The use of ICT in educational processes is still at the low level in some countries, therefore it is necessary to train many teachers at all levels in ICT to equip themselves for the reengineering of society through skills; ICT is the most efficient means of rapid dissemination of information and knowledge transfer, decentralization of work, expansion of the workforce, but it is also expensive. With the help of ICT, the teacher becomes a facilitator, supervisor and leader in classroom teaching. However, the mandatory acquisition of ICT skills by teachers should be given priority attention even though a large number of teachers do not have a basic level of knowledge of hardware and software or IT technology (Chinyere, 2014) and their digital competence related to the ability to use information and communication technology for work and communication with the existence of skills demonstrated "through the use of computers to find, evaluate, create, archive, present and share information, as well as social interaction using the Internet and social networks "(Marković-Blagojević, et al 2019).

E-learning experiences Serbian higher education institutions - Content analysis

In Serbia, the activity of higher education according to the Law on Higher Education is provided by universities, faculties, academies of vocational studies, high schools and colleges of vocational studies which have been accredited in accordance with the Law on Higher Education. Based on the accreditation, the Commission determines, among other things, whether the higher education institution or study program meets the standards set by the National Council. Also, it should be ascertained whether the conditions for the introduction of the program are met.

According to available data, there are 18 universities in Serbia today, of which 9 were founded and funded by the state, while 9 universities are privately owned. (Nat, 2020) The question is whether these universities, as well as other higher education institutions, follow trends in education, economic tendencies, technology development, ie different needs for educational profiles, and whether in accordance with these continuous evaluations of existing programs, they innovate or even if they find that they are completely obsolete. Therefore, is higher education in the Republic of Serbia developmental and progressive, and is the adequate knowledge offered to students thanks to educational programs? (Ristić, et al 2019)

There is still an insufficient knowledge base in Serbia when it comes to the effects of Covid-19 on higher education. Two significant surveys were conducted in April and August 2020 by the NajStudent portal whose publicly available data were used for further analysis. In the survey conducted by the site NajStudent.com (Najstudent, 2020) in the period from April 21 to April 27, 1,447 academics gave answers about the impact of the pandemic on their studies.

According to the data of the Republic Bureau of Statistics in the school year 2019/20. year, 241,968 students were enrolled at all higher education institutions at all study levels in the Republic of Serbia. (Republic Statistical Office, 2020)

It can be stated that the population size is 241,960, and that the sample is 1447, the level of reliability is 95%, the confidence interval is 2.57%, and the sample is adequate. In terms of representativeness of the sample, the entire sample consisted of students in the Republic of Serbia, so that the sample represents the entire population of Serbian students in the right way. Thus, it can be stated that the sample is representative, i.e. that it realistically reflects the actual structure of the population. It can be stated that the sample is adequate because it is large enough.

When asked what measures the faculties have taken to adapt to the state of emergency, almost half of the students stated that the professors sent PDF and PPT presentations with or without an audio recording. The results of the research indicated that every third professor holds online lectures, and 16% hold consultations on a fixed term. The majority of students, as many as 70%, believe that these changes have had a bad effect on their acquisition of knowledge, almost a quarter do not feel that there are big differences compared to regular lectures, while only 8% stated that they acquire knowledge more easily in this way.

Students rated their satisfaction with the implemented measures at higher education institutions due to the introduction of the state of emergency with an average grade of 3.19 on a scale from 1 to 5. Opinions among the student population on whether the faculty has taken all necessary measures to transfer knowledge are literally divided in the ratio of 50% to

50%.

Asked what faculties and colleges should do in these conditions, almost two-fifths of students considered that they should make professors more accessible, and the same percentage believes that information on the website of these institutions should be more accessible. About 20% of respondents had different suggestions, most often: standardization of online lectures, the introduction of an online colloquium, audio recordings followed by materials, etc.

When asked which of regular activities should be better organized at the faculty, the majority of respondents, almost 40%, think that these are colloquia, then 35% want them to be lectures, followed by consultations with 13%. Only every ninth student thinks that everything is well organized. (Student, 2020).

The new research was conducted on a sample of 1955 respondents during August 2020.

According to the population size of 241,968, a sample of 1955, a confidence level of 95%, a confidence interval of 2.21%, it can be concluded that the sample is adequate. In terms of representativeness of the sample, the entire sample consisted of students in the Republic of Serbia, so that the sample represents the entire population of Serbian students in the right way. Thus, it can be stated that the sample is representative, i.e. that it realistically reflects the actual structure of the population. It can be stated that the sample is adequate because it is large enough.

This research concluded that in addition to the organization of online study itself, the pandemic greatly affected the students themselves. This is supported by the fact that more than half of them lost their sense of studying, and furthermore the pandemic affected students, in a way that they needed more time to learn the material due to the lack of lectures and exercises. Two-fifths of respondents stated that they lacked contact with colleagues, while only 21% of them had more time to learn due to this situation. Respondents rated the work of the faculty in unforeseen circumstances, as well as the organization of online lectures and colloquia on an average of 3 on a scale from 1 to 5, where 1 is the lowest and 5 the highest.

