted. The approach selected to manage this project was able to deal with the development of software, hardware and mechanical projects in order to build the X86 board. However, it should consider "whole forest" instead of a "single tree" (Lee et al. 2019), this led to developing a plan that included a strong stakeholder analysis able to deal with the two customers (see Section 6) and psychological aspects, such as motivation. Agile was combined with a sequential approach (Bianchi et al., 2020) aiming at responding to constant requirement changes while being able to develop a high quality plan (Amaral Féris et al. 2017). For software development, this combination is useful when there is a need to develop a certified (or certifiable) software that should follow the principles espoused in the standard DO-178- software certification of safety-critical avionic systems – Belz et al. 2019). This combination of two distinct approaches was also adopted in the hardware development, because of the time pressure that led to plan procurement in a different way (to be discussed next) and because of the existence of standard DO-254 for hardware (Belz et al. 2019).

Scope management. The specification for developing the X86 board from scratch included two high speed processor (Intel Core i7, 2.0GHz, dual-core) for running embedded Fedora-Linux, Gigabit Ethernet, DVI and VGA videos outputs, USB and RS-232 serial ports, 16 Gigabytes of SATA memory on-board flash, a PCI express connection, and high power dissipation (around 100W).

Schedule management. Usually, the R&D team from the headquarters takes one year to deliver similar projects. In this project, the R&D team from the subsidiary had only five months. The planning was based on the critical path- the activities that determines the shortest time possible to complete the project (PMI 2017). This led the creating several alternative plans (plan "B") especially for procuring the required parts (discussed further below).

Quality Management. The quality that needed to be achieved by the X86 in five months was technology readiness level (TRL) 6. TRL is a method developed at NASA that estimates the maturity of technology (Straub 2015). To achieve this, the project team followed rigorous development standards (e.g. DO-178 and DO.24). Although the boards were not audited because of the time, special equipment was used like the Highly Accelerated Life Testing (HALT) and Highly Accelerated Stress Screening (HASS) chamber applied sudden temperature changes and vibration to eliminate design and production problems. During planning, two technical leaders- from the headquarter and from the subsidiary- used a tool named QPLAN to improve the quality of the plan (Amaral Féris et al. 2017) for developing the MC and the X86embedded in the MC. For example, QPLAN provided suggestions for the MC including the need to have face-to-face communication instead of interactions by e-mail and for X86 the need to adopt a test methodology for quality improvement.

Resource Management. With the support of the top manager, it was possible to allocate and demonstrate the value of project teams with a mix of very experienced team members along with junior engineers when developing electronic products for critical applications.

Communications Management. In order to plan, monitor and control, the project manager organised frequent meetings (every Tuesdays and Thursdays) and invited all team members involved in this projects (i.e. people from, R&D, quality, production, supply chain and finance areas) to discuss the status of the project with total transparency. In addition, there were ad-hoc meetings with a small number of people to discuss issues in depth that were not discussed in the status meetings.

Risk Management. The development of the X86 was considered a high risk-project, because of the extreme time pressure (already discussed) and the fact that it was the first development of a military board by the subsidiary who was known for developing software, but not hardware.

Cost and procurement management. As previously discussed, delivering the X86 within the planned budget before the CDR was outside the concept of success adopted for this project. However, delivering the X86 on time and with the required quality was critical to the success of the project. This necessitated a new approach of performing well-established activities in a different way- with creativity (Khedhaouria et al. 2017)- an unorthodox practice of Agile while also developing hardware. Particularly unusual aspects include the following: (1) Usually the electronic engineers design an electronic board and only when it is complete, they generated the bill of materials (BOM). This is a list of parts required to be purchased. However, the length of this process was incompatible with the aggressive delivery timeframe. The hardware engineer delivered several preliminary BOMs during the process of board design. The project manager then delivered this list to the buyers and asked them to purchase what was on each list. At the end, there was a set of electronic components that were not used in the X86 because the design of the board changed during this process. This represented the purposeful generation of muda (i.e. waste – Suárez-Barraza et al., 2016) to trade off on the speed of development. On the other hand, this strategy allowed components to be available on-time. (2) For items on the critical path, such as a printed circuit board (PCB) that required 12 layers- few suppliers were qualified to produce it)- the project manager requested to purchase them from more than one supplier. This also represents additional costs. However, the first supplier to deliver the PCB solved the problem of deadline for this critical item. (3) Because it is a military board, electronic components have more robust specifications, but this also reduces the number of available suppliers. To complicate matters, it is possible that customs may provision these components from abroad, in turn inducing delivery delays. As a result, some critical components were purchased twice, and the buyers asked the supplier to send via regular post and via a private company. The first set of components solve the problem of deadline!

Methodology

In order to analyse the changes in the relationship between headquarters and the subsidiary, we performed an exploratory and descriptive qualitative approach. The object of analysis was the description of technological knowledge generation flows between the headquarters and the subsidiary through multiple sources of evidence for analysing a complex contemporary phenomenon within its real-life context (Yin 2003).

The researcher team had access to key actors in the headquarters and subsidiary that participated in this process, including expatriates, inpatriates and local practitioners that participated in the development of the X86 and its implications to the headquarter and subsidiary. See Table 1.

In order to get a rich set of data, the authors made observations, collected organisational reports and performed semi-structured interviews (Creswell 2014). To undertake this project, the research team visited the laboratories and R&D offices eight times and taking handwritten notes of the documents made available by the organisation (the defence industry MNC does not allow to take photographs or electronic reproduction of any documents). This procedure complemented the triangulation of data from the analysis of documents including code of ethics, organisation charts, reports and procedures. In addition, there were also follow-up meetings during the development of the research that helped in clarifying issues and confirming findings identified during the interviews (see Clarke 2019).

Table 1: Subjects of the Research

Role	Area	Workplace	Working time in this MNC
Hardware engineering manager	R&D	Subsidiary	6 years
Software engineering manager	R&D	Subsidiary	9 years
Engineering director	R&D	Subsidiary	11 years
Engineering director	R&D	Headquarter	30 years
Technical engineer	Operations	Subsidiary	11 years
Operations director	Operations	Subsidiary	34 years
Former project manager	Projects	Subsidiary	5 years
Manager	Projects	Subsidiary	11 years
Director	Projects	Subsidiary	12 years
Vice President	Sales	Subsidiary	4 years
Former CEO	Presidency	Subsidiary	10 years
Former CEO	Presidency	Subsidiary	4 years

We collected 12 semi-structured interviews from the participants. These served to elicit an understanding of the phenomenon under investigation. We developed three distinct scripts with interview protocols (guidance questions) for conducting the in-depth interviews. These scripts included dimensions of the headquarters-subsidiary relationship, their role and the actors that participated in the process of generating technological knowledge in the subsidiary. Then, a coding process was carried out to prepare the data analysis. In detail, the data were organised into nine short labelled and exemplified categories (Creswell 2014). These included: (1) Type of knowledge developed, (2) Information management process, (3) Forms of communication, (4) Role of subsidiary and headquarter, (5) Role of the subsidiary's general manager, (6) Role of expatriates, (7) Evolution of the subsidiary's role, (8) Formalization of projects and (9) Projects involving innovations.

Discussion

Initially, the headquarters was of the view that the subsidiary did not have the capability to develop a military electronic board with this level of complexity in such a short period of time. However, key project team members had significant experience in the development of other critical applications (e.g. electronic boards for industry automation) and were confident and motivated to break this assumption in order to acquire greater autonomy in future projects. Moreover, the literature has provided considerable evidence that technological knowledge created by the subsidiaries is often absorbed by the headquarters. This has been described as a ‘reverse transfer of knowledge’ (Kogut and Mello 2017).

Another strength of the subsidiary is the fact that there are some peculiarities in relation to similar developments made by headquarters. For example, the size of the subsidiary organisation is considerably smaller than the size of the headquarters. This allowed the use of creativity in a NPD project and provided more flexibility in tailoring existing organisational processes and access to the top manager. In turn, these factors provided strong support to the project team through funding and removing political issues and obstacles at headquarters.

In addition, a successful stakeholder analysis was created through a sharing of common interests with the Air Force (the final customer). The development of a local knowledge is important for the Air Force. However, when the proposed solution was presented to the manufacturer of the aircraft (the intermediate customer), their initial reaction was negative. From their point-of-view, this project was very risky because it meant development from scratch of a complex military board in a restrictive time frame (instead of the usual. 12 months) as well as representing a ‘first’ for the subsidiary. However, as the Air Force understood the value of this project and knew the quality of the team members, they ended up supporting this initiative.

Ultimately, a demonstration of the technical capacity especially given the importance of the end-costumer, led to an increase in the headquarters trust of the subsidiary. For example, an engineer from the headquarters stated that “the subsidiary is “able to produce in the simplest, easiest and fastest possible way". As a result, the subsidiary now leads all national projects and contributes to the generate knowledge to the entire organisation (Kogut and Mello 2017). Moreover, the careers of several members of the team benefited and the communication between areas enhanced significantly, while the issues found during the project execution led to enhancement of internal processes.

Based on these outcomes, we proposed a tentative conceptual model that shows the value of project management innovation increasing subsidiary performance and thus, attracting headquarter attention. This model is based on Ambos and Birkinshaw (2010)'s work that proposed a model to explain the relationship between headquarter's attention, strategic choice and subsidiary performance. We adopted this model by focusing in the role of the subsidiary and highlighting the value of project management along with four moderating factors, including team expertise, motivation, top manager support and time pressure to deliver the new product, as discussed in detail in this paper. See Figure 1.

Figure 1: Tentative conceptual model (adapted from Ambos and Birkinshaw 2010)

Conclusions

This study examined the development of a military electronic board by a subsidiary, involving software, hardware and mechanical projects developed from scratch. This NPD was undertaken in much less time than development teams from the headquarter usually take. The project involved overcoming technical challenges and political issues that come from a scope change after the CDR, where requirements would usually be frozen. The project manager of the subsidiary, supported by the top manager and by the end-user customer, adopted an approach that moved beyond usual project management practices. The project management approach synthesised elements of Agile practices with the milestones, as well as the use of Agile for hardware development. It involved counter-intuitive parts acquisition, establishing alternative acquisition plans. The project was complex socially in that it necessitated a stakeholder analysis involved two customers often with conflicting interests. All parties required frequent communication and transparency and involved the attention of the project manager regarding the psychological aspects in order to motivate a skilled team to perform better than usual. Regardless of these difficulties, the NPD was delivered on-time, the headquarters level of confidence with its subsidiary increased significantly and the subsidiary was consequently granted more autonomy, including the leadership of all national projects.

This study contributes to research by showing that project management innovation, associated with team expertise, motivation and top management support can increase subsidiary performance even, under high time pressure. For practitioners, this study describes a set of unorthodox practices that can deliver NPD projects faster than usual and with the quality required.

The limitations of this research include a single case study of a specific project type in the defence sector. Future research may address this limitation by analysing the headquarter-subsidiary relationships in different project types and industries by using the model and methodology developed here.

Abstract

Many studies define the Participatory Guarantee System (PGS) as a social innovation to help small-scale organic farmers gain access to organic guarantee and promote social inclusion. This study explores farmer empowerment in PGS Pacet in Claket Village, East Java Province, Indonesia. Data obtained by Interviews with 15 farmers and were analyzed with empowerment theory. This study found that the organic farming and PGS model able to empower collective and individual farmers. In collective, PGS facilitates groups to increase their capacity to maintained business sustainability, expand the market network, and improve their group's income. For individuals, the PGS could improve farmers' agriculture and social skills, increase their self-esteem, and boost household income. Thus, the PGS model also provides access for farmers to build better relationships with consumers and communities in the village. Based on these findings, the PGS model is essential for organic farming communities, especially for smallholders.

Keywords: Empowerment, Participatory Guarantee System (PGS), Organic Farmers.

Introduction

According to statistical data, there are still 24.8 million poor people or 9.22% of Indonesia's population (Badan Pusat Statistik Indonesia, 2019). Of these, 63% live in rural areas and work as a farmer. Amid farmer poverty, other social problems faced are reduced agricultural land, lack of farmer's bargaining power in the market, decreased soil fertility, and climate change. Of the many difficulties, empowering farmers is a crucial concern to do as an effort to transfer power to farmers to improve welfare. Conceptually, empowerment gives strength to clients (individuals, groups, or communities) to increase their capacity and confidence in making decisions and solving their problems (Adams, 1996; Payne, 2005).

Academics promote organic farming as a potential model to improve farmer welfare in the long term (Padmanabhan, 2020). From an environmental aspect, organic agriculture uses biological processes in plants and animals to build soil fertility and control pests towards ecologically-based agriculture (Padmanabhan, 2020). Thus organic agriculture can provide benefits for the current and next generation. In the social aspect, organic agriculture can strengthen local communities' structure because agriculture is carried out by considering local conditions and leading to food sovereignty (Altieri, 2009).

In Indonesia, organic agriculture has increased in recent years. Between 2014 and 2018, there was an increase in the land by 121%, from 113,638 to 251,631 hectares (Aliansi Organis Indonesia, 2020). The growth of the organic market provides an advantage in achieving the economic scale of production and increases the risk of dishonest traders exploiting organic products' added value. Thus, organic standards become a concern for consumers (Robert Home, Hervé Bouagnimbeck, Roberto Ugas, 2017; Zanasi, Venturi, Setti, & Rota, 2009). The Government encourages the organic guarantee to be passed through third-party certification. However, third-party certification is considered burdensome for small-scale farmers because they bear enormous entry costs while farmer productivity cannot cover (Cuéllar-Padilla & Ganuza-Fernandez, 2018; Sacchi, 2019). A study shows that 59% of household-scale organic farmers only manage land less than half a hectare with the status of renting or working on land owned by others (Ningrum, V & Subroto, 2020). The third-party certification also affects consumers' high price (Fatimah, 2017; Sacchi, Caputo, & Nayga, 2015).

Cite this Article as: Vanda NINGRUM and Triyanti ANUGRAHINI "Empowering Organic Farmer Through Innovation in Indonesia: A Participatory Guarantee System Model" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The organic farmer organizations in the world build an innovative guarantee to help small farmers get an organic certificate at a low cost. International Federation of Organic Agriculture Movements (IFOAM) has promoted the PGS based on direct participation between farmers, consumers, and others (NGOs, traders, universities, etc.). They work together to verify that the farmers' cultivation is following organic standards in IFOAM. Producers and consumers share the cost of guarantee through PGS not to burden the small farmer (Cuéllar-Padilla & Ganuza-Fernandez, 2018; Nelson, Tovar, Rindermann, & Cruz, 2010). PGS also provides an opportunity to increase consumer trust because consumers are directly involved in the organic verification process (Zanasi et al., 2009). From the aspect of empowerment, PGS is an alternative to solve organic guarantees (Cifuentes, Vogl, & Padilla, 2018). Various countries, such as Spain, Italy, Brazil, Mexico, and several other Asian countries, including Indonesia, have adopted this PGS guarantee system to help small scale organic farmers.

This study focuses on exploring farmer empowerment in PGS Pacet in Claket Village, East Java Province. Indonesia. PGS Pacet has a slight development inviting farmers to join. At the time of its inception in 2018, there were only five female farmers with less than 1/3 hectare of land under management. In 2020 the farmers who have joined have reached 21 farmers with five groups, most of which are dominated by women. Currently, farmer groups have cultivated 50 types of vegetables, fruit, and tubers. The increase in organic farming in this village has made Claket Village a natural tourist attraction that provides organic farming education.

We use a qualitative approach based on in-depth interviews with purposively selected informants. During September and October 2020, authors interviewed 15 informants of 12 farmers, two consumers, and a facilitator for Aliansi Organic Indonesia (AOI). We organized data into categories based on themes (coding) using NVivo 12 software to categorize the interview transcript data.

Farmer Empowerment's Literatures

The main focus of empowerment is resources, agency, and achievement. Resources refer to control over physical, financial, human, and intellectual resources. At the same time, the agency is the ability and freedom of a person or community to make life choices. Resources and agencies can jointly achieve their "functioning achievements," both essential functions that are universally and on parts based on individual or community preferences (Sell & Minot, 2018). In empowerment, there must be a transformation in which disadvantaged communities can expand their ability to make changes for the better. Rowland (1997) explains that empowerment increases participation in making decisions and includes a process that makes people feel capable and entitled to make decisions. Empowerment must involve dismantling negative social constructs and seeing themselves as having the capacity and right to act and influence decisions. There are three significant dimensions in the empowerment process: personal, relational, and collective dimensions (fig. 1). The personal dimension in empowerment is developing self-confidence and individual capacities and removing internalized effects of oppression.

In comparison, the relational dimension is developing the ability to negotiate and influence the relationships and decisions' nature. The collective is where individuals work together to achieve a broader impact than they can get themselves, includes involvement in political structures, but may also include collective action based on cooperation rather than competition. Collective action can be focused locally, such as groups at the village level or the country level (Rowlands, 1997).

Fig. 1: Empowerment Dimensions

Source: Rowlands (1997) p.14

Agricultural empowerment studies have so far emphasized how farmers can innovate to carry out cultivation independently through organic agriculture (Altenbuchner, Vogel, & Larcher, 2017; Nath & Athinuwat, 2020). Besides, organic agriculture also allows strengthening the role of women in agriculture (Achandi, Kidane, Hepelwa,

& Mujawamariya, 2019; Altenbuchner et al., 2017; Lähdesmäki, Siltaoja, Luomala, Puska, & Kurki, 2019; Wright & Annes, 2016), strengthening the involvement of farmers in the production chain (Chisika & Yeom, 2020; Touri, 2016; Wright & Annes, 2016) and the ability to access technology (Beyene, Regassa, Legesse, Mamo, & Tadesse, 2018; Subashini & Fernando, 2018).

Although the aim is to provide organic guarantees to local consumers, the PGS model can encourage farmers in groups to work together and improve their abilities in agricultural practices through sharing knowledge and experiences. PGS also gives more attention to traditions, local ecology, social, and environment (Wangsa, 2017). In PGS, all parties have a collective commitment to implement organic principles in a joint action between farmers, consumers, Government, and other parties related to the organic food system (May 2019).

Results & Analysis

PGS Pacet

PGS Pacet was formed in 2018 and involved eight females and one male farmer divided into two groups: the Twelve and the Madani groups. In 2019, 8 other female farmers were joined and formed two groups, namely the Swadaya and the Miyatani Group. In early 2020, 7 female farmers were interested in joining and creating the Berdikari Group. Currently, the total number of farmers who are PGS members are 23 farmers divided into five groups. All land managed by the group has a lease status, with a land area controlled by the group between 500 to 3,600 meters. On this limited land, the farmer groups plant various commodities such as vegetables, fruits, and tubers. Each item is grown in turn, in limited but varied quantities. Currently, PGS Pacet has verified 54 types of commodities produced by farmer groups.

In the PGS Pacet activity, farmers learn how to treat organic land, plant cultivation and record all activities carried out by farmers on paper. For farmers, the process of taking notes on paper is an activity they consider problematic because most farmers' education is only at the primary level and they are not used to writing. However, the habits taught by PGS management familiarize farmers to keep these records. PGS documentation more a simple scheme than documents for third-party certificates; PGS allows farmers to fill forms themselves (Nelson et al., 2010; Sacchi et al., 2015). In PGS Pacet guarantees participation involves farmers and consumers.

Organic Farmer Empowerment

The authors can see the theme empowerment found in PGS Pacet as Fig. 2 below;

Fig. 2: The Theme Farmers Empowerment in PGS Pacet

Collective Empowerment

Collective empowerment develops when farmers work together to better impact than working individually or not being part of PGS. Group farming has a significant influence on empowering farmers in Indonesia (Maulini, Febrian, & Sutisna, 2019), especially for female farmers (Agarwal, 2020; Dohmwirth & Liu, 2020). The collective empowerment found in the PGS Pacet farmer groups from the results of this study included:

(1) Business Sustainability

Through groups within PGS, farmers can ensure their agricultural business's sustainability by resolving obstacles, such as cooperation in providing capital to lease land and planning crop management. The results showed that most of the farmers did not own land. Before joining the organic group, they were only seasonal farm laborers. The cultivation method in groups also allows farmers to carry out cultivation management to help farmers decide what they plant when they grow and how much they produce. By carrying out farming management, the market accepts all the group's commodities, and the crop rotation system can maintain nutrient fertility in the soil.

> *"On an area of 2000 square meters, it usually consists of 4-5 female farmers. So, from there, in each group, we make particular commodities, there are vegetables, fruit, and tubers. Here we have two groups that specialize in vegetables, then we make a planting schedule, and we record them on paper as documentation. In this planting schedule document, there is a division, in one group, in one area, for example, land, one of the five women we give a schedule of 4 to 5 types of vegetables. So there are about 25 types of vegetables in one land. Then we make a rotation in the ground; vegetables, fruit, and tubers have to keep rotating. This planting schedule is essential, so there is no overproduction (Miss. My, PGS Pacet Manager, September 2020).*

Most of the women farmers in the village generally do not only focus on farming. In their daily activities, they are responsible for domestic household activities such as cooking, cleaning, and caring for children. During limited time and energy, cooperation between farmers essential to maintain the farmer's garden, such as watering and cutting the grass.

(2) Networks

PGS Pacet builds networks with many parties such as farmers, consumers, agricultural servants, and village officials. However, the guarantee document only involves farmers and consumers, while agricultural servants and village officials are involved in the discussion process. The participation of many parties in PGS is needed to embrace a lot of support from the wider community.

> *So PGS is not just talking about guarantees. Still, on the role of farmers as producers, consumers, agricultural supporters, and village officials, PGS does not work alone but involves others' functions. Also, organic consumers are critical consumers, so when we invite them to attend, they can also be part of the guarantee, so their support is significant. Indeed, everything we do is for bridging with all parties "(Miss. My, PGS Pacet Manager, September 2020).*

PGS has two types of consumers: the end consumer (household) and distributors (traders). Consumers are the most critical network for farmers; apart from the fact that consumers are involved in the standard organic assessment, consumers also have a significant role in providing information on commodities that farmers must produce for the market. According to the Distributor, cooperation with PGS offers benefits for both farmers and consumers. PGS provides a forum for farmers and consumers to negotiate prices; the agreed price is fair for farmers and consumers.

> *"I like this collaboration with PGS Pacet, because we are open, so it's a Fairtrade. We discuss the price, if I give the seed, it means how much it will cost me, so there will be a discussion about the price, so the price we set is appropriate for the farmer and not too expensive for the customer, win solution for farmers and customers ". (Miss. Agn, Distributor, September 2020)*

The findings above show that PGS provides access for farmers to meet directly with consumers, where farmers can get information about market needs and open opportunities to expand the market. Farmer participation in the food chain helps farmers get a fair position in the market (Touri, 2016), even though the ability to negotiate in this market also affects women farmers to gain more excellent added value from their agricultural products (Wright & Annes, 2016*).*

(3) Organic Guarantee

After obtaining the organic guarantee, they feel that there is something to protect them, farmers are not alone but supported by many people, farmers are more convinced that the quality of their crops and more enthusiastic about farming.

> "*PGS protects us, the quality of our harvest can be guaranteed organic, we have more confidence in our cultivation." (Mrs. St, farmer, October 2020)*

Organic guarantees obtained by farmers can lead to higher farming motivation for the group. For farmers, PGS is not just organic legitimacy in the market, but also as an organization that becomes an identity for organic farmers. In other studies, agricultural quality standards through certification are considered significant in reducing the empowerment gap between men and women. Women have adequate access to training, assessment, and making decisions in the cultivation and marketing networks (Meemken & Qaim, 2018).

(4) Economic Contribution

The economic contribution felt by farmers is the increase in the group's amount of income because farmers get a more stable selling price compared to the previous conventional farming. Another economic contribution is the increase in consumers' number and area after obtaining a PGS certificate.

> *"Yes, it is the difference we feel. Previously our selling price was unstable; follow the price given to intermediaries. Now there is "PGS" which is very useful. " (Farmers St, October 2020).*

> *"Since we formed" PGS "and held meetings with consumers, so we have additional market share, the additions are in Malang, Gresik, Sidoharjo and Mojokerto. Previously we were only Surabaya "(Mbak My, PGS Pacet Manager, September 2020)*

Relationship Empowerment

(1) Relationship with Customer

The involvement of consumers in activities at PGS increases the interaction between farmers and consumers, thus creating a close and familiar relationship between farmers and consumers. Through this interaction, farmers can learn directly from consumers about updating market tastes and how to increase the added value of their agriculture.

> *"I have also been invited by PGS Pamor. There I met farmers and other consumers to talk about organic guarantees. It was January 2020. During the meeting, the farmers explained very transparently about fertilizers, pesticides, and how to cultivate them. Then the farmer asks what products are needed by consumers? So there is two-way communication from consumers to farmers. (Mrs. San, consumer, September 2020)*

> *"During the certification process, maybe every two weeks, I come to check the vegetables, check the harvester. Every time I meet with farmers, I also educate farmers about the wild plants around them that can be developed into more valuable products "(Mbak Agn, distributor, September 2020)*

The PGS model is part of social control because it contributes to creating social cohesion and building trust between farmers and consumers (Nelson et al., 2010; Robert Home, Hervé Bouagnimbeck, Roberto Ugas, 2017; Zanasi et al., 2009).

(2) Relationship between farmer groups

The success of the Madani Farmer Group then motivated women in the village to join organic groups. Although these farmers' success is not solely due to PGS, farmer groups, associations, and interactions facilitated by PGS become a place for women farmers to gather, not only to improve their skills but also to express their thoughts and feelings by farmers.

> *"Yes, we just said, we want to learn, if you want to join, please, from there my sister wanted to join, she said I could harvest together so that now the self-help group is triggered." (Mrs. Rn, Farmer, October 2020).*

> *"In group meetings, we usually tell stories about each other's family experiences, talk about family problems. If we were together, we spent a long time, from sunset to 9 PM we haven't returned home "(Mrs. Tik, farmer, October 2020)*

From the farmer's experience, PGS opens opportunities for farmers to share experiences (Hirata, Rocha, Assis, Souza-Esquerdo, & Bergamasco, 2019) and build closer relationships among farmers.

(3) Relationship with Neighbors

In PGS Pacet, farmers get pieces of training on organic cultivation techniques, crop management, making fertilizers, making natural pesticides, and other skills. According to interviews with farmers, the knowledge most often shared with other neighbors provides advice on dealing with pests if neighbors have problems with damage to their crops. This knowledge sharing is useful for the surrounding community because most people in Claket Village are farmers.

> *"There are a lot of tomato plants here, and pests often attack them, then I told them that organic fertilizers to solve pest problems" (Mrs. Pr, farmer, October 2020)*

Besides knowledge, organic agricultural products from farmer gardens are often given to neighbors if there is excess production. Farmers feel proud to provide healthy food for their neighbors, build better relationships and motivate them to do organic farming.

Personal Empowerment

The author found three personal empowerment themes in PGS Pacet: personal skills, self-esteem, and increasing household income.

(1) Personal Skills

Before joining organic farmer groups and PGS, all farmers practiced conventional farming and only knew cultivation in the garden since farmers form organic groups and PGS Pacet and communication skills with consumers, especially how to welcome consumers and present a product to consumers.

> *"Previously, I didn't know the various types of vegetables, I only knew about cabbage, mustard greens, and onions, but now I know the different kinds of vegetables. Since joining this group, I have been able to make a presentation in front of consumers, be able to learn better organic cultivation techniques, able to sell my crops to consumers ". (Mrs. Wti, Farmer, October 2020).*

According to PGS administrators, the PGS model can provide farmers with new knowledge about the organic farming management system as a whole. They were planning what to plant, how to produce it, how to maintain it, and how to market it. The organic standards in PGS also require farmers to make natural fertilizers and pesticides independently, thereby creating independence for farmers, farmers can independently produce production imports, and independent farmers market their products without depending on intermediaries.

> *"Farmers finally know that the agricultural system is not just planting and harvesting gardens, but now they know that agriculture is that they know the management system, the system, and record all on paper. Farmers know where the seeds come from, what pesticides are used for, you have to mention everything there. So far, the farmers in the group look smarter than other farmers". (Mbak We, Farmer, and PGS Pacet administrator, October 2020).*

(2) Self Esteem

Improvement of personal skills increases the sense of self-pride for farmers. Farmers feel they have productive activities that can be proud of their families and communities. Furthermore, female farmers consider farming to be entertainment for her during her busy household activities.

> *"A little bit confident. When asked by people, where are you from? Then I proudly answered from the garden. I feel like happy, there's something to be proud of ". (Mrs. Lk, Farmer, October 2020)*

> *"... I also want to have my entertainment in my heart, after doing household chores I want to have my entertainment" (Mrs. Tom, Farmer, October 2020)*

(3) Increase Household Income

An increase in income from group business has an impact on revenue for households. Farmers take advantage of this additional economy as family savings as protection if there are urgent family needs. Another advantage is that farmers can save farmers' expenses for consumption. The crops are not all sold but are used for their consumption, thereby reducing household costs. During the Covid-19 pandemic, Claket Village experienced a lockdown policy in three months (March - July). The Local Government severely restricted several markets, tourist attractions, restaurants, and human mobility; thus, agricultural products' demand decreased. Such jobs, like construction labor in the village, were also affected. The need for construction work fell so that most of the husbands of farmers lost their jobs. In contrast to the condition of organic farming, where the lockdown policy does not close their markets, farmers directly sell them to consumers without dependence on other parties. In such a situation, income from organic farming becomes the primary income in the family, as information from Mrs. Rn.

> *"My husband is a construction worker; now, my husband is having a hard time doing his job because of this Covid. Most of the activities are in the fields and helping to the garden. yes, this organic income is the foundation for the family. "(Rn Farmers, 2020)*

The personal skills obtained by farmers at PGS Pacet generate empowerment, especially for most women farmers, which ultimately improve household economic welfare. These results support other studies that found that organic agriculture can encourage women farmers' empowerment because of managing seeds, receiving various training, and increasing opinions (Altenbuchner et al., 2017). Besides, organic farming's main thing that must be strengthened is organic farmers' identity by managing organic agriculture's stigma. Lahdesmaki et al. (2019) analyzed the stigma of organic farming, which is considered difficult compared to conventional agriculture, which strengthens farmers to manage this stigma to encourage building the identity of organic farmers and the process of developing themselves to overcome their social difficulties in doing agriculture (Lähdesmäki et al., 2019).

Conclusion

Participatory Guarantee System is a social innovation that provides more benefits for participants than just the means of organic certification with lower costs. From the case studies found in PGS Pacet, we can conclude that organic farming with PGS can empower farmers because of the increased capacity for both farmer groups and individual farmers to improve welfare. For groups, PGS Pacet has changed the way farmers work, who previously only carried out production activities. Still, within this farmer group, PGS opens opportunities for farmers to be involved in post-production activities. For individual farmers, training and mentoring in PGS improves farmers' abilities, from technical skills in cultivation to communication skills between farmers and consumers and the rural community. From this study, we can define that capacity building for individual farmers can increase farmers' sense of self-esteem, especially for women farmers.

The PGS certificate challenge in Indonesia is that it has not received a guarantee from the Government; the Government only recognizes organic certification from third parties where it is still difficult for small scale farmers. Thus far, the PGS Model in Pacet is considered a grassroots movement to provide organic guarantees and empower small farmers both at the group and individual farmer levels.

Abstract

The article presents the impact analysis of the widespread use of advanced technologies on unemployment in the Russian regions. The authors believe that the transition to a new technological order, will restructure the labor demand in the regional labor markets of Russia. This restructuring will raise the demand for blue-collar workers, while those with university education will experience problems with employment. To confirm the proposed thesis, the authors used a correlation-regression analysis of space-time series. The study shows that most Russian regions have low potential for the new technological order transition. The use of this method allowed the authors to record a trend towards a decrease in the demand for people with university degrees, but also a significant difference between the regions towards the transition to the new technological order. Thus, the analysis results showed that high-tech regions with sufficient potential for the new technological order do not need a large number of people with higher education. At the same time, under the new conditions, high-tech regions are experiencing an acute shortage of workers with a secondary professional vocational education.

Keywords: Unemployment, Industry 4.0, Level of Education, Higher Education, Secondary Professional Education, Complete Secondary Education, High-Tech Regions

Introduction

Currently, a global restructuring of the world's economy to the new technological order is taking place. The so-called Industry 4:0, based on digital technologies and robotization is already beginning to influence the labor market, creating preconditions for structural shifts and its reformatting. As world experience has shown, the transition to a new technological structure is always accompanied by the labor release, due to the utility loss of some professional skills, which leads not only to the labor market restructuring, but also to an increase in the unemployment rate at the initial stage of the transition (Frey and Osborne, 2017; Harris et al., 2018; Larsson et al., 2014).

The global trends are also typical for the Russian regions. However, at present, not all Russian regions have the potential for the new technological order transition (Romanova, 2018). In the authors' opinion, most of the Russian regions, for various reasons, will remain in the fourth and fifth technological orders. Whereas the regions moving into the new technological order will be the first to experience an increase in the unemployment rate, amid a shortage of new specialists who will flow from other less successful territories. At the same time, the authors believe that the most sensitive and strong blow will fall on people with higher education.

In order to study the impact of new advanced (digital) technologies on unemployment in the Russian regions, the authors suggested a hypothesis: *the widespread introduction of the advanced technologies in the regions of the Russian Federation will have the greatest impact on people with higher education.*

Theoretical Overview

Scientists from different countries note that the level of digitalization risk is not the same for representatives of different professions and depends, among other things, on the level of education (Ghobakhloo and Fathi, 2019). Scientists note the decline in employment as a result of replacing human resources with machines (Kim et al., 2017). It is believed that education and interdisciplinary will contribute to success in finding and re-finding jobs to reduce income inequality. Education is the best antidote to unemployment (Angeloni, 2020). One of the consequences of digitization is the multitude of new forms of work and collaboration that will require the development of new skills and competencies. New forms of employment have advantages over traditional forms. For example, distance work allows women to combine work and family responsibilities (Tonkikh et al., 2019). Teleworking has become especially popular during the coronavirus pandemic. However, not all workers will be able to master the necessary for Industry 4.0 skills and competencies.

A large-scale research conducted by analysts (PwC) analyzed over 200,000 existing jobs in 29 countries and identified three waves of automation:

1. The algorithm wave (before the 2020s);
2. The increase wave (till the end of the 2020s);
3. The autonomy wave (till the mid-2030s).

The first wave of automation, which is observed at present, is primarily associated with the automation of simple computational tasks and the structured data analysis. The second wave of automation will entail a more dynamic change in the execution of many work tasks, in particular those that are routine and repetitive. The third wave of automation is associated with the active introduction of autonomous artificial intelligence and robotics, which will automate routine tasks, as well as tasks related to manual labor or manual dexterity. Evidence obtained for the Russian Federation suggests that in the short term the automation risk is low for all levels of education. The risk for graduates of higher education institutions in the first wave is 3%, for those with secondary professional education and complete secondary education - 1%, respectively. However, less educated workers are much more vulnerable in the long run. By 2030, the potential for job automation for people with higher education is expected to be 11%, for people with secondary professional education - 31%, for people with complete secondary education - 39% (Hawksworth et al., 2019). A negative consequence of automation is a decrease in wages for low-skilled workers (Lankisch et al., 2019).

Thus, automation will, on the one hand, help to increase the prestige of higher education in mainly technical areas of training. On the other hand, it will lead to the fact that older workers and graduates of unpopular majors who do not have the opportunity to get a second degree for free, will be forced to agree to less qualified and low-paid jobs (Harris et al., 2018). All of the above creates serious threats to the social-psychological well-being and psychological safety of employees: "a situation in which labor relations can be terminated by the employer at any time exacerbates the insecurity of work and negatively affects the psychological safety of employees" (Zemtsov, 2017).

Metadata

To prove the hypothesis the tools of correlation-regression analysis based on space-time series for 2018-2019 were used. During the analysis, three one-factor models were obtained, which were included in the system of equations:

$$\begin{cases} un_ed = f\ (constanta,\ tech) \\ un_ed2 = f\ (constanta,\ tech) \\ un_ed3 = f\ (constanta,\ tech) \end{cases}$$

where un_ed is the number of unemployed with a higher education, un_ed2 is the number of unemployed with a secondary professional education, un_ed3 is the number of unemployed with a complete secondary education, constanta is a free member, tech is the number of advanced technologies used, further advanced technologies.

Analysis Results

The results of the econometric analysis recorded a trend towards an increase in unemployment of people with a higher education when using new technologies in enterprises. Thus, the analysis of the advanced technologies impact on various categories of people, depending on their level of education, showed that at present this category is at risk. Whereas for other groups, no statistically significant relationship was found, and the resulting coefficient recorded a reverse correlation (Table 1).

Table 1: The results of the econometric analysis of the impact of the advanced technologies use in unemployment

Exogenous variables	Endogenous variate		
	un	un_ed2	un_ ed3
const	632,3***	1287***	455,5***
TECH	0,25***	-0,013	-0,009
R2	0,33	0,01	0,01
Prob (F-stat)	0,00	0,29	0,21

*Note: *** the significance probability of the obtained coefficient if the indicator is 99%.*

The obtained elasticity coefficient for the use of advanced technologies indicator in relation to unemployment for people with higher education amounted to 0.25. So it can be assumed that, on average, the following pattern has developed in Russia: with the modern technologies introduction at enterprises for every 1000 units, this process will release 250 people with higher education. Note that the obtained elasticity is average for Russia. Presumably, this sensitivity will be even higher in high-tech regions, especially Moscow. Whereas for other regions, the elasticity may be lower, especially for low-tech areas.

Spatial analysis of the advanced technologies impact on people with higher education confirmed this thesis. As can be seen in high-tech Russian regions, the relation between advanced technologies and unemployment for people with a university degree is much stronger, and the sensitivity (elasticity) of this relation is vertical. This sensitivity indicates the inelasticity of the demand for advanced technologies in relation to people with a higher level of education (Fig. 1). In other words, the process of digitization and robotization is an objective process that, in any case, will facilitate the replacement of people with higher education with technology. Whereas for other regions, this sensitivity is less sensitive, and therefore has a flatter appearance.

Sourse: Rosstat

Figure1: The relation between advanced technologies and unemployed people with higher education in the entities of the Russian Federation in 2018.

Another trend should be noted, there is an excess of people with higher education in Moscow, but there is a shortage of them in other high-tech regions. So, if Moscow is the only subject of the Russian Federation that fell into the first

quadrant, then such regions as Bashkiria, the Sverdlovsk Region and the Perm Territory entered the fourth quadrant in terms of the connection between technologies and the unemployed with higher education. From which we can conclude that these regions have a shortage of qualified personnel who do not have the digital skills necessary for the new technological order. This is proved by the report of the Department of Labor and Employment of the Sverdlovsk Region. Thus, according to the Department of Labor there is a persistent unmet demand from employers for specialists in the IT industry, which amounted to 237 vacancies in 2018[i].

If in relation between technologies and the unemployed with a higher education everything is unambiguous and the difference is only in the different regions sensitivity, then the relation between technologies and people with secondary professional education in Russia has a multi-vector situation (Fig. 6). Thus, Moscow, being a center of attraction for external and internal migrants, has absorbed a huge mass of people with higher education who have not found employment elsewhere. Whereas for people with secondary professional education in the region, there is an almost horizontal elasticity, which indicates both the shortage of industrial workers and the importance of the role of the people of this category for the new technological order. The same trend is typical for the Moscow Region (Fig. 2).

Sourse: Rosstat

Figure 2: The relation between advanced technologies and unemployed people with secondary professional education in the entities of the Russian Federation in 2018

Meanwhile, in the Sverdlovsk Region, Perm Territory, Bashkiria and a number of other regions, there is a steeper slope and a greater sensitivity for this category of people with respect to advanced technologies. Which can mean that there is no acute shortage of skilled workers in these regions.

It is interesting to note that in most Russian regions the unemployed people with secondary professional education are concentrated in the second quadrant, which indicates the lack of industrial production in sufficient quantities, so they cannot find employment in the labor market. Thus, in these regions, there is a backward correlation between technologies and the unemployed of this group. In other words, the introduction of advanced technologies reduces unemployment in low-tech regions of Russia for these people, which may mean an increase in demand for industrial workers, but with the development of digital skills.

Conclusion

The conducted research has confirmed the author's hypothesis that the advanced technologies have a multi-directional effect on different people depending on the level of education. In a new digital economy, there is no demand for a large number of people with liberal education, for this reason, the highest unemployment in this group is already observed in the regions that are moving to the new technological order.

Along with this trend, the use of advanced technologies involves the growth of blue-collar workers, but with the development of digital skills and competencies. Even today, in most Russian regions, there is a demand for such people. At the first stage of the transition to the new technological order, people with secondary professional education are the least vulnerable to the advanced technology's introduction in most regions of the Russian Federation.

For this reason, the authors believe that despite the spatial analysis results, which showed that most Russian regions today have low potential for the new technological structure transition, they are underestimated, because of the accumulated high level of human capital, which have historical experience in a short time to mobilize and master new work skills and competencies. And with a quick advanced technology introduction in these regions, there will be a process of reducing regional disparities between territories, as well as strengthening economic ties between them.

Abstract

The pandemic of the infectious disease COVID–19 caused by the SARS–Cov–2 coronavirus, officially announced by the WHO on March 11, 2020, has hit the global economy on multiple fronts. This paper analyzes the impact of the pandemic on the tourism sector and its ability to regenerate once the pandemic has ended. The subject of the research was the occupancy rate of bedrooms and bed-places in hotels and accommodation of a similar type according to the NACE 55.1 classification in five selected countries of the European Union in the period from January to July 2020 with the background of the occupancy rates in the years 2012–2019. The results have shown that even though the tourism sector has experienced a drastic decline in the face of the coronavirus pandemic, the occupancy rates in the analyzed countries quickly began to increase as soon as it was possible. With this observation the hypothesis about the high regeneration capacity of the tourism industry has been proven. This preliminary analysis allows for an optimistic view of the future of tourist services both for the ending of the pandemic and the sector surviving other possible crises in the future.

Keywords: COVID-19 Pandemic, Tourism, Industry, Regeneration.

Introduction

The pandemic of the infectious disease COVID–19 caused by the SARS–Cov–2 coronavirus, officially announced by the WHO on March 11, 2020, has hit the global economy on multiple fronts. The world has experienced major pandemics in the previous 40 years, however none of them had as damaging implications for the global economy (Gössling, Scott and Hall, 2020, p. 6). All sectors of the economy, except those whose production was intended to fight the virus, have been more or less affected by the pandemic. On the one hand, it was caused by a varying degree of restrictions introduced in most countries and the fact that a significant part of services could not be performed in compliance with the recommended sanitary regime. On the other hand, the conditions of such high economic risk meant that consumers could not be sure of their financial situation, which in turn translated into a reduction in demand for services.

One of the industries which have recorded significant losses is the tourism industry which is one of the most important global employers (UNWTO, 2020). For years, tourism has become an increasingly important sector of the world economy. According to data from the World Tourism Organization, in the period from January to September 2019, there was a 4% increase in the number of tourist check-ins in the world compared to the same months in 2018. An estimated 1.1 billion tourists travelled in the first nine months of 2019, which is 43 million more than in the same period in 2018 (UNWTO, 2019). With such a dynamic growth in the years preceding the declaration of the pandemic and the significant position of tourism in the global economy with previous concerns of overtourism (Higgins-Desbiolles, 2020, p. 611), the losses of the tourism sector caused by the economic crisis are becoming the object of scientific interest.

Research Subject

The subject of the research was the occupancy rate of bedrooms and bed-places in hotels and accommodation of a similar type according to the NACE 55.1 classification in five selected countries of the European Union in the period from January to July 2020.

The purpose of analyzing the impact of the COVID-19 pandemic on global tourism was to examine the economic effects of restrictions introduced to protect and save lives and human health, and to collect data that, in the long run, could help create a plan to minimize losses in the tourism sector in the event of economic crises, especially world health crises.

The tourism industry is highly prone to all crises, in particular crises on a global scale. However, the tourism services sector is very diverse and involves many intermediate industries responsible for the production of a wide variety of goods and services. Therefore, the research hypothesis was the possibility of a quick return of the tourism sector to the best condition and efficient reconstruction of the tourism market after the coronavirus pandemic.

Materials

The research material was obtained from the Eurostat database. The occupancy rate of rooms and the number of beds were analyzed in five European Union countries, the selection of which was made on the basis of the size of their accommodation bases expressed in the number of bed-places. The criterion was the number of beds, as it best reflects the capacity of the accommodation base.

The number of bed-places is determined by the number of people who can stay overnight in the beds provided in the place of accommodation, excluding extra beds, which can be prepared at the special request of the guest. It is worth paying special attention to the fact that with this definition a double bed is counted as two single beds, as it can accommodate two people.

The subject of the study was the occupancy in hotels and similar accommodation establishments according to the NACE 55.1 classification. This class covers the provision of accommodation on a daily or weekly basis, mainly for short stays. This type of accommodation includes furnished rooms and apartments. Among the services that characterize this class are daily room cleaning and bed-making, as well as the availability of additional services such as catering services, parking, laundry services, exercise rooms, congress facilities, etc. This class includes accommodation provided by hotels, aparthotels and motels, but does not include houses, flats or apartments, and in particular does not include such facilities to be rented for permanent use.

The occupancy rate in hotels and similar types of accommodation has been compiled by Eurostat as data expressed in percentage figures. The occupancy rate of bedrooms and bed-places was calculated as the ratio of occupied rooms to the net number of rooms available, therefore it is the number of rooms and beds actually available for rent.

In order to give a broader context to the changes in the percentage data in the period from January to July 2020, they were also compared with the corresponding data for the same countries, type of accommodation and units whose occupancy rate was considered in 2012-2019.

Tables 1 and 2 below illustrate the occupancy rate of bedrooms and bed-places in the analyzed countries in the period 2012-2019, expressed as a percentage. Increasing tendencies in the occupancy of both coefficients concerning almost all the years covered by the study are easily noticeable.

Table 1: Occupancy rate of rooms in hotels and similar type of accommodation in the analyzed countries in the period 2012-2019, expressed as a percentage

	2012	2013	2014	2015	2016	2017	2018	2019
Germany	57.10	57.90	59.10	60.23	61.80	62.07	62.72	63.04
Spain	56.10	57.20	59.20	61.97	65.72	67.07	66.77	67.22

Poland	41.00	41.50	46.50	21.80	8.50	10.80	23.40

Table 3: Occupancy rate of bed-places in hotels and similar type of accommodation in the analyzed countries in December 2019 and in the first quarter of 2020, expressed as a percentage

	12.2019	1.2020	2.2020	3.2020	4.2020	5.2020	6.2020
Germany	39.77	33.34	38.08	19.90	7.86	13.32	27.09
Spain	48.03	46.54	51.52	29.02	0	12.17	18.82
Italy	36.80	40.30	44.30	10.70	3.90	6.10	16.90
The Netherlands	42.10	37.50	44.10	18.80	2.70	9.90	24.20
Poland	33.90	34.60	38.70	17.30	6.80	8.40	19.90

Methods

Countries selected for the analysis were those with the largest accommodation bases in relation to the European Union member states in 2019. They were, in descending order, Italy (approx. 5.18 million beds), France (approx. 5.10 million beds), Spain (approx. 3.64 million beds), Germany (approx. 3.59 million beds) and the Netherlands (approx. 1.41 million beds). During the data collection, it was found that the database in question did not contain data for France that would allow it to be included in the compilation. Therefore, it was decided to consider Poland as the fifth country, which in 2019 ranked eighth on the list of European Union member states according to the size of the accommodation base (approx. 825 thousand beds).

The analysis was presented against the data from previous years regarding the worldwide growth of the tourism industry. As all the data on the occupancy rate of bedrooms and bed-places in 2012-2019 and in the first half of 2020 were presented as a percentage, only changes in percentage points over time were used to analyze the occupancy variability of the studied units.

A percentage point (p.p.) is defined as an arithmetic difference of two percentage values. It is calculated by substracting the initial percentage value from the final percentage value. The arithmetic mean was used to calculate the average percentage point changes.

Secondary research aprroach has been adopted as well.

Results (years 2012 – 2019)

Germany

Over the 8 studied years, the occupancy rate in Germany increased from 57.1% in 2012 to 63.04% in 2019. The occupancy rate of bed-places during the same period increased from 39.9% to 45.71%. Therefore, both of these values increased by less than 6 percentage points. Every year, the occupancy of rooms and beds increased by an average of about 0.85 percentage points. Both the largest and the smallest annual changes were recorded for the room occupancy - they amounted to 1.57 and 0.27 percentage points, respectively, and took place in successive years (an increase by 1.57 p.p. occurred at the turn of 2015 and 2016, and an increase by 0.27 p.p. at the turn of 2016 and 2017).

Spain

In the case of Spain, the occupancy rate of bedrooms in the period under consideration changed from 56.10% to 67.22%, thus increasing by around 11 percentage points over the eight years. The occupancy rate of bed-places, in turn, increased by around 8.5 percentage points, from 53% in 2012 to 61.48% in 2019. The room occupancy rate increased by around 1.6 percentage points each year, although in 2018 there was a slight annual decline (-0.3 percentage points). Bed occupancy increased by approximately 1.2 percentage points annually, but decreased in 2018 and 2019 (-0.93 p.p. and -0.21 p.p. respectively).

Italy

The room occupancy rate in Italy in 2019 increased by 9 percentage points compared to 2012: its amount changed from 42.8% to 51.8%. The occupancy of the beds increased from 40.9% to 49%, which is slightly more than 8 percentage points. The annual change in the occupancy of rooms and beds was around +1.3 and +1.15 percentage points, respectively. In 2013, there was a slight decrease in the bed occupancy (-0.4 p.p.).

The Netherlands

The structure of changes in the occupancy rate in the Netherlands was very similar to that in Italy, although the output percentages differed significantly, in particular for the occupancy of bedrooms. Over the years, it increased by slightly over 9 percentage points, from 62.9% in 2012 to as much as 72% in 2019. In the case of the bed occupancy rate, it was calculated that in 2019, compared to 2012, it changed by about 8 percentage points, as it increased from 42.3% to 50.2%. As in the case of Italy, the annual changes in room and bed occupancy rates averaged +1.3 and +1.15 percentage points, respectively. In 2019, both the room occupancy and the bed occupancy rate decreased slightly (-0.9 and -0.7 p.p., respectively).

Poland

Poland is characterized by similar percentage point changes in the occupancy rate of bedrooms and bed-places as Italy and the Netherlands - they were respectively 9.6 and 8.6 percentage points in 2019 compared to 2012. The occupancy rate of rooms increased from 41.1% to 50.7%, and the occupancy rate of beds - from 33.1% to 41.7%. Yearly average percentage point increases were around 1.4 and around 1.2 percentage points for room and bed occupancy rates, respectively.

Summary of the results from 2012 - 2019

As a result of the analysis of changes in the occupancy of bedrooms and bed-places in 2012-2019, increases in these percentages were found in all the analyzed countries.

The highest increase expressed in percentage points was observed over this period for the room occupancy in Spain (+11 p.p.). Compared to other countries, the lowest changes in the room occupancy rate were recorded in Germany (+6 p.p.). Italy, the Netherlands and Poland recorded very similar changes, oscillating at the level of 9 percentage points.

In the case of the occupancy rate of bed-places, the only country that stood out from the rest was Germany, with the smallest increase in 2019 compared to 2012, which was less than 6 percentage points. In the other studied countries, there was an increase by approx. 8 percentage points.

In all the countries, the average annual changes expressed in percentage points ranged between 0.8 - 1.6 percentage points.

Results (first half of 2020)

The occupancy rate of bedrooms

In terms of room data in the first half of 2020, the analysis of changes in the occupancy rate expressed in percentages showed declines. Figure 1 below shows the changes of occupancy rates, expressed as a percentage, for hotel rooms and similar types of accommodation in the five analyzed countries of the European Union.

Fig.1: Changes in the occupancy of rooms (expressed as a percentage) in hotels and similar accommodation establishments in the analyzed countries in the first half of 2020

In January 2020, compared to December of the previous year, there was a slight decrease in the occupancy of bedrooms in Germany and the Netherlands (by approx. 6 and 9 percentage points, respectively), in other countries the change was minimal. In February, there were slight increases in the occupancy rate in all the countries - on average 5 percentage points.

March was the first month in which all the countries in question recorded significant reductions in the room occupancy at an average of 28 percentage points. In April, the occupancy rate hit a record low (an average decline compared to March of around 20 percentage points).

Since May, the upward trend in the occupancy rate has been returning: the average increase has been around 7 percentage points. The country which stood out from the rest of the others, with an exceptionally high growth in May, was Spain with an increase of approx. 19 percentage points. In June, an average increase of less than 12 percentage points was recorded in all the analyzed countries.

The occupancy rate of bed-places

The situation is similar for the occupancy rate of bed-places. Figure 2 below shows the percentage changes in terms of the bed occupancy for hotel rooms and similar types of accommodation establishments in the five EU countries considered.

Fig. 2:Changes in the occupancy of beds (expressed as a percentage) in hotels and similar accommodation establishments in the five analyzed countries of the European Union

In January, the average change in the occupancy rate of bed places in the studied countries was -1.7 percentage points. In Italy, there was an increase of 3.5 percentage points compared to December of the previous year. In February, there was a slight, comparable growth in all the countries at an average of less than 5 percentage points.

As in the case of the room occupancy, the first month with a significant reduction in the occupancy rate of bed places in the analyzed countries was March - the average decrease among the countries in question was just over 24 percentage points. Again, April was a month with a record low bed occupancy (the average decrease compared to the previous month was around 15 percentage points).

As with the bedroom occupancy rate, bed occupancy in all the countries began to increase again in May, with the average change being less than 6 percentage points. Here, a country that stood out significantly from the rest was also Spain, where an increase of 12 percentage points was recorded. In June, the average increase in the bed occupancy in all the countries was less than 12 percentage points, although in this case in Spain the increase was much lower than in the other countries (+6.5 percentage points).

Discussion

COVID-19 resulted in numerous socio-cultural, economic and psychological impacts on the tourism industry (Sigala, 2020, p. 319). As the number of cases spread globally, the travel restrictions followed, beginning in the Wuhan region epicenter and reaching most countries by the end of March. Using country population data it has been estimated that 90% of the world's population were in countries with some level of international travel restrictions, with many of the countries having some degree of restritctions on internal movement as well (Gössling, Scott and Hall,, 2020, p. 7). The impact of the coronavirus pandemic on the occupancy rate of bedrooms and bed-places in the first half of 2020 can only be considered in terms of its size in previous years.

The analysis of the data for years preceding the pandemic outbreak (2012-2019) indicated that in all the studied countries, the occupancy rate of rooms and beds gradually increased year by year, with the average annual increase in occupancy in all the countries at an average of 1.2 percentage points. The highest increase expressed in percentage points that was observed during this period was for the room occupancy in Spain (+11 p.p.), which is not the only value at which Spain stands out from the other countries.

Figures 3 and 4 below illustrate how close to uniform was the increase in the occupancy of bedrooms and bed-places in the analyzed countries.

Fig. 3: The occupancy rate of bedrooms in the studied countries in 2012-2019 expressed as a percentage

Fig. 4: The occupancy rate of bed-places in the studied countries in 2012-2019 expressed as a percentage

The chronological order of events related to the pandemic also plays a huge role in understanding the course of changes in the occupancy rate of rooms and beds in the studied countries in the first half of 2020. The first reports of the coronavirus appeared as early as December 2019, and on January 4, 2020, WHO reported on the Wuhan pneumonia syndrome.

On March 11, 2020, the outbreak of the coronavirus was characterized by the WHO as a pandemic, which had a direct impact on healthcare events in the countries concerned. It was at the beginning of March when the highest numbers of new infections and deaths associated with them were recorded. Back then, governments also made decisions about the application of various health protection measures.

This difficult situation is accurately reflected in the collected data, which is clearly visible in Figures 1 and 2. Both in the case of the room occupancy and bed occupancy rate, March was the first month with a significant decline in all the countries. There is undoubtedly a correlation here with the declaration of the pandemic by the WHO and with the increasing restrictions in all countries affected by the pandemic at the time.

All the countries recorded a similar course of changes in the occupancy rate during the six months of 2020 under consideration, but Spain was the only one in April to achieve 0% occupancy for both bedrooms and bed-places. At the end of March, the number of cases in Spain exceeded 170,000 and there were also nearly 8,500 deaths. For comparison, on the last day of March, almost 72,000 cases with 775 deaths were found in Germany, about 105,000 cases with as many as 12,500 deaths in Italy, in the Netherlands 12.5 thousand cases along with 1 thousand deaths, and in Poland the number of cases oscillated around 2.3 thousand with 33 deaths (Worldometers).

Fig. 5: Changes in the occupancy rate (expressed as a percentage) of bedrooms and bed-places in hotels and similar accommodation establishments in the analyzed countries in the first half of 2020

The analysis of the percentage of the occupancy rate of bedrooms and bed-places in the five selected European Union countries in the first half of 2020 against the background of the same data for the years 2012-2019 clearly shows that despite the drastic decline caused by the global health crisis, the occupancy rate in the analyzed countries quickly began to increase again. In June 2020, the occupancy of both rooms and beds was again close to the occupancy rate in March this year. This means that the tourism industry is characterized by high regeneration ability. Based on the data from just six months and without clear forecasts of the progress of the pandemic in the world, it is impossible to estimate how quickly the occupancy rate of bedrooms and bed-places in the studied countries will return to a level comparable to 2019. However, it can be expected that the trend towards rapid regeneration shown here will also take place on a larger scale.

Despite the preliminary analysis allowing an optimistic view on the regeneration possibilities of the tourism sector, it is important to recognize the pandemic crisis as a transformative opportunity (Sigala, 2020, p. 312). The recovery of the industry should be a goal as important as reforming the industry to a new economic order. Key lessons of the COVID-19 crisis are the importance of community, social connections and society (Higgins-Desbiolles, 2020, p. 618) as well as the importance of local tourism and travel.

Summary

The data presented herein show that in the face of the coronavirus pandemic, the tourism sector has experienced a drastic decline. With the increasing number of cases and increasing restrictions, this industry had to almost completely cease operations, which resulted in a significant reduction in the occupancy rate of rooms and beds, which before the crisis, from 2012, was characterized by constant and almost uniform growth. The obtained results allowed to confirm the hypothesis about the high regeneration capacity of the tourism industry, even in the face of such a serious crisis as the global health crisis. The conducted analysis is only an introduction to research on the regenerative capacity of the tourist market, however, it allows for an optimistic view of the future of tourist services under the obvious condition of gradual disappearance and gradual weakening of the applicable restrictions.

Abstract

The paper addresses a strictly topical issue regarding the need to reconfigure education in the context of the Coronavirus (COVID-19) crisis the fundamental objective of the paper is to highlight the role of universities in providing the necessary tools and ways of learning and development, in a completely different context to what is practiced until now. In the paper, we specify the importance of digital learning and characterize the standards for students and teachers for the implementation of online education. We also show future trends in the field of education and analyse a questionnaire applied to 114 European universities focusing on the impact of the coronavirus crisis on higher education. We also present aspects related to online learning practiced at "Constantin Brâncuși" University, through the analysis of a questionnaire applied to the main educational actors. The investigation methods materialized in the documentary and comparative analysis of the data and information provided by reports, statistics, specialized articles and in the application and interpretation of some questionnaires.

Keywords: digital education, innovation, universities, creativity;

Introduction

The world is living in an unprecedented period of crisis. A virus alters the way of life, the way of thinking and acting, alienates people causing them o retreat into a world that nobody really knows what it will look like.

Israeli historian and Professor Yuval Noah Harari stated, "Humankind is now facing a global crisis. Perhaps the biggest crisis of our generation. The decisions people and governments take in the next few weeks will probably shape the world for years to come. They will shape not just our healthcare systems but also our economy, politics and culture. We must act quickly and decisively. We should also take into account the long-term consequences of our actions. When choosing between alternatives, we should ask ourselves not only how to overcome the immediate threat, but also what kind of world we will inhabit once the storm passes. Yes, the storm will pass, humankind will survive, most of us will still be alive — but we will inhabit a different world."(Harari, N., Y., 2020)

A new world is being born on the ruins of globalization, for which we, by necessity, toned to reshape and reinvent ourselves. The COVID-19 pandemic has created a number of challenges, not only for public health, but also for many other areas of activity, including education. The crisis generated by COVID-19 is a crisis that began in the field of health, but has immediately affected other areas of life, such as economic, social, political, educational, cultural, religious, etc. Understanding this complexity cannot be achieved with deterministic and linear thinking patterns. A major paradigm shift is required, through the development of systemic, probabilistic and nonlinear thinking.

The Research Methodology

The implemented research is based on documents and reform strategies and is founded on an analysis of several studies in the education field seeking to determine what are the challenges and opportunities for online education in universities.

The method of investigation used is the documentary analysis approach, which includeddocuments concerning digital education in the new context; articles, studies, reports, dedicated to public policies in the country and the EU.

We applied a series of questionnaires to students (200) and teachers (80) to determine the impact of the COVID-19 on the teaching process and also to determine the learning needs of students and the teacher training-development needs at ”Constantin Brancuși,, University of Targu-Jiu, Romania.
We also analyzed and interpreted a study involving a questionnaire applied to 114 universities in the European Union in the field of initiatives on the effects of coronavirus entitled Coronavirus - European Universities Initiative Impact Survey Results, of 2020

Through a comparative analysis on the areas that will be most affected by the COVID-19crisis and the elements that will be further developed, following this crisis, we have identified examples of good practices and measures that can be applied.

Challenges for the universities of today and tomorrow

In a context where volatility, uncertainty, complexity and ambiguity are key features, universities need to demonstrate organizational agility, resilience and rapid organizational change. At the same time, the transition from VUCA 1 (Volatility, Uncertainty, Complexity and Ambiguity) to the concept of VUCA 2 (Vision, Understanding, Courage and Adaptability) is required.

The coronavirus crisis is forcing universities to face long-term challenges in higher education, and some of the resulting changes could be permanent. "The pandemic is accelerating change in a tremendous way," says Bert van der Zwaan (Nature, 2020).

Universities already have online courses, but most teachers have had to rethink online media. More broadly, many institutions are learning the difficult way to deliver course materials through digital platforms, which is not the best way to teach them. on students. "Zooming the university is not a fair online learning" (Sarma, S., The Massachusetts Institute of Technology),

If universities resume their courses, the experience will be radically different. Teachers will be able to better respond to learning needs using both digital learning (such as video lectures) and face-to-face, allocating time in interacting with students to ensure that they understand the concepts taught. "We're talking about 'two-way learning.' (Witze, A., & Elizabeth Gibney)

The financial deficit facing universities around the world could mean new opportunities for cooperation, to develop innovative approaches, such as the European Universities Initiatives.

Even after the immediate financial crisis, the economic outlook could remain bleak. Some researchers say this could lead universities to focus on research and infrastructure projects that are most relevant to national interests in a post-pandemic world. For example, the British government is setting up a working group on research sustainability that aims to evaluate research projects in universities with a focus on planning the country's long-term future. (Witze, A., & Elizabeth Gibney)

Digital technology needs to make teaching more flexible and responsive. But this is not easy. It is not simply a tool that makes work completely predictable or unique. Even so, the education technology industry, backed by huge companies such as Microsoft and Amazon, continues to position itself as a solution to today's education problems. Some people even go so far as to suggest that technology can save higher education.

Some institutions have rapidly innovated and implemented e-learning, due in part to their familiarity with the tools specific to teaching approaches and considerations with e-learning. This allowed for greater student participation and involvement.

We have identified four valuable actions here: effective adaptation to rapidly changing circumstances, readiness, a willingness to collaborate and provide care and support, and a cautious attitude toward the educational technology being tested.

Online teaching can not stand alone. Teachers need training to involve students in online discussions and to facilitate a deeper understanding of the materials taught. Instructional designers can help teachers figure out how to learn best with technology and make the most of online learning. For institutions that are not prepared or planning measures, it is imperative to implement such methods as soon as possible, in order to avoid excessive demands and tensions arising from the rapid adoption of things. There is a clear need for post-secondary e-learning expertise and this crisis should

serve as a reminder that institutions need to cultivate these skills. Outsourcing online learning institutions in recent years could allow them to benefit from the expertise of other professionals.

As the pros and cons discussion progressess between supporters and skeptics, the impact of COVID-19 on educational institutions and students offers a chance to carefully examine educational technology in acute, crisis-driven contexts. Basic questions such as how to create involvement in online learning amid the COVID-19 pandemic, have led to studies that have shown that as students learn better when they are actively involved in the learning process than to passively listen to a lecture, during the coronavirus pandemic online courses have largely replaced traditional programs and student involvement has diminished. Other studies have highlighted the following steps in order to ensure involvement during in online learning.

- Strengthening the student-teacher interaction

When students and teachers are physically apart, it becomes more critical to create a social connection. While the students wait for the course to start, the teacher can use the chat function to ask them how they are doing and during the first session, guide them to the structure and requirements of the course.

This initial connection makes students feel more comfortable using the platform to provide questions and feedback during the course. It is a good idea to remind them to activate their videos. This makes them more responsible for paying attention to the class to avoid giving in to other distractions associated with learning at home.

- Planning assessments during the course with live student responses

Students' regular real-time answers provide valuable information about their opinions. These live responses allow the teacher to adapt subsequent courses to suit the level of understanding of the concepts and keep the students involved. For example, these unannounced assessments may take the form of short questions and surveys.

- Interaction between students

Stronger student interaction is needed and thus working in teams, with clear tasks, in virtual classrooms, has proven very successful. Group work allows students to deepen their understanding of the materials.

The International Society for Technology in Education (ISTE, 2017) has developed a series of standards for students and teachers, which provide a guide for implementing online education thus supporting students succeed in a society characterized by high technology.

The ISTE standards for students (2016) are :

1. Empowered student

This standard is beneficial because it was designed to encourage students to play an active role and to demonstrate their competence to use and choose technologies to achieve their learning objectives. Students gain feedback to improve their skills, customize their learning environments and build networks.

2. Digital citizen

The second standard focuses on raising awareness of responsibilities and rights to participate in a digital world. Students use technology safely and legally. They also demonstrate respect for intellectual property sharing rights.

3. Knowledge builder

Standards for students are also designed to build knowledge. Students improve their understanding of the world by effectively applying research methods to find information for their creative and intellectual concerns. This process encourages the development of theories and ideas.

4. Innovative designer

The fourth standard promotes creativity. Students design new solutions to real-world problems using different types of technologies. They use their critical thinking skills to solve open problems. Students are also involved in activities that address design constraints and calculated risks.

5. Creative communicator

The sixth standard allows students to create original works. One of the ways they can achieve this is by remixing digital resources in new contexts. Students think of new content by customizing it for their intended audience.

6. Global collaborator

This standard focuses on broadening students' perspectives. Students use digital tools to connect with students from different cultures and backgrounds. They use collaborative technologies to explore local and global issues and think of possible solutions from several points of view.

The ISTE standards for teachers describe their profile as follows:

1. Student

This standard emphasizes the importance of developing the technological skills that teachers need to meet current challenges. They achieve this goal by working with other professionals and exploring new practices that improve student outcomes. They work in professional networks and stay up to date on research that improves student learning.

2. Leader

Teachers are looking for leadership opportunities that shape and advance teaching and learning. They demand equal access to technology to meet the needs of all students. They also serve as role models for their peers, exploring and identifying new technological tools for learning.

3. Citizen

This standard involves creating opportunities for students, as they will help them make responsible social contributions. Teachers guide students on the safe and ethical use of technology. They teach them the importance of data protection, confidentiality and personal data management.

4. Collaborator

Teachers also need to spend time collaborating with students and colleagues. Work with colleagues to create learning experiences using digital tools. And with students, they use new digital tools to diagnose and fix technological problems.

5. Designer

This standard encourages teachers to design activities that are student-oriented and that reflect differentiated learning. They also use technology to personalize learning experiences that promote independent learning and adapt to students' needs.

6. Facilitator

Teachers create an environment in which students assume the right to learn. They establish learning opportunities by encouraging students to solve problems and innovate. They also shape creative expression and manage learning strategies in digital platforms and virtual environments.

7. Analyst

This standard focuses on using data to support and assist students in the learning process. Teachers use technology to design formative and summative assessments to provide feedback to students. This process guides progress as teachers communicate assessment data with students to promote student self-direction. “Less on-campus education and more distance learning” is emerging in the future, even if the COVID-19 crisis did not occur. Distance learning will develop as a result of unprecedented digitization and, with it, the need for education. custom. In addition, less importance will be given to the degree obtained and lifelong learning will become increasingly important. The university will have a completely different role and will move from the classic image of the ivory tower to the heart image of society, playing a decisive role in the life of society (Bert van der Zwaan., 2017)

Survey on the impact of COVID-19 on European Universities

The rapid spread of the COVID-19 virus across Europe has a substantial impact on higher education, with almost all institutions closing their doors to face-to-face activities and replacing them with online courses.

COVID-19 shows that there is an urgent need for much deeper cooperation between higher education institutions in the field of education, research and innovation. There is also a huge need to bring together and share online courses, data, digital infrastructure and research. COVID-19 has accelerated this need for a digital transformation of higher education institutions. (Coronavirus - European Universities Initiative impact survey results, 2020)

Following the application of a questionnaire to 114 universities in Europe, the following results emerged:

- 60% of higher education institutions consider that being part of a European university network has been helpful in resolving the current crisis difficulties due to COVID-19. Examples of what has been done in response to the pandemic include: brainstorming on common challenges, sharing best practices and solutions, pooling IT tools for distance learning and sharing online resources, maximizing online courses for all their students and maintaining international links, creating a common environment for sharing online teaching and good practice related to online teaching and virtual mobility, involvement of students from different universities in finding solutions to the challenges related to the pandemic, organizing virtual / combined mobility for the next year.
- Almost 80% shared good practices and measures to mitigate the impact of COVID-19 by providing e-learning tools and platforms, ad-hoc working groups on e-exams and e-testing, teacher training, common guidance for online students / learners, support through facilities (eg libraries, laboratories), activities / social assistance.
- 96% of institutions consider that they would have been better prepared to deal with this pandemic if their European University had already been fully operational. Examples of practices: A fully

functional EU digital interuniversity campus, with member universities combining online courses to provide high-quality continuing education through higher volumes of online courses for all their students, sharing the operational learning environment and common e-learning with common digital governance tools.Complete work infrastructure and tested methodology for joint joint courses in universities, with a strategy for managing mixed mobility (virtual and physical) and recognition mechanisms for students and staff. Development in collaboration with companies, regions and cities, short-term learning courses that provide employment at European level, "timely" skills, essential in the context of recovery, enabling them to have skills and qualify at any stage of their careers.

- 59% have started to communicate online courses or MOOCs that students from all their member universities can / will be able to access starting with the next academic semester Examples: creation of the first YUFE programs for the academic year 2020/2021 with common online courses ; blended and active learning (which can take the form of MOOCs) proposed through the development of connected learning communities; UNITE! and CIVICA is preparing an online course repository.
- 85% intend to move faster to a virtual European interuniversity campus
- 90% would consider it useful that Erasmus + accepts mixed mobility formats (ie short physical mobility, combined with virtual mobility) starting this autumn.

The YUFE- Young Universities for the future of Europe initiative is of great interest and importance for European countries and especially Romania, since it aims to become a single European university with various campuses throughout Europe. YUFE is proposed to offer a European university degree based on a combination of academic, professional and civic skills. The European degree of YUFE will be recognized and appreciated throughout the European Union and beyond. The intention is to start in 2021 (https://www.yufe.eu/).

RESULTS

The following figure is particularly suggestive to show which were and are still the areas affected by the COVID-19 pandemic, on a scale of 1 to 10, at the level of European universities, which participated in this questionnaire:

Figure 1: the areas affected by the covid pandemic 19

Source: Coronavirus - European Universities Initiative impact survey results, 2020

To the question "to what extent your higher education institution has implemented a series of measures specific to this period", it is evident that a very high share is online courses (95.1%), online evaluation (82.7%), support for mental health for students and staff (58%), adjustment of the academic calendar (46.7%) and others.

Figure 2: Extent of implementation of measures specific to the period
Source: Coronavirus - European Universities Initiative impact survey results, 2020

To the question "Planning for a quicker move towards a European virtual inter-university campus", the results show an overwhelming tendency (85%), to work in a virtual campus.

Figure 3: orientation towards a virtual campus
Source: Coronavirus - European Universities Initiative impact survey results, 2020

On the subject of the selection of the first four elements that will be most affected by the COVID-19 crisis in the middle of the period, it is noted that student and teacher mobility, student recruitment and internationalization will be substantially reduced:

Figure 4: The areas that will be most affected by the COVID-19 crisis in the middle of the period
Source: Coronavirus - European Universities Initiative impact survey results, 2020

The elements that will be further supported, following the COVID-19 crisis, at the level of the analysed universities are also suggestive:

Figure 5: Elements that will be further developed following the COVID-19 crisis
Source: Coronavirus - European Universities Initiative impact survey results, 2020

The study also discusses examples of good practices and measures found in Europe. Some examples are presented in Table no 1, below.

Table 1: Examples of good practices and measures

Measures	Examples
Measures for online teaching and virtual mobility:	Exchange of examples and processes for online teaching and examination and comparison of IT tools; Switching to an electronic platform for teaching and learning; Development of common virtual mobility and options for future mobility; Development of ad hoc working groups (eg on digital education, virtual mobility and the impact of COVID-19); Teacher training, online guidance for students / trainees, support

Exchange of good practices	Collection and exchange of ideas for virtual activities, exchange and training, on digital learning, IT tools and platforms, etc. Updating and discussing situations and measures taken by universities regularly through virtual means; Sharing experiences on specific issues related to COVID.

Source: processing: Coronavirus - European Universities Initiative impact survey results, 2020

Also, students positively appreciate virtual activities, as follows:

- ✓ Digital learning tools and platforms work very well (71%);
- ✓ Moderators, teachers, trainers organize activities well (71%);
- ✓ The quality of activities is good (63%);
- ✓ These activities encourage participants to learn (55%);
- ✓ Activities are relevant to the mobility of participants (71).

In such an unbalanced landscape and with current time constraints, an obvious solution would be inter-university collaboration. By combining existing resources, both in terms of infrastructure and pedagogical support, universities can ensure students' access to quality online learning. This does not have to mean a unified curriculum, so the diversity of the academic offer is not jeopardized in any way. The main idea is to join forces on issues that consume too many resources and take time to address independently at this time, especially expertise and support for the design and delivery of online courses. It sounds like a distrust, but unfortunately this is not the way universities operate.

Collaboration is not really in their DNA, and the academic landscape has become increasingly competitive in recent decades. Each university wants to preserve its identity (and number of students) and would rather emphasize its individual character than see potential similarities and collaborations with other institutions. In Europe, this is combined with the variety of national education systems that often draw unnecessary barriers to collaborative efforts. When collaboration happens, it is mainly about research and is much less common when it comes to educational programs. This is partly due to the fact that teaching is still seen as an individual activity. While informal teaching exchanges take place, they are rarely formalized as inter-institutional programs.

Aspects of education within „Constantin Brâncuși" University (CBU) in the conditions of the covid crisis 19

At the CBU level, we applied a series of questionnaires to students and teachers to determine the impact of the covid crisis 19 on the teaching process and also to determine the learning needs of students and the training-development needs of teachers.

To the question "How difficult was it to get used to the online activity due to the conditions imposed by the pandemic", most of the students, respectively 79.3%, answered that they had no problems regarding accommodation with the system of online activities, the remaining 20.7% say they have encountered some accommodation difficulties.

To the question "What were the factors that created difficulties in your activity on the online platform during the pandemic period" 61.2% of the students specified that among the factors that created difficulties, the most suggestive are: "lack socializing with colleagues and teachers," and "the stress of the whole situation".

The factors related to "access to digital media and devices" or "access to the Internet" did not constitute barriers to the conduct of online activities.

Regarding the factors that motivated them to work on the online platform during the pandemic, 51.5% of students appreciated at a high and very high level the "development of digital skills", 49.8% of students appreciated at a high level and very high "exploring internet and online resources" and 44.3% of students appreciated at a high and very high level "fully experiencing online and distance activity". This highlights the interest and availability of students for this type of learning.

To the question "What types of activities do you consider that would contribute to the development of competencies specific to your profession and that should be further developed in the higher education institution, of course in compliance with the curricular provisions specific to the university level", regarding the types of activities that would contribute to the development of profession-specific skills, we note again a balanced distribution of the answers "very high level" and "high level" to all six variants of activities or actions proposed in the questionnaire, which reveals, on on the one hand, the interest of students for professional and personal development, and on the other hand the wide

range of activities and actions with which teachers can meet students, helping them to acquire the skills of the chosen profession.

A ranking of the most appreciated activities, according to the weight of the answers "very high level" and "high level", is the following Table no 2:

Table 2: Item-percentage correlation

Item	Procentage
Participation and promotion of student support programs through national educational policies to facilitate the acquisition of digital technology according to the economic and social possibilities of students	54,6 %
Increased involvement and participation of students in student research activities and sessions	52,9 %
Development of counseling and career guidance activities	52,6 %
Approaching active - participatory teaching strategies to course, seminar and laboratory activities	50,9 %
Development of the material and institutional research base in accordance with the current economic, scientific and social context	49,5 %
Capitalizing on Erasmus + mobility and internship periods	42,6 %

Source: own processing

Concerning the teachers, the impact of the COVID-19 crisis was captured with a series of questions and answers, the most relevant being the following:

Regarding the need for support and guidance teachers for online activity, almost half of the respondents, respectively 46.3%, answered that they do not need help. Of the others, 31.7% consider that they need support regarding the technical aspects, 22% regarding the pedagogical aspects and 2.4% regarding the content aspects of the discipline.

It can be concluded that most of the teachers did not have any problems in terms of accommodation with the system of online activities.

Regarding the face-to-face activities that could not be carried out online, out of the seven response variants, the highest percentage had the option h) Authentic communication (human relationship) with 85.4%, followed by the option f) Feedback for prompt correction or for confirmation of purchases by 46.3%.

A ranking of activities that are difficult to carry out online, with a negative impact on student education, is given in Table no 3 and Figure 6.

Table 3: Item-percentage correlation

Item	Percentage
Authentic communication (human relationship);	85,4 %
Feedback for prompt correction or confirmation of purchases;	46,3%
Applications and projects (seminar / laboratory);	36,6 %
Monitoring progress;	36,6 %
Explanations for understanding concepts, relationships, phenomena (course);	31,7 %
Personalized support /; Individual counseling	29,3
Explanations for understanding concepts, relationships, phenomena (seminar);	19,5%
Lectures (course);	9,8 %

Source: own processing

Figure 6: Educational activities that are important for learning and are not forthcoming in distance learning.

Source: own processing

Regarding how each relates to this type of distance / online education, the answers were as follows:

- 43.9% of teachers answered that the way they do distance / online education is clear and easy to explain / understand;
- 36.6% of teachers answered that distance / online education is easy to implement;
- 29.3% of teachers answered that distance / online education helps them to complete their teaching tasks faster;
- 24.4% of teachers answered that distance / online education makes them more productive in their teaching activity;
- 21.9% of teachers answered that distance / online education helps them to improve their teaching activity.

Regarding the innovations in teaching practice, adopted in the course and seminar, the teachers considered the following aspects as the most relevant:

- Teaching on a video platform, discussions on the classroom platform at the same time with the possibility of individualized tasks;
- Partial tests during the online teaching activity, which determine students to go through the subject taught during the semester and not just in session;
- Online feedback from students after almost every course, by solving a grid test on the platform;
- Sending to students as many documents in audio and video format;
- Creativity in terms of the content of the exercises and topics proposed for solving, they have more effectively translated the theory into practice;

When asked if they had ever attended an online education course or training, 65.9% had not attended an online education course or training.

Thus, the need for training in the field of online learning is outlined, with a pedagogical support adapted to the new changes.

Beyond these practical aspects, which are particularly important, a change of mentality is also needed - the recognition that education in the digital environment is not in itself inferior to the classical one, with which we have become accustomed. The methods and tools differ and the courses have to be designed differently, but research in the field confirms that the results are at least as good, and in some cases even superior, compared to face-to-face teaching.

Conclusions

Universities play an important role in meeting the challenges of the current crisis and they will undergo major changes, rapid and with considerable consequences for the development of society in general. In this context, it is important

for universities to focus on capacity building, first from a pedagogical point of view and then from the perspective of integrating technology into the educational process.

Education in general will go through profound transformations and nothing will be the same. No students, no teachers, no students, no school, no university. Flexibility, openness, self-regulation of the entire educational system, in relation to the unpredictable dynamics of the world we live in, must be basic landmarks in the near future. The speed and depth of change are the coordinates of the future in education.

Types of Mobile and Virtual Consumer Interactions

Ahmed Y. MAHFOUZ
Prairie View A&M University, Prairie View, USA
aymahfouz@pvamu.edu

Abstract

Consumers find mobile and online shopping very convenient and cost effective. Online shopping would secure greater ubiquity and scale, given the current global pandemic. Different apps and web sites provide the appropriate platform for ecommerce transactions, medical needs through telemedicine, and entertainment through online movie streaming and gaming. This paper examined different types of these virtual interactions and created a scheme to allocate different kinds of consumers based on dimensions of their shopping habits and tendencies. Following the study's classification scheme, different types of shopping behavior emerged based on a sample of consumers surveyed. The results would be of benefit to business managers and app developers, resulting in richer online experiences for their target markets.

Pedagogy and Learning Theories Through Learning Management Systems

Ahmed Y. MAHFOUZ

Prairie View A&M University, Prairie View, USA
aymahfouz@pvamu.edu

Abstract

Virtual or remote learning has been growing in popularity, in both student learning and corporate training. Given the recent global pandemic, a majority of learning and training moved to distance learning on learning management systems and platforms, such as Canvas, Moodle, and Blackboard. Videoconferencing tools and collaborative software would become the *new* normal for both learning, business, and training needs. Most learners have not heard of Zoom prior to last year or the year before. Zoom and Microsoft Teams, the videoconferencing and collaborative platforms, would gain popularity over the industry leaders, such as Cisco WebEx. With its recent boom and spike in usage, *Zoom* is now a new verb with a new meaning in the vernacular, on par with *Google*. The present study showcased learning theories and their corresponding tools and apps in learning management systems. Such communicative tools cultivate a richer learning experience for learners and business trainees through higher levels of engagement and participation.

Abstract

The purpose of the research is to reveal the infrastructure for generating innovations based on R&D as a structural element of the digital economy ecosystem, which provides a trigger effect of accelerated digital development of the national economy, as well as to develop a mechanism for making management decisions about investing in R&D using a trigger. The authors revealed the configuration of the digital economy ecosystem based on innovation generation subsystem. The authors analyzed the dynamics of investment in R&D in the OECD countries-leaders and outsiders in the IMD Global digital competitiveness rating 2019, compared their structure, and evaluated the effectiveness in the form of the number of registered patents, changes in labor productivity, as well as indicators of "technology", "knowledge", and "future readiness". The authors suggested using the trigger mechanism in the process of making management decisions about investing in R&D, and also justified the criterion for differentiating public policy.

Keywords: the digital economy, R&D investments, the trigger, the digital economy ecosystem, generating innovation

Introduction

One of the regularities of the current stage of society development is the intensification of the penetration of digital technologies into all spheres of human life, which results in the formation of a full-fledged digital economy ecosystem. We are talking about creating a space for communication between various actors (producers, consumers, scientific organizations, public authorities, institutions), as well as using their access to shared scalable resources to create new value through the use of digital technologies.

However, the ecosystem of the digital economy, which is complex in its structure and the nature of interaction between subjects, is a dynamic substance. It is in the process of continuous development, which can be carried out both in the direction of growth and in the direction of inhibition. To ensure its dynamic development, it is necessary to investigate the sources of its acceleration, the so-called triggers that set the digital economy ecosystem in motion.

Perhaps one of these triggers may be the intensification of investment in R&D. From 2000 to 2017, total global R&D spending almost tripled — from US $ 676 trillion to US $ 2.0 trillion) (OECD, 1960; OECD, 2018). Thus, the rapid

Cite this Article as: Malika A. SADUEVA, Olga Y. KUZMINA, Elena E. KUKINA, Anna S. SHURUPOVA and Evgeniya K. KARPUNINA "Investment In R&D as A Trigger for Accelerated Development of The Digital Economy Ecosystem: A Comparative Analysis of OECD Countries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

growth of public and private investment in research and development during the period of industrial development (in 1960, it reached 69% of global R&D funding) helped the United States to become a global economic leader.

Can investing in R&D now be a trigger for launching the accelerated development of the digital economy ecosystem? What mechanisms should the state use to promote the development of R&D? The answers to these questions are relevant for this study.

Methodology

The purpose of the research is to reveal the infrastructure for generating innovations based on R &D as a structural element of the digital economy ecosystem that provides the trigger effect of accelerated digital development of the national economy, as well as to develop a mechanism for making management decisions about investing in R&D using a trigger.

Investigation phase:

1) Revealing the structural elements of the digital economy ecosystem, establishing the role and place of R&D in it.

2) Analysis of investment in R&D in some OECD countries for the period 1990-2018, research on the structure of investment in R&D.

3) Evaluating the results of investment in R&D as a reflection of the trigger effect.

4) Formation of a mechanism for implementing a differentiated policy in the field of investment in R&D for adaptation in leading and outsider countries of digital development.

The research is based on the works of scientists in the field of formation of the digital economy ecosystem, mechanisms for the development of R&D infrastructure, as well as institutional regulation of innovation.

Karpunina et al. (2020b) identifies the ecosystem of the digital economy with a space for interaction of subjects structured into subsystems depending on their functionality and having access to shared scalable resources, where the process of creating "value" is carried out on the basis of the use of digital technologies and communication channels. Prahalad and Ramasvami (2010) point to changing approaches to creating consumer value in the digital economy.

Moore (1996), Lepesh (2020) describe the features of the business subsystem functioning, as well as its changes in the digital environment. Sologubova (2017) emphasizes the importance of institutional regulation of the transition from an industrial to a digital economy.

Carter and Edvards (2001), Gibbons (1996), and Goldstein (2002) attempt to evaluate the impact of R&D using mathematical tools. Kohno et al. (2017) offer indicators and models for evaluating the effectiveness of public funding for research and development. The principle of operation of the trigger as an anti-crisis management tool is described by Chaya (2008).

The information base of the research is materials of IMD (2019), OECD statistics (2020a, b, c), Unesco Institute for Statistics (2020), World Bank (2020).

Research methods: method of theoretical analysis, method of induction and deduction, method of systematization, method of comparative analysis, system approach, graphical method, method of economic and statistical analysis.

Results

Karpunina et al. (2020b) identify four interacting ecosystems in the structure of the digital economy ecosystem (the business ecosystem, the consumer ecosystem, the ecosystem of talent and innovation, and the ecosystem of digital platforms and communications) that function within the appropriate institutional environment. However, according to the authors, the configuration of the digital economy ecosystem can have the following form (Fig. 1).

Fig. 1: Configuration of the digital economy ecosystem (compiled by the authors)

In the digital economy ecosystem, the process of creating a new product (its value) is determined by personalized consumer experience (Karpunina et al., 2020a). In this space, informed and active consumers form various online communities that have more market power, and form consumer requests, thereby becoming more involved in creating consumer value together with the company (Prahalad and Ramasvami, 2010).

According to Moore (1996), a business subsystem is an economic community of interacting enterprises that produce goods and services. In the digital economy, enterprises develop within the framework of network forms of management, using digital communication channels, and their activities are aimed at creating high-tech industries characterized by a high degree of technological processes automation based on the introduction of electronic and information and communication management tools, storage and transmission of information (Lepesh, 2020).

In the digital economy ecosystem, to meet the needs of consumers, enterprises must have access to the innovation generation infrastructure, which is a set of institutional entities: educational organizations, research structures, venture organizations, and institutions for the digital economy development. Educational organizations produce new personnel who carry the knowledge and skills necessary to create innovative products. The scientific basis is created by research organizations that carry out R&D in cooperation with higher educational institutions. Institutions for the digital economy development (technology parks, business incubators, innovation centers) allow to put into practice the achievements of science and technology.

All actors in the digital economy ecosystem implement their digital ambitions within the established "rules of the game", i.e. regulatory rules, technological standards, ethical standards, and other institutional regulatory measures (Sologubova, 2017).

According to the authors, the IMD global digital competitiveness rating can be used to assess the formation of the digital economy ecosystem, ranking countries by the degree of implementation and research of digital technologies leading to the transformation of state practices, business models and society as a whole (IMD, 2019). OECD countries occupy different positions in the IMD rating – the United States and European countries with mature economies are the leaders of the rating, while Colombia, Greece, Turkey, Mexico, and Slovakia complete the rating (table 1).

Table 1: OECD countries-leaders and outsiders in the IMD rating is, 2019

Country	Position in the rating	Number of points
OECD countries – the leaders of the ranking of IMD 2019		
USA	1	100
Sweden	3	96,07
Denmark	4	95,23
Switzerland	5	94,65
Netherlands	6	94,26
OECD countries-outsiders in the IMD 2019 rating		
Slovak Republic	47	62,62
Mexico	49	60,41
Turkey	52	59,79
Greece	53	59,63
Colombia	58	56,13

Source: compiled by the authors based on IMD (2019)

Let's analyze the dynamics of investment in R&D in the period 1990-2018 on the example of the OECD countries-leaders of the IMD global digital competitiveness rating (2019) and the OECD countries that complete the IMD rating (Fig. 2).

Fig. 2: Dynamics of investment in R&D (% of GDP) in OECD countries in the period 1990-2018
(compiled by the authors according to OECD, 2020b)

The dynamics of spending on research and development shows that most countries (Switzerland, Netherlands, United States, Turkey, and Colombia) are moving along a fairly smoothly developing trajectory. Sweden made a significant leap in R&D financing between 1990 and 2000, surpassing all the countries studied in terms of investment (as a percentage of GDP), and this trend continued until 2012, when Switzerland became the leader in R&D investment (as a percentage of GDP). Slovakia sharply reduced its investment in R&D in 1992, which continued until 2008.

Each country has its own structure of R&D financing. However, data analysis allows us to identify some patterns (table 2).

Table 2: R&D investment in selected OECD countries, 2019

Country	Position in the IMD 2019 rating	GDP (current prices) /billion US$)	GDP per capita (current US$)	Gross domestic spending on R&D, % of GDP	Gross domestic expenditure on R&D at current PPP $	R&D spending by Government, % of total R&D	R&D spending by Business, % от total R&D spending in PPP$	R&D spending by Universities and Private non-profit, % of total R&D	Number of researchers per million inhabitants
OECD countries – the leaders of the IMD 2019 ranking									
USA	1	21 427	65118	2,7	581 553,0	11,4	71,5	17,1	4 205
Sweden	3	530,8	51610	3,1	18 162,39	3,7	67,0	29,3	6 875
Denmark	4	348,1	59822	2,9	10 054,21	2,29	63,8	33,91	7 310
Switzerland	5	703,1	81994	3,2	18 688,49	0,89	71,5	27,6	4468
Netherlands	6	909,1	52448	2,0	21 463,06	11,9	56,0	32,1	4512
OECD countries-outsiders of the IMD 2019 ranking									
Slovak Republic	47	105,4	19329	0,9	1 486,94	28,3	36,8	34,9	2715
Mexico	49	1 258,3	9863	0,4	8 053,93	32,3	17,9	49,8	260
Turkey	52	754,4	9043	0,9	23 966,26	9,7	49,8	40,5	1160
Greece	53	209,9	19583	0,8	3 843,77	27,7	33,9	38,4	2791
Colombia	58	323,8	6432	0,3	2 208,88	8,95	42,6	48,45	58

Source: compiled by the authors according to the OECD (2020b), Unesco Institute for Statistic (2020), World Bank (2020)

The table clearly shows that in the OECD countries-leaders of the IMD 2019 rating, the share of R&D expenditures is high: from 2 to 3.2% of GDP. However, in outsider countries, it barely reaches 0.9% of GDP.

In the United States and most developed European countries, the business sector is actively involved in R&D financing, bearing most of the costs. The United States and Switzerland are the leaders in financing R&D expenditures by the business sector-71.5% of total R&D expenditures in these countries are covered by business structures. In Slovakia, Mexico, and Greece, the state co-finances R&D expenditures in approximately equal shares with business. In addition, in Colombia and Turkey, non-profit organizations and universities take on the majority of R&D investments.

When comparing the volume of R&D investment in current PPP, it becomes obvious that the world leadership belongs to the United States, where the volume of R&D investment in 2019 was US $ 581,553. 0 million, followed by Turkey (US $ 23,966.26 million), followed by the Netherlands (US $ 21,463. 06 million dollar), Switzerland (US $ 18,688. 49 million) and Sweden (US $ 18,162. 39).

Of course, when comparing the volume of investment in R&D, going beyond the OECD countries, China is the world leader in addition to the United States. According to Bloomberg, from 2009 to 2015, investment in R&D by American companies increased, but the main growth was in foreign investment, and primarily in China. In 2015, the United States invested about US $ 60 billion in Chinese research projects. At the same time, China itself began to experience an explosive growth in R&D investment: according to Capital IQ, from 2009 to 2015, it amounted to about 60% (Production Management, 2016).

The dynamics of R&D investment is significantly affected by economic instability. So, in the crisis years of 2008-2009, the largest western companies began to reduce their research and development budgets. According to McKinsey, in 2009, 40% of the world's top managers said they needed to reduce R&D spending, and 30% decided to reduce the number of R&D projects planned for the current year. However, some companies refused to reduce their investment in innovation, and some even planned to increase their budgets at the height of the crisis. As a result,

private sector investment in R&D in the West in gross terms only declined slightly in 2009, and in 2010 there was a steady growth again (Production Management, 2016).

Another global trend characteristic of the R&D sector during the crisis is the strengthening of connections between large companies and the educational environment and universities. For example, in 2009-2011, General Electric invested about $4 billion annually in research and development, including $800 million in new health products that were created at a research center in Bangalore with the involvement of students. The result was the release of the Mac 400 portable electrocardiograph at an adequate market price.

Why do major companies refuse to reduce their investment in R&D even in times of crisis and try to create a solid ballast of interaction with universities?

The fact is that the role of investment in R&D, described in the theory of corporate financial analysis, is extremely important for the development of enterprises.

Carter and Edvards (2001) and Gibbons (1996) mathematically assess the impact of R&D. An example of how this theory works in practice is the balanced portfolio of the R&D center of General electric Corporation, which includes the development of advanced technologies (15%), technical support for current business (15%), development of new generations of products/processes (35%), and advanced research (35%) (Goldstein, 2002).

The humanitarian and social results of investing in R&D at the macro level are: creating new jobs; improving working conditions; accelerating production processes and improving control over their execution phases; "transparency"of costs and results; increasing the flexibility of production processes and the speed of response in terms of adapting to changing external conditions.

An indicator of the economic performance of investments in R&D at the macro level can be: the number of patents received, which are the final result of innovative developments (fig. 3); labor productivity growth (fig.4).

Fig. 3: Patents by technology: Patents - total and specific technology domains (OECD)
(Source: compiled by the authors according to OECD (2020c))

The data provided by the OECD shows that the US is the leader in the number of patents created, with the amount of investment in R&D in monetary terms in the US higher than in European countries, but as a percentage of GDP less than in Switzerland. Most European countries systematically increased the number of patents created until the global financial crisis of 2015-2016, then there was a sharp decline in indicators. Slovakia, Turkey, Greece and Colombia in the period 2010-2018 showed unstable dynamics of patent activity with periods of unjustified growth and decline.

Fig. 4: Dynamics of labor productivity, annual growth in constant prices, %
(Source: compiled by the authors according to OECD (2020a))

The presented data allow us to conclude that in countries that invest in R&D at a high level, periods of decline in labor productivity as a result of global crises are less prolonged and less deep: for example, the US economy shows the smallest amplitude of fluctuations in labor productivity; Sweden and Denmark in 2008 showed a sharp drop in labor productivity, but in 2010 showed stable growth; in Switzerland, during the study period, there was only 1 decline in labor productivity in 2016. However, the Netherlands stands out from the general trend (with the average global volume of investment in R&D, the fall in labor productivity was observed 3 times in the period 2006-2016), as well as Slovakia, which shows a weak decline in productivity against the background of low R&D funding.

Thus, it is not possible to show a clearly established relationship between the volume of investment in R&D and their results on the example of the studied countries, due to the existence of factors that determine the effectiveness of the R&D investment process, except for the volume of investment: the distribution of spending over time; the strategy for implementing R&D; the duration of work from theoretical searches to the final result; the volume of the information base and its distribution over the entire investment period; the dynamics and results of implementing scientific developments at certain stages; established links between participants in research projects; investment culture and experience in organizing R&D. In other words, the efficiency of innovation generation depends on the quality of a single organizational and economic mechanism (Via Future, 2019; Kuznetsov et al., 2018; Kapustina et al., 2018).

In general, in 2019, the studied OECD countries were able to achieve the following values of the indicators "technology", "knowledge", and "future readiness", which reflect the implemented policy of investment in R&D (table 3).

Table 3: The values of the indicators "technology", "knowledge", and "future readiness" achieved by the OECD countries as a reflection of the implemented R&D investment policy, 2019

Country	Position in the rating by the indicator "technologies"	Number of points	Position in the rating according to the indicator "knowledge"	Number of points	Position in the rating according to the indicator "future readiness"	Number of points
OECD countries – the leaders of the IMD 2019 ranking

Source: compiled by the authors based on IMD (2019)

From the previous analysis and the data presented in the table, it is clear that investment in R&D, indeed, provides the implementation of the trigger effect of accelerated digital development. The trigger is used in various spheres of human life to automatically affect certain parameters that can be both quantitative and qualitative estimates.

The trigger value is a restriction on the value of a particular indicator, factor, or criterion that causes a significant change in the defined (limit) indicator. Its fluctuations are most significant for the conditions of functioning of a particular national economy (Chaya, 2008).

The values of the "R&D investment rate" indicator will determine the value of the T – trigger coefficient. The authors suggest calculating this indicator using the formula:

$$I_{R\&D}=(Nr * GDP)/Np \quad (1)$$

where $I_{R\&D}$– R&D investment rate; N_r- number of researchers per million inhabitants of the country; *GDP* – Gross Domestic Product, billion US$ a deduction of expenses for the social sphere, defense of the country; N_p – number of population in the country, people. The results of calculating the "R&D investment rate" indicator for the studied countries, as well as determining the trigger value, are shown in table 4.

Table 4: Calculating the "R&D investment rate" indicator and determining the critical trigger value

Country	$I_{R\&D}$
OECD countries – the leaders of the IMD 2019 ranking	
USA	0,26
Sweden	0,29
Denmark	0.43
Switzerland	0,37
Netherlands	0,23
OECD countries-outsiders of the IMD 2019 ranking	
Slovak Republic	0,05
Mexico	0,003
Turkey	0,01
Greece	0,05
Colombia	0,0004
The range of critical values of the T-trigger	0,23-0,43

Source: compiled by the authors according to the OECD (2020b)

The use of a trigger can become a necessary and sufficient condition for making managerial decisions and, when using the appropriate software, automate the management of any economic processes in the state (fig. 4).

Fig. 4: The mechanism of trigger action in the process of making management decisions about investing in R&D

(compiled by the authors)

If the value of the "R&D investment rate" indicator becomes a critical value for a particular country below the T coefficient, setting the trigger to this critical value signals the need to suspend first-priority expenditures and redirect available funds to R&D financing. That is, as soon as the value of the indicator "R&D investment rate" becomes less than the critical value of the coefficient T for this particular country, the trigger configured for this value is overturned (snapped) and requires the suspension of first-priority expenditures through the software system from the public administration system. Conversely, the upper limit (threshold) of a trigger is adjusted in the same way when it is tipped (snapped) in the opposite direction and does not allow increasing investment in R&D above the value of the T coefficient.

In addition, it has achieved a critical value of the T coefficient is the switching policy of increasing investments in R&D (government expenditures business investment in R&D and institutional conditions for the development of infrastructure to generate innovation, including direct and tax support for innovation-oriented companies, the creation of business accelerators, new industrial policy based on smart specialization) policy of maintaining investment activity in R&D(to stimulate consumer demand, development of digital tools for interaction in the "consumer-business structure" system for tracking well-founded consumer requests by the manufacturer, as well as strengthening links between business structures and subjects of the innovation generation infrastructure). Among the countries studied, Slovenia, Turkey, Greece, Mexico and Colombia have not reached the critical value of the T coefficient and should implement policies to increase investment in R&D to accelerate economic and digital development. The United States, Sweden, Denmark, Switzerland, and the Netherlands should implement policies to maintain investment activity in R&D, since the values of the "R&D investment rate" indicator in these countries are higher than the critical value of the T coefficient.

Conclusions

The authors justified their own vision of the configuration of the digital economy ecosystem based on the subsystem of innovation generation, and also revealed the specifics of all its structural elements.

The authors used countries from the IMD global digital competitiveness rating (2019), which assesses the formation of the digital economy ecosystem. The analysis involved 5 OECD countries-leaders of the IMD rating, and 5 OECD countries-outsiders of the rating.

The authors analyzed and compared with the dynamics of investment in R&D in these countries, their structure, and effectiveness of investment in the form of number of registered patents, changes in labor productivity, as well as indicators of "technology", "knowledge", "future readiness" assessed in the IMD (2019).

It is concluded that ensuring stable investment in R&D provides greater stability of the national economy, larger adaptability to changing environmental conditions and faster overcoming of crises, as well as a high level of technology development and knowledge generation.

The mechanism of trigger action in the process of making management decisions about investing in R&D is revealed, and a criterion for differentiating public policy is proposed – the critical value of the indicator "R&D investment rate".

Computer-Aided Grinding Process of Oil Seeds

Grzegorz SMIGIELSKI
Kazimierz Wielki University, Bydgoszcz, Poland, gs@ukw.edu.pl

Krzysztof TYSZCZUK
Kazimierz Wielki University, Bydgoszcz, Poland, krzytysz@ukw.edu.pl

Abstract

The grinding process of oil seeds requires careful selection of grinder input parameters to obtain a product with appropriate physical and chemical properties. The article presents a precise grinder design (with a measurement and control unit, and a genetic algorithm module), which facilitates selection of optimal settings of the mill during the industrial grinding process.

Keywords: Grinding, Dietary Supplements, Genetic Algorithm, Manufacturing System Technologies.

Introduction

Manufacturing high quality dietary supplements based on natural ingredients for human nutrition requires appropriate preparation of the biological material. In the dietary supplement manufacturing process, many factors are easily overlooked. Once the brand owner does not have the customer's best interests (healthy and efficiency), the rigorous manufacturing procedures are likely to be simplified. The result is the product might less efficiency or cause negative effects (Finley et al., 2019; Poniedziałek et al., 2018; JECFA, 2000; Golonka et al., 2019). The primary issue involves proper fragmentation thereof. Among the valuable seeds for preparation of dietary supplements are: flax (golden and brown), camelina, chia, fenugreek, black caraway, and mustard. Excessively high temperature during the grinding process of these seeds may be detrimental to the qualities of the product, e.g. the nutrient content or presence of harmful substances. The degree of fragmentation of the product is critical for its assimilability (Tyszczuk et al., 2018). In case of industrial-scale processing it is also vital to obtain the lowest energy expenditure by mass of the ground product. For each type of material the aforementioned parameters are a function of design features (e.g. shape of cutting elements) and process variables. For a given knife shape, a variable which affects the fragmentation degree the most is their linear velocity, which is a derivative of cutting disc (knife) diameter and their angular velocity.

Evolution in Grinder Design

Depending on the intended purpose and type of fragmented material there are several grinder designs. The authors and their associates are the originators of several grinders used for grinding biological and polymeric materials. Some of these solutions involve simple measurement units and manual control. Newer concepts employ microprocessor-based or computer-based measurement and control systems. Initially important for research purposes was obtaining the information on the temperature of the fragmented material and the possibility of changing the rotational speed. Determining the diameter of particles was done via vibrating screen after grinding. Subsequent stages of research made it possible to construct systems allowing the size of particles to be measured during the grinding process along with the ability to immediately change the parameters of the process (Śmigielski et al., 2019).

Precision Grinder

Precision grinder is a variant of a multi-disc grinder (Fig. 1), which comprises a stator with stationary discs (external) and a rotor with internal discs placed at determined distances (Fig. 2).

Fig. 1: Interior view of precision grinders without cover

Fig. 2: Sample design of the discs: stator and rotor

Controlling the grinder (Fig. 3) is handled via computer with an application designed in LabVIEW environment. U6 device by LabJack was used as a measurement and control unit. In order to control the rotational speed of the induction motor powering the grinder, a frequency converter was used, connected to the computer via RS485 bus, whereas the material dosage rate was controlled via an auger feeder with a dedicated controller. The measurement system allows recording the device operation parameters such as: electric current and power consumption by the motor, and temperature in the grinding chamber. The idea of using a virtual measurement device allows relatively quick adaptation of the measurement and control system for each grinder, which means the solution is highly versatile. The module used for measuring the particle size was designed for a different grinder. The fragmented material is transferred to the measurement chamber, where the particles are being photographed. Registration of the image was done via a 1.31 MP colour camera with a Pentax lens and a set of lens spacer rings. Within the software layer, Vision machine view module by LabVIEW was used, which allows cooperation with USB cameras (Relf , 2004; Rob, 2017). The resolution resulting from the vision field of the camera is 0.02 mm/pixel (Śmigielski et al., 2019). The fragmented seeds are assigned to appropriate diameter ranges (fractions) on the basis of recorded images.

Fig. 3: General view of a shredding stand

The precision grinder was supplemented with an additional optimisation software module based on a genetic algorithm (Rutkowski, 2012), which allows selection of grinding parameters (Fig. 4). Code sequence – the gene is created via control settings of the grinder (containing information on the rotational speed of the drive motor and feeder output). After the process is settled, measured are: grinder drive power, fraction share, expenditure – overall efficiency of the grinder.

Generation no. 1 contains 10 code sequences. Each code sequence was assigned a target function value. Target function value is increased when a fraction selected for assessment has a higher percentage in the fragmented product, and the amount of product in a given fraction passing through the measurement chamber is higher. Target function value changes when the power consumption of the system increases. To determine the influence of individual optimisation criteria, mass coefficients introduced before conducting the experiment are used:

$$C_{i,l} = \frac{k_Q Q_{i,l}(x) + k_m m_{i,l}}{k_n N_{i,l}},$$

where i – subsequent code sequence no., l – generation no., $Q(x)$ – fraction mass share x (%), m – grinder mass expenditure (conventional unit resulting from measurement chamber operation), k – mass coefficients, N – total power consumed by the measurement system (kW).

When the results for the entire generation are ready, the programme selects 4 best sequences based on the criterion of target function and transfers them to the genetic operation unit. Code sequence with the highest evaluation rating is transferred without changes to the next generation (cloning), whereas each two code sequences are subjected to hybridisation (reproduction). New code sequences constituting the next generation are subjected to mutation, namely the random change of bits at a low probability setting selected in the programme.

The new set of code sequences obtained through genetic operations constitutes a new generation, which is also subjected to testing, assessment and sorting by target function value. Values of optimised parameters are added to graphs. The number of generations is adjusted by the system operator. The result of the application is a file with grinder settings which make it possible to obtain a product of complex parameters at a reduced energy expenditure.

Fig. 4: Front application panel, including: smart control, results and genetic algorithm settings

Conclusions

Application of computer aid for controlling the grinding process significantly accelerated the experimentation and at the same time allowed obtaining input parameters characterised by obtained material possessing the highest possible product mass at 0.8 mm size, the lack of product temperature increase above 27-42 degrees Celsius and no precipitation of essential oils from the material during the grinding process. Such properties allow the use of biological materials in food industry for production of high-quality dietary supplements.

Abstract

State regulation of agricultural production is an essential component of state financial and economic mechanisms, due to the importance of the agricultural sector as a basic source of food security. However, for the purposes of state regulation of this industry, Ukraine has followed the other way from developed countries, as direct government financial support was directed not to medium and small agricultural formations, but to large enterprises and agricultural holdings. As a result of such a regulatory policy, Ukraine is currently experiencing a deterioration in the quality of land, declining quality of agricultural products, misbalance in the development of agricultural production, rising unemployment and impoverishment in rural areas. As a result, Ukraine's agricultural sector is unattractive to investors, which hinders its harmonious and sustainable development.
The analysis of the functioning of the current system of state regulation of agricultural production testified to its inefficiency and the need to find areas for improvement. Therefore, attention was drawn to the need to activate the financial levers to stimulate the development of agricultural production, in particular its small forms: personal farms, farms and more. To increase interest and the level of efficiency of state regulation of agricultural production, a combined mechanism of state regulation of small agricultural producers, based on the use of products of financial components such as lending, insurance and taxation.

Keywords*:* State Regulation, Agricultural Production, Microinsurance, Microcredit.

Introduction

The economic development of countries with economies in transition largely depends on carefully selected instruments and mechanisms of regulation, especially in the financial sector. In this case, the selected mechanisms must meet the conditions of authenticity and efficiency, which must take into account the peculiarities of the national economy and a particular area of economic activity. And, of course, a prerequisite is their focus on a positive economic outcome. At the same time, the financial mechanisms of state regulation, covering the areas of lending, taxation, financing, insurance are designed to provide a favorable environment not only for the development of the selected industry, but also for the formation of its investment attractiveness.

One of the priority areas of the national economy of Ukraine is agricultural production. Its development in the post-socialist period acquired an irrational direction practiced in foreign countries by stimulating the activities of large enterprises and ignoring the promotion of small-scale agricultural production. As a result, the country is currently experiencing the decline of some agricultural sectors, which leads to deteriorating soil quality, increased exports of agricultural products, destruction of rural areas and impoverishment of the rural population.

It is possible to improve the situation by introducing effective mechanisms of state regulation of agricultural production. In particular, in the field of farming - farms and personal farms.

Analysis of recent research and publications

The sphere of state regulation of agricultural production in developing countries raises a number of questions for scientists. In particular, Raian Divanbeigi and Federica Saliola (2016) note that the decline in quality and increasing

heterogeneity in the development of agricultural production is observed in those countries that ignore state regulation [1].

The team of authors headed by Y. Nesterchuk (2019) emphasizes the need to focus the attention and state regulation on farms as active participants in the field of small agricultural production. According to scientists, such attention from the state will be an incentive to create fair competitive conditions in this field and will increase the economic efficiency of such enterprises [2].

O. Salamin and S. Poperechny (2018) emphasize the inadequate effectiveness of state regulation in the field of agricultural production in Ukraine, focusing on the predominance of large producers and violation of the architectonics of this area of activity, which, in fact, destroys the infrastructure of the market [3].

The problems of the theory of regulation and transformation under their influence in the field of agricultural production are covered in the works of Jean-Marc Toussaint and Pierre Labart (2016) [4].

The previous number of views and approaches shows that the chosen topic is quite relevant in the field of scientific research, which is due to the need to optimize agricultural production as a priority source of food security.

Research Methods

The study is based on the dialectical method of cognition. The method of analysis has become essential in the process of elaboration of existing and identification of promising theoretical foundations of the mechanisms of state regulation of agricultural production.

The assessment of modern features of functioning of the sphere of agricultural production of Ukraine was carried out by means of an empirical method.

Correlation-regression analysis revealed a key factor influencing the performance indicator, which contributed to the identification of promising objects of state regulation of agricultural production.

Using the method of induction, the results of the study were generalized, and conclusions were formulated.

Results

Theoretical bases of state regulation of agricultural production in Ukraine

The purpose of the reforms carried out in countries with economies in transition is to change its role in economic activity and create economic preconditions for the country's restructuring. That is why state regulation of the economy is the tool by which one can balance the spheres and branches of activity in order to achieve the desired efficiency of the national economy. Currently, among the many economic views and approaches, it is necessary to distinguish four main vectors of state regulation (Fig. 1).

Fig. 1: Dialectics of views on the goals of state regulation among individual schools of economics [13, 14, 15, 17].

As we can see, the representatives of these classical schools are not marked by a unanimity of views on the objectives of state regulation. However, today we have fundamentally different business conditions, which also require a review of goals and approaches to the implementation of the last one. At the same time, special attention needs to be paid to outlining the mechanisms of state regulation in key areas of the national economy that are import-forming, in particular, the agricultural production sector.

Summarizing the realities of state regulation of agricultural production in Ukraine at the present stage, we believe that currently it can be implemented in five areas (Fig. 2).

Fig. 2: Components of state regulation of agricultural production in Ukraine

Based on the highlighted positions in Fig. 2, it should be noted that state regulation of agricultural production in Ukraine is carried out through direct and indirect financing. The most active is the budget component, due to which certain categories of agricultural producers have the opportunity to receive financing and economic, especially its component such as special programs.

At the same time, the possibilities of such economic instruments as prices and tariffs are not used properly; needs to review and significantly improve the legal and financial components and active development – investment. It is due to the underestimation and significant limitations of these components that the current mechanisms of state regulation in Ukraine do not ensure the achievement of the expected positive effect.

The current state of state regulation of agricultural production in Ukraine

State regulation of agricultural production in Ukraine takes the form of mostly direct budget support. Contribute to the receipt of funds from the budget to producers a number of special programs (Fig. 3, 4, 5).

Fig. 3: Levels of direct state financial support provided to agricultural producers in 2018 by regions of Ukraine, UAH million [12]

The levels of direct state financial support in 2018 increased significantly compared to 2014. However, according to the data of Fig. 3, their distribution between the regions of Ukraine is uneven. Significant gaps in the receipt of funds are explained by the fact that the conditions imposed on the recipients of financial resources are quite difficult, and therefore can meet them mainly large, sometimes medium-sized agricultural enterprises.

The imbalances in the development of agricultural production should be mentioned separately. In particular, government programs are aimed at developing certain, popular and profitable areas of activity, while less interesting segments for producers remain out of the state's attention. Currently, in the field of crop production, the state pays the most attention to horticulture, for which in 2018 there was a budget support program 2801350 "Horticulture Development" (Fig. 4).

Fig. 4: Amounts of direct state funding for the development of horticulture in the regions of Ukraine in 2018, UAH million [12]

The distribution of funds under the program "Horticulture" (Fig. 4) is also characterized by uneven distribution of funds. However, in this segment, it is due to natural and climatic conditions that contribute to the more active development of this area of activity in some regions, as well as the popularity of this industry in some areas.

The livestock industry has experienced a special decline over the last 28 years. The evidence is a significant reduction in livestock and poultry, as shown in Fig. 5.

Fig. 5: Dynamics of the number of farm animals in Ukraine in 1991–2019, thousand heads [9]

As evidenced by the data of Fig. 5, in 2019, compared to 1991, there was a decrease in cattle by 7.5 times, pigs – by 3.3 times, sheep and goats – by more than 7 times. This phenomenon is explained by the fact that animal husbandry,

in contrast to crop production, has a prolonged payback period, and therefore this industry is not popular with large agricultural enterprises and agricultural holdings. The exception is poultry farming, where the payback period of projects is much shorter, and therefore the reduction in livestock is insignificant. Nowadays, these areas of activity have become interesting for farmers and private farms. However, the state program 2801540 "Development of dairy and meat cattle breeding", which operated in 2018, focused on large producers (Fig. 6).

Fig. 6: Direct state financial support for the development of dairy and meat cattle breeding in the regions of Ukraine in 2018, UAH million [12]

According to the terms of the program, the amounts of budget funding were sent to legal entities that keep identified and registered dairy, dairy-meat and meat cows for each available cow on January 1 and stored on July 1 in the amount of UAH 1,500 per head cattle. The total amount of the program amounted to UAH 500 million [6].

In 2020, direct public funding in the field of animal husbandry is provided for a slightly expanded range of recipients in the following areas:

- subsidies for existing bee colonies – on a non-refundable basis will be provided to legal entities, natural persons-entrepreneurs and natural persons who are owners of bee colonies, for existing in the current year from 10 to 300 bee colonies in the amount of UAH 200 per bee colony;
- reimbursement of the cost of purchased breeding animals, bees, sperm and embryos – will be provided to legal entities and natural persons-entrepreneurs regardless of organizational and legal form and form of ownership for purchased by them domestic or imported breeding animals, bees, sperm and embryos up to 50% – costs, but not more than: for breeding heifers, cows – UAH 31,500 per head; for breeding pigs and boars – UAH 10,000 per head; for breeding ewes, rams – 11,000 UAH per head;
- for semen of bulls / boars – UAH 100 per dose (not more than 3 doses per head of cattle and 5 doses per head of pigs), sex – UAH 300 per dose not more than the 1st dose per head; bees – bee packages – UAH 500, queen bees – UAH 100; for cattle embryos - UAH 500 per piece;
- reimbursement of the cost of livestock facilities; compensation for the cost of facilities financed by bank loans – will be provided to legal entities regardless of organizational and legal form and form of ownership and natural persons –entrepreneurs, including family farms engaged in animal husbandry in the amount of up to 30% of the cost (excluding value added tax);
- compensation for the cost of facilities financed by bank loans – will be provided only to those entities that received such compensation in 2018 – 2019 in the amount of 25% of the amount of borrowed funds for a loan period of up to 5 years [10].

The selectivity of the segments of direct budget financing in agricultural production, giving preference to large agricultural producers has led to a deterioration of the environmental and quality component of economic conditions. In particular, large agricultural producers use intensive technologies that negatively affect the quality of land resources, destroying the fertile soil layer – chernozem. The quality of their products also does not meet European standards. However, if we change the economic conditions to ecological ones and provide balanced support, the potential of this sphere can increase many times over.

Given the shortcomings of the mechanisms of state regulation of agricultural production in Ukraine, we present some performance indicators that show generally negative economic trends.

The results of the functioning of state regulation of agricultural production in Ukraine at the present stage

One of the criteria for the effectiveness of state regulation of agricultural production in the country is the volume of agricultural production, as well as the volume of GDP produced by the relevant sector for a given year. These indicators guide the extent to which funds invested in the development of activities contribute to its development and increase the pace of production, which characterizes the economic efficiency of the process (Fig. 7).

Fig. 7: Dynamics of performance indicators of agricultural production of Ukraine in 2013–2018 [8]

During the study period, there are growing trends both in terms of GDP (+20.95.4 billion UAH) and in terms of GDP of agriculture (+44.1 billion UAH), and relative to the volume of agricultural production (+532.5 billion UAH) (Fig. 7). However, the share of agricultural GDP in total GDP is quite low: if in 2013 it was 2.05%, in 2014 - 2.0% with a further decline to 1.8% in 2017. And only with the revision of direct budget funding programs for agricultural producers, when farms were added to the cohort of recipients, the figure rose to 2.08%. Proof of this fact is the volume of agricultural production, which in 2018 showed significant growth compared to previous periods.

Another indicator of economic efficiency of state regulation of agricultural production in the country is the level of inflation, recorded both in the country as a whole and in a particular industry in particular, which we can trace by changing the consumer price index (Fig. 8).

Fig. 8: Dynamics of the level of consumer price indices in 2013 – 2018, % [8]

During the study period, there were fluctuations in consumer price indices (Fig. 8) for all presented objects. However, it should be noted that the level of the consumer price index for industry is always lower than the same indicator for agriculture and the national. At the same time, the studied indicator for agriculture is always higher than industry, and in 2014 it even exceeded the national one. This indicates a steady rise in prices for agricultural products, and therefore there is a high level of costs incurred by agricultural producers, which contributes to higher prices. That is, we can talk about the lack of effectiveness of measures of state regulation carried out in agriculture at this stage.

Currently, the low level of prices for agricultural products does not allow to provide both small forms of agriculture and their employees with an adequate level of income (Fig. 9). In addition, in rural areas, the share of the population with incomes below the minimum is higher than in Ukraine as a whole.

Fig. 9: Dynamics of the share of income from the sale of agricultural products in the structure of total household resources, % [16]

If in 2016 this figure in Ukraine was 3.8%, in rural areas – 3.9%; at the end of 2019, the situation worsened: the national rate was 1.1%, and rural – 1.3%. The lack of stimulation of agricultural production in small farms causes not only the impoverishment of the rural population, but also a decrease in the level of revenues of local government budgets, increasing their rotation and additional costs from higher budgets. Despite the improvement in the level of marketability of rural household products, its share in household incomes decreased in 2014 – 2018. However, small forms of agricultural management, in particular personal farms, should become the basis of a new state policy to stimulate entrepreneurial activity in agricultural production, improve the social situation in rural areas and the formation of food reserves.

Recalling the social component of assessing the effectiveness of state regulation of agricultural production, we focus on the unemployment rate of the rural population, which is not only evidence of poor state regulation, but also the cause of depression in rural areas (Fig. 10).

Fig. 10: The share of the unemployed population by place of residence in the total number of unemployed in 2014 – 2018, % [7]

During 2014–2018, the share of the unemployed rural population was over 40% (Fig. 10). At the same time, if the share of urban population decreased by 5.9 percentage points, then of rural population increased by the same percentage. If we take into account the share of unemployed in rural areas in the total unemployed population of Ukraine, it increased from 42.8 in 2013 to 48.0% in 2019. At the same time, according to statistics, it is in the countryside quite high level of informal employment: 39.6% in 2017 and 38.2% in 2018. That is, in fact, employment and hence income are in the shadows.

The unemployment rate is evidenced not only by the low level of social efficiency of ongoing state regulation measures. It demonstrates the lack of employment facilities. And employment in the agricultural sector is now recorded mainly in small and medium enterprises (Table 1).

Table 1: Dynamics of employment in agricultural production in 2013–2018, thousand people [5]

Indicator	2013	2014	2015	2016	2017	2018	Deviation (+ -) from 2018 to 2013
Number of people employed in agricultural production, total	3389,0	3091,4	2870,6	2866,5	2860,78	2937,6	-451,4
Including:							
- at large enterprises	38,8	46,6	48,3	38,1	27,5	32,8	-6,0
- at medium enterprises	410,8	390,0	374,7	359,3	336,5	324,8	-86,0
- at small enterprises	276,6	296,8	279,1	261,3	271,6	268,5	-8,1

The vast majority of the rural population, according to Table 1, employed in medium-sized enterprises. These include family farms. The second largest working rural population is small enterprises, which include personal farms. That is, it is a form of activity that can still be described as self-employment. The least numerous is employment in large agricultural enterprises, where there is a significant mechanization of production processes. That is, once again we are convinced that the sphere of state regulation of the development of agricultural production now bypasses the stimulation of a promising cohort of agricultural producers – medium and small enterprises. And the current regulatory measures have shown a negative effect, which has led to a decrease in the employment rate of the rural population and, consequently, its income, as noted above.

Considering the effectiveness of state regulation of agricultural production at the present stage of economic development of the industry, it is necessary to investigate the investment efficiency of measures (Table 2).

Table 2: Dynamics of investment efficiency indicators of state regulation of agricultural production in 2013 – 2018

Indicator	2013	2014	2015	2016	2017	2018	Deviation (+, -) from 2018 to 2013
GDP at actual prices, UAH billion	1465,2	1586,9	1988,5	2385,4	2983,9	3560,6	+2095,4
GDP of agriculture, UAH billion	30,1	31,2	35,1	40,8	54,7	74,2	+44,1
Total investment, UAH billion	249,9	219,4	273,1	359,2	448,5	578,7	+328,8
Investments in agriculture, UAH billion	18,6	18,8	30,2	50,5	64,2	66,1	+47,5
GDP ratio:							
- to the total investment	5,9	7,2	7,3	6,6	6,7	6,2	+0,3
- to the volume of investments in agriculture	78,8	84,4	65,8	47,2	46,5	53,9	-24,9
The ratio of GDP to agriculture:							
- to the total investment	0,12	0,14	0,13	0,11	0,12	0,13	+0,01

- to the volume of investments in agriculture	1,6	1,7	1,2	0,8	0,9	1,1	-0,5
Share of total investments:							
- in GDP	0,2	0,1	0,1	0,2	0,2	0,2	-
- in the GDP of agriculture	8,3	7,0	7,8	8,8	8,2	7,8	-0,5
Share of agricultural investments:							
- in GDP	0,01	0,01	0,02	0,02	0,02	0,02	+0,01
- in the GDP of agriculture	0,6	0,6	0,9	1,2	1,2	0,9	+0,3

The calculation of investment efficiency indicators of state regulation of agricultural production in the modern conditions of Ukraine's economy (Table 2) showed a low share of investments in agriculture both in the GDP of the state and in the industry itself. Moreover, it is in agriculture that there are declining trends in all indicators. From this we can conclude that the measures of state regulation do not increase the level of investment attractiveness of the studied industry.

The results of state regulation of agricultural production in Ukraine at the present stage indicate the need for its revision and search for new areas of implementation.

Directions for optimizing state regulation of agricultural production in Ukraine

Currently, the trends in the functioning of the agricultural sector indicate an active need to move from stimulating the development of large-scale production to support medium and small agricultural production, including small and specialized. Among the most important advantages of small and medium-sized forms of agricultural activity are the ecological approach to business, rational use of resources, production of organic products.

Therefore, the study of world experience presupposes the search for an effective model for Ukraine of the mechanism of state regulation of agricultural production, which on the basis of scientific innovations will be able to stimulate the development and functioning of small and medium agricultural producers: private farms, peasant farms and more.

The state's focus on a defined circle of producers will not only ensure the employment of the rural population and increase its welfare, but also actively implement research into real production activities, improve soil quality and reduce their plowing.

In any case, the sphere of state regulation of agricultural production should be aimed at small forms of management. And the proof of this was the correlation-regression analysis of the impact of selected factors on the GDP of the state (Table 3).

Table 3: Initial data for correlation and regression analysis of the impact of factors on the level of GDP, over the years [11]

Indicator	2012	2013	2014	2015	2016	2017	2018	2019
GDP at actual prices, UAH billion (in)	1404,7	1465,2	1586,9	1988,5	2385,4	2983,9	3560,6	3974,6
Volume of agricultural products, billion UAH (x_1)	258,3	308,1	370,8	544,2	631,1	690,9	843,3	840,6
State financial support, UAH	12,3	7,3	4,6	3,1	3,5	10,3	13,4	15,0

billion (x_2)								
Sales of agricultural products by large businesses, UAH billion (x_3)	19,4	23,4	31,6	61,2	53,0	38,9	54,8	70,0
Volume of sales of agricultural products by medium-sized businesses, UAH billion (x_4)	94,0	89,1	117,3	183,2	206,7	238,2	272,4	266,1
Volume of sales of agricultural products by small businesses, UAH billion (x_5)	53,8	53,7	71,2	117,9	155,0	190,6	213,3	202,7
- of which – micro-entrepreneurs, UAH billion. (x_6)	19,3	18,9	24,2	34,1	56,0	66,3	74,8	64,8
Income from the sale of agricultural products to and household, thousand UAH (x_7)	2,8	2,8	3,2	3,4	2,9	3,0	2,5	2,4

As a result of calculations, the multiple regression equation was obtained: $Y = 24.7914-103.0378X_1 - 390.6284X_2 + 232.8398X_3 + 200.9443X_4 + 508.2055X_5 - 1269.4732X_6 + 2510.2371X_7$.

Possible economic interpretation of the model parameters showed the following results:

- an increase in X_1 by UAH 1 billion leads to a decrease in Y by an average of UAH 103.038 billion;
- an increase in X_2 by UAH 1 billion leads to a decrease in Y by an average of UAH 390.628 billion;
- an increase in X_3 by UAH 1 billion leads to an increase in Y by an average of UAH 232.84 billion;
- an increase in X_4 by UAH 1 billion leads to an increase in Y by an average of UAH 200.944 billion;
- an increase in X_5 by UAH 1 billion leads to an increase in Y by an average of UAH 508.206 billion;
- an increase in X_6 by UAH 1 billion leads to a decrease in Y by an average of UAH 1269.473 billion;
- an increase in X_7 by UAH 1 billion leads to an increase in Y by an average of UAH 2510.237 billion

According to the maximum coefficient of elasticity $E_5 = 14.683$, from which we conclude that the greatest influence on the result Y has a factor X_5 – the volume of sales of agricultural products by small businesses, billion UAH.

We can test the hypothesis of general significance - the simultaneous equality of zero of all regression coefficients for explanatory variables:

H0: $R2 = 0$; $\beta 1 = \beta 2 = ... = \beta m = 0$.
H1: $R2 \neq 0$.

This hypothesis is tested using Fisher's F-distribution statistics. If $F < Fkp = F\alpha$; n-m-1, then there is no reason to reject the hypothesis H0. Tabular value for degrees of freedom k1 = 7 i k2 = n-m-1 = 8 - 7 - 1 = 0, Fkp (7; 0) = 0. Therefore, since the actual value is F> Fkp, the coefficient of determination is statistically significant and the regression equation is statistically reliable (the coefficients bi are jointly significant).

It was also found that in the studied situation 100% of the total variability Y is explained by the change of factors Xj, which proves the hypothesis about the statistical significance of the model parameters.

That is why, according to the study, state regulation of agricultural production in Ukraine should be directed to the sphere of small and medium agricultural production. Thus, it is necessary to activate the indirect influence which is embodied by means of financial components: crediting, insurance, the taxation.

Indirect state support in the tax sphere for small agricultural productions should stimulate them to active agricultural production and realization of state interests in this sphere. Therefore, such support should be a prerequisite: as one of the options, private farms will be able to become members of territorial production clusters.

And from this point of view it is necessary to reconsider the conditions of taxation of income of personal farms in the plane of collection of personal income tax. First of all, this is possible due to the change in the tax base, from the individual income of each taxpayer to the level of family income, as well as from the personal collection of tax to the payment of income of the entire personal farm. Thus, the mechanism of taxation of individual agricultural producers who have become members of territorial production clusters will be as follows (Fig. 11):

Fig. 11: The mechanism for collecting the tax on personal income under the state tax incentives for private farms that have become parties to regional industrial clusters

From the fig. 11 of the mechanism we see that the state can encourage personal farms to engage in agricultural production by replacing all currently paid by peasants taxes on personal income tax at differentiated rates, which will reduce the tax burden on such taxpayers.

In addition, a differentiated system of taxation of their incomes should be a significant stimulus for agricultural production by private farms (Table 4).

Table 4: Proposed scale of income taxation of small agricultural producers (private farms)

Tax base	Tax rate	Special conditions
Up to 2 tax-free minimums (TM)	0%	The non-taxable minimum is set at the level of the subsistence minimum determined by the law of Ukraine "On the State Budget of Ukraine" for the relevant year.
2 – 4 TM	5%	
4 – 6 TM	7,5%	
6 – 8 TM	10%	
8 – 10 TM	12,5%	
Over 10 TM	15%	

The proposed scale of personal income taxation takes into account the conditions and level of income of taxpayers, as well as allows to regulate the level of tax burden.

A separate condition should be the establishment of a non-taxable minimum at the level of the established subsistence level or, according to optimistic assumptions, at the level of the average wage in agriculture for the relevant period.

Also a prerequisite for the transition to the category of such payers is the registration of an individual agricultural activity, participation in the territorial production cluster and a high share (over 70%) of income from the sale of agricultural products produced on the farm or land share.

Such a mechanism of indirect state regulation stimulates the rural population to productive activities and at the same time will ensure the growth of employment in rural areas.

In addition to the above, the future effective model of state regulation of agricultural production in Ukraine should be based not only on the existing experience of foreign countries, but also take into account the peculiarities of the domestic economy in the studied area of production. After all, among the key factors in the functioning of the current model can be distinguished both positive and negative, which, in fact, go hand in hand, complementing each other (Fig. 12).

Fig. 12: Advantages and disadvantages of the domestic model of state support for agricultural production

Given the figures in Fig. 12 advantages and disadvantages of the current model of state regulation and based on the results of correlation analysis and own considerations on the need to change the priorities of agricultural production, we see the need to strengthen state regulation through financial instruments of indirect intervention.

Therefore, the developed and presented model of the combined mechanism of state regulation (Fig. 13) focuses on small agricultural producers (personal farms, farms, etc.), which operate both independently and within the envisaged territorial production clusters. The main levers of state influence on the activities of such agricultural producers are insurance companies that sell specialized insurance products, banks that provide concessional and microcredit, as well as local governments and the state – during taxation.

Fig. 13: Model of the combined mechanism of the state regulation of activity of small agricultural producers

Listed in fig. 13 model of the combined mechanism of state regulation of small agricultural producers is based on the fulfillment by recipients of funds of a number of conditions, including: agricultural activities on state-provided materials, planting material, biological assets and the use of exclusively organic technologies. At the same time, the state reserves the right to set prices for manufactured products and provide surcharges to the price for products of niche areas of production or high quality.

The categories of recipients of state support are divided into two groups: individual, which include personal farms that independently enter into agreements with the state and are registered by such business entities, and personal farms and small farms that are registered as business entities in within the established territorial production clusters.

For the former, there is a Microfinance Support Program, which unites donors of such support: banks that will provide microcredit services, insurance companies that will sell microinsurance products and the State Tax Service, which will control the taxation of such producers as payers of the single tax of group I. At the same time, it will be impossible to become a participant in the program without purchasing the necessary microinsurance products (1) from personal insurance, under which the insured is obliged to pay insurance premiums, and property and production insurance, where the state undertakes to pay insurance premiums. After the recipient has signed microinsurance agreements, he can apply for microloans on which the state repays part of the interest to the borrower.

Small-scale agricultural producers who have chosen the path of members of territorial associations of agricultural producers in order to become members of the Program of development of joint territorial agricultural production can also receive loans on favorable terms, when the state repays part of the interest to the bank. A mandatory condition for this is the conclusion of a comprehensive insurance contract with the insurance company.

Taxation in this case is carried out for personal farms in the form of personal income tax at progressive rates, and for small farms – in the form of a single tax (Group 4). In this case, such payers are exempt from all other types of taxes and fees.

In addition to the above, the peculiarity of the proposed model is that the above programs include research institutions that provide potential users of the program - small farmers with raw materials for activities: biological assets, zoned breeding varieties of crops and more. Higher education institutions also take part in the programs, which will provide consulting services to producers on participation in the programs, peculiarities of microfinance and microinsurance activities, etc.

Thus, the harmonious combination of the two proposed models of state support for small agricultural producers will not only fully ensure employment in rural areas, but also promote the development of all spheres of agricultural production and the economy as a whole.

Conclusions

The study revealed a number of problems caused by the current mechanism of state regulation of agricultural production. One of the main ones was ignoring the development of small and medium-sized farms, which led to the dominance of large-scale agricultural production, which focused on intensive production technologies, rather than indicators of organicity and product quality. As a result of these actions, the rural population is mostly uninterested in individual entrepreneurial agricultural activities, as it has no support from the state.

Among the negative consequences of the current mechanism of state regulation of agricultural production - a decrease in investment activity and, accordingly, the attractiveness of the industry, the impoverishment of the rural population and rising unemployment.

Improving the state of agricultural production in Ukraine is possible provided that the financial levers of state regulation are activated: lending, insurance, taxation. They became the basis for the development of a combined mechanism of state regulation of small agricultural producers.

Concentration of state regulation on small and medium-sized agricultural producers under the conditions determined by the combined mechanism will make it possible to reduce the negative phenomena in the financial and economic environment of the studied economic sphere and achieve its sustainable development.

Abstract

The *goal* of the research is to identify long-term trends in the foreign economic activity in the Russian region with a medium level of development and to evaluate the effects of macroeconomic shocks on them. *Methods of research.* The research has been carried out using the following techniques. Cluster analysis is used to identify homogeneous groups of regions with similar parameters of different types of foreign economic activity. Comparative analysis to establish model regions reflecting characteristics of the respective clusters development. Correlation and regression analysis to investigate the dynamics of different types of foreign economic activity and logical analysis to establish the nature of impact of macroeconomic shocks on the parameters of foreign economic activity. *Results.* The study identified the features of development of different types of foreign economic activities in the "medium" region of Russia. It has been estimated that the impacts of macroeconomic shocks on exports to the CIS and non-CIS countries, on imports from both groups of countries, on technologies and technical services exchange and on foreign investments are of different nature.

Keywords: Region, Foreign Economic Relations, Macroeconomic Shocks.

Introduction

State of foreign economic relations has been of interest to researchers for several hundred years, starting with mercantilists, including Russian ones (Pososhkov I., 2001). Views on the causes and objectives of foreign economic relations have been changing. However, the main thesis remains unchanged - their state characterizes the competitiveness of a country's products. To the greatest extent, it concerns the export of goods, works, services and technologies. Trends in globalization and peculiarities of political processes have a significant impact on foreign economic relations (Freire M.R. (2019); Head K. and Mayer T. (2010); Dorin M., Olaru M., Andreea M. and Eidenmüller T. (2016); Ezroh J. (2014)). The whole complex of economic and political relations between specific countries and their groups is essential (Kuzmina V.M., Timchenko M.V. and Naumik V.A. (2020); Timokhin A.D. (2019)). For Russian regions, spatial transformation (Bitarova M.A., Getmantsev K.V., Ilyasova E.V., Krylova E.M. and Treshchevsky Y.I. (2020)) and differentiation of social and economic development, among others in innovation sphere (Endovitsky D.A., Treshchevsky Y.I. and Terzi I.V. (2020)) are essential.

In the second decade of the twentieth century, significant changes took place in the system of global economic and political relations, which influenced the state of foreign economic activity of the Russian regions. They are the global financial crisis of 2008-2009 and the imposition of sanctions and counter-sanctions in 2014-2015. At present, the spread of coronavirus pandemic poses a serious threat to the foreign economic activity of the regions. Therefore, we attempted to analyze the state of foreign economic activity of one of the "medium" regions of Russia, Voronezh Region.

PAPINA "The Effects of Macroeconomic Shocks on Trends of Region's Foreign Economic Activity" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Methods of Research

Indicators reflecting various aspects of the region's external economic relations were selected for analysis – Gross Regional Product (GRP), GRP per capita, export to the CIS countries, export to non-CIS countries, import from CIS countries, import from non-CIS countries, export of technologies and technical services, import of technologies and technical services, foreign direct investments (inflow).

Due to the low concentration of information on foreign economic activity in the regions of the country, it had been necessary to review a significant number of resource books (Regions of Russia, 2002; 2003; 2004; 2005; 2006; 2007; 2008; 2009; 2010; 2011; 2012; 2013; 2014; 2015; 2016; 2017; 2018; 2019). Units of measurement for these indicators are defined in accordance with the abovementioned statistical compendiums.

The analysis was carried out in three stages.

The first stage was the construction of virtual clusters of the regions' foreign economic activity. The analysis was carried out by a conventional procedure (J.A. Hartigan and M.A. Wong (1979); I.D. Mandel (1988)). The total number of clusters adopted for calculation is five (this number of clusters in most cases reflects the nature and differentiation of Russian regions according to various combinations of socio-economic indicators).

Moscow is excluded from the research since its socio-economic characteristics differ greatly from other regions and differences between clusters are smoothed out compared with the capital's achievements. The regions of “the second order” included in the larger ones are also rejected in order to avoid re-counting. Regions with deficient data for the analyzed period left out from calculations.

The data for the following years are accepted for cluster analysis: 2000 (beginning of the new economy); 2005 (active market, but not economic overheating); 2009 (global crisis - macroeconomic shock); 2012 (calm year); 2015 (sanctions and counter-sanctions - macroeconomic shock); 2018 (the last year for which reliable statistics are available).

For general assessment of foreign economic activity level, the sum of normalized indicators above mentioned was adopted. The clustering has shown a significant differentiation of regions by the overall level of foreign economic activity development. The highest level as of 2018 was shown by the cluster, which comprises the following regions - Moscow Region, St. Petersburg and Tyumen Region. These are (excluding Moscow) the most developed regions in terms of almost all socio-economic indicators. The second (by the level of development) cluster includes industrially developed regions, among them - Leningrad Region, Krasnodar Territory, Rostov Region, Republic of Tatarstan, Nizhny Novgorod Region, Samara Region, Sverdlovsk Region, Chelyabinsk Region, Krasnoyarsk Territory, Kemerovo Region. The third position was taken by the cluster, which includes four large border regions - the Republic of Sakha (Yakutia), Magadan and Sakhalin Regions, the Chukotka Autonomous District.

The cluster that includes 21 regions (mostly with a differentiated economy of median level of development) is of great interest.

At the second stage, a selection of model regions reflecting the most the features of each cluster was carried out. The minimum distance from the virtual center of the corresponding cluster was accepted as a criterion for classifying a region as a model one.

The scope of the paper does not allow providing a broad overview of the each cluster’ study results. Therefore, the third stage is the correlation-regression analysis of the dynamics of each indicator of the model region of the cluster of medium level of development - Voronezh region. The analysis period is 19 years (from 2000 until 2018). The analysis was carried out using four functions most typical for socio-economic processes: linear, logarithmic (by natural logarithm), and power.

Results

The analysis showed that the general economic situation in the region is stable - GRP volume is growing. Moreover, its dynamics is well described by all three functions (Equations 1, 2, 3).

$y = 52333x - 123826$ (1);
$R^2 = 0.9513$
$y = 25860x^{1.1447}$ (2);

$R^2 = 0.9228$
$y = 316223\ln(x) – 255240$ (3);
$R^2 = 0.7152$
The type of the power function (Equation 2) at R-squared 0.92 even allows assuming an increase in GRP growth rates in the future. The actual values of GRP volume arranged by the years allow noting slight decrease in the growth rates in 2009 and 2015; however, decrease of GRP was observed in none of the years.

At stable region population, the same dynamics of GRP per capita is quite natural (Equations 4, 5, 6).

$y = 22.461x – 53.048$ (4);
$R^2 = 0.9538$
$y = 10.724x^{1.1597}$ (5);
$R^2 = 0.9281$
$y = 136.02\ln(x) - 110.07$ (6);
$R^2 = 0.7202$

Unlike the general economic indicators, the behavior of exports to the CIS countries is less stable (Figure 1, Equations 7, 8, 9).

Fig. 1: Exports to CIS countries (million USD)

$y = 38.263x – 37.149$ (7);
$R^2 = 0.7548$
$y = 21.441x^{1.1674}$ (8);
$R^2 = 0.9054$
$y = 251.04\ln(x) - 174.29$ (9);
$R^2 = 0.6689$

In addition to estimation of the overall trend, a significant shrinkage of exports to CIS countries during periods of macroeconomic shocks (2009 and 2015) is worth noting. Exports did not reach in 2012-2014 the "pre-shock" levels, although in 2016 there was some recovery in this area of foreign economic activity of the region. In this regard, further logarithmic curve dynamics are quite possible, especially if we consider the macroeconomic shock of 2020 caused by the coronavirus pandemic.

The dynamics of exports to non-CIS countries (Figure 2, Equations 10, 11, 12) essentially corresponds to the dynamics of exports to CIS countries.

Fig. 2: Exports to non-CIS countries (million USD)

$y = 44.427x + 141.95$ (10);
$R^2 = 0.7964$
$y = 107.77x^{0.7411}$ (11);
$R^2 = 0.8649$
$y = 308.97\ln(x) - 53.514$ (12);
$R^2 = 0.7931$

Despite the coincidence of general trends in exports to CIS and non-CIS countries, there was a lack of functions corresponding to the potential increase in export to non-CIS countries. In addition, the decline in exports to this group of countries during the global financial crisis began in 2008 and lasted two years. The macroeconomic shock of 2014-2015 began in this sphere as early as in 2012 and lasted up until 2016. At the same time, there was a significant increase in export volumes in 2017 and 2018, which exceeded the "pre-shock" period of 2012.

Imports from both groups of countries are much less stable than exports. Dynamics of imports from CIS countries and the functions characterizing it are presented in Figure 3 and in Equations 13, 14, 15.

Fig. 3: Imports from CIS countries (million USD)

$y = 15.628x + 135.18$ (13);
$R^2 = 0.2497$
$y = 74.731x^{0.565}$ (14);
$R^2 = 0.4846$
$y = 126.48\ln(x) + 29.584$ (15);
$R^2 = 0.3368$

As one can see, there is no pronounced trend. We can only talk about slight increase in imports over the past 19 years since the beginning of the XXI century. Macroeconomic shocks have an extremely strong impact on imports from CIS countries. In this case, we can talk about another shock – the overheating of the Russian economy, which began in 2006 and led to more than fourfold increase in imports in two years (from 2006 to 2008). The financial crisis led to halving of imports in 2009, and 2012 was the beginning of a strong decline in the indicator value. Moreover, unlike exports, import volumes remained virtually unchanged from 2015 to 2018.

Imports from non-CIS countries have a more stable dynamics (Figure 4, Equations 16, 17, 18).

Fig. 4: Imports from non-CIS countries (million USD)

$y = 41.061x + 14.707$ (16);
$R^2 = 0.785$
$y = 47.97x^{0.938}$ (17);
$R^2 = 0.899$
$y = 267.8\ln(x) - 129.18$ (18);
$R^2 = 0.6876$

The fact that the power function (Equation 17) presents almost linear dynamics of indicator values is of concern. As expected, there was a decline in imports from non-CIS countries during the global financial crisis. However, the initial volume corresponding to the period of overheating of the Russian economy (2006-2007) was restored already in 2010. The decline in imports from non-CIS countries during the period of sanctions and counter-sanctions (2014 and beyond) is significantly less than from CIS countries. Since 2015, import volumes have increased significantly.

The logic behind the development of relations in the sphere of import of technologies and technical services is different. The financial crisis of 2008-2009 did not have a significant impact on the dynamics of imports of technologies and technical services. In general, there is a gradual increase in the value of the indicator. The exception was 2015, when there was a multiple growth, and 2016, when the volume of technology imports returned to the initial level of 2014. Despite the positive dynamics, it can be argued that this form of foreign economic activity is not of practical importance for the regional economy, as its volumes do not exceed USD 25 million even during the peak growth period.

Fig. 5: Imports of technologies and technical services (annual payment, thousand USD)

There is practically no export of technologies and technical services from the region - it ranges from 1.5 million to 8.5 million US dollars. The dynamics is not described by any of the applied equations. Macro-economic shocks of 2008-2009 and 2014-2015 led to some growth in technology exports - the peak is in 2009. The dynamics of foreign investments in the Voronezh region (revenues) is shown in Figure 6.

Fig. 6: Dynamics of foreign investments in Voronezh region (million USD)

As can be seen, a significant surge in investments in 2011 and their reduction in 2013-2018 does not allow considering the entire period as qualitatively unified. In fact, there are three different processes: low, practically the same level of investment in 2000 - 2010; “surge” in investment in 2011 - 2012 (in fact, these years are a separate period); maintaining the volume of investment at the level of 150-250 million USD per year. Macroeconomic shocks do not affect the dynamics of foreign investment.

Conclusions

The analysis of Voronezh Region, which represents a group of medium-developed Russian regions in terms of foreign economic activity, showed that the general economic indicators have a stable growth trend throughout the entire period of the "new economy" 2000 - 2018. Macroeconomic shocks of 2008-2009 and 2014-2015 did not have a significant impact on the economy. However, foreign economic activity is subject to significant changes.

Exports to CIS countries declined during the global economic crisis, but quickly returned to pre-crisis levels. The period of sanctions and counter-sanctions had a negative impact on exports to these countries. Form of correlation-regression equation suggest three case scenarios: growth by a linear function, higher growth by a power function, and decline in growth rates by logarithmic function.

Exports to non-CIS countries are subject to macroeconomic shocks (2008-2009 and 2014-2015). However, in both cases intense post-crisis growth is observed.

The dynamics of imports from CIS countries is extremely unstable. Macroeconomic shocks have a significant impact on it, along with other factors that are difficult to predict. Imports from non-CIS countries are more stable and may continue to increase at existing or declining rates. Macroeconomic shocks exert influence on imports from this group of countries, but the influence on imports from non-CIS countries is lower than on imports from CIS countries in terms of volume and time.

The volumes of exports and imports of technologies and technical services are insignificant and depend on hardly predictable factors. It is not yet clear how macroeconomic shocks affect this type of foreign economic activity.
The volume of foreign investments changes abruptly with the general upward trend. The changes are not related to macroeconomic shocks.

Abstract

Burnout is an increasingly prevalent syndrome among physicians, with specific organizational factors contributing to its alleviation. This study aimed to assess the prevalence of burnout, its association with Internal Marketing (IM), and the use of IM practices within Romanian health care organizations. 332 Romanian physicians completed the Maslach Burnout Inventory–GS, the Internal Marketing Questionnaire, and a survey regarding socio-demographic and occupational characteristics. Statistical analyses included χ^2 for individual differences, Pearson correlations to measure the relationships between study variables, and hierarchical regressions, for the associations between IM, socio-demographic and occupational factors, and burnout. The prevalence of high-level burnout was 22.6%, with IM accounting for 67% of burnout variance. The IM usage was moderate (48.8%) and often not labeled as such. IM, multiple jobs and specialty were significant predictors of global burnout and cynicism ($p<.001$). IM only predicted exhaustion ($p<.001$), while IM and multiple jobs predicted personal inefficacy ($p<.001$). The contribution to burnout of occupational and socio-demographic factors was not significant. Our findings encourage acquisition and optimization of IM practices as an efficient public health strategy against burnout.

Keywords: Internal Marketing, health care organizations, organizational behavior, Public Health strategies

Introduction

Current health care systems are often described by many consumers as being "busy", "complex", or even "chaotic" (Bria et al, 2014). This perception stems, in part, from high general expectations regarding the quality of health services, as well as increasing demands for "personalized medicine" and "patient-centered care" (Gheorghe and Liao, 2012; Gheorghe et al, 2018). Consequently, health care systems are constantly subject to pressures from stakeholders, be they policy makers,

health care analysts or health care consumers, aiming to implement the best possible quality of care in the most cost-efficient manner. In many low- and middle-income countries, this challenge is difficult to overcome, as their health care systems are fragile and lack the capacity to ensure delivery of services to those in need (Bria et al, 2013). In the particular case of Romania, these underlying factors were supplemented in the last three decades by a series of controversial health care reforms, which impacted the autonomy, prestige, and feelings of accomplishment of many health care professionals throughout their careers, as well as during their formative years in medical school. Thus, burnout syndrome became a prominent issue among Romanian physicians, regardless of their age or specialty (Bria et al, 2014; Bria et al, 2013; Popa-Velea et al, 2014; Popa-Velea, 2014; Popa-Velea et al, 2019).

Studies conducted so far and aiming to define burnout in medical contexts have provided a series of methods to address its causal factors, be they psychological, organizational and occupational (Bria et al, 2013). For example, frameworks such as the Job Demands Resources (JD-R) Model (Schaufeli, 2017) may represent a useful conceptual reference for monitoring the extent of burnout and prevent its onset, through the increase of personal engagement and internal motivation. However, in those cases where JD-R Model cannot provide a satisfactory answer, the Marketing field may offer other kind of strategic solutions to burnout, under the form of Internal Marketing (IM).

IM is a concept which describes employees as “internal consumers”, while the organization is considered a market that includes both suppliers and demanders of services, who together, form an “internal supply chain system” (Foreman and Money, 1995; Tsai and Tang, 2008; Berry and Parasuraman, 1991).

In terms of burnout prevention, IM could represent an efficient organizational tool, considering the literature reports pointing out its efficiency in changing employees’ attitudes and behaviors (Gronroos, 1990; Ahmed and Rafiq, 1995; Varey, 1995). Still, despite its undoubtable benefits, the implementation and coordination of IM practices may be a challenging task, as only a small number of organizations implement IM practices (Rafiq and Ahmed, 2000), due to a lack of consensus among scholars regarding what this implementation constitutes, as well as which measurement instruments to use and how they should be applied. In the health care field, even fewer studies are available, with specific interest in IM or its assessment (Iliopolos and Priporas, 2011; Azedo et al, 2012; Chang and Chang, 2007)..

Our study aims to address this gap in current knowledge about IM in health care settings and, especially, to gain insight into the possibilities of preventing burnout through the use of IM. The identification of potential associations between IM and burnout could help guide the development of new organizational strategies striving for the prevention of burnout in health care professionals. Specifically, the objectives of this research were:

(1) to examine the prevalence of burnout among Romanian physicians working in health care organizations;
(2) to identify the current IM practices in Romanian health care organizations;
(3) to measure the impact of IM on burnout.

Research Methodology

Participants

Participants comprised physicians from five Romanian private health care institutions, the selection being made on convenience sampling. The choice to study individuals working in private health care was based on the higher accessibility to physicians in this domain, also taking into consideration that previous national research has mostly been confined to public health organizations. The steady increase in the number of private health care organizations in Romania, over the last years, has resulted in a total of 187 distinct companies (National Institute of Statistics, 2017), making these kind of institutions an important segment in the medical job market.

Out of 1060 physicians initially approached for the study, that would guarantee a significant statistical threshold p of 0.05 and an accepted error of ± 3, 332 (31.32%) agreed to participate. This percentage of respondents could represent an argument in favor of interest regarding this theme among Romanian physicians, or at least among those working in private practice. All participants completed written informed consent forms. Out of 332 physicians, 245 (73.8%) were females and 87 (26.2%) were males. Mean age was 42.6 (±13.8). 183 (55.1%) were senior physicians and 149 (44.9%) were specialist physicians, 95 (58.7%) were smokers and 47 (14.2%) suffered from sleep disorders. The vast majority of physicians were

permanently employed (52.4%). 232 (69.9%) had multiple jobs as physicians, and worked between 47 and 51 hours/week (26.2%).

Procedure

The design of the study was cross-sectional. Data collection was conducted between October 2019 and January 2020. The study instruments were printed and enclosed in sealable envelopes, in order to ensure confidentiality.

IM was measured through the 15-item Internal Marketing questionnaire, adapted to the Romanian health care context (Foreman and Money, 1995). The items of the IM instrument were divided into three components: "Vision" (3 items), "Development" (4 items) and "Rewards" (8 items), measured on 5-point Likert scales (1 - Totally Disagree to 5 - Totally Agree). In health care settings, it has been described as displaying good validity, as well as reliability (Azedo et al, 2012). The global score of IM was computed by summing up the scores of Vision, Development and Rewards components.

For assessing burnout, we used the 16-item Maslach Burnout Inventory - General Survey, which consisted of 3 dimensions: "Exhaustion" (EX) (5 items), "Cynicism" (CY) (5 items) and "Personal Inefficacy" (PI) (6 items) (Bakker et al, 2002). We selected the MBI-GS instrument due to its universal applicability, as well as its confirmed cross-sectional validation among occupational domains, revealing a high level of robustness (Bakker et al, 2002; Mäkikangas et al, 2001) including in the health care field (Qiao and Schaufeli, 2011). All items were scored on 7-point Likert scales ranging from 0-Never to 6-Every day. The global score of burnout was computed by summing up the scores of EX, CY and PI.

Statistical Analysis

Data was collected and processed using the SPSS Statistics 20.0 software package. The first stage of the analysis included a description of the sample, using measures of statistical dispersion for quantitative variables, and frequency for qualitative variables. Threshold values for the classification of burnout into "high", "moderate" and "low" levels were calculated by splitting the scores into thirds (Maslach and Leiter, 2008). Likewise, IM scores were clustered into "high", "moderate" and "low" categories by splitting into thirds. A series of $\chi 2$ tests for independent samples were performed to detect significant differences among these groups, and Pearson correlation tests were conducted to determine the associations between variables and their subscales.

The second stage of the analysis comprised several hierarchical regressions designed to investigate the strength of the associations between the predictor variable IM and the predicted variable, burnout, as well as its components.
The threshold for statistical significance in all tests was $p < .05$.

Results

Prevalence of burnout and its components

75 (22.6%) of the participants had high levels of burnout. High EX was encountered in 102 physicians (30.7%), high CY in 142 (42.8%) and high PI in 108 (32.5%). Significant socio-demographic differences among individuals with high global burnout were related to specialty, and having multiple jobs. Regarding burnout components, socio-demographic differences in subjects with high EX were significantly related only to specialty; in those with high CY, they related to specialty and the number of multiple jobs, whereas in cases with high PI, they related to specialty, number of multiple jobs, and sleep disorders (Table 1).

Perceived use of IM practices

To assess the use of IM, its scores were split into thirds and, subsequently, classified into low, moderate and high. The vast majority of respondents perceived IM to be moderately used (48.8%) (Table 2). Although some respondents could not specifically identify vision as being an IM component of the health care organization at which they were employed

(41.3%), they did benefit from other IM components, such as the development of personnel (53.3%) and reward payments (51.8%).

Table 2: The perceived level of Internal Marketing usage in practice

Scale	Subscales	Perceived levels of usage		
		Low	Moderate	High
Internal marketing	Vision	137 (41.3%)	118 (35.5%)	77 (23.2%)
	Development	108 (32.5%)	177 (53.3%)	47 (14.2%)
	Rewards	111 (33.4%)	172 (51.8%)	49 (14.8%)
	Global	110 (33.1%)	162 (48.8%)	60 (18.1%)

Associations between burnout and IM

The means, standard deviations, and Pearson correlations of all the observed variables are depicted in Table 3. The average mean scores for IM and global burnout were 3.71 (SD = ± .58), and 2.36 (SD = ± .97), respectively. The two constructs were significantly correlated at $p < .001$ and $p < .05$ and all correlation coefficients were >.50. IM established an indirect and moderate relationship with burnout ($r = -.66$, $p < .05$).

Table 3: Descriptive statistics and Pearson correlations of study variables

Variables	M	SD	IM	Vision	Development	Rewards	BO	EX	CY
IM	3.71	0.58	-						
Vision	3.78	.85	.57¤	-					
Development	3.75	.65	.87¤	.50¤	-				
Rewards	3.67	.64	.94¤	.41¤	.69¤	-

**p<.05; ¤p<.001; M = mean; SD = standard deviation;*

IM = internal marketing; BO = burnout; EX = exhaustion; CY = cynicism; PI = personal inefficacy.

To measure the contribution of each category of the study variables (IM, socio-demographic, and occupational factors) to burnout variance, several hierarchical multiple regressions were conducted, using the stepwise method.

Three regression models emerged, which included the following predictors (Table 4):

- model 1: IM;
- model 2: IM and socio-demographic factors (gender, age, smoking and sleep disorders);
- model 3: IM, socio-demographic factors and occupational factors (specialty, professional level, type of employment, number of working hours / week and having multiple jobs).

Table 4: Hierarchical linear regression models for burnout and its components

Burnout	Model	*R*	R^2	Adj. R^2	Standard error of the estimate	R^2 change	*df1*	*df2*	*F* change	Sign. *F* change
EX	1	.60[a]	.365	.363	4.26	.365	1	330	189.50	.001
	2	.60[b]	.365	.363	4.26	.365	1	330	189.50	.001
	3	.60[c]	.365	.363	4.26	.365	1	330	189.50	.001
CY	1	.57[a]	.332	.330	3.48	.332	1	330	163.96	.001
	2	.57[b]	.332	.330	3.48	.332	1	330	163.96	.001
	3	.59[c]	.356	.350	3.43	.011	1	328	5.810	.016
PI	1	.63[a]	.397	.395	4.96	.397	1	330	216.85	.001
	2	.63[b]	.404	.400	4.94	.007	1	329	4.02	.046

	2	.66[b]	.437	.435	11.03	.437	1	330	256.12	.001
	3	.67[c]	.459	.454	10.85	.010	1	328	6.26	.013

IM = internal marketing; EX = exhaustion; CY = cynicism; PI = personal inefficacy; df= degrees of freedom; R^2= coefficient of determination; Adj. R^2= Adjusted R^2.

[a]Predictors: (constant), IM;

[b] Predictors: (constant), IM, gender, age, smoker status, sleep disorders;

[c]Predictors: (constant), IM, gender, age, smoker status, sleep disorders, specialty, professional level, type of employment, number of working hours/week, multiple jobs;

[d]The global score of burnout was computed by summing up the scores of EX, CY and PI.

Within all three regression models, EX was predicted by IM (standardized beta = -.60, t =-13.766, p<.001), explaining 60% of the variance.

CY was predicted by IM in model 1 and model 2 (standardized beta= -.57, t =-12.805, p<.001), by IM (standardized beta =-.54, t = -12.112, p<.001), type of specialty (standardized beta =-.12, t =-2.793, p<.001), and multiple jobs (standardized beta = -.10, t =-2.410, p<.05) in model 3. In model 1 and model 2, 57% of the variance in CY was explained by IM, and in model 3, IM, type of specialty and multiple jobs contributed to 59% of CY variance.

In model 1, PI was predicted by IM (standardized beta =-.63, t =-14.726, p<.001). In model 2, PI was predicted, additionally, by sleep disorders (standardized beta =.08, t = 2.0, p<.05). In model 3, PI was predicted by IM (standardized beta = -.61, t =-14.342, p<.001), as well as multiple jobs (standardized beta =-.11, t =-2.706, p<.001). The variables included in model 1 and model 2 explained 63% of the variance in PI, and the variables in model 3, explained 65% of the variance in PI.

The global burnout score was predicted in all three models by IM (standardized beta =-.63, t =-15.291, p<.001). In model 3, multiple jobs (standardized beta =-.11, t = =-2.845, p<.05), and type of specialty (standardized beta =-.10, t =-2.503, p<.05) contributed as well. The variables included in model 1 and model 2 accounted for 66% of the variance of global burnout, and model 3 explained 67% of variance in global burnout.

Discussion

Burnout is frequently linked to occupational stress and may have significant undesired effects on individuals, organizations and consumers (Maslach and Leiter, 2008). Gaining knowledge about its prevalence, the preventive impact of new organizational resources (such as IM) and their degree of implementation can be of paramount importance in designing the most appropriate strategies for reducing the risk and subsequent costs of burnout.

Our findings reveal that the prevalence of high-level burnout among Romanian physicians working in health care organizations was 22.6%. A possible explanation for this result may arise from the selection base itself, which is consistent with the description of private health care units as offering higher value-driven performance, quality-controlled work systems, and working conditions more tailored to both consumers' and physicians' expectations (Robontu, 2017). When analyzing the distinct components of burnout, we found their prevalence in our sample to be similar to that described in the literature, with the highest percentage pertaining to CY (42.8%) (Raggio and Malacarne, 2007). This may be a reflection of how physicians progressively distance themselves from their work, especially since, in our sample, 111 of 142 physicians high in CY had multiple jobs, entering a vicious cycle of routine. Managers must address this phenomenon by maintaining the internal motivation of employees, which is a good vehicle for keeping them consistent and productive (Todnem, 2005), and by cultivating abilities, such as adaptability, self-efficacy and achievement orientation (Hofstede, 2001).

The use of IM practices was perceived to be moderate (48.8%). This finding is, in part, satisfactory for Romania, considering that concepts such as IM are mostly acknowledged in developed countries and are not popular in societies (such as the Romanian one) facing a long-term transition of structures and mentalities from a communist health care system to a democratic one. In the context of a centrally-oriented and rigid hierarchical health care system, such as the Romanian one, the aforementioned values may be underestimated, as many processes specific to IM and local small-scale initiatives to implement them, may be underreported, for fear of negative consequences. It is also possible that, being only informally and / or non-systematically applied, this concept may trigger an incorrect usage (Gounaris, 2006), or not to be understood in the same way at different hierarchy organizational levels (Azędo et al, 2012).

Regarding the correlations of IM and burnout as well as its components, they were all statistically significant, negative, and moderate. These findings required a subsequent in-depth analysis, involving several hierarchical

regressions, which showed that global burnout was mainly influenced by IM, with insignificant contribution of the other considered variables (specialty, multiple jobs and sleep disorders).

Specifically, on burnout components:

- the relationship of EX with IM was significant (as IM explained 60% of EX variance), and was not influenced by other demographic or occupational factors. This finding suggests that, in order to decrease exhaustion in physicians, organizations should implement more IM-oriented programs, focusing on development objectives such as raising self-confidence, problem-solving abilities, mental strength and resilience (Rafiq and Ahmed, 2000);

- CY was influenced by IM, specialty and having multiple jobs. The last two factors contributed little to CY, this result being inconsistent with the literature (Qiao and Schaufeli, 2011). In contrast, IM explained 59% of CY variance, suggesting that health care organizations should implement employee training workshops, with the aim of raising their motivational level and encouraging them to explore new ideas and potential actions, so as to increase their interest in their work (Popa-Velea et al, 2019). Employee training may be conducted to ensure that employees know what tasks should be performed, and why (Rafiq and Ahmed, 2000);

- concerning PI, our results confirmed that this burnout component is correlated with IM, as well as with performing multiple jobs, this explaining 67% of the variance in PI scores. A high predisposition to PI may be overcome by implementing learning programs, in order to avoid stagnation, boredom and ineffectiveness, and to provide stimulating organizational tasks, skills and knowledge related to the job (Chang and Chang, 2007). PI may be also overcome by applying an adequate reward system: the incentives given to physicians should be tailored to their individual performance, with periodic adjustments (Foreman and Money, 1995; Berry and Parasuraman, 1991).

Since IM has been shown to contribute to global burnout, we analyzed which component of IM has the strongest correlation with burnout scores. This proved to be *the reward system.* Establishing an efficient reward system is described in the literature as being able to reinforce the organization's core values, such as excellence, innovation and respect, as well as increase employees' self-confidence, acting as a powerful trigger for them to invest more effort into gaining personal skills and knowledge (Gounaris, 2006).

Conclusions

Our study confirms the role of IM as strongly contributing to decreased levels of burnout and its components. In a landscape characterized by paucity of information about the impact of organizational factors on burnout risk, limited financial resources, and a poor knowledge of the balance between organizational risks and assets, our findings may represent a starting point for designing an array of solutions for preventing burnout, which could be suitable in Romania and other related contexts. Providing knowledge regarding burnout risk and elaborating efficient organizational strategies for the implementation of IM practices could not only lower the prevalence of burnout syndrome in physicians, but also help in building sensitivity towards the integration of "Relational Capital" (Gheorghe et al, 2018) in Public Health practice.

Acknowledgments

This study was conducted using personal funds. The authors would like to warmly thank Iolanda Panaitiu, M.D., for her precious input in this study.

Abstract

The article is devoted to the modelling and planning method of searching the area in order to find the missing person. In the introduction we present scenarios and concepts in the field of search theory, referring to recognized sources of literature in this field. In addition, we present methods for evaluating the effectiveness of a site search, based on the theory and own studies introduced earlier. The most important part of the work is the search planning method taking into account field conditions, resources and qualifications of the searchers. Both the optimization model and the heuristic method of solving the formulated sentence are original. The application developed on this basis has been integrated with the system for collecting and processing information about missing persons in the framework of a geo-location server called CEZAR. The method has been tested for a number of cases. Selected cases are presented here.

Keywords: Searching missing person, optimization model of search planning, IT search planning application.

Introduction

Formal basis

The SEARCH AND SCREENING studies by Bernard Osgood Koopman in 1946 are used as a theoretical basis in modelling the process of searching for lost people. The study was created in the OPERATIONS EVALUATION GROUP OFFICE OF THE CHIEF OF NAVAL OPERATIONS NAVY DEPARTMENT. It concerned in particular the search and detection of marine targets. However, the model and methods contained in the study have also become the basis for the development of models and methods of searching for missing persons in land search and rescue operations (Search and Rescue (SAR)). In this section we will present basic models and methods for assessing the probability of detecting missing persons. The methods of estimating the effectiveness of a terrain search are based on many researches done by teams from many countries interested in effective finding lost people (Frost, J.R. and Stone, L.D.,2001), (Frost, J.R. , 2000), (Koopman, B.O., 1946), (Kratzke T, Stone L.D. and Frost J.R.,2010), (Stone, L.D.,2004). The optimization problem of search planning is quite unique and is formulated and solved by our team within the project financed by National Research and Development Centre (Nr DOB-BIO/12/01/2018).

Search scenarios

Let us assume that two search scenarios are being considered. Searches carried out on the basis of the site vetting through successive "observations" in a limited fragment of the searched area, separated by a certain period of time. It is assumed that the results of subsequent glances at the examined fragment may or may not result in detection of the searched object. The results of subsequent observations are independent of each other, and the chance of detection is identical in each subsequent glance.
Assuming that:

- g - the probability of detecting an object with one "observation",

Cite this Article as: Andrzej NAJGEBAUER, Jarosław RULKA and Wojciech KULAS " Models and their IT Application for Search Planning" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- p_n - the probability of detecting a u object in the n-course of "observation".

- T - the time (number of observations) necessary to detect the missing object and taking into account the assumptions made, we obtain the following dependence:

$$P\{T \le n\} = p_n = 1-(1-g)^n, n = 1,2,... \tag{1.1}$$

According to the adopted model, the probability of detecting the object sought exactly as a result of subsequent observations is equal:

$$P\{T+k\} = P_k = (1-g)^{k-1} \cdot g, \ k = 1,2,... \tag{1.2}$$

Using this relationship, you can determine the expected number of observations necessary to detect the desired object:

$$E\{T\} = \sum_{k=1}^{\infty} k \cdot (1-g)^k \cdot g = \frac{1}{g} \tag{1.3}$$

a) The search is carried out in such a way that the examined fragment of the area is subject to continuous observation. If we assume that the probability of detecting the object sought in a short period of time is γdt, it can be shown [4] that the following relationship exists:

b) $P\{T < t\} = \begin{cases} 1-e^{-\gamma t} & t > 0 \\ 0 & t \le 0 \end{cases}$,

We write this down as $P\{T < t\} = 1-e^{-\gamma t}, \quad t > 0$ (1.4)

$$E\{T\} = \overline{T} = \int_0^{\infty} t\gamma e^{-\gamma t} dt = \int_0^{\infty} e^{-\gamma t} dt = \frac{1}{\gamma} \tag{1.5}$$

The above dependencies are correct assuming that over time, the values of g and γ. However, with the passing of the search time, both the mutual position of the searched object and the searching team change. The conditions in which the search is carried out may also change. Thus, dependencies (1.1) and (1.4) obtain a character:

$$P\{T \le n\} = p_n = 1-(1-g_1)(1-g_2)\cdot..., n = 1,2,... \tag{1.6}$$

and for continuous observation:

$$p(t) = P\{T < t\} = 1-e^{-\int_0^t \gamma(u)du}, \quad t > 0 \tag{1.7}$$

Dependence of detection intensity on distance.

It has a major impact on values and has a distance between the observer and the object being sought. This distance varies with the duration of the search. Therefore, the proper procedure will be to determine the relationship between the values g and γ from the distance marked as r. The distance will result from the adopted search model and the location of the object sought. To determine the relationship $\gamma(r)$ the following case is considered:

- The observer is at a height h above the ground

- Intensity $\gamma(r)$ the detection of the searched object is directly proportional to the solid angle, corresponding to the size of the object located at a distance in the distance r from an observer.

The situation described by the assumptions is shown in Fig 1, based on considerations of (Koopman B.O., 1946) we have formal analysis:

Fig. 1: The space angle

It can be shown that the solid angle SB, corresponding to an object with dimensions a,b remotely

r is:

$$SB = \frac{a \cdot b \cdot h}{s^3} = \frac{a \cdot b \cdot h}{\left(h^2 + r^2\right)^3} \tag{1.8}$$

Intensity of detection $\gamma(r)$ is therefore proportional to the value:

$$\gamma = \frac{k \cdot h}{s^3} = \frac{k \cdot h}{\left(h^2 + r^2\right)^3} \tag{1.9}$$

And for r ? h approximation can be made:

$$\gamma \approx \frac{k \cdot h}{r^3} \tag{1.10}$$

Dependencies (1.9) and (1.10) are called “inverse cube law of sighting”.

Proportionality factor k takes into account:

- area of the facility $R = a \cdot b$;
- weather conditions;
- field conditions;
- equipment and observer's ability to detect the object.

Terrain Model

The Search Planning function is based on the previously introduced terrain model.

The multi-resolution model of the terrain based on the division of a fragment of the terrain using a four-tree can be defined as follows:

$$Z_I^L(t) = \left\langle G_I^L(t), \Psi_I^L(t), \zeta_I^L(t), a \right\rangle \tag{1.11}$$

where:

L – resolution level (depth of the root-square division, number of digits in the description of the square number in a quadrant system).

G_I^L – Berge's graph without a loop, whose vertices are the squares of the terrain and the arcs connect the adjacent squares (if there is a possibility to pass between them). The number of vertices of this graph (2L*2L) is equal to the number of squares into which the square-root is divided and depends on the resolution level, i.e. the number *L*. It is suggested that the way the graph creates connections between the adjacent vertices (adjacent zones of the terrain) is as shown in Fig 2.

$\Psi_I^L(t)$ – a set of functions described on the tops of the graph.

$\zeta_I^L(t)$ – a set of functions described on the graph branches.

a – length of square root side

a) b)

Fig. 2: Example of a fragment of the terrain and its division into homogeneous squares according to the size (a) and graph (b) of the potential connections and connections selected for the fragment of the terrain with (a) (bold edges in the graph (b)).

Methods of estimating the effectiveness of a site search

Detection of an object moving on the curve

The particular analyses were realized by project team and described in (Najgebauer, A., et al. 2019), some results are presented here on the basis of the project.

Using the terms (introduction), it is possible to determine the probability of detecting an object moving in relation to the observer on the curve (only the case of continuous observation will be considered) (Koopman 1946):

Fig. 3: Trajectory of movement of the object sought, relative to the observer.