Suggesting what could be better organized, the respondents named almost all segments of study, primarily the organization of exam deadlines, then timely information regarding classes and exams, lectures and consultations, organization of exercises and practical classes, but also colloquia, while only every 11th respondent said that everything was well organized. The research clearly shows the negative impact of the effects of the Covid 19 pandemic on students and the overall study process. (Student, 2020)

E-learning ITS Experience Case study: Get quality right the first time

About company

Information Technology School Belgrade (ITS) as College of Vocational Studies is an independent higher education institution that has four accredited study programs of Information Technology, Computer Multimedia, Electronic Business and Information Systems. Information Technology School was founded by two leading regional companies in the IT area – LINK group and Comtrade. Since 2018 ITS has organized master vocational studies as well, within one accredited program of Information Technology. The business results so far, from the beginning of its work, show that ITS manages to operate with a positive result (ensure the provided services to students with quality study, supported by modern IT and other equipment, regularly paying salaries to employees).

Professional competence and immense experience of the founding companies serve as a guarantee of a quality education and a successful career. (Information Technology School, ITS – Belgrade, 2020) LINK group is a multinational company working in professional education and certification in IT and modern business, as well as software development. (Link Group, 2020) Comtrade is a dynamic and well-established group of technology companies, with a 25-year track record of innovation and steady development of some of the world's most advanced software. (Comtrade, 2020)

ITS, as a private higher education institution, is financed from tuition fees, which is currently the only source of income. The organizational structure has all the elements provided by the Law on Higher Education of the Republic of Serbia and others necessary for efficient management and achievement of the goals it has set for itself.

Although ITS is a vocational school, it still pays attention to research and scientific work, primarily through the participation of its teachers in scientific conferences, the publication of papers in journals, and the implementation of projects begins. The complete organization and all activities are aimed at achieving the mission, vision, goals, and tasks

of ITS as a vocational school that strives to continuously develop and improve its work. ITS regularly and qualitatively performs its basic activity - the implementation of accredited study programs but does not neglect the training of teachers throughout the research. ITS continuously improves its organization and supplements or changes the basic acts (Statute, regulations, instructions, quality documents) in order to improve the overall work.

ITS has functional form of organization. Functional organizational structure is statistically the most common method of organizational structure and represents the oldest type of project organization. It represents the total opposite in relation to the project organizational structure. It is based on grouping people by expertise and specialization of performing certain jobs in the sector in which they are assigned.
The characteristic of this structure is that in a hierarchical relationship, employees in the sectors are accountable only to the managers of those and exclusively those sectors, while the managers of these sectors are accountable to the top managers, often directly to the director of the company.

In the functional structure, it is common to create departments such as accounting, marketing or research and development. The division of labor in a functional structure is not based on the type of product or project supported, but on the type of work performed. In an organization that has a functional structure, members routinely work on multiple projects or support multiple production lines simultaneously.
Major stakeholders are: Investors, employees of ITS, ITS management, students, parents, community, Ministry of Education, Science and Technology, alumni.

Human resources management in a (business) organization represents a precondition for its success. (Ilić, Ranković, Dedić, 2020). This truth is recognized as a business philosophy of ITS. ITS has developed the Smart University concept with the concept of smart education, smart e-learning, smart campus, smart classroom, conducting the transformation from a traditional university into a smart university using smart software systems, smart hardware systems and equipment, smart technologies, smart pedagogy, stakeholders etc. All of its teachers and associates have all the necessary digital competences improving themselves on a regular basis in order to be able to follow world educational trends and develop their ICT skills.

Problem

At ITS, staff nurture two-way communication with students. Communication takes place in lectures and exercises, during the semesters. Direct communication also takes place at the consultations that take place on the school premises. Other communication takes place through ICT media. All forms of direct teaching (lectures and exercises) and consultations with students have been conducted on school premises, supported by modern information and communication technologies.

State of emergency in the Republic of Serbia was declared on March 15th, 2020. The summer semester of the 2019/20 academic year is underway. During the state of emergency, initiated by the Covid-19 pandemic, it was not possible to organize lectures nor face-to-face consultations with students in the high school premises due to the declared state of emergency, as well as after that due to epidemiological measures and prohibition of assembly. When the state of emergency is lifted it was necessary to organize consultations and exams, while ensuring compliance with epidemiological measures to protect employees and students.

Solution

Students open a corporate mail account on the mail server immediately after enrolling in the first year of study. Through this mail account, students receive automatic messages that are integrated with all software solutions used at its level. Also, students receive regular and up-to-date information from the student service on their email account, but they can also communicate with ITS teaching and non-teaching staff and with their fellow students. Experience shows that this form of communication and exchange of information is very popular and accepted among ITS students. Also, the following software solutions were used for communication at ITS:

- Information system (IS ITS)
- Distance Learning System (DLS)
- Content Management Server (CMS)

- Student Web Portal
- Library software.

Using all the above services, students were able to continue to study regularly and attend lectures. Classes were held via live stream, teaching materials were published on the portal after each class, videos of all lectures were archived and professors were available for video consultations. During the conditions where we all stayed longer in our homes, ITS students had the opportunity to take advantage of that time and master the covered material. We believe that this will be confirmed in the exam period when the conditions for the first exams are met.