We assume that the position of the object at moment t is defined by the coordinates $\xi(t),\eta(t)$. It follows from this that:

$$\gamma(r(t)) = \gamma(\sqrt{\xi^2(t)+\eta^2(t)}) \tag{2.1}$$

Thus, if an object moves from a point (ξ_0,η_0) up to (ξ_k,η_k) on time (t_0,t_k). The probability of its detection is determined by the dependencies (1.7) and (2.1):

$$p_C = 1 - exp[-\int_{t_0}^{t_k} \gamma(\sqrt{\xi^2(t)+\eta^2(t)})dt, \quad t > 0 \tag{2.2}$$

If marked by C The curve on which the detected object moves and by its speed in relation to the observer can be saved as a curve (2. 2):

$$\begin{aligned} p_C &= 1 - e^{-F[C]} \\ F[C] &= \int_C \frac{1}{w}\gamma(r)ds \end{aligned} \tag{2.3}$$

Objects moving in a straight line

A special case of the curve is a straight line, on which the object sought moves at a constant speed in relation to the observer. Assuming that the line of movement of the searched object is parallel to the axis of ordinates (0Y) of the coordinate system, such a situation can be presented using Fig 4.

Fig. 4: The searched object moves along a line parallel to the ordinate axis (0Y) of the coordinate system.

In this case, the relation (2.3) takes the form:

$$
\begin{aligned}
& p_C = 1 - e^{-F[C]} \\
& F[C] = \int_{t_0}^{t_k} \gamma(\sqrt{x^2 + w^2 t^2})dt = \\
& \qquad = \frac{1}{w}\int_{y_0}^{y_k} \gamma(\sqrt{x^2 + y^2})dy \\
& y_0 = w \cdot t_0; \quad y_k = w \cdot t_k
\end{aligned}
\tag{2.4}
$$

Particularly interesting is the case described in the diagram in Fig 4. when the object being sought moves at a constant speed along its straight line for a long time before and after reaching the greatest approximation to the position of the observer (a point with coordinates $(0, x)$.

In this case, the probability of detection is only dependent on the coordinate value. From the formula (2.14) and taking into account "inverse cube law of sighting" ((1.9) or (1.10)) we obtain formulas:

$$a) \quad p(x) = 1 - e^{-\frac{2m}{(h^2+x^2)}}$$
$$or \tag{2.5}$$
$$b) \quad p(x) = 1 - e^{-\frac{2m}{x^2}}$$

where: $m = \frac{k \cdot h}{w}$.

Using the relation (2.5), a very interesting size is defined:

$$W = \int_{-\infty}^{+\infty} p(x)dx \tag{2.6}$$

Size is called "effective search (or sweep) width".

The interpretation W can be done based on the following model:

- the observer moves through the space in which the detected objects are evenly distributed (average of objects per unit area) with the speed
- all objects remain at rest or move with the same speed vector

Then, the expected number N_0 of objects detected by the observer in a unit of time is:

$$N_0 = W \cdot N \cdot w \tag{2.7}$$

The product $W \cdot w$ is called "effective search (or sweep) rate".

Uwzględniając zależności (2.15) oraz (2.16) otrzymujemy:

$$W = 2\sqrt{2\pi m} = 2\sqrt{\frac{2\pi kh}{w}} \tag{2.8}$$

Random Search

The random search is a case that meets the following assumptions (Koopman B.O., 1946]:

a) The location of the searched object is equally probable in each sub-area of area A.
b) The observer or observers move randomly in area A and independently of each other.
c) Each section of the road of a single observer is short in relation to the sum of lengths of all roads, but much longer than the potential detection range.
d) The observer always detects an object that is within the W/2 range on both sides of his or her path and never outside that range.

Fig. 5: Random scheme of searching in area R.

If the above assumptions are met, the probability of detecting an object, with the total length of the observers' route of a is in the form of:

$$p(a) = 1 - e^{-W \cdot a / R} \tag{2.9}$$

Assuming that each observer moves at a constant speed, the length of the road travelled is a product of the search time and speed to date. Thus, the relation (2.9) can be written in the form:

$$p(t) = 1 - e^{-W \cdot v \cdot t / R}, \quad t > 0 \tag{2.10}$$

In the article (Koester, R.J., et al.), the relationship is presented $p(C_t) = POD(C_t)$ where

$C_t = W \cdot v \cdot t / R$ was defined as the "coverage" of the exploration area by the existing explorations carried out at time t. Then:

$$POD(C_t) = p(t) = 1 - e^{-W \cdot v \cdot t / R}, \quad t > 0 \tag{2.11}$$

Parallel Search

Basing on considerations in (Koopman, B.O. 1946, p.29), parallel searches are carried out as shown in the figure 6.

Fig. 6: Parallel search.

The following assumptions are considered:

a) The object sought is located randomly according to an even distribution.
b) The search line is infinitely many, located at a distance S.
c) The probability of detection is assumed to be (2.5 b)).

With the above assumptions, the probability of detecting an object is (Koopman, B.O., 1946, p.30):

$$POD(S) = erf\left(\frac{\pi\sqrt{2m}}{S}\right) = erf\left(\frac{\sqrt{\pi}}{2}\cdot\frac{W}{S}\right) \tag{2.12}$$

A special case of parallel searches, described among others in (Koopman, B.O., 1946) is presented in Figure 7 and the following considerations:

Fig. 7: Parallel search in a limited area.

Assumptions:

a) Searches shall be conducted in an area of size $N \cdot S \times b$
b) Prospect located on an evenly distributed basis over the prospect area
c) Searches are conducted on N randomly distributed lines of total length $N \cdot b$

With the above assumptions, the probability of detection is determined by a relationship:

$$POD(S) = 1 - e^{-W/S} \tag{2.13}$$

Fig. 8: The illustration of detection probability for parallel searches.

Formulas (2.2) and (2.3) have time dependent versions in the literature (Koester, R.J., et al., 2004, p.53):

$$\begin{aligned} &POD(t) = 1 - e^{-W \cdot t \cdot v / R} \\ &for \quad R = N \cdot S \cdot b \\ &POD(t) = 1 - e^{-\frac{W \cdot t \cdot v}{N \cdot S \cdot b}} \\ &if \quad t : t \cdot v = N \cdot b, \quad then \\ &POD(t) = 1 - e^{-\frac{W \cdot N \cdot b}{N \cdot S \cdot b}} = 1 - e^{-\frac{W}{S}} = P(S) \end{aligned} \tag{2.14}$$

Similarly, for (2.12) we find a relation:

$$POD(t) = erf\left(\frac{\sqrt{\pi}}{2} \cdot C_t\right) = ref\left(\frac{\sqrt{\pi}}{2} \cdot \frac{v \cdot W \cdot t}{R}\right) \tag{2.15}$$

Estimation of the effective search width W

From the relationships presented above it follows that for the purpose of determining the value of

POD it is necessary to know the probability function of detecting an object marked as $p(x)$ and defined by the relationship (2.5). The relationship (2.9) - (2.15) shows that the following are to be determined $POD(t)$ and $POD(S)$ it is sufficient to know the effective search width W (2.6). The value of this parameter is dependent on many factors:

- the speeds of movement of the observer.
- type of terrain.
- terrain.
- terrain cover.
- weather.
- seasons.
- time of day (lighting)

- the experience and fatigue of the seeker.

Estimating this parameter is very difficult. Performing the relevant experiments requires complex and expensive ones. Publication (Koester, R.J., et al. 2004) describes the rules of conducting and results of the experiments, concerning the collection of data for the estimation of the parameter W for a fixed set of conditions. These tests are not sufficient to determine the values of W for any conditions. However, the presented results may provide a reference point for evaluating the value of the parameter W under different conditions than those described in the report. For illustration purposes, we are quoting selected tables with data from this research. Summary of the determination of the Effective Search Width is presented in (Koester, R.J., et al., 2004)

The following data must be provided for the search planning function:

- area with division into sectors for which an initial classification is made as to coverage (12 types) and corrugation

Table 1: Classification of coverage type for terrain (sector). Own sources

Type of coverage	Type No.	% open	% forest	%swampy	% bushy	% grassy	% watery
open	0	80-100	0-20	0-20	0-20	0-20	0-20
forest	1	0-20	80-100	0-20	0-20	0-20	0-20
swampy	2	0-20	0-20	80-100	0-20	0-20	0-20
bushy	3	0-20	0-20	0-20	80-100	0-20	0-20
grassy	4	0-20	0-20	0-20	0-20	80-100	0-20
watery	5	0-20	0-20	0-20	0-20	0-20	80-100
Open-forest	6	30-50	30-50	0-20	0-20	0-20	0-20
forest-swampy	7	0-20	30-50	30-50	0-20	0-20	0-20
open-bushy	8	30-50	0-20	0-20	30-50	0-20	0-20
grassy-swampy	9	0-20	0-20	30-50	0-20	30-50	0-20
watery-forest	10	0-20	30-50	0-20	0-20	0-20	30-50
watery-bushy	11	0-20	0-20	0-20	30-50	0-20	30-50

- It is determined for certain types of formations (tiraliers, triples) depending on the type of sector coverage and corrugation: the rate of movement of the formation (sweepSpeed) and the effective observation width (sweepWdth). The calculation of the above parameters takes into account the composition of the formation (due to experience). Reference sweepWdth established for a single experienced prospector for particular types of coverings, the following was assumed

0	1	2	3	4	5	6	7	8	9	10	11
142	62	36	62	36	36	106	36	36	36	62	36

The values of sweepWdth and sweepSpeed are calculated using specific procedures.

- The presumed color of the searched for clothing is also taken into account, which has an impact on the reference width of observation by an experienced searcher in a particular type of search area coverage.

The formulation of the search plan optimization task and the method of its solution

The total search area is divided into sub-areas (segments) with homogeneous field characteristics and established probabilities of the object in a given segment. The figure below illustrates a hypothetical, exemplary division of the area into segments.

Fig. 9: Example division of the search area into segments (sectors).

R_i – area of the i-th sub-area (sector).

c_i – type of i-th sub-area (sector), $c_i \in C$. $i \in \{0,1,2,\dots,I\}$, I – number of sectors to be searched.

For the sake of completeness we assume that the sectors to be searched are numbered with positive numbers (i > 0), index i = 0 is assigned to an area not subject to search, which complements the search space (the so-called . rest of world).

We assume that the search is carried out by search units (formations) consisting of at least one man, which have specific equipment supporting the detection process. Among the types of search units, we can distinguish:

- a fast three,
- tyralier,
- Dog patrol,
- UAV.

The searches are carried out by the formations in a systematic way, which consists in passing through parallel lanes with a constant distance (the so-called walking) between people and subsequent lanes without the sub-areas already searched in previous positions.

We also assume that human resources are divided in a separable way according to their qualifications (set of qualification indexes $\{1,\dots,N\}$).

Every j-th type of prospecting unit ($j \in \{1,2,\dots,J\}$) we will be characterized by:

- d_j – minimum number of persons,
- u_j – maximum manning,
- s_j – intervals (spacing),
- g_{jn} – minimum number of members nth Qualifications for the entire staff (personnel qualification structure required),
- h_{jl} - required equipment (number of equipment) formation (lth kind of equipment $l \in \{1,\dots,L\}$).

The effectiveness of the search by a particular unit of a particular type can be characterized by a function: $esr(tt,j,a)$ - fan ounce describing the effective rate of search depending on

- t – terrain type,
- j – types of formation,

- $a = [a_n]_{n\in\{1,\dots,N\}}$ – staff structure in terms of qualifications (number of people with specific qualifications).

The decision-making process is described in a sequence of successive stages, in which the search plans are determined as updates to the previous plan. Events determining the moments of start/completion of subsequent stages are end of search in specific sectors or arrival of new forces. A plan update is an engagement of new and/or released forces within the current plan (after taking into account the completion of activities in specific sectors).

We assume that each time we make a decision, we maximize the exploration effort by engaging all available forces in an acceptable (reasonable) manner. Allocated effort in a sector means allocating individuals (with specific qualifications) to specific formations of a particular type (the range of the number of formations of each type operating in that sector is limited to M).

By the search plan $X(t_k)$ at k-th stage (at t_k) we will understand the matrix for allocating the number of people (by qualification) to units (formations) of a certain type for action in the specific sectors.

$$X\left(t_k\right)=\left[x_{ijmn}\left(t_k\right)\right] \tag{3.1}$$

where:

$x_{ijmn}(t_k)$ – the number of qualified individuals assigned to activities within the m-th type formation in the i-th sector as part of the new Phase 1 exploration plan at the time of the t_k.

Searches within the same sector carried out by different units (formations) are carried out in a systematic and coordinated manner, which means that there is no overlap of searched areas within and between stages. The activities at a given stage are carried out in parts of the sector not yet searched.

$SA_i(t)$ – total searched area (checked) in the i-th segment until t. The area of the checked lanes resulting from the way the search was carried out (parallel lanes while keeping the walk).

In view of the assumptions made, the effort $SA_i(t)$ in the sector is arithmetically accumulated (summed up) within a stage and between stages. We can therefore assume that:

$$SA_i\left(t_k\right)=SA_i\left(t_{k-1}\right)+SA_i\left(t_{k-1},t_k\right)=SA_i\left(t_0,t_k\right) \tag{3.2}$$

whereby:

$$SA_i\left(t_{k-1},t_k\right)=\sum_j SR_{ij}\left(t_{k-1}\right)\cdot\left(t_k-t_{k-1}\right), \tag{3.3}$$

$SR_{ij}(t_{k-1})$ – the total pace of checking the lanes of all formations of this type participating in the i-th sector within the plan of the moment t_{k-1}. The value of the total rate is determined from the formula

$$SR_{ij}\left(t_{k-1}\right)=\sum_m sr\left(tt_i,j,x_{ijm}\left(t_{k-1}\right)\right) \tag{3.5}$$

Due to the implementation of activities in parts of the sectors not yet searched, we assume that the effective EC coverage in a given stage is determined in relation to the area of the sector not searched at the beginning of the stage

The probability of detecting an object at the beginning of the k-th stage in the i-th sector over a period of time (t_k, t_{k+1}) based on (2.12) is:

$$POD_i\left(t_k,t_{k+1}\right)=\operatorname{erf}\left(\frac{\sqrt{\pi}}{2}\cdot EC_i(t_k,t_{k+1})\right) \tag{3.6}$$

where:

$EC_i(t_k,t_{k+1})$ – the total effective coverage of the i-th sector over time (t_k,t_{k+1}) is (concerns the part of the sector not yet searched for)

$$EC_i(t_k,t_{k+1})=\frac{ESA_i(t_k,t_{k+1})}{R_i-SA_i(t_k)} \tag{3.7}$$

Total effectively searched area in the i-th sector over time (t_{k-1},t_k) is:

$$ESA_i\left(t_k,t_{k+1}\right)=\sum_j ESR_{ij}(t_k)\cdot\left(t_{k+1}-t_k\right) \tag{3.8}$$

$ESR_{ij}(t_k)$ – the total rate of effective search for all formations of this type participating in the i-th sector within the plan of the moment t_k.

$$ESR_{ij}\left(t_k\right)=\sum_m esr\left(tt_i,j,x_{ijm}\left(t_k\right)\right) \tag{3.9}$$

$x_{ijm}(t_k)$ - vector of personnel (number of people with particular qualifications) of the *m*-th formation

The participants in the *i*-th sector are involved in activities in the i-th sector under the plan from the moment of t_k.

Due to the effects of exploration activities in accordance with the previous (old) exploration plan from the moment of t_{k-1} the probability distribution changes POC. Update of the probability distribution POC is done at the moment as follows:

$$\begin{aligned}POC_i\left(t_k\right)&=\frac{\left(1-\frac{SA_i(t_{k-1},t_k)}{R_i}\right)\cdot POC_i\left(t_{k-1}\right)+\frac{SA_i(t_{k-1},t_k)}{R_i}\cdot\left(1-POD_i\left(t_{k-1},t_k\right)\right)\cdot POC_i\left(t_{k-1}\right)}{\sum_l\left(1-\frac{SA_l(t_{k-1},t_k)}{R_l}\right)\cdot POC_l\left(t_{k-1}\right)+\frac{SA_l(t_{k-1},t_k)}{R_l}\cdot\left(1-POD_l\left(t_{k-1},t_k\right)\right)\cdot POC_l\left(t_{k-1}\right)}=\\&=\frac{POC_i\left(t_{k-1}\right)\cdot\left(1-\frac{SA_i(t_{k-1},t_k)}{R_i}+\frac{SA_i(t_{k-1},t_k)}{R_i}\cdot\left(1-POD_i\left(t_{k-1},t_k\right)\right)\right)}{\sum_l POC_l\left(t_{k-1}\right)\cdot\left(1-\frac{SA_l(t_{k-1},t_k)}{R_l}+\frac{SA_l(t_{k-1},t_k)}{R_l}\cdot\left(1-POD_l\left(t_{k-1},t_k\right)\right)\right)}=\\&=\frac{POC_i\left(t_{k-1}\right)\cdot\left(1-\frac{SA_i(t_{k-1},t_k)}{R_i}\cdot POD_i\left(t_{k-1},t_k\right)\right)}{\sum_l POC_l\left(t_{k-1}\right)\cdot\left(1-\frac{SA_l(t_{k-1},t_k)}{R_l}\cdot POD_l\left(t_{k-1},t_k\right)\right)}.\end{aligned} \tag{3.10}$$

Summary probability of success (for the entire exploration area) for the updated (new) exploration plan over a period of time (t_k,t_{k+1}).

$$POS\left(t_k, t_{k+1}\right) = \sum_i \left(1 - \frac{SA_i(t_k)}{R_i}\right) \cdot POC_i\left(t_k\right) \cdot POD_i\left(t_k, t_{k+1}\right) \tag{3.11}$$

Moment of the current end kth stage (start of stage *k+1*) is determined by the occurrence of an exploration termination event in any sector.

The predicted moment of completion of the current stage can be determined from the formula:

$$t_{k+1} = \min_i \left\{ t_{k+1}\left(i\right) : \sum_j SR_{ij}\left(t_k\right) > 0 \right\}, \tag{3.12}$$

where

$t_{k+1}(i)$ – the closest possible moment of completion of exploration in the i-th sector.

The condition in the above definition of a harvest excludes sectors that do not have a unit allocation under the current exploration plan.

Next minute $t_{k+1}(i)$, in which the entire area will be searched i-th sector We can determine from dependencies:

$$R_i - SA_i\left(t_k\right) - SA_i\left(t_k, t_{k+1}\left(i\right)\right) = 0 \tag{3.13}$$

After the transformations we get:

$$t_{k+1}\left(i\right) - t_k = \frac{R_i - SA_i\left(t_k\right)}{\sum_j SR_{ij}\left(t_k\right)} \tag{3.14}$$

Determining the current, initial (base) search plan $\bar{X}(t_k)$ and the human resources available $Z_n(t_k)$ resulting from the potential termination of activities in specific segments or the arrival of new forces.

$$\bar{x}_{ijmn}\left(t_k\right) = x_{ijmn}\left(t_{k-1}\right) \cdot b_i\left(t_k\right) \tag{3.15}$$

$$Z_n\left(t_k\right) = \sum_{i,j,m} x_{ijmn}\left(t_{k-1}\right) \cdot \left(1 - b_i\left(t_k\right)\right) + \Delta Z_n\left(t_k\right) \tag{3.16}$$

$$B(t_k) = \left[b_i\left(t_k\right)\right] \tag{3.17}$$

$B(t_k)$ – binary vector informing about the continuation or completion of the search in the i-th sector according to the old assignment. A value of 0 means the end of exploration in a given sector, which results in zeroing the effort allocation to that sector within the framework of updating the previous plan and returning the released resources to the available pool.

$\Delta Z_n(t_k)$ – new forces arrived at the moment t_k (vector by qualification).

The problem

The goal is to maximize the probability of success within a specific time horizon determined by the moment t(k+1) of the nearest event resulting from the planned (forecasted) completion of the search in any segment.

Input data:

- Current initial search plan $\bar{X}(t_k)$ (after the update related to the completion of activities in selected sectors).
- A set of search sectors together with the current probability of the object being located in this area $POC_i(t_k)$.
- $\Delta Z_n(t_k)$ – new forces arrived at the moment t with a breakdown of your qualifications.
- $B(t_k)$ – binary vector informing about the state of search in the sectors.
- Characteristics of search unit types
- Function describing the effective rate of search depending on the type of unit, personnel structure, type of terrain.
- $H_l(t_k)$ – current, available equipment of the l-type.

Decision variables:

- $Y(t_k)$ – additional allocation of people within the new units (formation) to sectors based on available resources.

Criterion function:

$$\max_{Y(t_k)} \rightarrow POS\left(t_k, t_{k+1}\right) \tag{3.18}$$

Restrictions:

1. The new search plan is a modification of the previous plan, taking into account the completion of work in specific sectors and adding new allocations of forces

$$x_{ijmn}\left(t_k\right) = \overline{x}_{ijmn}\left(t_k\right) + y_{ijmn}\left(t_k\right) \tag{3.19}$$

2. No modification of the allocation for operating units according to the previous plan

$$\forall\left(i, j, m\right)\left[\sum_n \overline{x}_{ijmn}\left(t_k\right) > 0 \Rightarrow y_{ijmn}\left(t_k\right) = 0\right] \tag{3.20}$$

3. The overall effort allocated must be met by available human resources with established qualifications n

$$\forall_n \sum_{i,j,m} y_{ijmn}\left(t_k\right) \le Z_n\left(t_k\right) \tag{3.21}$$

4. Each formation of a particular type assigned at a given stage to a particular sector must comply with the manning constraints

$$\forall\left(i, j, m\right)\left[\sum_n y_{ijmn}\left(t_k\right) \le u_j\right] \tag{3.22}$$

$$\forall\left(i, j, m\right)\left[\sum_n y_{ijmn}\left(t_k\right) \ge d_j\right] \tag{3.23}$$

5. Each formation of a particular type assigned at a given stage to a particular sector must meet the restrictions on the qualification structure of members

$$\forall(i,j,m,\tilde{n})\left[\frac{y_{ijm\tilde{n}}(t_k)}{\sum_n y_{ijmn}(t_k)} \geq g_{j\tilde{n}}\right] \tag{3.24}$$

6. For each formation of a particular type assigned at time t, the required equipment must be provided

$$\forall(l)\sum_{i,j,m} e_{ijm}(t_k)\cdot h_{jl} \leq H_l(t_k) \tag{3.25}$$

$$e_{ijm}(t_k) = \begin{cases} 1 & : \quad \sum_n y_{ijmn}(t_k) > 0 \\ 0 & : \quad \text{otherwise} \end{cases}$$

7. A single additional allocation must not be negative

$$y_{ijmn}(t_k) \geq 0 \tag{3.26}$$

The idea of an algorithm to find the best search plan

The idea of the algorithm is based on a two-level search of the solution space. The first level concerns the allocation of units of a specific type to specific sectors (the space of two-dimensional binary arrays). Searches within this space are performed through a full overview. Then, in a given step for a fixed allocation of units to sectors, a solution search is performed on the second level, which concerns the allocation of human resources with different qualifications to units within their overall allocation.

Within the second level of solution search, in the first step a preliminary, even distribution of human resources to units is made. It consists of iterative allocation of one person with the given qualifications (starting with the highest) to each unit with minimum and maximum staffing requirements. The solution is evaluated and becomes the starting point for a search of your nearest neighbourhood. The closest neighbourhood is determined by:

- a single exchange of an experienced person for an inexperienced one for a fixed pair of units or
- a single transfer of a person between a fixed pair of units.

If a given neighbourhood is better with an output (central) solution, it becomes an output (central) solution and searches move to a new neighbourhood. The searches end when the current, best output (central) solution does not have a better closest neighbour.

The best solution found locally is compared to the current best solution within the human resources allocation under test. When it is better, it replaces the current best solution.

Applications and Experimentation

After the development of the methods and integration with Geo-localization server we have the following procedure of runtime:

(1) On the tab "Actions", add a new action as a type by specifying "Open area search".

(2) Go to the system tab and start the geo-location module form.

(3) Loading the search segment by sector with sector coverage classification and POC (POA) filling - using a calculator or manually.

(4) Introduction of personal resources, divided into experienced and inexperienced ones.

(5) Designation of a search plan (allocation of a certain number of types of search formations (fast triples or tyraliers (extended lines)) with their composition in terms of the number of experienced and inexperienced individuals in each sector).

(6) Calculation for each sector: effective land cover and effective search rate and probability of detection in each sector.

(7) Reading the results. – allocation of formations to the sectors.

Expected result:

- Application launched.
- Launched form for entering people search issues with a new action of the type "Open area search" added.
- Launched geo-location and search planning module with a marked point indicating the last known location.
- Displaying the area according to the entered parameters.

After switching on the CESAR system, we have a number of possibilities to plan searches in the area outside the city or in urban parks and forests.

Display of map in CESAR (geo-localization server):

Fig. 10: CESAR screen.

Introducing a case from the main application:

Fig. 11: Case of search.

Fig. 12: Location of IPP

Introduction of search sectors in the selected area.

Sector 1:

Fig. 13: Sector determination and description

Fig. 14: Sector visualization

Fig. 15: Sectors of search with parameter probability of being missing in the area (POC (POA))

Moving to planning - 1 stage:

Fig. 16: Planning of search table.

Filling in personal resources:

Fig. 17: Planning of search table - resources determining.

Start planning - develop a search plan:

Fig. 18: Allocation plan.

Start of plan implementation in stage 1:

Fig. 19: Implementation of the exploration plan in stage 1.

Completion of stage 1:

Fig. 20: Completion of the exploration plan in stage 1.

Start planning the second stage:

Fig. 21: Allocation plan. Stage 2- beginning .

Stage 2 planned:

Fig. 22: Allocation plan. Stage 2- decision.

The implementation of the plan has begun:

New forces arrived and the 3rd stage was planned:

Fig. 24: Stage 3 - new forces arrived.

Stage 2 completed and stage 3 planned:

Fig. 25: Stage 2 completed, stage 3 planned.

The 3rd stage has been started:

Fig. 26: Implementation of plan - stage 3.

End of the search:

Fig. 27: Completion of stage 3. End of search.

The planning and implementation sequence is presented. Accelerated time demonstration.

Conclusions and Recommendations

The presented article about the search planning function gives the basis for the implementation of calculation methods, based on the terrain model with the assumed accuracy of square mapping and using the experimental data for determining the value of the effective search width W for given search sectors and appropriately selected search units. The algorithms should be tested on data close to real or real. Such data should be obtained as a result of analysis of real cases or as a result of an interview with police representatives participating in the missing people's search.

Abstract

Innovative and investment development of territories is an important element in the development of the country's economy. The article examines the factors that influence the investment and innovative development of the regions of the Russian Federation. The degree of influence of factors is determined through the construction of an econometric model. Modeling is carried out through the Gretl 1.9.11 software product using the least squares method.

Keywords: Innovative Development of Territories, Investment Development of Territories, Regional Economic Development.

Introduction

The issues of innovative and investment development of the economy at various levels are quite relevant at the present time. Many researchers consider this issue at the level of development of countries. And only a small proportion of foreign and Russian authors study innovative and investment development at the level of the constituent entities of the Russian Federation.

Domestic scientists and analysts in their predominantly theoretical designate the factors that influence or determine the innovative and investment development of the region. And only a few researchers prove the impact on investment activity using the mathematical apparatus. Note that, as a rule, the authors study the innovative or investment development of regions or regions that are part of one federal district. Institutional traps of innovative and investment activities are a serious obstacle on the path to well-balanced development of modern Russia's regions. Practice of economic players functioning shows that the regions lacking clear strategic orientation toward capital creation and increase are not capable to generate and maintain the key factors of success in competitive struggle.

Formulation of the problem

In recent scientific studies using economic and mathematical models as the most frequently used factors influencing the innovative and investment development of regions, such factors are identified as: - indices of the physical volume of the gross regional product; - dynamics of labor productivity; - the number of advanced technologies used; - the volume of innovative products, works and services in industrial production; - the cost of technological innovation in industrial production;- unemployment rate;- the proportion of industrial organizations that carry out technological innovations; - budgetary funds aimed at financing innovation.

It is interesting that the economic and mathematical models obtained by the researchers do not allow to fully determine the entire range of factors that influence the level of innovation and investment development of the subjects. The results of such scientific works reflect a high degree of dependence of innovative and investment development on

budget financing and do not show the possibility of dependence on other sources and instruments of financing.

The purpose of this study is to identify the factors influencing the investment and innovative development of the constituent entities of the Russian Federation. The article uses the methods of a systems approach, analysis, synthesis and modeling. Modeling was carried out using the Gretl 1.9.11 software product using the least squares method.

Results

According to the analysis of publications and statistical data of all regions of the Russian Federation in the field of innovation and investment development and areas adjacent to it, it was proposed to use a number of other factors that, in the opinion of the authors, are influencing innovation and investment activities. The volume of innovative goods, works, services is proposed as an explained variable. This indicator is the most objective indicator of the innovative and investment development of territories. Let's take a closer look at each proposed factor.

In domestic publications, the indicator is considered - the cost of technological innovation in industrial production. However, innovations are applied not only in industrial production. Therefore, as the first explanatory variable, the model includes an indicator of a wider scope, namely, the cost of technological innovation of organizations. It allows you to consider the cost of technological innovation in all areas of production and activities.

The next factor is internal expenditures on research and development in the constituent entities of the Russian Federation. It reflects the actual cost of carrying out research and development in the country. Their assessment is based on statistical accounting of the costs of carrying out research and development by organizations' own forces during the reporting year, regardless of the source of funding.

Since innovative activity is a type of activity associated with the transformation of ideas (usually the results of research and development or other scientific and technical achievements) into technologically new or improved products or services introduced on the market, into new or improved technological processes or production methods (transmission) services used in practice, the internal volume of expenditures on research and development should have a significant impact on the level of innovative development as a whole.

Due to the presence of an obvious relationship between research, development and innovation, it is necessary to check the degree of influence on innovation activity and such an indicator as - the number of personnel engaged in research and development, by category for the constituent entities of the Russian Federation. We believe that this indicator is more appropriate than the indicator - the unemployment rate used by many domestic scientists.

According to the above, it is also necessary to check the degree of influence on the innovative activity of the indicator that determines the proportion of organizations that carried out technological, organizational, marketing innovations. The level of innovative activity is defined as the ratio of the number of organizations that carried out technological, organizational or marketing innovations to the total number of organizations surveyed for a certain period in the region.

The scientific works of domestic scientists do not reflect the fact that there is a possible dependence of the innovative and investment development of territories on the investment potential. As a rule, the work of scientists is reduced to the study of joint innovation and investment development of territories.

We consider it necessary to check the dependence of innovation on investment in the same territory. The indicator chosen as an index of investment development, was - the share of the investment potential of the region in the all-Russian potential. Information about this can be found on the website of the rating agency "Expert RA". Note that the methodology for calculating this indicator is public.

The agency publishes an annual report with ratings and stages of its determination for all Russian regions. An important aspect is that it is accredited by the Central Bank of the Russian Federation. Currently, the Central Bank of the Russian Federation has accredited only five agencies.

In the process of calculating the investment potential of the constituent entities of the Russian Federation, the rating agency "Expert RA" also determines the factors directly related to the innovative potential of the regions. Therefore, the model included the following indicator - the rank of the region's innovative potential.

Domestic scientists in their studies point to the existence of a direct relationship between innovation and investment activities and the amount of budgetary funding [15-20]. Therefore, the model included a factor that is directly related to budget financing: budget expenditures of a constituent entity of the Russian Federation for applied scientific research in the field of national economy.

Thus, the model includes factors that, for the most part, were not used in the study of innovation and investment development using mathematical modeling. Several factors have been replaced with more appropriate ones or taking into account more activities.

Note that the initial data for the construction of this model were the official statistics, the analytical portal of the Ministry of Finance of the Russian Federation, the website of the Federal Treasury and the website of the Expert RA rating agency.

The study used a sample of 415 observations of the above indicated indicators for the period from 2015 to 2019 of all constituent entities of the Russian Federation. The parameters of the model are estimated using the least squares method. Modeling was performed using the Gretl 1.9.11 software product. The simulation results are presented in the form of the formula (1):

$$Y = -4921{,}66 + 1{,}88 * X1 + 1{,}02 * X2 + 0{,}01 * X3 + 1176{,}3 * X4 + 790{,}01 * X5 - 58{,}27 * X6 - 68{,}83 * X7 + 24{,}28 * X8 , \quad (1)$$

where Y - the volume of innovative goods, works, services, million rubles.

X1 - the cost of technological innovation of organizations, million rubles;

X2 - internal expenditures on research and development in the constituent entities of the Russian Federation, million rubles;

X3 - the number of personnel engaged in research and development, by category for the constituent entities of the Russian Federation, people;

X4 - the proportion of organizations that have carried out technological, organizational, marketing innovations, %;

X5 - the share of the investment potential of the region in the all-Russian potential, %;

X6 - the rank of the region's innovative potential;

X7 - the rank of the investment potential;

X8 - budgetary expenditures on applied scientific research in the field of the national economy, million rubles.

In the resulting model, the coefficient of determination (R-squared) is approximately 0.75. This indicates the average quality of the model. Fisher's criterion (F-test): Fact = 193.99> Ftab. The obtained value of the Fisher criterion reflects the statistical significance of the regression equation, as well as the possibility of its application for the analysis and forecasting of economic processes.

Furthermore, the statistical significance of the regression parameters was checked by the Student's test. The results of the tests revealed that the regression coefficients for the factors X1, X2, X4 are statistically significant, and the rest are not. Similar findings were obtained by using the built-in function of the program "Sequential elimination of redundant variables", supporting the conclusion about the need to exclude variables X3, X5, X6, X7, X8.

Next, a model was built using the least squares method after excluding statistically insignificant factors. The simulation results are presented in the form of the formula (2):

$$Y = -4909{,}54 + 1{,}92 * X1 + 1{,}03 * X2 + 1194{,}13 * X4 \quad (2)$$

In the resulting model, the coefficient of determination (R-squared) is approximately 0.8, which indicates that this model approximates the data well enough and can be used in the analysis and forecasting process. Fisher's test (F-test) also confirms the statistical significance of the regression equation.

Next, we examined the statistical significance of the regression parameters and checked it for multicollinearity. The value of the Student's test indicates that the X4 factor is significant with a probability of 95%, and the X1 and X2 factors - with a probability of 99%. There is no multicollinearity.

As a result of the tests carried out, the model can be recognized as correct and is a theoretical proof of the existence of a relationship between the volume of innovative goods, works and services produced in the country and specific economic indicators.

It should be noted that when constructing the model, the principles of a limited number of factors were taken into account (since with too many factors, the practical value of the model in the form of its ability to reflect the patterns of development of the studied processes decreases) and simplicity of the model (too complex dependencies on a limited time interval can to the detriment of the main to a greater extent reflect the secondary relationships between variables).

Conclusions

Having analyzed the regressors of this model, the following conclusions can be drawn:

1) An increase in the cost of technological innovation of organizations by 1 million rubles. leads to an increase in the production of innovative goods, works, services by 1.99 million rubles, thus acting as a significant factor in increasing the innovativeness of the economy;

2) The internal costs of research and development have a similar effect - as a result of their increase by 1 million rubles. the growth of the volume of produced innovative goods, works, services by 0.93 million rubles;

3) In direct proportion to the volume of innovative goods, works, services, an increase in the proportion of organizations that have carried out technological, organizational and marketing innovations affects.

Currently, the country's innovation and investment system are fragmented, which limits its development even in the face of improved infrastructure. Thus, government initiatives and, accordingly, funding are aimed primarily at industries that can provide a limited impact on the economy (education, science, development of an innovative environment). The transformation of products developed within the framework of state-funded projects into competitive and commercialize ones is difficult due to the low interest of private business in using innovations as the main factor of production and a source of growth.

The share of private funding in R&D spending is low. At the same time, the lack of innovative activity on the part of private companies leads to their loss of positions in competitive markets and the separation of scientific developments from what is required by business.

Small and medium-sized businesses are poorly involved in the creation of innovative goods, works and services, which do not have enough own funds to modernize production and implement innovations and have limited access to financing markets.

In connection with the above, the key factors in the formation of an innovative model of the economy are government efforts to increase the innovation and investment activity of large business. This will create a synergistic effect together with ongoing initiatives to support education and science, as well as the development of financing instruments and simplify access to them, which will make the innovation and investment market more competitive, as well as increase the level of innovation and investment development of the territories.

In the study, a model was built, which is recognized as correct and is a theoretical proof of the existence of a relationship between the volume of innovative goods, works and services produced in the country and specific economic indicators. The list of factors influencing the investment and innovative development of territories remains incomplete and needs further research.

Abstract

Islamic finance has been showing growth in turnover for several decades, and most experts predict positive dynamics in the future. This is due to a number of factors, in the first place, the rapid growth of the Muslim population, which is growing at a significant rate and by 2050 will amount to 2,494 million people. Also, in addition to the population, the economic power of the Muslim states is also growing, which is expressed in the growth in the volume of GDP that is created in the Muslim states. The data reflecting the GDP indicator shows that compared with 1913, the GDP of the Muslim world has grown from 1.5% of the world GDP in 1913 to 10.2% of the total GDP in 2011. In order to forecast and assess the development of Islamic finance, it is important to assess the dependence of the main indicator, reflecting the scale of development of the Islamic financial system - the total assets of Islamic banking on other indicators. The dependence of these indicators is supposed to be determined based on the formation of a correlation-regression model. Based on the model obtained, the following conclusions can be drawn about the influence of such indicators as the number of banks, the number of Muslim population, as well as the number of countries in which Muslim banking operates.

At the same time, in a number of Muslim countries there are problems associated with various political and social crises that periodically occur in Muslim countries. In a number of countries such as Syria, Afghanistan, Iraq there is a civil war. This hinders the development of Islamic finance and the economy in general. The COVID-19 pandemic has had a huge impact on economic development. In this regard, it is relevant to assess the current state and possible new areas of activity of Islamic financial organizations in the world economy.

Keywords: Islamic Finance, GDP, Financial Instruments, Sukuk, Banking, Regression, Correlation, Microfinance, Digital Technologies

Introduction

Islamic finance has been showing growth in turnover for several decades, and most experts predict positive dynamics in the future. This is due to a few factors, in the first place, the rapid growth of the Muslim population, which is growing at a significant rate and by 2050 will amount to 2,494 million people (Gorohov, 2014). Also, in addition to the population, the economic power of the Muslim states is also growing, which is expressed in the growth in the volume of GDP that is created in the Muslim states. The data reflecting the GDP indicator show that compared to 1913, the GDP of the Muslim world has grown from 1.5% of the world GDP in 1913 to 10.2% of the total GDP in 2011 (Gorohov, 2014).

One of the innovations that ensured the growth of Islamic finance was the issuance of bonds such as sukuk, the growth rate of which is constantly growing. This indicates the widespread use of this tool for attracting investment in projects of a state or even interstate scale (Islamic Development Bank, 2018).

Cite this Article as: Aliskerov Murad, Ajdar Ajupov, Anastasia Kurilova and Kirill Kurilov "Current State and New Directions of Activity of Islamic Financial Organizations in The World Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The concept of sukuk is based on the refusal to charge interest when issuing borrowed funds and is justified by a general lock (riba) on loan interest in force in Muslim countries. (Gafarof, Kurilov, Kurilova, 2016; Nomani, 2006). The largest share in Islamic finance is played by such a key player in the Islamic finance market as the Gulf Cooperation Council, which includes countries such as Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and the United Arab Emirates. This region accounts for 45.4% of the total share of Islamic finance (Islamic Financial Service Board, 2019). The second place is occupied by the Middle East region (excluding GCC) and South Asia with a share of 25.9%.

The third place in terms of total assets and financial transactions is held by the South-East Asia region, which has a 23.5% share of the total assets and transactions in the Islamic world.

Africa ranks last in total financial transactions in terms of assets and financial transactions, with a share of 1.6% (Islamic Financial Service Board, 2019).

As for the issue of sukuk as a type of financial instrument, Malaysia is the leader among Muslim countries with the volume of issuance of sukuk bonds in the amount of $ 6.22 billion, or 47.62%.

Next are the countries of the Gulf Cooperation Council: Saudi Arabia - $ 3.50 billion, or 26.74%, the United Arab Emirates - $ 2.12 billion, or 16.26%, Kuwait - $ 500 million or 3.83% and Qatar - $ 497 million, or 3.81%. In the same period, the top five major industries included oil and gas ($ 2.30 billion in transactions), utilities and electricity ($ 2.30 billion in transactions), real estate ($ 1.94 billion in transactions). dollars), transportation (amount of transactions - 1.84 billion dollars), telecommunications (amount of transactions - 1.54 billion dollars).

It should be noted that the volume of assets and banking operations in the Islamic financial system is growing rapidly. Thus, according to the state in 3Q19, Islamic banking assets increased by 12.7% and amounted to 72.4% of the total volume of Islamic banking assets and operations. Transactions in securities, including sukuk and funds, increased by 23.5%, while the share of Muslim insurance increased by 3.2%. At the same time, the share of insurance operations in Islamic finance is still insignificant, about 1.1% of the total volume of operations and assets (Islamic Financial Service Board, 2019).

Formulation of the problem

In order to forecast and assess the development of Islamic finance, it is advisable to assess the dependence of the main indicator reflecting the scale of development of the Islamic financial system - the total assets of Islamic banking on other indicators.

Table 1: Dynamics of indicators of development of Islamic banking, prepared by the authors based on data Islamic Financial Service Board, 2019; Gorohov, 2014; Vagitov & Igonina, 2014.

Year	Total assets of Islamic banking, billon USA doll.	Number of Islamic banks, units	Number of Islamic windows, units	Muslim population, million people	Number of countries where Islamic banking operates, units
2007	505	362	163	1235	39
2008	639	420	194	1359	44
2009	822	435	197	1547	49
…	…	…	…	…	…
2019	1768	644	238	1986	62

To assess the dependence of the total assets of Islamic banking, we will use indicators such as the number of Islamic banks, the number of Islamic windows (units serving visitors in accordance with Sharia norms), the number of Muslim population, etc., the number of countries in which Islamic banking operates. The data presented in Table 1 were obtained based on data published by the Islamic Financial Service Board, 2019; Gorohov, 2014; Vagitov & Igonina, 2014, as well as their own forecasts and calculations.

Results

The performed calculation of the correlation of the indicators indicated in table 1 to the total assets of Islamic banking made it possible to obtain a matrix of paired correlation coefficients in table 2.

Table 2: Pairwise correlation coefficient matrix

Index	Total assets of Islamic banking, billon USA doll. (Y)	Number of Islamic banks, units (X1)	Number of Islamic windows, units (X2)	Muslim population, million people (X3)	Number of countries where Islamic banking operates, units (X4)
Total assets of Islamic banking, billon USA doll. (Y)	1				
Number of Islamic banks, units (X1)	0,990	1			
Number of Islamic windows, units (X2)	-0,745	-0,781	1		
Muslim population, million people (X3)	0,983	0,974	-0,673	1	
Number of countries where Islamic banking operates, units (X4)	0,976	0,965	-0,623	0,992	1

Analyzing the data of the matrix of paired correlation coefficients, we can conclude that there is a strong positive relationship (more than 0.97) between the total assets of Islamic banking, the number of Muslim population and the number of countries in which Muslim banking operates. The number of Islamic windows in which Muslims are serviced according to Sharia law, according to Table 2, has a negative value (-0.745) on the total assets of Islamic banking. Such a negative relationship is associated with an insufficient number of observations, since an increase in the availability of services for the Muslim population would lead to the opposite result, i.e. growth of bank assets.

In a study of Islamic banking conducted by Vagitov & Igonina, 2014, similar data were obtained. However, the level of dependence on the main indicators was lower and did not exceed 0.75. Such differences are explained by an increase in the data series by six observations from 2013 to 2019, as well as a possible change in the strength of the relationship between the indicators.

Let's calculate the parameters of the regression equation (correlation) based on the data obtained. We will calculate the parameters of the regression equation using Microsoft Excel. The calculation results are shown in table 3.

The resulting regression equation, reflecting the dependence of the indicator of total assets of Islamic banking on the factors indicated in Table 1, will have the following form (1).

$$Y = -1064.41 + 1.856 * x_1 - 0.786 * x_2 + 0.403 * x_3 + 12.309 * x_4, \quad (1)$$

Table 3: Model of dependence of total assets of Islamic banking on influencing factors

Index	Coefficient	Standard error	t-statistics	P-value
Const	-1064,690	364,723	-2,919	0,043
Number of Islamic banks, units (X1)	1,856	1,786	1,039	0,357
Number of Islamic windows, units (X2)	-0,786	1,946	-0,404	0,707
Muslim population, million people (X3)	0,403	0,851	0,474	0,660
Number of countries where Islamic banking operates, units (X4)	12,309	33,537	0,367	0,732

Regression statistics are shown in Table 4.

Regression statistics show that the value of the multiple correlation coefficient (multiple R) is 0.993 and is close to one, which shows that the relationship between the factor and the resulting indicator is quite high.

By interpreting the results of the obtained model, the following conclusions can be drawn. An increase in the number of banks by one unit leads to an increase in the total assets of Islamic banks by USD 1.86 billion. An increase in the Muslim population of 1 million leads to an increase in assets of $ 0.44 billion, and an increase in the number of countries in which Islamic banking operates leads to an increase in assets of $ 12.3 billion.

Table 4: Regression Statistics Equation (1)

Index	Coefficient
Multiple R	0,993553282
R-square	0,987148124
Normalized R-square	0,974296248
Standard error	62,41811079
Observations	13

The resulting regression equation allows forecasting the future volume of assets in the Islamic financial system as the influencing factors change.

Conclusions

Analyzing the data obtained as a result of the formed regression equation, we can conclude that the growth of total assets in the Islamic financial system will directly depend on the availability of financial services to consumers - the population of Muslim countries.

Therefore, an important direction in the development of the Islamic banking system will be to increase points of access to financial services through an increase in the number of Islamic windows, as well as through the expansion of microfinance services.

The development of the provision of microfinance services is especially relevant in the context of the fact that today it is necessary to provide access to financial services for more than three million people, mainly the poor, of whom more than 85% live in Bangladesh, Indonesia, Pakistan and Sudan. According to experts, now the sector consists of 300 financial service providers, mainly represented by non-governmental organizations and cooperatives, while the level of involvement of the banking sector in the provision of microfinance services is still low.

In this regard, it is relevant to implement microfinance programs on a digital platform. Lending based on digital technologies is spreading rather quickly. From loan application to credit assessment, loan disbursement and repayment - all transactions and all interactions can be digitized. This transformation will significantly reduce the cost of operations and make these services possible and affordable for everyone (Khvan A.A., Konvisarova E.V., 2017).

A real example of the effective implementation of digital technologies in the financial sector is the Kenyan company M-Pesa, which supplies financial services to subscribers of the mobile operator Safaricom. The service is currently ported to the IBM platform for Vodafone. Within the framework of this system, it is possible to open and close deposits, make payments to other subscribers of the system, as well as use the services of microfinance services, which have become more accessible by reducing the cost of transactions due to the absence of the need to maintain bank offices, as well as cash transactions. The rapid success of this system in Kenya allowed the system to be scaled up to two more countries, Tanzania and Afghanistan. Also, this system is being implemented in South Africa, since in this country 13 million economically active residents do not have a bank account.

Thus, the participation of Islamic financial organizations in the organization of a digital platform would add to equation (1) another additional factor that affects the total volume of Islamic banking assets - the number of active users of mobile payment systems. The widespread introduction of this area would make it possible to quickly bring microfinance services to most of the population and obtain a positive economic and social effect.

It should be noted that most of the Muslim countries have become the arena for the development of regional and global social and political crises, which have caused the emergence of multimillion strata of the population from the category of refugees, have set new requirements to meet the needs of various categories of clients. Small entrepreneurs and businessmen found themselves on the verge of bankruptcy in the countries affected by these crises. More than 30 million refugees around the world, mostly related to Islamic countries, have either completely lost access to financial services, or have it in a very limited format. According to statistics, the largest number of refugees are natives of Muslim countries: Afghanistan, Somalia, Syria and are in neighboring Muslim countries. Accordingly, if not for this factor, the current growth rates of the world Islamic finance market would have had even higher rates (Koren A.V., Pustovarov A.A., 2018).

While highlighting the importance of this issue, it should be noted that the United Nations High Commissioner for Refugees (UNHCR) has introduced the possibility of a loan guarantee for microfinance service providers who work specifically with refugees. Another surprising innovation in response to humanitarian disasters has been the use of money (cash, electronic) instead of first aid supplies. Such cash transfer programs are obviously different from microfinance programs, where recipients are expected not to repay the disbursed funds. These financial services are designed for a short time, but they highlight the importance of gaining access to finance as one of the UN's sustainable development goals. The implementation of such programs would not only ensure the successful development of the Islamic financial system but would also provide financial services and support to the population of countries such as Syria, Palestine, Iraq in which there is an open war or martial law. In the future, as the situation stabilizes in countries and regions with a tense political and social situation, the payment system available to most of the population would become the basis for future economic growth.

Abstract

This paper deals with the investigation of the relationship between tourism and economic growth. The research theoretically proved modern tourism was a wide-spread dynamic industry with high impact on economic development, damaged by COVID-19 crisis. This paper aims to analyse changes in the tourism industry to forecast recovering of tourism activity in the view of quarantine restrictions. For achieving the goals, the authors used the extrapolation model ARIMA. The object is the routs plotting requests of Apple users in Poland, Estonia, Latvia, Lithuania, Hungary and Czechia from 13 January to 9 May 2020. The forecast has been conducted under several conditions as follows: 1) without the introduction of quarantine restrictions from 11.03.2020; 2) taking into account the quarantine restrictions on movements. The findings demonstrated that the adopted quarantine measures have a significant impact on overcoming the recession in the tourism industry in conditions of economic, social and political tension. Herewith, there is a slight positive tendency in recovering tourism. The results provide background for future researchers on developing a strategy to overcome the tourism recession.

Keywords: COVID-19, Domestic Tourism, Economic Growth, Pandemic, Tourism.

Introduction

The globalisation process with expanding the political, economic, scientific and culture communications is the main trigger for tourism industry development. In turn, the tourism activity allows getting to know better the historical-cultural heritage almost of any country, engage in the customs and traditions of different nations and expand their worldview. Consequently, tourism could be associated with rest, pleasure and new impressions for most of the people.

Cite this Article as: Oleksii LYULYOV, Yana US, Tetyana PIMONENKO, Aleksy KWILINSKI, Tetyana VASYLIEVA, Nataliya DALEVSKA, Jan POLCYN and Viktoriia BOIKO " The Link Between Economic Growth and Tourism: Covid-19 Impact" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

However, tourism is one of the most profitable and dynamic economic industry. The tourism impact enlarges upon the key economic sectors as follows: the production of consumer goods, trade, building, transport and communication, agriculture, etc. Thus, it is a useful tool to improve the economic development of any country or territory due to the increasing the GDP; engaging additional currency; providing additional workplaces involved in the hotel and restaurant complex, transport industry and related industries; developing the related industries; the growth of revenue from taxes into the budgets of all levels; etc. (Pimonenko, et al., 2019; Lyulov, et al., 2018).

Notably, the border openness of countries has increased. In turn, the tourism freedom of Ukrainians estimated by the Henley Passport Index showed a positive tendency (Figure 1). It worth noting on 17 May 2017 the EU and Ukraine signed the agreement on visa-free regime. Herewith, Ukrainians may travel to EU countries with tourism or business goal to 90 days without a visa. Consequently, the number of countries not demanding the visa from Ukrainians increased in 1,56 times. Upon that, since the second quarter of 2020, the Ukrainians may travel to 129 countries without the visa. However, among the analysed countries which have a similar Soviet Union past, the leader is Lithuania while the Lithuanians are free to visit 181 countries as of 2020. Notably that in 2017 more than 14 million foreign tourists visited Ukraine, while the average income from which was 526,5 USD per entrance. Herewith, the tourism industry generated 1.4% of GDP, while provided 1.3% workplaces.

Fig. 1: The Dynamic of the Henley Passport Index of Latvia, Lithuania, Estonia and Ukraine (2006-2020) (created by the authors based on (Henley, 2020)

According to the Travel & Tourism Competitiveness Index, which reflects the competitiveness of a country's tourism industry by criteria such as business environment, protection and safety, health and hygiene, human resources and labour market, environmental status and others, Ukraine ranked 78th out of 140 in 2019 (Table 1). It should note that compared to 2017, Ukraine rose in the ranking by 10 positions.

At the same time, the competitiveness of Ukraine's tourism industry is lower by 3.2% compared to the global average, while in the EU the competitiveness is higher: in Estonia - by 9.1%, in Latvia - by 5%, in Lithuania - by 3.3%. In turn, the constant leader in this ranking is Spain, whose competitiveness in the tourism sector is higher by 41.4% compared to the global average.

The analysis of the experience of developed countries in tourism indicated that the geographical location of the region, the natural resources, climate conditions as well as the rich historical and cultural heritage are the main factors to attract the tourists. However, the demand generation on tourism services depends on some other factors that could increase or decrease the level of demand (Lyulov & Pimonenko, 2017; Letunovska, et al., 2017):

- economy-wide – the level of material welfare of consumers, developing the programs of improving the tourism industry, engaging the investments, correlation between the working and free time of employees, etc.;
- social and demographical – age, gender, education, profession, social status, condition of marriage, financial situation, residence, etc.;
- cultural and socio-psychological – the psychology of consumption, the priorities in the system of spiritual values, religion, etc.;
- personalised and behavioural – lifestyle, targets, personal characteristics, temperament, preferences, motives, etc.

Table 1: Travel & Tourism Competitiveness Index in 2019
(created by the authors based on (World, 2019))

Country	Rating position	Score	Absolute growth compared to 2017		Absolute growth compared to the global average rate, %
			rating position	score (%)	
Spain	1	5.4	0	0.3	41.4
USA	5	5.3	1	2.6	36.6
Italy	8	5.1	0	1.9	32.2
China	13	4.9	2	3.2	27.2
Thailand	31	4.5	3	2.6	16.9
Turkey	43	4.2	1	2	9.8
Estonia	46	4.2	-9	-7	9.1
Latvia	53	4	1	1.8	5
Lithuania	59	4	-3	1.5	3.3
Egypt	65	3.9	9	7	1.3
Marocco	66	3.9	-1	2.2	1.2
Ukraine	**78**	**3.7**	**10**	**6.5**	**-3.2**

According to the mentioned above, the tourism industry provides a particular region with cash inflows from tourists and increases the turnover of commodities and workplaces. In turn, for developing the tourism industry, it is necessary to implement the following: to provide cooperation between the tourism agencies and regional authority for popularising the region widely; to engage all participants of small business for developing common tourism concept coordinated by the regional authority; to focus on the inhabitants of close big cities and tourists in one day trip or vacation.

Literature Review

The investigation of the tourism impact on economic development is a goal of the significant number of scientific publications. Furthermore, tourism issues concern experts from the different professional field such as marketing, management, culture, medicine, ecology, etc. In turn, the systematisation of scientific publications on the link between economic growth and tourism demonstrates a positive tendency of publication activity. In the frame of this article, 1698 publications indexed by the Scopus database were analysed. The search was conducted by the keywords "economic growth" and "tourism" in the title, abstracts and keywords of publication. The limitation criterion was published articles in the period from 2000 to 2020.

According to Figure 2, the number of scientific publications in investigating the economic growth and tourism relationship presented in the Scopus database increased by more than 21 times in 2019 related to 2000. Moreover, the most massive part of documents was published by scientists from the USA (12%), China (11%), Great Britain (7%) and Malasia (7%). It worth noting than the link between tourism and economic growth is investigated in different subject areas as following in the field of social science (28%), Business, Management and Accounting (24.3%), Ecology (11%), Economics, Econometrics and Finance (9.7%), etc.

Fig. 2: The Dynamic of Publication Activity on the Link between Tourism and Economic Growth
(created by the authors using Scopus tools)

To deeper investigate the thematic directions of analysed publications, the bibliometric analysis was conducted using the VOSviewer tool. It worth noting that this tool allows building the network map on the base of the keywords co-

occurrences in the investigated publications. Moreover, it visualises the co-occurrence links with other keywords and calculates the total strength between them(Us, et al., 2020). Thus, set a limitation criterion minimum 5 of occurrences of keywords and excluding the irrelevant keywords, the network map was built with 249 items grouped in the clusters (Figure 3). In turn, the network map of keyword demonstrates different combination variants of the keywords as inside, so outside the cluster. It worth noting that different colours highlighted the specific cluster. Furthermore, the size of circles indicates the frequency of appearing the keyword in the scientific documents. Then, the bigger the diameter of the circle is, the more frequent the keyword is used. Herewith, the distance between circles indicates the link strength between two items.

Fig. 3:The Network Map of the Theme Directions of Scientific Publications on Link between Tourism and Economic Growth (created by the authors using VOSviewer tool)

Following Figure 3, the network map consists of 9 clusters, which combine the investigate keywords on thematic closeness. Herewith, the most significant red cluster (61 items) is directed on research in the relationship between tourism and environmental issues. In turn, the green cluster (49 items) is intended to investigate the link between economic growth and tourism development. Then, the blue cluster (48 items) aimed at research on economic development, tourism and climate change.

In turn, the most articles on investigating the link between tourism and economic growth were published in scientific journal sa follows *Tourism Economics (Q1), Tourism Management (Q1), African Journal Of Hospitality Tourism And Leisure (Q3), Current Issues In Tourism (Q1), Journal Of Sustainable Tourism (Q1), Journal Of Travel Research (Q1), Tourism Analysis (Q2),* etc.

In turn, the summarisation of literature resources allowed selecting the significant number of scientific publications which are one of fundamental for tourism development. In turn, (Kmeco et al., 2019; Krajcik et al., 2019; Tyelyetov et al., 2012) dedicated to the investigations of the economic essence of tourism. While analysis of the tourism industry impact during the longterm period is researched in work (Tovmasyan, 2019). It worth noting, in the articles (Kljucnikov, et al., 2020; Lee, et al., 2013; Preechawong, et al., 2019; Lyulyov & Shvindina, 2017) the authors indicated in the linear relationship between economic growth and tourism development. Furthermore, in the frame of the articles (Chygryn et al., 2020; Bogachov et al., 2020; Dalevska et al., 2019; Dementyev & Kwilinski, 2020; Tkachenko et al., 2019a; 2019e; Boiko et al., 2019; Kuzior et al., 2019; Kwilinski et al., 2020a; 2020b; 2020c; Lakhno et al., 2018; Kharazishvili et al., 2020; Kondratenko et al., 2020; Dzwigol. 2019a; 2019b; 2020a; 2020b; Pająk et al., 2016; 2017; Dzwigol & Wolniak, 2018; Dzwigol & Dzwigol-Barosz, 2018; 2020; Ponomarenko 2018a; 2018b; 2018c; 2019; Dzwigol et al., 2019a; 2019b; 2019c; 2019d; 2020; Prokopenko et al., 2015; 2018; 2019a; 2019b; Kwilinski et al., 2020a; 2020b; Miśkiewicz, 2018; 2019; 2020a; 2020b; Miskiewicz & Wolniak, 2020; Bilan et al., 2019a, 2019b) the authors investigate the longterm relationship between tourism, digital economy, CO2, the foreign direct investments and economic growth. In particular, the researchers noted that the state of the tourism industry, the

foreign direct investments and CO2 level have a positive impact on the economic development, while the tourism and foreign direct investments negatively influence on the level of CO2. The authors in the papers (Czyżewski et al., 2019; Furmaniak et a., 2018; 2019a; 2019b; Kwilinski, 2018a; 2018b; 2019; Kwilinski et al., 2019a; 2019b; 2019c; 2019d; 2019e; 2019f; 2019g; Kwilinski & Kuzior 2020; Prokopenko, O., & Miskiewicz; Tkachenko et al., 2019b; 2019c; 2019d; Saługa et al., 2020; Savchenko, 2019) analysed the impact of industrial companies development on economic development and tourism in the region. The researchers Shubert S., Brida J., Ricco V. in the publication (Schubert, et al., 2011) noted that increasing the demand for tourism services lead to the improving of the economic situation and expanding the partnership between countries. The special attention is paid to investigating the state and opportunities of the Ukrainian tourism industry as well as its influence on the economic development in work (Teletov et al., 2012).

Li, et al., 2006	United Kingdom	TVP-ECM (error correction models and time-varying parameter)	Modelling tourism demand focusing on spending per tourist.
Kulendran & Dwyer, 2012	Australia	BSM (the Basin Structural Model)	Modelling the seasonal number of visitors in tourism depending on climate issues.
Kulendran & Shan, 2002	China	The naïve "No Change" model	Modelling the tourism demand in the view of Chinese "open door policy".

The systematisation of scientific publications in tourism modelling (Table 2) allowed noting many different econometric models, approaches and techniques used in tourism development forecast. Moreover, the theoretical results allowed to assume there was no single overperformed model to use for forecasting in tourism. In the frame of this article, the ARIMA(*p, d, q*) model was used to make the forecast of tourism recovering from COVID-19 in the view of two scenarios of development.

Methodology

In the frame of this article, the integrate autoregressive model ARIMA(p,d,q) was used to analyse the changes in the tourism industry and develop the short-term forecasts of tourism activity in consideration of the influence of quarantine restrictions. Notably, this model allows accurately reflecting the impact of COVID-19 on the tourism industry on the base of which it is possible to develop the strategy of tourism recovering. Thus, it worth noting, that ARIMA(p,d,q) model is a class of statistical models used to analyse and forecast time series data. Based on the paper (Krukov & Chernyagin, 2011), the ARIMA(p,d,q) model has the following form:

$$(\Delta^d X_t) = \sum_{i=1}^{p} \varphi_i \, (\Delta^d X_{t-1}) + \varepsilon_t + \sum_{j=1}^{q} \theta_j (\Delta^d \varepsilon_{t-j}) \, , \varepsilon_t \sim N(0, \sigma_t^2) \quad (1)$$

The short form of the ARIMA(*p,d,q*) model is:

$$\varphi(B)(1-B)^d X_t = \theta(B)\varepsilon_t \quad (2)$$

where $\varphi(\bullet)$, $\theta(\bullet)$ – polynomials of degree p and q,
B – lag operator ($B^j X_t = X_{t-j}, B^j \varepsilon_{t-j}, j = 0, \pm 1, \ldots$),
d – sequential difference order ($\Delta X_t = X_{t-1} - X_t = (1-B)X_t, \Delta^2 X_t = \Delta^2 X_{t+1} - \Delta X_t = (1-B)^2 X_t, \ldots$).

It worth noting that at the first time the systematic approach to developing ARIMA(p,d,q) model was presented by George Box and Gwilym Jenkins in 1976 (Ma, et al., 2018). Given that, the methodology of developing the ARIMA model consists of several main steps as follows:

1. Model identification that best suits the actual process under consideration.

On the base of calculated estimates for the autocorrelation and partial autocorrelation functions, the preliminary conclusion on the integration order d and the order values of the autoregression operators and the moving average p and q is done.

The primary model describing the stationary process is the autoregressive model with p-order. In turn, the autoregressive process means the dependence on the current level from the previous ones. The autoregression model (AR) p-order is expressed as

$$Y_t = \varphi_0 + \varphi_1 Y_{t-1} + \varphi_2 Y_{t-2} + \ldots + \varphi_p Y_{t-p} + \varepsilon_t, \quad (3)$$

where Y_t – level of time series at the time point t (dependent variable);
$Y_{t-1}, Y_{t-2}, \ldots, Y_{t-p}$ – the levels of time series at the time points $t-1$, $t-2$, …, t – respectively (independent variables);
$\varphi_0, \varphi_1, \varphi_2, \ldots, \varphi_p$ – estimated coefficients;
ε_t – random walks describing the variable impacts unaccounted for the model (3).

The moving average (MA) model is a linear regression of the predicted time series value relative to the current and previous observed variables. Moreover, the random components are expected to be mutually independent and conform to a normal distribution with mean 0.
Thus, the model of moving average q-order is denoted as:

$$Y_t = \varepsilon_t - \omega_1 \varepsilon_{t-1} - \omega_2 \varepsilon_{t-2} - \ldots - \omega_q \varepsilon_{t-q}, \quad (4)$$

where Y_t – level of time series at the time point t (dependent variable);
ε_{t-1} – the values of remains i-time periods (independent variables);
$\omega_1, \omega_2, \ldots, \omega_q$ – estimated coefficients.

In accordance with the above-mentioned models, the combination of the autoregression model (AR) and moving average model (MA) present the model ARMA(p,q) :

$$Y_t = \varphi_0 + \varphi_1 Y_{t-1} + \varphi_2 Y_{t-2} + \ldots + \varphi_p Y_{t-p} + \varepsilon_t - \omega_1 \varepsilon_{t-1} - \omega_2 \varepsilon_{t-2} - \ldots - \omega_q \varepsilon_{t-q}. \quad (6)$$

2. Parameter Assessment on the Base of Regression Methods.

Based on the calculated autocovariance for identified ARIMA(p,d,q) model, the initial estimates of moving averages parameters is done. The parameters are estimated based on the least square's method and the maximum likelihood principle.

3. The Diagnostic Testing the Adequacy of the Model.

The remains of the developed stochastic model (ε_t) are used to diagnose the adequacy of the model. Thus, the model quality and remains uncorrelatedness need testing.

4. Using the Model for Forecasting.

According to the abovementioned, in the framework of this paper, a stationary series were obtained using statistical tests for the presence of a unit root (Augmented Dickey-Fuller unit root test). Since, under the Dickey-Fuller statistics, the initial series was non-stationary. Thus, the operator of taking successive differences was used to go to the stationary series. After obtaining a stationary series, the model was identified by evaluating its parameters. Its series of residuals were analysed to check each trial model for adequacy.

Results

As the economy is closely related to tourism development, the significant contraction of tourists is one of the reasons for increasing poverty and economic crisis. It worth noting, several scenarios of economic influence on the tourism industry can be: 1) direct (generating the income from business in the hotel and restaurant business, transport sphere and tourism organisations); 2) indirect (investing in the tourism industry); 3) indicative means the spending the income by the beneficiaries of direct and indirect influences such as the owner of the organisation, employees, etc. (Vasylieva, et al., 2017).

According to the statistical data, 2019 year was one of the most prosperous for tourism and became the trigger for economic development and increasing employment rate. In general, tourism income was 10.3% of global GDP (8.9 USD trillion). Furthermore, the tourism industry provides over 330 mln workplaces (1 out of 10 employees works in the tourism industry). In turn, the total investments cost in the tourism industry was 948 USD billion (4.3% of total investments) (Report, 2019).

In turn, the analysis of statistical data shows that people in Ukraine travel much less compared to ones in EU countries. Thus, in 2018, citizens of Ukraine made 4.48 million trips within Ukraine. This number of trips indicates only about 11% of Ukrainians travelled both inside and outside Ukraine, while in 2015 the corresponding share was less than 5%.

Unfortunately, a significant decline in the number of tourist trips by Ukrainians was in 2014-2015 as a consequence of the political crisis in 2013 and the military conflict in the east part of the country. Following Figure 4, among the analysed EU countries, the most significant number of trips was made by Estonian citizens where one resident had about 6 visits in 2018, while by Lithuanian and Latvian – about 2 visits.

Fig. 4: The Internal and External Trips of Ukrainians, Estonians, Lithuanians and Latvians (2012-2018) (created by the authors based on data of Eurostat (2020), SSC of Ukraine (2020)

However, tourism development has fallen under the influence of the pandemic COVID-19 since the end of 2019. Thus, wide-spreading the virus and implementing the quarantine measures on the global level caused slowing the tourism activity (Figure 5). Following the data of the World Tourism Organization (WTTC), the entrances entirely or partly were forbidden on 96% directions of April 2020. It worth noting all counties of Africa, Asia and Pacific as well as the Middle East, 93% of EU countries and 92% countries of Americas imposed limitations on the movements of people because of COVID-19 spreading.

Fig. 5: Changes in Destination Dynamic of International Tourists by the World Regions (% of the previous year) (created by the authors based on (World, 2020)

In turn, there are four main types of limitations to prevent the wide COVID-19 spreading:

1) total or partial borders closures for international tourists;
2) possibility of access to particular places;
3) absolute or partial prohibition against making flights;
4) quarantine procedures, self-isolation, visa ban, etc.

The analysis of official resources allowed noticing the vast amount of publications on the forecast of COVID-19 influence on the tourism industry as on the national as international levels. In turn, according to the estimates of WTTC, the tourism industry would experience damage of 22 billion USD and cause decreasing world DGP by 30% and increasing the unemployment rate by 2.9%. In turn, the WTTC report on the tourism change impact on COVID-19 indicated that the power of the current crisis caused by COVID-19 is fivefold power than the world financial crisis in 2008. Furthermore, the Bloomberg and International Civil Aviation Organization predicted that aviation activity would be on the brink of bankruptcy (World, 2020).

Table 3: The dynamic pattern of site traffic (from December 2019 to April 2020) (SimilarWeb, 2020)

	blablacar.com.ua	3.85	3.25	3.1	3.35	1.4	-63.54

Nowadays the tourism activity depends on the high level of transport and communication networks, restaurant and hotels complex, social sphere, etc. In turn, the limitation of movements caused by the quarantine regime led to significant losses in the mentioned above spheres. Table 3 demonstrates the traffic dynamic of the company sites providing tourism services by month from December 2019 to March 2020. Thus, the traffic of analysed sites in the category "Air travel" decreased by 68%, while in the category "Accommodation and Hotels" – by 73,2%, "Travel and Tourism" – by 44,7%, "Grounded transportation" – by 69%. According to the analysed sites, the level of demand decreased most of all in the category "Accommodation and Hotels."

Restrictions on international travel, as well as the introduction of quarantine to combat the spread of the COVID-19 pandemic, lead to large-scale losses in the tourism industry. It worth noting that the current crisis has biological nature, and an effective vaccine has not yet been invented to prevent the COVID-19 virus. Thus, the lack of drugs, mass quarantine and large-scale self-isolation has become the main methods of combating COVID-19. Consequently, the freedom of residents' movements in most countries is severely restricted.

Figure 6 displays the dynamics of people moving during the COVID-19 pandemic. The initial data are the requests of plotting the routs by the users of Apple products in Ukraine from 13 January 2020 to 09 May 2020. Thus, with the entry into force of quarantine restrictions, the walkings and drivings declined sharply. At the same time, the lowest number of people walking and driving denoted on 19 April 2020 (-64.66% compared to 13 January 2020), after which there is a positive tendency of movings. Moreover, the number of driving trips remained consistently higher during the investigated period, though much lower than the baseline level on 13 January 2020.

Fig. 6: The Dynamic Changes in the Number of the Request of Plotting the Routs by Apple Users in Ukraine (13.01-09.05.2020) (created by the authors (Apple, 2020).

Thus, based on the ARIMA model, which is one of the most popular extrapolation models, the forecast of several scenarios of the COVID-19 impact on the driving trips by Ukrainians was made upon the following conditions:

1) without the introduction of quarantine restrictions from 11.03.2020;
2) taking into account the quarantine restrictions on movements.

Thus, developing this model provides short-term forecasting of change of inquiries of inhabitants of Ukraine concerning laying of routes for movement by vehicles. In general, the built forecast can be used in making management decisions to develop a strategy for overcoming the tourism recession.

Thus, the empirical study was conducted using EViwes software based on daily requests from users of Apple products in the routing of routes within Ukraine from 13.01.2020 to 09.05.2020. The dynamics of the studied series is shown in Figure 7.

		t-Statistic	Prob.*

Fig. 8: The First Differences of the Logarithmic Time Series (Augmented Dickey-Fuller Unit Root Test)
(calculated by the authors)

Thus, since the dynamics of requests was unstable, the forecast model development may be inaccurate. In this regard, the studied time series was reduced to a stationary one using the first differences of the time series logarithm (Figure 9). As a result, the time series is stationary and can be used to build the ARIMA model forecast.

For the first development scenario, we will analyse the dynamics of requests in the case when the people in Ukraine would not be limited to quarantine measures from 12 March 2020 and continue their usual way of life. The data for the study were selected from 13 January to 11 March 2020.

Fig. 10: The Forecast of the Number of the Requests of Plotting the Routs by Apple Users in Ukraine without Quarantine Restrictions (from 13.01.2020 to 11.03.2020)

In turn, Figure 10 demonstrates the short-term forecasting the requests dynamics of Ukrainian residents in laying travel routes by vehicles until 11 May 2020 according to data from 13 January 2020 to 11 March 2020, while in Figure 11 – until 11 July 2020 based on data from 13 January 2020 to 11 May 2020.

Fig. 11: The Forecast of Number of the Requests of Plotting the Routs by Apple Users in Ukraine with Quarantine Restrictions (from 11.03.2020 to 11.07.2020)

Fig. 12: The Forecast of the Number of the Requests of Plotting the Routs by Apple Users in *a)* Czechia; *b)* Poland; *c)*Estonia; *d)* Hungary; *e)* Latvia; *f)* Lithuania in Case of Quarantine Restrictions (from 09.05.2020 to 10.07.2020)

Thus, the obtained results of the forecast indicate that the adopted quarantine measures had a significant impact on the movement of residents within investigated countries. Particularly, if the quarantine measures were not introduced from 12.03.2020 and the population continued to live a normal life, the trend of movement would have rapid growth and did not have a significant impact on tourism in Ukraine. However, the second development scenario, subject to the introduction of quarantine restrictions from 09.05.2020, indicates that the dynamics of population movement will have a slightly positive trend that slowed down the tourism activity.

Figure 12 demonstrates the forecast models for EU countries which allowed assuming if the quarantine proceeds, the tourism activity would totally recess. Thus, it is strategically important to: form a reliable image of the investigated countries and increase the competitiveness of the tourism market; forme new proposals, ensuring a high level of hygiene and safety; attract innovative management methods and active use of modern information technology.

Conclusions

The systematisation of scientific resources indicated a growing publication activity on the link between tourism and economic growth. Notably, the bibliometric analysis based on the VOSviewer tool allowed to identify 9 clusters demonstrating the thematic areas of scientific publications in the investigated field. It worth noting that the most massive cluster (61 terms) aimed at studying the relationship between tourism and environmental issues. In turn, a slightly smaller cluster (49 terms) mainly indicated the study of economic growth and tourism development. The third big cluster (48 terms) is thematically focused on research in the field of economic development, tourism and climate change.

In the frame of this work, it was established that the tourism industry played a significant role in the economic growth of any country. However, nowadays the tourism sector is one of the worst-affected by the outbreak of the COVID-19 pandemic. Moreover, measures taken to combat the COVID-19 pandemic have harmed economic growth and have significantly restricted population movement, both inside and outside the country.

The development of domestic road tourism is one of the areas of recovery of the tourism sector. Given that, the paper predicts possible scenarios for the development of the tourism industry in Ukraine and EU countries of post-soviet past (Latvia, Lithuania, Estonia, Poland, Czechia and Hungary) during the pandemic COVID-19 based on the dynamic requests for routs plotting by Apple users in Ukraine (from 13 January to 9 May 2020). The development of domestic automobile tourism is one of the areas to begin recovering of the tourism sector. Based on the ARIMA model, the authors developed the possible scenarios for the development of the tourism industry of Ukraine during the pandemic COVID-19. The model was based on the number of the Apple users requests for plotting the routs in Ukraine from 13 January 2020 to 9 May 2020. In turn, the obtained results of the forecast indicated that the adopted quarantine measures have a significant impact on overcoming the recession in the tourism industry in conditions of economic, social and political tension.

Funding

The research was funded by the grant from the National Research Foundation of Ukraine “Economic and mathematical modelling and forecasting of the COVID-19 influence on Ukraine development in national and regional contexts: public health factors and socio-economic and ecological determinants” ID 2020.01/0181) and Ministry of Education and Science of Ukraine (№ g/r 0120U102002) .

Abstract

This study summarizes the existing world experience on scientific and methodological approaches for assessing the macroeconomic stability of the national economy. The systematization of the scientific background allowed concluding the absence of unitized terminological apparatus to define the concept of macroeconomic stability. This study aims to develop the methodology of integrated assessment of the level of macroeconomic stability of the national economy under improving its conceptual bases. The object of this study is country Ukraine, its neighbour countries and countries that have recently joined the EU. For data processing, the authors used the program of statistical analysis Stata 14. The analysis of macro stability indicators was conducted at different stages of the economic cycle: 1) pre-crisis period (2000–2006); 2) crisis period (2007–2010); and 3) the post-crisis period (2011–2017). The authors proposed the methodology for the integrated assessment of the level of macroeconomic stability of the national economy based on the concept of the pentagon model of macroeconomic stability. Therefore, this model considered five main guidelines of state stabilization policy as follows: 1) GDP growth; 2) unemployment rate; 3) inflation rate; 4) external debt; 5) state budget balance. The obtained results of testing the proposed approach for assessing the level of macroeconomic stability allowed concluding that the largest level of decline in the static indicator of macroeconomic stability of the national economy in 2011-2017 was in Ukraine and Serbia. The authors noted that results of this study are considered to be the base for future investigations aimed at improving the conceptual bases of integrated assessment of the level of macroeconomic stability of the national economy.

Keywords: Macroeconomic Stability, Economic Growth, Index of Macroeconomic Stability, Pentagon Model

Introduction

In the conditions of uncertainty and extreme variability, the current trends in the national economy of Ukraine require the identification of qualitative and quantitative criteria of macroeconomic stability of the national economy to timely assess and neutralize the adverse effects of their convergent and divergent influences.

In turn, timely detection of negative trends of the qualitative and quantitative criteria changes of macroeconomic stability allows responding promptly to internal and external shocks and increase the level of competitiveness.

Cite this Article as: Oleksii LYULYOV, Tetyana PIMONENKO, Aleksy KWILINSKI, Yana US, Olena AREFIEVA, Oleksandr AKIMOV and Denys PUDRYK " Government Policy on Macroeconomic Stability: Case for Low- and Middle- Income Economies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Moreover, that goes to accelerate economic growth. However, it is essential to select a set of indicators that intimate the level of macroeconomic stability.

According to the image recognition theory, the main requirements for the selection criteria of the set of indicators are:

1. Regulatory and compliance with recognized and adopted regulations, which provide not only the fact of enshrining them in official statistics but also regulatory approval of the methodology of their collection (regardless of whether these indicators are statistics, sociological research or observation materials).
2. The possibility of empirical measurement. Thus, there should be the possibility to quantify the criteria.
3. Have high reactive informativeness, which provides fast and timely information about the activation of possible factors.
4. Have the property of holistic. Herewith, on the one hand, they are self-sufficient for the indicative reflection of a manifestation of a threat. However, on the other hand, in combination with other indicators, they can indicatively reflect another threat occurs that could not be displayed by no single indicator.

However, the systematization of the scientific background allowed concluding the absence of unitized terminological apparatus to define the concept of macroeconomic stability. In turn, it is one of the reasons for the lack of a single accepted by all researchers and experts way to solve the problem of choosing a set of indicators and method of measuring and assessing the level of macroeconomic stability of the national economy.

This study aims to develop the methodology of integrated assessment of the level of macroeconomic stability of the national economy under improving the conceptual bases of integrated assessment of the level of macroeconomic stability of the national economy.

Literature Review

The vast number of scientists devoted investigated the issues on the development, selection of requirements (criteria) for many indicators of estimating the macroeconomic stability of the national economy as the main subject. In turn, Ismihan M. (Ismihan et al., 2005) proposed to assess the level of macroeconomic stability using the unified indicators of inflation, public debt, external debt and exchange rate volatility. In the investigation (Suntsova, 2012) the author proposed to choose the parameters of assessing the macroeconomic stability of the national economy based on evaluating the macro-financial stability of the state and conduct it in the following stages:

1. Polycriteria assessment of the level of socio-economic development.
2. Grouping of key macro-financial indicators.
3. Evaluation of exogenous and endogenous effects.
4. Interpretation of the obtained results and development of recommendations.

The starting basis for the analysis of selected indices is International Financial Statistics (International Financial Statistics), official data of the Ministries of Statistics of a particular country and statistics of central banks of the respective countries (Suntsova, 2012).

In the paper (Radionova, & Malkovskaya, 2017) Radionova I. evaluated the results of macroeconomic policy by deviations from the equilibrium values of macroeconomic variables, which is based on the neoclassical idea of general equilibrium as a result of the interaction of aggregate markets. Moreover, the researcher noted that "the implementation of this approach involves certain stages of analysis as follows: the formation of time series of variables, construction of regression equations and evaluation of their quality, determining the equilibrium values of variables and estimating deviations from the actual values of macroeconomic variables.

Furthermore, the researchers Najarzadeh R. and Shahri V. propose to use the indicator of GDP volatility as an indicator of macroeconomic stability. In the papers (Lyulyov, 2018a; Iqbal, & Nawaz, 2010; Martínez-Vázquez, & McNab, 2006; Wanta, 2018; Lyulyov, 2018b), the scientists used the Misery index, which is the sum of the unemployment rate and the inflation rate, as the main parameters of macroeconomic stability.

Jaramillo L. and Sanchak C. (2007) and Kordos M. (2019), studied the index of macroeconomic instability, which combines inflation, budget deficit, exchange rate volatility, and loss of international reserves.

The scientists Kvasha T. and Stepashko V. proposed to follow the principle of complexity and systematics when choosing a set of indicators. That is, for selecting a system of indicators that comprehensively characterize the state of the system and helps to adjust it based on the formation of various tools and mechanisms (Lyulyov, 2017; Liulov

et al., 2020; Chygryn et al., 2020; Bogachov et al., 2020; Dalevska et al., 2019; Dementyev & Kwilinski, 2020; Dzwigol, 2019a; 2019b; 2020a; 2020b; Dzwigol & Dźwigoł-Barosz, 2018; 2020; Kondratenko et al., 2020; Kwilinski, 2018a; 2018b; 2019; Lakhno et al., 2018; Miskiewicz, 2018; 2019; 2020a; 2020b; Ponomarenko et al., 2018a; 2018b; 2018c; 2019; Prokopenko et al., 2015; 2018; 2019a; 2019b;; Prokopenko & Miskiewicz, 2020; Tkachenko et al., 2019a; 2019e). The authors in the investigations (Bilan et al., 2019a; 2019b; Bublyk et al., 2017; Kotenko et al., 2015; Pająk et al., 2016; 2017) proved that shadow economy and financial stability had negative impact on the macroeconomic stability and economic growth. The authors in the paper proved the linking between macroeconomic stability, innovation development and investment climate in the country (Lyulyov et al., 2017). Thus, the linking among green investment, innovation development (Lipkova et al., 2016) and economic growth as a main indicator of macroeconomic stability was confirmed in the papers (Dkhili, 2018; Lyulyov et al., 2017; Pimoenenko et al., 2018; Pimonenko, 2018; Pimonenko et al., 2017a; 2017b; Masharsky et al., 2018). The scientists in the papers (Harafonova et al., 2017; Boiko et al., 2019; Dzwigol et al., 2019a; 2019b; 2019c; 2020a; 2020b; 2019b; Furmaniak, et al., 2018; 2019a; Kharazishvili et al., 2020; Kwilinski et al., 2019a; 2019b; 2019c; 2019d; 2019e; 2019f; 2019g; Kwilinski & Kuzior, 2020; Kwilinski et al., 2020a; 2020b; 2020d; Miskiewicz & Wolniak, 2020; Saluga et al., 2020; Savchenko et al., 2019; Tkachenko et al., 2019b; 2019c; 2019d; Liubkina et al., 2019) proved that level of macroeconomic stability of the country influenced on the stable development of the industrial sector. In the papers (Kvitka et al., 2019; Dźwigoł et al., 2018) the scientists proved that education, research and development were the core indicators of macroeconomic stability.

In the report on the international experience in calculating macroeconomic indicators and their use, Sanjay Kalre identified the following criteria: 1) indicators should consider the specifics of the country; 2) have a clear economic significance; 3) wide statistical coverage; 4) consider cyclical behaviour (Kalra, 2012).

Methodology

A comparative analysis of the theoretical basis for assessing the level of macroeconomic stability of the national economy showed that using the concept of macroeconomic stability pentagon fully allows meeting the requirement to ensure the reliability of comparisons of different countries and achieve the main goals of stabilization policy.

The director of the Institute of Finance in Warsaw, Professor of Economics Grzegorz W. Kolodko (Kolodko, 1993) proposed a model of the pentagon of macroeconomic stability "Macroeconomic stabilization Pentagon" (MSP). This model is designed to assess the level of economic development, considering internal and external imbalances. The model of the pentagon of macroeconomic stability is based on the calculation of five key indicators that reflect the five signs of macroeconomic stability, viz:

- the growth rate of GDP (r);
- the unemployment rate (U);
- the inflation rate (CPI);
- balance of the state budget to GDP (G).
- balance of current turnover to GDP (CA) (Kolodko, 1993).

The MSP provides the country's achievement under five goals of macroeconomic stability: 1) stable economic growth, measured by the growth rate of GDP; 2) increasing in employment while decreasing in unemployment; 3) increasing the internal balance by reducing inflation rate, 4) providing a balanced state budget, which can support the financing of domestic debt without inflationary effects 5) maintaining the current account balance at a level that allows reducing external debt. The indicators mentioned above represents the apex of the pentagon (Figure 1).

Fig. 1: The Pentagon of Macroeconomic Stability "Macroeconomic Stabilization Pentagon"
Source: developed based on (Kolodko, 1993).

However, the analysis of macroeconomic stability based on the MSP model has a static character. Thus, it does not consider the fluctuations of MSP indicators components and the risks of losing their stability. It should note that the obtained results of the analysis indicated the cyclical interaction and interdependence of indicators of macroeconomic stability of the national economy.

Based on the review of the basic concept of the pentagon model for assessment of macroeconomic stability developed by Gz. Kolodko and modified by K. Zaman and B. Derlik (Zaman, & Drcelic, 2009), G. Hurduzeu and M. Lazar (Hurduzeu, & Lazar, 2015), A. Malina and D. Miersva (Malina, & Mierzwa, 2014), J. Pedraza (Pedraza, 2012), R. Ionita (Ionita, 2015) and others, it follows that the above concepts consider the cyclical fluctuations of indicators for assessing the macroeconomic stability of the national economy.

In this regard, for eliminating the disadvantage, this study proposed a three-step approach to assessing the level of macroeconomic stability of the national economy: 1) Assessment of the static indicator of the level of macroeconomic stability of the national economy for the i-th country (MSi); 2) Evaluation of the cyclic component of the MSc; 3) Assessment of macroeconomic stability of the national economy.

The first stage is to determine the static component of the macroeconomic stability of the national economy based on the modified pentagon model (Zaman, & Drcelic, 2009):

$$MS_i = \sum_{j=1}^{n} A_j = \sum_{j=1}^{n} \left(\frac{X_j - X_{min}}{X_{max} - X_{min..}) \times 10}\right) \quad (1)$$

where A_j – normalized value j-component of the synthetic indicator MS; X_j – real value j-component of the synthetic indicator MS; X_{max} та X_{min} – maximum and minimum values of the synthetic indicator MS.

The maximum level of the static indicator of macroeconomic stability can reach 50. In turn, the value of each sub-index cannot exceed the level of 10. Table 1 presents the thresholds of the static indicator MS.

Table 1: The thresholds of the static indicator MS

THRESHOLDS	LEVELS
MS is (40;50]	the high level of economic stability
MS is (30; 40]	stable economy
MS is (20; 30]	semi-stable economy
MS is (10; 20]	the low level of economic stability
MS ≤10	volatile economy

Source: developed by the authors

The second stage is to calculate the deviations of the actual values variables from the equilibrium ones using the Godric-Prescott filter selecting the cyclic component of each of the elements of the synthetic indicator of macroeconomic stability of the national economy. In turn, the arithmetic means of the standard deviations allows considering the negative deviations of the equilibrium values of the parameters from the optimal value.

It should note that considering the standard deviations of the variables would take into account the negative trends that can be offset by the achieved stabilization of all other components. Moreover, it ensures that all MS components have equal sample volatility. Thus, the most stable components do not exclusively control changes in the index. The mathematical formalization of the calculation of these indicators involves the use of formulas (2; 3):

$$Skewness_j = 100 \times \frac{\frac{1}{n}\sum_{i=1}^{n}\left(\frac{x_i - \bar{x}}{\bar{x}}\right)^3}{\left(\frac{1}{n}\sum_{i=1}^{n}\left(\frac{x_i - \bar{x}}{\bar{x}}\right)^2\right)^{3/2}} \quad (2)$$

where Skewness – the asymmetry index of the j-component of the macroeconomic stability indicator (MS); x_i – the value of the respective component of the macroeconomic stability indicator (MS) in the i-period; $\bar{x}$ – the average value of the respective component of the macroeconomic stability indicator (MS) for the analysed period; n – the number of analysed periods.

$$Kurtosis_j = 100 \times \frac{\frac{1}{n}\sum_{i=1}^{n}\left(\frac{x_i - \bar{x}}{\bar{x}}\right)^4}{\left(\frac{1}{n}\sum_{i=1}^{n}\left(\frac{x_i - \bar{x}}{\bar{x}}\right)^2\right)^2} \quad (3)$$

where $Kurtosis$ – the dimension of occurrence of extreme deviations of the j-component of the macroeconomic stabilization indicator (IMS).

Suppose the value of $Skewness$ indicator is close to 0. In that case, it indicates the symmetrical distribution of the j-component of the macroeconomic stability indicator (MS) while the impact of crises or booms would affect its reduction or increase, respectively. In turn, the non-zero value of the asymmetrical indicator (positive or negative) indicates instability. It means the predominance of positive (or negative) shocks.

The analysis of Skewness together with 3 $Kurtosis$ indicators allows completely demonstrate the impact of sharp unusual fluctuations in the country on the components of the macroeconomic stability indicator (MS). Herewith, in the case a symmetrical distribution of the individual components of the macroeconomic stabilization indicator (MS), the $Kurtosis$ indicator is equal to 3 or 300%. The value of more or less than the specified level indicates the tendency of the variable to extreme values. In the frame of the author' approach for assessing the macroeconomic stability of the national economy, it is proposed to calculate the cyclic component by the following formula (4):

$$MS_{cyc_i} = \left(\sum_{j=1}^{n} \sqrt{\frac{1}{T} \sum \left(c_{tj} - mean(c_{tj}) \right)^2} \right) / n \qquad (4)$$

where c_t – the cyclic component of the value of the j-element of the synthetic indicator *MS; mean* (c_t) – the cyclic component of the value of the j-element of the synthetic indicator *MS; T=1…t* – period for analysis.

$$c_t = X_t - \tau_t \qquad (5)$$

where X_t– the actual data of the value of the j-element of the synthetic indicator *MS*; τ_t – trend component.

The trend component is extracted from the actual data series y_t by solving the expression:

$$\min_{\tau_t} \sum_{t=1}^{T} ((y_t - \tau_t)^2 + \lambda((\tau_{t+1} - \tau_t) - (\tau_t - \tau_{t-1}))^2) \qquad (6)$$

The last stage is to calculate the ratio of static and cyclical indicators of macroeconomic stability of the national economy. It allows assessing the conversion of state regulatory policy. Furthermore, for providing a clear idea of the level of macroeconomic stability, it is necessary to conduct a graphical interpretation of the pentagon of macroeconomic stability as well as compare the MS indicator with the sum of standard deviations of MS subindexes considering the distribution asymmetry and extreme deviations.

Results

The first stage of the empirical investigation confirmed the need to consider the cyclical component. In turn, the authors assessed the level of macroeconomic stability of the country using the basic concept of the pentagon for assessing the macroeconomic stability of the country. In this case, the study object is Ukraine, its neighbour countries and countries that have recently joined the EU. For conducting the calculation, it was used the program of statistical analysis Stata 14. Tables 2-4 present the analysis of the MS indicator at different stages of the economic cycle: pre-crisis period (2000–2006), crisis period (2007–2010) and the post-crisis period (2011–2017).

Therefore, in the pre-crisis period, most countries except Croatia and Serbia showed a stable level of macroeconomic stability. Table 2 indicates that the level of IMS achieved in Ukraine in 2003 was the highest in comparison with other analysed countries and amounted to 41.36. Profiles of macroeconomic stability of the analysed countries are presented in Figures 2-4.

a)

b)

Fig. 2: The Pentagon of the Index of Macroeconomic Stability in *A)* Ukraine and *B)* Croatia (2000-2006)
Source: the authors' calculation

At the same time, for the entire pre-crisis period of 2000-2006, Belarus showed the best dynamics of macroeconomic stability (the level of the IMS indicator increased from 32.36 in 2000 to 45.39 in 2006). It should note that in terms of macroeconomic stability, the best IMS indicator for the entire analyzed period was achieved by Belarus in 2006.

Considering the crisis intensity from 2007 to 2010 through the prism of violating the acceptable range of macroeconomic stability, it is clear that the economies of the investigated countries could be divided into:

- crisis-resistant countries: Belarus;
- countries with moderate resilience to crises: Ukraine, Lithuania, Poland, Bulgaria, Georgia, Moldova;
- countries with low resilience to crises: Latvia, Croatia, Romania, Armenia and Serbia.

Source: the authors' calculation

Based on the IMS indicator, the comparison of the macroeconomic stability of the European Union was conducted. Therefore, the findings showed that the economies of Latvia, Lithuania and Poland had become more stable every year since joining the European Union in 2004. This situation had been observed until 2008. However, the financial crisis has negatively affected the stability of the economies of the investigated countries. It should note that from 2011 to 2017, Romania, Poland, and Lithuania significantly reduced the gap between IMS values achieved in the pre-crisis period (2000-2006). Besides, this process was the fastest in Romania. Its economy could be described as moderately stable – 31.40. Despite the low level of the IMS indicator in Croatia (in 2015 it was 19.59), the country's economy had been showing a tendency to improve macroeconomic stability significantly since joining the European Union in 2013.

Thus, the largest decrease in IMS from 2011 to 2017 was registered in Ukraine (17.97), Croatia (19.59), Serbia (19.43). Since 2006, the macroeconomic stability of Ukraine has deteriorated. The situation began to change in 2010-2012, but after 2012 macroeconomic stability began to decline significantly and reached its minimum in 2015. Thus, comparing the macroeconomic stability in 2000-2006 with 2011-2017, the area of the pentagon in 2017 reached minimum value (Fig. 4b).

Table 5 indicates the similarity of macroeconomic stability trends for the investigated countries. According to the obtained data, the highest effects of similarity of macroeconomic stability trends were recorded between Lithuania and Latvia (0.89), Georgia and Latvia (0.88), Bulgaria and Croatia (0.8), Belarus and Croatia (0.86). It indicates about almost ninety per cent coincidence economic growth rate. Armenia, Belarus, and Serbia are among the countries with the highest number of positive pairwise correlation coefficients exceeding 0.7. Negative values in the table indicate an inverse relationship. Thus, the upward trend of one country is accompanied by a downward trend of another. The obtained results of macroeconomic stability have shown an imbalance in the shapes of pentagonal surfaces. In turn, it indicates the growth of the main macroeconomic indicators of countries at different rates. Thus, in particular, the highest average GDP growth in 2000-2017 remained at the level of 6.92% of annual growth, which was demonstrated by the Armenian economy. However, despite the peak growth of this indicator in 2003 to 14.04, the total value of IMS was 25.10. It corresponds to a moderately stable economy. Among other EU countries, this result is impressive. However, it should note that it was achieved against the background of low unemployment, which for the period 2000-2005 reached more than 30%. The lowest average GDP growth in 2000-2015 was in Croatia (1.68%). Although, it should note the positive GDP growth in 2015 against the decline in 2009-2014 (approximately -7.4% in 2009 and - 0.4% in 2014). In turn, Croatia, Latvia and Lithuania have experienced the largest recessions. The Latvian economy decreased by 21% in 2008-2010, and the Lithuanian economy - by 12% in 2008-2009. The average GDP growth in Ukraine for 2000-2017 was 4.03% of annual growth. The period of the significant decline in GDP dynamics was 2009 and 2010, by 14.33% and 3.78%, respectively. It is reasonable to note years: 2005, 2006, 2007, when the economy showed growth of the specified indicator at a high level - to 10% a year.

Source: the authors' calculation

It is worth noting that as a result of the financial crisis, macroeconomic stability has deteriorated in each of the analysed aspects. Thus, the high level of unemployment (about 29%) contributed to the deterioration of the situation in Armenia, and the high level of the budget deficit in per cent to GDP (-12%) and external debt (168% of GDP) to the Latvian economy. The highest inflation rate in the period from 2007 to 2010 was in Ukraine. Analysis of the growth rate of inflation in Ukraine economy has indicated a big problem because in the analysed period its level reached double digits. Thus, in particular, in 2015, the inflation rate rose to 48.72. At the same time, as noted in the study (Vasilyeva, 2013), one of the critical factors in weakening the country's economic productivity is inflation. Besides, it is supported by expanding consumer lending to households, which does not correspond to the macroeconomic level of economic development. As can be seen from Table 6, two of the five indicators of macroeconomic stability in Ukraine are distributed with left-wing asymmetry: real GDP (-1.05); budget deficit (-0.26).

Source: the authors' calculation

However, the most significant negative impact on macroeconomic stability has the indicator of real GDP, because the value of the asymmetry coefficient, which is less than 0.5, can be ignored (Kolodizev & Maksimova, 2016).

Source: the authors' calculation

In addition, it is appropriate to emphasize the presence of right-side asymmetry (Table 7) of each of the indicators of macroeconomic stability in Poland. In turn, it indicates a high probability of favourable deviations in the future.

At the next stage, for considering the negative deviations of equilibrium values of parameters from their optimal value deviations of actual values of variables from equilibrium are calculated.

It should note that low values of the ratio of static indicator MS with the sum of standard deviations of cyclic components of its subindexes indicate a high risk of losing macroeconomic stability and low synchronization of regulatory policies in its main areas (Table 5).

The most considerable level of decline in the static indicator of macroeconomic stability of the national economy from 2011 to 2017 was in Ukraine and Serbia.

Fig. 5: The Calculation of the Level of Macroeconomic Stability for Ukraine, Georgia, Moldova, Armenia, Belarus and Serbia

Source: the authors' calculation

The level of macroeconomic stability of the national economy in Latvia, Lithuania, and Poland has been growing every year since they became the EU members until the crisis of 2008. Besides, Romania, Poland, and Lithuania significantly reduced the gap between macroeconomic stability of the pre-crisis levels in 2011–2015, where this process was the fastest in Romania.

Despite the low entry-level of macroeconomic stability of the Croatian national economy after joining to the EU, the dynamics of its macroeconomic stability has gained momentum.

Therefore, the low level of standard deviations of the cyclical components of macroeconomic stability of the national economy for the EU countries indicates the effectiveness of the conversion of the state policy of these countries on macro stabilization.

Conclusions

The empirical results of this study confirmed the need to consider not only static but also cyclical components for evaluating the level of macroeconomic stability of the national economy. In this regard, the conceptual framework for integrated assessment of the level of macroeconomic stability of the national economy has been improved.

The authors proposed the methodology of the integrated assessment of the level of macroeconomic stability of the national economy. Unlike the existing ones, this methodology based on the concept of the pentagon of macroeconomic stability and consider five main guidelines of state stabilization policy: GDP growth, unemployment, inflation, external debt, state budget balance. Besides, it systematically combines the static component of macroeconomic stability of the national economy and its cyclical component. Moreover, it allows assessing the conversion of state regulatory policy to achieve macroeconomic stability of the national economy. The results of testing the proposed approach to assessing the level of macroeconomic stability showed that the largest level of decline in the static indicator of macroeconomic stability of the national economy in 2011-2017 was in Ukraine and Serbia.

It is determined that the level of macroeconomic stability of national economies of Latvia, Lithuania, Poland has been growing annually since their joining to the EU before the crisis of 2008. Besides, Romania, Poland, and Lithuania significantly reduced the gap between macroeconomic stability of the pre-crisis levels in 2011–2015, where this process was the fastest in Romania. Despite the low entry-level of macroeconomic stability of the Croatian national economy after joining to the EU, the dynamics of its macroeconomic stability has gained momentum. It is established that the low level of standard deviations of cyclical components of macroeconomic stability of the national economies of the EU countries indicates the effectiveness of the conversion of public policy of these countries on macro stabilization.

Funding

This research was funded by the grant from National Research Foundation of Ukraine “Quadrocentric recrusive model of Ukrainian unshadow economy to increase its macroeconomic stability” (Application ID: 2020.02/0238)

Abstract

The results of the national economy functioning determined by the huge complex of factors: structure of the national economic complex, the share of leading industries, the effectiveness of their development and the impact on socio-economic indicators of the country and regions of oil extraction complex. The purpose of the paper is to investigate the scientific approaches to the impact of oil price fluctuations on the economic growth of exporting countries and assessing the interaction of economic growth of the national economy and factors of the oil industry. To study the cointegration and causal relationships of the development of national economy the paper proposed a two-tier approach: on the basis of the heterogeneous modified OLS (FMOLS) model, a linear relationship is established between the indicators of economic development (GDP, capital and labor costs) and indicators of the functioning of the national economy (volumes of oil production and rent payments for oil); the causal links between the economic growth of national economy, the volume of oil production and rent payments are determined by the Granger method based on the developed time series model (VECM), which allows you to adjust the short-term dynamics of parameters depending on the identified long-term relationships between variables and their deviations. The results of the study of cointegration and causal links between the development of the oil industry and the national economy showed that the growth of oil production and the level of rent payments for oil increase GDP for OPEC countries, high and middle-income countries. For countries with low and below average income levels, a 10% increase in oil production leads to a 0.2% increase in GDP. Insignificant economic benefits for this configuration of countries are associated with the lack of systematic modernization of the industry and necessitate a change in the system of state regulation of exploration and use of oil fields, the transition from extensive to intensive development of oil production complex for high value added products.

Keywords: national economy, assessment, oil production, oil prices, oil rent

Introduction

The efficiency of the national economy of any state is determined by the structure of the economic complex, the share of leading industries, the effectiveness of their development and the impact on socio-economic indicators of the country and regions of oil production (Dzwigol, 2020). The relevant assessment becomes especially relevant for the countries - leaders in oil production, where the oil industry is the dominant industry, which largely determines the vectors of development of countries, socio-economic policies, the level of innovation and more. Estimation and econometric modelling of macroeconomic growth models includes a variety of approach methods, ranging from

production functions and vector autoregressions to nonparametric modelling (Klymenko, 2016; Czyżewski, 2019; Hasan, 2019).

Literature Review

Considerable attention of domestic and foreign scientists is focused primarily on the study of the impact of oil price fluctuations on the economic growth of exporting countries (Bhowmik, 2019; Bilan, 2019c; Brychko, 2019; Mishchuk et al, 2020; Kostiukevych et al, 2020). The oil factors of the countries selected for the study have an impact on both political and economic processes, which in turn leads to price fluctuations, investment uncertainty, inflation, changes in the stock market and economic growth of the national economy (Dźwigoł, 2018; Naser, 2019; Vasilieva, 2017; Kalyayev et al., 2019; Akimov et al., 2020). In turn, the works (Bogachov et al., 2020; Boiko et al., 2019; Chygryn et al., 2020; Dalevska et al., 2019; Dementyev & Kwilinski, 2020; Dzwigol, 2019a; 2019b; 2020a; 2020b; Dzwigol & Dzwigol-Barosz, 2018; 2020; Dzwigol et al., 2019a; 2019b; 2019c; 2020a; 2020b; Furmaniak, et al., 2018; 2019a; 2019b; Kharazishvili et al., 2020; Kondratenko et al., 2020; Kwilinski, 2018a; 2018b; 2019; Kwilinski et al., 2019a; 2019b; 2019c; 2019d; 2019e; 2019f; 2019g; Kwilinski & Kuzior, 2020; Kwilinski et al., 2020a; 2020b; 2020d; Lakhno et al., 2018; Miskiewicz, 2018; 2019; 2020a; 2020b; Miskiewicz & Wolniak, 2020; Pająk et al., 2016; 2017; Ponomarenko et al., 2018a; 2018b; 2018c; 2019; Prokopenko et al., 2015; 2018; 2019a; 2019b; Prokopenko & Miskiewicz, 2020; Saluga et al., 2020; Savchenko et al., 2019; Tkachenko et al., 2019a; 2019b; 2019c; 2019d; 2019e) are devoted to sustainability in economic development at various levels of activity, allowing us to analyze the relationship in energy consumption more deeply.

Thus, the first study of the impact of oil prices on macroeconomic indicators of the country was conducted in 1983 by G. Hamilton in "Oil and the Macroeconomy since World War II". The researcher proved that the increase in oil prices has a more significant impact on changes in macroeconomic indicators than its fall (Hamilton, 2009; Abaas, 2018; Augbaka, 2019; Akimova et al., 2020).

R. Jimenez-Rodriguez and M. Sanchez (Jiménez-Rodríguez, 2005) in their work "Oil Price Shocks and Real GDP Growth - Empirical Evidence for Some OECD Countries" based on the use of multivariate VAR-analysis of panel data (formula1), for both linear and nonlinear models , found a significant relationship between oil prices and macroeconomic indicators of OECD countries. At the same time, the authors note different effects on changes in macroeconomic indicators due to lower and higher oil prices for different types of OECD countries: exporting and importing countries (Yevdokimov, 2018; Singh, 2019; Mlaabdal, 2017; Lyulyov, 2019a; Panasiuk et al., 2020). In particular, for importing countries, rising oil prices negatively affect their economic growth, and for exporting countries (UK and Norway) there is a diametrically different nature of the impact: rising oil prices have a significant negative impact on UK GDP growth, while Norway receives benefit from rising oil prices.

$$y_t = c + \sum_{i=1}^{p} \Phi_i \, y_{t-i} + \varepsilon_t \qquad (1)$$

where y_t – vector (n × 1) of endogenous variables (real GDP, effective exchange rate, oil price, wage level, inflation rate, short- and long-term interest rates).

A similar conclusion is reached by scientists (Haque, 2019; He, 2019) studying the relationship between oil prices and macroeconomic aggregates (gross domestic product, consumer prices and unemployment) for 26 OECD countries during 1980-2011 on the basis of econometric methods:

- cross-sectional dependence test:

$$CDLM1 = T \sum_{i=1}^{N-1} \sum_{j=i+1}^{N} \widehat{\rho_{ij}^2} \sim \chi_{\frac{N(N-1)}{2}}, \qquad (2)$$

- root tests:

$$\Delta y_{it} = a_i + \beta_i y_{i,t-1} + \gamma_i f_t + \varepsilon_{it}, \qquad (3)$$

H0: βi=0

H0: βi<0 i=1,2…N1, i= N1+1, N1+2,…N,

- panel integration tests.

The tests confirmed the existence of a long-term relationship between oil prices and macroeconomic aggregates. At the same time, the scientists (Kasztelnik, 2019; Kuzior, 2019) are indicating a statistically significant and negative impact of oil prices on gross domestic product, consumer prices and unemployment.

Omojolaibi J. (Omojolaibi, 2015) conducts his research on the impact of oil prices on the macroeconomic indicators of the oil-dependent country Nigeria for 1985-2010 years:

$$\begin{cases} CPI_t = \sum_{k=0}^{\infty} S_{11}(k)V_{1t-k} + \sum_{k=0}^{\infty} S_{12}(k)V_{2t-k} + \sum_{k=0}^{\infty} S_{13}(k)V_{3t-k} + \sum_{k=0}^{\infty} S_{14}(k)V_{4t-k}, \\ GDP_t = \sum_{k=0}^{\infty} S_{21}(k)V_{1t-k} + \sum_{k=0}^{\infty} S_{22}(k)V_{2t-k} + \sum_{k=0}^{\infty} S_{23}(k)V_{3t-k} + \sum_{k=0}^{\infty} S_{24}(k)V_{4t-k}, \\ M_{2t} = \sum_{k=0}^{\infty} S_{31}(k)V_{1t-k} + \sum_{k=0}^{\infty} S_{32}(k)V_{3t-k} + \sum_{k=0}^{\infty} S_{33}(k)V_{3t-k} + \sum_{k=0}^{\infty} S_{34}(k)V_{4t-k}, \\ OP_t = \sum_{k=0}^{\infty} S_{41}(k)V_{1t-k} + \sum_{k=0}^{\infty} S_{42}(k)V_{2t-k} + \sum_{k=0}^{\infty} S_{43}(k)V_{3t-k} + \sum_{k=0}^{\infty} S_{44}(k)V_{4t-k}, \end{cases} \quad (4)$$

where CRI -inflation, M_2 -money supply, GDP -gross domestic production, V_{it-k} – uncorrelated white noise values, $S_{ij}(L)$ – polynomials of the lag operator.

Structural equation (4) can be transformed into a vector equation:

$$X_t = [\ CPI_t\ GDP_t M_{2t} OP_t] \text{ та } V_t = [V_{1t}\ \ V_{2t}\ \ V_{3t}\ \ V_{4t}] \quad (5)$$

In a study (Cheng, 2017) on the impact of oil prices on Singapore's macroeconomic indicators, the authors found that changes in oil prices have little negative impact on gross domestic product, inflation and unemployment in the country. Another important conclusion is the establishment of a tendency to reduce the intensity of the impact of oil factors in Singapore since 1989 on economic growth (Bilan, 2019a; Kwilinski, 2018).

Ghalayini L. (Ghalayini, 2011) in order to investigate the impact of oil prices on economic growth uses tests on the causality of Granger:

$$GDP_t = C_0 + \sum a_i\, GDP_{t-i} + + \sum \beta_i\, P_{t-i} + \varepsilon \quad (6)$$

$$P_t = C_0 + \sum a_i\, P_{t-i} + + \sum \beta_i\, GDP_{t-i} + \varepsilon \quad (7)$$

where GDP_t – gross domestic product of the study country in the t-th period, P_t – the price of oil of the studied country in the t-th period.

The G-7 and OPEC countries were selected as the objects of Galaini's research (OPEC, (2018). Based on the analysis, the scientist concludes that for most countries there is no interaction between changes in oil prices and economic growth.

The significant influence of these oil factors on economic growth was reflected in the work of M. Mohammed (Mohammed, 2018) using a lag autoregressive model (3.8) based on Angola data for the period 1985-2015, the author concludes about the integrated processes of increasing oil production and economic growth. At the same time, the lack of inverse causality of economic growth to oil production, according to the author, indicates the dependence of Angola on external demand for its oil. Thus, the government needs to pursue a policy of economic diversification in order to minimize adverse global economic shocks associated with a sharp decline in global oil demand (Levchenko, 2018; Lyulyov, 2019b; Pimonenko, 2018; Teletov et al., 2020).

$$\begin{cases} \Delta Y_t = a_0 + \sum_{i=1}^{m} \beta \Delta Y_{t-i} + \sum_{i=1}^{n} \varphi \Delta OP_{t-i} + \theta_1 Y_{t-1} + \theta_2 P_{t-1} + \varepsilon_{1t} \\ \Delta OP_t = a_0 + \sum_{i=1}^{m} \beta \Delta OP_{t-i} + \sum_{i=1}^{n} \varphi \Delta Y_{t-i} + \theta_1 OP_{t-1} + \theta_2 Y_{t-1} + \varepsilon_{1t} \end{cases} \quad (8)$$

where Y – logarithm of the country's GDP, OP – the level of oil production in the country.

However, this result is the opposite of the conclusions of (Tamba, 2017). Based on the annual data for the period 1977–2010, J. Tamba investigated the causal relationship between oil production and economic growth. The results obtained using the vector autoregressive model (VAR) and the Wald test indicate that there is no causal relationship between the variables. In addition, an additional conclusion of the study is the need to introduce a transparent system of oil revenue management in the state, which, accordingly, will contribute to the economic growth of the state in the future (Vasilyeva, 2019; Miśkiewicz, 2020). Another group of scientists concluded that development of the oil complex produces significant environmental damage. To decrease the greenhouse gas emission could be realized through providing renewable energy and implementation the sustainable development principals in the oil industry (Cebula, 2018; Mentel, 2018). In this, case the authors (Chygryn, 2018; Chygryn, 2014; Bilan, 2019b) proved the positive impact of green investment on decreasing GHG emissions and increasing the share of renewable energy.

H. Choi and S. Yoo (Choi, 2016) concluded that the relationship between oil consumption and economic growth in Brazil has a two-way causality. Researchers note that Brazil's economic growth is driven by oil consumption, so reforms to overcome oil consumption restrictions should be implemented to minimize possible reductions in GDP. According to Pakistani scholars (Awan, 2018), such a reform should also be followed by the Government of Pakistan.

Because the results obtained from single-root tests, the joint integration and Granger causality based on error correction models (ECMs) have shown that there is a bilateral causality between oil consumption and economic growth in Pakistan. This means that increasing oil consumption directly affects economic growth (Marcel, 2019).

Alhatlan K. (Alkhathlan, K. A. (2013) conducted a thorough study of the relationship between oil production and economic growth in Saudi Arabia from 1971 to 2010. The paper emphasizes the presence, both in the short and long term, of a statistically significant impact of rent payments from oil production on the real gross domestic product of the country. This study is based on the solution of a system of equations:

$$\begin{cases} y_t = \beta_0 + \beta_1 or_t + \beta_2 inf_t + \beta_3 dco_t + \varepsilon_t \\ y_t = \beta_0 + \beta_1 or_t + \beta_2 inf_t + \beta_3 dco_t + \beta_4 tot_t + \varepsilon_t \\ y_t = \beta_0 + \beta_1 or_t + \beta_2 inf_t + \beta_3 dco_t + \beta_4 tot_t + \beta_5 wr_t + \varepsilon_t \\ y_t = \beta_0 + \beta_1 or_t + \beta_2 inf_t + \beta_3 dco_t + \beta_4 wr_t + \varepsilon_t \end{cases} \quad (9)$$

where y_t – real GDP per capita, or_t – the amount of rent payments from oil, inf_t – inflation, dco_t – the level of domestic oil consumption used in the industrial sector, tot_t – trade openness.

Methodology

To study the impact of the oil industry on the socio-ecological and economic development of the national economy, Ukraine is the object of study, and for comparison - 20 countries that have signed a cooperation agreement for economic, energy, financial and cultural cooperation under the initiative "One Belt and One way "and according to the World Bank are divided into three subgroups:

- high-income and above-average countries (Belgium, Italy, Kazakhstan, the Netherlands, Germany, Poland, Russia, Romania, Turkey, France),
- OPEC countries (Algeria, Indonesia, Iran, Qatar, Kuwait, United Arab Emirates, Saudi Arabia),
- countries with low and below average income (Ukraine, Uzbekistan).

To study the cointegration and causal relationships of the development of national economy in general, the paper proposes a two-tier approach:

1) on the basis of the heterogeneous modified OLS (FMOLS) model, a linear relationship is established between the indicators of economic development (GDP, capital and labor costs) and indicators of the functioning of the national economy (volumes of oil production and rent payments for oil);

2) the causal links between the economic growth of national economy, the volume of oil production and rent payments are determined by the Granger method based on the developed time series model (VECM), which allows you to adjust the short-term dynamics of parameters depending on the identified long-term relationships between variables and their deviations.

$$\text{FMOLS-model: GDP} = \text{F (K, L, OP)} \rightarrow \text{GDP}_{it} = \alpha + \beta_1 K_{it} + \beta_2 L_{it} + \beta_3 OP_{it} + \varepsilon_{it} \quad (10)$$

where GDP_{it} – GDP of the i-th country per capita in period t; K_{it} - capital costs of the i-th in the period t (gross fixed capital formation); L_{it} - labor costs of the i-th country in the period t (economically active population aged 15 years and older); OP_1 - volumes of oil production, OP_2 - volumes of rent payments for oil; β_1, β_2, β_3 - coefficients of elasticity, respectively, capital, labor, oil production; α - the level of technological development of national economy, which is determined by establishing the coefficients of elasticity of capital, labor, oil production, rent payments; ε - statistical error; t - research period; i - country of study.

$$\text{VECM-model: } \begin{cases} GDP_{it} = \alpha_0 + \sum_{i=1}^{m} \beta_{ik} \Delta GDP_{i,t-1} + \sum_{i=1}^{n} \eta_{ik} \Delta OP_{i,t-1} + e_{1t,} \\ OP_{it} = \alpha_0 + \sum_{i=1}^{m} \theta_{ik} \Delta OP_{i,t-1} + \sum_{i=1}^{n} \mu_{ik} \Delta OP_{i,t-1} + e_{1t}, \end{cases} \quad (11)$$

where α_0 – equation constant; $\beta_{ik}, \eta_{ik}, \theta_{ik}, \mu_{ik}$ – calculated system parameters; $\Delta GDP_{i,t-1}$ – change in GDP of the i-th country in the t-th period compared to the previous year; $OP_{i,t-1}$ – change parameters; e – statistical error.

Results

The traditional factors of change in demand and supply of oil on the world market, which forms the level of oil prices include: the scale of oil production; geopolitical position of the main oil-exporting regions; information on the depletion of oil reserves on the planet; oil and oil reserves in oil-importing countries and the level of reserves of oil-

exporting countries; statements by OPEC members on production quotas and price targets; oil infrastructure; environmental problems, etc.

The table 1 and 2 show the results of the regression analysis of the impact of the price per barrel of Texas oil on the economic growth of the European Union and the World during 1986-2019.

Table 1: Determining the Impact of the Price per Barrel of Texas Oil on the Economic Growth of The European Union during 1986-2019.

The simulation results showed that the growth of oil production positively increases GDP for OPEC countries and countries with high and above-average incomes, which is primarily due to increased demand for oil, according to the foresee of International Energy Agency.

For low- and below-average-income countries, a 10% increase in oil production leads to a corresponding GDP growth of 0.2% on average.

Table 4: The Results of Cointegration and Causation of Oil Production and Rent Payments for Oil and Economic Growth of the National Economy

Insignificant economic benefits for this type of country are associated with the lack of modernization of the industry and require a change in the paradigm of subsoil development, the transition from extensive to intensive development (strengthening technological development for high value-added products).

Positive values of parameters β_1 and β_3 for countries with high and above-average income and OPEC, their high statistical significance at the level of 1-5% suggest that countries with high and above-average income, OPEC use the amount of rent payments for oil for development technological progress contributing to increased economic development. With an increase in oil rents by 10% for low- and below-average-income countries, GDP will shrink by 0.3%, and the two-sided causality between these parameters indicates, on the one hand, the ineffectiveness of policies to support the development of those sectors of the economy. related to the extractive industry, and on the other hand about the inefficiency of market reforms carried out in the oil industry due to the instability of state institutions.

Conclusion

Conducted investigation gave the opportunity to concluded according the main features of the global energy market. 1. The world oil market is a recipient of the influence of global objective manifestations of the world economy, its social and political processes. Therefore, his study necessitates the study of relevant trends, institutions, market elements and features of their impact on pricing processes.

2. The level of consumption of oil and related products of its refining is determined by the level of development of each country.

3. Global trends in the development of innovative technologies, the development of alternative energy, the slowdown in the global economy cause certain changes in the growth of oil consumption.

4. Global objective and subjective development trends: uneven geographical location of fields, the creation of oil cartels that defend the interests of certain stakeholders and global institutions, in general, largely determine the monopoly position in the oil market.

5. The world oil market is constantly affected by the effects of various contradictions that arise between major stakeholders and market players and that have different economic, political, social and environmental interests.

6. The development of the world oil market is not stable; its development trends are determined from time to time in relation to the world leaders in oil production.

7. International policy in the field of environmental protection, the introduction of measures by countries to combat global climate change, the implementation of commitments by countries in the field of low-carbon development change the trends in the consumption of petroleum products.

The results of the study of cointegration and causal links between the development of the oil industry and the national economy showed that the growth of oil production and the level of rent payments for oil increase GDP for OPEC countries, high and middle-income countries. For countries with low and below average income levels, a 10% increase in oil production leads to a 0.2% increase in GDP. Insignificant economic benefits for this configuration of countries are associated with the lack of systematic modernization of the industry and necessitate a change in the system of

state regulation of exploration and use of oil fields, the transition from extensive to intensive development of oil production complex for high value added products.

Abstract

The performance of the phones has evolved considerably, but the applications are the ones that really turn them into indispensable tools for everyday life, both professionally and personally. Developers are constantly rushing to keep up with the trends of the technological world. Every time something innovative appears, people's demand goes to it. Thus, in relation to trends and innovation, companies have begun to realize the importance of mobile application development services. Therefore, mobile application development companies are trying to come up with applications that have better interfaces, using new coding practices. The authors aim to conduct research to highlight the increasing use of mobile phone applications in carrying out activities within an organization. An organization of the categories of applications available in Google Play and AppStore is performed, their main features being underlined. At the same time, the criteria that must be taken into account when developing a mobile application are presented.

Keywords: Mobile Application, Business Environment, Customer Experience

Introduction

The technological advances that are gradually taking place in almost all fields of activity only bring benefits to large and small companies around the world which, through regular investments, have the possibility to streamline many of the activities that take place within them. If about a decade ago, all these companies focused exclusively on investments in technological equipment, today many companies choose to invest in various software applications that can be easily integrated into industrial processes and beyond. Software applications created especially for these environments have completely revolutionized many industrial sectors and not only, which is why they have become so popular in the world.

There are currently a variety of applications used in industrial environments, from a simple enterprise management application to a complex inventory application. Each of these applications have been developed in order to improve the quality of services offered but also in order to streamline the working time of employees.

Mobile applications have given power into the hands of customers. The world has already become mobile. By 2019, the number of mobile phone users will exceed 5 billion. There is no doubt that consumers use their phones to look for the things they want to buy or the activities they undertake. Mobile applications are beginning to be preferred to the detriment of websites.

Mobile applications allow the collection of information about customer preferences through the actions they perform. This information is used to show them personalized content so that they can make more prompt decisions. Companies that provide iPhone and Android application development services are already using artificial technology to learn user behavior and show them their products and services based on their preferences.

A good mobile application can offer an advantage over competitors who do not yet have one, bringing a great benefit by the fact that they can be accessed at any time and from any device. Thus, a mobile application becomes as important as online presence. Mobile applications are used by people of all ages, however young people have a special penchant

for them. However, their use, according to Figure 1, is a high percentage for people who are actively participating in the labor market.

Fig. 1: Average monthly hours per mobile app user by age (https://www.simform.com/the-state-of-mobile-app-usage/)

Fig. 2 shows the main categories of applications for mobile phones, as well as user preferences for them. Although the first places in terms of spending time are represented by applications that help in recreational activities, which is correlated with the preference of young people for applications, are used in significant numbers and those intended for finance, productivity by the adult public.

Fig. 1: Average weekly time spent in-app (https://www.simform.com/the-state-of-mobile-app-usage/)

State of the Art

Islam (2010) analyses the results of using a mobile application in a business environment. The mobile app development has increased in the last years. Therefore, the authors guided their research to be a global one in order to present statistical data about the impact and ethical perspective of mobile application from past and current years.

Chowdhury (2020) designed the concept for a BI mobile app and a prototype for it. They used a heuristic solution to conduct the tests which concluded with the observations that users are able to access the entire information in a single platform and it provides an up to date BI support for entrepreneurs and their businesses.

Cristofaro (2020) conducts a business model research that is a combination between qualitative and quantitative of 2250 mobile applications from Google Play Store using evolutionary lenses to interpret the results. E-business models are evaluated multiple times due to the modifications of the multi-level environment.

The research of Nastas (2019) focuses research on the biometric authentication through mobile device and its use regarding mobile applications that are developed to target different business areas. This comes from the necessity of security and the high degree of mobile applications usage in various business activities.
According to the study realized by Hajhmida (2020) mobile app developers have a huge challenge when it comes to publish their work on the official stores. Therefore, mobile applications need to remain in top ranking. This research presents an automated method to analyze data collected from Facebook that predicts mobile app breakout. The authors designed statistical features for user's sentiment regarding each post and machine learning techniques to develop a prediction model. One of their results consists in the fact that likes associated to a Facebook page are the key factor in increasing mobile application raking.

Ghosh (2020) uses a method to retrieve data from mobile devices in order to describe an unpleasant user experience of mobile applications.
The demand for qualitative mobile applications has increased as these are used more and more to complete the business circle. A Fuzzy Association Rule algorithm is used by Kabir (2017) to establish the experience of application users which can lead to a better usability. In their tests the authors consider a supply change management system to which are linked a considerable number of mobile application users. In their evaluation there are used twelve factors correlated with usability from ten usability evaluation models.

Due to the increasement of mobile applications, a considerable number of companies try to use them to develop stronger relations with consumers. This results in developing applications that take into account consumer preferences. Tarute (2017) gathered data from 246 respondents and used structural equations modeling to interpret the results. Consumer engagement influenced their intention to use continuously mobile applications.

Ecosystems of mobile business lay on innovations and facilitate the transactions of users in a multi-sided market. Winter (2018) proposes a model of success factors of mobile ecosystems to present an empirical framework for Android.

Evolution of Mobile Applications

Software can include the full range of programming products, usually consisting of the operating system (the most important in a computer's memory because it is the software that controls the computer), drivers and application programs. In some special cases, parts of the software are incorporated from the construction into the hardware components - by using preprogrammed integrated circuits.

In some areas, software means primarily the data that devices or computers work with, such as digitized images, sounds and music tracks, computer games, digitized movies, videos, and many other similar data. In extreme cases, even physical data carriers or "media" are considered to be "software", such as CD and DVD optical discs, VHS and MiniDV video tapes, audio tapes, etc. In other words, software is the application, the program that uses raw information resources (data, numbers).

A computer system cannot process data without being programmed. A program consists of a sequence of instructions that converge toward the solution of the problem to be solved. There are two categories of programs as it can be seen in Table 1:

Table 1: Categories of programs

Type of program	***Description***
System programs	*Application programs*
Coordinates the way the system components work and provides assistance in the operation of application programs. They are said to be basic software and consist of low-level programs that interact with the computer at its basic level. They are designed to facilitate the efficient use of computer system resources and to provide tools for the development and execution of application programs. These programs are developed for	Designed to solve problems specific to an application. They are said to make up application software. These programs perform data processing in accordance with the necessary information requirements; being made mainly by specialized software companies. Computer applications are those programs that are designed for users to use the computer in a specific problem and to perform a specific task (word

certain types of computer systems and cannot be used on other types. They are provided by the manufacturers of the computer systems or by specialized companies.	processing, billing, DTP, graphics applications), each with a specific function.

Mobile applications are constantly evolving. New applications are always appearing, and curiosity makes us try them. Now, in the context of the Covid-19 pandemic, we are using mobile applications more than in previous periods. On the one hand, professional and educational activity has moved to the online environment, and on the other hand, isolation at home has increased the time spent in front of screens. Below, in Table 2, there are presented the existent types of applications.

Table 2: Categories of applications

Games	Most applications are games. There is a long list of game categories available (logic, action, adventure, etc.). On the other hand, they are also among the most frequently used applications.
Education	In the category of educational applications there are also offering interactive means of learning. Many of them are methods of learning foreign languages or general culture. Also included in this category are applications for editing documents.
Business	Among the business applications there are series of applications that act as tools for entrepreneurs, such as finance management, inventory management or financial analysis. They are used to automate operations, which brings some benefits to companies.
Tools	The tool applications include a number of basic programs that help optimize the phone's performance or are useful for regular activities. Many of them are pre-installed and do not require downloading. These include the calendar, computer, reminder, notes, weather, flashlight, and phone cleaners.
Advertising	Entertainment applications help people to relax in their free time. These include watching movies and series, viral videos, etc.
Life style	Lifestyle applications are the ones that help people respect a certain lifestyle. For example, there are applications that remind people to drink water or that count the steps we take every day. Among them are the applications with physical exercises, but also those of dating and travel.
Music	Music and audio applications include those applications that allow people to listen to music of different genres or that help create music.
Books	Book and reference applications include those applications that contain e-books. These are usually paid applications.
Personalization	Personalization apps help people customize, create, or customize themes, widgets, wallpapers, new actions, voices, and navigation bars. These applications help people to transform their phone from all points of view.
Productivity	Productivity applications are frequently used due to their usefulness. These applications include documents and worksheets, budget management, planners, task management applications.

In conclusion, there are a lot of categories of mobile applications. These are useful tools in human lives or even ways to spend their free time.

Insights of Mobile Applications

Set of applications helps to better organize the activities within any enterprise. Moreover, these applications will help us reduce a number of expenses, but especially time considering that everything becomes much more intuitive thanks to the functions that these applications come with.

At first glance, these applications may seem a little complex or involve a fairly high investment, things that are far from reality in fact. The applications in question have been developed in such a way as to be as easy to use as possible by any employee and in addition, they do not involve high costs and can be easily implemented. They are developed specifically for a specific type of platform. The features are:

- They allow to take full advantage of the features that are built into mobile devices.
- They allow to take advantage of the distribution channel and showcase that represent the application stores of different manufacturers (App Store, Google Play)
- They must go through a pre-publication review process, both of the initial version of the application and of subsequent updates.
- Allow push notifications on devices
- Purchases from the App Store are associated with an account that the user must register, bank details are stored in that account. That way, they don't have to provide their account number every time they make a purchase.
- Work offline
- Native Look & Feel: both the appearance of the application and the user experience are better.

Each platform performs a different control of the content that is published. The best known are:

iOS: Its review and approval process takes between 4 days and 2 weeks. If they do not meet the requirements they set, they reject the publication of the application in their store.

Android: automatically published to personal store

Table 3: Type of programming applications

Web applications	
Description	Characteristics
These types of applications reach a larger number of users. A company can develop a web application or adapt the content of the web page to the mobile channel. The biggest disadvantage they have is that they do not appear in app stores, therefore the company has to put more effort both in marketing for users to know it and in physical resources for the application to work properly.	• Multiplatform: are compatible with any device. • Simpler technology than in native applications • Allows SEO and web analytics • Both its content and its functionality do not depend on the approval of third parties.
Hybrid solutions	
They are native applications, which in some sections show web content that can be uploaded from another server or from within the application. Apple does not allow this type of application because its content cannot be reviewed.	Once we have decided on the type of application, we need to choose the business model we will use. There are several: • Payment or Premium request • Free application • Freemium Model (Most used)

The process of programming mobile applications involves a variety of resources (from human to technological) which puts most companies - whether or not they have an IT profile - in difficulty.

From the type of application to its architecture, the definition of the core functionality and operating system for which it should be developed and optimized, these decisions often seem overwhelming for companies.

On the other hand, as an effect of online consumer behavior, the development of a mobile application has become a mandatory step for any company that wants to remain profitable and stable in the long run. Users of mobile applications promoted by a business have multiple expectations such as those shown in Figure 3.

Figure 3: Applications characteristics expected by users

The choice of the mobile application you are going to develop must be made according to several criteria such as those presented in the Table 4.

Table 4: Criteria's for application development

Based on
Technologies / programming languages used
• Native applications - mobile applications created for a certain operating system (an application developed for Android cannot be used on iOS), being developed in relation to the particularities of a platform. (Programming languages: for Android - Java, Kotlin, for iOS - Swift or Objective-C). • Hybrid applications - mix between native and web applications: download from the application store and can interact with a number of features in devices (as well as native applications). (Programming languages: HTML5, CSS, and JavaScript and is based on HTML for display in the browser). • Web applications - web pages that behave like mobile applications and can be accessed without installation. (Programming languages: HTML, CSS, JavaScript, jQuery)
Key audience
User - generating benefits at the individual level • productivity; • communication; • inventory; • billings.
Business - helps to extract overview data to simplify business decisions • streamlining processes; • CRM applications; • analysis applications; • applications for process management; • personnel management applications.
Client - most of which materialize into independent mobile applications that help increase the profitability of a business in specific segments. • Real estate: web portals, CRM solutions; applications for calculating and comparative analysis of offers, property search functions based on smart filters, property presentations, etc. • Medical field: mobile applications that allow online appointments / consultations or an optimized management of internal processes (communication between different medical centers, offices, departments, access to the patient file to quickly see data on medical history, etc.), such as triage, health monitoring, etc. • Finance and insurance: CRM solutions, for offers from brokers, applications that allow financial analysis, etc.

• Transport and courier: car fleet management for the company providing transport services (points of interest, routes, driver behavior, consumption, etc.), mobile applications to connect customers with service providers and to facilitate communication and real-time tracking of deliveries, etc.
• E-commerce and retail: for online shopping, comparison of several offers, etc.
• HR: applications that enable dynamic communication between several types of users (recruitment companies, client companies, applicants) and the transfer of data and documents in a secure and dynamic way, mobile applications for recruitment and evaluation processes (synchronization of offers with applications, 360 evaluations, etc.)
• Tourism: mobile applications for reservations, for discovering new destinations according to certain expectations (by using smart filters), etc.

Conclusions

Lately, the fashion for mobile applications has come for all kinds of online services, including online stores. For many of them I consider a much greater utility of an application due to the fact that there can be send personalized notifications and somehow make the user a little more captive.

In recent years, the need for companies and entrepreneurs to associate a mobile application has become urgent. It is a tool that facilitates all the work of the user interested in buying certain products or using various services, as a result it generates respect and loyalty to brands.

This environment does not create discomfort to the customer considering that errors are much rarer in the case of an application or software than in the case of interpersonal relationships and the means of promotion that result from them. The keys to mobile application creators are functionality and, at the same time, user expectations. Thus, a mobile application is designed according to the purpose of the entity with which it is connected.

Through a mobile application, small businesses have the opportunity to improve the customer experience because the information will be easy to access. The feedback system allows companies to customize their application to improve the user experience and turn them into loyal customers. Also, the introduction of a short order module for the purchase of products contributes to the increase of sales. The applications offer a more convenient way to browse online and shop anywhere and anytime. Maximizing sales can also be achieved by sending alerts and notifications about a product, service, discounts and other offers.

Adding custom features to an application gives a company a competitive advantage over competitors in the field. Most of the time, small companies focus on the specific needs of customers to grow their business. A custom application perfectly adapted to the business contributes to the development of the company, keeping customers and stability in front of the competition. Rewards system, loyalty, push notifications or integration with social networks are just some of the features needed for a customized solution.

The intelligent planning of such a digital tool will also ensure a quick location of the company, important information and statistics about customer preferences, personalized payment system, project prioritization, mobile CRM.

Applications can solve a business's problems, allowing optimal use of resources, reducing losses and displaying a professional image to customers. Mobile applications are also used in the business environment of companies for a better organization of resources, a transparent communication, easier flow of information, improved security of access and solving tasks.

Abstract

Government policy on excise taxes on alcohol consumption has remained a relevant research topic for scholars in Russia and abroad. Strong alcohol continues to dominate consumer preference in Russia, which leads to a number of negative consequences. This makes it ever more urgent a task to modify consumer preferences toward low alcohol beverages, wine and beer. The article analyzes government alcohol pricing policies aimed at reducing alcohol consumption in Russia and the European Union and their impact on alcohol consumption. The study compares the excise tax rates for alcohol, their patterns of change in Russia and the EU member states. Trends in the volume and structure of alcohol consumption under the influence of excise duties in Russia and the EU are examined. The author substantiates the need to improve the excise tax policy with regard to alcohol by incorporating the experience of other countries. This study seeks to analyze and assess the effectiveness of government measures to regulate the consumption of alcoholic drinks in Russia and the EU and to work out suggestions for improving the Russian system of excise taxation.

Keywords: Excise tax, alcoholic beverages, government excise tax policy on alcohol, tax rates, structure of alcohol consumption.

Introduction

Today, excise taxes are one of the key tools that governments have at their disposal for regulating the production and consumption of "harmful" products", including alcohol. Alcohol consumption generates a number of negative effects, resulting in a substantial burden for health care, the economy and society as a whole (Becker G., Murphy K., 1988; Babor T., et al., 2010). Reducing alcohol consumption and changing the structure of such consumption by shifting demand from strong drinks to low-alcohol beverages, wine and beer is, therefore, an extremely pressing task. An anti-alcohol policy that results in higher retail prices of alcohol has been proven effective globally. Any such policy primarily implies the introduction or excise taxes on alcohol or an increase in existing tax rates (Anderson P., Baumberg B., 2006; Cook P.J., Moore, M.J., 2002; Xu X., Chaloupka F.J., 2011; An R.P., Sturm R., 2011).

In order to fight off the negative effects of excessive alcohol use, most national governments make regular attempts to introduce regulation for the alcohol market. Over the past decade, the Russian Federation, too, has been making active efforts in this area. There are plenty of studies analyzing the effectiveness of anti-alcohol policies (Babor T., et al., 2010; Wagenaar A. et al., 2009). The majority of the authors consider other countries' situations, but there is a number of works looking at alcohol consumption in Russia and assessing the effectiveness of alcohol policies there (Radaev V.V., Kotelnikova, Z.V., 2016; Pridemore W. et al., 2014). The studies found that modern alcohol control policies being implemented by the Russian government are in general quite effective as regards their impact on consumption (Iadrennikova E.V., Busse R.A., 2020).

Alcohol consumption can be regulated and consumers' preferences can be modified towards beverages with a lower ABV by regularly indexing excise rates. This is the strategy that is followed by the Russian Federation. Regulation can also be enforced through levying excise tax at varying rates depending on the type of drink. Such an approach is common in the EU member states.

Cite this Article as: Elena V. IADRENNIKOVA and Viktoriia A. KORETSKAIA-GARMASH "Comparative Analysis of Excise Tax Policy and Its Impact on Alcohol Consumption in EU Countries and Russia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

This study seeks to analyze and assess the effectiveness of government measures to regulate the consumption of alcoholic drinks by means of excise taxes in Russia and the EU and to work out ways of improving the Russian system of excise taxation.

The study proceeds from a hypothesis that improving the system of excise taxes on alcoholic drinks in Russia by imposing higher taxes on spirits, lowering tax rates for wine and beer should help to further reduce per-capita alcohol consumption, encourage consumers to shift their preferences in favor of lower-alcohol products and lead the way to a healthier structure of alcohol consumption in the Russian Federation.

Methods

The research methods included a study of the present-day systems of excise taxes on alcohol and their peculiarities in Russia and the EU, as well as of state anti-alcohol policies employing the excise tax toolkit. A comparative analysis was performed of the size, dynamics and types of tax rates that are applied to the main types of alcohol-containing products in Russia and the EU for the period 2008-20.

The main types of alcohol both in Russia and the EU member states are spirits, beer, beer cocktails, wines and other alcoholic beverages. In the Russian Federation, spirits include alcoholic beverages with over 9% ABV (the most popular one being vodka; the category also includes cognac, strong liquors, brandy, and calvados, etc.) The beer group covers beers with an ABV over 0.5%. Between 2013 and 2016, the category also included fortified beer-containing drinks and beer cocktails. Other low-alcohol drinks with an ABV under 9% are cider, medovukha, perry, champagne, and sparkling wines.

A study was conducted of changes in the volume and structure of alcohol consumption in Russia and the European countries under the influence of excise taxation tools. The study of the trends in and structure of alcohol consumption by the adult population of Russia and the EU member states covered the period 2008-16. National alcohol consumption data was reported by the World Health Organization in litres of pure alcohol per year per person older than 15.

Data on tax rates was found on the website of the Federal State Statistics Service (gks.ru), the Federal Tax Service (nalog.ru), and the European Commission (ec.europa.eu). Alcohol consumption data was retrieved from the website of the World Health Organization (apps.who.int). Works by Russian and foreign scholars served as the methodological and theoretical framework of the study.

Results and Discussions

Analysis of alcohol tax policy and its impact on alcohol consumption in the EU

Indirect taxes in the EU member states are harmonized. National laws on excise taxes in the European countries are drafted with consideration for the union's legislation, and excise taxes must be in compliance with Council Directives of 19 October 1992: Directive 92/83/EEC establishes the structures of excise duties on alcohol and alcoholic beverages, categories of alcohol and alcoholic drinks subject to taxes, reduced rates for small breweries and small distilleries, certain products and geographical regions; Directive 92/84/EEC sets out the minimum rates applicable to each category of alcoholic drinks, and reduced rates for certain regions of Greece, Italy, and Portugal (European Commission. Taxation and customs union, 2020). Under the Directives, the list of excisable alcoholic drinks includes beer, wine (still and sparkling), intermediate products (port and sherry), and strong alcoholic drinks (ethyl alcohol). EU legislation only sets harmonized minimum rates. This means that EU countries are free to apply excise duty rates above these minima, according to their own national needs.

Excise tax rates have remained unchanged between 2008 and 2020 in the majority of EU countries. It is interesting to compare the rates of tax for spirits and drinks with less alcohol by volume in EU countries. Another interesting point is a zero rate for wines in 15 out of the European Union's 28 member states. A comparative analysis of excise rates that are imposed on the main types of alcoholic drinks in Russia and EU countries as of 2020 is presented in Table 1.

Table 1: Comparative analysis of the rates of excises on the main types of alcoholic beverages in Russia and EU countries in 2020

author's calculations
**Excise duties in Russia were converted into euros by using the average exchange rates of the Central Bank of Russia as of January-September 2020 (1€=79.3766 rbs.).*
***In EU countries, beer excise rates vary in proportion to alcohol content while in Russia, the excise rates are set in roubles per litre. Since beer excise rates are expressed in a variety of ways, for the purpose of comparability, these rates were converted to euro per litre of beer of 12 degrees Plato or 4.8% ABV.*
****Excise rates for wines of different strength (champagne) are indicated after the slash, the highest rate is imposed on stronger alcoholic beverages.*

It is noteworthy that strong alcohol is subject to a high excise duty rate in EU countries. Bulgaria is the only country where the rate of excise duty is only slightly above the minimum rate. The actual rates are more than double the minimum rate in 19 EU countries (68%) and more than triple the minimum rate in 11 countries (39%). It is a different story when it comes to drinks with a lower ABV. First of all, EU countries can charge no excise on still and sparkling wines, and many of them do take advantage of that. For example, zero tax is applied to still wines in 15 EU countries (54%); nine countries apply a zero rate on sparkling wine (32%). Second, the minimum tax rate for beer and beer-containing drinks is 61 times less than the rate for strong alcohol. The actual rate for beer is only slightly higher than the minimum rate in seven countries (25% of all EU member states). Among them are, first and foremost, Germany and the Czech Republic, the world's leading beer making and beer drinking countries, followed by Bulgaria, Spain, Luxembourg, Romania, and Slovakia. Only 13 out of the 28 EU countries (46%) have tax rates for beer that are more than triple the minimum rate, matching or being higher than the tax imposed on beer in the Russian Federation. Therefore, EU countries have a great variety of excise tax rates applicable to various types of alcoholic drinks in order to regulate alcohol consumption and shift the preferences of consumers towards alcoholic drinks with less alcohol by volume.

We shall now look at how alcohol consumption by the adult population of EU countries changed between 2008 and 2016, as recorded by the World Health Organization (Tab. 2).

Table 2: Recorded annual per capita (15+) consumption of alcohol in EU countries in 2008-16 (litre per capita of pure alcohol)

Year / EU country	2008	2010	2012	2014	2015	2016	Percentage change 2016 (2015) on 2008	Country ranking (2015)

In general, alcohol consumption among adults is quite high in 23 out of the 28 EU countries, exceeding the WHO-recommended "safe limit" of 8 litres per annum. The majority of the countries reported a decrease in per-capita consumption over the period of observation, but five nations (Bulgaria, Malta, Lithuania, Sweden, and Italy) saw a slight increase in alcohol use. This is largely attributable to unchanging tax rates throughout the period of observation,

which resulted in excise duty rates actually decreasing by a more than a third due to inflation. The biggest decline in alcohol use was observed in Greece, Romania, Cyprus, Croatia, and Finland. In Finland and Greece, the decline is in correlation with high rates of excise duty.

Analysis of alcohol consumption by adults in EU countries shows that the majority of EU countries that are similar to Russia in terms of mindset and drinking culture saw per-capita alcohol consumption decrease between 2010 and 2016, but not drastically. Over the period of observation, recorded per-capita alcohol consumption in the examined EU countries decreased by an average of 2 to 15%. With annual per-capita alcohol consumption at 8.42 litres, Spain and Finland score at a comparable level with Russia. Austria, the Czech Republic, France, Ireland, Portugal and a number of other countries overtake Russia in alcohol use, while the Nordic countries – Norway and Sweden – and Italy and Greece boast a much lower level of alcohol consumption at around 6.5 litres per person. However, the structure of alcohol consumption in all those countries differs a lot from Russia's: in 12 countries (43% of all EU member states), including Germany, the Czech Republic, Belgium, Denmark, and Finland, beer is the dominant beverage, accounting for 40 to 56% of all alcohol consumed; while in France, Italy, Portugal, Sweden and some other countries (9 out of the 28 EU countries) wine is the most consumed alcoholic beverage (44 to 65%). Together, wine and beer account for 75 plus percent of alcohol consumed. Strong spirits dominate the alcohol consumption structure (≥40%) in four countries only (Bulgaria, Estonia, Cyprus, Slovenia). Three countries (Hungary, Malta, Great Britain) consume approximately equal volumes of wine, beer and strong spirits.

The overwhelming majority of EU countries prefer beverages with lower alcohol by volume (beer and wine), and the structural composition of alcohol consumption there is close to ideal with minimum negative effects (the share of beer in total alcohol consumption is 50%; wine 35%; spirits 15%) (Edwards G., et al, 1994). Consequently, the excise duty policy of European countries that applies considerably different tax rates to different types of beverages has proved highly effective. Nevertheless, it is advisable to regularly adjust the tax rates for inflation or allow for higher-than-inflation rate increases in order to push for further reduction in per-capita alcohol intake in EU countries. That would prevent the tax burden on alcoholic beverages from decreasing due to inflation.

Analysis of alcohol tax policy and its impact on alcohol consumption in the Russian Federation

Unlike EU countries, Russia has been increasing the rates of excise duty for alcoholic beverages almost annually. We shall examine how the rates of excise duty for alcohol in Russia changed and compared between 2008 and 2020 (Tab 3).

Table 3: Rates of excise duty for main types of taxable alcoholic beverages in the Russian Federation in 2008-20

Year / Indicator	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018-2019	2020	Change in 2020, in % to 2008
1. Excise tax, rouble/litre of ethyl alcohol													
1.1. Beverages with over 9 % ABV	173	191	210	231	300	400	500	500	500	523	523	544	314.5
1.2. Beverages with less than 9% ABV	110	121	158	190	270	320	400	400	400	418	418	435	395.5
2. Excise rates, rouble/litre													
2.1. Wines, fruit wines, winy beverages produced through natural fermentation without adding ethyl alcohol (except for champagne and sparkling wine)	2.35	2.6	3.5	5	6	7	8	8	9	18	18	31	1319.1

2.2. Champagne and sparkling wines	10.5	10.5	14	18	22	24	25	25	26	36	36	40	380.1
2.3. Beer, 0.5-8.6% ABV	2.74	3	9	10	12	15	18	18	20	21	21	22	802.9
2.4. Beer, over 8.6% ABV	8.94	9.8	14	17	21	26	31	31	37	39	39	41	458.6

Source: Federal Tax Service of the Russian Federation. Official site (2020). Retrieved from: https://www.nalog.ru/rn66/related_activities/statistics_and_analytics/forms/, author's calculations

Over the past decade, the excise tax policy in Russia has sought to constantly increase the tax rates. It is noteworthy that there is a negative trend of the rates for low-proof drinks growing disproportionately faster. Between 2008 and 2020, the tax rates increased 210% for spirits, 1,220% for wine, and eight-fold for beer.

Over the observed period, excise duty on spirits with over 9% ABV showed the smallest increase of a mere by 210%. This does not encourage consumers to reduce their intake of strong alcoholic beverages and is one of the reasons why spirits account for the biggest share in the structural composition of alcohol consumption in Russia (Tab.4). A comparison of taxes on strong alcohol across countries shows that Russia belongs to the countries with the minimum level of taxation, which is not typical of other nations in the northern latitudes. For example, in Finland, Sweden, and Ireland, the rates of excise duty for strong alcohol is 520 to 610% higher than in the Russian Federation (Tab 1). Consequently, there is the potential for further increases in excise duty rates for spirits.

The tax rate for beer in the 0.5 to 8.6% ABV range increased eight-fold, reaching 22 roubles per litre in 2020, which is much higher than in other countries of the Eurasian Economic Union (EEU) and even in such leading beer producing and consuming nations as Germany (the tax rate in Russia is 190% higher than Germany's) and the Czech Republic (the rate is 90% higher in Russia).

At the start of the observation period, excise tax rates for wine (with the exception of champagne and sparkling wines) in Russia were low. However, the tax rate for this type of alcoholic drinks increased significantly – by 1,220% - over the span of 13 years. The tax growth on wine has been the highest although wine accounts for the smallest share of total alcohol consumption in Russia (Tab 4). Our analysis shows that many European countries now employ a zero tax rate or an economically negligible rate of tax for wine. That is primarily the case in such top wine producing countries as Spain, Italy, Portugal and France, where zero taxation is meant to support their wine industries. Such an approach would be a promising option for Russia, too, because wine is a low-proof drink, and zero or near-zero tax would support winemaking and help change the preferences of consumers toward healthier drinking habits.

The rate of tax for spirits has, therefore, been insignificantly adjusted towards higher values, unlike the rate for low-proof drinks. This trend indicates that pricing tools of alcohol regulation policy primarily target beverages with lower ABV (wine and beer) rather than spirits. Consequently, the alcohol tax policy of Russia needs some modification. It is necessary to increase tax pressure on strong alcohol and reduce tax pressure on low-proof drinks in order to shift the preferences of consumers towards alcoholic drinks with less alcohol by volume.

Trends in the per-capita consumption of alcohol by adults in Russia and the structural composition of alcohol consumption are summarized in Table 4 for the period 2008-16 using the WHO data.

Table 4: Recorded annual per capita (15+) consumption of alcohol in Russia and consumption structure in 2008-2016

Year / Indicator	2008	2009	2010	2011	2012	2013	2014	2015	2016	Change in 2016, in % (percentage points) to 2008
1. Registered alcohol consumption in litres of pure alcohol

Other alcoholic beverages	0	0	7.4	7.5	7.7	7.7	8.1	8.2	9.5	-

Source: World Health Organization. Official site (2020). Retrieved from: http://apps.who.int/gho/data/node.main-euro.A1039?lang=en&showonly=GISAH#, author's calculations

Table 4 shows that per-capita alcohol consumption in Russia decreased significantly (by 30.4%) from 12.09 litres in 2010 to 8.42 litres in 2016. The structural composition of consumption changed, too. Among the beverages that account for the biggest tax revenues, the biggest drop in consumption was observed for spiri1ts, including vodka and cognac (minus 47.2%). The consumption of beer was down 29.4%, which is largely due to higher tax rates and, consequently, higher prices. The World Health Organization has a category of "other alcoholic beverages" that includes fortified wines, cider, fruit wines, etc. Consumption volumes of beverages included in the category can be equally distributed between spirits and wine.

Over the period of observation, per-capita consumption of strong alcohol has been decreasing in Russia as beverages with lower alcohol by volume, especially beer, have taken over a portion of the consumption share of hard spirits. This indicates that excise tax has been fulfilling its regulatory function rather successfully. Analysis of tax rate trends by type of alcoholic beverages in Russia shows that the existing tax policy with regard to alcoholic beverages primarily aims to reduce the consumption of low-proof drinks rather than hard spirits, hence the need for modification.

Options for improving alcohol taxation in the Russian Federation

The analysis has enabled the following suggestions as to how to improve alcohol tax policy. In Russia, the development of alcohol tax policy should pursue the goal of further increasing the rate of excise duty for strong alcohol and reducing the rate for beverages of lower alcohol by volume. To achieve that, greater rate differentiation needs to be employed in order to change the structural composition of consumption. The following modifications are suggested:

1. Increasing the excise tax rate for alcohol with ABV over 9%. The tax rate per unit of pure alcohol is almost the same for beer and spirits. This does not help the task of shifting consumer preferences toward low-proof alcohol beverages. The excise tax on spirits in Russia is low in comparison to other countries. There is, therefore, a feasible opportunity - and a need – to increase the tax on spirits as that would generate extra revenue for the government and help reduce the intake of strong alcohol.

2. Lowering the duty on beer and introducing a zero tax on natural wine without added alcohol in order to support the domestic winemaking industry and beer brewing and boost the share of low-proof alcohol (wine and beer) in the alcohol consumption structure in Russia.

The implementation of the above measures could help change the price structure of alcoholic beverages and provide an incentive for a shift in consumer preferences toward low-proof drinks such as wine and beer that are less harmful to health.

In EU countries, it is advisable to regularly adjust the tax rates for inflation to prevent the actual tax burden on alcoholic beverages from decreasing due to inflation and further reduce alcohol use in the EU.

Conclusion

Russia has been implementing its anti-alcohol policy in a more pronounced way (manifested in annual increases in alcohol tax rates, tougher regulation of alcohol production, distribution and consumption) than the EU member states. Nevertheless, the structural composition of alcohol consumption in the majority of EU countries appears healthier

(with low-alcohol drinks – wine and beer - dominating the consumption structure) than in Russia (where strong spirits account for the biggest share of total alcohol consumption). Alcohol consumption is regulated and consumer preferences are influenced towards low-alcohol drinks by means of alcohol tax rate differentiation. Analysis of tax rate trends by type of alcoholic beverages in Russia shows that the existing pricing methods primarily target low-alcohol beverages (wine and beer) rather than hard spirits, so Russia's alcohol tax policy needs some adjustment. Over the period of observation, alcohol consumption has declined both in Russia, and the majority of the EU countries. The structural composition of alcohol consumption has changed there, too, which is evidence of excise duty working pretty well as a state regulation tool for alcohol consumption. In Russia, the alcohol tax policy could be improved through higher tax rates for strong alcohol and lower rates for beverages with lower alcohol by volume. That would modify the preferences of consumers towards low-alcohol wines and beer that are less harmful to health. In EU countries, it is advisable to regularly adjust the alcohol tax rates for inflation to prevent the actual tax burden on alcoholic beverages from decreasing and to further reduce alcohol use.

Abstract

Cosmetics and makeup are the goods commonly associated with a healthy lifestyle and beauty as they are used to highlight one's best features and to hide imperfections. These goods are consumed by all population groups who anticipate to effect an agreeable visual impression. The demand for cosmetics is heavily influenced by users' comments and opinions on social media concerning the quality and effects of different products as well as advertising campaigns in mass media and the price levels. This study tests the hypothesis that the introduction of excise duties on luxury cosmetics in Russia will create a protective barrier against the imports of counterfeit goods. We use the case of China to show that consumption tax on cosmetics can be quite effective in this respect. The study provides an overview of the global trends in the cosmetics market and taxation of luxury cosmetics in China. The sales of cosmetics of mass market and luxury brands are considered. The volume and structure of the imports of cosmetics to Russia are analyzed. The conclusion is drawn concerning the potential of excise duties on luxury cosmetics in Russia in combatting the imports of counterfeit products.

Keywords: Consumption Tax, Excise Duties, Cosmetics, Luxury Cosmetics, Mass Market Cosmetics, China, Russia

Introduction

All modern taxation systems comprise excise duties. Excise duties are indirect taxes on the sale or use of specific products, which allow the government to regulate the volumes of consumption of such goods. The Tax Code of the Russian Federation (Tax Code of the Russian Federation Part 2, 2000) defines excise duties as federal indirect taxes on consumption of specific groups of goods included into the prices of these goods, with the tax burden being shifted from the taxpayer to consumer.

The fiscal function performed by excises is determined by Article 182 of the Tax Code of the Russian Federation, which stipulates that the objects of taxation in this case are the imports and sales of excisable goods while exports of excisable goods are generally exempt from excise duties.

Legislative stipulation of the categories of excisable goods is at the core of the regulating and fiscal functions performed by the consumption tax, which ensures the fulfillment of the social justice principle.
In modern tax policies, excises are levied on a relatively narrow tax base (Pepelyaev, Kudryashova and Nikonova, 2015). Excise duties are imposed on luxury products mostly consumed by high-income groups; the goods deemed to be harmful to consumers' health; and the goods that are damaging to the environment.

According to the above-described criteria, three key groups of excisable goods can be identified: alcohol and alcoholic drinks; tobacco products; and energy products and electricity (Mayburov and Ivanov, 2020).

Cosmetics and beauty products are a part of the global beauty market aiming to meet the needs of all social groups through its various segments with different price ranges. In world practice, high-quality cosmetics and beauty products are included into the lists of excisable goods, as is the case with the Chinese taxation system.

IADRENNIKOVA "Fiscal Prevention of Counterfeit Cosmetics Imports: The Impact of Consumption Tax on Luxury Cosmetics (the Case of Russia and China)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Global beauty market is valued at €200 billion annually; 43% of this market is dominated by six manufacturing companies - L'Oreal, Unilever, Estee Launder, Procter&Gamble, Coty and Shiseido.

Depending on its applications, cosmetics can be divided into skincare, makeup, perfumes and personal hygiene products. Skin and haircare products account for 59.0% (Russian-Style Beauty) of the beauty market. They are meant to perform the following key functions - cleansing, moisturizing and nourishing. Makeup products rank second with 19.0%; perfumes and personal hygiene products, 12.0% and 10.0% respectively.

As people's financial well-being is growing, they become more interested in buying luxury makeup cosmetics and professional cosmetics (Russian-Style Beauty). While the beauty market generally grew by 4-5%, the growth of the luxury segment in 2017 reached 8.5-9.5%. The main consumers are Asian countries, as they make up 37% of the global sales.

The value of the Russian market of cosmetics and beauty products is estimated at €5 billion euro or 2.5% of the global market. It is, however, smaller that one fifth of the worldwide revenue of L'Oreal (Russian-Style Beauty).

The scale of imports of cosmetics and beauty products from different countries to Russia (see Table 1) (Imports of perfumes, cosmetics and toiletries by country, 2020).

Table 1: Imports of cosmetics and beauty products to Russia in the total volume of imports in 2013-2018, %

Country	2013	2014	2015	2016	2017	2018	Deviation, in percentage points	
							2018/ 2013	2018/ 2017
France	27.3	26.3	26.0	25.0	26.2	25.5	-1.8	-0.7
Germany	14.2	14.2	13.0	12.9	11.4	11.3	-2.9	-0.1
Italy	7.2	7.5	7.8	8.4	8.5	9.4	+2.2	+0.9
USA	6.6	5.7	6.0	5.4	6.1	6.8	+0.2	+0.7
Poland	6.0	5.8	6.5	6.1	6.2	6.0	0	-0.2
UK	5.1	5.5	5.4	5.6	5.1	4.5	-0.6	-0.6
Ireland	4.4	4.5	5.0	4.6	4.4	4.1	-0.3	-0.3
China	3.1	3.6	4.3	4.4	4.5	4.5	+1.4	0

Belarus	2.7	1.7	1.6	1.8	2.0	2.2	-0.5	+0.2
Other countries	20.5	22.4	21.1	22.4	22.6	22.7	+2.2	+0.1
Total	100.0	100.0	100.0	100.0	100.0	100.0	-	-

As Table 1 shows, the largest long-standing exporter of cosmetics and beauty products to Russia is France, the world leader in cosmetics. France accounts for over a fourth of all the imports into Russia and is followed by Germany and Italy.

Between 2013 and 2018, there was a decline in the imports of cosmetics from France by 1.8 percentage points in comparison with 2013 and by 0.7 percentage points in comparison with 2017. Imports from Germany declined most significantly - 2.9 percentage points in comparison with 2013 and 0.1 percentage points in comparison with 2017.

There was an increase in the imports of cosmetics from Italy to Russia by 2.2 percentage points in comparison with 2013 and by 0.9 percentage points in comparison with 2017; from China, by 1.4 percentage points in comparison with 2013 while in comparison with 2017 the volume of imports remained virtually unchanged - at 4.5%. In 2018, in comparison with 2017, the imports from the USA grew by 0.9 percentage points and from Belarus, by 0.2.

The structure of imports to Russia by types of cosmetics and beauty products (see Fig.1).
As Fig.1 illustrates, in 201,8 the imports of cosmetics and beauty products decreased in comparison with 2013 and 2014. 2016 was a truly disastrous year for sales of perfumes and toilet waters, shaving products, antiperspirants and deodorants as well as oral care products.

Regardless of the specific period, between 2013 and 2019, the import structure was dominated by makeup products, skincare products, manicure and pedicure products, whose imports since 2016 were rising steadily from 907 million

dollars and reached 1,190 million in 2018. Imports of haircare products were also on the rise, reaching 461,0 million dollars in 2018, which exceeded the corresponding figures of 2015-2017. A similar upward trend was observed for shaving products, deodorants and antiperspirants. In 2018, however, the imports of perfumes and toilet waters and oral care products dropped from 189,0 million dollars in 2017 to 186 million.

Fig 1. Structure of imports to Russia by types of cosmetics, mln dollars

In 2018, mass market products accounted for 81% of the imports while luxury cosmetics, for 19% (see Fig.2).

Fig 2. Sales of cosmetics and beauty products, by segment, %

Mass-market cosmetics are mostly sold through large networks of perfume stores and drogeries, which accounted for about 75% of the market in 2018. The network of drogerie stores Magnit Kosmetik is at the top of the ranking, followed by L'Etoile and Rive Gauche.

To gain a better idea of the size of the Russian luxury cosmetics market, we can look at the number of drogerie networks, which has grown almost threefold - from 100 to 276 companies. The share of drogerie stores on the Russian market exceeds 25% (it should be noted that this figure takes into account only the sales of cosmetics and cosmetic accessories) (see Table 2).

Table 2: Channels of distribution of perfumes and cosmetics from July 2018 to June 2019

Distribution channels	Share, %	Increase in monetary terms, %	Increase in volume terms, %
Hypermarkets	15.6	-3.0	-10.0
Supermarkets	6.0	+2.0	-3.0

Discount stores	14.3	+17.0	+11.0
Perfume networks and drogeries	37.5	-7.0	-1.0
Non-network perfume stores and household shops	6.0	-20.0	-16.0
On-line stores	7.9	+23.0	+23.0
Others	12.7	-6.0	-7.0
Total	100.0	-2.1	-1.6

As Table 2 shows, between July 2019 and June 2019, sales fell by 1.6% in volume terms and by 2.1%, in monetary terms in comparison with the same period of the previous year. On-line sales of perfumes and cosmetics are the fastest growing area. This segment grew by 23% both in monetary and in volume terms in the last year.

Cosmetics and beauty products are sold in retail stores, which are now rivaled by online platforms, including over 35,000 informal stores. There are currently over 6,000 domain names imitating the names of official websites of fragrance brands. Informal stores also use logos and color schemes similar to those of official brands, contextual advertising, targeted marketing via SMS and instant messengers.

Informal stores sell counterfeit products through unofficial online forums: in 2018, for example, over 3.6 posts were detected with offers of wholesale perfume deals. In some ads, the offers included several famous brands at once.

The Russian government tried to tackle the problem of counterfeit cosmetics and perfumes by introducing the procedure of mandatory labelling of perfumes and toilet waters. The purpose of the governmental decree 'The List of Individual Goods Subject to Mandatory Labelling by Means of Identification' was to prevent illegal imports, manufacturing and sales of goods, including fake ones, and, as a result, reduce the size of the 'black' and 'grey' markets and improve tax collection. The next step was to introduce labelling codes (QR codes or radio frequency identification tags (RFID), containing the information about the manufacturer and production date). Since 1 December 2019, this rule has been also applied to perfumes and toilet waters.

In 2018, clothing and textiles make up the largest share of fake goods - 36% of the total volume - in member countries of the Eurasian Economic Union. Toys account for 13%; footwear, 7.6%; bags and belts, 5.6%; labels and packaging, 2.3%. The share of counterfeit perfumes and beauty products seized by the police was 0.3% of the total amount of fake goods.

In this respect, Chinese experience of taxing consumption of cosmetics and beauty products is especially worthy of interest, especially in the light of China's tax reforms of 2016. In order to stimulate domestic consumption of cosmetics, the central government issued revised lists of excisable goods in September 2016. The consumption tax rate on higher-end products was lowered from 30 % to 15 % (see Table 3).

Table 3: Elements of the consumption tax on cosmetics and beauty products before China's fiscal reform of 2016

Taxable goods	Import duty rate, %		Consumption tax rate, %	VAT, %
	Reduced	Standard		
Perfumes	10	150	30	17
Lipstick	10	150	30	17
Eye makeup	10	150	30	17
Nail polish and nail lacquer	15	150	30	17
Powders	10	150	30	17
Skin care	6.5	150	0	17
Other skincare and beauty products	6.5	150	30	17
Shampoo	6.5	150	30	17

The notion of 'high-end (luxury) cosmetic products' was formulated to denote cosmetics with a final price above 10 yuan per ml or gram or 15 yuan per item produced in China or imported into the country (see Table 3). All other types of cosmetic products, except from high-quality goods, are exempt from taxation.

Lowering the consumption tax on cosmetics and beauty products has provided an incentive for the development of domestic production and created a barrier to the entry of foreign goods into the Chinese market as the import duties were set at the rate of 6.5-15% and VAT (17%). Thus, Chinese consumers are encouraged to change their preferences for domestic vs foreign products. It should be noted that a fourth of the Chinese market is occupied by the products of such companies as Procter&Gamble (USA),12,6%; L'Oreal (France), 9,1%; and Shiseido (Japan), 3,6%.

Unlike China, Russian legislation specifies the criteria for distinguishing mass-market cosmetics from their luxury counterparts, necessary for compiling a list of excisable goods.

Table 4 shows the main differences between the market segments of cosmetics and beauty products according to the international classification.

Thus, following the data in Table 4, a conclusion can be made that, despite the number of advantages of luxury cosmetics in comparison with mass- and middle-market goods, these goods remain inaccessible to mass consumer on a regular basis but instead are something that only few can afford.

Conclusion

In general, the Chinese taxation system is similar to many other systems in the world, despite some peculiarities rooted in the country's traditions and history. Its system of indirect taxation is not an exception and comprises a consumption tax levied on specific categories of commodities, considered harmful to society, luxurious or seen as capable of inducing respect for Chinese traditions.

Healthy lifestyle, which implies consumption of 'green' cosmetics and beauty products free of any toxic ingredients, promotes the demand for organic luxury cosmetics, including perfumes and toilet waters. As a result, there are now 40,000 specialized cosmetics stores and offices of direct sales companies.

If we look at the sales of luxury cosmetics and beauty products in Russia, we will see that they account for 19.0% of the total sales, which means that it would be reasonable to include them in the list of excisable goods.

Luxury cosmetics brands use exclusive, proprietary formulae, high-quality organic ingredients, 70-80% of natural and biologically active substances, natural preservatives such as colloidal silver, tea tree oil and so on, innovative technologies. Luxury makeup products are normally sold in specialized stores or beauty salons to ensure their authenticity since such brands run the largest risk of being counterfeited.

Luxury cosmetics are produced by such staples of beauty industry as Elizabeth Arden, Yves Saint Laurent, Nina Ricci, Chanel, Estee Lauder, Clinique, Helena Rubinstein, Givenchy, Christian Lacroix, Dior, Shiseido and other fashion houses.

Abstract

Judicial delays are a common fact that later years increased its influence on the market performance. This study focuses on the relationship between judicial delays and market leavers, on the relationship between the Judicial Effectiveness and the Corruption Perception Index. The global and regional data analysis revealed strong-holds among these events. Another study was applied on European Union countries, for being able to empirically test and reflect through a regional quantifiable frame Romanian's entrepreneur perception about judicial terms delays over the losses and bankruptcy spectrum their company experience.

Keywords: Corruption, Bankruptcies, Judicial Effectiveness, Correlation, Regression

Introduction

Time is a valuable resource for any enterprise, especially when related to cash-flow registers. Waiting for a resolution in a commercial law case implies valuable resources (pretended amounts and judicial fees) to be unlocked and used for business reasons. Delays in judicial Romanian system are a common fact, that in recent years has become a real threat not only for the market performance of a company but also for the existence of the legal entity. Delays in solving a commercial case are regarded as total days above the normative threshold (procedural stated maximum period in order to present a resolution) from this paper's perspective.

There is empirical data collected by the authors (http://portal.just.ro/SitePages/acasa.aspx) that prove later years' various delays in granting a judicial result. Summing the empirical data, there were many faults, of different causes that induced this situation. In commercial law, even if courts grand the winning part, alongside with the amounts required, the interest as well, it is very often cheaper for companies who owe money to use it for different other purposes and wait until a court decision is issued for paying the money. Other company owners even profit the favorable legislation and create a different company for each business they run, and should they need to pay greater amounts of money they simply let that company go bankrupt, because in practice more often there is no consequence for them.

The companies described above usually ask their lawyers to delay as much as possible the outcome of the trial, hence they use all legal possibilities to achieve such results.

For example, until some time ago, it was mandatory for courts of law to suspend the trial should one of the parties raise the non-constitutionality exception. At present this legislation was changed, due to multiple delays. However, there are other possibilities for a party to ask for more terms in order to postpone the outcome of the trial (saying they have a new lawyer, postponing for acknowledging various documents, or sometimes, even recuse the judge, and risking a fine, in desperate situations). There are as well objective reasons for delays, amongst which the most common are the delays due

to legal experts not submitting their reports in time - it is actually usual for an expert to delay the trial at least 1-2 terms, and some -times such delays postpone the case for months. Another reason for delays is the necessity to obtain any documents from institutions, in which case the court drafts a request directly to the institution, which is obliged to answer, but very often they are slow. After the judge issues the first court decision, which can usually be appealed, in practice very often it takes a very long time until the decision is drafted, in order that the parties to be able to appeal it. Even if the procedural code provides a period of 30 days for drafting court decisions, in practice parties are often forced to wait for months and, because usually the appeal suspends the enforcement of the court decision, the entire process is delayed.

In consequence, this situation was perceived by the entrepreneurs as a threat to their place on the market, and in a significant manner, a trigger for bankruptcy or market exit. And very much related to administrative inadequacy that is mainly subjected to corruption issues in the state. This is not a novelty in Romania and has many nuances. In 2002, legal frame and taxation was perceived as having a downsize influence over entrepreneurial incentive (https://www.wall-street.ro/files/143876-401.pdf) for in 2018, the main obstacles for business incentive being pointed towards bureaucracy, legal volatility, the relationship to state authority and corruption (https://www.impacthub.ro/wp-content/uploads/2020/09/Studiu-ROWIN-12sept.pdf). According to SocialProgress.org, Romania registers low to medium scores on Social Progress Index 2020 international ranking, with modest values (but not alarming) in what concerns access to justice (0.77) and corruption (44.0) (https://www.socialprogress.org/index/global).

In scientific literature there are various studies for measuring the impact of bureaucracy (Ashyrov, Masso, 2020; Wang et al, 2020; Luo, Kaul, 2019; Kochnev et al, 2018), corruption (Tourish, Craig, 2020; Rose, 2020; Marchini et al, 2020; Gago-Rodriguez et al, 2020; Huang, Yuan, 2020) and legal volatility (Kucik, 2015; Duncan, 2014) over business incentive. There are international agencies such are Heritage Foundation and Transparency International that measure societal indicators that include judicial effectiveness, government integrity or perception on corruption issues. There is a substantiated fact that the Index of Economic Freedom includes Judicial Effectiveness and Government Integrity in its calculation (https://www.heritage.org/index/about). There was also found specific literature on the relationship between corruption and economic freedom (Zhang, 2012). But we have found scarce scientific literature on the procedural delays (quantified by the Judicial Effectiveness) over business incentive.

Our paper aims filling a gap in this area of research, by focusing on the relationship between judicial delays and the enterprise's activity on the market. The first part of the study focuses on the relationship between the Judicial Effectiveness (one of the descriptors for the Index of Economic Freedom) and the Corruption Perception Index. To find out if there might be quantified any influences (or correlations) (on global scale) between the judicial delays and the perception about discretionary will (i.e. corruption). Further, we'll investigate the influence of Judicial Effectiveness over market leavers (expressed in two ways: as number of enterprises that were registering bankruptcy and exits of enterprises), and the influence of Government Integrity over the same indicators for 22 OECD countries. And, for being able to empirically test and reflect through a regional quantifiable frame Romanian's entrepreneur perception about judicial terms delays over the losses and bankruptcy spectrum their company experience, we've studied Judicial Effectiveness influence over the number of enterprises in the European Union.

In the fourth part we present the results of our findings, and in the last section we conclude, and we offer our ideas for further investigation.

A World of Justice and Economic Freedom

As mentioned before, one thing researchers seem to agree with is judicial performance, operationalized as the ability of courts to avoid delays in the delivery of justice and trust in legal systems (Magalhaes, Garoupa 2020).

The performance of the courts, given the fact society and economy as a whole experience a digital era, when everything runs faster and the promises of constant improvements are high, has an important role for the well-functioning of the market (Frade et al, 2020) as courts are among the institutions that have the greatest impact on economic performance (Lorizio, Gurrieri, 2014). The World Bank acknowledges the importance of sound judicial systems to good governance and economic growth and scholars investigate various judicial reforms all over the world (Messick, 1999). There are studies for analyzing the impact of judicial efficiency over the entrepreneurial incentive on using court proceedings in the resolution of financial distress (bankruptcy procedures) (Mruk et.al, 2019), while others circumambulate on the centralization idea of legal authority in order to provide a clearer, more coherent, and more predictable legal infrastructure for patent law (Wagner, Petherbridge, 2004). Various analyses on determinants of the performance of commercial district courts, in terms of the number of resolved cases were conducted in Poland (Beldowski et al, 2020) and the most significant

finding was that an increase in the number of judges and auxiliary court staff can significantly enhance the number of resolved cases. On the contrary, the evidence from Nepal shows that multi-court judging exhibits a negative effect on judicial productivity at case resolution (Grajzl, Silwal, 2020). The relationship between size and judicial performance was tested using a Weber predictive model and there was found a positive relationship between size and formal rationality and a negative relationship between size and substantive rationality (Smith et al, 2020).

Other authors (Belermann, Christmann, 2020) substantiate the role of using prior judicial decisions for the efficiency of justice in civil law matters in a country. The experience of improving efficiency on public service by merging courts proved positive for some legal systems (Agrell et al, 2018) while for others judicial selection is a critical factor for judicial performance (Vakilifathi, Kousser, 2020). There are evidences that poor judicial administration also contributes to cases backlogs (Sen, 2020). In some regions of the world, the magistrate training, number of servers, quantity of assessments, IT tools, transparency and monthly payment are tested to be the main factors that induce judicial performance and also the political factor may exert influence over jurisdictional benefits (Ferreira, Borges 2020). In other regions, belonging to OECD countries, there are other reasons, such as intrinsic motivation (induced by extrinsic means) of the judges for inducing a more collaborative manner to assign cases and to promote judicial collegiality and mentoring (Murray et al., 2020).

There are evidences for the impact a performant judicial system has on the whole performance in the public sector and how discrepancies in development are related to this issue (Nissi et al, 2019). The relationship between institutional (judicial and political) and monetary dimensions of corruption were investigated for 16 developing and emerging economies and where the judicial corruption has higher stakes, the innovative activities of enterprises decrease (Riaz, Canter, 2020). Other authors estimate technical efficiency of judicial system for policy makers' purposes, in order to diminish bureaucracy induced delays (Ippoliti, Tria, 2020).

As such, authors were able to identify the main hypothesis for this investigation:

1. There is a quantifiable relationship between judicial effectiveness and the entrepreneurs' perspective on the corruption seen as related to the delays in courts.
2. There is a quantifiable relationship among judicial effectiveness and government integrity (best describing the macro-environment influenced by delays in courts) and market leavers.

Methodology

Taking into consideration the specificity of the study, the authors conducted a desktop research for finding the most important factors that impede or influence the judicial effectiveness, also the entrepreneurs' perspective about legal environment. Scientific literature was investigated in order to reflect the state of the art of the relationship among judicial system, perception of corruption and bankruptcy or market leaving.

In order to test the influences hypothesized about economic freedom and perceived corruption, applying the statistical investigation principles on 183 countries, authors found data matching and thus selected 178 countries on three years span. Even if there were 534 observation, thus proving statistical consistency, the fact that Index of Economic Freedom considers Judicial effectiveness since 2017, let authors no option to conduct a longer time-span investigation. The correlation was tested, and a regression model could be identified, also tested. Further, the same type of statistical investigation was applied for UE data (28 countries).

In order to describe if justice performance and government integrity have a quantifiable influence on business environment, authors selected data from OECD countries (also a few relevant non-OECD countries). Correlation and regression analysis were applied on investigating: a) Judicial Effectiveness on bankruptcies and on market exits (57 observations, 2017-2019); b) Government Integrity over bankruptcies and on market exits (57 observations, 2017-2019). Statistical significance was reported as satisfactory for a probability of .95.

The third numerical study, that was directed towards reflecting the direct and clustered influence of judicial effectiveness on the total number of enterprises was applied to EU-28 data. Correlation and regression were applied to 28 countries.

Results

The Judicial Effectiveness (one descriptor for Index of Economic Freedom) and the Corruption Perception Index statistical investigation proved to be highly correlated both on global scale (.83) and on European level (.86). Regression analysis fully validated the main hypothesis and described a quantified relationship between those indicators as presented below:

Table 1: Judicial Effectiveness on the Corruption Perception Index between 2017-2019, regression testing on global scale and for European Union-28

Regression Statistics Global scale		***Regression Statistics European Union - 28***

Source: Authors' own realization according to data collected and analyzed from https://www.transparency.org and https://www.heritage.org

Further investigating the assumption that developed economies prove their efficiency also through their judicial effectiveness and government integrity, authors collected, tested and found statistically significant results of the investigated indicators on data regarding market leavers available at: https://data.oecd.org/. Here are the results:

Table 2: Judicial Effectiveness and Government Integrity on Bankruptcy and Exits (OECD countries, 2017-2019)

Regression Statistics for Judicial Effectiveness on Bankruptcies		**Regression Statistics for Government Integrity on Bankruptcies**	**Regression Statistics for Judicial Effectiveness on Market Exits**	**Regression Statistics for Government Integrity on Bankruptcies**
Multiple R	0.243017	0.151713	0.507517	0.446357
R Square	0.059057	0.023017	0.257573	0.199235
Adjusted R Square	0.041949	0.005253	0.235737	0.175683
Standard Error	86.97163	88.6216	36.15441	37.54802
Observations	57	57	36	36

Source: Authors' own realization according to data collected analyzed from https://data.oecd.org/ and https://www.heritage.org

Feeble indirect correlations were found among Judicial Effectiveness, Government Integrity and Bankruptcy rate for developed countries. On the contrary, when looking at the correlation and regression testing data for the same indicators on the market leavers there is a significant causality, also influence (for 0.95 probability, P -value <0.005) for both Judicial Effectiveness and Government Integrity on business operativity on a market.

The third part of the numerical research was applied on a regional level, Romania being a member of European Union since 2007, in order to reflect the entrepreneur's perspective on judicial delays in a more homogenous manner. Because of the limitations related to data scarcity for later years (there were comparable data for only two years) and market leaving indicators (Euro-Stat database provides data on the number of enterprises), there was found a negligible correlation between Judicial Effectiveness and the total number of economical enterprises operating on the market in a specific timespan.

Conclusions

Delays in Court (seen as Judicial Effectiveness) influence in a highly amount all over the world citizens perception on corruption issues. There is a validation of the principle that law sustains democracy through free market perspective's and market efficiency from this point of view. Authors found that judicial delays are highly related to other issues that belong to democratic process and reflected in a clean or vicious manner on public opinion about democracy. In this manner was found the proof to validate various entrepreneur's perspective on market legal framework that impede their success.

Developed countries experience further support the validation of the subjective perspective with data on market leavers quantified as bankruptcy rate and market exits. The results of the study proved that Judicial Effectiveness and Government Integrity cause a feeble influence on bankruptcy but a significant one on market exits of the companies in developed countries.

Even if we were not able to support the presumption about direct judicial delays' influence on business incentive on European level, we have presented a method for investigating this phenomenon that may be further quantified and detailed when data reported by international agencies suffice.

Abstract

In paper, we consider digital technologies development results for geo-information support to sea ports activity. In studies, we used methods of data bases constructing, web-technologies and virtual reality tools. Also, we used Foresight technologies, theory of decision making under uncertainties and risk management. As digital tools, we propose to use digital online platforms, which integrate heterogeneous hardware and software resources with the use of web-technologies in distributed networks and wide application of cloud services. As study result, we demonstrate geo-information support system for Russian sea port Ust-Luga. For data exchange and preliminary discussion we used platform https://www.researchgate.net/profile/Valery_Abramov2/ while research.

Keywords: Digital Technologies, Geo-Information Support, Sea Ports, Climate Change, Covid-19

KORINETS, Vladimir A. BOLSHAKOV and Tatiana V. VEKSHINA "Digital Technologies for Sea Ports Geo-Information Support while climate change and Covid-19" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Introduction

Currently, global environmental economy including sea ports activity (SPA) is within Industry 4.0 period, when while climate change and Covid-19 pandemic. Now, many businesses are planning and implementing a wide range of information technologies (Lukyanov, 2019), (Drabenko, 2019), (Grobitski, 2016), (Frolova, 2019), (Trunin, 2019). Industry 4.0 leads to serious technological changes in geo-information support (GISS) for sea ports activity (SPA), including natural risks management (NRM) (Berboushi, 2014), (Ershova, 2018), (Garcia, 2018), (Isaev, 2015), (Istomin, 2018), (Shilin, 2019), which requires the development of new tools, including practical learning area (Averkiev, 2020), (Korinets, 2020), (Popov, 2019).

In paper, we describe the development results of digital technologies for geo-information support to SPA within geo-information management (GIM) paradigm (Burlov, 2018), (Gomazov, 2018), (Fokicheva, 2016), (Lednova, 2014), (Malakhova, 2014), (Yaily 2019), (Zavgorodniy, 2020), in large environmental projects (Mandryka, 2019), (Popov, 2014), (Popova, 2019), (Rumyantseva, 2017), (Zhigulsky, 2018) within environmental economics (Bidenko, 2019), (Golosovskaya, 2014), (Karlin, 2014), (Karlin, 2009), (Kolbina, 2020), (Popov, 2016). We paid significant attention to geo-information support systems (GISS) within climate change and covid-19 pandemic context (Bournashov, 2014), (Gogoberidze, 2014), (Chestnov, 2020), (Chusov, 2012), (Estrin, 2020), (Tatarenko, 2020), including the issues of information collection and processing (Fokicheva, 2019), (Khaimina, 2014), (Popova, 2019), (Tatarnikova, 2019), (Ya, 2019). Developed digital technologies for GISS to SPA while climate change and covid-19 pandemic, considered in this article, take these factors into account.

Methods and data

In research, we used Foresight technologies, theory of decision making under uncertainties, risk management approach, methods of data bases constructing, web-technologies and virtual reality tools. Also, we used big data technologies (Popova, 2019), (Yaily, 2019) From the point of view of geo-information management, geo-space is structured to allocate the interconnected components of the solution space (Bidenko, 2019). While study, we used data bases and tools of geo-information digital online platforms (GIDOPs) Earth (Bolshakov, 2020), (Sanina, 2020), and EOS, including its Land Viewer (LV) product (Prostakevich, 2020), (Vekshina, 2020).

Results

As a result of performed using foresight technology research, we put forward the claim that in present conditions of climate change and Covid-19 pandemic, it would be advisable to develop sea ports infrastructure with the aim of geopolitical risks management for global economics, which are summarized in (Prostakevich, 2020). Preference should be given to those sea ports, where climate change leads to an improvement in their overall operating conditions, for example, a reduction in the timing of ice risks in their waters. As GISS basement, we propose to use the tools of geo-information digital online platforms (GIDOPs) Earth (Bolshakov, 2020), (Sanina, 2020), and EOS, including its Land Viewer (LV) product (Prostakevich, 2020), (Vekshina, 2020). As an example, we consider the Russian port of Ust-Luga. In figure 1, we show a general view of this port location on the Gulf of Finland's map (red rectangle).

Figure 1 - General view of sea port Ust-Luga's location on the Gulf of Finland's map (red rectangle)

Relatively recently, the entire Gulf of Finland and the water area of the port of Ust-Luga were covered with ice for several months in winter. In figure 2, we show a satellite image of the Gulf of Finland on April 4, 1996, visualized with Natural Colors Application of LV product. It can be seen that the ice cover covers almost the entire water area of the Gulf of Finland, including the area of the future sea port of Ust-Luga (red rectangle), the construction of which began in 2000 and continues to this day.

Figure 2 - Gulf of Finland's space image on 04/04/1996 visualized with Natural Color Application of LV (red rectangular is Ust-Luga sea port area)

In figure 3, we show a satellite image of the Gulf of Finland on February 4, 2020, visualized with Natural Colors Application of LV product. Comparative analysis of figures 2 and 3 shows that due to climate change in the Gulf of Finland, there is a significant terms reduction of ice cover presence in the area of sea port Ust-Luga, which allows to allocate it as a priority object for development of sea port infrastructure of Russia. This is exactly what is happening now, the Ust-Luga seaport is developing at an accelerated pace and by the year of 2025, the area of the port facilities will be expanded to 1,600 hectares.

Figure 3 - Space image of the Luga Bay at Ust-Luga seaport on 06/02/2020 visualized with Natural Color Application of LV (red rectangular is Ust-Luga sea port area)

Note, significant terms reduction of ice cover presence at sea port Ust-Luga is an important incentive for private investors. And these investments are actively increasing. Currently, the port is carrying out intensive work on dredging the so-called approach channels and construction alluvial areas in the southern part of the port to the East of the Luga river mouth. The associated negative impact on the environment is the increased turbidity of the waters in the Bay and the violation of the natural habitat of bottom fauna. In figures 4 and 5, we present space images of the Luga Bay with Ust-Luga sea port on 23/09/2020 visualized with Natural Color Application of LV (red rectangular is Ust-Luga sea port area).

The use of special satellite image visualization applications as part of the proposed GISS (figures 6 and 7) made it possible to clearly identify the washed-up areas. The best results were achieved with the use of NDWI Application of LV (figure 7).

Figure 4 - Space image of the Luga Bay with Ust-Luga sea port on 23/09/2020 visualized with Natural Color Application of LV (red rectangular is Ust-Luga sea port area)

Figure 5 - Enlarged space image of the Luga Bay at Ust-Luga seaport on 23/09/2020 visualized with Natural Color Application of LV

Figure 6 - Enlarged space image of the Luga Bay at Ust-Luga seaport on 23/09/2020 visualized with Land/Water Application of LV

Figure 7 – Enlarged space of the Luga Bay at Ust-Luga seaport on 23/09/2020 visualized with NDWI Application of LV

As a result of the analysis of open mass media using the query system as part of the developed GISS, it was found that the above-mentioned dredging works are performed using the latest dredging vessel *Kronshlot* built in 2016 (figure 8).

Figure 8 – Dredging vessel *Kronshlot* built in 2016

We also established that dredging in the southern part of the port of Ust-Luga is expected to be carried out until the end of 2020, so increased turbidity in the Luga Bay will be observed further, until the end of these works.

Note, discussion of the environmental consequences of the above-mentioned dredging operations in sea port of Ust-Luga is not task of this article.

Discussion

Proposed above low-cost GISS for SPA can be used in educational and training purposes. The essential task of university practical learning (UPL) in the field of SPA is to teach students the practical aspects of work with GISS for SPA tools, which requires a developed learning base within special geo-information systems (GIS) laboratory. In some cases, real practical work in special GIS laboratory can be undergoes with virtual reality (VR) technologies (Korinets, 2020), (Popov, 2019), that can reduce total cost of learning process.

Conclusion

In article, we consider results of digital technologies development for geo-information support to SPA. In research, we used Foresight technologies, theory of decision making under uncertainties, risk management, methods of data bases constructing, web-technologies and virtual reality tools. As study result, we suggest to use GIDOPs Earth and EOS, including its LV product, as the main technological tools within GISS for SPA. We demonstrate possibilities of GISS for sea port Ust-Luga. As essential result, we propose to use developed GISS as basement for subsequent sea ports, including educational and training purposes. The research results presented in this article has significant scientific novelty and can be useful for private investors, public environmental organizations of the civil sector and state environmental control bodies.

Acknowledgment

While study, Professor Mikhail Shilin, full professor in Applied Informatics Department within Information System and Geo-Technologies Institute at the Russian State Hydrometeorological University (AID ISAGTI RSHU) and Associate Professor Nikolay Popov, head of geo-information systems laboratory in Arctic and Subarctic Institute at RSHU (LGIS IAS RSHU), gave us very useful consulting. Platform https://www.researchgate.net/profile/Valery_Abramov2/ was used for preliminary discussion and data exchange while this research.

Abstract

The Russian Federation currently faces the need to develop effective incentive mechanisms for research and development for the benefit of organizations in the real economy and create effective research and development (R&D) financing instruments, including non-budget financing. We propose methods for analytical consolidation of budget and non-budget expenditures on science for more effective assessment of R&D spending. Proposed methods will enable to increase the transparency of science funding, enhance the efficiency of public spending, identify new sources of non-budget funding for research and development.

Keywords: Science Funding, Budget and Non-Budget R&D Financing, Science And Technology Development.

Introduction

Current world trends show not only a transformation of social and economic systems, increased competition in world markets, changes in the structure of productive forces, redistribution of financial resources and concentration of geopolitical risks, but also reflect the irreversible process of development of the knowledge-based economy, accelerated formation of a new scientific and technological order of society, exponential growth in the knowledge-intensive industries, development of intellectual and educational potential of a person, emergence of new knowledge, scientific expertise, which until a quarter of a century ago was unthinkable and incomprehensible not only for the ordinary people but also for the scientific perception. The study shows a negative trend in the development of Russian science that funds from the federal budget that remain the main source of funding for basic and applied research within the framework of State programs. Russia continues to lag significantly behind many developed countries in its share of science expenditure, which is financed from extrabudgetary sources. It is vital that Russia do not remain on the sidelines of the world's scientific, technological and innovative processes and maintain and strengthen its position in the world's scientific, technological, innovative, information and intellectual cluster.

Research on the evolution of mechanisms and instruments to stimulate research and technological activity in the Russian Federation's State programs has been carried out in the past, in our view, does not reflect a complete and objective picture. The authors of this study have proposed effective mechanisms for stimulating research activities

for the benefit of organizations in the real sector of the economy. In order to improve the efficiency of the Government's management of research and development and to create effective instruments for financing R&D from extrabudgetary sources.

Material and Methods

There were used such formal methods as classification, analysis, synthesis, deduction, induction, and comparative data analysis.

Results and Discussion

The practice of performing scientific and technological activities in the majority of technology companies which are successful in the market indicates that the process of an innovative product development is not divided into a research phase and, in fact, an innovation phase. At the same time, it should be noted that the need to separate the research phase into a particular phase can emerge in two cases: first, when a company does not have internal scientific expertise but, at the same time, has a strong independent research partner organization, which can carry out the company's orders for research and development; second, when companies have internal research centers (especially at large companies), which do relatively autonomous research and have their own plans for scientific research.

Both approaches are used in Russia, but as opposed to leading nations in scientific and technological innovation, companies in the real economy in Russia rarely have their own research facilities. For example, metallurgical company PAO Severstal has their own research institute in Cherepovets; JSC AvtoVAZ, the automaker in Togliatti, relies on a research center established jointly with German partners. The alternative when companies perform research activities using external scientific organizations is widespread in Russia and traces to the practices of the Russian defense industry. For example, St Petersburg Polytechnic University continuously works with defense plants under long-term agreements, and research activities around this cooperation became one of the university's priorities.

A study by the Boston Consulting Group provided a systematic comparison of research and innovation activities in 50 most innovative companies in the world. In the given report, all the leading companies have the following common features in a research study by Ringel, Grassl, Baeza, Kennedy, and Manly (2019):

– a significant turnover of financial resources, which enables to maintain scientific departments and purchase the latest equipment for their full-fledged work;
– obligatory leadership in the world market in a relatively narrow segment (there are exceptions, for example, German conglomerate Siemens AG, automobile corporation Toyota Motor Corporation);
– a closed cycle of work from developing a long-term strategy to organizing a dealership network around the world.

Abroad, in many cases, companies in the real economy and diverse external scientific organizations don't make public their collaboration, but they cooperate as part of their main activity at all stages of product creation. For example, in the United States, commonly, long-term research financing from the private sector belongs to the core activities of universities. Various research activities come with multiple approaches to defining research areas and subjects. There is a trend to evaluate the feasibility of basic research based on the expected impact for society. This is also reflected in the relationship between the phases of the full cycle "research - development - approbation – production". However, as a rule, the public sector is responsible for providing financing for basic research due to its long-term impacts on society, while the business sector is interested in applied research and development, which can potentially bring higher economic returns to the mid-term (less often - in the short term) perspective.

Socio-economic implications of productive interaction between the public and business sectors in the field of R&D are set out in figure 1.

Fig. 1: The relationship between the public and business sectors in the field of R&D and socio-economic implications of this interaction

It can be pointed out that the process of creating intellectual property assets receives financing both from the public and business sectors. The public sector, through R&D, primarily seeks to achieve such outcomes as GDP growth and better quality of life for citizens; while the business sector wants to improve product competitive position, increase profits and reduce costs.

Russia ranks eighth in the world in terms of total R&D spending and is currently increasing budget allocations to basic and applied research. According to the Russian Federal Treasury, the cash execution of federal budget allocations to basic and applied research under Russia's 32 national programs in 2019 totaled 440,486.18 million rubles, including 191,085.45 million rubles spent on basic research, and 249,400.73 million rubles spent on applied research (Table 1).

Table 1: Cash execution of federal budget allocations to basic and applied research under Russia's national program in 2017-2019

Indicator	2017		2018		2019		Deviation (+,-) 2019 to 2017	Change rate, % 2019 to 2017
	The amount, thousand rubles	Proportion, %	The amount, thousand rubles	Proportion, %	The amount, thousand rubles	Proportion, %		
Cash execution of federal budget allocations, including	338572,4	100	368925,1	100	440486,1	100	101913,7	130,1
on basic research	116188,0	34,3	148120,0	40,1	191085,4	43,4	-74897,4	164,5
on applied research	222383,4	65,7	220805,1	59,9	249400,7	56,6	27017,3	112,1

The cash execution of federal budget allocations to basic and applied research under national programs has increased by 30.1%. The most significant growth of budget spending was on basic research - 164.5%; the increase of spending on applied research has reached 112.1%. Furthermore, in the period under review, we observe an increase in the share of spending on basic research: from 34.3% in 2017 to 43.4% in 2019 and a decrease in the share of spending on applied research: from 65.7% to 56.6%. It is worth noting that in 2019 the proportion of cash expenditure of the federal budget on basic and applied research under Russia's 4 out of 32 national programs amounted to 88.29% of the total spending on research and development for civilian purposes (figure 2).

Fig.2: Cash expenditure of the federal budget on fundamental and applied research in 2019, %

Ilyina, Zharova, Burlankov (2018) mentioned that research into the development of methods for determining the efficiency of funds allocation on research and development has been actively evolving. It should be emphasized that at the current stage of the transformation of the research and development sphere and its integration into economic activities, the process of analyzing the efficiency of R&D spending should include measures aimed at improving the management of R&D activities and the development of effective incentive tools for the R&D sphere at the various phases of the innovation cycle.

The development of effective incentive mechanisms for research activities for the benefit of organizations in the real economy under Russia's national programs is inextricably linked to the task of improving the efficiency of public administration methods in the sphere of research and development and creating effective instruments of R&D financing. The primary goal, in this case, is to introduce a management mechanism in the field of science and technology development in Russia, aiming to improve the investment attractiveness and efficiency of investments in the sphere of research and development, improve the performance and relevance of research and development.

The appropriateness of the application of particular instruments aimed at developing the R&D sector can change depending on the various phases of the innovation cycle (basic research, applied research, experimental design). As a result, an effective method of systematizing management solutions under the national program Science and Technology Development is the distribution of these instruments by technology readiness levels (TRL).

TRL phase 1 implements the management instruments according to the basic research plan, including by doing the following - provide subsidies to world-class research centers; give access to scientific and technological information; award grant financing for the projects of the Russian Science Foundation (RSF) and the Russian Foundation for Basic Research; support the RSF projects, etc. TRL phases 2-3 and 4-7 implement government support measures for R&D with a focus on applied research and experimental design, including the implementation of Russian Government's orders No. 220 aiming to attract leading scientists to universities and science organizations and establish world-class laboratories led by top scientists; carry out science and technology projects and set up high-tech production facilities based in science cities, etc.

TRL phases 4-7 of the national program Science and Technology Development use the management tools aimed at delivering scientific and technological outputs in the form of new practical solutions for the use of technologies in manufacturing new products and providing services. These tools include the following measures - promote cooperation between Russian universities and organizations in the real economy to set up new high-tech production facilities; support the implementation of complex science and technology programs (CSTP), including by receiving non-budget financing; establish centers for the National Technology Initiative; support and develop resource sharing centers and unique scientific installations. The bulk of R&D financing under the national program Science and Technology Development is controlled by the management mechanisms which belong to TRL phase 1. At TRL phases 2-3, with the maturity of technology readiness levels, non-budget financing should increase with a simultaneous reduction of federal budget funding and its further increase at TRL phases 4-7 (according to the report of Ilyin (2019)).

However, in the opinion of the authors of this article, the instruments used to secure non-budget financing, first, are not sufficient to reverse the prevailing tendency of government budget financing of R&D, and second, the majority of measures for attracting the business sector to science are advisory in nature and are not attractive for the private sector. This circumstance is working against the achievement of scientific and technological breakthroughs set out in the Strategy for Science and Technology Development.

For Russian science, federal budget funding remains the main source of financing for basic and applied research. This type of financing has always suggested control over the activities of the investee, particularly if it is federal budget spending.

Table 2 sets out GDP growth rates and comparative growth rates of science funding from the federal budget. The growth rates of public financing of science do not exceed the projected GDP growth rates, which indicates that the amount of public financing is not sufficient.

Table 2: Comparative growth rates of GDP and public financing of science

Indicators	2013	2014	2015	2016	2017	2018	2019	2020*	2021*	2022*
Science financing from federal budget, billion Roubles	425,3	437,2	439,3	402,7	377,8	420,4	489,1	506,2	518,9	540,7
Growth rate, %	119,4	102,8	100,4	91,7	93,8	111,3	116,3	103,5	102,5	104,2
GDP, billion Roubles	72985,7	79030,0	83087,3	85616,0	91843,1	104629,6	110046,0	112 863,0	120 364,0	128 508,0
Growth rate, %	107,2	108,2	105,1	103,0	107,3	113,9	105,2	102,6	106,6	106,8
Proportion of budget financing in GDP, %	0,58	0,55	0,53	0,47	0,41	0,40	0,44	0,45	0,43	0,42

** as per the draft federal law 'On the federal budget for 2020 and for the planned period 2021 and 2022*
*** Authors' calculations based on Russian Statistics Agency (Rosstat) data*

The data indicate a decline in the growth rates of the federal budget's science spending before 2016 thereafter the public spending has only increased, and the largest increase occurred in 2018 and 2019. However, for this to have positive effects, a replacing and outpacing growth of non-budget spending is required but there is no statistical evidence for this (figure 3).

Fig. 3: The proportion of non-budget funds in total R&D financing, %

The main reasons for the low growth rates of non-budget funds in science include the following:

1) the absence of motivation for the business sector to invest in science, high risks of no return of investment, poor development of technologies for commercialization;

2) skeptical attitude towards science in the society as a result, among other things, of the reputation losses of the Russian Academy of Sciences (RAS) and a long-running campaign in the media to discredit the Academy;

3) underdeveloped mechanisms for attracting private investments in science. The concentration of the majority of scientific expertise in public research institutions, which are, to a significant extent, is secret and closed.

However, when making decisions on the selection of measures to stimulate non-budget R&D investment, it is necessary to consider that, despite the current more realistic goal setting, such decisions will undoubtedly increase the burden on economic agents. Furthermore, increased administrative regulation and/or pressure to attract non-budget funds may lead to other problems in the economic system (for example, widespread hiding of profits and, hence, a decrease of the profit tax base - in the event of introducing mandatory contributions to R&D from the profits of enterprises and business organizations).

To avoid an imbalance of the economic system, it is necessary to implement a set of measures that will provide a comprehensive solution to this problem, considering social, economic, legal, and institutional aspects. One of the main directions of the reforms underway should be an increase in the proportion of industries with high added value

in the Russian economy. Possible solutions to this problem could include both improving the statistical tools for R&D cost accounting and stimulating enterprises and business organizations of various forms of ownership to assign costs to research and development and include them in statistical records.

The current situation is caused, on the one hand, by the requirements of the strategic documents aiming to increase internal R&D spending to ensure accelerated science and technology development and the transition to a "smart" economy, and on the other hand, by the multichannel nature of R&D financing with no single system of budgetary and statistical records. This situation calls for the development of proposals to consolidate R&D spending in one instrument aimed at achieving the strategic goals in science.

National program 'Science and technology development of the Russian Federation' is to become such an instrument as the main tool for the implementation of Russia's Strategy for science and technology development and the single strategic planning document aiming to develop the nation's intellectual capability; provide scientific, technological and intellectual support for structural changes in the economy; ensure an efficient organization and technological update of science, technology, and innovation (high-tech) activities.

In a research study by Klimanov V., Safina A., (2017) under the current legal and regulatory framework for the development and implementation of the national programs, only public funds must be recorded in the national program (non-budget financing can be included for reference only). At the same time, the national program Science and Technology Development proposes to carry out the consolidation of science spending in two phases: Phase 1 consolidates all federal budget funds allocated to science, and Phase 2 consolidates non-budget funds. However, the consolidation of funds from non-budget sources should be based on the same principles and terms as the consolidation of budget funds, but it has to be included in the national program for reference purposes.

At the same time, it is worth noting that neither administrative measures only nor factual (non-analytical) inclusion in one document (national program Science and Technology Development) of all federal budget expenditure and non-budget funds will solve the problem of including all R&D spending from the other national programs into the national program Science and Technology Development.

Conclusions

In addition to funding consolidation measures, the following actions are to be taken:

- centralize the recording of R&D output in the Unified state information system for recording the R&D output for civil purposes (EGISU R&D). Public authorities should additionally work with subordinate R&D organizations to provide correct data showing the amount of budget and non-budget funding and real intellectual property output upon the completion of work;
- develop a culture of identifying and recording the intellectual property assets;
- develop communication tools between R&D organizations and organizations in the real economy;
- objectify data about the achieved R&D outcomes and their practical application, with the further use of information recorded in the EGISU R&D to inform management decisions;
- use the EGISU R&D data to improve competition, including focusing government support on the most productive and efficient IP owners;
- provide R&D information transparency for the society and at the same time ensure the lawful rights and interests of the authors of scientific ideas and achievements;
- introduce a particular section on science in the Budget classification code as a necessary alternative to the consolidation of all expenditures on science in a single national program;
- improve R&D accounting rules;
- interlink the forms of accounting, tax, and statistical reporting.

Another way to improve the commitment of business to R&D should be the active introduction of a "qualified customer" model into the economic practice and the development of complex science and technology programs and projects. Klypin et al (2019) mentioned that these projects are proposed in a particular sub-program of national program Science and Technology Development to achieve the priorities set out in Russia's Strategy for science and technology development approved by the Russian President's order of 01.12.2016 No. 642. This includes the creation of a coherent system of developing and implementing strategically significant science and technology projects with the participation of organizations in the real economy and a qualitatively new approach to the approval of scientific and technological output, and the evaluation of its impact.

The proposed measures and their integration into the R&D management and financing system are considered to lead to more efficient public financing of science, increased non-budget R&D funding and more transparent R&D spending.

Acknowledgments

This study has been carried out with the financial support of the Ministry of Science and Higher Education of the Russian Federation under public assignment of the RIEPP for 2020 No. 075-01402-20-02 dated 07.04.2020 (project "Scientific and methodological, expert and analytical support for the assessment of the implementation of national program Science and technology development of the Russian Federation").

Conflict of Interest

We, as the authors of this article, declare with full responsibility that we have no existing or potential conflict of interest with any third party which may arise from the publication of this article. This declaration relates to the carrying out of scientific work, collection and processing of data, writing and preparation of this article, and making the decision to publish the manuscript.

Abstract

COVID-19 outbreak affected countries around the world including Malaysia in their tertiary education sector. In order to break the chain of COVID-19, Government of Malaysia enforced a Movement Control Order starting on March 18, 2020. Open and Distance Learning (ODL) was seen as a priority for teaching and learning method used during the outbreak. Thus, this study aims to identify the technological tools used by students in ODL and identify the preferred method and platforms by students in ODL. This study adopts quantitative method. A survey was used to determine the method and platforms preferred by Library and Information Science (LIS) students during ODL in Universiti Teknologi MARA (UiTM). The findings proved that students able to access the internet either by using mobile data, Wi-Fi or both. In addition, ODL method preferred by students is video recordings/ narrations. For students who preferred live lectures/ discussions, the platform that they opt for is Google Meet. Students preferred WhatsApp as the platform in receiving information from their lecturers and Google Classroom as an application platform to download teaching materials and assignments. Therefore, by identifying students' condition and preferences for ODL may assist lecturers and universities all around the world towards a successful teaching and learning process. Besides, other universities around the world can use the findings from this study to structure an effective policy and plan to ensure the success of ODL in their institutions that can improve the online teaching and learning process.

Keywords: 1. Open and Distance Learning 2. Online learning 3. Technological tools.

Introduction

Open and Distance Learning (ODL) was seen as a priority for teaching and learning method used during COVID-19 pandemic as precaution actions to ensure schools and academic institutions can continue its operation in the education system. Furthermore, this pandemic is being describes as a global crisis without precedent and this affects mostly the whole living system operations including the education system (Hall et al. 2020). The pandemic obviously give impact on the tertiary education sector in Malaysia when Government of Malaysia enforced a Movement Control Order starting on March 18, 2020 to break the chain of COVID-19 (Ain Umaira Md Shah et al. 2020). Universities themselves rapidly introduced new forms of teaching and learning, where shifts to online teaching, new forms of assessment and innovative digital communication tools are all evident (Raaper & Brown 2020). It is obvious that ODL is mediated by technology and the internet. Having access to both is vital for a successful teaching and learning process.

The digital technology such as desktops, laptops or smartphones can help students in ODL. However, from the research done by researchers, it was found that there are Library and Information Science (LIS) students from Universiti Teknologi MARA (UiTM) Negeri Sembilan Branch who do not participate in online studies due to technological constraints and access to the internet. In addition, there are lack of studies conducted on the implementation of ODL particularly on how students access to technology and what are the online learning method and platforms that they prefer to use during ODL involvement.

Therefore, the objectives of the study are:

1. To identify the technological tools used by students in ODL
2. To identify the preferred method and platforms by students in ODL

Literature Review

Open and Distance Learning (ODL) Deployment

Today's world challenge is a pandemic crisis. As we are all aware, because of the COVID-19 pandemic, things are shifting and changing rapidly and the effect, enforceability and interpretation of laws may be affected by future events. (Deliu 2020). This crisis has caused a sudden interruption of schools, colleges, universities, and other government institutions to use electronic learning system (e-learning) (Soni 2020). During these extreme times, students may have short-term and long-term disruptions in their education. The Higher Education Ministry of Malaysia has announced that all teaching and learning programmes in universities should be conducted through online platform. However, these are subject to the authorities from time to time by looking at the progress of COVID-19 cases and scenarios in Malaysia. Students are allowed to be involved in the resumption of physical face-to-face teaching and learning programmes but have to prioritise safety and physical distancing measures (Landau 2020). Thus, ODL have a great

contribution to educational processes today. Knowledge can be translated into a two-way online communication as a proactive partnership and at the same time ensuring one's safety and it is not necessarily be acquired in classrooms (Bernama 2020). The pivot from in-school classroom teaching and learning to entirely distance models of education is happening right now as necessitated by the COVID 19 crisis (Doucet et al. 2020). ODL are innovations to adapt to today's world. It is a combination of open learning and distance learning. Distance education has become a norm during the pandemic of COVID-19 to sustain the educational processes when students and teachers are constraint to have a face-to-face teaching and learning. This allows the students to self-pace through the online content. There are usually no set times for distance classes (Jenkins et al. 2017). ODL is different with the concept of blended learning. Blended learning is the combination of face-to-face and online delivery where 30-60% of the course content is electronically delivered. The electronic delivery can be either asynchronous or synchronous. Also sometimes termed as Hybrid Learning (Ministry of Education Malaysia 2014). In addition, blended learning is a method of teaching and learning by the combination of traditional class activities with computer-mediated and online instructions (Allen, Seaman & Garrett 2007). However, the similarities between ODL and blended learning are both methods required the students and teachers to access and use technology for teaching and learning.

Technological Requirement

Technology impose the changes in education. It give impact in the educational development. It moves the conventional methods to an e-learning environment that is a learning that facilitated and supported through the use of information and communications technology (ICT). It may involve the use of some, or all, of the following technologies; namely, desktop and laptop computers, software (including assistive software), interactive whiteboards, digital cameras, mobile and wireless tools (including mobile phones), electronic communication tools (including email, discussion boards, chat facilities & video conferencing), Virtual Learning Environments and learning activity management systems (Ministry of Education Malaysia 2014).

Students should be able to have access to technology and the internet as these are an important elements in ODL for their learning process. Thus, technology can support the ubiquitous learning and allow a combination of synchronous and asynchronous learning (Doucet et al. 2020). For effective learning, students should be allowed to choose one that suits their learning preferences or that can be personalised to their needs (Ministry of Education Malaysia 2014). Students may become bored and are quite likely to poorly perform on evaluations if learning preferences and teaching methods occasionally do not match (Litzinger et al. 2017).

Researchers have found out by an observation made on 23rd March 2020, Google Trends in Malaysia showed that the searches on 'Google Classroom', 'Zoom App' and 'Zoom Meeting' was recorded as the three highest search terms. These are online platforms that can support teaching and learning to be conducted online. They are many others available online platform such as Googel Meet, Microsoft Teams, Loom and Google Hangouts. In addition, data collected by Statistics Department of Malaysian Communications and Multimedia Commision (2018) highlighted that there are 28.7 million internet users in 2018. The average duration of daily use of Internet for age group of 20's are 8 hours per day and made them as the highest age group that access the Internet. This shows that supposedly university students should not have any issues regarding on ODL teaching and learning methods. Based on previous research conducted by Aminudin, Karthikeyan and Priyadarshana (2019) a study is needed on the practices of open, distance, and online learning along with the advances in new technology and the changing needs of students. It is compulsory for students to have access to technology and the Internet during ODL. Without a stable internet connection, the learning process will be disrupted. Furthermore, if students do not possess any learning facilities such as a laptop or a mobile phone, it is impossible to conduct the ODL for both lecturers and students and this will give impact to the students' performance. Furthermore, the implementation of ODL requires students' engagement, motivation and interaction. Students should be required to interact with one another, with the instruction, with the content, with the entire class, in small groups or teams, one-on-one with a peer, etc. (Ministry of Education Malaysia 2014).

Data Collection Methods

This study adopts quantitative method. A survey was used to determine the method and platforms preferred by Library and Information Science (LIS) students during ODL in UiTM for the course of 'Introduction to Cataloging'.

Research design and sample

Students of Semester 4 from UiTM Negeri Sembilan Branch, Rembau Campus were selected as the research sample in this study. The questionnaire was sent to students who had registered for a 'Introduction to Cataloging' course (course code - IMD 223) in semester March 2020-July 2020.

Population

The population consisted of 92 registered students for the course of IMD223. The students' population would be able to address the research questions as they are the participants who must undergo and completed the subject for the said semester.

Data Collection Instruments

To understand the preferred online learning method and platforms in ODL required by students, an analysis has been conducted based on the data extracted from the questionnaire. All the findings were analized using IBM SPSS 25.0 software.

Questionnaire

The questionnaire was circulated to Semester 4 students from UiTM Negeri Sembilan Branch, Rembau Campus. The questionnaire had ten MCQs to meet the objectives of this study.

Data Analysis

This study applied descriptive statistics to meet the research objectives because the respondents represent the population of Semester 4 students of IMD223 from UiTM Negeri Sembilan Branch, Rembau Campus. The descriptive statistics include frequency and percentage analysis, crosstabulation table and bar chart are used to identify students preferred online learning method and platforms in ODL.

Frequency Analysis

This study employed primary data from 92 respondents of Semester 4 students of IMD223 from UiTM Negeri Sembilan Branch, Rembau Campus. Table 1 shows the summary of data analysis for this study. There are 43 male students (46.7%) and 49 female students (53.3%) involves in this study.

Result found that more than half of the students live in city which are 62 students (67.4%) while only 30 students (32.6%) live in rural area during ODL was implemented. This analysis finds out that majority of the students have their own desktop or laptop (n = 89, 96.7%) and only 3 students (3.3%) do not have any desktop or laptop. The 3 students (3.3%) that do not have any desktop or laptop used their smartphone for ODL.

For the category of internet access, there are 55 students (59.8%) used their mobile data, 15 students (16.3%) used Wi-Fi and 22 students used both of mobile data and Wi-Fi as their internet access. Table 1 also reveals that 45 students (48.9%) prefer live lectures or discussions as the ODL method while another 47 students (51.1%) prefer video recordings or narrations. Most of the students prefer video recordings or narrations as ODL method compared to live lectures or discussions. The students that choose live lecturers or discussions as their ODL method reveals that their most preferred platform application is Google Meet (n = 36, 80%), Zoom (n = 7, 15.6%), Facebook (n = 1, 2.2%) and Discord (n = 1, 2.2%).

The most convenient application of platform that preferred by students when receiving information from lecturers is WhatsApp application which is 62 students (67.4%), followed by 20 students (21.7%) prefer Google Classroom, 7 students (7.6%) prefer Telegram, 2 students (2.2%) prefer E-mail and only 1 (1.1%) student prefer I-Learn/ uFuture (an online learning platform in UiTM). Meanwhile, the most convenient application of platform that preferred by students to download the teaching materials and assignments is Google Classroom which is 34 students (37.0%), followed by 28 students (30.4%) prefer WhatsApp application, 12 students (13.0%) prefer E-mail, 11 students (12.0%) prefer Telegram and only 7 student (7.6%) prefer I-Learn/ uFuture. For the category of students who received the "B40 - Internet Allowance", more than half students (n = 47, 51.1%) did not receive this allowance, while another 45 students (48.9%) received the "B40 - Internet Allowance".

Table 1: Summary of Data Analysis

Items	Frequency (N = 92)	Percentage (%)
Gender		
Male	43	46.7
Female	49	53.3
Where do you live during ODL implementation?		
City	62	67.4
Rural	30	32.6
Do you have any desktop or laptop?		
Yes	89	96.7
No	3	3.3
i. *How do you complete assignment that will be given by lecturer if you choose 'No' answer for question before?*		
Smartphone	3	3.3
What kind of internet access do you use?		
Mobile Data	55	59.8
Wifi	15	16.3
Both	22	23.9
What is you preferred method for ODL? If your answer is 'Live lectures/ discussions', please answer next question.		
Live Lectures / Discussions	45	48.9
Video Recordings / Narrations	47	51.1
i. *What is your most preferred application of platform?*		
Google Meet	36	80.0
Zoom	7	15.6
Discord	1	2.2
Facebook	1	2.2
What is the most convenient application or platform you prefer in receiving information by lecturers?		
WhatsApp	62	67.4
E-mail	2	2.2
Google Classroom	20	21.7
Telegram	7	7.6
I-Learn / uFuture	1	1.1
What is the most convenient application or platform you prefer to download the teaching materials and assignments?		
WhatsApp	28	30.4
E-mail	12	13.0
Google Classroom	34	37.0
Telegram	11	12.0
I-Learn / uFuture	7	7.6
Do you received the 'B40 – Internet Allowance'?		
Yes	45	48.9
No	47	51.1

Crosstabs Analysis

Table 2 shows the cross-tabulation table of students' location during ODL implementation with preferred method of ODL among Semester 4 students of IMD223 from UiTM Negeri Sembilan, Rembau Campus. The crosstabs table below reveals that 51.1% students (n = 47) prefer video recordings/ narrations and 48.9% students (n = 45) prefer live lectures/ discussions as the ODL method. Based on 51.1% students (n = 47) prefer video recordings/ narrations as the ODL method, there are 57.4% (n = 27) from city area and 42.6% (n = 20) from rural area. Meanwhile the other 48.9%

students (n = 45) prefer live lectures/ discussions as the ODL method, it is come from 77.8% (n = 35) city area students and 22.2% (n = 10) rural area students.

Table 2: Live Lectures vs Video Recordings

Location during ODL Implementation	Preferred Method of ODL		Total
	Live lectures/Discussions	Video Recodings/Narrations	
City	35 (77.8%)	27 (57.4%)	**62 (67.4%)**
Rural Area	10 (22.2%)	20 (42.6%)	**30 (32.6%)**
Total	**45 (48.9%)**	**47 (51.1%)**	

By referring to Table 3, the cross-tabulation table of internet access with preferred method of ODL among Semester 4 students of IMD223 from UiTM Negeri Sembilan Branch, Rembau Campus shows that 51.5% students (n = 47) who choose video recordings/ narrations as ODL method can access the internet through mobile data which are 72.3% of students (n = 34), 14.9% (n = 7) students can access through Wi-Fi and 12.8% students (n = 6) access through both of mobile data and Wi-Fi. While the other 48.9% students (n = 45) that chose live lectures/ discussions as ODL method, they access the internet through mobile data which are 46.7% of students (n = 21), 17.8% (n = 8) students can access through Wi-Fi and 35.6% students (n = 16) access through both of mobile data and Wi-Fi.

Table 3: Internet Access vs ODL Method

Internet Access	Preferred Method of ODL		Total
	Live lectures/Discussions	Video Recodings/Narrations	
Mobile Data	21 (46.7%)	34 (72.3%)	**55 (59.8%)**
Wi-Fi	8 (17.8%)	7 (14.9%)	**15 (16.3%)**
Both	16 (35.6%)	6 (12.8%)	**22 (23.9%)**
Total	**45 (48.9%)**	**47 (51.1%)**	

Discussions

Respondents Demographic Profile

According to Table 1, the total percentages of female students are higher than male students because overall population of female students in the campus are bigger than male students. This finding is supported by National Center for Education Statistics (2020) that stated the enrollment numbers of female students are higher than male students in American academic institutions since few years ago. Besides that, percentage of students live in city area is higher than students live in rural area probably because some students who live in rural area have moved to urban areas by staying at relatives' houses to get better internet facilities during ODL implementation. According to The Star (2020), some students, especially those living on islands and plantations, do not have efficient internet access, apart from not having facilities like computers, smartphones or other mobile devices that can facilitate the delivery process of online teaching and facilitation (PdPc) sessions.

Research Objective 1: To identify the technological tools used by students in ODL

Result demonstrates that 96.7% of students have their own desktop or laptop for ODL. Students preferred to have desktop or laptop because desktop computers are more powerful with many features, convenient keyboard, easy to use with mouse and have larger monitors. Besides that, laptop computers are highly portable and allow users to use the computer almost anywhere (England.edu 2020). However, there are 3.3% students only have smartphone during ODL implementation. Smartphone is not preferred by students for ODL because of the unstable internet connectivity, and the size of the screen and keypad which makes smartphone is not convenient for learning. Besides that,

smartphone did not support some file/ format, hang during important learning moments, intruding the learning sessions with incoming calls and the issue of a constant draining batteries.

In terms of internet resources, half of the respondents prefer to use mobile data than Wi-Fi because the former is more convenient. When using mobile data, students do not have to depends on a desktop or laptop with internet connection. All they need is just a smartphone with mobile data that supports the internet connection. Therefore, accessing internet is hassle free without wired, modems etc. Moreover, files and documents can be easily downloaded on their phone. Notes, assessments and other online learning contents can be downloaded online, Email can be read and sent anytime and anywhere. Apart from that, students do not have to install any software repeatedly. All they need is internet recharge cards. They just have to buy the cards and instantly can access the internet. Students can also subscribe for 3G or 4G internet data plan at a lower price in the market.

Research Objective 2: To identify the preferred method and platforms by students in ODL

From the analysis, it can be concluded that video recordings/ narrations are the most preferred ODL method among Semester 4 students of IMD223 from UiTM Negeri Sembilan Branch, Rembau Campus. Video recordings of lectures offer various benefits to the user (Nieder, Borges & Pearson 2011). Students can repeat the lecture subsequently at any time and place. They might gain time because the way to the lecture hall is no longer necessary (Spickard et al. 2002). For students who were convenient with live lectures/ discussions, the preferred platform they choose to use is Google Meet rather than Zoom, Facebook and Discord. Students were comfortable if the lecturers use Google Meet in delivering their subject contents since Google Meet gives personal connection that is missing from face-to-face class time. Furthermore, it helps students to communicate more clearly with facial expressions, body language and intonation, and pushing record and talking can be much faster than other forms of communication.

The most convenient application or platform choose by students when receive any information from lecturers is the WhatsApp application. There is a research done by Spickard et al. (2002), highlighted that WhatsApp is a free messenger application that works across multiple platforms like iPhone and android phones, and this application is being widely used among undergraduate students to send multimedia messages like photos, videos, audios along with simple text messages. Moreover, as mentioned by Fogg (2008), since internet facility is required for using WhatsApp, lots of information can also be accessed in real time and sharing that information through technology is both instantaneous and convenient. In addition, WhatsApp messenger has the following collaborative features such as multimedia, group chat, unlimited messaging, cross platform engagements, offline messaging, no charges involved, pins and users name (Bere, 2012)

Meanwhile the most convenient application of platform that preferred by students to download the teaching materials and assignments is Google Classroom. As stated by My e-Learning World (2020), the Google Classroom is a tool to facilitate instructor-learner communication and ensure easy feedback and smooth document sharing. The system guides both students and teachers through the process gently with the use of push notifications and emails. The learning tool is able to alerts students to receive assignments and turn them in on time.

Conclusion

The study has investigated and identified the LIS students' online learning method and platforms preferences during ODL specifically on students Semester 4 who had registered for 'Introduction to Cataloging' course (course code - IMD 223) for semester March – July 2020 in UiTM Negeri Sembilan Branch, Rembau Campus. The investigation led to identifying the technology tools used by the students and their preferred method and platforms used during ODL since not all students involved in online studies due to technological constraints and access to the internet.

The study has contributed to the understanding of the usage and effectiveness for teaching and learning method used during COVID-19 pandemic as precaution actions to ensure schools and academic institutions can continue its operation in the education system. The finding proved that students able to access the internet either by using mobile data, Wi-Fi or both. This shows that accessing internet is not an issue for students as they are able to be connected via online. Besides that, ODL method preferred by students is video recordings/ narrations due to this method allow students to have a flexible learning whereby they can learn ubiquitously and at any time. For students who preferred live lectures/ discussions, the platform that they opt for is Google Meet. Students also preferred WhatsApp as the platform in receiving information from their lecturers and Google Classroom as an application platform to download teaching materials and assignments.

The contribution of this study can be seen in term of providing relevant data and information to the various parties especially to the lecturers and the university. The university must have a comprehensive ODL policy to meet the

needs of students and lecturers. A lot of training programs should be conducted to enrich lecturers with enough knowledge and skills to ensure ODL can be delivered successfully. In international educational circles, there has long been a call for "Maslow before Bloom" (Doucet et al. 2020), which argues that students' basic needs must be met before academic learning can be fully embraced. Furthermore, according to Everett (2015), engaging students in learning is important to ensure persistence and improves academic achievement. Therefore, by identifying students' condition and preferences for ODL may assist lecturers and universities all around the world towards a successful teaching and learning process. Last but not least, it is obvious that other universities that are implementing ODL can use the findings from this study to structure an effective policy and plan to ensure the success of ODL in their institutions that can improve the online teaching and learning process.

Justyna BERNIAK WOZNY
University of Information Technology and Management, Rzeszow
jberniak@wsiz.edu.pl

Abstract

The Business Process Management Lifecycle shows schematically how to implement and manage processes in an organization. Its task is to present the main idea or cardinal principles of Business Process Management (BPM) in a way that allows their uniform and intuitive understanding by those participating or who are to participate in the implementation. The aim of this paper is to analyze the impact of the Knowledge Management (KM) on the Business Process Management Lifecycle evolution and consequently on the evolution of the Business Process Management Systems. The article is an important contribution to the theoretical reflection on the current state and further evolution of BPM and BPM Lifecycle and Systems from the KM perspective. In the practical sphere, the article indicates the need to change the approach to creating iBPMS systems, with particular emphasis on the necessary changes in the principles of knowledge creation and distribution mechanisms.

Keywords: Business Process Management (BPM), BPM Lifecycle, Business Process Management Systems (BPMS), Knowledge Management (KM).

Introduction

Business organizations in the Knowledge Economy (KE) operate in an environment which is being shaped by rapid changes driven by four mutually stimulating and strengthening factors exhibiting high dynamism: the growing volatility and pace of operations; globalization and changes in the principles of competition; changes in business culture and social conventions; development of information and communication technologies (Szelągowski, 2014). In such environment, one of the most practical business concepts is the concept of Business Process Management (BPM) (Plattfaut, 2014). As each product and service delivered to the market is the outcome of many activities, business processes are the key instruments for organizing these activities and for improving the understanding of their interrelationships. However, along with the change of requirements imposed by the KE, BPM itself is also constantly evolving. It cannot be limited as in traditional BPM to the structured, repeatable business processes. Due to the dynamic nature of business, it must also encompass processes which require real-time knowledge management and the performance of which is dependent on the knowledge of the knowledge worker and the individual requirements of the client. Thus, the aim of this paper is to analyze the impact of the Knowledge Management (KM) on the Business Process Management Lifecycle evolution and consequently on the evolution of the Business Process Management Systems.

Business Process Management and Knowledge Management

The research stems from two theoretical grounds: Business Process Management and Knowledge Management. The following subsections briefly introduce these conceptual backgrounds and the way they impact each other as the foundation for analyzing the evolution of the BPM Lifecycle and Systems.

Business Process Management

Business Process Management enables the design, analysis, optimization, automation, and diagnosis of business processes by: separating process logic from the applications that run them; managing relationships among process participants; integrating internal and external process resources; and monitoring process performance (Burlton, 2001). As highlighted by Gabryelczyk and Roztocki (2018), BPM is a common and established management concept that helps to increase organization effectiveness, efficiency, and flexibility. The role of BPM is to provide techniques and software to design, enact, control, and analyze business processes involving humans, organizations, documents, and other sources of information (Marjanovic and Freeze, 2011; Di Ciccio, Marrella and Russo, 2015). Kemsley (2011) classified processes on the basis of their unpredictability ("*degree of structure*") and defined:

- fully structured processes which after having been modeled, can be repeatedly instantiated and executed in a predictable and controlled manner;
- semi-structured processes - structured processes with ad hoc exceptions and unstructured processes with predefined fragments;
- fully unstructured processes, where it is impossible to define a priori the exact steps to be taken in order to complete an assignment.

Most business functions involve semi-structured processes that do not have the same level of predictability as the routine structured work due to the requirements of an increasingly more hypercompetitive business environment. The fully structured processes mainly include production and administrative processes. As research by various organizations demonstrates, structured processes account for about 20-40% of all the processes within the organization and this percentage seems to be constantly decreasing (Olding and Rozwell, 2015). This means that 60% to 80% of the processes are impossible to simply repeat in the form of a once-defined standard process, as there are simply no standard processes in the KE. Structured and structured with ad hoc exceptions business processes should be more and more automated in order to minimize costs and execution time, and at the same time ensure stable, expected quality and relieve employees from their implementation. Unstructured with predefined fragments and unstructured BPs should be increasingly based on individual, team, and organizational knowledge and, consequently, become increasingly more flexible, as well as adjusted to the changing execution context (Richter-von Hagen et al., 2005). Effective management of business processes requires the use of different methodologies depending on the nature of BPs. A mistake in selecting a methodology (e.g. an attempt to strictly automate diagnostic and therapeutic processes or placing highly qualified employees at the production line and demanding creativity and flexibility from them) is one of the most serious risks for process implementation or management. Therefore, as one of the first steps in preparing the implementation or improvement of business processes, it is necessary to assess the nature of business processes in order to select the appropriate method and appropriate systems supporting BPM.

Knowledge Management

Knowledge should be understood as the fluid combination of information, experiences, and the context, which enable the ongoing evaluation and acquisition of new knowledge and enable the organization to achieve its goals. It is considered to be the foundation of competitive advantage (Nonaka and Takeuchi, 1995). From an organizational point of view, human knowledge can be classified as implicit or tacit knowledge, which is personal, context-specific and thus hard to formalize and communicate; and explicit or codified knowledge, which is transmissible in systematic and formal language among individuals or groups (Polanyi, 1967).

Knowledge Management (KM) is the organizational process for acquiring, organizing, and communicating both tacit and explicit knowledge. KM enables the creation, communication, and application of knowledge of all kinds to achieve business goals and is an integral part of an organization's strategy to improve business performance (Nonaka and Takeuchi, 1995). KM is also increasingly recognized as a strategic practice of knowledge-intensive companies, based on the knowledge-intensive business processes (kiBPs) defined as processes whose conduct and the delivered value depends on the creative and innovative use of knowledge by process executors in accordance with the context of execution (Gronau and Weber, 2004; Vaculin, 2011; Rodrigues et al., 2015; Little and Deokar, 2016).

The Knowledge and Process Continuum

The concepts of knowledge management and business process management are naturally gravitating towards one another, or perhaps even becoming unified (Jung, Choi and Song, 2007; Taylor, 2012). The integration of both these concepts on the foundation of acknowledging the empowered role of the employees and the new role of the management enables the creation of a concept which does not have the shortcomings of traditional business process management. This, in turn, allows for the restoration in process management of the constant, systemic possibility to respond to fast-paced, qualitative, unforeseen changes in the hypercompetitive environment (D'Aveni, 1994).

It is impossible to find organizations using only tacit knowledge or only explicit knowledge. As noticed by Inkpen and Dinur (1998) the distinction between explicit and tacit knowledge should not be viewed as a dichotomy but as a spectrum with the two knowledge types as the poles at either end. Similarly, it is impossible to find an organization using only fully structured or only fully unstructured processes. Consequently, the two knowledge types (explicit/tacit) and two process types (structured/unstructured) should be classified on a continuum representing the smooth, evolutionary transition of the organization between the use of only explicit knowledge in structured (repeatable) processes and readiness to use all knowledge (including tacit knowledge) in unstructured (unpredictable) processes (Figure 1). Delivering in the KE innovative, individualized products requires more and more unstructured processes that require more and more extensive use of tacit knowledge.

Fig. 1: The Knowledge and Process Continuum

The Evolution of the BPM Lifecycle

The Business Process Lifecycle has the role of a "roadmap" of the fundamental business-process-managing process in the organization. Its role is to present the cardinal principles of process management in a manner which enables their coherent and intuitive understanding by those participating in the implementation at present or in the future. As the next step in evolution, BPM Lifecycle is discussed based on the Knowledge and Process Continuum.

The process lifecycle

Process lifecycles in the organization are usually presented in illustrative form as a closed sequence of cyclical stages. Process lifecycle models prepared within the framework of traditional business process management are divided into stages presenting subsequent steps of the process lifecycle in the organization. There is a plethora of the BPM life cycle models proposed by academics (Table 1) and professionl bodies, for example as:

- Strategize, design, implement, compose, execute, monitor & control (Software AG, 2011);
- Define, model, simulate, implement, execute, monitor, analyze, optimize (Gartner, 2014);

- Model, implement, execute, monitor, optimize) (PNM SOFT, 2017);

Table 1: BPM life cycle models

Van de Aalst (2004)	(1) process design (2) system configuration (3) process enactment (4) diagnosis
Netjes et al. (2006)	(1) design (2) configuration (3) execution (4) control (5) diagnosis
Zur Muehlen and Ho (2006)	(1) specification of objectives and analysis of the environment (2) process design (3) process implementation (4) process enactment (5) process monitoring (6) process evaluation
Weske(2007)	(1) design and analysis (2) configuration (3) enactment (operationalization, monitoring and maintenance of processes) (4) evaluation
Hallerbach et al. (2008)	(1) modeling (2) instantiation/selection (the configuration or selection of variations according to the context) (3) execution (4) optimization
Verma (2009)	(1) define organization objectives (2) identify organizational processes (3) classify processes (4) choose the process that has the best contribution (5) determine the use of the most appropriate tool, whether it is for incremental or radical change (6) implementation of the improvement project (7) process monitoring
Pourshahid et al., 2009	(1) discovery & model/ remodel, (2) validation & simulation, (3) deployment & execution, (4) monitoring & performance management, (5) improvement
Houy et al. (2010)	(1) strategy development (2) definition and modelling (3) implementation (4) execution (5) monitoring and controlling (6) optimization and improvement
Gulledge et al. (2011)	(1) model (2) simulate (3) implement (4) deploy & execute (5) monitor (6) optimize
Di Ciccio et al. (2015)	(1) (re)design (2) configuration (3) enactment (4) diagnosis

	(3) implementation, (4) monitoring and controlling, (5) refining and planing
Dumas et al. (2018)	(1) identification (2) discovery (3) analysis (4) redesign (5) implementation (6) monitoring & controling

Due to the identified necessity of approaching the process lifecycle from the perspective of implementing and performing multiple processes in the organization "global" life cycle of processes in the organization will be call Business Process Management Lifecycle in organization (in short: BPM Lifecycle).

The traditional BPM Lifecycle and its limitations

If we take a diagram depicting the BPM Lifecycle and replace symbols corresponding to subsequent stages (usually circles or ellipses) with symbols for subprocesses known from the Business Process Model and Notation (BPMN), the BPM Lifecycle will depict a normal, sequential "relay" process with only one feedback loop, the goal of which is to ensure periodical analysis and improve the process model on the basis of data derived in the course of its execution. This is the case of most of the models presented in the Table 1.

Fig. 2: The BPM Lifecycle as a process diagram in the BPMN notation.
Source: Author's own elaboration, on the basis of Dumas, La Rosa, Mendling & Reijers, 2018, 23.

In effect, processes cannot be improved upon or even changed at all during performance itself – this is possible upon completion and analysis alone. This is fully in accordance with the principles of the traditional concept of process management based on the fully structured processes, in which process performers are prevented from introducing changes in the course of performance itself. The course of the process is defined in the form of an "algorithm," prepared prior to initiating performance itself. In consequence, traditional process management lacks the possibility of quick usage of knowledge obtained by the performers in the course of the proces performance. In effect, this concept enables the use of robotic process automation (RPA) to automate traditional, repetitive processes, but does not provide the operational use of more advanced new technologies, such as process mining, machine learning (ML), or artificial intelligence (AI), in the course of performance.

The BPM Lifecycle Opened to Semi-structured Processes

Among the process lifecycle models within the framework of traditional process management, a truly significant qualitative change was proposed by the authors of the Process Mining Manifesto belonging to the IEEE Task Force on Process Mining (2012) (Fig. 3).

Fig. 3: The process lifecycle in the process mining methodology.
Source: Author's own elaboration, on the basis of IEEE Task Force on Process Mining, 2012, 4.

The process execution stage has been supplemented with an additional "Adjustment" loop, the aim of which is to adapt the process in the course of performance itself. The standard process lifecycle has also been supplemented with a (re)configuration stage, in which changes are made to process-based executive systems (e.g. workflow management, document management, RPA, or BPMS) without having to repeat the implementation stage performed e.g. as the result of creating separate process performance scenarios. When recommending the change of the process lifecycle, the authors of the Process Mining Manifesto have stressed that organizations should also include the possibility of adjusting processes in the stage of designing processes and their supporting IT tools ("Analysis" loop). This is a clear step toward changes to the process lifecycle, which allows for the management of semi-structured processes. Later on it was followed by rsearchers by adding the redesign stage to the BPM Lifecycle models (Di Ciccio et al. (2015) or Dumas et al. (2018)).

The BPM Lifecycle in Knowledge Economy

For business process management to be compatible with the requirements of the KE, it is essential to systematic, ongoing knowledge management through its use, verification and creation of new knowledge during the the design and execution of business processes is necessary. This, however, requires taking the concept of process lifecycles in a direction in which the performance of a process will not be equal with the perfect repetition of the standard, but rather, the repetition or dynamic adaption of the standard with the best possible results in mind, in a manner which is the most adequate in a given context and within the limits of the executive privileges of the performer. Such adaptations may be introduced by: process performers; process performers with the use of ICT solutions (e.g. online ML/AI); elements of autonomic AI. The postulated changes have been introduced in the process lifecycle model designed by Szelągowski (2019) in accordance with the concept of dynamic BPM (Fig. 4).

Fig. 4: The process lifecycle in dynamic BPM
Source: Author's own elaboration, on the basis of Szelągowski, 2019, 72.

The subsequent stages of the BPM Lifecycle of dynamically managed business processes are as follows:

Defining goals - of the project of implementing business process management, of the megaprocesses, and of knowledge management in the organization, as well as the principles of implementation themselves;

Preparation of the project and the organization for the implementation of process management, including assessment of the nature of business processes executed by the organization (e.g. unpredictability, knowledge-intensity);

The (re)Design stage - process descriptions and their corresponding data, created increasingly with the use of real data analysis with the use of process mining techniques or simulation research (digital twin).. Proposed process descriptions, to the extent tailored to the nature of the BPs, in the form e.g. of flow models or checklists. Prototypes of process-centric application (workflow, RPA or BPMS/iBPMS), which have been cleared for testing, should be consulted with in-house and external experts, and with practitioners who use them daily, through e.g. communities of practice or social media.

The Implementation and adjustment stage - process descriptions are implemented. Should it turn out that a designed process or configuration of a process-centric application does not meet the expectations of the users, it is possible to return to the (re)Design stage in order to prepare the process descriptions and process-centric applications once again.

The Execution and monitoring stage - business processes are performed and dynamically adapted according to context of the execution by process performers (or in the future – autonomic AI as well). Data on their performance is collected on an ongoing basis. They are also analyzed on an ongoing basis and, thanks to the use of ML / AI elements, used to support process executors. Empowered knowledge workers adapt described business processes to the requirements of a specific context of performance and the changing general conditions of process performance, using your tacit knowledge and, if required by the situation, creating new knowledge..

The Analysis and diagnosis stage. In addition to business processes being monitored in the Execution and monitoring stage, business processes are nevertheless evaluated *ex-post* by means of standard control actions and discovering the actual course of the executed processes (e.g. process mining or ML) and evaluating the results of the implemented improvements (e.g. ML or AI). Improvements resulting from practical attempts at innovation, which have been given a positive evaluation, may be introduced directly following in the Execution and monitoring stage or the (re)Design stage, without the necessity of going through the Implementation and adjustment stage.

The Evolution of the Business Process Management Systems

The evolution of the BPM Lifecycle in the organization led to the evolution of requirements for Busines Process Management Systems (Aalst, Bichler and Heinzl, 2018). Starting from two opposing positions:

- (Adaptive, Dynamic) Case Management Systems - support for processes with unpredictable course and not fully known, but potentially knowledge intensive,
- traditional BPMS - support for processes with a known and strictly repeated course thanks to having all the knowledge necessary to perform the processes before performing them;

vendors strive to support business processes, regardless of their nature - their unpredictability or knowledge intensity.

Recognizing the breakthrough of the changes taking place, in 2012 Gartner published the first Magic Quadrant for Intelligent Business Process Management Suites Report (Gartner, 2012), in which it unequivocally communicated the emergence of a new class of systems and explicitly recommended not to compare the presented results with previous reports on traditional BPMS systems. Three years later, Gartner published two reports the Magic Quadrant for BPM-Platform-Based Case Management Frameworks (Gartner, 2015a) and the Magic Quadrant for Intelligent Business Process Management Suites (Gartner, 2015b) at a weekly interval. These reports were basically based on the products of the same suppliers and presented the same functional criteria, as if Gartner could not decide how to assess the changes taking place in the market and, just in case, described management support systems from two different angles: extensions of traditional BPM and case management. In 2017 and 2019, Gartner published only reports on iBPMS, adding as a necessary functionality the support of iBPMS systems for designing and implementing semi-structured and unstructured processes in accordance with the Adaptive Case Management (ACM) methodology (Gartner, 2017; Gartner, 2019b). The evolution of iBPMS systems, as reflected in subsequent reports, clearly moves towards the possibility of supporting the use of dynamic BPM and enabling the implementation of the social BPM i.e. supporting the increasing use of knowledge in managing business processes by empowered knowledge workers (Pucher et al., 2014). At the same time, increasingly important for Gartner's evaluation of the products of individual vendors is the integration of technologies within the iBPMS framework that can support:

- acquiring knowledge about performed processes (process mining, real-time analytics, predictive analytics, ML / AI);
- process automation (IoT, RPA, ML / AI, IoT, Blockchain),

at all stages of the BPM Lifecycle. In its assessment of iBPMS systems, Gartner takes into account both, the support of structured processes, optimized on the basis of explicit knowledge possessed by the organization at the design stage, and unstructured processes, for which the achievement of the assumed goals requires from knowledge workers use of tacit knowledge in a manner fully adapted to the context of implementation.
The analysis of Gartner reports, as well as parallel reports of other organizations (e.g. Forrester or BPTrends), shows that in practice vendors and systems that do not support all types of BPs, combining features of traditional BPM, such as process flow modeling, with typical case management features, such as the ability to freely choose or create tasks to be performed (ISIS Papyrus, 2016, Pegasystems, 2020) do not count any more.

Conclusion

The development of BPM requires taking into account processes of different nature and the introduction of a qualitative change to the BPM Lifecycle, which would account for the possibility, and in the case of a large majority of semi-structured and unstructured processes – the necessity of using the knowledge of the process performers to tailor the processes to the context of a specific performance. Without this change it is impossible to make efficient use of new technologies, such as process mining, machine learning, or artificial intelligence. In the KE, implementations of process management in accordance with the traditional BPM Lifecycle were seen, and remain to be seen, as a success only because they pertain to structured (static, repeatable, routine, unchangeable) processes. However, the situation is changing as the share of structured processes in the organization is dynamically going down together with growing usage of new ICT technologies, among which one should primarily mention those which work in real time: process mining, machine learning, and artificial intelligence.

The BPM Lifecycle evolution presented in the paper requires the adjustment of methodologies and tools supporting process management with a view to the efficient use of both emerging ICT technologies and the knowledge of the organization. This primarily requires the analysis of the possibilities of using new IT tools and stimulating changes

during specific stages of the BPM Lifecycle with the use of developing IT tools, starting with structured process described with the use of easily accessible explicit knowledge, the automation of which is possible with the use of RPA tools, which are relatively quick to implement (Aalst, Bichler and Heinzl, 2018). Following the analysis, with the growing process maturity and knowledge management maturity of the organization, it is possible to naturally gravitate toward implementing increasingly more "intelligent" systems with a view to supporting processes requiring increasingly larger access to and use of tacit knowledge, revealed with the use of process mining, ML, AI, or simply iBPMS.

Summarizing the current evolution of functionalities of iBPMS systems, it can be concluded that the *de facto* unification of BPMS and ACMS systems has already taken place and that the further development of iBPMS is also heading towards more and more comprehensive support of knowledge management. This is the result of iBPMS support for all types of processes, regardless of the predictability requirements, but also the intensity of knowledge. This is the direction expected by researchers (Marjanovic and Freeze, 2011), and at the same time even imposed by the development of ML / AI technology and methodologies (Pucher et al., 2014). Further evolution in this direction will enable organizations to actually implement KM in their daily operations thanks to the possibility of verifying their knowledge and acquiring knowledge from the ongoing business processes, which will significantly impact the competitiveness and speed of development of the organization (Jung, Choi and Song, 2007). The distinctiveness of the concepts of traditional BPM and Case Management (as well as Knowledge Management) is already going down in history, replaced by a more natural dynamic BPM (integrated with KM), not by theorists' decisions, but under the pressure of practitioners, expecting better and better use of the dynamism of people and teams performing processes and learning from daily successes and failures. The subject of future works will be an in-depth analysis of the speed and scope of the signalled changes taking place, also taking into account the readiness of the business to implement them in everyday operations.

Abstract

Tourism is an area of vital interest to the Portuguese economy, having been, in 2019, the largest export economic activity in the country, accounting for 52.3% of services exports and 19.7% of total exports, having tourist revenues recorded an 8.7% contribution to Portuguese GDP (INE). Low density regions such as the territories of Vale do Côa, which, in their absence, would face great difficulties to develop are essential factors for development. The Tourism Strategy 2027 identified people as the main assets (single cross-cutting asset), differentiating assets (such as climate and light, history and culture; the sea; nature; water), qualifying assets (gastronomy and wines; events artistic, cultural, sports and business) and emerging assets (well-being, living). Tourism can take on a double dimension in these territories, on the one hand, constituting itself as a method of dynamizing and changing space, implementing new social and consumption patterns, generating new practices and multiple impacts, on the other, boosting local tourist resources (natural, heritage and cultural), beneficially contributing to the local economy. Promote Regions is a multidisciplinary challenge. This paper present a contribution-approach to promote regions heritage through a IT solutions based on mobile devices and making a restaurant digital menu a window to the promotion of reginal material and immaterial heritage, business promotion and cultural education, using the Côa Museum restaurant as a start point.

Keywords: Mobile Applications; Model; Tourism; Rural Regions.

Introduction

"When one thinks about food, there is an expectation of happiness – food brings people together; food allows people to "experience" other cultures" (Mannur, 2009). Gastronomy plays an increasingly significant role in tourism as an essential component of tourism consumption and production, in the context of regional development (Richards, G., 2012). However, food is rarely seen as part of cultural heritage in the public sense. Although they are generally considered a significant part of culture, eating habits are not seen as an aspect of heritage. Therefore, the role of food as a heritage and cultural driving force in the development and sustainability of cultural tourism requires further attention. This interpretation, growing in importance, was elevated to an intangible asset of the cultural heritage through the Resolution of the Council of Ministers nº. 96/2000, published in D.R. nº. 171/2000, Series I-B of 26 July 2000. This classification initiated a value chain process for gastronomy, products and their producers.

The Strategy Tourism (ST) 2027 aims to position Portugal as one of the most competitive, innovative and sustainable tourist destinations in the world and a reference in the production of goods and services for tourism worldwide, considers gastronomy and wine as one of the ten strategic assets of national tourism including people, climate and light, history and culture, the sea, nature, water, artistic-cultural, sports and business events, well-being and living - living in Portugal.

The same document identifies the product Gastronomy and Wines as a strategic asset to qualify the destination, which enriches the experience and adds value to the tourist offer of the territories. In the same vein, the argues that

Cite this Article as: Carlos R. CUNHA, Aida CARVALHO, Elisabete Paulo MORAIS and Bruno NAVARRO "Using Mobile Apps and a Digital Restaurant Menu to Promote Heritage in Rural Regions" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

gastronomy is closely related to the social identity of destinations and is made up of cultural, economic and historical values, many symbolic elements and territorial icons. Being an important factor in strategies to diversify destinations, gastronomy enriches and promotes the tourist offer, attracting different audiences and valuing the quality of local production. The contribution to the local economy comes through its multiplier effect, capable of leveraging other areas of business, such as accommodation, entertainment activities, services in general, agriculture, creative industries. Indeed, if corrected articulated with other products, gastronomic tourism will contribute to the mitigation of seasonality and increase the will stay of tourists. Nowadays, knowing only the characteristics or the nutritional table of foods is not enough, it is fundamental to know and share the history, the spectrum of flavours, the confection techniques and the ingredients through authentic experiences and identities (Pine and Guilmore, 2011). In the new demands, the need to safeguard the food heritage in favour of cultural diversity and the richness of integral and sustainable development emerges. Thus, we start from a set of interrelated and complementary themes, forming the conceptual framework of the object of this project to be undertaken.

Given the current challenges imposed by Covid-19, there is evidence that consumer behaviour is changing, both among citizens (generally as a response to the need for healthier lifestyles) and with tourists who are increasingly curious to explore know-how, experience and the supply of tourism offers a way to do so in an ethical manner. With the creation and promotion of the interactive menu it is intended that the visitor gets more information about the products. This perspective of development and knowledge sharing allows the visitor to responsibly maximize the benefits in / for the local communities and minimize negative social or environmental impacts, thus helping the local population to conserve fragile cultures and habitats, promoting circular economies. Maintaining the true essence of food production and regional gastronomy supply. The interactive and inclusive menu project of the Côa Parque Foundation restaurant consists of the creation of interactive content, storytelling of the products, ways of life of the producers. The project aims at the development of tourism, enhancement of local agriculture, transmission of knowledge of practices through the enhancement of gastronomy and natural resources. This project aims to develop gastronomic tourism in the region, as well as to create opportunities for a greater tourist flow in other economic activities of the municipality/region.

Revision of the Literature

Heritage and tourism organizations have had to cope with three important incremental changes: the move to an experience and entertainment economy, the digital revolution with its resultant participatory culture, and, consequently, recognition of technology as one of the essential components of the cultural experience (Di Pietro et al., 2015).

Each society prints its own characteristics in gastronomy, through the preparation of typical dishes that are incorporated into local customs, which offers a differential for each region in typical cuisine. In this sense, through gastronomy it is possible to observe in communities the construction of identities, preferences, tastes, customs and the feeling of belonging to the place. Such factors allow to create a kitchen with characteristics currently being used in tourism to highlight the peculiarities of a particular culture (Pereira, Assis and Brito, 2020).

The rapid growth of the hospitality industry has attracted the interest of many researchers in recent decades (Li et al., 2017). Research dealing with restaurants, in particular, has grown significantly over the last 30 years (Di Pietro, 2017).

Restaurants have provided a research topic throughout the literature, from different points of view. First, from the management perspective, restaurants have attracted scholarly interest, regarding issues such as profitability (Thompson, 2009), the concept of capital structure (Upneja and Hua, 2006) and corporate social responsibility (Ham and Lee, 2011). Second, from the customer perspective, academic research has focused on restaurant, the measurement of customer satisfaction and loyalty (Gupta et al., 2007), food quality, restaurant atmosphere and service, and brand perceptions (Hyun, 2009). Finally, another important set of studies has focused on examining the restaurant sector from the tourism and hospitality industry perspective. This perspective addresses topics such as identification of the information sources and motivations that affect consumer preferences when selecting restaurants and tourist attitudes toward luxury restaurants (Cheng and Peng, 2018), among others. From this approach, the general implication is that tourism organizations and restaurants make a significant contribution to the creation of experiences (Matson-Barkat and Robert-Demontrond, 2018). The present work will focus on this latter perspective, creation of experiences, promoting and disseminating material and immaterial heritage.

A restaurant menu serves as the first point of communication with customers. It presents the customer with cues about the impending dining experience (Magnini and Kim, 2016).

A menu can determine the brand image and the personality of the restaurant (Magnini and Kim, 2016) and a correctly designed menu will direct customers' attention to a particular menu item. Given the importance of a menu within restaurant operations and management, a plethora of research studies have examined menu design and its impact on

customer responses and intentions (Yang, 2012; Wansink and Love, 2014; Ozdemir and Caliskan, 2015). These restaurant menu studies fall into two research streams, namely menu item placement and menu design properties.

Despite the extensive research in this field, research on restaurant menus is limited to static visual presentation on paper menus and, thus, provides few insights into dynamic and multimodal presentations on digital platforms. Among the various advantages of digital menus, multimodality would make digital platforms distinctive from conventional paper menus.

The distinctive benefits of digital menus come from digital displays, such as computer screens or touchscreens, that allow consumers to browse and choose food products and to have enhanced visuals and descriptions about foods. Digital menus also could present a great amount of information and they facilitate cross-selling opportunities by suggesting beverage pairings with dishes that customers want to order. As a result, digital menus foster consumers' interaction, resulting in more vivid mental images of food selection, more enjoyment, improved convenience and stronger encouragement for food selections.

Conceptual Model

The proposed conceptual model focuses on transforming a restaurant's menu into a window for the promotion of material heritage, intangible heritage, business and the promotion of cultural education. This view is supported by the use of information and communication technologies and in particular through the use of mobile devices, a mass object nowadays, as a means of accessing an information and services infrastructure.

The menu of a restaurant is, today, a persistently physical object capable of providing very little information about the products it contains. Some examples, described above, have carried out a process of digitizing the information on a menu, increasing the quantity and quality of the information provided to the consumer. However, there is still, in our opinion, a long way to go to maximize the potential that a menu can have as a vehicle to satisfy consumer needs when choosing a gastronomic menu and, not least, as a vehicle for promoting heritage. material and immaterial that revolves around gastronomy and, finally, as a vehicle for generating business.

Conceptual Model Vision

The proposed model, shown in figure 1, is centered on the ability to transform a restaurant menu into a purely digital object, accessible through mobile devices that can be made available by the restaurant and / or through the use of customers' mobile devices. The degree of sophistication of today's smartphones and their ability to connect to the Internet have made these devices an excellent support for accessing information and services. Cumulatively, the multimedia diversity of content that can be made available through digital applications is very vast today. In this sense, in the context of a menu, information about a gastronomic dish may contain text, image, video, and links to various content and / or external services. To this extent, content that allows a more objective and realistic perception of what will be the experience of tasting a gastronomic dish will be available. And yet, in this experience, the promotion of an entire heritage set that gravitates to this gastronomic dish may be made possible, such as: the origin of the ingredients; cooking methods (which can be ancestral and / or strongly regional); intangible heritage associated with the gastronomic dish (e.g. stories and / or legends associated with the origin of the dish); information about the cultural heritage exists in the places associated with the gastronomic dish; information on complementary products, such as a more appropriate choice of wines; etc. From a business perspective, and sustained by the fact that, often associated with gastronomic tourism, there is housing tourism, wine tourism, and the sale of products that make up the preparation of gastronomic dishes; the act of disgusting a meal can leverage e-commerce opportunities, individually supported by a given commercial agent and / or cooperation networks that offer complex and transversal tourism products.

As far as promotion and territorial cohesion is concerned, the proposed vision for a restaurant menu enhances the dissemination of institutional information about the territories, promoting them, something especially important in low density territories - which are typically very rich in heritage material and immaterial and, more specifically, gastronomic heritage. This vision can leverage the economic sustainability of these regions and their business fabric.

Finally, it is important to focus on that a gastronomic tasting experience is often a family experience. Where adults and children coexist. The latter, due to their specificities, tend to be consumers less interested in the perspectives described above. However, they are consumers and play an important role in the process. How can we answer them? In our opinion, a digital menu, accessible through mobile devices, presents a unique opportunity to catapult younger consumers to applications that promote heritage. As? Through the provision of small games (e.g. didactic, recreational and / or serious games) that, in the interest of the younger audience (often children) can generate empathy and even interest in material and immaterial heritage. We probably cannot wait for the attention of a creation to watch a video that presents the story of a region, or a legend associated with a gastronomic dish. However, we will captivate your attention with a small game that is a mix of entertainment and education. Thus, contributed to cultural education.

Figure 1: Conceptual Model

It is important not to forget that, in a tasting experience, the act of choosing and waiting for a meal, contains a waiting time which is typically sufficient to allows the enjoyment of the set of information and services that our model (and vision) proposes.

A New Restaurant Menu Concept

The figure 2 presents our restaurant menu perspective. We propose three lines of action in the development of a menu that allow you to explore and maximize the surroundings of a tasting experience and what it can leverage. The three perspectives can be characterized as follows:

- **Menu as information on what will be tasted:** We propose a digital menu capable of taking advantage of multimedia capabilities. In this sense, text, images, videos and links with information and external services should be used, so that the consumer can obtain the maximum information about the menu and the various gastronomic dishes offered by the restaurant; can understand the process of making the dishes, the genuineness of the ingredients and the complementary products, such as which wines should accompany the dish, etc. Likewise, it must support the rating of the dishes and the tasting opinions of consumers. This information is useful for both the consumer and the restaurant manager.
- **Menu as a promoter of material, immaterial heritage and cultural education:** The regions have in their cultural DNA a set of material and immaterial heritage. Often, the material and immaterial heritage merge. In the case of gastronomy, regional gastronomic products are steeped in cultural aspects - ancestral cooking practices, associated legends, places of origin with history. The act of scrolling through a menu, in the format in which we propose it, will allow obtaining information about the places of origin of the ingredients that are used in the preparation of meals and, in this way, catapult the places and their heritage to the consumer.
- **Menu as an enhancer of business opportunities:** The act of tasting, associated with the consumption of other associated products, such as wine, arouses numerous times a need to buy. On the other hand, obtaining information or services that gravitate around the menu (e.g. rural tourism products, wine tourism) may lead to the reservation of tourism products and services that will allow consumers to discover the regions of origin of the products. This model opens a window for the transformation of a digital menu into a driver for e-commerce and the generation of business opportunities.

Figure 2: The restaurant menu concept

Conclusion and Final Remarks

The use of IT and Web enables users to interact and share their experiences. Consumers are encouraged to enter comments on the Internet regarding their stay and experience, thus sharing this information with other potential consumers creating a viral marketing effect. This sharing of views takes the form of word-of-mouth marketing (WOM) and can prove beneficial to institutions or, on the other hand, quite inconvenient if they introduce negative comments. The TripAdvisor helps almost 460 million travellers a month plan the best trip with the help of over 830 million assessments and opinions from 8.6 million accommodations, restaurants, experiences, airlines and cruises (Tripadvisor, 2020). One of the main changes is that users are no longer just consumers of content and information but also producers. Online comments and other content mean that most consumers find much more information about a particular location through access to information or comments left by other consumers who have already used the same location (Kotler, 2012). So the more streamlined and differentiated the content, the greater the possibility for positive reviews.

Tung & Ritchie (2011) highlight the influence of Storytelling as a prominent type of narrative designed to directly create consumers' memories about experiences, while. Morgan et al. (2010) refer that, in the tourism literature, the narrative has been used to analyze stories and themes about an interpretive environment that is intended to be explored, arguing that if leisure and tourism experiences are, to a certain extent, identity work, that will involve participants in narratives about themselves, people and places they encounter. The stories about the destination interact with the personal narratives of the visitors to create an experience incorporated in the place, which will be all the better when the tourist feels involved and an active part of the process in the recreation.

It is in the context set out above that this article proposes the use of mobile applications and a reengineering of a restaurant menu, making it a window for the promotion of territories, their heritage and, equally, contributed to the generation of business, which is fundamental to the competitiveness of regions, especially rural regions. This work, carried out with its focus on the museum of Côa, has in progress the creation of a prototype application that materializes the proposed model and can contribute to involve the consumer / tourist in the region and its cultural ecosystem.

Abstract

Digital signature schemes allow to exchange digital documents in a form that guarantees authenticity of the sender and full integrity of the data received. Any intentional or unintentional modification of the document is recognized, thus rendering the signature invalid. This paper describes a real-life case study in which the digital signature was corrupted merely by opening the file with the use of the macOS Preview app. Corruption may go unnoticed by the app user, leading to the submission of a digitally signed document with an invalid signature affixed thereto. In this paper, a method of reverting such changes is presented, along with recommendations for Apple software developers on how to prevent users from unintentional modification of signed documents.

Keywords: digital signature, macOS, document authenticity, pdf

Introduction

Digital signature schemes (Merkle 1989) usually employ asymmetric cryptography algorithms to ensure authenticity and integrity of the signed data, along with non-repudiation of its origin. Digital signature schemes are widely used in cryptographic protocols, software distribution, financial transactions, contract management and even for securing connections with websites. They may be used in any scenario in which detection of tampering with or forgery of electronic data is crucial.

Nowadays, when the volume of data sent in their digital version only increases steadily, the significance of digital signatures for modern economies is growing rapidly. Properly deployed digital signature schemes allow companies to send all documents to their customers using email, for instance, thus offering a cheaper alternative to sending paper documents and providing customers with a tool that guarantees authenticity of data. Digital signatures fostered the development of e-governments, enabling companies and citizens to submit digitally signed documents to governmental agencies without relying on the standard paper form. According to (Statista 2020), more than 77% of companies in Spain were using digital signatures in 2017. In countries such as Estonia (e-estonia 2020) and Poland (gov.pl 2020), citizens are also capable of digitally signing documents using their national ID card.

A digitally signed document is extremely sensitive to modification of its content. With even a single bit flipped, the entire digital signature will be rendered invalid. This definitely makes digital signatures more reliable than their traditional counterparts, but also requires software vendors to apply additional security measures when working with such files. In this paper, we present a case study concerning the macOS Preview app and a signed PDF file which was modified while being read. This case should be considered a warning for PDF file users and an indication of a bug that requires to be fixed by Apple Preview developers.

Pdf Signature

The ability to use digital signatures when working with PDF documents was first introduced in version 1.3 of the PDF specification (Adobe 2008). This feature allowed the data contained in the PDF document to be authenticated and the user who created the digital signature to be identified. The idea of digital signatures in PDF files is based on signature handlers. In the specification, Adobe described a few handlers that supported a limited number of digital signature types and gave an opportunity to other vendors to create new ones that would be specific to their business needs and requirements.

Cite this Article as: Michał GLET and Kamil KACZYŃSKI " Digital Signature Corruption – Macos Preview Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In general terms, a digital signature is created in a PDF file by computing a digest (using hash function) of the specific PDF content data. This computed hash is stored in the PDF document. To verify that the specific PDF content has not been changed, the verifier must re-compute the digest and has to compare it with the one stored in the document. Differences in digest values indicate that the specific PDF content data has been modified after the document was first signed. Of course, the digest value in the PDF document is stored in the form of a digital signature format, such as, for instance, PKCS7 (RFC2315, 1998) or CAdES (RFC5126, 2008). This means that the value of the computed digest is secured and its authenticity is ensured e.g. by a digital certificate used by the user in the process of creating the digital signature.

According to Adobe DigSig (Adobe, 2020), the default digital signature format used by Adobe software is called *adbe.pkcs7.detached*. PDF specification 1.7 allowed for an additional use of *adbe.x509.rsa_sha1*, *adbe.pkcs7.sha1* and *ETSI.CAdES.detached*. *Adbe.pkcs7.sha1* stores the signature in the PKCS7 (RFC2315, 1998) format and allows only the SHA1 (NIST 2002) hash function to be used. *ETSI.CAdES.detached* stores signature in the CAdES (RFC5126, 2008) format and allows e.g. SHA1, SHA2 (SHA256, SHA384, SHA512) (NIST 2008) or RIPEMD160 [Dobbertin et al., 1996] to be used as the hash function. A similar list of hash functions could be used with *adbe.x509.rsa_sha1* and *adbe.pkcs7. detached* signature formats. In all formats, a signature based on RSA (Rivest et al., 1978), DSA (NIST, 2000) or ECDSA (NIST, 2013) could be used as well.

Case Study

The investigation was undertaken after an issue with verification of a qualified digital signature in a PDF file was reported. The reported issue was quite weird – Adobe Reader was not able to identify and verify the digital signature after working with the file in the macOS environment.

Figure 1. Blue rectangle – digital signature not recognized by Adobe Reader.

The review commenced by performing a binary analysis of the PDF file's content. The file was marked as compatible with version 1.7 of the PDF specification (Adobe 2008), – the file started with *%PDF-1.7*. According to binary content, the file was created on 2020-02-25 at 14:12:33 +0100 and was modified on two occasions. The first modification was performed at 2020-07-21 12:14:20 +0200. It added the digital signature to the PDF file. The digital signature was marked as *ETSI.CAdES.detached*. According to (Adobe, 2020), this type of digital signature is compatible with version 1.7 of the PDF specification and with Adobe Reader software starting from version 10.x. So, there should be no problems with using this file in Adobe Reader. The second modification was carried out on 2020-07-23, at 08:13:28 +0000 and was marked as performed by macOS 10.15.5 – binary file contained value << */Producer (macOS Wersja 10.15.5 \(kompilacja 19F101\)*. This was the next clue that linked the problem with verification of the digital signature with the macOS environment – the last modification of the file was performed by macOS and after file was thereafter improperly processed by Adobe Reader.

The next stage of the analysis focused on the latter modification. This modification was carried out in the incremental mode (according to paragraph 7.5.6 of [Adobe, (2008)). Because of this, all data generated by this modification were added at the end of the PDF file. Data from the original PDF file were not modified. The modification added, for instance, the *AAPL:AKExtra* element. This tag is not a part of version 1.7 of the PDF Specification (Adobe, 2008)], so it could not be processed correctly by Adobe Reader. Additionally, new elements contained direct references to the digital signature added in the first modification– references to element *Signature-ae67c2f2-17fa-40d9-88aa-b290ab203371*. There is quite high probability that this is the cause of all problems with identification and verification

of the digital signature by Adobe Reader. Adobe Reader did not understand those elements that contained references to the digital signature, so was not able to process the digital signature in a correct and convenient manner.

Figure 2. Some data added in the second modification.

The third part of the analysis focused on whether it was possible to show that the PDF file contained a valid and unaltered digital signature and that the signed data had not been modified. The approach adopted was very simple – the second modification was performed in the incremental mode (7.5.6 (Adobe, 2008)), so why not just delete the related data from the PDF file. Removal of data related to this modification should revert the PDF file to its previous state –identical to that after the first modification. Data introduced by the second modification were added to the PDF file after the first occurrence of the *%%EOF* element. Removal of everything that was present after the first occurrence of the *%%EOF* element solved problem – the digital signature was correctly identified and verified by Adobe Reader.

Figure 3. Digital signature identified and verified by Adobe Reader.

The final stage of the analysis focused on the reasons behind the modification introduced by macOS. A quick interview with the user who reported the problem failed to answer this question. He was sure that he had not done any conscious modifications affecting this PDF file and that macOS had not informed him about any modifications at all. It sounded quite weird, so the entire sequence of events needed to be verified. Firstly, the PDF file, without the second modification, was opened in macOS 15.5.5 using the Preview app that is the default software for viewing PDF files. The Preview application displayed the PDF file's data and an additional box with information about the digital signature embedded in the file. This additional box with the signature data was moveable – its position could be changed by using the drag-and-drop method. Quite shockingly, the movement of this box altered the PDF file immediately, without warning the user and without asking for permission, and added data similar to that added in the second modification of the analyzed file, as described above. The Preview application broke the PDF file and rendered its digital signature unreadable and unverifiable for Adobe Reader and for other similar software (e.g. software to verification of PAdES signatures, such as Certum proCertumSmartSign).

Figure 4. Movable box added in Preview application.

Conclusions

In this paper, we presented a case study concerning a PDF file's digital signature that was corrupted by macOS Preview software. The corruption resulted, in this case, in serious consequences for the company. The document was considered invalid, which resulted in rejection of the submitted bid. The company's representatives had no way of knowing that opening the file in macOS Preview could be devastating for their business.

The case study performed showed that Apple Preview had added some graphical elements to the PDF file, displaying some detail information about the digital signature used. Unfortunately, these new elements were not compatible with PDF Specification 1.7 and, thus, were not correctly interpreted by such software as Adobe Reader - undoubtably one of the most commonly used PDF viewers that allows to verify digital signatures.

It is quite clear that the modification performed by Preview should not have taken place. Apple Preview developers should implement a feature which clearly alerts users that a modification will be introduced to a signed PDF file. Preferably, such files should be opened in the read-only mode and potential changes should be saved in a copy of that file. Regardless of the above, users of PDF software should check if the file's signature is correctly recognized by Adobe PDF before submitting it.

Olympic Games Legacy: Sports Facilities and Related Infrastructure as A Factor of Long-Term Regional Economic Dynamics

Dr. Nikolay V. GONTAR

passat01@mail.ru

Dr. Valentina I. ODINTSOVA
Don State Technical University, Rostov-on-Don, Russian Federation
odintsova1749@mail.ru

Abstract

Olympic Games Legacy is often a significant problem for cities hosting the Olympics or FIFA Championships. At the same time, the formation of an extensive sports and non-sports infrastructure makes it possible to include the Olympic Games Legacy in the economic processes and social development of the cities where events are held. The article examines the example of Sochi, the host city of the XXII Winter Olympic Games in 2014, and analyzes the model that made the Olympic Games Legacy an element of urban sustainability. The article discusses the transformation of economic and non-economic factors in the use of Olympic Games Legacy. It also analyzed the change in the role of the Legacy in shaping the economic trajectory at three stages: before the start of the covid-19 pandemic, during the period of restrictions associated with the pandemic, and during the projected recovery from the crisis. The position of the city as an all-Russian resort is considered as the basis for the model of inclusion of the Olympic Games Legacy in Sochi in the processes of sustainable development of the city and the region. This made it possible to fully use the transport, engineering and other related infrastructure built for the Olympics, and also made it possible to maintain the functionality of sports facilities. These processes are analyzed in the article taking into account the multi-level dynamics of tourist visits in the world, Russia and Sochi in the period before the pandemic and in 2020. In addition, in relation to modern conditions, measures of state support for tourism as a key economic sector for Sochi are considered. Such measures are seen as an important tool for supporting the Olympic Games Legacy and preserving the role of its sporting elements as a factor in the economic development of Sochi.

Keywords: Olympic Games Legacy, Sport, Tourism, Sochi, Regional Politics.

Introduction

The global sports industry provides a significant infrastructure to support global sports. Such infrastructure (actually sports and accompanying), in turn, acts as a significant resource not only for holding sports events, but also for the formation of the development potential of cities and regions. As stated in Changing (2011)…, in the 2000s. sports projects attracted more and more funds, advertising budgets for sports events grew, businessmen invested in sports clubs, and sports facilities were built.

The long-term growth factors of the sports industry are: the growth of the world economy, the growing influence of TV advertising, the expansion of paid formats of sports broadcasts. In 2010, the revenues of the global sports industry amounted to $ 121.4 billion. Over the next 5 years, the annual growth rate was estimated at 3.7% (to $ 145.3 billion in 2015). North America is the key region for generating income from sports (41%). Excluding major events from the analysis, the global growth rate reached 4.7%. In the structure of the sports industry's income in the situation of the routine calendar (up to 2020), approximately 1/3 came from ticket sales and income from sponsors, and the rest came from the sale of broadcasting rights and merchandising.

Tourism is a significant resource for the development of the sports industry, it is a dynamic industry, accounting for about a third of the volume of trade in services in the world. According to Worldbank .. (2012), over the past 30 years, the contribution of the service sector to economic growth has exceeded the contribution of industrial production. In the structure of trade in services, about 1/4 of the world's trade in services is transport services, and about 1/3 is tourism, as reported by Balaeva (2009).

In the "Classification list of service sectors" of the GATT, within which approx. 160 service sectors in 12 directions, both tourism (4 groups) and sports (5 groups) appear. The profits of the sports industry are generated in large part by tourist visits to global sports events. However, the legacy of the Olympics and other world sports

Cite this Article as: Nikolay V. GONTAR and Valentina I. ODINTSOVA " Olympic Games Legacy: Sports Facilities and Related Infrastructure as A Factor of Long-Term Regional Economic Dynamics" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

tournaments often gives rise to the problem of the further use of the sports and other material infrastructure created for the competition (the problem of "white elephants"). At the same time, one of the most successful examples of managing such a legacy is London 2012. The article examines the example of the Russian city of Sochi, the city of the 2014 Winter Olympics and football matches of the 2018 FIFA World Cup, and infrastructural heritage as a factor of sustainable development of Sochi.

Studies of the problems and effects of the creation and subsequent use of sports and related infrastructure at the regional and city levels indicate the widespread occurrence of the effects of large sports tournaments, which is emphasized, for example, by Kasimati et al (2008). Essex and Chalkley (2004) analyze the Winter Olympics as a trigger for the transformation of urban and regional politics. As emphasized by Smith (2009), the positive effects of sporting events can spread to peripheral territories. At the same time, in the temporal aspect, Leopkey and Parent (2012) emphasized the problems of linking the Olympic Games Legacy with its long-term effects.

Turning to the physical infrastructures created for the Olympics and other global sports forums, Kassens-Noor (2013) and Pereira (2018) substantiated the importance of the created transport heritage of the Olympics over a long time period (1992-2012) and the importance of such a heritage in transforming the accessibility of urban spaces. In general, the role of the post-Olympic legacy in the development of public spaces is studied, for example, by Preuss (2013), both in connection with the FIFA world championships and Olympics. Urban renewal and gentrification, increased safety are noted as significant effects, which is also noted by García (2004) in relation to sporting events in Glasgow 1990, Sydney 2000 and Barcelona 2004.

The successful experience of creating a safe and sustainable London space in preparation for the 2012 Olympics is described, in particular, by Fussey et al (2011). Describes East London's “De-Risking” in detail as part of Smith's (2014) revival plan ahead of the 2012 Olympics.

Finally, the social transformation of the space of cities hosting sports tournaments, the development of urban entrepreneurship, the growth of public interest in sports (which is associated with the development of sports and related infrastructure) were analyzed as significant, which is described using the example of the level of physical activity and sports among children and adolescents by Craig and Bauman (2014).

Today, the crisis in the sports and tourism industries is triggered by the covid-19 pandemic, which led to the suspension, in particular, of the football championships in European countries, the postponement of the Tokyo Olympics and the FIFA European Championship from 2020 to 2021, which generates significant crises in the sports industries and tourism and also requires an analysis of their prospects.

Methodological Framework

The preparation and conduct of sports competitions form the sports and related infrastructure of cities and regions where the Olympics and other global competitions are held. Research on the post-competitive use of such infrastructure is being conducted as part of the Olympic Games Legacy concept. This concept includes tangible and intangible heritage, economic, cultural, social, political and other aspects, according to McKay and Plumb (2001). Another way of structuring Olympic Games Legacy is 6 types: urban and environmental, sports, economic and tourism-related, political, cultural, social and communication-related, educational, as mentioned by MacAlloon (2003). At the same time, we are talking not only about the legacy of the Olympics, but also of major world tournaments, such as the World and European Football Championships. In this regard, based on the accepted classifications, an attempt was made to structure the legacy of the Olympics in Sochi as a resource for the development of the region.

Due to the fact that the use of sports and other facilities after world tournaments is not as significant as during their holding, sporting events of this kind give rise to problems of the subsequent management of the infrastructure. The article examines a model in which infrastructure of sports, transport, energy and urban economy has formed the potential for sustainable development of the vast territory of Sochi. The basis of this role of Olympic Games Legacy was the nature of Sochi's economy, its position as a resort of all-Russian importance.

However, the role of the legacy in Sochi is also seen as a resource that allowed Sochi to pass relatively smoothly through the period of restrictions caused by the SARS-CoV-2 (covid-19) pandemic and economic constraints in 2020, and can contribute to resilience during the recovery from the restrictions in the end of the pandemic.

In this regard, a step-by-step change in the impact of Olympic Games Legacy on the development trajectory of Greater Sochi was considered, and the accompanying factors that determined the use of this heritage in Sochi's core tourism sector were analyzed.

In connection with the study of the role of sports and related infrastructure in the formation of the sustainability of regional economic dynamics, the article uses methods of comparative statistical analysis, building a model for the use of Olympic Games Legacy in the specific conditions of Greater Sochi, and uses the analysis of factors of inclusion of heritage in economic dynamics.

Structure of the Olympic Games Legacy in Sochi

Sochi is a Russian resort on the Black Sea with the only subtropical zone in the Russian Federation, located in good transport accessibility from the centers of domestic Russian solvent demand for tourist services (Moscow, Central Russia), the center of Russian seaside tourism. Also Sochi and the Krasnodar region are an important direction of Russia's regional policy, as noted by Gontar (2006).

Sochi became the host city for the XXII Winter Olympic Games in 2014. Sochi also hosted the 2018 FIFA World Cup matches. The resort town of Sochi has a population of 530 thousand and is an area of 3.5 thousand square km. The Olympiad competitions were held in the south part of Sochi.

Preparations for the Olympics became the largest investment project in Russia in the 2010s. Significant funds were invested in the preparation of the events (over $ 50 billion in the preparation of the Olympics and over $ 10 billion in the preparation of the World Championship).

In addition to the corruption component, large expenses for the preparation of the Games were caused by a large influx of guests to the event. The guests of the Olympic Games in Sochi were approx. 4 million people. In addition, Sochi also hosted matches of the 2018 FIFA World Cup (in total, the championship in Russia was attended by 3 million guests).

For the 2014 Olympics, 11 sports facilities were built in Sochi. The coastal cluster included: Fisht Olympic Stadium (later transformed into a football stadium), Bolshoi Ice Palace, Puck Ice Arena, Ice Cube Curling Center, Iceberg Winter Sports Palace, Adler Arena. The Olympic Park was created. The mountain cluster included: the Laura ski and biathlon competition complex, the «Rosa Khutor» ski center, the «Russkiye Gorki» ski jumping complex, the «Sanki toboggan» sports center, and the «Rosa Khutor» extreme park.

In the structure of expenses for the Olympics, sports facilities accounted for only 17.6%. The rest of the funds were directed to the development of the Sochi territory and the infrastructure necessary for the Games and tourist visits. In Sochi, 42 hotels were built, which made it possible to increase the number of beds in them by 25 thousand, including in 4* and 5* hotels.

Reconstruction of the engineering infrastructure of Sochi affected 53 water supply and sewerage facilities, according to Artemova (2015). A new 50 km long Adler-Krasnaya Polyana railway-highway was built, which includes 28 bridges, 59 flyovers and 12 tunnels. About 200 new thermal power plants with a total capacity of over 500 MW have been built. These stations increased the potential of the Sochi power grid by 2.5 times, according to Shekhovtsov (2012). Also a new Dzhubginskaya thermal power plant was erected.

In general, the infrastructure legacy of the 2014 Olympics amounted to approx. 400 objects. By 2014, 360 kilometers of roads and 200 kilometers of railways had been laid and reconstructed in Sochi. The Sochi air terminal complex has been reconstructed and modernized on the eve of the Olympics. In 2012, the center of Sochi was connected by rail to the airport. A significant contribution to the development of the transport system was the construction of a backup to Kurortny Prospekt (before the Olympics, the avenue was the only through highway in Sochi along the coast).

In preparation for the Olympics, the F1 racing complex was built, and the seaport was reconstructed. To service the mountain cluster, 11 cable cars have been built. At the same time, the mountain cluster has a relatively stable potential for tourist demand, and includes 23 tracks 77 km long, of which 13 are sports, according to the Russian newspaper .. (2014).

The most significant objects of support for the Olympics, which were then included in the work of resort hotels, include the Tulip Inn Omega, RADISSON BLU RESORT & CONGRESS CENTER, and the Russian Seasons Hotel. The new hotel fund in Sochi, including 35 hotels with 20 thousand rooms, allowed to increase the number of rooms in Sochi to 57 thousand, which is more than in Moscow (41.3 thousand).

Model of Olympic Games Legacy inclusion in the formation of long-term sustainability of the economy of Sochi and the Krasnodar region

After the competition, Sochi's Olympic sports facilities were either reformatted or used for their original purpose. For example, the «Fisht» (Olympic opening stadium) was reconstructed in anticipation of the FIFA World Cup, the ice rink became the home of the Sochi Hockey Club, and most of the other facilities continue to perform their functions during regular competitions. The mountain cluster is also a place of active tourist visits to get acquainted with the facilities of the Olympics, as well as the Olympic village in the Imeretinskaya lowland (Coastal cluster).

In September 2014, the Sochi Tennis Academy and Figure Skating School became a training base for young athletes. The skating center «Adler-Arena» was transformed into an arena with tennis courts. The All-Russian Children's Sports and Recreation Center has opened in the Olympic Park. The Fisht stadium hosts regular matches of the Russian Premier League.

Speaking about the model of Olympic Games Legacy inclusion in the formation of sustainable economic growth in Sochi and the Krasnodar region, one should take into account the traditional structure of the influence of such a heritage on changes in the cities where the Games and FIFA Championships are held. Thus, the urban environment, the transport system, and public spaces are being improved. A number of districts are being gentrified. In addition, the impact on the social environment is manifested in the reduction of crime, the involvement of young people in sports.

In the situation of Sochi, Olympic Games Legacy, first of all, strengthened the specialization of the city as a resort by improving transport accessibility (airport, train station complex), developing a hotel system, increasing tourist attractions (Olympic Park, Olympic ski cluster). Thus, the key was the model of mutual support for the functioning of the Olympic Games Legacy due to the tourist profile of the city, and, conversely, the development of this profile due to the Olympic Games Legacy. This is due to the fact that Sochi remains a resort city, where HORECA employs approx. 172 thousand people, as noted by Olympic results .. (2014) Sochi also took 2nd place in the ranking of Russian cities popular for family vacations, according to Gureeva (2014).

The second significant aspect of the existing model was the inclusion of Olympic Games Legacy in the processes of regional development during the period of stable global processes (including 2019), during the covid-19 pandemic, and (predictably) during the recovery period after the pandemic. At the same time, if during the period of the Olympics the sports and related infrastructure were used as much as possible, in the post-Olympic period the predominant load was retained by non-sports facilities in Sochi, focused on ensuring the life of the city. The factors of inclusion of Olympic Games Legacy in the formation of the sustainability of economic processes, and the role of heritage in these processes, are different at different stages - tables 1 and 2.

Table 1: Dynamics of factors of use of Olympic Games Legacy in Sochi

Factors	**During the period 2014-2019**	**Covid-19 pandemic period (2020)**	**Post-pandemic recovery period (prognosis)**
Economic	An increase in the number of hotels of different categories, An increase in the transport accessibility of Sochi, a fall in the ruble exchange rate and a decrease in opportunities for foreign recreation for residents of the Russian Federation	Dominance of Sochi in the domestic tourism market, Preservation of deferred tourist demand due to quarantine until June 2020 and restrictions on population movements	Slow recovery of household income and limited potential for tourism abroad (focus on Sochi as a leading maritime destination), Recovery economic growth
Non-economic	Growth in the quality of the urban environment, Implementation of the state program for the development of the Olympic heritage, the interest of Russians in the facilities of the Olympics	The inability to fly abroad for tourism purposes due to the pandemic, Continuation of sports events in Sochi in autumn-winter 2020	The rate of recovery from the pandemic, Severity of state restrictive measures, The return of global tournaments in Sochi for certain types of competitions

Table 2: Impact of Olympic Games Legacy in Sochi on the economic dynamics of the city

Area of influence	**During the period 2014-2019**	**Covid-19 pandemic period (2020)**	**Post-pandemic recovery period (prognosis)**
Role for the city	New quality of the urban environment, transport infrastructure, transport accessibility for flights from cities of Russia and European countries, expanding the list of 4* and 5* hotels; increasing incomes of the population engaged in serving tourists; growth in the flow of tourists.	Preservation of economic activity due to the resumption of the summer tourist season from June 2020; support of other industries through tourism	Continued demand from Russians for rest in Sochi; Fast recovery due to lack of conservation of tourist sites and hotels
Role for Russia	The growth of the city's recognition in the world as a	Meeting the demand of Russians for recreation	Recovery of the economy of one of the

	Russian resort, the inclusion of Russia in the F1 racing calendar, the holding of stages of world competitions in winter sports, the training of athletes from Russia at the bases in Sochi, the development of children's sports tourism	by the sea in the absence of international flights, Ensuring the safety of recreation by meeting demand without flying abroad	largest regions of Russia as a "growth point" for the economy; preservation of the key tourist destination for Russians' recreation in a situation of slow restoration of communication with other countries

Characterizing (within the framework of the noted interaction of Olympic Games Legacy and the traditional tourist function of the city) tourist activity in Sochi during the period under review, we note that after the Olympics, Sochi hosted approx. 5 million tourists. However, the limited opportunities for Russians to visit resorts abroad due to the depreciation of the ruble since 2014 led to an increase in visits to Sochi. In 2018 and 2019, there was a recovery in the flow of Russians abroad due to the stabilization of the economic situation.

In Russia by 2019, more than 50 million tourist trips were made. The Krasnodar region was visited by about 16 million tourists. In 2019, the Krasnodar region became the leader in Russia in terms of the share of the cost of hotel services and other temporary accommodation for tourists. The share of the Krasnodar region was 24.0%, Moscow - 21.7%, St. Petersburg - 10%.

More than 76 million people were accommodated in hotels and similar places for collective accommodation of tourists in Russia in 2019. At the same time, Moscow accounted for 20.4%, the Krasnodar region - 10.9%, St. Petersburg - 8%.

The Sochi Olympics gave an impetus to the development of the hotel business in Sochi (in Russia, the FIFA World Cup 2018 served as such an impetus). So, if in 2013 the area of rooms in hotels and similar places for tourist accommodation in Russia reached 11.5 million square meters, then in 2019 it reached 22.2 million square meters. In the Krasnodar region, indicators increased from 1.8 to 4.3 million square meters.

However, the situation in the global and Russian tourism industry has become significantly complicated in 2020 due to the spread of the coronavirus and restrictions imposed by the governments of the countries of the world on international flights and travel within countries.

In 2019, which preceded the year of the pandemic, the number of international tourist trips made worldwide reached 1.5 billion, an increase from 2018 by 4%, according to the UNWTO. The growth of international tourism has continued for 10 consecutive years.

However, in 2020, due to the spread of the coronavirus, strict quarantine measures were taken in the spring of 2020, tourist trips were reduced, and mass sports competitions were canceled. From May-June 2020, some of the competitions and flights resumed. However, the Tokyo Olympics and the FIFA European Championship were postponed, which reduced both sports tourism and tourism in general. The industry recovery began only in the second half of 2020.

According to the UNWTO World Tourism Barometer and Statistical Annex (2020), in the first half of 2020, global tourism lost almost 2/3 of its volume. In June, the drop in tourist arrivals was 93% compared to the level of 2019. The drop in arrivals by about 440 million resulted in losses to the tourism industry in the amount of about 460 billion dollars. At the same time, in countries such as China and Russia, the flow of tourists inside the country has increased. By mid-autumn 2020, according to UNWTO, the following losses had occurred:

- Loss of 850 million to 1.1 billon international tourists,
- Loss of US$ 910 billion to US$ 1.2 trillion in export revenues from tourism,
- 100 to 120 million jobs at risk.

Tourism in Russia and Sochi was also hit by a pandemic in 2020. However, the rapid onset of the warm season and the slowdown in the spread of the epidemic in Russia made it possible to open resorts in June. In addition, the Government of the Russian Federation took measures to support demand in the industry, thus avoiding a catastrophic decline in the industry. In summer, the decrease in the number of tourists to mass destinations was only 30%. At the same time, the Krasnodar region has been visited by about 9 million tourists since the beginning of the year. In general, domestic tourism in Russia reached 70% of the level of 2019. This was facilitated by measures to return to Russians from the state budget part of the costs of tourist trips around the country. According to the cashback program, at the beginning of October 2020, vouchers were bought by about 70 thousand people. The second cashback program was launched on October 15th. More than 250 hotels and other accommodation facilities in the Krasnodar region, including Sochi, took part in the program of subsidizing recreation.

In 2019, the Krasnodar region (and, above all, Sochi) received 17.3 million tourists. From January 1 to September 15, 2020, 8.7 million tourists visited the Krasnodar region, which is 39% less than in 2019. During the velvet season, 4 * and 5 * hotels are still in demand. The occupancy of hotels with a developed infrastructure reaches 75%.

Among the measures that are designed to support the tourism industry in Russia and create conditions for the rapid recovery of the industry, one can name the measures of the federal government - Table 3

Table 3: Current and adopted support measures for enterprises of the tourism industry during a pandemic, according to the Federal Agency for Tourism.

For small and medium businesses	For large businesses
Subsidies for tour operators for reimbursement of losses related to air travel; Access to the tour operator's personal liability fund; Delay in the provision of accounting and industry reports; Refunds for canceled and rescheduled events; Renewal of licenses and permits; Interest-free loans for payment of salaries; Grants for wages, urgent needs, utility bills; Subsidizing access to borrowed funds at a preferential rate; Deferral of lease payments; Moratorium on bankruptcy, tax sanctions and audits; Tax holidays; Tax exemption on subsidies to SMEs; Extending tax payment deadlines for SMEs; Subsidies for the resumption of activities	Renewal of licenses and permits; Interest-free loans for payment of salaries; Moratorium on bankruptcy, tax sanctions, audits; Tax holidays; Resumption subsidies

In addition to government measures and programs to support tourism, the Krasnodar region also has regional support mechanisms. For example, in 2020 there is a regional program «South health resort», which aims to promote the resort potential of the region and increase the occupancy of sanatoriums in the low season. The program started on October 15, 2020 and will end on May 1, 2021. According to the program, residents and guests of the region can take advantage of health tours for 2-7 days or 2-3 weeks. Also in the region today, grants are provided, which are designed to stimulate the tourism enterprises of the region to develop tourist routes, upgrade infrastructure.

Conclusion. The holding of world-class sports tournaments forms an extensive sports and related infrastructure, contributes to the formation of a new quality of the urban environment, the involvement of the population in sports, and the development of entrepreneurship. Due to the lack of demand for many structures after the Olympics and world championships, the regions where they are held often face the problem of the legacy of the Olympics. The example of Sochi demonstrates a model that made it possible to avoid the formation of «white elephants» due to the fact that the facilities of the 2014 Olympics were built in the tourist center of Russia and turned out to be in demand as objects of tourist visits and as sports arenas. Also, engineering and transport structures have become the most important infrastructure element in demand. Both the sports and non-sports infrastructure of the Olympic Sochi became one of the factors of the stability and competitiveness of the economy of Sochi and the Krasnodar region in the period after the Olympics (2014-2019), during the period of coronavirus restrictions in international tourism in 2020. It will also contribute to the region's recovery from recession. Measures of state and regional support for tourism as an industry can be named as a key factor in the implementation of this scenario.

Abstract
The purpose of the study is to reveal the impact of the COVID-19 pandemic on the economic security of Russian regions, as well as to determine the appropriate directions for stabilizing the socio-economic situation. The authors identified specific features of the COVID - 19 pandemic that determine the nature of its impact on regional development. The authors structured the economic security of the region in terms of the emergence of risk factors and threats from the COVID-19 pandemic (economic security of the real sector of the economy of the region; economic security of the financial sector of the region; economic security of the social sphere of the region), and also defined a list of economic indicators that characterize each element of economic security. The authors analyzed the dynamics of indicators of economic security of Russian regions during the beginning of the pandemic based on operational data from the Federal state statistics service of the Russian Federation, as well as concluded that the impact of the COVID-19 pandemic on the state of economic security of Russian regions is heterogeneous, certain indicators of economic security at the regional level are decreasing. The authors suggested ways to stabilize the economic security of Russian regions.

Keywords: economic security, region, COVID-19, threats, recession, risk factors, economic security indicators

Introduction

In the modern world, there is a whole range of threats that undermine the economic security of states. And they are not always economic, technological, or man-made.

Viral epidemics regularly occur in the global space, which become a real disaster for humanity and its prosperous existence. Over the past century alone, the world has experienced a number of major viral epidemics: Spanish flu, SARS, avian flu, swine flu, Ebola, and others.

Viral epidemics bring an increase in deaths from viruses, direct harm to the health of the population, as well as significant damage to the economy. Thus, according to the world economic forum, the annual global cost of moderate to severe pandemics is about $ 570 billion, or 0.7% of global income (Weforum, 2018).

KARPUNINA "Economic Security of Russian Regions: Risk Factors and Consequences of the Covid-19 Pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The COVID-19 pandemic has become a real challenge to the global economy, which, according to analysts, will result in the loss of the world economy in the amount of $5.5 trillion in the next two years and the deepest peacetime recession since the 1930s (Bloomberg, 2020). The Russian regions did not remain aloof from what is happening.

The introduction of quarantine measures, the suspension of most of the country's enterprises, the blocking of international industrial and commercial communication channels, as well as the transition to remote work have led to a critical reduction in many socio-economic parameters of the national economy of Russian Federation.

What is the impact of the COVID-19 pandemic on the situation in the regional dimension, how has it affected the parameters of economic security of Russian regions, and is it possible to minimize the negative consequences for the economy of territories? Finding the answer to these questions requires a thorough analysis of the situation.

Methodology

The purpose of the study is to reveal the impact of the COVID-19 pandemic on the situation of Russian regions through the prism of assessing their economic security, as well as to determine the directions for stabilizing the socio-economic situation in regions of the country.

Investigation phase:

1) Identification of structural elements of the region's economic security and economic indicators that characterize them.

2) Analysis of the dynamics of indicators of economic security in Russian regions during the pandemic and systematization of risk factors.

3) Identification of ways to stabilize the economic security of Russian regions.

Research methods: comparative analysis method, systematization method, economic analysis method, system approach, induction and deduction.

Information base of the research: statistical data of the Federal state statistics service of the Russian Federation, the Ministry of Finance of the Russian Federation, the rating Agency RIA Rating, conference materials.

Theoretical Basis of The Research

In the scientific literature, the concept of economic security is identified with providing the economic system with decent living conditions and personal development, maintaining a certain level of socio-economic stability, as well as having a military-political potential to prevent internal and external threats to society and the state (Huber et al, 2010; Karpunina et al., 2019).

The economic security of a region is a multi-factor substance that is determined by the influence of financial, political, economic, and social factors of the internal and external environment on the balance of various components of the region's economic system (Edelev, 2007; Kremlev et al., 2007; Kalinina, 2010).

Shubina (2017) emphasizes that the economic security of a region depends on: the current state of the region's economy; the nature of the threats affecting it; the existing potential for economic development (the availability of natural resources, the degree of development of the industrial sector, favorable conditions for business development); the ability of the region's economy to innovate; the level of competitiveness of the region's economy.

Speaking about the threats from viral epidemics to humans, researchers point out that they cause a loss of income during the period of disability, an increase in expenses related to the purchase of medicines and medical care, and a growing probability of losing a job (Karpunina et al., 2020). In turn, the mass disability of employees negatively affects the activities of enterprises: the quality of labor decreases, as well as its productivity, which leads to a decline in production, and, accordingly, to a downturn in competitiveness and a reduction in profits, i.e., undermining the economic security of the enterprise.

Assessing the impact of viral epidemics in the regional context is very time-consuming, while at the country level, researchers note the damage in the form of a sharp increase in costs for the health system associated with the prevention and medical treatment of infected people, reduced labor productivity and disruption of the normal

functioning of the economy, which reduces the economic security of the state (Bloom et al., 2018; Fan et al., 2016; Brainerd and Siegler, 2003; Qiu et al., 2018).

Results

The COVID-19 pandemic, unlike previous viral epidemics, has specific features that determine the nature of its impact on regional development:

- intensity of virus spread and global reach: from December 2019 to March 2020, the virus has spread around the world, and the number of infected people continues to grow (Sochnenkova, 2020;Bugaenko , 2020);
- complete suspension of socio-economic activity in all regions and countries as a measure to counter the spread of infection (restrictions on movement; interruption of work of enterprises; transfer of employees of some enterprises to a remote work format; blocking of international communications and trade) (Kranov, 2020; Sheremet, 2020);
- complete uncertainty and inability to predict the rate of infection and the end of the pandemic (Ranepa, 2020).

The direct consequence of the pandemic, according to Rosstat, was a drop in Russia's GDP in the first half of 2020 of 3.4%. The decline occurred in the industrial sector, construction, and trade. The volume of investment in fixed assets has decreased, the real monetary income of the population has reduced, and unemployment has increased. Overall indicators for the country were made up of the results of individual regions with heterogeneous dynamics (RIA Rating, 2020b).

We structure the economic security of the region for the study of threats under the influence of the COVID-19 pandemic as follows (Orlova et al., 2016):

- economic security of the real sector of the region's economy;

- economic security of the region's financial sector;

- economic security of the social sphere.

Accordingly, the following threats to the economic security of the region in the context of the COVID-19 pandemic can be identified (Fig. 1).

Fig. 1: Threats to the economic security of the region in the context of the COVID-19 pandemic (compiled by the authors)

Various approaches based on a set of indicators can be used to assess the economic security of the region (for example, in the methodology of Novikova and Krasnikov (2010) highlights 22 main indicators with their threshold values).

In accordance with the structure of economic security proposed by the authors, the following groups of socio-economic indicators can be identified to assess the impact of emerging threats (table 1).

Table 1: Indicators of economic security in the region (by structural elements)

Structural element of the region's economic security	Indicators
Economic security of the real sector of the region's economy	1) Volume of GRP per capita, % 2) Industrial production index, % 3) Investment in fixed assets per capita, % of GRP
Economic security of the region's financial sector	1) The level of the regional budget deficit, % of GRP 2) Loan volume, % of GRP 3) Share of unprofitable organizations, % 4) Consumer price index, % 5) State debt of the region, thousand rubles
Economic security of the social sphere of the region	1) Unemployment rate, % of the labor force 2) The share of the population with incomes below the subsistence minimum, % 3) The average per capita monetary income of the population, rubles. 4) Annual growth rate of real incomes of the population, %

Source: compiled by the authors

Interpretation of the analysis results is based on the threshold values of the main indicators of economic security of Russian regions presented in the works of Krivorotov and Kalina (2010), Tatarkin et al. (2007), Mityakov et al. (2013), Korableva and Karpov (2019), as well as the average Russian values.

Exceeding the threshold values for positive indicators and finding the values of negative indicators below the threshold indicates the appearance of signs of a decrease in the economic security of the region.

The collection of statistical data by regions of the Russian Federation is carried out in annual terms, as well as the determination of threshold values for economic security indicators. At present, there is a problem of collecting operational statistical data to assess changes in the level of economic security of regions during the pandemic. In this regard, the proposed list of indicators for assessing the economic security of regions will be incomplete. However, the operational data of the Federal state statistics service of the Russian Federation (2020) and the rating Agency RIA Rating (2020) for the first half of 2020 allow us to make a preliminary assessment of the state of economic security of Russian regions.

According to the results of the first half of 2020, industrial production in the Russian Federation decreased by 3.5%, while in the same period of 2019, growth in the industrial sector was 2.2%. Meanwhile, industrial production growth in the first half of 2020 was recorded in the Tyumen region (+28.6%) (due to the launch of a new manufacturing enterprise Zapsibneftekhim), the Tula region (+26.3%), and the Republic of North Ossetia-Alania (+25.9%).

The decline in industrial production in the first half of 2020 was recorded in 41 regions of the Russian Federation (RIA Rating, 2020b). The most significant decline was recorded in the Republic of Tyva (-39.1%) (due to a sharp fall in mining), Sevastopol, Kostroma region, Ulyanovsk region and Kaliningrad region. In other regions, the drop in industrial production did not exceed 10% (Federal state statistics service of the Russian Federation, 2020).

Production in the manufacturing sector increased in 45 regions in the first half of 2020 (57 in 2019). But there are regions that are characterized by growth-the Magadan region (+75.0%), the Tyumen region and the Altai Republic.

In the first half of 2020, the construction industry as a whole in Russia experienced a decrease of 0.5 % (in 2019 – an increase of 0.1%). Nevertheless, the growth of the construction industry in 2020 is typical for the Kostroma region, the Astrakhan region and the Ingush Republic. Positive dynamics of development of the construction industry was noted in 46 regions of the Russian Federation.

In the first half of 2020, the volume of investment in fixed assets in the Russian Federation decreased by 4.0% (compared to + 1.1% in the same period in 2019), but in 44 regions of the Russian Federation, the volume of investment in fixed assets increased (primarily in the Republic of Kalmykia) (RIA Rating, 2020a).

The negative impact of the pandemic was a 6.4% reduction in retail trade turnover in Russia as a whole: retail trade turnover remained at the same level in six regions, while the remaining 78 regions experienced a decrease in the indicator.

Reduction of real monetary incomes of the population in the first half of 2020 occurred in 64 regions of Russia, compared to the same period in 2019, they decreased by 3.1%. However, in 20 regions of the country, the real monetary income of the population has increased (for example, in the Chukotka Autonomous district).

In the first half of 2020, nominal wages in the country as a whole increased by 5.8% (in the same period of 2019, it raised by 7.1%), namely in 84 regions of the Russian Federation.

The COVID-19 pandemic created conditions for an increase in unemployment - up to 6.0% (in the same period of 2019 - 4.6%). At the same time, an increase in unemployment was recorded in 81 regions. In 3 regions (the Smolensk region, the Novosibirsk region, and the Kamchatka territory), it remained unchanged; in the Chukotka Autonomous district the unemployment rate decreased.

In the first half of 2020, there was a total deficit of consolidated budgets of all regions of Russia in the amount of 213.7 billion rubles, but consolidated budgets in 38 regions were executed with a surplus.

According to the Ministry of Finance of the Russian Federation, the total volume of state debt of the Russian regions amounted to 2,139 trillion rubles: in 33 regions showed the dynamics of growth of public debt, in 32 regions of the country there was a decrease of debt, and it remained unchanged in 20 regions (Minfin, 2020).

Thus, operational data indicate that the negative impact of the COVID-19 pandemic on the economic security of Russian regions is uneven. We systematize the available data on the socio-economic development of some regions of the country to confirm the conclusion (table 2). To do this, we select several typical recipient regions of Russia (Rosinfostat, 2020): The Dagestan Republic (1 place in the list of subsidized regions 2020 – government subsidies amounted to 72892 billion), Tambov region (27th place in the ranking of the most subsidized regions, government subsidies amounted to 9523 billion), Pskov region (43rd place – state grants totaled 4685 billion roubles), and also the largest donor regions: the Khanty-Mansi Autonomous district (Ugra), Moscow, Yamalo-Nenets Autonomous district.

Table 2: Indicators of economic security of Russian regions during the COVID-19 pandemic

The name of the indicator	Actual indicator		
	Region of the Russian Federation	January-September 2019	January-September 2020
Industrial production index, % compared to the same period of the previous year	Dagestan Republic	104,8	100,1
	Tambov region	100,8	107,0
	Pskov region	107,4	99,7
	Khanty-Mansi Autonomous district (Yugra)	101,1	92,6
	Moscow	107,4	103,2
	Yamalo-Nenets Autonomous district	112,7	97,3
Volume of investment in fixed assets, in comparable prices as a percentage of the same period of the previous year	Dagestan Republic	128,6	100,8
	Tambov region	49,9	100,5
	Pskov region	100,6	88,1
	Khanty-Mansi Autonomous district (Yugra)	89,9	115,7
	Moscow	102,0	108,2
	Yamalo-Nenets Autonomous district	129,8	120,4
Consumer price indices for goods and	Dagestan Republic	101,7	102,8
	Tambov region	103,2	103,2

services, as a percentage of the same period of the previous year	Pskov region	101,9	103,1
	Khanty-Mansi Autonomous district (Yugra)	101,7	102,2
	Moscow	102,7	102,5
	Yamalo-Nenets Autonomous district	100,9	101,5
Unemployment rate, % of the labor force	Dagestan Republic	13,0	15,7
	Tambov region	3,9	5,0
	Pskov region	5,1	6,9
	Khanty-Mansi Autonomous district (Yugra)	2,5	3,4
	Moscow	1,4	3,3
	Yamalo-Nenets Autonomous district	1,9	2,6
Dynamics of real monetary income of the population, in % to the same period of the previous year	Dagestan Republic	106,4	87,4
	Tambov region	98,6	86,6
	Pskov region	105,6	95,3
	Khanty-Mansi Autonomous district (Yugra)	102,7	97,5
	Moscow	102,4	96,3
	Yamalo-Nenets Autonomous district	105,4	100,7
State debt of the regions of the Russian Federation, thousand rubles	Dagestan Republic	9 796 336	9 327 936
	Tambov region	17 440 635	19 074 426

	Khanty-Mansi Autonomous district(Yugra)	14 400 000	13 000 000
	Moscow	30 000 000	30 000 000
	Yamalo-Nenets Autonomous district	16 624 425	16 410 976

Source: compiled by the authors according to the Federal state statistics service of the Russian Federation (2020), the Ministry of Finance of the Russian Federation (2019, 2020)

In general, the data presented in the table allow us to conclude: a decrease in industrial production in most of the analyzed regions during the pandemic (in 5 out of 6 analyzed regions); an ambiguous dynamics of the behavior of fixed capital investment: 3 regions experienced an increase, 3 regions decreased; a slight increase in the rate of inflation in the first half of 2020; a significant growth in unemployment and a drop in real monetary income of the population in all the studied regions of the country; on the multidirectional dynamics of growth/reduction of the state debt of the regions (in 2 regions there was an increase, in 2 – a reduction, in 1 – remained unchanged).

The analysis of the dynamics of key macroeconomic indicators allows us to make a conclusion about the heterogeneity of the impact of the COVID-19 pandemic on the state of economic security of Russian regions. It is likely that the decline in key indicators of economic security in Russia's regions will continue in the future and will become noticeable at the regional level.

Reducing the identified threats to economic security from the COVID-19 pandemic requires the implementation of a set of public policy measures, including:

1) implementation of preventive medical measures to minimize the likelihood of new epidemic threats, development of a network of medical institutions, including through the use of advanced digital technologies (use of online services, phones and other digital transactions in case of emergencies), which allow to track the geography of the spread of viruses and save time when responding to an outbreak (ITU, 2015; Karpunina et al., 2020);

2) state support for businesses in the context of a pandemic to stimulate entrepreneurial activity, including through the use of tax tools and grant support;

3) social policy measures for the protection of socially vulnerable segments of the population, support for the population who lost their jobs due to the pandemic;

4) education policy – development and implementation of educational programs for retraining and advanced training of specialists;

5) the policy of accelerated digital development is to bridge digital gaps between regions, equalize access to the Internet and use digital platforms and services to form a solid basis for the national economic system, ensuring smooth operation and provision of goods and services in the event of an epidemic threat.

Conclusions

The authors identified the specifics of the COVID-19 pandemic, which had an impact on the dynamics of the development of Russian regions. The authors identified structural elements of the region's economic security to systematize risk factors and threats from the COVID-19 pandemic, and also identified a list of economic indicators that characterize them. The authors analyzed changes in indicators of economic security in Russian regions based on operational data from the Federal state statistics service of the Russian Federation in the first half of 2020, they concluded that the impact of the COVID-19 pandemic is heterogeneous in the context of economic security in various regions of Russia, as well as the likelihood of deterioration of economic security in the future. The authors proposed a set of public policy measures to level the identified threats to economic security from the COVID-19 pandemic.

Abstract

The purpose of the research is to reveal the specifics and conduct a comprehensive analysis of the scientific and educational potential and the system of ensuring the economic security of the state as a basis for strengthening the positions of the BRICS countries in the global competitive space. The authors identified the structural features of the country's scientific and educational potential and identified its components (personnel, material and technical, economic, organizational and managerial), as well as assessed the development dynamics (within the BRICS group and in comparison, with some developed countries). The authors systematized economic security threats from the scientific and educational potential. It is concluded that China and Russia among the BRICS countries have a more stable position in terms of economic security, due to the state of their scientific and educational potential. The authors proposed tools to reduce economic security threats of the state from the scientific and educational potential development.

Keywords: economic security of the state, scientific and educational potential, BRICS, integration processes, digital economy

Introduction

The problem of ensuring economic security is becoming more and more relevant for modern states. This is due to the growing geo-economic instability, the negative impact of regularly recurring economic and financial crises on the stability of national economies, integration processes as a characteristic feature of the development of modern international economic relations, as well as the strengthening of the global world multipolarity in the new digital space. The latter is associated with the formation of new conditions for the digital environment, tougher competition for leadership, and increasing gaps between countries that are actively developing digital technologies and countries that remain aloof from technological development. So, experts of the World economic forum claim that the countries-leaders of digital development by 2025 can receive a cumulative increase in cash flow at the level of 122%, while the outsider countries - by 10% (Weforum, 2019).

The BRICS countries are considered by experts as the main contenders for leadership positions in the new global digital economy. Of course, their starting positions are completely different. The BRICS countries are characterized by an asymmetric level of development and accessibility of infrastructure components of the digital economy

KARPUNINA "Scientific and Educational Potential as A Factor in Ensuring the Economic Security of The State in Terms of The Digital Development Intensification: Analysis and Assessment for The BRICS Countries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

ecosystem (Inchakova and Mitrofanova, 2020). If in recent years China has been competing in the development and implementation of digital technologies with the world leader the United States, accounting for a fifth of global GDP by PPP (20.1%), the rest of the BRICS countries are still strengthening their positions in the development of digital technologies, demonstrating restrained positive dynamics and intentions to accelerate modernization in all areas of activity.

The basis for inclusion in the processes of digital competition at the global level is the developed scientific and educational potential of the country, which has resources for continuous reproduction, as well as a comprehensive system for ensuring the economic security of the state, which can protect the country from emerging risks and threats.

Literature Review

Kleiner (2018) considered the digital economy as organizations, business processes, innovative projects, and infrastructure systems interacting with each other in a localized space in order to create and circulate material and symbolic goods and values.

Karpunina et al. (2019), Molchan et al. (2019) systematized the advantages and challenges for individuals, businesses and national economies from digitalization, showed how the introduction of digital technologies affects the productivity of production factors and the economic growth dynamics. Brynjolfsson et al. (2018) in his research reflected the nature of the impact of digitalization on consumer welfare. Cooper and Kaplinsky (1989) argued that digital technologies and the Internet lead to an increase in the capabilities of countries ' economic systems and generally have a positive impact on the world economy.

At the same time, Hansen and Nissenbaum (2009) compared digitalization to a disaster, focusing on the emergence of numerous threats to the security of States and individuals. The lack of knowledge about the impact of the digital economy and related phenomena on human activity, the labor market, business, public administration, as well as global institutions that regulate this area is of concern to economists, managers, and politicians (Bukht and Heeks, 2018). For example, Zhang and Chen (2019) point to the possibility of increasing problems of income inequality among workers in developed and developing countries in terms of digitalization.

Researchers are also interested in the progress of digitalization in the BRICS countries. Thus, the current vectors of interaction between the BRICS countries on the formation of the digital economy ecosystem are reflected in works of Inshakova and Mitrofanova (2020). Studies by Bragina (2018), Spartak (2018), Tkachenko (2018), Davidson and Yang (2020), Ignatov (2020) attempt to compare and evaluate individual parameters of the digital economy of the BRICS countries.

Methodology

The purpose of the study is to reveal the specifics and assess the scientific and educational potential and the system of ensuring the economic security of the state as a basis for strengthening the positions of the BRICS countries in the global competitive space.

Research objectives:

- to determine the structural features of the country's scientific and educational potential;

- to analyze the dynamics of the scientific and educational potential development of the BRICS countries and systematize the corresponding economic security threats;

- to offer tools to reduce the economic security threats of the state from the scientific and educational potential.

Research methods: theoretical analysis method, graphical method, induction and deduction method, comparative analysis method, economic analysis method, system approach.

Information base of the research: open statistical data of the World Bank (2020), IMF (2018), OECD (2020), documents of strategic importance of the Governments of the Russian Federation, India, Brazil, China, materials of monographs and conferences.

Results

In General, in 2019, the BRICS countries provided 33.4% of global GDP, with nominal GDP reaching 20.8 trillion US dollars (Economicdata, 2020). In 2019, China overtook many of the world's leading countries in terms of GDP,

as well as in terms of the size of the digital economy sector, and came close to the world leader – the United States. India has achieved a GDP that is ahead of the United Kingdom in value terms, but when analyzed in terms of "GDP per capita", this equality disappears, but the digital sector in India is inferior to that in the UK. The other countries of the BRICS group (Russia, Brazil, and South Africa) lag behind the leading countries both in terms of GDP and the share of the digital sector in GDP (figure 1).

Fig. 1: Comparison of BRICS countries and developed countries in terms of GDP and the size of the digital economy sector (compiled by the authors according to World Bank (2020))

Another indicator of the country's digital development level is the export of ICT products. And in this case, the positions of the BRICS countries are very different. China is ahead of the world's leading countries in terms of this indicator 549954 million US dollars against 138,651 million US dollars in the United States. In contrast, Brazil, Russia, India, and South Africa lag behind developed European countries, the United States, and Japan by several times (figure 2).

Fig. 2: Exports of ICT goods in BRICS and developed countries, million US dollars, 2019 (compiled by the authors according to OECD (2020d))

What determines success in building China's digital economy, and, conversely, what does Russia, India, Brazil, and South Africa lack to achieve digital leadership? Probably, in the transition to a new model of digital development, a special role is played by knowledge, produced innovations and new technologies, which are the result of the functioning of the scientific and educational potential of the country.

According to Shafikov (2006), scientific and educational potential is the potential of the education system contained in educational structures, which is aimed at the development of science, improvement of scientific products, as well as conducting research.

According to the authors, the following components can be distinguished in the structure of the scientific and educational potential of the state: personnel, material and technical, economic, organizational and managerial. Let's analyze them in the size of the BRICS countries.

1) The personnel component.

It is logical to divide the characteristics of the personnel component into two parts: the teaching staff of higher education institutions that provide training of highly qualified personnel and carry out scientific activities; the staff engaged in research and development in scientific organizations. Thanks to higher education institutions, the scale of training of highly qualified scientific personnel is expanded. The number of teaching staff in Russia in the period 2013-2018 decreased by 26.1% due to a reduction in the number of students and a decline in the number of educational organizations (Federal state statistics service of the Russian Federation, 2020). In addition, the conditions for postgraduate studies have changed due to the transition of the Russian Federation to the Bologna education system in 2010, which resulted in a sharp decrease in the number of postgraduates engaged in scientific activities and ensuring continuity in the scientific field – by 43% in the period from 1995 to 2015.

In contrast, in Brazil, the state's education policy was aimed at improving the literacy rate of the population, and the number of University teachers increased from 349,110 in 2014 to 362,307 in 2017 (i.e. by 3.4%) (OECD, 2020b). Meanwhile, in the UK, USA and Germany in 2014-2018, there was an increase in the number of University teachers from 6.8 % (in Germany) to 12.1% in the UK. The number of University teachers in the United States exceeds the number of University teachers in Russia by 2.2 times.

The number of research and development personnel per 1 million people in the BRICS group is significantly lower than in developed European countries, the United States and Japan. According to official data, only Russia is approaching the required level in terms of the number of researchers (Fig. 3).

Fig. 3: Number of researchers per million inhabitants, 2019 (compiled by the authors according to Unesco Institute for Statistic (2020))

This situation with the staff engaged in research activities in the countries of the BRICS group is a serious concern.

2) Material and technical component.

An important component of the scientific potential of universities and research organizations is the material and technical base of R&D. Its development and constant updating in accordance with modern requirements is a prerequisite for the intensification of scientific and educational processes, improving the quality of scientific results, as well as the competitiveness of scientific, technical and innovative products. In addition, in a digital environment, the level of access to information and its completeness are important, they are provided with access to the Internet and opportunities to use ICT in professional activities. The BRICS countries are characterized by a lower level of physical infrastructure development: they have a lower speed of Internet access (among the BRICS countries, Russia has the highest speed (68.8), but it is far from the average European speed (250)), the number of active users and households with Internet access.

Nevertheless, they exceed the OECD average in terms of Internet connection costs (from $ 10.1 US PPP in Russia to $29.9 US PPP in Brazil) (Spartak, 2018; Shuisky, 2019; Ignatov, 2020).

In general, the BRICS countries are developing their universities and their material and technical base. This is especially true in China (Peking University, Tsinghua University and Fudan University are leaders in all rankings) and Russia (Degtereva and Chernysheva, 2018). In 2016, India developed a plan for the formation of ten public and ten private universities of international level, however, the problem of its implementation was significant underfunding, so the Indian institutes of technology are only world-class higher education institutions (RIA, 2017).

4) Economic component

The scientific and educational potential depends not only on the number of qualified personnel and the number of researchers, but also on the amount of funding for both University science and R&D in research organizations.

Research expenditures at all types of universities in 2019 were (in constant prices (2015) and constant PPP): 3,896 in Russia, 21,125 in Germany, 11,384 in the UK, and 53,958 in the US. That is, on average, in developed countries, these costs are 7.5 times higher than, for example, in Russia (OECD, 2020a).

R&D funding to an even greater extent determines the state of scientific and educational potential, as well as its implementation. In this aspect, the BRICS countries show different dynamics.

For example, according to available data from the OECD (2020), we can compare the dynamics of R&D financing in Russia, South Africa, and some developed countries (figure 4).

Fig. 4: Dynamics of R&D financing in 2010-2016 in BRICS countries and some OECD countries, millions US dollar, current prices, PPP (compiled by the authors according to OECD (2020c))

It becomes clear that in all the countries under review, the dynamics of R&D financing in the period 2010-2016 is positive (with the exception of Russia, where in 2016 there was a decrease of 3.3%). However, the amount of funding in Germany exceeds the same indicator in Russia by 3 times, in South Africa-by 30 times.

In 2019, Brazil and China invested 2.1-2.3% of GDP in R&D development at the level of developed European countries, which strengthened their positions in the global R&D market (figure 5).

Fig. 5: R&D expenditures in BRICS and developed countries, % of GDP, 2019 (compiled by the authors according to OECD (2020e), Unesco Institute for Statistic (2020))

Note that the structure of R&D financing varies in the analyzed countries: in the United States, Japan, and most European countries, business structures are involved in R&D financing, which cover an average of 60 to 70% of all expenses; in developing countries, most of the R&D expenditures are financed by the state or non-profit organizations (Unesco Institute for Statistic, 2020).

6) The organizational and managerial component is largely determined by the state of the institutional environment, its ability to adapt to the changing conditions of the formation of a new technological order (Inshakov and Fesyun, 2014). For example, in China, the strategy for the development of science and technology is aimed at increasing the independence of industrial potential from the technologies of developed countries, while special attention is paid to fundamental research in those areas of science that guarantee China's entry into the world's technological leaders in the future (Slepak, 2012, 2014). Indeed, China competes in the development and implementation of digital technologies with the world leader the United States, it accounts for a fifth of the world's GDP by PPP (20.1%). India, as a regional leader, successfully incorporates national priorities into the agenda of international platforms for deepening it cooperation between countries and took the 3rd position in the world GDP in PPP in 2019 (8.18%) (Ignatov, 2020). Russia (3.02%) considers the development of ICT as the most influential tool for economic development and maintaining the competitiveness of the domestic economy, and demonstrates positive dynamics in ensuring access to ICT and the use of digital technologies (Government of the Russian Federation, 2018). Brazil (2.40%) is implementing a National strategy for the development of science, innovation and technology, gradually strengthening its position on the world stage in terms of digitalization and ICT (Government of Brazil, 2018). South Africa began to join the processes of forming the digital economy only in 2016-2017, increasing investment in the development of network infrastructure and developing demand for digital products in the domestic market, but at the international level it still has a significant lag (Ignatov, 2020).

The presence of a developed scientific and educational potential is a condition for the economically secure position of the state.

Slepak (2012, 2014) calculated indices of scientific and educational potential and proved the existence of a high correlation between the average per capita monetary income of the population and scientific and educational potential. The researcher noted that in regions with low values of scientific and educational potential, unemployment rates are significantly higher, which means that the level of economic security of the territory in this case decreases. This situation may be compounded by destructive and transformative digitalization (Fossen and Sorgner, 2019).

In addition, the growth of unemployment becomes a trigger for launching further threats to economic security - increasing social tension, migration outflow of the population. A separate problem in the digital economy is the increased information vulnerability of citizens, enterprises, and public authorities, which weakens the economic security of the state if appropriate protection measures are not taken (Karpunina et al. (2019), Karpunina et al. (2020)).

The existence of factors that limit the development of the country's scientific and educational potential (financial, economic, ideological, human, and institutional) leads to a decrease in the level of economic security of the country and its lag in the international space (Fig. 6).

Fig. 6: Scientific and educational potential and factors of its influence on the economic security of the state (compiled by the authors)

The analysis of the BRICS countries revealed a clear advantage in the development of the scientific and educational potential of China and Russia, which are characterized by the most favorable trends in the development of the

education system, R&D, and innovation. Brazil and India have stable average positions in the analyzed indicators. South Africa currently has a slow development of the education and science system, lower R&D indicators among other BRICS member countries, and mixed trends in processes (Antipova and Rodionova, 2016). This means that China and Russia among the BRICS countries have a higher level of economic security, due to the level of development of their scientific and educational potential.

Strengthening the position of the BRICS countries in the global digital space requires the implementation of the following measures within national economies: modernization of the education system for training highly qualified specialists to ensure continuity in R&D; introduction of the principle of co-financing projects by business, as well as creating conditions for stimulating business activity in terms of R&D support; overcoming interregional digital gaps and territorial alignment in terms of access to the Internet, development of digital infrastructure; implementation of cybersecurity strategies at the national level; intra-integration educational and scientific cooperation of the BRICS countries as a basis for spreading the knowledge economy, innovation, high technologies and network readiness.

Conclusions

The authors revealed the content of the concept of "scientific and educational potential of the state" and identified its structural components (personnel, material and technical, economic, organizational and managerial). The authors analyzed the state and dynamics of development of each of the selected components in the BRICS countries, gave a comparative assessment with the leading countries of the world (USA, Japan, United Kingdom, Germany). The article offers a conceptual model of the relationship between scientific and educational potential and its impact on the economic security of the state. The authors proposed public policy measures to strengthen the position of the BRICS countries in the global digital space by developing their scientific and educational potential.

Abstract

This study is devoted to development of an algorithm for identifying critical points of trend change or sharp jumps in economic systems. The time series of fractal dimension local values serves as an indicator of the economic system stability. The paper analyzes the stock quotes fractal characteristics of the five largest companies in different periods of time. The relationship between the dynamic stability violation and the fractal dimension deviation from the optimal value has been proven. These stability boundaries are built on the basis of a linearly weighted moving average and time series fractal dimension. Prediction of critical points and sharp jumps of trend is reduced to determining the intersection points of the fractal dimension local values curve with the curve of the normal system state boundaries. Threshold values of fractal dimension local values are analyzed to identify critical points. The results showed that the accuracy of determining the critical points using the fractal dimension local values increment is higher in comparison with the method of threshold values. However, the type of critical point can only be determined using the last one.

Keywords: Critical Point, Fractal Dimension, Financial Time Series, Investment Risk, Stock Quotes.

JEL Classification: C65; D58, E37.

Introduction

One of the most important institutions of the market system is the stock exchange, where the purchase and sale of shares and bonds of joint stock companies, as well as government bonds, takes place. Funds are mobilized through the stock exchange for investment in fixed assets of the industry.

Forecasting is by far the most important and urgent problem in the economic sphere. Financial markets, investment and lending activities need new tools for making correct forecasts and obtaining high-quality risk assessments. Today, one of the most popular methods of forecasting crisis phenomena is the "signal" method, which consists in developing threshold values for a selected indicator or a set of indicators, the intersection of which, with a certain probability, signals the threat of a financial crisis [Kaminsky & etc., 1998; Kaminsky, 1999].

Classical approaches to analyzing the risks of financial markets and economic units, such as fundamental and technical analysis, are often subject to cross-criticism and have several disadvantages compared to each other. It has been proved that time series of financial data, for example, stock quotes, have fractal statistics (Edgar E. Peters, 1994), the analysis and modeling of which can be performed using fractal methods. One of the promising directions of fractal analysis is the study of the dynamics in time of such a characteristic as fractal dimension. Modern research in the field of fractal methods develops tools for fractal analysis and adapts them to economic data (J.W. Kantelhardt, 2012; Kumar S. and Deo N., 2015; F. Schmitt, D. Schertzer and S. Lovejoy, 2001).

The research is aimed at predicting critical events (sharp surges, collapses or points of trend change) of stock prices in the financial market. The solution of these problems is of particular interest for the field of investment, and the application of methods of fractal and multifractal analysis gives a new understanding of the nature of economic processes from the point of view of physical phenomena and makes available many tools that have not been previously applied to the study of economic systems.

Materials and Methods

Time series of stock quotes are convenient for testing fractal methods in that they contain a sufficiently large number of measurements. To analyze the dynamics of quotations, the time series of daily stock prices of five companies were selected: Amazon, Facebook, Apple, Tesla and Lukoil. Statistical data cover the period from 04.24.2015 to 04.08.2020 inclusive.

Let's find out how different the signals are: calculate the values and plot the graphs of the multifractal spectra of the signals under consideration. The multifractal spectrum effectively shows the distribution of the scaling factors for the signal, i.e. provides a measure of how much the local regularity of a signal changes over time. A signal that is monofractal exhibits nearly the same regularity throughout time and therefore has a narrowly supported multifractal spectrum. Conversely, a multifractal signal exhibits changes in signal regularity over time and has a multifractal spectrum with broader support.

Let's determine the singularity spectra D (h) and Hölder exponents h for the signals under consideration and plot their graphs. The graphs of the constructed multifractal spectra are shown in Figure 1. They suggest that the series of stocks under consideration are multifractal signals.

Figure 1: Graphs of multi-fractal spectra (singularity spectra) of time series

Source: Authors

The total scaling factor range (h) is:

1. 0,8343 for Amazon series (h ∈ [0,2277; 1,062]),
2. 0,9452 for Facebook series (h ∈ [-0,0038; 0,9414]),
3. 1,1005 for Apple series (h ∈ [-0,2750; 0,8255]),
4. 1,6856 for Tesla series (h ∈ [-0,8034; 0,8822]),
5. 0,8559 for Lukoil series (h ∈ [-0,0006; 0,8553]).

The values of the fractal indicators D, H and μ correlate with the complex non-periodic behavior of real time series, in which trends and flats chaotically replace the stochastic movement. At 1 <D <1.5, the time series have a long-term correlation, and a persistent market condition appears, which is completely characterized by the fractal dimension indicator. In this case, quantitative mathematical analysis is more reliable, which makes it possible to predict the current economic situation precisely with the help of classical methods of analysis. Moreover, the fractal dimension value close to one indicates the imminent end of the current trend. At D = 1.5 ± 0.05, the behavior of the system is stochastic and is well described by classical statistical methods, i.e. the distribution of stock prices in the market is Gaussian only if the fractal dimension is in a narrow range. At 1.5 < D <2, the time series becomes nonlinear, an antipersistent state of the stock price arises, the time curve becomes unstable and is ready to move to a new state. With such a range of fractal dimensions, it is necessary to use an analysis of the fundamental factors of the state of the economy.

The fractality index μ is also an indicator of the stability of the initial time series: the larger the value of μ, the more stable the behavior of the series, and the smaller μ, the stronger the trend is expressed in the original series, in other words, the case $\mu < 0.5$ can be interpreted as a trend, and the case $\mu > 0.5$ as a flat.

Let's calculate the main multifractal characteristics of the initial time series based on the obtained exponent values α of the power spectral density function, $D = 3 - \alpha$. The values of multifractal characteristics are presented in table 1.

Table 1: Values of the time series main fractal characteristics for the entire period under consideration

No.	Company name	Exponent of the power spectral density function, α	The Hurst Exponent, $H \in [0; 1]$	Fractal dimension, $D = 2 - H \in [1; 2]$	The spectral dimension, $\beta \in (-\infty; +\infty)$	Order of integration, $d = \beta/2 \in (-\infty; +\infty)$	Fractality index, $\mu = D - 1 \in [0; 1]$
1	Amazon	1.7894	0.7894	1.2106	2.5788	1.2894	0.2106
2	Facebook	1.8772	0.8772	1.1228	2.7544	1.3772	0.1228
3	Apple	1.9966	0.9966	1.0034	2.9932	1.4966	0.0034
4	Tesla	1.9558	0.9558	1.0442	2.9116	1.4558	0.0442
5	Lukoil	1.8569	0.8569	1.1431	2.7138	1.3569	0.1431

Source: Authors

The analysis of indicators indicates the persistence of the considered time series of stock quotes. As can be seen from Table 1, the values of the Hurst exponent are in the range characterizing the persistence of the considered time series. The fractal dimension values indicate a steady state, long-term correlation and the possibility of forecasting the current economic situation.

There are various methods for calculating the fractal dimension of signals, including Box-counting method, Multiresolution Box-counting Method (MRBC), Multiresolution Length Method (MRL), Katz Method, Sevcik Method, Higuchi Method, Detrended Fluctuation Analysis (DFA), Average Wavelet Coefficient (AWC). In the study of Raghavendra B. S. and Narayana Dutt D. (2010), a study of the influence of various parameters on the fractal dimension was carried out. The MRBC, MRL, Sevchik and Higuchi methods were found to be insensitive to waveform amplitudes (dispersion). Katz's method showed that as the amplitude increases, the fractal dimension increases. The Higuchi, MRBC, MRL methods showed the greatest efficiency in assessing the fractal dimension of oscillograms, and the results of the accuracy of the MRBC and MRL methods are comparable to the results of the Higuchi method. One of the most accurate methods is also the method of average wavelet coefficients and the method of deterministic fluctuation range. Let us determine the values of the Hurst exponent by the method of normalized range (R / S-analysis) and the fractal dimension of the series of indices by the most famous methods: the Higuchi method, DFA method and AWC method. The calculation results are presented in table 2.

Table 2: Fractal dimension and Hurst exponent values of time series

No.	Time series	DFA method	Higuchi	AWC method	Hurst exponent
1	Amazon	1.5280	1.4220	1.5790	0.9831
2	Facebook	1.4734	1.4972	1.5052	0.9786
3	Apple	1.5924	1.4633	1.6369	0.9837
4	Tesla	1.4401	1.6264	1.5412	0.9233
5	Lukoil	1.5323	1.4305	1.5721	0.9997

Tsvetkov V. P., Tsvetkov I. V., Gulyaeva O. S. (2007) and Kudinov A. N., Tsvetkov V. P. and Tsvetkov I. V. (2009) found that the fractal dimension value can serve as an indicator of the number of factors affecting the system. If the fractal dimension is less than 1.4, the system is affected by one or more forces that move the system in one direction. If the dimension is about 1.5, then the forces acting on the system are multidirectional, but more or less compensate each other. The behavior of the system in this case is stochastic and is well described by classical statistical methods. If the fractal dimension takes on values greater than 1.6, then the system becomes unstable and is ready to move to a new state. The results of calculating the fractal dimension for the time series under study indicate the stability of economic systems, since the fractal dimensions have values close to 1.5.

Results

To substantiate the feasibility of using fractal analysis methods for studying crisis periods, we study the behavior of time series of stock quotes for Amazon, Facebook, Apple, Tesla and Lukoil in the period from 04.24.2015 to 04.08.2020. It is important to consider data of a different nature: indicators that are stable and indicators with a high degree of volatility. Figure 2 shows the different behavior of the time series of Amazon stock quotes.

Figure 2: Amazon stock quotes in different time periods

Source: Authors

Let us determine the fractal dimension values by the Higuchi method of the studied time series in different years from 04.24.2015 to 04.08.2020. The calculation results are presented in table 3.

Table 3: The fractal dimension values of companies stock quotes time series in different periods

No.	Time series	The fractal dimension values					
		2015	2016	2017	2018	2019	2020
1	Amazon	1.2336	1.3704	1.3819	1.4299	1.5553	1.4118
2	Facebook	1.4879	1.5142	1.2586	1.4676	1.6450	1.2896
3	Apple	1.4975	1.5665	1.4300	1.4907	1.3710	1.3617
4	Tesla	1.5742	1.6651	1.4803	1.8026	1.4148	1.3961
5	Lukoil	1.7181	1.4733	1.4237	1.4124	1.4873	1.2807

Source: Authors

Let's analyze the dynamics of the time series fractal dimension of Facebook stock quotes. In 2016, one can observe rare jumps in the company's stock price. The maximum change in daily yield in 2016 occurred on January 28 and amounted to 12.01%. The next dramatic changes occurred on April 28, when the daily yield increased by 10.11%. The next shocks came in early June, when on June 2, the yield increased by 7.11% compared to June 1, and on June 3 again returned to the previous values, having decreased by 6.69%. On the remaining days of 2016, the daily return on Facebook shares varied within 1.5%. The fractal dimension of the time series is 1.5142. 2017 is characterized by

a more stable level of return on the company's shares. The maximum change in share prices occurred on July 27, 2017 and amounted to 3.90%. The fractal dimension value, calculated from the time series of quotes in 2017, is 1.2586, which is significantly lower than its value in 2016. The next year 2018 is unstable. The maximum change in share prices in 2018 was 18.25%. During this period, one can observe an increase in the fractal dimension up to 1.4676. In the spring and summer of 2019, for a number of stock quotes of the company, one can observe multiple daily jumps in the stock price from 10.22% to the maximum in 2019 of 22.99%. Thus, tracing the change in the dynamics of the fractal dimension of the time series of Facebook stock quotes, one can notice an increase in the fractal dimension both directly during periods of sharp changes in the stock price and in the previous period. At the same time, after a significant decrease in the fractal dimension, a period of trend change follows, which can be observed in 2018. This result is clearly visible for the time series of Facebook stock quotes. Figure 3 shows the dynamics of stock quotes and a diagram of changes in the fractal dimension of the time series of Facebook stock quotes.

Figure 3: Dynamics of stock quotes and a diagram of changes in the fractal dimension of Facebook stock quotes time series

Source: Authors

For Tesla, the situation with the assessment of changes in the fractal dimension is somewhat different from all considered time series. In the period from 2015 to mid-2019. there is no clear trend in the dynamics of stock quotes. A slight upward trend can be observed in 2017 and negative dynamics until October 2019. Changes in the maximum values of daily yields during this period range from 8.59% in 2017 to 13.40% in 2018. The values of the fractal dimension are also not stable, and in 2015, 2016 and 2018 indicate instability and readiness to move to a new state. On October 7, 2019, a sharp jump can be observed, which changed the daily yield by 16.97% and an uptrend that followed. At the same time, the value of the fractal dimension decreased in 2019 to 1.4148, which indicates the stability of the company. Thus, for the time series of Tesla stock quotes, the high value of the fractal dimension in 2018 indicates future changes in the trend. Note that for the time series of Facebook stock quotes, the period of trend reversal followed a significant decrease in the value of the fractal dimension. Figure 4 shows the dynamics of stock quotes and a diagram of changes in the fractal dimension of the time series of Tesla stock quotes.

Figure 4: Dynamics of stock quotes and a diagram of changes in the fractal dimension of Tesla stock quotes time series

Source: Authors

Thus, the fractal dimension of a certain value can be used as an indicator of a crisis or a "flag" of a catastrophe. To predict the crisis development of the economic system, it is advisable to pay attention also to the periods preceding the crisis stages.

For further investigation of the nonstationary dynamics of fractal dimension, the “sliding window” method was applied, the essence of which is as follows. First, in the time series of stock quotes, a sequence of 60 values is selected and for these data the fractal dimension is calculated using the Higuchi method. After that, the interval moves to the right along the time series by one value, and the fractal dimension is calculated again. Repeating this procedure throughout the entire study period, we obtain the local values of the fractal dimension. The dynamics of the values of the time series of Lukoil stock quotes in comparison with the dynamics of the local values of the fractal dimension of the signal are shown in Figure 5.

Figure 5: Dynamics of Lukoil stock quotes and local values of the fractal dimension
Source: Authors

For a fairly long period of time until January 2017, an upward trend can be observed in the time series of the company's stock quotes, accompanied by changes in the daily yield within 5%. Local values of fractal dimension during this period remain within the normal state from 1.3 to 1.7. In the period from 533 to 583 days, we see a sharp increase in the values of the fractal dimension to a maximum of 1.9039 on day 573. On day 604, the value of the fractal dimension again decreases to the value found across the entire time series, and we see the beginning of a change in the trend direction that began on day 628, i.e. 01/11/2017. This downtrend lasted until mid-June 2017, after which the trendline direction reversed and persisted until February 2020. Local values of the fractal dimension from 1681 to 1725 days, which corresponds to the period from 11/29/2019 to 01/12/2020, exceed the values of 1.6. Thus, abnormally high values of the fractal dimension warn of an impending trend change long before this moment.

Analysis of the dynamics of fractal dimensions of stock quotes time series of companies indicate the existence of a limiting fractal dimension, when approaching which instability and possible crisis manifestations arise.

In the paper of Gafarova, E.A. and Dobikova, D.V. (2012) when analyzing the dynamics of the fractal dimension of the exchange rates of developed and developing countries, it was shown that the lower and upper boundaries of the fractal dimension for a crisis-free state are 1.3 and 1.7, respectively. However, these boundaries of the normal state of the system do not always allow judging about the violation of stability and can determine a sufficiently large number of false signals. Thus, an overestimated value of the fractal dimension of the time series indicates a less stable state of the system, a number of stock prices will be characterized by sharp jumps in quotations, and the threshold of the normal state will be less sensitive to changes. A low value of the fractal dimension indicates a more stable state of the system. With a relatively low value of this indicator, the initial series of stock quotes will be characterized by a fairly smooth trend change and the absence of sharp drops and jumps, the threshold of the normal state will be more sensitive, which can be seen in Figure 6, which reflects the boundaries of the normal dynamics state of the fractal dimension time series of Tesla stock quotes.

Figure 6: Dynamics of Tesla stock quotes, local values of the fractal dimension and the normal state boundary

Source: Authors

To predict the critical states of the system, it is important to find the boundaries of the threshold of the normal state, which depend on the current local values of the fractal dimension and the fractal dimension of the entire time series.

Forecasting is reduced to determining the intersection points of the curve of local values of the fractal dimension with the indicators of the upper and lower thresholds of the normal state. Such an event will be a signal for a future crisis in the time series (a sharp jump, trend change). The value of the lower and upper thresholds will affect the appearance of signals. Calculations show that for financial series the upper and lower boundaries of the normal state of the system can change. Therefore, it is necessary to determine the boundaries of the normal state in such a way that the critical states of the system can be identified for both an unstable and a stable period of the time series. A signal will be considered false if, after its appearance, there are no further trend change points or sharp jumps.

The threshold values of the normal state of the system for the initial time series will be determined on the basis of moving averages and the total fractal dimension of the series. As a result of the experiments, the boundaries of the normal state were resolved as follows:

$$FD_{up}(t) = \frac{1}{4n}\sum_{k=1}^{4n} FD(t-k) + 0.1FD;$$

$$FD_{dn}(t) = \frac{1}{4n}\sum_{k=1}^{4n} FD(t-k) - 0.1FD,$$

$FD_{up}(t)$, $FD_{dn}(t)$ – upper and lower limits of the normal system state,
$n = 60$ – width of the window for calculating of the fractal dimension local values,
FD – time series fractal dimension calculated by the Higuchi method.

The intersection of the fractal dimension local values with the upper or lower normal state boundary means the beginning of a signal – a critical point – a trend change or a sharp jump. As you can see, if both the signals of the lower and upper thresholds take place on a relatively short interval, this can serve as an indicator of a change in the trend of the time series of the company's stock quotes. If the signals are rare and appear separately – there is either an intersection of the upper or lower threshold of the normal state - one can judge the critical point of a sharp jump in the time series under study. Figure 7 shows a graph of Lukoil stock quotes and a number of local values of fractal dimension with found boundaries of the normal state.

Figure 7: Dynamics of Lukoil stock quotes, local values of the fractal dimension and the normal state boundary

Source: Authors

Let's analyze the critical points and critical areas of Lukoil stock quotes. The intersection of the fractal dimension local values with the upper normal state boundary from the 88th to the 124th day can be regarded as a quick fall in the share price, which occurred on the 154th day and amounted to 15%. The next single signal appears on the 183rd day and signals an upcoming small rise in quotes. The next single signal appears on the 220th day and indicates an upcoming sharp decline in quotations by 16.5%. Then the signal appears in the area of the 400th day, first at the lower and then at the upper threshold of the normal state. This is followed by a change in the trend direction, accompanied by two more critical points at the lower threshold of the normal state, which indicate the continuation of growth without changing the trend.

Then, in the area of the 600th day, a critical point appears, first at the upper and then at the lower border of the normal state. This was followed by a change in the direction of the trend. The next signal appears first at the lower and then at the upper border of the normal state, which indicates an impending trend change, which happened immediately after the 810th day.

The next critical area appears in the period from 953 to 1092 days. Following him in the quotations of the company's shares, one can observe an unstable situation with sharp jumps in quotations. On the 1208th day, a single critical point appears, crossing only the lower border of the normal state, after which a sharp jump in quotations by 18% followed. The next critical points appear at the border of the upper threshold, without crossing the normal line, from 1200 to 1300 days. This period corresponds to frequent and sharp jumps in the company's stock prices. The next signal appears in the area of 1580-1600th day, first at the lower and then at the upper border of the normal state of the system. About 15 days later, there was a significant increase in quotations, accompanied by the appearance of another signal at the upper threshold of the normal state. The next critical area took shape from 1772 to 1790 days and contains several critical points at once, arising alternately at different boundaries of the normal state. These signals can be regarded as a sharp drop and a trend reversal that followed.

Thus, only one critical point in the 800th day area remained unpredicted, which signaled a trend change. A number of local values of the fractal dimension do not cross the lower boundary of the normal state, although they approach it.

Let's consider Facebook stock quotes and the resulting series of local values of the fractal dimension for Facebook (Figure 8). For the Facebook stock quotes series, out of the most significant 23 critical points, only two points were not predicted.

Figure 8: Dynamics of Facebook stock quotes, local values of the fractal dimension and the normal state boundary

Source: Authors

The analysis results show that crisis periods are characterized by sharp jumps in the fractal dimension local values. Therefore, it is necessary to consider the possibility of using increments of fractal dimensions to identify critical points.

The increments at the current time moment will be found as the difference between the current and the previous values of the fractal dimension. To identify the threshold of the normal state, it is necessary to determine the normative value, the excess of which will serve as an indicator of the critical state. Let us fix the normal state of the system with the value of increments of the fractal dimension not exceeding 0.025FD, where FD is the fractal dimension of the time series of the company's stock quotes.

For the time series of Facebook stock quotes, the number of predicted critical points turned out to be 4 more than what was revealed using the threshold values of the normal state of the fractal dimension (Figure 9). That is, the analysis of increments of local values of the fractal dimension is more sensitive to changes in the structure of the original time series.

Figure 9: Dynamics of Facebook stock quotes, local values of fractal dimension and normal state boundaries, and a graph of increments of local fractal dimension values

Source: Authors

The results of a comparative analysis of methods for identifying critical points are presented in Table 4.

Table 4: Comparative characteristics of methods for the detection of critical points

Time series	Number of critical points	Normal state threshold method			Method of increments of local fractal dimension values		
		Number of predicted critical points	Number of false signals	Percentage of correctly predicted critical points	Number of predicted critical points	Number of false signals	Percentage of correctly predicted critical points
Amazon	27	24	2	0.83	22	0	0.81
Facebook	23	21	1	0.88	23	0	1.0
Apple	14	13	2	0.81	14	2	0.88
Tesla	25	22	0	0.88	22	0	0.88
Lukoil	16	15	0	0.94	16	0	1.0

Source: Authors

The study shows that the method of increments of local values of the fractal dimension is more sensitive to changes in the structure of the time series under study and makes it possible to identify a greater number of critical points of the system in comparison with the method of threshold values of the normal state. It should be noted that the method of increments of fractal dimension reveals critical points, but does not allow determining the type of critical point.

Conclusion

The paper analyzes the prerequisites for applying the methods of fractal and multifractal analysis to the data of financial systems. For efficient markets theory (EMH), an important measure of market efficiency is the volume of trades. However, the biggest market crashes occurred when liquidity was low along with high trading volume. Low liquidity can be characterized as unbalanced trading volume. Thus, explaining market crashes from an EMH perspective becomes difficult. The fractal market theory (FMH) has become an alternative to the efficient market theory. Unlike EMH, FMH claims that prices cannot reflect all available information, they only reflect information that is relevant only for a specific investment horizon.

The paper analyzes the stock quotes fractal characteristics of the five largest companies in different time periods. The relationship between the fractal dimension of the stock prices dynamic and their trend has been proven. The time series of the fractal dimension local values, obtained by the sliding window method, serves as an indicator of the economic stability of the economic system. The boundaries of the normal state of economic systems have been shown. An algorithm has been developed for determining the upper and lower thresholds of the normal state of fractal dimension for the purpose of predicting critical events. To implement it, the statistical method of linearly weighted moving average and the total fractal dimension of the series were used. The analysis of the threshold values of the increments of the local values of the fractal dimension to identify critical points. The results showed that the accuracy of determining the critical points using the increment of local values of the fractal dimension is higher in comparison with the method of threshold values. However, the type of critical point can only be determined using the method of threshold local values of the fractal dimension.

The proposed algorithm for identifying critical points of trend change or jumps in stock quotes helps to identify in advance the upcoming change in the time series trend direction, thereby helping investors to make a managerial decision on further actions in relation to this economic system. This approach draws attention to the systematic failure or progress of the system, which helps to level non-fundamental short-term unrest in the financial markets and reduce the likelihood of investment risk for an economic entity in an environment of turbulence, which may be caused by unreasonable influence from speculators. The developed algorithm can be used as an auxiliary tool for an investor to develop an optimal trading strategy and reduce investment risks.

Abstract

The problem of depletion of resources, the transition to sustainable development and the model of a green economy made it necessary to increase the efficiency of the use of economic resources. In particular, a lot of attention in various countries of the world is paid to improving energy efficiency and energy saving. In conditions of limited primary energy resources, the task of their careful use remains strategically important. The article discusses ways to solve this problem at the macroeconomic and microeconomic levels. The authors proposed to form an energy efficiency cluster. Such clusters can be implemented in structural and industrial policies. For these new integration formations, organizational schemes and management methods are proposed. The possibilities of state regulation of their creation and development are also considered.

Keywords: Energy Efficiency, Energy Consumption, Energy Saving, State Economic Policy, Energy Efficiency Cluster, Industrial Cluster.

Introduction

In modern conditions, the problems of ensuring the energy efficiency of the economy have become very relevant (Dunlop, 2019; EU, 2012; EU, 2019; European Commission, 2012; Kong et al., 2016; Makridou et al., 2015; Vertakova and Plotnikov, 2019; and other). As you know, the first impetus to improve energy efficiency was given by the global oil crisis of the 1970s (Johnson and Wilson, 1982). A significant increase in world prices for primary energy has led to an understanding of the irrationality of the previous model of business activities. Energy is no longer cheap. Ensuring competitiveness at all levels (national, regional, enterprise, products) required tight cost control. In this regard, efforts have been made to reduce energy consumption and improve energy efficiency.

Today (2020) the level of prices for primary energy in the world markets has significantly decreased. This is due to both the competition between the largest oil exporters (first, we are talking about the actions of Saudi Arabia) and the pandemic of the new coronavirus infection Covid-19. As a result of measures taken by national and regional governments, restrictions have been introduced for many types of economic activity. Borders have been closed for private travel, many businesses have been stopped, the work of shops and restaurants has been restricted, the population is advised not to leave their homes, etc. As a result, the demand for energy has dropped significantly. This led to a drop in prices.

The fall in prices was especially dramatic in the second quarter of 2020, when the "first wave" of the pandemic was observed (Figure 1). Later, prices stabilized at 35-40 USD / bbl. This is due to both the reduction in supply and the adaptation of the world economy to the pandemic shock. From the standpoint of the problem under consideration, a

Cite this Article as: Vladimir PLOTNIKOV, Ivan MAKAROV, Ekaterina BARBASHINA, and Oleg MAKAROV "The Energy Efficiency Instruments for The Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

favorable situation has developed. The cost of primary energy has dropped. This allows less attention to be paid to energy saving issues.

Source: Trading Economics, 2020a.

Fig. 1: Crude oil prices at last year (West Texas Intermediate - WTI).

But strategically (Pirogova et al., 2020a), the situation has not changed. The observed crisis (Figure 2), according to available estimates, will be replaced by recovery growth in 2021-2022. After this "rebound", the global economy may return to growth rates approximately equal to those before the crisis (about 3% per year). China's economy, the largest economy among the countries of the world (in terms of purchasing power parity), has already overcome the crisis. After falling in the 2nd quarter of 2020, it is growing steadily again (Figure 3). Although economic growth in China is gradually declining, it remains above the world average. This means that energy consumption tends to increase (Pirogova et al., 2020b).

Source: IMF, 2020.

Fig. 2: Global GDP growth.

In conditions of limited primary energy resources, the task of their careful use remains strategically important. This task is relevant for many countries of the world. There is a steady trend towards energy efficiency in the economy (Figure 4). This is a global trend. If the economies of countries and regions, as well as individual enterprises do not consider this trend, they will quickly lose their competitiveness.

It should also be noted that improving energy efficiency is in good agreement with the internationally recognized Concept of Sustainable Development and the Green Economy Model (Kara et al., 2014; Vertakova and Plotnikov, 2019; Wang et al., 2014; and other).

Materials and Methods

When solving the problem of effective design of regulation of national and regional markets, one should consider the trend of increasing energy efficiency. Taking it into account will help to increase the competitiveness of enterprises. At the same time, it is necessary to consider the presence of significant regional and sectoral heterogeneity of markets. The heterogeneity is manifested in the existence of industries that perform different functions in the national (regional) economy and different social functions. Also, heterogeneity is manifested in the unevenness of spatial development (Makarov et al., 2019; Plotnikov et al., 2018; Polozhentseva, 2016; Sanabria Gómez, 2017; Vertakova et al., 2015; and other). Moreover, the heterogeneity can be related to institutional factors. Therefore, it is necessary to consider the existing sectoral and institutional specifics.

Sector-institutional specificity, when analyzed at the micro level, is formed under the influence of the specifics of companies operating in certain industry markets. It is based on the combination of resources and the presence of goals, which are the embodiment of the strategic vision of the development of enterprises by their management. As important institutions of the external environment of enterprises, it is necessary to single out the state structural (including industrial) policy (Graham O.L.Jr., 1992). Moreover, this policy is specific in relation to the industry of enterprises functioning.

Improving energy efficiency is a strategic national challenge. Therefore (especially in developing countries), it is often viewed as a task solved primarily by the state, at the macro level of economic regulation. With this approach, the importance of enterprise management decisions is reduced. The potential for organizational and technological efficiency is declining. This is because enterprises receive the benefits from energy efficiency to a greater extent in

the form of indirect effects. The strength of their manifestation significantly depends on the information and analytical component of industrial policy.

With this approach, important factors are:

- Updating regulatory instruments in line with new technological advances and energy management standards.
- Formation of information bases (national, regional, sectoral) of effective and accessible technologies related to the rational use of energy resources.
- Formation of systems of competencies and qualifications in the field of energy efficiency. This task is solved through targeted training and retraining of personnel of enterprises.
- Monitoring the energy efficiency of industry and other sectors of the economy, forecasting the volume and structure of energy consumption.
- Formation and replication of cases of typical engineering activities and practices in the field of energy efficiency for mass implementation.

In addition to the macro approach to regulating energy conservation, a micro approach should also be used. It consists in the competitive actions of enterprise management. These actions are aimed at increasing the energy efficiency of production processes, sales, logistics, etc. At the same time, in addition to the modernization of existing enterprises, it is necessary to create a complex of modern industries that meet modern energy efficiency criteria. This task is being solved by attracting private investment. It is necessary to stimulate investors to create energy efficient, energy saving and “green” industries.

That is, the process of implementing the principles of an energy efficient economy should be bi-directional. It should go both "from above" and "from below". This will allow achieving a synergistic effect in this area. The nature of this effect is the growth of the energy efficient sector of the economy. This, firstly, stimulates all economic agents to introduce new energy efficient technologies. Secondly, even those sectors of the economy where these technologies are not used receive indirect effects associated with savings on various types of resources. Thirdly, the prerequisites are being formed for the creation of groups of associated energy-efficient industries. That is, new energy efficient clusters are being formed, which play the role of “energy efficiency poles” in the economy of the country and the region (similar to the “growth poles” in the theory of François Perroux, 1988).

Results and Discussion

In order to increase the efficiency of sectoral and regional markets, as indicated above, clusters can be formed. The cluster approach to optimizing economic processes has become widespread. It has proven its effectiveness in practice in many countries (Njøs and Jakobsen, 2016; Polozhentseva and Klevtsova, 2015; Sopoligová and Pavelková, 2017; Vertakova et al., 2016; and other). Due to the importance of the energy efficiency problem, its connection with the Sustainable Development Goals, the government can act as a coordinator in the creation of clusters. The functioning of clusters will help to reduce transaction costs and increase the efficiency of the economy as a whole.

The institutional embodiment of the coordination mechanism can be formalized by analogy with the Chambers of Commerce and Industry. The coordinating body that is being created can also work by analogy with the regulatory bodies of sectoral markets (for example, energy markets). Such regulators have been created and are successfully operating in the USA and Europe. Its financing scheme can be mixed. It can be partially financed from the state budget, as well as from contributions from professional market participants.

The main goal of the formation of such a financing scheme for the functioning of the regulator-coordinator is to focus on achieving the maximum efficiency of the functioning of this institution. Efficiency is ensured by considering the interests of enterprises and government (society). In addition, blended financing ensures the independence of management from both the authorities and major market players. To ensure the maximum efficiency of this body, it is possible to introduce the practice of targeted financing of the state component of the cash flow and procedures for performance auditing and public reporting.

In the energy efficiency cluster, interconnections between enterprises are built on principles that promote resource conservation, reduce the impact on the ecosystem, efficient and safe use of waste, etc. The result is a more favorable impact on the environment, the achievement of high economic and social performance indicators. The need to distinguish between economic growth and resource consumption to achieve environmental and social goals determines the importance of effective management of the clusters under consideration.

With the localization of energy efficiency cluster enterprises in a small area, eco-industrial parks can be formed (UNIDO, 2019). They are like conventional industrial parks, but with different functions. The direct economic effects from the development of eco-industrial parks include: the introduction of eco-innovations; increasing the competitiveness of companies and products; improving resource efficiency and energy efficiency; reducing waste; increased value added; reducing risks; growth in investment volumes.

If we consider the most successful schemes involving the use of cluster models focused on the integrated development of territories, including the development of social infrastructure, then it is necessary first of all to consider the Chinese zones of technical and economic development. These special zones combine the principles of strategic planning for regional and industrial development and the active initiative of private capital. Cluster development, due to its complex nature, is proposed to be regulated based on program-targeted management technologies.

Achieving sustainable and energy efficient development of enterprises is determined by considering several factors (Figure 5). The presented scheme reflects a combination of external and internal factors. One of the key external factors is the strengthening of global competition in an evolving economy that encompasses the markets for goods, services and capital, and other components of economic development. Competition is intensifying in the markets of industrial products, which are undergoing significant changes in connection with the outlined growth in the consumption of industrial products in the world. The processes of acquisition by foreign investors of factors of production (and enterprises) are growing in those countries where governments and local businesses do not support the development of their industrial production. A similar threat exists, for example, in Russia.

Of the internal factors, the insufficient level of human capital development should be noted. This problem is also typical, for example, for Russia. This is due to the unresolved problems of asymmetry of socio-economic development, with the mono-profile nature of the development of many cities. Modern technologies have significantly increased the requirements for labor qualifications in industrial business and reduced employment in it. This has reinforced the previously existing imbalances. There is also a reverse trend in spatial development. In world practice (especially during the Covid-19 pandemic), there have been trends in the outflow of the population from large cities to small ones, where high-tech industries are located, to rural areas that develop alternative businesses.

Conclusion

The combination of the cluster approach, the Chinese experience of the evolution of the Zone of Techno-Economic Development and the ideology of program-targeted management allows us to propose an approach to the formation of a strategy for the spatial and sectoral framework for ensuring energy efficiency in industry and the economy as a whole. According to the author's concept, the formation of a spatial and sectoral framework for energy efficiency should facilitate the process of restructuring the economy and structural balancing of the production basis of the economy.

Abstract

Over the years, society has put greater emphasis on simplifying everyday tasks and welcoming the idea of a digital world (Juan et. al., 2004). Speech recognition has advanced substantially over the last decade. Today, more people rely on digital assistants to accomplish everyday tasks. Amazon, the world's largest online retailer, took advantage of the new era of smart assistants and created Alexa, a digital assistant built into Amazon's services and devices, such as Echo, Dot, and Amazon TV (Wetzel, 2018). This paper analyzed the growing market of speech recognition software, and its positive and negative impacts on consumers, focusing on Amazon Alexa, which offered a larger range of options over its competitors.

Keywords: Speech Recognition, Ecommerce, Privacy, Personal Assistants.

Speech Recognition: History and Industry

For years society has been interested in speech recognition from gps systems, to language translators, and it has played a vital role in the technology industry. Bell Labs was able in 1952 to build the "Audrey" system, which recognized numbers but only could recognize one voice, and IBM in the 1960's released the Shoebox software, which processed sixteen spoken words in English (Pinola, 2011). In the 1970's, the U.S Department of Defense funded the Speech Understanding Research (SUR) program, one of the largest speech recognition programs in the world (Pinola, 2011). This research created the *Harpy* system, that was able to comprehend a little over 10,000 words, a major leap for the industry; engineers were beginning to get a better sense of the possibilities that would be advanced speech recognition. In the 1980's, the industry began shifting from less template-based ideas to pattern recognition (Juan et. al., 2004). Pattern recognition allowed for more finite options and created software that learned along the way.

Pattern recognition models were used as an indicator of a word from an unknown sound. At the end of the 1980's, a children's toy was released that could respond to speech, but only if a break was taken in between each word. In the meantime, speech recognition software microprocessors had become faster; so, in the 1990's, Dragon Dictate became the world's first company to release speech recognition software to the public, as it was mainly used for businesses and the government and was not yet released for personal use. In 1993, Apple entered the world of speech recognition which would later lead to Siri. Speak-able items were apart of Apple's plain talk software and enabled consumers to control their computers through speech without the hassle of programming the computer beforehand. Speech recognition had made major advancements over the last few years, and more companies are looking to create products that include this software (Pinola 2011).

Amazon in Business

Amazon is the mogul of the e-commerce industry. Amazon is the center for e-commerce, business transactions, entertainment, streaming, and cloud services (Murphy, 2017). This company has become a place where consumers can buy almost anything; and, with the introduction of Amazon Prime, consumers were given the opportunity to receive shorter shipping times and exclusive offers catered to Prime members. Amazon runs a complicated logistics operation as well; by 2017, Amazon had built in excess of one-hundred eighty huge warehouses, twenty-eight centers for sorting, fifty-nine delivery stations, and sixty-five central hubs for the two-hour same day delivery (Gershgorn, et. al., 2017).

Cite this Article as: Aliyah M. GRAY, Ahmed Y. MAHFOUZ and Kishwar JOONAS "The Evolution of Speech Recognition Through Amazon Alexa" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

With the acquisition of Whole Foods, Amazon added over 300 more distribution centers in 2018 (Gershgorn, et. al., 2017). The company operates in over 10 countries with a revenue of 177 billion dollars in 2017 (Enright, 2018). With the introduction of Alexa, Amazon created a line of products that act as personal assistants, and differs from its competitors, such as Google Home and Microsoft Cortana. Amazon created Alexa Businesses, which allows companies to better streamline their processes. Alexa is able to order office supplies, work with IT, and Amazon partnered with popular companies such as Salesforce, WeWork, and Concur to make Alexa more versatile. Amazon has proven to be the leader of speech recognition and will only continue to add products to its line. The speech recognition industry includes the following: Amazon Echo and Echo Dot, Google Home, Google Home Mini, Amazon Echo Plus, Amazon Echo Spot, Amazon Echo Show, Amazon Echo Dot Kids Edition, Apple HomePod, Google Home Mini, Apple Siri, and Microsoft Cortana, etc.

Motivating Factors

Amazon focuses on the consumer and continues to be the largest hub for e-commerce and offers many other services, such personal assistants via speech recognition. When Amazon released Echo in 2014, it was an immediate success. With any adoption of technology, there is always the fear of privacy. With a product such as Echo, this fear is increased due to the fact that the product itself was built to learn as it goes. This case will address the following questions in regards to Amazon and Alexa:

- Is Alexa worth the privacy risk?
- What is Amazon doing to ensure their consumers' privacy is protected?
- How has Amazon's consistent business model contributed to its overall success?

According to techcrunch.com, 11% of Amazon users own an Amazon Alexa device, which is the equivalent of about 39 million people. With such a large consumer base, many users do not question the privacy aspect of these products, and unknowingly sign away the rights that could potentially be used by third parties in exchange for convenience (Martinez & Cameron, 2018). Amazon had a small number of cases in which privacy was violated with an Alexa product, but never due to hackers. Amazon continues to increase and monitor consumer privacy. Alexa has proven to be one of Amazon's best-selling products. This study will focus on how consumers can better protect themselves, as well as Amazon's role in protecting consumers. This study will also focus on the extensive engineering that goes into creating Alexa. and how Amazon's solid business model has led to their overall success.

Solutions

Strategy for Change

The business strategy and solution for Amazon to improve Alexa's privacy is for consumers to take advantage of the privacy options, as Amazon plans to add more features in the future. Amazon has taken what they believe to be the necessary measures to protect consumers by not allowing third-parties to download information and constantly initiating intensive security reviews (Montag, 2018). Amazon is only responsible for security of their servers, software, and the facilities that hold AWS (Kohgadai, 2018). With such advanced products. it is the responsibility of the consumer to ensure they are taking the correct precautions. Consumers are offered options to clear their voice recordings; many consumers are unaware that once Alexa is activated the system automatically saves the interaction. Consumers are able to manage permissions and choose what devices Alexa is connected to. Data transparency is a major factor for many buyers. and if Alexa is listening at all times, the option is given to review and delete recordings. As other defensive measures. it is suggested that consumers mute their Alexa products if not in use and avoid connecting sensitive accounts to Alexa.

Target Market

Amazon breaks segments its target market into 4 categories: demographics, situational, physiographic, and geographic. The demographic segmentation is composed of those people between the age of 25 to 50 years old; 45% of that group are regular online buyers. ranging from 35 to 49 years old ("Amazons Approach to Audience Segmentation", 2018). The lifecycle stage for this segmentation ranges from single to empty-nest. The situational segmentation involves consumers who view convenience as one of the major reasons for shopping online, the online discounts, and the attraction to lower online prices. The psychographic segmentation looks at the cognitive reasons why consumers purchase Amazon products: consumer loyalty, and those consumers who enjoy the aesthetics of the website. Lastly, the geographic segmentation involves Amazon having international appeal; the company focuses on developed areas, and Amazon has found that in rural areas smartphones are more of a necessity.

Consumer readiness plays a big role in market segmentation, as well their willingness to engage in this new age of technology (Zhu et al., 2003). Although demographics of all kinds use Amazon services, the company still uses advertisements that are centered around its market segments. The overall goal of any marketing team is to maintain loyal relationships with consumers. Research has shown that consumer loyalty is based upon financial, social, and structural bonds; most important of these are financial bonds, meaning the consumer has faith that they are getting the best price for the product (Hsieh et. al., 2011).

Role of Technology

One of Amazon's goals is to increase the interaction between consumers, and for this interaction to run smoothly, there has to be a level of motivation in the consumer to want to interact with the system (O'Brien, 2010). E-commerce main focus is to find ways to create revenue solely behind online traffic (Rayport, 1999). Jake Williams, founder of Rendition, a cybersecurity firm, analyzed the likelihood of Alexa devices being hacked and found that the likelihood was a lot smaller than many would think. Alexa is a virtual assistant that is only able to receive information from 2 sources: the consumer's voice and from the Amazon servers (Montag, 2018). There is a misconstrued conception that making purchases through the Alexa devices would reveal personal bank information if hacked; when in actuality credit card information is stored on the Amazon servers, and there would have to be a major security breach for this system to be hacked (Montag, 2018).

Since Alexa is not an app and does not provide visuals. developers must create a code that follows the sets of flow of both information and language (Hansen, 2017). Developers are also required to predict how people will phrase certain questions; this requires a higher level of language expertise (Hansen, 2017). When analyzing new technology, companies have to decide to adapt early or wait until more information has been acquired (Kumar, 2016). In October of 2017, Amazon opened its first research center in Germany whose focus was mainly on AI, and by partnering with Microsoft, Amazon provided its engineers with an easier way to use open-source AI (GreyB 2018). Engineers are able to collaborate with Microsoft products, such as Cortana, so both devices are able to communicate to one another (GreyB, 2018).

Outcomes of Success

Amazon released Alexa's first product, Echo, in early 2014, and within the first month sold 3 million products (PYMNTS, 2016). Consumer reviews has given Amazon the motivation and research to surpass its competitors such as Apple, who for years has held a prominent spot in the tech industry for smart devices. Scot Wingo, chairman of Channel Advisor. stated that he believes Echo, by itself, will become a 1 billion-dollar company. Consumers enjoy the Echo because the voice recognition that can be heard from a far distance (PYMNTS, 2016).

Amazon has created a product that is capable of holding small conversations and follow demands. A portion of Amazon's success is their dedication to teaching others how to develop the skills, just like those of their engineers, with the hope that they will expand their knowledge and create products of their own (Cheng. 2018). The overall goal of any company is to create products that can be substituted, and Amazon has done just that. Voice recognition is the new wave in computing, and consumers are eager to use devices that have human-like abilities (Cheng, 2018). When Amazon first began selling books in the late 90's, it was clear that the company had no regard to their low profitability, but the company was adamant it would create loyal customers, and later they would make up for losses (Rayport, 1999). Amazon prides itself on the fact that it is able to easily function at low margins, as the company did when it first began, ensuring its financial stability (Levy, 2011).

Challenges and Failures

Since the release of Alexa products, Amazon has had minimal privacy issues until a few years later. A family in Portland, Oregon was recorded by Echo, and the recording was sent to a friend. Many users are aware of the blue ring that appears when Alexa is initiated, and Amazon insisted that the alleged security breach woken Echo up due to a word sounding like Alexa (Zhou, 2018). After the conversation was recorded, Alexa then heard another similar phrase to "send message" initiating the text message, and according to Alexa engineers, Alexa then asked out loud to whom to send the recording to (Zhou, 2018).

Many people found this string of events very unlikely, and many consumers began to question whether they were unknowingly being recorded. Later in that same year, many people reported having a conversation about a specific product and then seeing an ad appear for that exact product on their cellphone or laptop. Amazon has released multiple ways for consumers to feel protected when using an Alexa product. Amazon has input all the necessary requirements to keep their consumers protected.

It is the job of consumers to protect themselves when buying these products. Amazon has posted and released many ways for consumers to feel protected. Too much blind faith is placed in these smart products, but unfortunately history has shown that mistakes are commonly made in the tech industry, so everyone needs to take precautions. Tamara Dinev and Paul Hart developed a study that collected data from 422 subjects and analyzed the relationship between social awareness and Internet literacy. The pair found that Internet literacy had a negative correlation to Internet privacy concerns, whereas social awareness has a positive correlation in relation to Internet privacy (Dinev and Hart, 2014). This study showed that those who are socially aware have more concern in regard to Internet privacy.

Reflections and Lessons

Through this study many lessons can be learned. One major lesson is that companies should focus on customer loyalty, not short-term and immediate revenue success, even if profit margins are low at the beginning to attract a bigger market share. Amazon has been able to create a business model to have long-term sustainable revenue. Over time, the company has learned the importance of consumer loyalty, and with the creation of Alexa, Amazon has continually updated its user features, so that the consumer can be in control of what information is shared, stored, and made public.

The creation of Alexa allowed Amazon to create their own code with a personal set of engineers, who can continue to add advancements. By creating their own systems, engineers are given more flexibility when it comes to logistics and are able to choose what companies they want to partner with while staying within their core values. Fast Company went to the Amazon headquarters and spoke to the director of the product division, Toni Reid and the head scientist for Alexa, Rohit Prasad. During the interview the two employees were able to give details behind their success.

One reasoning behind this success was that they adopted a process whereby teams work backwards based on possible press releases, meaning each team write a press release for a new project as if it has been released already, and then work backwards on how to make it a reality. By making the decision to not have a screen for Alexa products, Amazon learned that it would have to manually adjust the AI to work at a larger scale. Reid stated that creating products was simple due to the fact that Amazon listened to customer requests and found ways to fulfill them.

Amazon prides itself in educating current and future engineers on how to create and edit the code for Alexa. Amazon created the Alexa Champions Program, which recognizes those engineers who give back to the community and take time out to educate the future web engineers (Bixenspan, 2016). This program has made it quick and simple for developers to enhance their skills, because Amazon has made it so that developers are able to change the current code without having to rewrite the entire server code (Bixenspan, 2016).

April Hamilton, an Amazon employee, created a blog called *LoveMyEcho* where she provides tips for users and developers on how to enhance the Alexa experience (Bixenspan, 2016). Platforms, such as hers, solidifies Amazon's mission to share information with others, because ideally the company would love to see Alexa become the foundation for all smart assistants.

Conclusion

Speech recognition has become the new phenomenon in today's society. Speech recognition has allowed consumers the most natural way to interact with their home devices. Amazon created Alexa to assist with everyday tasks and created virtual assistants which were able to understand different voices and provide information on command. Speech recognition will continue to advance and will play a major role in the number of opportunities tech companies now have. Studies show that AI is a limitless space with a plethora of possibilities.

Abstract

In the study, the authors examined the current trends in the development of low-rise housing construction (hereinafter referred to as MEHS) in Russia and in the countries of the European Union (hereinafter referred to as the EU) in the context of the global economic recession in 2020. On the example of foreign experience, the prospects for the development of MEZhS in Russia are proved. The factors hindering its development are identified, recommendations are given to eliminate the negative influence of these factors with continuous internal control of risks. A classification of low-rise buildings is carried out, an analysis of the dynamics of construction volumes, commissioning, the share of MEZhS in the total volume of housing construction is carried out, analogies are drawn between MEZhS in Russia and in the EU countries to identify incentives for further development.

Keywords: low-rise housing construction (MEZhS), individual housing construction (IZhS), development incentives, internal control

Introduction

In modern conditions of the global economic recession associated with the COVID 19 pandemic, low-rise housing construction remains a promising segment in the housing construction market. According to experts in research Pavlyushina, Muzychenko, Kheifets (2020), the current global recession is developing much faster than in previous crises. The sharp drop in GDP in all countries of the world in the second quarter of 2020 is associated with quarantine restrictions on economic activity in a number of industries. Thus, according to data published by the official website of the EU statistical office ec.europa.eu, in the second quarter of 2020, the GDP of European countries fell by an average of 11.6%, forming the highest deficit since 2002. According to the Ministry of Economic Development of Russia, in April 2020, Russia's GDP decreased by 12.0%. However, the experience of past crises has shown that MEZhS will withstand, and in Russia it can become a certain catalyst for the construction industry, creating a full-fledged alternative to panel and monolithic apartment buildings (MKD).

Research Methodology

The purpose of this study is to analyze the state and prove the prospects for the development of MEZhS. The objectives of the study are to consider current trends and incentives for the development of MEZHS in Russia and in the EU countries, to identify factors that impede the development of MEZHS in Russia, to give recommendations to stimulate the development of MEZHS in Russia, using continuous internal control. The study carried out the classification of MEZhS, analysis of the dynamics of the volume of construction, commissioning, the share of MEZhS in the total volume of housing construction, drawn analogies between MEZhS in Russia and in the EU.

Research Results

Low-rise buildings are defined as buildings no more than three stories high.

MEZHS classification groups:

Group 1: individual housing construction (hereinafter referred to as IZHS) - these are separate houses for one family, without the possibility of dividing them into independent objects;

Cite this Article as: Natalia V. LAZAREVA and Elena N. SHTYKOVA "Low-Rise Housing Construction: Incentives for Development, Internal Control" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Group 2: block houses - houses of blocks with common walls, the number of blocks is limited to ten, each block is for one family and is located on its own land plot with access to the common territory;
Group 3: low-rise apartment buildings.

The classification of the type, type and methods of MEZhS is presented in Table 1.

Table 1: Classification of types of low-rise housing construction (MEZHS)

Building type	Construction method	Housing market view
– IZHS – locked houses – multi-apartment low-rise buildings	– individual (builds population) – organized (complex construction by the organization - developer)	– cottages and estates - individual buildings; – townhouses - block houses with a small plot of land for several owners; – multi-apartment low-rise buildings

Distinctive features of these buildings:

- lack of elevators and a centralized waste chute;
- lightweight engineering infrastructure;
- optional state examination of project documentation.

Analysis of the dynamics of the volume of commissioned housing as a stimulus for the development of MEZhS

Research Showcases of statistical data https://showdata.gks.ru/finder/descriptors/ on housing construction in Russia show that in 2020 compared to 2019, there is a dynamics of volume reduction. In the second and third quarters of 2020, the volume of housing construction decreased by 7.99 million square meters compared to the fourth quarter of 2019. m (-7.4%) and 538 thousand sq. m (-0.5%). Note that the negative dynamics of the first quarter of the year is explained by the seasonality factor: the mass commissioning of residential properties traditionally falls on the III – IV quarters of the year, therefore, at the beginning of next year, there is a decrease in the number of projects in the phase of active construction. In the second and third quarters of 2020, the worsening situation due to the spread of coronavirus infection strengthened the downward trend in housing construction. Commissioning of housing in 2020 showed a similar negative trend. In the first half of 2020, compared to the first half of 2019, the total volume of commissioned housing decreased by 2.2 million square meters. (-7.3%). The area of new housing in the individual housing construction sector has also decreased. Compared to the same period in 2019, in 2020, the figure fell by 1.3 million square meters. (-9.1%), according to Actual information and analytics on housing construction https: //our house.rf.

However, it should be noted that there is a positive trend towards an increase in the volume of housing commissioned in Russia in the third quarter of 2020. The indicator of the growth rate (decline) of residential buildings commissioning after a significant decrease in the second quarter of 2020 from 98.7 points to 88.6 points, in the third quarter rose to 97.7 points. In the individual housing construction sector, the volume of commissioning increased from 6.3 million sq.m. in the second quarter of 2020 to 10.8 million sq. m. in the third quarter. The dynamics of housing commissioning for the current period of 2020 is shown in Figure 1.

Compiled according to Rosstat data https://rosstat.gov.ru/folder/14458

Fig. 1: Housing commissioning in 2020 in Russia

Russian analytical reviews on housing construction, in research Tuzov, Sabelnikov, Arapova, Jafarov (2019), reveal the relationship between crisis moments in the economy and the behavior of the construction sector. The reaction of the latter is to increase the volume of housing commissioning and reduce the number of starts of new construction projects. Rosstat does not collect data on the start of new housing construction, therefore, the crisis phenomena in this area of the economy can only be tracked by indicators of commissioning. Note that these indicators were formed by the developers' decisions taken in earlier periods, and experts estimate such a "delay" about a year. The construction business is characterized by inertia and retains positive dynamics for a longer time during the crisis, but it also recovers more slowly afterwards. Let's take the Russian crisis that began in 2014 as an example: the volume of housing commissioning began to accelerate with a general slowdown in investment processes in the economy and reached its maximum in 2015, at the height of the crisis.

The EU countries reacted in a similar way to the global crisis. According to Eurostat ec.europa.eu, in European countries in the construction sector, the maximum decline in production was observed in May 2020, then in the third quarter of 2020 there was a positive trend, production in construction increased in August by an average of 2.5%.

Analyzing the statistical data, it can be concluded that in recent years there has been a steady trend towards an increase in the total volume of housing commissioned in Russia by the share of MEHS (Fig. 2).

Over the past four years, the share of MEHS increased from 45.92% in 2016 to 49.10% in 2019. This is largely due to a change in the structure of demand for housing (residents are switching their interest to housing in the suburbs - an alternative to a city apartment) and the emergence of state support for the development of MEHS ... In addition, the growth in the share of MEZhS is facilitated by: the speed of construction associated with the mobility of the production and technical base; the main focus on the use of the local resource base; more efficient construction logistics; the ability to build small-sized housing in remote and rural areas. A new product appeared on the housing market - “cottage village”.

Compiled according to Rosstat data https://rosstat.gov.ru/folder/14458

Fig. 2: The share of low-rise residential construction in the total volume of housing commissioned Russia

Despite the positive dynamics, the Russian indicators of MEZhS commissioning lag significantly behind the MEZhS volumes in Europe. After analyzing the statistics of residential premises occupied by owners in the EU countries, the authors came to the conclusion that in some developed countries the share of individual houses reaches 88% (Netherlands). Individual houses occupy a high proportion of the total housing stock in France (81%) and Germany (82%). More than half of the residents of the Czech Republic (58%), Austria (60%), Hungary (62%) live in individual houses. It should be noted that in many European countries MEZHS is part of the urban development model. Studying the data of the EU Statistical Office on residential premises occupied by owners in 2015, it can be concluded that “35% of Europeans lived in apartments, 9% - in low-rise buildings with several owners (townhouses), 58% - in individual cottages” [five]. While the majority of Russian residents continue to live in apartment buildings.

In the research of the marketer Balaev (2009), “in European countries the price in prefabricated low-rise buildings popular for the population per 1 sq.m. living area is lower than in apartment blocks, the construction of such houses allows you to form a large living area per person ”. For example, in Germany there are 231 sq.m. per person. per person, in Finland 17, in Russia 9.

It should be noted that this tendency towards an increase in area is also outlined in Russia, since the actual cost per square meter of individual housing construction is cheaper than in apartment buildings. In 2018, it amounted to 23,000 rubles, while in MKD this figure was 34,000 rubles according to Rosstat. Over the past three years, the average size of commissioned individual residential buildings (hereinafter referred to as IR) has been growing, in contrast to apartment buildings, and in 2018 it reached 139.1 sq. m, a maximum since 2000 in Russia. The excess of

the area of IR over the area of an apartment in an apartment building by an average of 2.7 times undoubtedly contributes to the improvement of living conditions of the population of Russia

In fact, in research Shatilo (2015), "prices for residential real estate are significantly differentiated within cities and represent an important factor in spatial social stratification".

As mentioned above, MEZhS in Russia is subdivided into individual construction (houses built by the population) and organized construction (houses built by organizations). Rosstat does not provide a clear classification of statistical data on MEZhS in the context of these types of construction. After conducting a detailed analysis of statistical data for 2016-2019, the authors came to the conclusion that most of the MEZhS in Russia refers to individual construction, which ranges from 93.5% to 96.8% of the total. During the study period, the volume of organized construction is constantly decreasing (Fig. 3).

Compiled according to Rosstat data https://rosstat.gov.ru/folder/14458

Fig. 3: the ratio of the volume of input of MEZhS in the context of individual and organized construction

Thus, in the sphere of the Russian MEZhS, the problem of reducing complex organized buildings can be distinguished. In turn, in case of individual construction, there are often violations of building codes by private owners when they independently provide their sites with engineering infrastructure and high risks of non-compliance with construction technologies. In this regard, stimulating the construction of complex MEZhS projects, implemented in an industrial way around cities, would solve the problems of rational use of land, more economical spending of funds for construction, and regulation of population density. The foreign experience of MEZHS reflects the advantage of building organized residential communities, making housing more affordable and comfortable. In addition, the use of innovative methods in the production of materials for MEZhS will reduce construction costs, for example, housing built using 3D printing technology in the USA, China, smart houses with minimal energy consumption being built in Russia.

Factors hindering the development of MEZHS

At the present stage, the development of MEZhS in Russia is impeded not only by the risks characteristic of low-rise construction of residential buildings, but also by the following factors:

– The approved general plans of cities and settlements do not provide for the development of territories under the MEZhS;
– mortgage lending of the MEZhS market is underutilized due to the lack of standards (this makes it difficult to assess the subject of the pledge); that is why MEZhS houses are not liquid enough as collateral in comparison with apartments. In research Idrisov, Ponomarev (2019) "the implementation of infrastructure mortgages in Russia can increase the average annual rate of economic growth", in this regard, taking into account research Kosareva, Polidi (2019) "monitoring and assessment of the situation in the housing market and mortgage lending" is, along with the "welfare of the population", the main "mainstream » according to modern scientific research Naiden & Belousova (2018).
– there is no normative legal regulation in the field of MEZhS. For example, there is no clear definition in the typology of the less common form of MEZhS - a townhouse, which entails problems with the registration of land plots.

Risks specific to MEZHS

The types of risks typical of MEZhS are presented in table. 2. Identification of risks and their continuous internal control help to identify incentives for the development of MEZHS.

Table 2: Characteristics of the types of financial and management risks that reduce the development of low-rise housing construction

Risk groups	Types of MEZHS risks, their causes
Management risks	failure to fulfill plans and obligations in terms of the volume and quality of construction; unjustified overstatement of the estimated cost of objects; lack of responsibility for the violations committed; lack of reserves to cover force majeure circumstances and unprofitable contracts; attraction of counterparties without due diligence; lack of predictive assessment of the demand for objects and the solvency of potential buyers; bankruptcy of the developer; lack of readiness for digitalization; decrease in the effectiveness of strategic and operational management, others.
Financial risks	unreliable assessment of assets and liabilities; lack of analysis of the results of the internal control system; not conducting an inventory of assets and liabilities; improper accounting of income, expenses, assets, liabilities and disclosure of information in financial statements; understatement of taxes payable to the budget and unreasonable tax optimization, others.

Project financing, in research Karminsky, Burekhin (2019) "gives a full guarantee of the safety of citizens' funds and excludes their risks associated with possible unfair actions or bankruptcy of the developer". In research Dolganova, Deeva (2019) at the present stage of digitalization, the priority is "diagnostics of the company's readiness for the initial stage of digital transformation". It is obvious that, in research Litvintseva, Karelin (2020) “the positive impact of digitalization is observed in economically developed and wealthy regions”, in contrast to less developed ones, due to the best financial security. In research Zuev M.B., Zuev B.P., Bulgakova (2020) "Strategic management is intended to direct the influence of management to ensure future competitive excellence," as opposed to operational current enforcement of plans and commitments.

Internal control of incentives for the development of MEZHS is aimed at:

- assessment of the quality and volume of construction to achieve efficiency;
- calculation of predicted solvency and demand for objects by consumers;
- analysis of international practices of MEZhS value;
- ensuring information transparency, reliability of accounting and reporting of the developer.

Activities proposed to stimulate the development of MEZHS

The following proposed top-priority recommendations are aimed at increasing the volume and pace of low-rise housing construction in Russia, helping to stimulate the development of MEHS:

- increasing the volume of land plots for development under the MEZhS by approving new general plans with the provision of social, engineering and transport infrastructure; application of standard design documentation, standard layouts of MEZhS projects;
- development and approval of lending standards of the MEHS, allowing to reduce mortgage rates compared to rates in apartment blocks, since in research Kurichev, Kuricheva (2018) “there is an equilibrium relationship between the supply of new housing and net migration”, the suburban area develops, in research Kuricheva, Popov (2016), “mainly along transport corridors” contributing to the development of MEZHS.

Discussion of the Results

Despite the economic downturn in the 2nd quarter of 2020, the development trends of MEZHS in the EU countries and in Russia are assessed as positive. MEZhS is subdivided into three types: IZhS, block houses, low-rise apartment buildings. There are two types of MEZhS - individual (built by the population) and organized (built by the developer). Despite the increase in the share of MEZhS in Russia in recent years, these indicators are still far from those in the EU countries. The problem of reducing organized complex buildings in Russia is revealed, while the European experience proves their advantage over individual housing construction. The factors hindering the development of MEZhS in Russia are considered. Specific recommendations are given to stimulate the MEZhS.

Conclusion

The development of low-rise housing construction in the countries of the European Union has shown the advantages of this type of construction over apartment buildings. Modern trends in the development of low-rise construction of residential buildings in Russia have proved their prospects even in the context of the economic crisis, while ensuring continuous internal control of risks.

Integrative Methods for Sustainable Competitive Advantage

Gheorghe TOLU
Polytechnic University, Bucharest, Romania, email: georgetolu@gmail.com

Daniel GHICULESCU
Polytechnic University, Bucharest, Romania, email: daniel.ghiculescu@upb.ro

Abstract

The paper deals with some integrative methods applied by a Romanian organization, manufacturer of electrical discharge machines, aiming at Sustainable Competitive Advantage (SCA). Some aspects of the strategic management process are presented, emphasizing the stage when the integrative methods must be applied. Some fundamental aspects of Customer Matrix, Producer Matrix and Risk Cube are presented. Finally, they are applied for the mentioned above organization, determining some solutions leading to SCA.

Keywords: Sustainable Competitive Advantage, Customer Matrix, Producer Matrix, Risk Cube.

Introduction

The strategy of an organization is the result of the strategic choice of its management regarding the paths it will follow and the means it will use to achieve the strategic objectives. The ways to achieve the strategic objectives are multiple, in this sense, the management of the organization must have clear options of how to achieve the strategic objectives. The main factors of an organization's strategy are resources, deadlines, sustainable competitive advantage. Resources are provided in strategies, usually globally or in the form of investment funds, and the origin of these funds could be own resources or borrowed resources. Strategic resources are material, human, informational and financial resources.

The terms incorporated in the strategy include: the initial term that represents the start date of the strategy, intermediate terms that represent the significant evolutions in the achievement of the strategic objectives, the final term that stipulates the date on which the implementation of the strategy ends. Competitive advantage is considered a fundamental priority for the management of the organization. The purpose of the strategy is to create and maintain a competitive advantage over competing organizations. Competitive advantage means that the organization achieves superior products from the Customer's point of view, compared to similar products offered by the competition. The advantage can be measured by cost advantages, differentiation, and market focus and is mentioned in the book *"Competitive Advantage"* written by Porter (2003).

Cost advantages that allow the organization to obtain higher profit margins than their competitors, even if they set their prices around or below market prices. Differentiation is the provision by the organization of a product or service, which is perceived by consumers as unique in the market, completely different from other products and services. Market focus is the ability of the organization to cover an individualized market.

Strategic Management

Strategic Management is the process by which strategies are formulated and implemented. The strategic dimension of management is ensured by the existence of a strategic thinking and an organizational culture favorable to change and performance in an external competitive environment. The competitive advantage achieved by an organization in relation to other organizations with which it is in competition, designed over time, gives the organization a strategic competitiveness. The fundamental principles of Strategic Management are setting the direction, concentrating efforts, and ensuring consistency and is mentioned in the book *"Strategic Management"* written by David et al (2016).

Strategic Management Process Model

Strategic Management is a complex process and is represented in the Figure 1.

Cite this Article as: Gheorghe TOLU and Daniel GHICULESCU "Integrative Methods for Sustainable Competitive Advantage" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig. 1: Strategic Management Process Model is mentioned in the book *"Strategic Management"* written by Wheelen et al (2010).

The analysis of the external environment represents the starting point for the realization of the strategy. The external environment is general and competitive. The analysis of the internal environment includes: the structure, the culture, the resources, the capabilities, the essential competencies, and the possibilities of obtaining the sustainable competitive advantage. The formulation of the strategy consists in establishing the vision, mission, objectives, and strategic options. The implementation of the strategy is the realization of the strategic plan through specific programs, budgets, methods. Performance evaluation and control is done by reporting to objectives and making corrections and is mentioned in the book *"Strategy for Enterprise"* written by Butler (2005).

Quality Management

The design and implementation of a Quality Management system, which is essential to be associated to Strategic Management, are influenced by the objectives, the products it provides, the existing processes and the size and structure of the organization. The adoption of Quality Management in the organization must be an important strategic decision. Applying the principle of continuous improvement can lead to engaging a consistent approach across the organization for continuous performance improvement. Quality control (CC) and data quality assurance (CA) procedures are designed to avoid the introduction of errors in data sets - process called data contamination. There are two basic types of contamination: addition and omission. CC procedures are effective in reducing added errors. There are mechanisms applied before the data are obtained and which control the way in which they are acquired and registered and is mentioned in the book "Quality Management" written by Oprean et al (2008).

CA procedures are used to detect both omissions and additions after the data have been obtained and recorded, involving graphical and statistical methods. Data processing methods are used in all stages of Strategic Management Process: environmental analysis, formulation, implementation, and evaluation of the strategy and is mentioned in the book "Management in micro and nanotechnologies" written by Marinescu et al (2005).

Advanced Methods of Sustainable Competitive Advantage

The following integrative methods to obtain SCA are applied even in the first stage of the strategic management process (Figure 1), which begins with external and internal analysis.

The Customer Matrix

The Customer Matrix is an instrument used to achieve SCA. Different variants of this instruments are conceived. In this variant, the variables of Customer Matrix are Price and the Perceived Use Value (PUV) by the customer. The strategic options represent the displacements to the cardinal points (N, S, E, W) (Figure 2) and is mentioned in the book "Elements of Competitive Strategy" written by Faulkner et al (2000).

Fig. 2: Displacements in the Customer Matrix is mentioned in the book *"Elements of Competitive Strategy"* written by Faulkner et al (2000).

Moving to North (N) is the fundamental strategic option. The organization offers the customer a product at the same price, but with a higher value than that of competing organizations. Shifting the strategy to the North leads to an imitation reaction from the competition. The strategy adopted in this case is to focus on a single segment.

Moving to West (W) is the main strategic option. The organization offers the customer a product with the same value, but at a lower price than that of competing organizations. Shifting the strategy to the West leads to an imitation reaction from the competition. The organization must always reduce costs and the adoption of this long-term strategy is difficult to achieve.

Moving to North-West (NW) is the most useful path and involves increasing the value (PUV) while reducing the perceived price. This strategy is possible when the organization acts in the directions defined by Michael Porter: cost decrease, and product differentiation by increasing quality. These directions are based on continuous innovation and is mentioned in the book *"Innovation and Entrepreneurship"* written by Drucker (2015).

Moving to South (S) involves reducing the PUV and keeping the price constant.

Moving to East (E) involves increasing the price without the addition of PUV. The strategy can be profitable in crisis situations of various sectors of activity of innovative organization.

Moving to the South-East (SE) involves increasing the price at the same time as reducing the PUV and is useful in the short term when it was a quasi-monopoly in a certain sector of activity. The consequence is a strong damage to the image of innovative organization.

The Perceived Use Value (PUV) can be calculated using the relation:

$$\text{PUV} = \sum_{i=1}^{n} p_i \cdot x_{ir} \tag{1}$$

where:

x_{ir} is the relative value of quality characteristics i
and
p_i is the weight of quality characteristic i.

For a best control of given weights p_i, they must satisfy the condition:

$$\sum_{i=1}^{n} p_i = 100\% \tag{2}$$

if p_i is expressed as a percentage
or

$$\sum_{i=1}^{n} p_i = 1 \tag{3}$$

if $p_i < 1$.

Because the values of quality characteristics x_i are expressed in different units of measurement, they must be converted to relative values. For this, we consider a standard scale at which the value 0 corresponds to the weakest value of parameter x_{imin}, and the value 1, the best value of parameter x_{imax}.

To assign a normed value on the scale 0…1 to an effective value x_i, the interpolation relation is used:

$$x_{ir} = \frac{x_i - x_{imin}}{x_{imax} - x_{imin}} \tag{4}$$

The construction of Customer Matrix consists in going through the following steps:

Step 1: The elaboration of competitive strategy has as starting point, the identification of market segments. It is necessary to distinguish whether a particular customer is part of market segment found. Their assessment is based on the analysis of weights given to the quality characteristics (PUV dimensions).

Step 2: PUV dimensions are determined by asking customers what quality features they appreciate in a product. It is recommended to avoid questionnaires that lead to confirmation of Producer's options.

Step 3: Determining the weights for the PUV dimensions is done by asking customers what most important quality characteristics are appreciated and how the weights given to each quality characteristic should be distributed to a product.

Step 4: Determine the PUV, based on the PUV dimensions and weights for own product and competition. If the input data (x_i and p_i) are correct, then the performance evaluation should be between exaggerated levels of optimism and pessimism. In this way, a pro-competitive organizational culture is formed.

Step 5: Position the products in the Customer Matrix based on the variables: the perceived use value and the price perceived by the customer. A good way to check is to revalue the Matrix positions with changes in market share.

Step 6: Adopt specific strategies depending on the position of products in the Customer Matrix. The main competition takes place in a North-West (NW) direction.

The Producer Matrix

The Producer Matrix is an instrument for internal environment analyzing of organization in relation to other competitors from the same industry. Different variants are designed. In this case, the variables of Producer Matrix are Unit Costs and Efficiency (Figure 3).

Fig. 3: The Producer Matrix variables is mentioned in the book *"Elements of Competitive Strategy"* written by Faulkner et al (2000).

The Producer Matrix establishes the relationship between the Unit cost and the competencies of organization creating the Perceived Use Value (PUV) by the customer.

There is an indirect link between the Customer Matrix and the Producer Matrix.

The competitive advantage can be obtained because of moving to North-West (NW) in the Customer Matrix. The organization can only act on the Producer Matrix in two directions reducing costs and increasing efficiency.

Moving to West (W) in the Producer Matrix by reducing costs can be followed by rising prices, which involves moving to East (E) in the Customer Matrix.

If the West (W) movement is insignificant, in the Producer Matrix, an insufficient decrease of costs, it is unlikely that it can be maintained in the Customer Matrix, by reducing the price in conditions of high competition.

The improvement of competence leads to a shift North (N) in the Producer Matrix, the effect being moving North (N), South (S) or not at all in the Customer Matrix, depending on the customer reaction to the quality characteristics of product.

The construction of Producer Matrix consists in going through the stages:

Step 1: For cost analysis is used the value chain of Michael Porter which includes all the processes that contribute to the construction of product (Figure 4).

Fig. 4: The internal value chain is mentioned in the book *"Competitive Advantage"* written by Porter (2003).

Step 2: To define the market segment it is necessary to obtain the agreement of management team on the market segment to which the product is addressed. The Producer Matrix is elaborated to include the competencies of market segments on which the organization intends to launch.

Step 3: In order to identify the essential competencies, the question that the management team must answer is: what are the operating competencies, system, focused on costs that the organization must have in order to win the market segment, on which it acts.

Step 4: To assess the competencies of organization, the analysis must be extended to the main competitors in the market segment. The purpose of rating is to place competitors on the Producer Matrix.

The aggregate note of operating and system competencies is calculated using the relation:

$$N_{os} = \sum_{i=1}^{n} p_i \cdot C_{osi} \tag{5}$$

where:

C_{osi} represents the quota given to the operating or system competency i on a unitary scale,
and
p_i is the weight given to the competency i.

For a good control of weights pi granted, they must satisfy the condition:

$$\sum_{i=1}^{n} p_i = 100\% \tag{6}$$

The value of aggregate note *Nos* determines the position of vertical organization with the Efficiency in the Producer Matrix. To determine the position on the horizontal axis, information on the production costs of competitors is required. This refers to the profile of competence focused on reducing costs.

This assessment allows the classification of competitors based on external information.

The aggregate grade of cost focused competencies is calculated using the relation:

$$N_{fc} = \sum_{i=1}^{n} p_i \cdot Cfci \tag{7}$$

where:

C_{fci} is the share given to competency i focused on costs,
and
p_i is the share given to competency i.

For a good control of weights pi granted, they must satisfy the condition:

$$\sum_{i=1}^{n} p_i = 100\% \quad (8)$$

Step 5: Elaboration of competency Producer Matrix based on the aggregate grades determined in Stage 4 are used to determine the coordinates of competitors. Depending on the position of organization in the matrix, strategies for improving competence can be developed. The main competition takes place in the North-West (NW) direction.

The Risk Cube

The Risk Cube is a complex method that has the advantage of leading to an appropriate decision strategic of organization development, based on external and internal analyses. Based on the combinations between Customer and Producer Matrices, are designed different variants. The most important combination of these previous instruments is the following:

Combination 1: The Customer Matrix has a high PUV and a high price of product. The Producer Matrix has a high efficiency and a high production cost (Figure 5).

Fig. 5: Combination 1 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

Combination 2: The Customer Matrix has a low PUV and a high price of product. The Producer Matrix has low efficiency and low production cost (Figure 6).

Fig. 6: Combination 2 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

Combination 3: The Customer Matrix has a high PUV and a high price of product. The Producer Matrix has low efficiency and high production cost (Figure 7).

Fig. 7: Combination 3 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

Combination 4: The Customer Matrix has a low PUV and a low product price. The Producer Matrix has low efficiency and low production cost (Figure 8).

Fig. 8: Combination 4 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

Combination 5: The Customer Matrix has a high PUV and a low price of product. The Producer Matrix has a high efficiency and a low production cost (Figure 9).

Fig. 9: Combination 5 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

Combination 6: The Customer Matrix has a low PUV and a high price of product. The Producer's Matrix has low efficiency and high production cost (Figure 10).

Fig. 10: Combination 6 of the two matrices is mentioned in the book *"Strategic Management"* written by Ghiculescu et al (2015).

The Risk Cube helps to establish the most appropriate strategy of organization and contains the following steps:

- the relationship between the product and the market is established,
- determine the requirements of customers in the market,
- the competencies of organization are analyzed.

If they are insufficient, it is established how the gap between the required and the current level can be covered. The problem can be solved by internal development alliance, or acquisition, each with different degree of risk. These strategic options are the main variables of cube, the first option being internal development because it is the least risky.

The second option the alliance involves operating with a partner, over whom the organization has limited control, so, a higher level of uncertainty.

The third option, the acquisition, is even more risky because it is necessary to harmonize the competencies of all the organizations involved, a difficult process that can ultimately lead to an overall imbalance. Risk analysis shows that it grows as the innovative organization moves away from the markets it operates and the products it makes.

The first least risky option is to make the same product for the same market, the organization being based on internal development. If the product is in decline or the market is already saturated, the other three options with increasing risk are considered:

- launching the same product in a new market,
- making a new product for the same market,
- launching a new product in a new market (Figure 11).

Fig. 11: The Risk Cube variables is mentioned in the book *"Elements of Competitive Strategy"* written by Faulkner et al (2000).

The second option is to launch the same product on another market, which involves rebuilding the Customer's Matrix and that of Producer to meet the new price and quality characteristics of market.

The third option is to make a new product on the same market and only involves the change of Producer Matrix because the competence for achieving the new value of use perceived by the Customer (PUV) and the costs of making the new product differ. Considering the restricted resources of the organization, a gradual strategy is recommended by approaching a risk minimization and is mentioned in the book *"Implanting Strategic Management"* written by Ansoff et al (2018).

The fourth option is to launch a new product in another market and will require updating both Customer and Producer Matrices. These options can be achieved through internal development alliance, or acquisition in ascending order of risk. In the Risk Cube, these strategic options can be characterized by a higher level of detail.

For the same product, the same market there is the following additional strategic options:

- keeping the current direction,
- withdrawing from the market,
- concentrating activities,
- increasing the market share.

Maintaining the current direction of innovative organization is a useful strategy if the market share is high and a Sustainable Competitive Advantage (SCA) has been obtained. The risk increases if the organization is not attentive to new trends that manifest themselves in the general external environment and to the evolution of competitive environment and is mentioned in the book *"Strategic Management"* written by Barney et al (2012).

Withdrawal from the market is a useful strategy of innovative organization if the market share is small, external threats is stronger and its competence are reduced. Timely withdrawal of organization is a useful strategy if losses can be minimized and resources can be leveraged in other markets or in other industries. The condition is that the barriers to exit from the market are not high, high expenses and advance payments are irrecoverable.

Concentrating the activities of innovative organization is the useful strategy in the phases of economic recession. It implies the consolidation of position in the sectors of activity in which it has a more favorable position.

The innovative organization withdraws from low-profit activities. The strategies associated with the concentration are cost decrease based on cost-focused competence and market leadership strategy.

Increasing market share is essential in the maturation phases of a sector of activity. If the industry is in the launch phase, competitors can evolve quickly and without increasing market share. The strategy is realized by methods that lead to movement to the North-West (NW) in the Customer Matrix.

The same product strategy, new market is characterized by a higher level of risk. It is necessary to develop a new Customer Matrix because changing the market involves new requirements related to PUV size and price. It is necessary to re-evaluate the position of innovative organization in the Producer Matrix.

New product strategy, the same market is riskier than any of strategic options presented. Even if the new product addresses the same market, it has different characteristics, requiring a change in the Customer Matrix. By default, the Producer Matrix must be developed to highlight the competence needed to make the new product.

The strategy can be applied using the following methods:

Making complementary products, taking over a new product based on a license or franchise, making a new product through own research and development. The construction of complementary products presents the lowest level of risk because the strategy is the closest to the current activity. There is a risk of financing above the allowed limit of new activities in the profitable activity. This risk increases with the degree of expansion.

The acquisition of a new product based on a license or franchise has the advantage that the product has been tested on the home market. The product thus no longer requires additional investment in research and development. The risk is that the new market is different from the original one, and Customers may have different preferences from those in the home market.

Making a new product through your own research and development is the riskiest strategy. The strategy is appropriate for organizations with financial, human, informational and material resources. Innovation competences need to be doubled by operational competence, especially in marketing and sales activities to capitalize on high Perceived Value Products (PUV).

New product strategy, new market presents the highest risk of strategies presented. If an organization has a large market share with another product, it can launch a new product in the same market, based on Customer loyalty to the brand.

Once the strategies have been analyzed and adopted using the Risk Cube, it is necessary to evaluate and control the strategies by the management team and the staff at the lower levels of innovative organization using nonconventional technologies.

A Case Study

The Customer Matrix

We have to evaluate the EDM machine made by suppliers from four countries: Japan (JP), Germany (DE), France (FR) and Romania (RO), using Customer Matrix, relative to the Romanian organization whose strategy is elaborated in the strategy management process described above.

The stages of creating the Customer Matrix are:

Step 1: Market segmentation. The product addresses a market segment formed by organizations in Romania, which use EDM processing for the active surfaces of molds. They are particularly interested in the precision and high quality of surfaces obtained.

Step 2: Identify the dimensions of PUV.

Users are interested in the following product features:

Overall dimensions:

(01) machine length (L),
(02) machine width (l),
(03) machine height (h),

(04) machine mass (M),

Worktable dimensions:

(05) table length (L_m),
(06) table width (l_m),

Working tank dimensions:

(07) tank length (L_c),
(08) tank width of (l_c),
(09) tank height (h_c),
(10) maximum mass of machined part (m_p),

Work races:

(11) X axis travel (X),
(12) Y axis travel (Y),
(13) Z axis travel (Z),

Positioning accuracy:

(14) positioning tolerance on X and Y axes ($T_{pX,Y}$),
(15) positioning tolerance on Z axis (T_{pZ}),
(16) average positioning dispersion on X and Y axes ($6\sigma_{X,Y}$),
(17) average positioning dispersion on Z axis ($6\sigma_Z$),
(18) reverse repositioning tolerance on X and Y axes ($T^{-1}_{pX,Y}$),
(19) reverses reposition tolerance on Z axis (T^{-1}),

Fast forward speeds:

(20) speed of fast advance on X and Y axes ($v_{sX,Y}$),
(21) speed of fast advance on Z axis (v_{sZ}),

Productivity:

(22) productivity in the materials of copper / steel materials ($V_{W,Cu/st}$),
(23) productivity in the pair of graphite / steel materials ($V_{W,gr/st}$),

Minimum Ra roughness of processed surface:

(24) minimum roughness at torque of copper / steel material materials ($R_{a,Cu/st}$),
(25) minimum roughness at torque of copper / metal carbide materials ($R_{a,Cu/MC}$),

Dielectric unit:

(26) filter fineness (f),
(27) injection pressure of dielectric fluid (p_{inj}),
(28) suction pressure of dielectric fluid (p_{asp}),
(29) coolant temperature (t_r),

EDM generator:

(30) maximum current stage (I_{max}),
(31) minimum current stage (I_{min}),
(32) maximum pulse time (t_{imax}),
(33) minimum pulse time (t_{imin}),
(34) maximum priming voltage (U_{0max}),
(35) minimum priming voltage (U_{0min}).

Step 3: Determining the weights of PUV dimensions.

Weights pi are awarded by a team of potentially qualified users. To reduce the subjectivity in the weighting, the average values p_{imed} given by the team members were determined. The sum of weights satisfied the relation (2).

As users are interested in the accuracy and quality of surfaces processed, they have given greater weight to the characteristics: (14), (15), (16), (17), (18), (19), (24), (25), (26), (31), (33) and lower weights of characteristics: (01), (02), (03), (04), (05), (06), (07), (08), (09), (10).

Step 4: PUV evaluation of products. The absolute values of x_i quality characteristics corresponding to the four products of companies from Japan (JP), Germany (DE), France (FR), Romania (RO) were centralized in Table 3. Depending on the weakest value of parameter x_{imin} and the best value of parameter xi_{max}, for each quality characteristic relative value was assigned on a normed scale from 0 to 1 based on relation (4).

Using the relation (1) PUV were determined for the products, the resulting values being found on the last line of Table 3.

Step 5: Determine the positions in the matrix.

The positioning of products in the Customer Matrix based on the two coordinates (Price and PUV) was represented in Figure 12.

Fig. 12: Customer Matrix for the products

Stage 6: Development of strategy.

The strategy necessary to obtain SCA for the Romanian organization is formulated based on date provided by Customer Matrix. The market segment to which the product is addressed consists of organizations from Romania, which do not have high financial resources and are therefore sensitive to the price variable.

From this point of view, the Romanian product occupies a favorable position in the matrix in relation to the competitors. The prices of analyzed cars are influenced by the competence related to costs.

In the current conditions related to the global economic crisis, the Romanian organization must continue to pursue westward movement (continuous cost decrease). In Romania, the costs of production factors are relatively low compared to the rest competitors from Japan (JP), Germany (DE) and France (FR).

The calculation of variables related to Perceived Used Value (PUV) for the analyzed products are presented in Table 3.

Table 3: PUV evaluation for the products

Nr.	Technical Characteristic	JP		DE		FR		RO		p_{imed}
		x_i	x_{ir}	x_i	x_{ir}	x_i	x_{ir}	x_i	x_{ir}	[%]
01	L [mm]	3000	1	3500	0	3200	0.6	3400	0.2	1.5

22	$V_{W,Cu/st}$ [mm^3/min]	450	0.67	500	1	400	0.33	350	0	2
23	$V_{W,gr/st}$ [mm^3/min]	550	1	550	1	450	0.33	400	0	2
24	$R_{a,Cu/st}$ [μm]	0.05	1	0.1	0.86	0.1	0.86	0.4	0	8
25	$R_{a,Cu/MC}$ [μm]	0.1	1	0.2	0.86	0.2	0.86	0.8	0	8
26	f [μm]	5	1	10	0	6	0.8	6	0.8	4
27	p_{inj} [MPa]	0.1	1	0.1	1	0.05	0	0.06	0.01	3
28	p_{asp} [MPa]	0.05	1	0.03	0.33	0.02	0	0.02	0	3
29	t_r [°C]	4	1	6	0	6	0	4	1	1
30	I_{max} [A]	50	0.5	60	1	50	0.5	40	0	3
31	I_{min} [A]	0.5	0	0.5	0	0.4	0.25	0.1	1	5
32	t_{imax} μs]	1000	0.67	1200	1	800	0.33	600	0	2
33	t_{imin} [μs]	0.5	0.56	1	0	0.8	0.22	0.1	1	5
34	U_{0max} [V]	200	0.55	250	1	180	0.36	140	0	3
35	U_{0min} [V]	100	0.33	120	0	100	0.33	60	1	3
TOTAL		PUV_{JP} = 68.58		PUV_{DE} = 49.46		PUV_{FR} = 47.24		PUV_{RO} = 41.56		100%

But compared to other competitors in China, which enter the Romanian market in the current conditions of strong globalization, the organization in Romania is inferior. Therefore, the Romanian organization must develop other competence focused on reducing costs. In terms of PUV size, the Romanian product is the lowest rated compared to competitors, so moving north remains the main strategic option.

In order to ensure efficiency, it is based on the Romanian organization's focus on increasing the quality characteristics that have been quoted with high weights, which aims to ensure performance on the accuracy and quality of processing required by users.

As the competition takes place in the North-West (NW) direction, by composing the two movements mentioned above, the Romanian organization moves to the North-West (NW), aiming to obtain in perspective of Sustainable Competitive Advantage (SCA).

The Product Matrix could be used further to identify the needed competences for the organization to effectively improve the position of its product in the Customer Matrix. In this case, it is outward that Romanian organization

must find innovation competition to determine North (N) movement, to be vectorially combined to West (W) one. Furtherly, these innovation competencies, which are essential can be found, using Risk Cube instrument.

The strategic alliance between EDM machined manufacturer and a Research Institute and an University could be the solution gain these competencies, to achieve the technological transfer from an innovated product to a ready to market one, with improved position in the Customer Matrix.

The Producer Matrix

With the help of the Producer Matrix, it will be analyzed whether the Romanian organization has the essential competence necessary to enter the market segment of EDM machines, having the advantage of low cost at similar performance compared to EDM machines of competitors.

Stage 1: The market segment of EDM users consists of organizations, which operate in the field of injection mold manufacturing. Customers are interested in the accuracy and quality of surfaces generated by EDM. The financial resources they have are limited and therefore, price and cost are a success factor in this market segment.

Step 2: To obtain a percentage distribution of costs, the value chain analysis was used (Figure 13).

Fig. 13: Percentage distribution of costs on the internal value chain.

Step 3: The essential competencies required for the market segment to which the EDM machine is addressed are:

- Operating Competence: Technology (TC), Supplying (SC), Marketing (MK),
- System Competence: Innovation (IC), Quality Assurance (QA), Value Increase (VI),
- Cost Competencies: Coordination and Control (CC), Continuous Cost Decrease (CCD), Production Factors Cost (PFC), Economies of Scale (ES).

Step 4: Is the rating of core competencies relative to the main competitors in Japan, France, and Germany, which operate in the approached market segment. (Figure 14 and 15).

Fig. 14: Operating and system competence.

The aggregate note of operating and system competencies (*Nos)* was determined using the relation (5):

$Nos = 30\%TC + 10\%SC + 10\%MK + 25\%IC + 20\%QA + 5\%VI = 0.3 \times 0.2 + 0.1 \times 0.7 + 0.1 \times 0.1 + 0.25 \times 0.3 + 0.2 \times 0.3 + 0.05 \times 0.8 = 0.315$.

Fig. 15: Competence focused on costs.

The aggregate grade of cost-focused competencies (*Nfc)* was determined using the relation (7):

Nfc = 50%*CC* + 30%*CCD* + 15%*PFC* + 5%*ES* = 0.5 x 0.3 + 0.3 x 0.25 + 0.15 x 0.8 + 0.05 x 0.1 = 0.35.

Step 5: The aggregate scores determined above lead to the establishment of the competitors' positions in the Producer Matrix (Figure 16):

Fig. 16: Producer Matrix of competitors

Stage 6: In relation to the competing companies, the Romanian organization is better positioned on the unit costs axis, due to the lower Production Factors Costs (*PFC*). In the long run, however, that competence will lose value as labor costs increase.

If it must move West (W), the organization must develop its Coordination and Control (*CC*) and Continuous Cost Decrease (*CCD*). These two competencies focused on costs are addressed, according to SR EN ISO 9001: 2015 of Quality Management.

Because customers are interested in the precision and quality of surfaces processed by EDM, the organization is interested in increasing its efficiency competence and obtaining a perceived use value as high as possible.

If it is forced to move North (N), the organization must increase its Innovation Competence (*IC*) with action and Technology Competence (*TC*).

By the vectorial composition of the trips, the organization is directed to the North-West (NW), this representing the direction of the competition.

From the analysis of the value chain, it is observed that the values of administrative and management expenses are disproportionate compared to those regarding infrastructure and marketing activities. Resources can be taken from those allocated to management and administrative activities.

For the elaboration of the development strategy of the organization, it is necessary to increase the weights in the organizational structure, through investments in infrastructure, which affects the technological competence and through the development of the marketing department, which influences the economic performances.

The Risk Cube

The Risk Cube tool is applied for the Romanian organization, which aims to develop through the manufacture of EDM machines specialized in the field of micro-processing.

With the help of the Customer Matrix, the evaluation of the Romanian organization product compared to the competitors from Japan (JP), Germany (DE) and France (FR) is performed.

Adding the results from Producer Matrix, we obtained a low PUV and low Efficiency. (Figure 17).

Fig. 17: Combination of Customer and Producer Matrices

If the distance between the Romanian organization and its competitors is large on the axis of effectiveness, it is necessary to create Alliances with other organizations specialized in the field, which could increase the Efficiency by adding chiefly innovation competencies. These organizations are Research Institutes and Universities that achieved results in the research project at laboratory level (Technology Readiness Level - TRL3).

In the first stage, the Romanian manufacturer will develop The Same product on The Same market, based on its high value-added competence, which involves modernizing the EDM machines in the product portfolio, in accordance with current requirements, at low costs and prices.

In the second stage, the Romanian organization will develop new EDM machines for high precision processing, i.e. The New product on the Same market, e.g. micro-EDM by implementing the results obtained in the research projects, by ultrasonic assistance of the material removal process, carried out within the alliances of which it is part (Figure 18).

Fig. 18:The Risk Cube Strategic Options

Conclusions

A series of integrated instruments, available for an organization like Customer Matrix, Producer Matrix and Risk Cube are used to attain and maintain Sustainable Competitive Advantage (SCA).

One can notice that the position of a product in the Customer Matrix, which determines a long-term profitable position on the market is strongly supported by the competencies provided by Producer Matrix, and furtherly, the source of these needed competencies could be indicated by using Risk Cube.

The only effective improvement of Customer Matrix position can be done by appropriate displacements, in the inner of the organization, i.e. within Producer Matrix.

For the presented case study, the Romanian Producer of electrical discharge machines, which has competencies of series fabrication, the effective solution to obtain the improved position in Customer Matrix could be a strategic

alliance with research institutes and universities with high qualified human resources and previous innovation results in this very specialized area.

Further research will be dedicated to better integrated the presented instrumented with forecast methods and applied them effectively for helping organizations to obtain Sustainable Competitive Advantage (SCA) during a longer time horizon.

Abstract

This paper refers to the current situation of the population in the South-Muntenia Region, highlighting the social situation of this region, as well as the factors that influence the evolution of the population. At the national level, there is a demographic decline, due in particular to the low birth rate in comparison with the death rate, but also to the migration of the population, to areas with a higher standard of living. This is analyzed, it is obvious for the situation of its rural area in the South-Muntenia region in the direction of the marked demographic decline, in the situation of care in this regard regarding the need to take measures. Also regarding the works and encourages mentions or a series of measures designed to stop this demographic decline recorded in the analyzed region. Unfortunately, the low birth rate correlated with the high mortality recorded in this area, reveals gloomy prospects regarding the evolution of the countryside in the South-Muntenia region.

Keywords: Rural Development, Demography, Population.

Introduction

The South-Muntenia region is one of the 8 development regions of Romania, with an area of 34,453 kmp. It has 7 counties: Argeș, Prahova, Dâmbovița, Teleorman, Giurgiu, Ialomița and Călărași. In this paper, a series of data was analyzed, both quantitatively and qualitatively. Data from the National Institute of Statistics (INS) concerned the population registered at national level, birth, mortality, nuptiality and divorce, with particular reference to the South-Muntenia region.

The relief is a varied one (south the lowest altitudes, while in the north the highest altitudes are encountered, even over 2500 meters). Regarding the structure of the relief, it is divided as follows:

As far as the hydrographic network is concerned, the Danube River is the main watercourse. There are also other water courses such as: Olt, Argeș, Dâmbovița and Ialomița.

The economy of the region is concentrated in the counties of Argeș and Prahova, being highly industrialized, specialized in the oil and chemical industry, but also in the construction of cars (Dacia). At the top, the main economic activity is represented by agriculture, here meeting some of the largest agricultural farms in Romania and beyond.

In the work of Bold I. et all (2003) it is mentioned that the word "rural" comes from Latin ruris (referring to culture, occupied or arranged territory). Also, in Dona I. et all (2005), the rural is defined as the place that includes all the activities that take place outside the urban area, consisting of 3 parts: administrative communities, pronounced dispersal of the population and the special role of forestry and agriculture.

Material and Method

The purpose of the paper is to highlight the demographic decline recorded in the South-Muntenia development region, located in Romania. By analyzing quantitatively and qualitatively the data on the evolution of the residing population in the urban environment, compared to the rural one, of the birth, mortality, nuptiality, but also of the labor force, it was possible to determine the main causes that led to the demographic decline recorded. The data used in the study, coming from the National Institute of Statistics (Romania), and the period taken into consideration was between 2012 and 2018.

Results and Discussions

During the analyzed period, the population residing on January 1 in Romania registered a decrease of approximately 2.8%, reaching in 2018, a population of 19.5 million inhabitants, compared to 2012, when it exceeded the threshold of 20 years. millions of inhabitants (Fig. 2).

In the South-Muntenia region it is observed that the demographic decline is more pronounced in the urban area, compared to the rural area, so that if in the rural area there was a decrease in 2018 compared to 2012 of about 5.6% (3.23 % at national level), in the rural area during the same period, the decrease was about 5% (2.23 at national level) (Fig. 3.).

This can be determined by the fact that in the urban area predominantly young people are found, due to the jobs located in the urban area, while the rural area is characterized by an aging population and the lack of jobs. All these things cause the young people from the urban area to migrate to other countries, in search of a higher standard of living, while in the rural area, the number of deaths exceeds that of the births, thus causing the population decrease in the rural area (Fig. 3 .).

According to the above table it can be noted that among the component counties of the South-Muntenia region, the most marked decrease of the population registered in 2018, compared to 2012, was found in Ialomiţa county by about 6% (Table no. 1).

Regarding the birth rate in the rural area, it is noted that at national level it registered a decrease of 2.3%, so that in 2012 the number of newborns was 92.6 thousand, while in the year 2018 was only 85.8 thousand people. Also the most drastic decrease was recorded in Calarasi county (-15.6%), while at the opposite pole was Prahova county (-3.2%) (Table no. 2.).

This can be attributed to the low number of young people, who contributed to this decline in birth rates registered in rural areas.

The evolution of mortality registered in the rural area in the South-Muntenia region registered a slight decrease of 0.1% in 2018 (137.7 thousand deaths), compared to 2012 (137.8 thousand deaths) (Table 3.) .

We can see that in the area of rural area in the region of South-Muntenia in 2018, the number of births was only 15 thousand, while the number of deaths was over 137 thousand, so that the number of deaths was 9 times higher only in the case of births, which contributed to the demographic decline at both the regional and country level (Table no. 2, table no. 3.).

The tradition maintained by the generations, regarding the marriage, is maintained in the rural area, so that it presents an upward trend in the South-Muntenia region, because if in 2012 the number of married persons was 6.9 thousand, in 2018 it reached a number of over 9.4 thousand married persons, an increase of 31.8% compared to 2012. However, the largest increase in the number of married persons in the rural area was registered in Giurgiu county, increasing by 58.1 % in 2018 compared to 2012 (Table no. 4).

Table 5: The evolution of the divorces from the rural area in the South-Muntenia region, classified according to the counties in the composition

Regarding the number of people who have divorced in the South-Muntenia region from the rural area, the trend is an ascending one, so that if in 2012, their number was 9.5 thousand, in 2018, their number was over 11 thousand people. It should be noted that although the tradition regarding marriages is maintained, at least in the rural area, it can be observed that if in the last years the divorce met mainly in urban areas, now this phenomenon is quite widespread in the rural area (Table no. 5.).

It should be noted that if at the level of 2018, in the South-Muntenia region of the rural area, the number of married people in the rural area was 9474 while the number of persons who divorced was 2292, with a share of about 24% of the total number of marriages (Table no. 4, Table no. 5).

Source: INS database, accessed 27.08.2019.

At national level, the employed population registered a downward trend, so that if in 2012 the number of people working was 8.57 million people, while in 2017, their number was 8.36 million of people. Also, in 2018, of the total 8.36 million people, 1.74 million were active in the field of agriculture, forestry and fisheries, decreasing by more than 30% compared to 2012, when the population employed in this sector it was 2.5 million people.

Regarding the region of South-Muntenia, reporting the year 2018 to 2012, there is a decrease of 30.9% of the employed population in the field of agriculture, forestry and fisheries. This can be accounted for by the fact that people able to work, have chosen to migrate to other countries, with a higher standard of living, working either in the same field or in another field. Also, technology plays an extremely important role, as the new generations of agricultural machines in parallel with the built-in intelligence packages, counteract the decrease in the labor force requirement of farms.

Conclusions

At national level, there is a sharp decrease in the number of inhabitants, so that if in 2012 their number was about 20.1 million inhabitants, in 2018, it was only 19.5 million inhabitants.

The many problems facing the rural area, including the lack of jobs, contribute to the migration of the young population from the rural area, to the neighboring urban centers, or to other regions in other countries of Europe, especially in the context where the possibility of crossing borders it is no longer an impediment, with Romania's accession to the European Union in 2017.

For example, in the plain area of the South-Muntenia region, the main economic activity is agriculture, which is quite compact, with large and very large farms being highlighted, so that family farms do not find their place in this region. Also, family farms could represent a possible solution to increase the number of inhabitants from the rural area, in the context in which all family members are involved in this type of business.

The lack or poor development of the utilitarian infrastructure, lead to a low standard of living. This favors the migration of the population from the rural area to the urban centers. The development of the utilitarian infrastructure can be solved by accessing the European funds, but the localities whose budgets are anyway low, cannot ensure the co-financing of the projects meant to improve the utilitarian infrastructure.

According to table number 6 we can see that the labor force decreased considerably in 2017 compared to 2012, in the South-Muntenia region by about 31%. This is due in particular to the population that has reached the legal retirement age.

All these problems represent a vicious chain, for which solving these problems in turn will not diminish the exodus of the population from the rural environment. In this sense, concrete action must be taken in all the major challenges that rural areas face.

We must also be aware that the trend, both at European and local level, is leading to urbanization of the population, but even so, the rural area must be protected by making investments designed to slow the migration of the population from these areas.

Résumé

De longue date, la science économique a identifié la confiance comme étant un facteur essentiel de l'échange économique. Plus récemment, les sciences de gestion ont estimé que cette confiance repose elle-même sur l'intégrité, à savoir le respect de la promesse donnée même si l'intérêt économique ou le sentiment envers celui qui a fait confiance a changé. Michael Jensen a affirmé que le respect même de cette promesse fonde l'identité même de la personne, sans toutefois s'expliquer. Le présent travail se propose de mobiliser la pensée de Paul Ricoeur pour étayer celle de Michael Jensen.

Mots-clés : Intégrité, promesse, Ricœur, phénoménologie.

Introduction

L'intégrité fait l'objet d'une recherche assidue par les sciences de gestion depuis le milieu des années 1990. Elle est un facteur de production qui a été trop longtemps ignoré par la théorie (Jensen et al, 2010). Peu à peu, l'intégrité se dessine comme étant une question de promesse honorée, comme nous le verrons dans un premier temps. La phénoménologie de Paul Ricoeur permet de comprendre que le membre d'une organisation honore sa promesse pour des raisons identitaires, comme nous le verrons dans un second temps.

L'intégrité, une question de promesse honorée

Dans leur article séminal sur la confiance, Mayer, Davis et Schhoorman (1995) ont identifié l'intégrité comme étant l'une des trois caractéristiques d'une personne amenant à lui faire confiance, aux côtés de la compétence et de la bienveillance. On comprend qu'il faille de la compétence : à quoi bon, sinon, déposer son bien (l'usus de l'entreprise, son avenir personnel, etc.) dans les mains d'un autre ? On compte sur le fait qu'il saura déployer tout son savoir et son savoir-faire pour le préserver, voire le développer mieux qu'on ne le ferait soi-même. On comprend également qu'il faille de la bienveillance, une forme de savoir-être qui incite, selon son étymologie précise, à veiller sur le bien de l'autre. Mayer, Davis et Schoorman (1995) ont estimé que la bienveillance reposait sur un attachement, entendu comme un sentiment qui oriente positivement envers celui qui est bénéficiaire de la bienveillance. Ils ont ajouté que, hélas, comme tout sentiment, la bienveillance est sujette à changement, pour ne pas dire à versatilité. L'intégrité, autre savoir-être que la bienveillance, est alors cette sorte de force intérieure qui, malgré l'absence de sentiment favorable envers celui qui nous a fait confiance et s'est rendu vulnérable en remettant son bien à notre garde, nous amène à nous comporter conformément à notre parole.

Quelques années plus tard, en 1999, les mêmes auteurs ont proposé une échelle de mesure de l'intégrité :

1. La direction générale a un fort sens de la justice.
2. Je ne me suis jamais demandé si la direction générale allait scrupuleusement mettre en pratique ses paroles.
3. La direction générale s'évertue à être équitable dans ses échanges avec les autres.
4. Les actions et comportements de la direction générale ne sont pas très cohérents entre eux (résultats de l'évaluation à inverser).
5. J'apprécie les valeurs de la direction générale.
6. Des principes sains guident le comportement de la direction générale.

Cite this Article as : Philippe JACQUINOT " Intégrité Managériale : Un Etayage De La Pensée De Michael Jensen Grâce A La Phénoménologie De Paul Ricœur" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

On retrouve, quoique de manière plus détaillée, la question de la tenue de la promesse : il s'agit de mettre en pratique les principes qu'on a énoncés, à commencer par ceux de justice et d'équité.

Simons (2002), laissant de côté la question du contenu de la promesse – les principes de justice et d'équité – s'est concentré sur la question de la tenue elle-même de la promesse. Il a proposé un construit, celui d'intégrité comportementale (*behavioral integrity*), qu'il a défini comme étant : « le schéma perçu d'alignement entre les mots et les actes » (p. 19). Avec plusieurs de ses collègues, il en a donné, en 2007, une échelle de mesure :

1. Les paroles de mon responsable hiérarchique sont en adéquation avec ses actions.
2. Mon responsable hiérarchique tient ses promesses.
3. Mon responsable hiérarchique pratique ce qu'il prêche.
4. Mon responsable hiérarchique fait ce qu'il dit vouloir faire.
5. Mon responsable hiérarchique se conduit en conformité avec les valeurs dont il parle.
6. Mon responsable hiérarchique fait preuve des mêmes priorités que celles qu'il décrit.
7. Quand mon responsable hiérarchique promet quelque chose, je peux être certain que cela va arriver.
8. Quand mon responsable hiérarchique dit qu'il va faire quelque chose, il le fait.

Jensen et deux de ses co-auteurs, Werner Erhard et Steve Zaffron, ont complété, en 2018, le travail de Tony Simons. Ils ont préféré l'expression de promesse honorée à celle de parole tenue. Et ils ont défini la parole honorée comme étant le fait de tenir sa promesse ou, à défaut de pouvoir le faire, dès qu'on le sait, d'alerter les personnes concernées et de remédier au désordre qu'on a pu créer en ne tenant pas sa promesse. On peut être intègre au sens de Jensen et de ses co-auteurs sans l'être au sens de Simons puisqu'on peut ne pas réaliser la lettre de ce qu'on avait promis. En outre, pour Michael Jensen et ses co-auteurs, la promesse peut avoir été faite implicitement alors que pour Simons elle doit avoir été donnée explicitement. Pour Michael Jensen, fait ainsi preuve d'intégrité celui qui honore une promesse implicite alors que, pour Simons, il n'y a pas ici matière à démonstration d'intégrité.

Par ailleurs, Jensen (2014) a affirmé que, pour tenir sa parole, l'intègre fait preuve d'une grande « auto-discipline » (p.17). Autant le calcul coût sur bénéfice doit être fait par l'intègre avant de promettre, autant celui-ci s'interdit un tel calcul au moment de tenir (p. 21). Il s'agit d'un changement radical de paradigme pour Michael Jensen qui avait auparavant assuré que l'homme est un optimisateur permanent (Jensen et Meckling, 1976 ; Jensen et Meckling, 1994), comme l'ont souligné Jacquinot et Pellissier-Tanon (2018).

Dans ce même article de 2014, Michael Jensen a également affirmé que « La parole que l'on se donne à soi-même est une part critique de notre intégrité. Le fondement même de l'intégrité est de se déclarer à soi-même 'qui je suis est ma parole' et 'je donne ma parole à moi-même que je suis une personne intègre'. Sans ce fondement, vous ne serez jamais une personne intègre. » (p. 17). Mais Michael Jensen n'a pas justifié son affirmation. Le chercheur doit s'employer à trouver une telle justification. Il peut s'appuyer sur la phénoménologie de Paul Ricoeur.

La promesse honorée, une question d'identité

La personne intègre est sa parole, a affirmé Michael Jensen. Cette phrase parle à tout lecteur assidu de Paul Ricoeur, phénoménologue de référence en matière d'identité. Bien sûr, Paul Ricoeur a relevé, avec l'essentiel de la littérature, qu'une personne est reconnue grâce à une opération mentale consistant à faire un rapprochement entre celui qui se présente à nous maintenant et celui qui s'est manifesté à nous quelques secondes, jours ou années plus tôt. Et il a appelé cette identité *idemité* (ou mêmeté). Surtout, Paul Ricoeur l'a distinguée d'une autre identité dont il a eu l'intuition et qu'il a appelée *ipseité*. A la recherche de cette *ipséité*, Paul Ricoeur s'est intéressé à l'autre que soi, successivement en tant que celui qui agit, celui qui se narre et celui qui est sujet à imputation morale. Son ouvrage majeur, *Soi-même comme un autre*, publié en 1990, rend compte de cette progression et, spécifiquement plus intéressant pour notre propos, on peut y lire que « la tenue de la promesse […] paraît bien constituer un défi au temps, un déni du changement : quand même mon désir changerait, quand même je changerais d'opinion, d'inclinations, 'je maintiendrai' » (p.149). L'homme est, en effet, capable de placer « la constance à [lui]-même au-dessus des intermittences de [ses] désirs, dans le mépris des obstacles et des entraves extérieures » (p. 267). Cette constance, qui fait qu'on tient sa parole, est l'*ipséité*. Autrement dit, tenir sa parole résulte d'une constance qui est l'être même, ainsi manifesté à soi et aux autres.

Michael Jensen a non seulement affirmé qu'une personne est sa parole mais il a aussi déclaré que l'intégrité repose sur la parole donnée à soi-même d'être une personne intègre. La lecture de l'ouvrage *post-mortem* de Paul Ricœur, *Parcours de la reconnaissance* (2004), nous éclaire également. L'auteur s'est posé la question : « d'où l'énonciateur d'une promesse ponctuelle tire-t-il sa promesse ? » (p. 191). Il a répondu lui-même : « d'une promesse plus fondamentale, celle de tenir sa parole en toutes circonstances ; on peut parler ici de "la promesse avant la promesse".

C'est elle qui donne à chaque promesse son caractère d'engagement : engagement envers… et engagement à… Et c'est à cet engagement que s'attache le caractère d'ipséité de la promesse qui trouve dans certaines langues l'appui de la forme pronominale du verbe : je m'engage à. Cette ipséité, à la différence de la mêmeté [par référence à l'idem] typique de l'identité biologique et caractérielle d'un individu, consiste en une volonté de constance, de maintien de soi, qui met son sceau sur une histoire de vie affrontée à l'altération des circonstances et aux vicissitudes du cœur. C'est une identité maintenue malgré…, en dépit de…, de tout ce qui inclinerait à trahir sa parole » (p. 191-192). Pour Paul Ricœur, l'*ipseité* est donc fondée sur une engagement originel donné à soi-même de tenir ses promesses. Nous pouvons au surplus noter que, dans ce même ouvrage, Paul Ricoeur a élevé la promesse au rang de paradigme (selon son expression même) d'un aspect de la personne.

En définitive, pour Paul Ricœur, l'intégrité est bien, comme Michael Jensen l'a affirmé, une question d'identité et de promesse fondée sur une promesse originelle, faite à soi, de tenir ses promesses. Il s'agit d'ailleurs, pour ces deux auteurs, d'une question paradigmatique. Le présent travail permet, conformément à son objectif, d'étayer la pensée de Michel Jensen en mobilisant la phénoménologie de Paul Ricœur.

Digital Technologies for Communication in Social Work

A. PEREIRA-GARCÍA
Corporación Universitaria Minuto de Dios – UNIMINUTO, Bogotá, Colombia,
alexander.pereira@uniminuto.edu.co

Abstract

The practice of social work has as one of its main characteristics the constant interaction with the users, object of their attention and intervention. In these interaction processes, communication constitutes a fundamental dynamic for the identification and solution of social problems, since social interaction is based on a communicative dimension. In the context of virtuality, accelerated in the context of the covid-19 pandemic, various interactions in social work have moved towards digital spaces. The communication processes, in this way, have now been placed in the virtual world. The document proposes an approach to some reflections on the aspects of electronic communication in social work and the relevance of the issue in the process of training future social workers.

Keywords: Social Work, Communication, Digital Technologies, Covid-19.

Communication and Social Work

The processes of communication constitute one of the most relevant dimensions in social work in accordance with the interactive nature of the discipline. The direct approach to users with the aim of improving their well-being and living conditions implies a process of constant communicative exchange. In practically all scenarios of social work, the ability to communicate effectively is a requirement for the achievement of the proposed objectives. In this sense, Barreto-Pico (2017) states that efficient communication is indispensable for the fulfillment of the social worker's mission.

The social worker acts as a facilitator of the relationships between subjects and social institutions and in this process fulfills various functions such as guiding the population to achieve its objectives and promoting participation in its own transformation processes (Barreto-Pico, 2017). In addition, from an investigative dimension, the professional makes an approach to the particular experiences of the subjects, to their contexts, perceptions and worldviews with the objective of understanding their reality and their problems. In all these areas, the communicational exchange is a transversal dimension in the professional practice of social work.

In fact, the service provided in the resolution of personal or family problems that people suffer has as a background the careful study of the client in their family and social environment, which "involve the transmission, reception and interpretation of non-verbal and verbal messages in order to communicate the nature of experience by sharing thought and feeling and in order to influence the behaviour of others" (Day, 2014, p. 15). From here, communication can be thought of as a process that cuts across social relations, and the way in which communicative processes are established has a decisive influence on relations between professionals and users and on improving the living conditions of the people who are the object of professional attention and intervention.

Methodological Approach

In the framework of the research project "Cyberintervention in Social Work", an approach was made to the experiences and perceptions of social work students in a university institution in Bogotá, Colombia, through the application of semi-structured interview instruments. In this phase of the work, the aim was to identify the relationships between disciplinary dynamics and aspects related to the digital society. Particular emphasis was placed on the relationships between social work and ICTs that deepened as a result of the pandemic. The current contingent reality has highlighted the relevance of digital technologies in the communication processes between social workers and users. This issue becomes important in the dynamics and experiences of virtual and distance care that are generated as a result of the social distancing policies regulated for the control of the covid-19 pandemic during this year.

ICT and communication in social work

Day (2014) has shown that the dynamics of attention to users by social workers have a high communicative component, however, this process is not reduced to the simple provision of information. Attitudes, gestures, among other forms of expression or language, become significant elements to bring the professional and users closer together in the search for solutions to the social problems that afflict them. Given that many people assume their reality as a private matter, a high capacity for empathy and trust is required (Romero, 2017), such that people decide to provide confidential information to professionals seeking to understand their particular reality.

On the other hand, Day (2014) says that many users find it difficult to sufficiently understand the institutionalized and bureaucratic processes that are at the base of the relationship between the State and citizens. The completion of forms and other instruments for recording and collecting information often requires a complex technical process. This often involves the social worker in translating the information so that it is easily understood by users.

Language accuracy, efficiency in the exchange of information, and understanding the intentions and interests of the actors are key aspects of the communication process in social work. In a certain way, these elements are thought of as part of the dynamics of the traditional attention in social work, which are basically a disciplinary paradigm. However, the positioning of digitalization as an extension of social life and, particularly, the situation of the covid-19 pandemic that led to the acceleration of digitalization in many scenarios, have raised questions for the understanding of social work, its approaches, practices and methods.

It is clear that the digital society, thought as a dynamic centered on knowledge, has put in the exchange of information its main characteristic. The so-called information and communication technologies, ICT, have positioned themselves in the contemporary world as structuring factors of social life. Its most relevant characteristic is precisely its capacity of interconnection from the exchange of data. Byrne & Kirwam (2019) state that "social workers continue to recognize the centrality of relationship in social work practice but are trying to build and mediate relationships with service users in a fundamentally changed context since the theorization of relationship in social work was originally developed". Specifically, the different forms of electronic communication suggest a new framework of interaction.

Byrne & Kirwam (2019) state that "modes of electronic communication are not simply add-ons to society but are altering the social texture of society including the ways that people relate and interact with others". Of course, although it seems to be an alternative to face-to-face interaction, virtuality really implies a transformation in the dynamics of approaching the other. In the case of the research project, the students' perceptions about the digital tools were investigated, a majority of informants stated that the ICT mediation constitutes a contingency related to the demand of social distancing derived from the pandemic but that it does not replace the face-to-face approach to the users. The idea of direct contact as part of the practice of social work is ingrained.

However, some studies have shown that consumer demand for online clinical services is increasing, this in a case of inquiry into therapeutic communication practices via email (Mattison, 2012). In a similar vein, Bullock & Colvin (2015) technological communication in the United States has been gradually incorporated into the practice of social work in both administrative and therapeutic tasks. In addition to favoring communication with people who are located in isolated or distant places, digital tools have the advantage of establishing rapid and permanent contact, which generates an attraction for the communication processes, while favoring a greater follow-up of the users and the processes they experience in terms of professional attention. In the research project some informants agree with the perception of the advantages regarding frequent contact with their users, due to the possibilities of telephone and electronic communication supported in the use of social networks.

Molina et al (2015) recall that communication is an agent that models culture, so that the transits of the communicative process into the world of virtuality lead to a modification of interpersonal and institutional relations, the production of meaning, cultural identification and the predominant ethics, among other spheres. Communication cannot be understood simply as an exchange of information but as the staging of life experience mediated by electronic tools. Thus, electronic communication produces a certain type of social relations that can be favored by its mediation or, on the contrary, generate problems for the achievement of an efficient and adequate interaction between professionals and users.

Final Considerations

It has been reaffirmed that communication occupies a central place in practices related to social work given the need for approach and frequent contact with users. The mediation, the interview, the intervention and other processes related to the professional practice of social work are being modified by the relevance that electronic communication has assumed in today's world. These changes are substantial challenges for thinking about social work in the context

of the digital society. In many cases there is a perception of the instrumentalization of digital technologies by social workers, professionals and those in the process of training, given that technological mediation is affirmed as a contingent alternative to the traditional -and official- practices of social work, which are largely based on face-to-face work.

In the course of the research project some aspects have been identified that can be considered key in the intellectual debate on the relationship between ICT and social work. These issues, however, have not been sufficiently addressed in the training processes of social workers in the educational institution under study. This shows an urgent need to assume the reflections on the disciplinary horizon in the framework of the information society. The processes of electronic communication are far from facilitating the exchange of information; on the contrary, what they show is a particular way of understanding the social world, the problems experienced by human groups, and the forms of possible solutions in a reality that has crossed the borders of direct encounter and is built on new foundations, those of digitalization.

Abstract

The impact of cyber security is growing at an exponential rate. This can be attributed to the increase in the number of devices and the increase in utilization of cyberspace, connected devices and networks to store, transfer, access and safeguard information. With the increase in the usage and popularity of cyber security, the researches and studies pertaining to the topic have also increased. This paper focuses on analyzing and scrutinizing existing studies and literature to ascertain the intricacies of cyber security and its importance for organizations.

Keywords: Cyber-attacks, threat, Stalking, Identity Theft, Phishing, Worms, Intellectual Property.

Introduction

The dawn of information has ushered in an era that has led to numerous innovations and inventions. The advancement in technology can be described as a boon to humanity considering the benefits it has availed (Purdy, 2016). But one of the greatest developments that has taken place in technology has to be „Internet". The Internet has not only revolutionized the way people communicate and interact but has given rise to a new dimension known as the Cyberspace.

The term cyberspace seeped into daily vernacular during the 1990s when fields such as networking, digital communication, and internet were on the rise and started gaining prominence. The definition of cyberspace has experienced many variations over the years as the scope of advancements in technology and the utility of the internet has increased. But it can be defined as an intangible domain within which the interaction and exchange of information by computers and an assortment of networks occur.

But along with benefits of a particular entity also comes numerous threats and drawbacks. The drawbacks in the case of cyberspace refers to the cyber-attacks. Cyber-attacks are best defined as a maneuvers designed to bypass the security of a device or network to access, alter or destroy information (Conteh & Schmick, 2016). To fend off such attacks and any other intrusions that might harm the device or network cyber security came into being. Cyber security is best defined as the concept that deters cyber-attacks and protects the validity of the data of a system or network. The evolution of the internet from a medium of exchanging and transferring information to a medium used for conducting business, financial

Cite this Article as: Sayed Sayeed AHMAD, Rabia Saeed MALIK, Ihab WATTAR and Abdul SAMAD "Importance of Cyber Security in an Enterprise" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

transactions and advertisement has highlighted the need for cyber security in order to protect one‟s relevant and confidential information. Therefore, it has become one of the most important concepts and practices in recent times.

The cyberspace has expanded and is now full of a multitude of assorted users, content and information. This has allowed the possibility of the scope of attacks within the cyberspace to access, alter or destroy information. In fact, the number of connect devices in the world have already exceeded the human population and according to Statists, by the year 2020, the number of devices connected to the internet would surpass 50 billion (Statista, 2012). Therefore, adequate cyber security has become a paramount necessity for individuals, businesses, nations, and any entity that possesses or uses a connected device.

The paper primarily aims to „explore the importance of cyber security, the domain of operation of cyber security and its future scope. This paper employs interpretivist approach to qualitative research by interviewing a network security professional. Furthermore, additionally; primary and secondary both types of data are collected for study. The Study concludes that there is a unanimous consent regarding the importance of cyber security to organizations. There is a need for integration of cyber security in training and development to improve awareness and knowledge among employees regarding cyber security. Moreover, organizations also need to systematic review of every system and division to evaluate areas where cyber security is needed while organizations must also realize that there is a need for Cyber security measures and protocols irrespective of the nature of organization.

The interview revealed that while cyber security is an indispensable part of an organization and can effectively deal with cyber-attacks, cyber security protocols and would always be in a situation where they would respond to a threat rather than deal with it proactively.

Literature Review

In the year 2015, an article aimed at exploring the importance of Cyber Security explains the variety of cybercrimes and attacks as: Cyber Stalking, Identity Theft, Phishing, Worms, Theft of Intellectual Property, Trojan Horses, salami attack, DoS and DDoS, Viruses, and Spoofing [1]. The study also provides an overview of the propensity and frequency of cybercrimes and attacks have increased over a span of 4 years from 2010 to 2013. The study does not reach any conclusion and focuses more on the aspect of cyber security against cybercrimes and explains the various types of attacks. It does however highlight the need for cyber security considering the scenario of increasing cybercrimes and attacks.

An article published in the year 2015 in the National Cyber security Institute Journal aimed at focusing on the need of cyber security in journalism [2]. The research begins with highlighting the importance of journalism and the pertinent information prodded by it that helps in creating awareness and informing numerous people, then it pivots to the primary point of the study which is that there is increasing need for journalists to be educated on cyber security and to provide them with relevant tools. The need for journalists to be cognizant about the intricacies of cyber security has increased because of the approach and resources of organizations and government to ascertain the information of journalists and their sources. The study cites instances such as the Watergate Scandal of 1972 and the 2004 case of a CIA source for which a journalist was charged with „contempt of court‟ because of not revealing the source [2]. The industry of journalism and its associated organizations need to be adept at using tools of cyber security. Another instance was highlighted by the study which mentions how the documents leaked by Edward Snowden could not be released in time and were delayed because the journalist, Glenn Greenwald, revealed that Snowden had to guide him in every step on how to securely communicate.

Another article published in the year 2015 in the National Cyber security Institute Journal aimed at focusing on the possibility of cyber security in Healthcare [3]. The research begins with highlighting a crucial point that why is adequate cyber security absent from healthcare systems? The study emphasizes that patients should be provided with an assurance regarding confidentiality and privacy of their information. The study explores numerous avenues though which cyber security could be implemented and how it could complement healthcare. The study explores a multitude of avenues that include “Risk Assessment for Availability” while also exploring approaches such as exception handling and third party-risk management. But perhaps the most important and valid point of the study was the recommendation to develop “Unique Patient Identifier” at a national level [3]. The study argues that development and implementation of such a system would enable in resolving issues related to identity thefts and insurance scams. The study concludes by methionine that the need for cyber security in healthcare is paramount as it would not help with issue of confidentiality and privacy of the patients but it would also help in dealing with other issues such as insurance scam.

A 2016 article in the International Journal of Advanced Computer Research aims at describing the fundamentals of cyber security pertaining to attacks of social engineering [4]. The primary aim of the study is evaluation of the vulnerabilities in the infrastructure of IT aspects of an organization. The study had a broad scope and details the reason behind the growth in cyber-attacks while at the same time it also explores the impact of cyber-attacks on the organization and how cyber security can deal with such attacks and reduce the exposure of the organization. The study explores social engineering and explains how social engineering, the art of exploiting human weaknesses, is utilized by cyber-attacks to disrupt an organization. [4]. The study concludes that the best possible way to avoid and evade such attacks is to improve the level of education provided to employee regarding cyber security and vulnerabilities which can be targeted. Furthermore, it also states that one of the most common targets for such an attack are new employees.

An article in the International Journal of Cyber Criminology, 2014, aims at analyzing the nature of groups related to cybercrime [5]. The study explores the relationship between organization and cybercrime and various aspect of cybercrime including but not limited to definition, scope, challenges, etc. The study offer an insight into how organizations have been created for the sole purpose of committing cybercrimes. The study then cites and analyses cases pertaining to cybercrimes committed by organization and on organizations and their effects, such as Ryan Cleary: DDoS on SOCA; Aaron Swartz: Content Downloader; Andrew Auernheimer: Apple iPad Snoop. The study concludes by highlighting an important question: "whether organizations and individual offenders pursue similar goals. [5]" The study concludes that while there are similarities in the objectives of organizations and individuals both in relation to cybercrimes, there are also differences. It is further stated in the study that there is an apparent lack of information and research into this topic. But the study also highlights an important observation that organized cybercrime is relatively still in infancy and it is bound to evolve into a threat of substantial magnitude. Thus, there is an imperative need to improve the cyber security and adapt to future situations.

The Cyber Security Officer of Huawei Technologies, Andy Purdy, filed a report in the year 2016 that foci sued on addressing the issues of cyber security in context of supply chains [6]. The report claims that while organization invest huge amount of resources to improve their supply chain‟s effectiveness and efficiency, they do not consider other factors that may potentially harm the validity of the supply chain. The study focuses on the concept of supply chain risk management and explores mechanism that can be implemented in the supply chain to minimize risk from the point of cyber security. The report explores the NIST (National Institute of Standards and Technology) framework which intends to help organizations in not only understanding but managing their risks in a manner that propels them towards a stated of preparedness. The report highlights and explores a multitude of assorted factors that affect supply china of organizations while the report also explores various initiatives that are in progress or have been implemented to address the risks of supply chain. These initiatives are: Underwriters Laboratory, ENISA, SAFECode, the initiative by EastWest Institute, etc. [6]. Additionally, the report also analyses various initiatives that have been started and implemented by countries such as Japan, United States of America, China, and UK.

A report in the year 2017 aimed at exploring the intricacies of cyber security in non-governmental and non-profit organizations. The report highlights the fact that while organizations that have profit as their main objective and governments have one primary attribute in common with non-governmental and non-profit organizations that is their intention to secure their data. With the advent of the age of information and computers, every organization irrespective of their objectives have started employing the use of computing to attain effeteness and efficiently in their operations and activities. The report highlights and explores methods and approaches though which non-governmental and non-profit organizations can protect their data while at the same time report also recommends numerous ways which can be used by the organizations to safeguard their data. One of the key aspects which is pointed by the report is that organizations need to generate awareness among their employees and volunteers regarding cyber threats. This report further emphasizes that training and development of employees should include a session of cyber security to provide them information on the concept and to educate them about the fundamentals of the concepts.

Methodology

There are many steps that are included in this research process; literature review, data collection, data analysis, and conclusion.

Data Collection

50 randomly selected employed individuals were given a survey questionnaire of 10 questions. For the purpose of qualitative research, a network securities supervisor of a company in Dubai was interviewed. The interview with the

expert was a semi-structure interview; the primary purpose of the interview was to explore the concept in its practical application. The Interviewee was asked some personal questions and some questions specific to the environment of the company. Some of the answers and information provided by the interviewee has not been included due to their confidential nature.

The interview questions and answers

What are your thoughts about the evolution of cyber-attacks, cybercrime and cyber security?

I believe cyber-attacks and cybercrime have become more common in their frequency. One of the factors that has helped the evolution and spread of attacks and crimes is the fact that they have bifurcated into numerous methods of intrusion. This has helped in increasing their effectiveness and diminishing the capacity of cyber security since for every method a new counter measure has to be created, tested and implemented. Thus, in my view cyber security, even though it has evolved, the pace of evolution is slow in comparison to that of cyber-attacks and cybercrimes.

How often does your company have to deal with attacks?

I cannot provide you with exact details and numbers because of confidentiality and it being privileged information but I can tell you that the frequency of attacks in the case of our organization is not as high as some of the originations of other industries. The frequency and intensity of cyber-attacks and cybercrimes very commonly depends on the nature of the industry in which the organization operates. That being said, our company does have to face attacks but they are minor in comparison and are swiftly dealt with, such attacks include Trojan Horses, viruses, Worms, etc. These attacks usually disrupt daily operations and can infect the entire system if not dealt with in a timely manner.

What according to you is the future of cyber security?

In my personal view, not a lot will change for cyber security in the future. Do not misunderstand me, while I believe that cyber security will always evolve to deal with a cybercrime or cyber-attack, it will always be at a disadvantage because of the nature of attacks. While cyber security can pre-empt attacks and crimes, they can still be of numerous variations and can be altered a bit to attack in a different manner, thus, requiring cyber security protocols and approaches to evolve as well. But it will always be responding to a threat rather than proactively dealing with every threat.

How important is cyber security for an organization?

Cyber security is one of the most important aspects and practices for an organization. The reason for cyber security being of such importance is that it the last line of defense against cyber-attacks and cybercrimes that can potentially ruin an organization by accessing, sharing, deleting or stealing their confidential information.

The interview of the network security supervisor proved to extremely insightful as it provided a pragmatic view of an experience professional in the field of cyber security. The interviewee was helpful in explaining the utility of cyber security in deterring cyber-attacks to maintain the credibility, integrity and validity of the data of an organization. He further pointed out the dangerous repercussions that would have to be faced by organizations if the cyber security is inadequate. Another point was raised by the interviewee: that cyber security protocols would always be in a situation where they would respond to a threat rather than deal with it proactively.

A survey was conducted among 50 respondents to understand their views regarding the need for cyber-security in the particular organization they are working. The results of the survey are described below.

72% of the respondents think that their organization requires proper cyber security and only 28% of the individuals responded that their particular organization does not require cyber security as show in figure 1.

Figure 1

Almost ninety percent of the individuals that participated in the survey responded that their company has cyber security tools to detect viruses in their system. A total of 43 respondents said that their companies have adequate tools to detect the viruses. Only 6 responded with No for that question while one respondent skipped the particular question as show in figure 2.

Figure 2

From the survey conducted it is clear that most of the companies do not have an in-house IT technician to handle their network traffic. Only 40% of the individuals participated in the survey said they have an in-house IT technician to handle their network traffic. 60% of the respondents said 'No' as show in figure 3.

Figure 3

Most of the employees strongly believe that their company is capable of handling cyber-attacks. 86% of the respondents said that their company is capable of handling various cyber-attacks while only a small percentage of people said their company can't handle a cyber-attack. 14% of people responded 'No' for that particular question as show in figure 4.

Figure 4

A good number of people participated in the survey believes that data encryption is an effective way to avoid cyber-attacks and prevent attackers from stealing their data. A total of 44 respondents said that they trust data encryption method to protect their valuable organization information while 6 respondents said the data encryption won't be of much use as show in figure 5.

Figure 5

30% of the individuals that participated in the survey said that their organization network was hacked by hackers at least once. Most of the companies were not able to penetrate by the hackers and 70% of the respondents said that their company was exposed to any cyber-attack in the past as show in figure 6.

Figure 6

When the sampling population was asked about the information security policies in their companies, the results were almost 50-50. 42% of people said that their company had adequate network security policies while 58% of respondents said their companies don't have any information security policy as show in figure 7.

Figure 7

Most of the participants in the survey believe that their company network is not able to penetrate by small time hackers. 78% of the respondents said that their company network is secure and cannot be breached by small time hackers and organizations. A small percentage, 22% of respondents said that their network is even vulnerable against small time hackers and their company network is not all secure as show in figure 8.

Figure 8

Most of the respondents strongly believe that the usage of anti-virus software and network security division in the organization is the best strategy to prevent cyber-attacks. 90% agreed to the use of anti-virus software and 84% agreed to the operation of a network security in the organization. Employee awareness and cyber security policies got 78% and 76% respectively.

Utilization of advanced security technologies got 64% while the departmental security analysis was considered a better strategy only by 30% of the survey respondents as show in figure 9.

Figure 9

When the people participated in the survey were asked about the strategy that could be used by the hackers to get into their system as well into their company network, 94% of the respondents said that by means of portable devices the viruses can get into their system and then to their network. 92% believe that though internet download the hackers gets in to their system.88% and 72% of the respondents believe that online advertisements and e-mails are the strategies used by the hackers to penetrate their cyber security. Inside hacks and outside hacks received 30% each backing and the phishing website strategy and hardware hacks received 68% and 48% backing respectively by the respondents as show in figure 10.

Figure 10

Findings & Discussion

The findings of the study can be divided into sections based on the nature of the information. This also helps in classifying findings on the basis of the type of data, i.e., secondary data and primary data respectively.

The literature review provided numerous important insights into cyber security and its relationship and importance in context of organizations. Few of the key aspects that became apparent during the course of literature review are that there is a lack of awareness and knowledge among employee of organizations regarding the importance and fundamentals of

cyber security. Three of the studies that were scrutinized in the literature review highlighted the importance and need for educating employee with regard to cyber security.

While three studies that were analyzed and reviewed in the Literature Review highlighted the need for improved cyber security in different types and divisions of organizations. Two of those studies pointed to an apparent lack of cyber security and its knowledge in organizations: Healthcare and Journalism. While the third study highlights the need for cyber security regarding supply chain risk management.

One of the studies also highlights the evolution experienced by cybercrimes and cyber-attacks by enumerating its various forms. The study highlighted a very significant fact, since the study was specifically on India; it highlighted the astounding increase in the number of cyber-attacks and cybercrimes, in addition to emphasizing the multitude of intrusions which have to be dealt with by cyber security.

While another study helped in highlighting the relationship of human factor is cybercrimes and attacks. The study provided an interesting outlook on the issues associated with cyber security as it pointed out that while the adequateness of cyber security is important, it is also imperative that the use of the network, system or device be aware about the outcomes and effects of cyber-attacks. The study further highlighted social engineering as a possible blind spot that cyber security cannot deal with even if it does undergo further evolution.

While analysis of the article in the International Journal of Cyber Criminology, 2014, provided interesting findings regarding the relationship between organizations and individual in context of cybercrimes and cyber-attacks. But the findings pertain to the cybercrimes and attacks by organizations rather than on organizations. The study pointed out that organized cyber-attacks and crimes are currently not as frequent as those of individuals but nevertheless they have proven to be harmful and dangerous. The study then provides examples of this point as proof of the problems that might arise for organizations that are targeted by such groups and highlighted the importance of cyber security.

Based on the findings of the literature review and the interview of the network security supervisor, a lot of relevant information has been amassed. The accumulated data has revealed numerous findings which are pertinent in dealing with issues of cybercrime and cyber-attacks.

The discussion will be classified on the basis of the type of data, i.e., secondary data and primary data (literature review and interview).

Some of the major points for deliberation revealed by the analysis of literature review are the lack of awareness among employees in organizations regarding cyber security and associated threats and implications. In the age of information, it should be imperative for organizations to trains and educate their employees in context of cyber security. One of the main reasons that this should be the main focus for organizations is because almost every field in all of the organizations now utilize IT and associated devices and software, this fact combined with the estimation that by the year 2020 there will be more than 50 billion devices connected to the internet should be a sign that should not be missed by organizations that cyber security in indispensable. One of the most obvious ways this situation can be rectified is through proper education and training. Every organization should initiate mandatory sessions on cyber security for each of their employee, regardless of their role in the organization.

Furthermore, industries and concepts that have not adopted cyber security should do so as quickly as they can in order to safeguard their data and information. As mentioned in the article, there can be problems if employees in general are not cognizant of cyber security. The example of Edward Snowden and Glen is just one of the examples in the field of journalism that highlight the need for education and awareness regarding cyber security. Journalists have to routinely interact with numerous informant and sources for information that is potentially damaging, additionally; they are also responsible for protecting the identity of their sources. Moreover, various fields also need to look into the possibility of integrating with or adopting cyber security. One such example is mentioned in a study above, supply chain risk management.

Organizations need to assess all their divisions and activities to ascertain areas that might be vulnerable to cyber-attacks and cybercrimes. Implementation of cyber security at such juncture would help organization in protecting their assets while growing and evolving at the same time. This would also help organizations deal with the fallout that can be experienced from corporate espionage.

Therefore, organizations need to:

- Integration of cyber security in training and development to improve awareness and knowledge among employees regarding cyber security.
- Systematic review of every system and division to evaluate areas where cyber security is needed.
- Need for Cyber security measures and protocols irrespective of the nature of organization.

Based on the findings of the interview it can be said that the importance of cyber security is paramount and undisputed. The network security supervisor emphasized the importance of cyber security at every question and further pointed out that nature of industry and organization matter in the intensity and frequency of attacks. But one of the key points of discussion from the interview is the point that cyber security protocols would always be in a situation where they would respond to a threat rather than deal with it proactively.

This should be a concern for organizations as cyber security indispensable in deterring cyber-attacks. There has to be a conscious collaborative effort between not just organizations but nations in order to create a solution which would enable cyber security to be a step ahead of cybercrimes and attacks.

From the survey, it is clear that cyber security is necessary for most of the companies. Another major finding of the study was that a large number of respondents said that their company was not exposed to any cyber-attacks and still almost every company has already implemented cyber security tools to detect viruses in their systems. Data encryptions in the companies were strongly backed by the respondents of the organization. They agreed that the data encryption method will prevent hackers from stealing their data and company information. Another major finding of the study was that most of the does not have any cyber security policies in their company and still most of them strongly believe that their company network can't be broken by any small time hackers and hacking groups. Utilization of anti-virus software's and network security division in the organization were strongly supported by the respondents as a better strategy to prevent various cyber-attacks and secure their confidential data's. Employee awareness programs, cyber security policies and utilization of advanced security technologies also received decent backing from the respondents. From the survey analysis, it is very clear that the hackers use portable device and infected internet files as a main strategy to get into the systems of the individuals. Online advertisements, phishing websites and e-mails hacks were also employed by the hackers to penetrate the network security of the organizations.

Conclusion

The Study concludes that there is a unanimous consent regarding the importance of cyber security to organizations. However, acknowledgement of cyber security as being indispensable is not important. There needs to be conscious effort on the part of organizations to improve their current measures and protocols of cyber security.

One of the chief concerns is regarding the lack of awareness among employees in organizations regarding cyber security and associated threats and implications. There is a need for integration of cyber security in training and development to improve awareness and knowledge among employees regarding cyber security. Additionally, organizations also need to systematic review of every system and division to evaluate areas where cyber security is needed while organizations must also realize that there is a need for Cyber security measures and protocols irrespective of the nature of organization. The interview revealed that while cyber security is an indispensable part of an organization and can effectively deal with cyber-attacks, cyber security protocols and would always be in a situation where they would respond to a threat rather than deal with it proactively.

The survey assisted the study to have a clear image regarding the cyber security awareness among the various companies. The study showed that portable devices and malicious internet files were commonly employed by the hackers to get into the system of the organizations. The study also revealed that a few numbers of companies were already exposed to the cyber-attacks. Even though most of the companies do not feel that they are not a potential target for the cyber-attacks, still they have implemented various cyber security tools to protect from attacks. Companies can make use of data encryption in their systems to prevent the disclosure of confidential data and information. Even though the hackers get into the network of the company, the data they collect would be useless until they can decrypt the files using the appropriate decrypting key. Organizations should have an in-house IT technician to handle the traffic in the network and

analyses them. The IT technician will be also able to provide adequate advice to the company management regarding the security challenges and adequate steps are to be implemented according to the changing conditions. Implementation of network security division and utilization of anti-virus software are the major strategies that can be used by the companies to prevent cyber-attacks. With the various cyber security strategies implemented by the companies, they strongly believe their network is not vulnerable to small time hackers and groups.

Abstract

Entrepreneurial activities could be perceived as an act of establishing businesses, indulging in risks that involve finance in profits anticipation. Of all tribes in Nigeria, it appears no one has done better than the Igbos in establishing small-scale businesses through a special scheme known as "Nwa-boyi" that evolved from their cultural background. In spite of the prevalence of the scheme in Igbo land, southeast Nigeria and its application for exploits in small scale businesses by the Igbos in villages, town and cities across Nigeria, the connectivity of "Nwa-boyi" with the culture of Igbo land is seemed not to have been fully illustrated in academic literature. The present article intends to address this gap in knowledge using data from secondary source and content analysis as the methodology. The article strives to discover how the value, beliefs and other cultural factors of Ndigbos have contributed positively to the success of indigenous Igbo business mentoring. The paper commends the scheme but suggests its inclusion in the customary law of Igbo land to safeguard against fraud or a breach of agreement between the 'Oga' and 'Nwa-boyi'

Keywords: Cultural Relevance, entrepreneurship, indigenous Igbo business mentoring,

Introduction

Human culture as illustrated in several studies plays eminent roles in the lives of mankind. Such roles involve dictating and shaping of behaviours or conducts; determining means of livelihood etc. In respect of the former, the moral values are impacted on children in every family and any child who lacks moral values is taught to adjust so that he or she can live a successful life. In the latter, some occupations are embedded in cultural heritage and they define how some persons earn a living. In Yoruba land, female genital mutilation is still actively practiced in some communities and persons engaging in the act (alabe) usually earn their living through the occupation.

Apart from culture, the environment could play a cogent role in determining people's occupation. Hence, while some people, by the reason of their culture and environment engage in agriculture and herding or cattle rearing,

Cite this Article as: Dare Ojo, OMONIJO, Chiamaka Ogechukwu, JOE-AKUNNE, Michael C. ANYAEGBUNAM, Edith AWOGU-MADUAGWU and Olusola B. OKUNLOLA "Exploring Cultural Relevance in Entrepreneurship: The Case of Indigenous Igbo Business Mentoring (Igba-boyi)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

some specialise in fishing, trade and commerce etc. This analogy goes to illustrate the major occupations of the three major ethnic groups in Nigeria (**see Table i**)

Table i: The Major Ethnic Groups in Nigeria and Occupations

SN	Ethnic Groups	Occupations
1	Hausa/Fulani	Farming and herding or cattle rearing, art and artery
2	Yoruba	Farming, white-collar jobs, vocation in arts
3	Igbo	Trade and commerce, entrepreneurship
4	Ijaw	Farming and fishing

Source: Researchers compilation, (2020)

It is then expedient to show that all of the above-mentioned occupations contribute to personal and societal development. The place of agriculture/ herding in Northern Nigeria in the production of groundnuts, rice, yams, tomatoes, onions etc could be very difficult to ignore in the lives of prominent farmers in the region and the nation's economy (Adams and Mortimore, 1997). Also, the place of agriculture in areas of food and cash crops - rubber, coffee, timber and white-collar jobs in the lives of successful farmers among Yorubas. The contributions of the elite class in ministries and various agencies to national development are equally crucial to national economy. In Igbo land, studies have shown the contributions of entrepreneurship to personal and national development. For instance, Orugun & Nafiu, (2014) argues that Igbo business persons plays active roles the development of the Nigerian economy vial their entrepreneurial activities which have been considered the backbone of the Nigeria's economy. However, since the thrust of this paper is on Igbo entrepreneurship, its scope shall be restricted to the main strategy of raising entrepreneurs in the region.

Entrepreneurial activities could be perceived as an act of establishing businesses, indulging in risks that involve finance in profit anticipation. This goes to corroborate Schumpeter, (1939) on entrepreneurship being the motivating factor of modernity with specific features like the tendency of taking risks, innovation in areas of being proactive. Although, studies have shown sign of entrepreneurial actives across Nigeria, but it appears none of the two hundred and fifty ethnic groups in the country consider entrepreneurship as a major occupation than the Igbos, in the South East Geopolitical zone.

The seriousness of the Ndigbos in promoting entrepreneurship could be located in their indigenous strategy for raising entrepreneurs via small scale enterprises. This is popularly known as "igba-boyi" which is specially designed for youth to be attached to business mentors in the trade of his choice for a period of four to five years, as maybe agreed by the mentor and the youth parents or guardian. The period is to enable the youth learn the rudiments of business transactions and securing financial assistance to establish his personal business.

As illustrated in several studies, Igba Boyi" evolved from the cultural background of Ndigbos (Nnadozie, 2002; Obunike, 2016; Odili, & Ona, 2017). In spite of the prevalence of the scheme in Igbo land and its application for exploits in small scale businesses by the Igbos in villages, town and cities across Nigeria, the connectivity of "igba-boyi" with the culture of Igbo land is seemed not to have been fully illustrated in academic literature. The present article intends to address this gap in knowledge using data from secondary source and content analysis as the methodology. The article strives to discover how the value, beliefs and other cultural factors of Ndigbos have contributed positively to the success of indigenous Igbo business mentoring.

The paper is divided into three subsections. These include, the introduction, literature review and concluding remarks.

Literature Review

The Concept of Culture

The term culture is perceived differently by authors across the globe but with one focus which is hinged on the beliefs, norms etc being passed from one generation to another Omonijo**,** Anyaegbunam, Okoye, Nnatu, Okunlola, Adeleke, Olowookere, Adenuga & Olaoye (2019). However, the perception of (Bibeau & Corin, 1995; Nastasi & Hitchcock, 2016; Bonnie, Nastasi, Prerna, Arora & Kris Varjas 2017) on culture being: (i) the system of knowledge, meaning and action is considered in this work; and (ii) the beliefs, behavoiurs, substances and other features which a group of persons or groups of people within and outside a given locality shared as imperative to this discourse.

Reason being that the system of knowledge, beliefs and behaviours which are crucial elements of culture could have a strong connection with the indigenous Igbo business mentoring. In recent past, studies conducted on entrepreneurship have shown a link between cultures and people's beliefs, values and behaviours. Since people live by their cultures, the beliefs and values inherent in a given culture could go a long way in determining behaviours.

Thus, the roles of cultural differences between people have a decisive effect and influence a variety of individual behaviours. These include the decision to be self employed instead of becoming an employee (Mueller and Thomas, 2000). Hence, culture serves as the fundamental system of values common to a certain group of people and has the capacity to shapes the development of certain personality traits that motivate persons in the society to engage in behaviours which may not be evident in other societies (Mueller and Thomas, 2000).

Examination of Research on Igba Boyi

Igba Boyi is an indigenous Igbo name ascribed to apprenticeship or business mentoring in Southeast Nigeria. The name has its root in the language and culture of Ndigbos and it means serving masters to secure business skills and finance for establishing small scale business. Thus, it is a kind of informal and unstructured training scheduled for a definite time, which a person must undergo before acquiring entrepreneurial skills.

The practice affords the youth, most especially an opportunity to enroll in business mentoring or apprenticeship for training and financial resources to establish a small-scale business without sourcing for funds upon the completion of the training. The practice according to Orugun & Nafiu, (2014) is strongly connected to the Igbo Trade Apprenticeship System (ITAS) or the commencement of 'Ndigbo' commercial education philosophy (Dibia, 2013).

Since its inception, studies have shown that it serves as the arrowhead of Easterners entrepreneurship as it emphasizes seeking opportunities for investment through creativity, innovativeness and clients' fulfillment as well as the judicial allocating limited resources in a reliable traditional configuration (Orugun and Nafia, 2014).

The review of literature has shown that the practice is similar to modern strategies for establishing businesses in development nations. Such includes venture capital,

Exposition of Research on Entrepreneurship

According to Sarea & Hamdan, (2018), the term entrepreneurship has been in existence since 1732. Its commencement could be traced to the work of Richard Canillton who happened to be the first scholar to ascribe a definition to entrepreneurship as persons willing to carry out forms of arbitrage or getting involved in anything that has to do with financial risk, most especially with respect to a new business (Minniti and Levesque, 2008).

Right from the commencement of the 21st century, the expediency of entrepreneurial activities started gaining grounds among government officials, policy makers and investors as a factor that engenders economic growth and an element of encouraging job creation with the purpose of reducing poverty. Given this, studies for finding how entrepreneurship could contribute to economic growth, job creation and poverty reduction began to increase in most developing countries that are seriously facing the problem of unemployment and poverty.

Consequently, the perspectives of many authors on entrepreneurship are anchored on terms related to snatching the chance or opportunity irrespective of resources Stevenson and Jarillo, (1986); the means of taking decisions on entrepreneurship with a focus on inclusive tactic and style of leadership on the usefulness of identifying opportunities Timmons, (1999); the spirit of challenge and adventure that commercializes the opportunities seized at risk Drucker, (1998) cited in Park, (2017). Others include activities relating to perspicacity or judgment which entrepreneurs consider essential rather than describing it as a psychological state of human life Hisrich and Peters (1998); creating new businesses through management and innovation demonstrate by the entrepreneurs challenging spirit Song (2011) and the involvement of entrepreneurship as an important factor in improving business performance and how efforts should be expended to cultivate competency in business Park and Ahn (2016).

The foregoing is an indication that definitions of entrepreneurship varies and it depends on the situations, ethnic background, countries and individuals who indulge in it. However, the perspective of Miller (1983) which perceives entrepreneurship as a behaviour that re-distribute or re-combines resources with innovation and enterprising spirit as well as risk-taking mind to create value is seems to be more applicable to the practice of indigenous Igbo business mentoring for establishing small scale business.

The practice, right from the stage of identifying opportunity for mentorship to the stage of skill acquisition and financial resources for establishing small scale business involves recombination of resources with innovation and enterprising spirit coupled with risk-taking mind to create value in the sense of business transactions to ease unemployment and to facilitate personal development and to ensure societal development. This gives credence to the perspective of Schumpeter (1939) on entrepreneurship being the motivating factor of modernity with features like risk-taking tendencies, innovation-seeking spirit and pro-activeness.

As argue by Park (2017), central to entrepreneurial activities lies the existence of a positive energy that brings about changes via responding to a changing environment with the mind of innovation and creativity. The emergence of indigenous Igbo business mentoring could be traced to a positive energy developed by Ndigbos for their survival after the Nigerian civil war. As illustrated by Aremu and Buhari (2017), the scheme was designed as a reaction against the acute problem of starvation experienced in the course of the war and the aftermath state of hopelessness. These created in them the mind of innovation and creativity in business via an indigenous apprenticeship model for raising entrepreneurs.

With this practice actively in place, entrepreneurship could be greatly enhanced to address the problem of unemployment and poverty among the youth population. Also, it could assist in solving the problem of low and falling economic growth in a developing country such as Nigeria.

Elements of Entrepreneurship

Scholars have shown various elements of entrepreneurial activities in their studies. For instance, the work of Schumpeter (1939) focuses on how the spirit of entrepreneurs is usually after or looking for innovation, taking risk and engaging in pro-activeness while the study of Lassen *et al*. (2006) emphasized on entrepreneurship features like adventurousness, self-sufficiency, innovativeness and long term orientation. Due to recent times comprehensive and systematic studies, Miller, (1983) contends that taking risk, innovativeness and proactiveness could be considered the prominent elements. Given this, the study discusses the following three characteristics as core elements of entrepreneurship.

Innovativeness

For authors such as Schumpeter, (1939) and Van de Ven (1992), innovation is considered a vital element of entrepreneurship. This is not because it gives room for organizational and cultural management to realise the importance of new ideals and behaviours, but its expediency in stimulating new merchandises and services, unique experiences, research and development for new methods and creativity as well as technological development Lumpkin and Dess (1996). In the view of Lee (1999), which is quite different from the perspective of (Schumpeter, 1939; Van de Ven 1992), much emphasis was laid on innovation arising from market survey, advertising and experimental management procedure arising for organization. Kang (2011) views innovation as a potent strategy for promoting investments for constant development of new technologies. Kang (2011), also add an improvement in products with the view of gaining upper hands in areas of competition as aspect of elements of entrepreneurship.

The emergence of indigenous Igbo business mentoring could be regarded as a new innovation into entrepreneurships in Nigeria that has contributed to national development in areas of impacting skills and rendering financial assistance to prospective entrepreneurs who might have successfully completed mentoring to establish their businesses.

Risk Bearing

Bearing risk as an element of entrepreneurships is considered by Jung, (2015) as undertaking or deciding to take a decision which could be risky in an environment or situation that is not certain with the hope of adequately securing or capturing various opportunities involved. However, studies have shown that risk-taking varies among entrepreneurs (Bin and Park, 2002). Thus, while some entrepreneurs engage in low risk-taking inclination and make cautious decisions so as to avoid the danger of engaging in high risk-taking others strive to engage in high risk-taking tendency. Such entrepreneurs usually strive to make decisions faster in order to capture any opportunity.

The usefulness of risk-taking usually manifests in the degree of entrepreneurs to boldly challenge uncertainties or enjoy taking such decisions (Sexton and Bowman-Upton, 1986). However, Park (2017) believes that such an action in business is only meaningful if entrepreneurs are proactive in making use of opportunities at hand and not just accepting the risks.

Enrolling in indigenous Igbo business mentoring could be regarded as risk-taking. This is because it involves serving for many years, mostly under unpalatable working conditions in anticipation of financial settlement. Although, the probability of acquiring business skill could be very bright but the death of either Oga or boyi could lead to frustration along the way. Also, the oga may decide not to settle his mentee due to the poor state of the economy or market or other flimsy pretexts. In such a case the long-term objective of participating in the scheme could have been defeated.

Pro-activeness

Lumpkin and Dess (1996) view pro-activeness as the entrepreneurs or companies' ability to preoccupy market opportunity or maintaining a principal position in the market. Given this, companies or business can develop new products and also try to find means of obtaining new opportunities in an uncertain environment. Such businesses or organisations can vigorously strive to secure a leading or discriminative position in a newly established market (Kim, 2015). In addition to this, Kim, (1994) argues that proactiveness is the behaviour of entrepreneurs to actively involve in market changes, one step ahead of their counterparts. For Covin and Slevin (1991), it involves business owners competing aggressively more than others. Apart from this, it could be regarded as a future-oriented disposition which permits entrepreneurs to predict the future in order to make strategic decisions.

Considering the above analysis, it could be deduced that entrepreneurs engage in forecasting in order to secure opportunities that are related to market and demand. It could also be reasoned that entrepreneurs are not just simply counteracting their competitors, they consistently introduce some new products/services, development and management techniques into their companies.

Entrepreneurship usually manifests in form of small-scale to middle-scale and larger-scale enterprises. However, the present study focuses on the small-scale business which is to be discussed in the next section.

Study Area

Igbo is equally known as Southeast geopolitical zone of Nigeria (Slattery, 2016). Inhabitants are called "Ndigbo's". The total land area is about 15,800 square miles or about 41,000 square kilometres. It comprises of five states- Imo, Enugu, Anambra, Ebonyi and Abia. The region is enclosed on all sides by large rivers and other local tribes from southern and central Nigeria. Such include Bini, Ijaw, Ogoni, Igala, Urhobo, Yako etc. (Slattery, 2016). Although there are many industries in Igbo land, the major occupation of inhabitants is trade and commerce, which is been facilitated through the traditional apprenticeship known as indigenous Igbo business mentoring.

Theoretical Insight

Anthropological Entrepreneurship Theory

Several theories of entrepreneurship have emerged in academic literature in the recent past Omonijo**,** Adetola, Lawal, Odukoya, Olowookere, Okunlola & Rotimi, (2019). Prominent among them being the anthropological theory which is based or formed or developed on the crucial role which the concept of human cultural heritage plays in determining the success of entrepreneurial activities in a given society.

The theory is strictly associated with works of North and who argue that anthropology entails the commencement of human customs, its development and beliefs which people share per time in their respective localities. Human society is diverse. Similarly, the culture of human beings is diverse. In-spite of that its specificity in every ethnic background is obvious in different societies globally. Thus, as human society is diverse, the culture that determines how humanity lives their lives is varied. However, the specificity of culture in the diversity could be acknowledged in each cultural background across the world and it could influence the success of entrepreneurship. Thus, the connectivity between Igbo culture and Igba Boyi in line with this theory could be perceived in two ways:

Firstly, the belief of Ndigbos in seeing themselves as a communal group who work together on the basis of their common ancestry, language, history, etc. has not only helped the evolution and development of Igba Boyi Obunike, (2016) but its recycling of Igba Boyi in their respective villages, Towns and communities. Youth which could be loitering the street of their communities or engage in criminal activities are constantly recruiting into business mentoring and later be opportune to set up their personal businesses.

Secondly, it appears entrepreneur Ndigbos have realized the role of social interaction in every cultural setting and that must have informed their active involvement in social interactions with indigenes of other ethnic groups where they operate. Social interaction promotes entrepreneurial development and it must have been assisting in the promotion of Igbo businesses outside their geographical locations.

Thirdly, language is an aspect of anthropological entrepreneurial theory which Igbos must have considered and adhere to strictly in order to promote their businesses. The ability of Ndigbos to learn and speak the language of the host community must have been assisting them in their business transactions.

Although, anthropological theory of entrepreneurship undermines the role of opportunity and resources-based theory of entrepreneurship, but the theory is more suitable for an article of this nature because it is indigenously based.

Igbo Cultural Heritage in Connection with Business Mentoring and Development

According to Akeredolu-Ale, (1975) one of the problems besetting the growth of indigenous entrepreneurship in less developed countries is the tendency to underplay the implications of the peculiar history of developing countries. The culture is an aspect of history of any given society and it influences values and motivation for economic opportunities. Among other things, it involves collective means of allotting experience, beliefs, attitudes and values to members of the society from one generation to another. Also, it entails teaching of ideas, imitation and behaviours (Boyd and Richerson, 1985). Thus, the evolution of entrepreneurial activities in local environments is directed via communal /cultural ways of life and beliefs, and the source of business, the sayings of the people as well as their legacy Chachar, De Vita, Parveen and Chachar, (2013). Hence, the belief and communal ways of life, among other things, engender entrepreneurial activities.

Based on the belief of "Ndigbos" the world is called "Uwabuahia" which means a market place. In several studies' markets are described as the epicentres of human communities, social and business or economic interactions (Agozino and Anyanike, 2007). Its existence and the patronage of persons who are business-oriented have been associated with a successful life.

The social interpretation of market in Igbo culture could be viewed in naming the first four days of the week with market days- Nkwo, Afo, Oye and Eke. Each of these markets holds in 4 days, apart from daily markets such as Ekoawka in Awka, Anambra State. Additionally, the culture of Ndigbos states that any child born on any of the following market day is named after the market day (seeTable ii).

Table ii: Market Days, Children Names Among Ndigbos

SN	Market days	Week Days	Children names	
			Woman	**Man**
1	Nkwo	Thursday	Mgbankwo	Okwonkwo or Nwankwo
2	Afo	Wednesday	Ngbafor	Okafor or Nwafor
3	Oye	Tuesday	Mgboye	Okoye or Nwoye
4	Eke	Monday	Ngbeke	Nweke

Source: Researcher's compilation, (2020)

In every culture across the globe, name is very vital, as it goes to illustrate the identity of the people from one generation to another. Identifying market with names in some cultures gives the impression that market is the source of livelihood or success of the people in that culture. (Obunike, 2016).

With reference to business or economic transactions in market places, it could be reasoned that markets deals with economic value which could determine the success or failure of business persons in life. Since the major feature of every market is bargaining, people go to market to buy and sell, but bargaining precede purchasing and whosoever has the greatest power of bargaining with the resources at he or her disposal may likely become more successful in business transactions. This may likely account for why most parents in Igbo land usually employ this philosophy to bargain and negotiate with successful traders in their communities to engage their sons in mentoring for "Idu-Odibo" and skills needed to set up business in order to avoid being victims of unemployment and abject poverty in Nigeria.

Besides, Ndigbos perceive themselves a communal group who work together on the basis of their common ancestry, language, history, etc. Obunike, (2016). This could be used to explain the concept of "Igba Boyi" and its recycling within communities and states in Igbo land. The recycling must have given room for extended families orienting members into "Igba-Boyi" strategy which provides a good platform for entrepreneurship to run through families in many towns and communities in Igbo Land from one generation to another promoting the development of children propensity to follow the footsteps of their mentors or parents from one generation to another.

Therefore, it could be deduced that the culture of Igbo is now enriched with entrepreneurial strategy for economic, social, human and physical development, in as much as Obunike (2016), submits that various communities in Igbo land dominate certain lines of product or business as indicated in **Table iii:**

Table iii: Some "Ndigbo" Family Names, Line of Business and Sources

SN	Family Name	Line of Business	Sources
1	Akokwa local entrepreneurs	Kitchen utensils and household equipment	Obunike (2016)
2	Nando indigenous traders	Pharmaceutical drug business	Obunike (2016)
3	Nnewi indigenous entrepreneurs	Motor parts and transport business	Egwu, Ogbu, Ogunji, Oselebe & Udu (2011)
4	Alor indigenous entrepreneurs	"ogboabada" (wrappers),	Obunike (2016)
5	Abiriba indigenous traders	Okirika" (second-hand materials)	Obunike (2016)
6	Agulu indigenous traders	Bread making	Obunike (2016)
7	Ebonyi indigenous traders	Petty businesses and farming	Obunike (2016)
8	Awka-Etitipeople	Cosmeticsline of business	Obunike (2016)
9	Uke people	Tobaccostuff and articles	Obunike (2016)
10	Nsukka entrepreneurs	Palm wine	Obunike (2016)
11	Awka indigenous traders	Blacksmithing	Obunike (2016)
12	Others		

Source: Researcher's compilation, (2019)

Dwelling on the above, one could agree with Obunike (2016) that Igbo entrepreneurs engage entrepreneurial skills in increasing and forming new markets through opportunity utilization which could be a catalyst of economic growth and national development.

Besides, the fascinating aspect of Igbo culture lies in what is regarded as self-help and self-enterprise. Instead of relying of human connections Ndigbos rely on self-help. This seems to have become a song and an ideology in Igbo land.

Concluding Remarks

This work discussed the connectivity between the culture of Igbo land in southeast Nigeria with 'Igba Boyi', the indigenous apprenticeship for raising entrepreneurs among the youth population. From the inception of the scheme, its usefulness in raising business persons to create wealth and employment for 'Ndigbos' has been documented in the literature. Apart from that, other literatures have illustrated its contributions to economic development of Nigeria (Orogun and Nafiu, 2014). This goes to show that some people are still living by their culture, even in modern society where people are discarding some of their cultural practices, because they constitute impediment to national development.

This paper has brought to the fore the fact that while some cultural practices are harmful and constitutes impediment to the economic and human development, others such as the culture of Igbo land is on the side positive side. The positivity could be located in the raising successful business persons and contributing to wealth and job creation to foster human and economic development. The paper is of the view that if every aspect of human culture is positively employed in the same way the culture of Ndigbos has been deployed to entrepreneurship, some of the problems confronting development in Nigeria could be greatly resolved. The paper advocates for the support from government at all level to enrich the scheme for greater impacts in the lives of the youth population.

Abstract

Previous studies have shown several traditional apprenticeships in different vocations or occupations. These include dying, pottery, the weaving of cloth and hairdressing known as "onidiri" in Yoruba land, southwest Nigeria etc. Previous studies have shown that most of these occupations are in existence in other geopolitical zones of Nigeria except the indigenous Igbo business mentoring which is strictly restricted to Southeast Nigeria. Although, most of these apprenticeships are meant for skill impartation, spite of that it appears that indigenous Igbo business mentoring is unique in certain areas which are yet to be fully illustrated in academic and business literature in Nigeria. The present study intends to address this flaw in knowledge. It engages data from the secondary source which means, materials from the library and internet were used to collect information for the study while it considers content analysis as the most appropriate methodology due to its nature. The paper argues in the concluding section that the selected forms of apprenticeship share a common boundary with indigenous Igbo business mentoring but strictly different in areas of the financial assistance known as "idu-odibo" available for the youth who engaged in the scheme ("igba-odibo") but such an opportunity is not in existence in other apprenticeships. Where payment is concerned in other apprenticeships, it involves apprentices paying for the skills learnt and certificates to be issued for practice. The idea of masters or mentors offering financial assistance to the apprentices for a start-up makes the indigenous Igbo business mentoring a unique one.

Keywords: Differences, selected forms of Apprenticeship, indigenous Igbo Business Mentoring,

Introduction

Several decades ago, before the advent of British imperialism, Nigerians main sources of income were farming, herding, fishing, petty trading, occupations in art and craft etc., depending on people's cultural backgrounds in most cases. Then, Nigerians never experienced high level of unemployment, poverty and criminality that characterize daily life in towns, villages and cities across Nigeria today (Olawale, 2018). Apart from the social problem of slave

trade Ibenegbu (2017), Nigerians never had it so rough in terms of what to eat, wear and where to live. The advent of colonialization brought about white-collar jobs in various organisations created by the colonialists. The quest for literacy in running colonial administration and other colonial establishments resulted in the introduction of formal education as a major means of skills acquisition (Robin, 2011). Thus, various schools were established by the colonialists and allied missionaries to impact knowledge on Nigerians (Metz, 1991).
At independence, Nigerians were still engaging in farming, but in collaboration with white- collar jobs, trading, herding fishing etc. until crude oil was discovered at Oloibiri in Delta State, precisely on Sunday 15th of January 1952, by Shell Darcy, currently called Shell Petroleum Development Company of Nigeria (SPDC). Due to the first time of unearthing crude oil which had the capacity of yielding or producing lucrative international trade to earn foreign exchange for national development, the discovery was regarded as historic (Internet Archive, 2011)

Besides, the breakthrough was recorded after fifty years of failed oil exploration and presented a great opportunity of flinging Nigeria into the publicity of the Petro-State globally (Internet Archive, 2011). However, instead of employing the proceeds from crude oil to upgrade and develop subsistence agriculture to extensive and intensive farming like that of Denmark in Europe, Ministry of Environment and Food of Denmark (2016); invest in quality education like South-east Asia to spur advancement in science and technology, the Nigeria elite, both in the military and politics squandered the resources and plunged the nation into a recession which eventually marked the commencement of high rate of unemployment and poverty (Morphy, 2007).

The adverse effects of unemployment and poverty among others resulted in the escalation of criminality, mostly among the youth population (Omonijo, Anyaegbunam, Obiorah, Nwagbo, Olowookere & Caleb, 2019). The reaction of the policy-makers to the high rate of poverty, unemployment and criminality, although not with an honest intention, led to the inclusion of entrepreneurial studies and apprenticeship education alignment schemes in the school curriculum Decker, (2019) with the aim of permitting or enabling graduates become self-employed after graduation.

Prior to the introduction of entrepreneurial studies in higher educational systems, apprenticeships were more or less left for drop-out students and students who had primary or secondary education but couldn't proceed to higher institutions due to poor academic performance or lack of sponsors or both Olulu & Udeorah, (2018) while education to higher institutions was meant for academically-inclined students.

However, the scenario began to change with the high rate of unemployment and poverty that negatively affected all classes of people, such as educated, uneducated, brilliant not brilliant, primary and secondary etc. Since educationally inclined students began to experience unemployment and poverty, most of them began to participate in entrepreneurship, vocational training and apprenticeship for self-employment as alternatives to white-collar jobs (Adesina, 2013; Olowookere, Emuchay, Babalola, Odukoya, Omonijo, Adekeye and Agoha, 2019).

The benefit accrued to such innovative may not be restricted to graduates themselves, but other skilled and unskilled persons who could be employed in such employments. Although both entrepreneurship, vocational studies, apprenticeship are very crucial to this discourse, the paper is more or less interested in an apprenticeship which could be viewed as a special arrangement for skill transfer between mentees and mentors in some traditional and modern occupations. The arrangement usually lasts for a couple of years to enable mentees to acquire skills required for effective practice.

Studies have shown that apprenticeship has been in existence in the world for several decades (Morgan, 2001). For Morgan, (2001) in particular, its origin is traceable to the medieval period in Europe, prior to Nigerians contact with West that brought about modernity and introduction of apprenticeship in modern occupations that were not well pronounced in the past. These include tailoring, repairs in electronics, machines, bicycles, motorcycles, cars etc. However, studies have shown that tradition apprenticeships are still in existence in occupations such as dyes and dyeing Akintonde and Areo, (2013), cotton spinning Sani (2013); pottery Gosselain, (1992); Smithing Ogundele (2005); blacksmithing David & Sterner (2012); iron smelting Sani (2013), manufacturing Oyeneye, (1980), Igbo traditional business school Agu & Nwachukwu, (2020) etc. in Nigeria

While the works of the above authors are commended for focusing on traditional occupations where apprenticeships are still practiced in Nigeria, it has been observed that these authors ignored the differences between other forms of apprenticeships and indigenous Igbo business mentoring which is regarded as a traditional method of engaging

apprenticeship for promoting small-scale enterprises and entrepreneurship in Igbo land, south east geopolitical zone of Nigeria.

Although, the work of Oyeneye (1980) focused on informal sector repairs services and manufacturing enterprise, while Agu & Nwachukwu, (2020) focused on Igbo traditional business school which is very relevant to the present study, the two studies are not without flaws. These include the restriction of Oyeneye, (1980) study to the informal sector repairs and manufacturing enterprise in Yoruba land and that of Agu & Nwachukwu, (2020) on Igbo traditional business school without any consideration for examining the differences between other forms of apprenticeships and indigenous Igbo business mentoring.

The importance of this piece is hinged on an apprenticeship which some authors have considered a viable strategy for personal empowerment and societal development but it could be observed that it has been underused in Nigeria in providing solutions to the problem of poverty and unemployment in Nigeria.

The paper is divided into three subsections. These include the introduction, literature review and concluding remarks.

The Study Area

Igbo is equally known as the Southeast Geopolitical Zone of Nigeria (Slattery, 2016). Inhabitants are called "Ndigbo's". The total land area is about 15,800 square miles or about 41,000 square kilometres. It comprises of five states- Imo, Enugu, Anambra, Ebonyi and Abia. The region is enclosed on all sides by large rivers and other local tribes from southern and central Nigeria. Such include Bini, Ijaw, Ogoni, Igala, Urhobo, Yako etc. (Slattery, 2016). Although there are many industries in Igbo land where some persons earn a living but the major occupation of inhabitants is trade and commerce. Some authors have strongly associated the growth in trade and commerce in Igbo land with the traditional apprenticeship system known as indigenous Igbo business mentoring (Obunike, 2016; Iwara, Amaechi & Netshandama, 2019).

The Conceptual Clarifications

Apprenticeship

In this piece, apprenticeship is considered as a learning process whereby persons who are a novice in a particular field of human endeavour try to practically engage in training. Such training aims at turning them to professionals at the end of the training and through years of experience or practice after the training. The training of such usually involves structured and unstructured programmes. The structured aspect could be considered on-the-job training and it requires acquiring knowledge, skills, attitude or discipline needed to function effectively in a given work. The unstructured apprenticeship is usually engaged in traditional occupations, where the rules of formal organisations may not suffice or be strictly applied.

Authors such as Craig and Bittel, (1967) posit that apprenticeship could be a combination of related technical instructions and on-the-job training to grant an opportunity for employees to learn the theoretical and practical aspects of the trade, craft and other jobs. Besides, Haliru, (2019), argues that it can be in form of the Business Apprenticeship Training Centre (BATCs), like the one in Kaduna, which was set up to train Nigerian youth nationwide could be regarded as one of such training since it focuses on vocational training for a trade, commerce and industry.

In another dimension, Anyanwu (1981) submits that apprenticeship is a system of helping new workers to acquire practical training to complement theories learnt in educational systems to fulfil the requirements of new works. In addition to the above, an apprenticeship could be viewed as a way of integrating guidance and counselling on mentees since most of them reside with their mentors.

Studies have shown that the length of apprenticeship varies across professions or sectors and culture and in most cases, such depend on the proficiency of the mentees. While those who are very brilliant could spend lesser years mentees who are not easily catching up with the training could spend longer years.

The main purpose of encouraging apprenticeship is to make provision for people to develop their potentials for immense contributions into their personal lives and societal advancement.

The drive for apprenticeship reached the climax in Nigeria when the rate of unemployment began to increase at an alarming rate (Omonijo, Adetola, Aborishade and Olowookere, 2020). The negative effect of the high rate of unemployment-poverty and high crime rate prompted the government to introduce National Directorate of Employment to train persons to be self-employed in some of the occupations in **Table i** and others not listed.

Davy & frakenberg, (2019) divides apprenticeship into two, independent and cooperative apprenticeships. The former is being organized by employers of labour without the involvement of a higher education system and their curriculums. In this case, theories learnt on campus are not relevant to the practical training designed for apprentices. In cooperative apprenticeship, employers of labour and educational systems usually organize and manage apprenticeship.

Also, Olulu & Udeorah, (2018) discussed two types of apprenticeship. The first being customary apprenticeship which can be categorized along with the ethnic groups. This includes the indigenous Igbo business mentoring. The second aspect is the apprenticeship under the Nigerian Labour Act of 2014. This Act stipulates that apprentices comprehend the terms and conditions of practices such as age requirement, freedom to decide either to enrol in apprenticeship or not.

The main purpose of apprenticeship is to stimulate self-employment among the youth population but the drive to ensure effective trained in skills, trade and learning is very weak in Nigeria due to several problems. Such include the outdated law governing apprenticeship which is dwindling the spirit of entrepreneurship among the youth population (Olulu & Udeorah, 2018).

Mentoring

Mentoring according to Bozeman and Feeney, (2007) cited in Idemudia, (2011) is a process involving the transformation of knowledge (formal or informal), social capital and psychosocial backing considered by the beneficiary as appropriate to work. This author also argues that it entails face-to-face informal communication during a sustained period of time, between persons who are considered to possess cognate knowledge and individuals who are novice (protégé) Idemudia, (2011).

Dwelling on the above definition, mentoring could be considered a process that involves time, an assistance process, the relationship of self-development between a mentor and protégé Idemudia, (2011). The mentor is generally expected to mediate an expert knowledge for the novice, help develop the novice's full potential in a diverse area of human endeavours (Ilieva-Kolev, 2015; Kunaka and Moos, 2019). For Kunaka and Moos (2019), it

has successfully been engaged as a valuable private development instrument in both business and academic environments as it bridges between business and academia. However, the thrust of this paper is on the indigenous Igbo business mentoring and its contributions to small scale enterprise and development.

The Concept of Indigenous Igbo Business Mentorship

The concept of indigenous Igbo business mentoring is a new form of apprenticeship in trade. Several authors have used different names to describe the concept but nearly all of them are related to Igbo names. These include "Imu Ahia", Agozino, & Anyanike, (2007); "Igba-odibo" Obunike, (2016); "Nwa Boy" Omonijo, Adetola, Lawal, Odukoya, Olowookere, Okunlola & Rotimi, (2019); "Igba-Boyi" Iwara, Amaechi & Netshandama, (2019) and others. Hence, any of the above terms is used to describe Igbo business mentoring in this piece.

The concept is relatively new in academic and business literature due to its neglect for several decades. However, a cursory examination at the practice across Nigeria among entrepreneurs shows that it could be regarded an indigenous form of business mentoring that permit youth to acquire business skill and financial assistance to set up their small-scale enterprises in order to better their lots, family members and society at large. It could also be regarded as another form of informal education that lunches youth into the business world. Apart from that, the concept could be regarded as another form of apprenticeship that ensures skill acquisition for youth in trade and commerce. In addition to the above, "Nwa Boy" is considered Igbo model of rising entrepreneurs since its applicability is peculiar to the South-East Geo-Political Zone of Nigeria (Udeze, 2014 cited in Omonijo, *et al*., 2019).

The Indigenous Igbo business mentoring could be akin to the Cognitive Apprenticeship Theory developed by Collins, Brown and Newman (1989) as the process where a principal of a skill teaches that skill to an intern in order to develop the potentials in him or her.

Its origin could be considered post-civil war phenomenon in South-East Geo-Political Zone of Nigeria and it could be associated with the quest for survival among youth after the war. As illustrated by Aremu and Buhari (2017), the acute problem of starvation experienced in the course of the war negatively affected them and it prompted them to device ways of settling themselves in business. The concept according to Orugun and Nafiu (2014), later became an indigenous apprenticeship model for raising entrepreneurs through the Igbo business learning culture otherwise known as Igbo Trade Apprenticeship System (ITAS). This apprenticeship scheme is considered unstructured training or scheme arranged for a definite period of time, which youth undergo so as to gain a desirable aspect of entrepreneurship skill through the development and automation of the ITAS in order to earn themselves a business of a lifetime (Dibia, 2013 cited in Omonijo, *et al.,2019*).

According to Ejo-Orusa (2019), there are two main forms of the 'Nwaboi' apprenticeship. These include 'Nwaboi' who learn a craft or skill, which is generally called 'Imu-Oru Aka' and those who learn a trade. 'Ndigbos' call this 'Imu-Ahia'. However, it should be noted that the scope is very wide, as it accommodates different types of business transactions, crafts and skills. Ejo-Orusa, (2019) also argues that the system is more traditional and never integrated with an organized private sector and the armpit of government support and oversight.

Just like other forms of skill acquisition, indigenous Igbo business mentoring is not without flaws. Such include the connectivity of the scheme with child labour. Studies have shown that most teenagers who supposed to be learning in educational systems are running the scheme in Igbo Land. The implication of males preferring apprenticeship to education in any society could be very grave because, with education, national development could be very difficult to attain.

Demarcation Between the Selected Forms Apprenticeship and Indigenous Igbo Business Mentorship

In this study, occupations, where apprenticeship is being carried out to train intern, is regarded as forms of apprenticeship. Some of such crafts are indicated in **Table ii**

Table ii: Various Forms of Apprenticeship

Source: Researcher's Compilation, (2020)

According to Olulu & Udeorah, (2018), these forms of apprenticeship are widely engaged by persons of different ethnic backgrounds in the country, but they are prevalent among the Hausa/Fulani and Nupe in Northern, Igbo in the South East and Yorubas in the Southwest. While some of them could be related to the cultural background of people, others are not. Those that are related to the culture are being passed from one generation to another.

In respect of the present study, apart from trading, the forms of apprenticeship listed in **Table ii** may not relate to the indigenous Igbo business mentoring, because the scheme is purely on business transactions while some of the occupations listed are crafts and arty. However, the connectivity between apprenticeship and indigenous Igbo business mentoring could be located in skill impartation for self-employment and betterment of one's life as well as societal development.

In terms of the differences, the following line of distinctions can be drawn between the two:

In apprenticeship mentioned in **Table i and ii,** apprentices usually pay money for skill acquisition but the enrolment and training under indigenous Igbo business mentoring are free. Apart from that, the 'Oga', the mentor is responsible for feeding, accommodating and the health care of any 'Igba Boyi', mentee under him throughout mentorship. The case of apprenticeships in **Table i and ii** is quite different. Nevertheless, the probability of one's siblings coming to learn a trade under the tutelage one's brother or sister, may not be ruled out. In that wise, the mentor has dual roles to perform. These include the roles of a brother or sister, as the case may be, guidance, provider of accommodation, feeding and health care, and even the money to be used to establish the business or trade at the end of the apprenticeship. This means, the biological bond has a strong relationship with apprenticeship but the case of indigenous Igbo business mentoring is quite different. Without any biological affiliation, such responsibilities are being performed to persons of Igbo extraction.

Further to that, forms of apprenticeship listed in **Table i and ii** are not directly connected to one tribe in Nigeria Olulu & Udeorah, (2018), persons of different ethnic backgrounds usually engage them for skill acquisition and as a method of self-employment while indigenous Igbo business mentoring is strictly connected to the culture of 'Ndigbos'. Such a connection could be found in 'Ndigbos' perceiving themselves as a communal group who work together on the basis of common ancestry, language, history, etc. Obunike, (2016). This could be used to explain the concept of "Igba Boyi" and its recycling within communities and states in Igbo land. The recycling must have given room for extended families to orientate members into "Igba-Boyi" strategy. The strategy that has provided a good platform for entrepreneurship to run through families in many towns and communities in Igbo Land from one generation to another promoting the development of children propensity to follow the footsteps of their mentors or parents from one generation to another (Obunike, 2016).

Apart from the above, apprentices who engage in skill acquisition in apprenticeship listed above usually sought for funds to establish their small-scale businesses. Although, their parents, relations, guidance or well as wishers could be of help in providing the required funds for a start-up, it may not be compared with indigenous Igbo business mentoring that makes provision for such funds through the 'Oga' at the end of mentoring. At any rate, cases of some 'Ogas' defrauding their 'Nwa Boyi' may not be ruled out, but it appears such cases are not common.

While the above forms of apprenticeships are occupations on their own (**see Table i and ii**), indigenous Igbo business mentoring comprises of several businesses as illustrated in **Table iii.** Thus, its engagement is not restricted to only one trade or craft but several other business engagements.

Concluding Remarks

This paper examined the differences in selected forms of apprenticeship and indigenous Igbo business mentoring. Although, some previous studies have shown that the two are strongly related in areas of skill acquisition indigenous Igbo business mentoring is quite different in areas of providing accommodation, feeding, health care and financial assistance for the apprentice. The provision of funds alone could be viewed as great assistance considering the problem of raising funds for a business start-up in contemporary Nigeria. The unique aspect of indigenous Igbo mentoring lies in accepting apprentices and according them shelter, food, health care to survive in the course of mentoring and making provision for funds to establish a business at the end of mentoring without any biological association.

This to some extent can be compared with the apprenticeship law in South Africa that makes provision for financial assistance and company attachment or start up pack for apprentices at the end of training. Although, company attachment or start-up pack is not applicable to Igbo business mentoring, because the government of Nigeria is responsible to the plight of common man but their selfish interests. Thus, the financial assistance rendering to apprentices at the end of their apprenticeship comes only from the faithful masters who are committed to transform the lives of the youth population. This paper lauds such a humanitarian service to humanity and hope that it would be kept alive and be upgraded and extended to other areas of life. Also, apprentices "igba boi" who serves their masters meritoriously are commended for their contributions to their masters' business development. This paper hopes that if the mutual relationship is kept alive and greatly improved on it could be of great assistance in building or encouraging self-employment drive in poverty and unemployment ridden society like Nigeria.

Abstract

In modern society, several studies have focused on women affairs in both developed and developing countries. Through some of such studies, some significant improvements have been recorded in the status of women in developed nations while the reverse has been the case in most developing countries such as Nigeria, mostly in the areas of education, maternal health, entrepreneurship and national development. This means women in developing countries are negatively affected in terms of education, maternal health, entrepreneurship and contributions national development in Nigeria. The present paper intends to discuss how women are negatively affected in these areas using data retrieved from a secondary source and content analysis as its methodology. The article used radical feminism theory to gain insight into the plight of women in Nigeria and advocated equal opportunity for men and women to develop their potentials in its concluding remarks. This could go a long way to ensure the transformation of women lives from poverty to affluence and enhance their immense contributions to societal development. Since contributions to national development depend on potentials which do not have any gender connotation, equal opportunity should be granted to male and female for capacity building. Such an effort could greatly enhance national development than when only one gender (male) is solely empowered.

Keywords: Patriarchy, women's education, maternal health, entrepreneurship and development

Introduction

The term development has occupied the mind of mankind for several decades but the yardsticks which are being used to determine the concept have remained unstable over the years. Such include variables like politics, economy,

education, health care, nutrition, dwelling, etc. Although these are all relevant concepts in the field of development but the concern of this article in hinged on the human aspect which is generally known as human development.

Human development is the means of expanding the abundance of human life; instead of focusing on economic growth which may not reflect positively in the lives of ordinary citizens the focus of scholars in this area of sociology is hinged on how life is been made comfortable for mankind. Hence, UNDP (2019), argues that it is a strategy that human beings employ to create fair opportunities and choices for a better lifestyle.

In recent times, such strategies include a country's level of literacy, health care, unemployment and poverty level, entrepreneurship drive (Binder & Georgiadis, 2010). However, it could be noted that these variables could make meaning or be useful when human beings are allowed to develop their potentials irrespective of gender. On that ground, national development could be achieved faster and easier than when only one gender (male) is empowered.

Despite this, studies have shown that women's contributions to development, mostly in developing countries are hindered due to the norms of patriarchy. The norm for several decades has been empowering men to subjugate women, not minding their indispensable roles in society (George, Ozoya & Amoo, 2017; Afolabi, 2019).

The roles of women christened as indispensable in this piece might not be an intention to undermine the roles of men in development but an attempt to broadcast and commend the burden of women on crucial aspects of human life which are absolutely beyond the reach of men. These include:

a. The conception of babies for nine months;
b. Bringing forth of babies or giving birth to them in a painful situation;
c. Nurturing and educating children firstly by informal and later by formal method; and
d. Developing children morally, socially, religiously and psychologically.

These are cogent aspects of life that are exclusively meant for women. They are not only essential in maintaining society but crucial in transcending human society from one generation to another. Any carelessness on the part of women to adequately enforce the above-mentioned roles could lead to the escalation of indecency, abnormality, truancy, moral decadence, criminality in human society, all of which undermine national development.

Dwelling on biology and divine roles in human society, the encroachment of men into most of the above roles could be regarded as an exercise in futility. This is because it would be considered an abnormal or a taboo for men to develop breast, virginal, conceive and give birth to babies. Besides, the role of breadwinner ascribed to men in the society appears to have made it practically impossible for them to perform other roles of women which are not related to biology and divinity.

To 'win bread', a lot of energy is needed to be dispensed outside the home in work-related activities from morning till evening, and if possible, till night. Thus, the execution of such a vital role goes with physical, financial, social and psychological challenges. Thus, when men arrive home, they are expected to bath, eat, relax and sleep so as to be refreshed for the assignments lineup for attention or execution the next day. Although, in some homes, women are breadwinners, yet they are still subjected to subjugation despite the fact they carry out the role exclusively meant for men.

In spite of the above-mentioned indispensable contributions of women to life, the priority places on women affairs, most especially in areas of education, health, and entrepreneurship appears to be very weak in developing countries. Although, some literature state that women are well treated in developed countries, but the case of developing countries, where millions of women are seriously experiencing subjugation due to the norm of patriarchy (Okeke, Anyaehie, Ezenyeaku, 2012; Solomon, 2018) could be regarded as an issue of concern to scholars worldwide.

Patriarchy is a cultural practice that supports the subjugation of women and the superiority of men without any scientific evidence. Solomon, (2018) argues that patriarchy emerges from Greek word "Patriarkhēs" which literarily means the father of a given race or the chief of a race while authors such as Christine & Dudley Jr., (2020) traced the source of patriarchy to two Latin words "Pater (father) and arch (rule)", all translates to the rule of the father, strongly backup by the norm of patriarchy.

The irony is that the incapability, irresponsibility, insensitivity, lack of ingenuity and brilliance of a man does not confer the title of rulership or dominion on a woman who is more capable, sensible, brilliant, sensitive and responsible than the man in the family. His inability to perform social, cultural, and economic responsibilities in the family is immaterial. So long a man gets married to a woman, he has automatically become her superior in

developing countries and it appears the pathetic situation is aggravating due to the nature of developing countries which is characterized by illiteracy, poor exposure and underdevelopment.

At the root of patriarchy lie norms, beliefs and practices that determine how human beings live their lives. The addiction of men, to these norms, beliefs and practices is responsible for behaviours that manifest in the maltreatment of women. The irony of it all is that modernity and global campaign for its eradication are yet to yield a fruitful result largely because the practising communities are sticking to their tradition or culture. Thus, in spite of the general outcry for change, studies have shown that the position of women has not improved greatly in many developing countries, including Nigeria, most especially in their access to education, maternal care, entrepreneurship and contributions to national development (Firestone, 1970; Hanisch, 2009; Feminist Majority Organisation, 2020). It is on this premise the present article was conceived. The article is sub-divided to deliberate on the concept of education and its negative effect on women, health care, entrepreneurship and contributions to national development.

Literature Review

The Concept of Education

Education can be viewed as the wealth of knowledge and understanding which human being usually acquired at the end of studying or training in a particular field of human endeavour. Also, it could be regarded as a means of developing potentials in all spheres of life. It can equally be viewed as a process of obtaining literacy or skill needed to transform one's life, family members and the entire society in as much as it is a major requirement for securing work placement, affluence, influence and human development in general (Sivakumar & Sarvalingam, 2010). Thus, it is the bedrock of national development (Odia & Omofonmwan, 2007).

The foregoing is an indication that without education, the transformation ever recorded across the world could be practically impossible. The immense development in the field of education is responsible for the advancement in science and technology that has brought comfort to human beings in contemporary societies than in traditional societies when human energy was required to achieve feats and well-being.

Given the importance of education and the heavy resources required to ensure its actualization in qualitative terms, its responsibility becomes that of the government (Rahman and Uddin, 2009). The huge resources realized via tax, mineral resources etc. are under the control of the government and they are expected to be properly engaged in ensuring quality education. However, the management of such resources has been a serious problem among the elites in different parts of the world. While the elites in most developed nations are prudent in managing their resources, their counterparts in developing countries squander their nation's resources (Odukoya, Omonijo, Misra & Ahuja, 2021). Consequently, while education is well funded in the former, it is poorly sponsored in the later Husain & Syed, (2016) and this may likely be one of the reasons why education in the former is highly developed than the latter.

Women's Education in Nigeria

The usefulness of education must have prompted the world organisations, mostly the UNICEF, (2020) to consider it the right of every child, irrespective of where they live and their circumstances. However, the strict compliance of countries to its implementation is traceable only to developed nations while the leadership of developing countries such as Nigeria play lip-service to its implementation.

Consequently, 10.5 million children between the age of five and fourteen are out of school (UNICEF, 2020). Apart from children, another group that are badly affected in developing countries is women. Despite the adoption of the 1948 Universal Declaration on Human Rights, studies have shown that seventy-two million females are out of school (Gender statistics, 2010). Besides, out of the 774 million adult illiterates worldwide, 64% are women (Gender Statistics, 2010).

Women suffer this plight because they are regarded as properties that will eventually end up at the men's kitchen due to the distribution of social roles. In most villages in Nigeria, a girl-child is not given the right to education like the male-child because she is considered another man's property. The major implication is that the potential of such a child that is needed for the transformation of the society is being ruined. This corroborates Rölz, (2016) who argues that educating females is a strong instrument of combating global poverty, but women in developing countries may not attain their potentials due to improper or lack of formal education.

Studies have shown indicators that reveal the trends and pattern of education in developing countries, Nigeria inclusive, such measures include literacy, enrollment status and years spent in school (Rolz, 2016). The World Bank cited in Rolz, (2016) shows that each of these indicators leads to the same conclusions; the level of female education is low in the poorest countries, with just a handful of exceptions, and by any measure, the gender gap is the largest in such societies.

The foregoing prompted The United Nations Millennium Development Goal (MDG) to sponsor gender equalization (Aja-Okorie, 2013). Through this goal, it is mandatory for every country to empower women through education, but the position of women in Nigeria is yet to be greatly improved due to several limitations out of which patriarchy dominates (Olowookere, Omonijo, Odukoya and Anyaegbunam, 2020).

Maternal Health

Maternal health entails the medical services that are needed to women who are pregnant, aborted and nurturing babies. It also involves the care dimensions of family planning in most societies. In Nigeria, it is being organised as follows:

Table i: Tiers of Maternal Health Care, Locations and Activities in Nigeria

SN	Tiers	Locations	Activities	Sources
1	Primary	Nearest to women in each of the local governments	The tier handles antenatal cases, child delivery and postnatal.	Umana, (2018)
2	Secondary	Could be far to women's location but in existence in each of the 36 states	The tier handles complicated cases that cannot be handled in the primary	
3	Tertiary	Could be very far to women residence, but in existence in special locations within the country	The tier treats cases that secondary tier cannot handle.	

Source: Researchers' Compilation, (2020)

Although, studies have shown that maternal health problem is just one of the numerous challenges confronting the health sector in Nigeria but infectious and communicable diseases are other notable ones that often result in death. Other root causes of death according to Muhammad, Abdulkareem & Chowdbury, (2017) are HIV/AIDS, malaria, diarrhetic, malaria, protein/energy malnourishment, meningitis, cancer, infections related to lower respiratory, stroke and others.

The problem of health care has continued to generate problems in Nigeria due to the shortage of health personnel to attend to the large crowd seeking medical attention. Studies have shown that such medical experts are in large number but based in developed nations where they are well treated (Umana, 2018). Thus, there are twenty-seven medical doctors per one thousand Nigerians (Public Health Foundation of Nigeria, 2017). The gloomy state infrastructures, unfriendly attitudes of staff to patients, shortage of vital drugs and poor-quality service, water supply and electricity (Umana, 2018). Given this, the World Health Organisation (2019) ranked Nigeria's health care 187th among 191 United Nations member states.

The complicated health care in Nigeria is compounded with poor economic policies and factors related to politics, poverty and governance. Women are badly affected due to the inability to access medical care on their own because most of them are not educated and they are underemployed and underpaid.

Access of people to health care is another major criterion for determining human development index. While the problem could be regarded as a general problem, the case of maternal health is horrible and it has been a major concern to many developing countries. According to the World Health Organisation (2019), almost one hundred per cent of maternal death globally occur in developing countries with half and twenty per cent in West Africa and Nigeria respectively.

Specifically, the WHO (2019) states that from 2005 to 2015, over six hundred thousand cases of maternal death were recorded in Nigeria while less than nine hundred thousand cases of near-miss cases were reported. Thus, a woman in Nigeria has a one in twenty-two-lifetime risk of dying in the course of pregnancy, childbirth or

postpartum or post-abortion which may never be compared with developed nations that have the lifetime risk of one in forty-nine thousand.

Any woman lost to maternal death could be regarded as potential lost to national development. The more a country continues to experience such, the more she loses potential materials to national development.

Entrepreneurship

Just like other concepts in social sciences, entrepreneurship has been defined in several ways. These include the act of creating or extracting value Gaddefors & Anderson, (2017); a system premeditated to design, launch and run a new enterprise. Such a business is usually very small at the initial stage, but could later grow to a medium and large-scale business; the eagerness and ability to establish, organize and manage enterprises, not minding the risks it portends to make profits (Yetisen, *et al*., 2015).

The foregoing is an indication that entrepreneurship entails the act or a process of producing persons who are ready to take a risk in going into business transactions in order to earn profits, either to better their lots or ensure the transformation of families and human society at large. Over the years, experiences have shown that such an act or process do not entertain gender connotation, but the ability to possess features disposing to success in business transactions and it could be possessed by a man or a woman. Despite this, studies have shown that human factors predisposing entrepreneurship are more favourably disposed to men than women in developing countries Adenuga, Omonijo, Ogunyemi and Olowookere, (2020). Such could be traced to the norms of culture and patriarchy as well as biological factors.

Hinderance which human tradition places on women's entrepreneurship via culture lies in the denial of inheritance such as money, land, houses, cars etc. In most societies in Nigeria, women are not permitted to inherit their fathers' property. Such property is usually transferred to men in the family. This is because, when a woman gets married, she lives her father's house to leave permanently with her husband and his kindred. Her rights in that family are no longer tenable. The importance of inheritance in the life of a brilliant woman who has business initiative or prowess may not be quantified, judging from the problem of raising funds for a start-up in most developing countries. With a substantial wealth inherited, the foundation of a flourishing business could be laid and maintained by women who are prudent in managing resources. But when they are prevented from accessing such a vital opportunity, their business potentials could be destroying and that could be a major hindrance to women's contributions to national development.

The aspect of limitations which biology has placed on women's entrepreneurship could be located in areas of conception, childbirth, bread feeding and upbringings. These could be regarded as demanding tasks for women and those who are not physically strong may not be able to combine them with the stress of managing entrepreneurship, except if such an economic activity could be suspended till after childbearing.

Theoretical Point of View

Several theories have discussed the plights of women globally. Such include Marxist feminism, liberal feminism, radical feminism and others. While all of them have made some useful contributions to understanding the status of women in the society, mostly in developing countries, the focus of this paper is on radical feminism because of its strong connection with patriarchy and culture.

The origin of radical feminism has been traced to the work of Robin Morgan, Shulamith Firestone and Carol Hanisch in the year 1967 (Firestone, 1970; Hanisch, 2009; Feminist Majority Organisation, 2020). These authors were inspired by the rate at which women's position was neglected by the antiwar groups and civil rights crusaders led by men several decades ago. The neglect ignited their anger and prompted them to commence the movement as well as the protest in 1968 at Miss America Pageant, Atlantic City, New Jersey.

Radical feminism blames the disparity between men and women on patriarchy. In order to ensure women's freedom, radical feminist authors have refused to accept equality with men but suggested the total destruction of patriarchy, a complete end to domestic violence and rape. Ardent among such authors include Andrea Dworkin, Ellen Willis, Firestone, (1970) and Hanisch, (2009). They seriously contend with the act of dividing societal rights, power and privilege between men and women in the society using gender because of its connection with patriarchy and advocate for its abolition.

Dwelling on the above, radical feminism has a point that needs to be commended with all seriousness. Such is located in tracing the root of women's subjugation in the society to patriarchy, most especially in developing

countries such as Nigeria. To say that the norms of patriarchy backed up by the culture undermine women's position in the society is not an understatement; it reflects the social reality of women's subjugation. However, it becomes pertinent for radical feminists to note that every society operates by its culture and since patriarchy has a strong link with the culture of human society, the emergence of rules governing marital affairs could be very difficult to challenged and altered successfully.

Such rules include women leaving their father's house for their husbands' house after marriage, bearing their husband's name and raising children in the same name. Also, the dowry and bride price paid on women by their husbands in most societies are heavy (**See Table ii**); it gives the impression that women are being purchased by men. It appears such a heavy dowry has given men the right to consider women as their property.

Table ii: Communities, States and Dowries/bride price in Nigeria

SN	Communities	State	Dowries/Bride price	Source
1	Mbaise people	Imo State	From N300,000 to N500,000	Onuoha, (2020)
2	Annang people	Akwa Ibom	From N500,000 to N700,000	
3	Ikwerre inhabitants	Rivers state	One million naira	
4	Ngwo People	Enugu State	Not stated	
5	Bororos	Northern Nigeria	Ten to fifty live cows	
6	Ijebus	Ogun State	Not stated	
7	Nkpa	Abia State	Not stated	
8	Efik	Cross River	From N500,000 to 3 million	

Source: Researchers Compilation, (2020)

Besides, radical feminists have failed to realise that biology and spiritual engagements have already drawn a line of demarcation between men and women and any attempt to alter the demarcation could be regarded as an exercise in futility. Although, women have options of securing unlimited freedom for themselves in society such could be possible under the following conditions:

a. Forgetting about marriage and denying themselves the joy of sexual satisfaction under martial obligation. Although, they can have a sexual relationship with some men but such women are never considered responsible in most cultures;
b. Remaining childless, because it is not possible to conceive without having sexual intercourse with a man. Although, they can bear children outside marriage such children will be regarded as bastards in most cultures and it goes with ridicule;
c. Be ready to stay in their fathers' houses or their own houses as long as they live and
d. Be ready to cater for themselves.

Judging from human nature that needs comfort, companion, social interaction, emotional stability, the above conditions could be very difficult to apply to women, who are more often regard as weaker sex. Although, it may succeed to some extent in developed nations due the individualist nature of such countries but its application to women's situation in developing countries could be tantamount to subjecting women to a miserable lifestyle because:

i. Most women are poorly educated, unemployed, underemployed and underpaid and may not be able to cater to their needs;
ii. An unmarried woman is considered irresponsible and does not enjoy the respect from the African culture;
iii. Giving out daughters in marriage is a thing of joy in Africa culture. Hence, unmarried daughters are always a concern their parents; and
iv. Husbands are considered the crown of women in African culture "ade ori", thus any woman without a husband does not have a crown "ade ori" and is vulnerable to humiliation

Given the above, it could be a good idea if feminist theorists could reconsider their anger and bitterness against patriarchy and men domination and commence advocating for fair treatment of women in society.

Concluding Remarks

This paper discussed issues surrounding women's education, maternal health, entrepreneurship and development in Nigeria. The paper craved the indulgence of policymakers and strong advocate of patriarchy to the fact that education, health, entrepreneurship are cogent areas of human development that demands contributions from every

member of the society, irrespective of gender. The more a society gives equal participation to her inhabitants without any disparity the more advantageous it becomes for such a society. This goes to corroborate Giri, (2006:24) in a book titled "Deprived Devis: Women's Unequal Status in Society," that "The evidence is overwhelming that education improves health and productivity and that the poorest people gain most. When schools open their doors wider to girls and women, the benefits multiply."