ITS did not interrupt its work at any time during the state of emergency. Classes were regularly held via live stream, using Distance Learning System of the LINK group company, as the school founder.

The state of emergency was lifted but the epidemiological measures banning gatherings were still in place. Schools and colleges were particularly affected by the current situation due to the nature of their activities and will probably be the last where the situation will completely normalize.

ITS professors were extremely dedicated to the students and regularly performed their duties even in the state of emergency, beside their professional competencies and obvious digital competences. In compliance with all the recommended measures, they used to come to work and teach, using live stream from ITS classrooms. They were also available to students via video conferences and responded to their mails within 24 hours.

In addition to live stream, all broadcast lectures and exercises were recorded and saved in a special video archive on the Distance Learning platform. This option is especially useful for ITS students when preparing for exams because each lecture can be reviewed multiple times.

ITS managed to adjust quickly and conduct all the classes even in the state of emergency because it has used the Distance Learning System in the schoolwork since 2006, when the school was founded. It applies a huge number of software services to support the teaching process. Live stream has been part of regular ITS service since 2015 and has now only gained in importance.

In addition to live stream, this platform also includes online courses that help students master the teaching material as efficiently as possible and prepare for the exams. Students can also have access to online tests to check their knowledge in each subject that give them an insight to how much material they have mastered and what they still need to work on.

Teaching material was regularly published on the student portal after each given lecture in all subjects, both basic and master studies. Mimeographed course notes and textbooks are available to students for all subjects of the studies with subject teachers as their authors. There is also a collection of multimedia materials for learning and testing knowledge, as an additional learning resource. It is also enabled to register exams online via student portal and have access to all electronic test results.

ITS students have also followed the classes over their phones in the last period. IOS and Android applications have been available to them. They can use these applications to access the Distance Learning System, scheduled Live Class sessions and video archives. This free app provides easy access to all lectures and online lessons. It is enough to install the application on their phones- then they can easily go through the anticipated material or watch online classes.

In addition to live stream, regular video consultations were also conducted, with professors of all subjects of basic and master studies, using Google Meet service once a week for 60 minutes, for each subject in the semester. The professors discussed the covered material live with the students. They were also available for all student questions.

Employees in professional services were available all the time during the state of emergency and continued to provide technical and software support to ITS students. Student service was available for all questions by email and telephone while technical support provided students undisturbed conducting of teaching, announcement of the schedule and all teaching materials on a daily basis.

In accordance with the recommendations of the Ministry of Education, Science and Technological Development the exams were conducted in April, June and July. Epidemiological measures were followed as well as other

recommendations regarding the continuation of online lectures, exercises and consultations, volume of examination material and financial relief.

Reflection upon the training results, analysis and lessons learned

The selected model of learning and the combination of lectures and exercises, the choice of teaching forms, the way of checking what has been learned shows good results. Student`s grades are in the expected ITS average, and students through the survey show satisfaction with different elements.

Assessment of student satisfaction (Results of student surveys on the quality of teachers' work) within the survey at the end of each semester is important for obtaining student`s satisfaction, but not the only element that is important. Different surveys have been formed in forms for student surveys. Management conducts analyses of realized surveys that are periodically conducted with the aim of determining the degree of satisfaction of ITS students with the quality of the teaching process and the conditions of studying at ITS. The surveys also determine possible remarks and suggestions of students, which serve as a basis for improving the overall functioning of ITS.

The engagement of associates and professors in the permanent and temporary bodies of the school is also assessed after every semester. The quality of teaching literature, textbooks, books, scripts, collections of assignments, practicums, electronic materials that are posted on the student portal, is regularly controlled by students through surveys and management.

Survey on the quality of pedagogical work of teachers and associates has been conducted with the students of basic and master vocational ITS studies in the 2019/20 study year. (Student Survey Analysis 2020) The survey was conducted in mid-August 2020. It was started due to the epidemiological situation and emergency caused by the coronavirus pandemic (Covid-19), immediately after the end of the exam period in June. The survey was finished after four weeks in order to give students enough time to express their impressions after all the activities during the summer semester and conducted distance learning, so that they could also evaluate the conduct of exams and not just pre-exam obligations. The survey was conducted electronically and is anonymous.
The following elements, related to teachers, were evaluated:

1. clarity and comprehensibility of lectures,
2. the previous grades with the teacher correspond to the demonstrated knowledge of a student
3. communication and email response speed
4. transparency and the emphasis of the most important
5. encouraging student involvement and participation in teaching
6. good preparation for a class
7. the manner of conducting the exam with this teacher
8. contemporaneity of the programme
9. objectivity and proper relations with students

There are nine elements on the quality of pedagogical work of teachers and six elements of associates (associates are not evaluated for the following elements: contemporaneity of the programmer, the previous grades with the teacher correspond to my demonstrated knowledge and the manner of conducting the exam with this teacher) that were evaluated.

There were 1515 students of basic vocational studies who participated in the research, most of them second year students 37,56 (n=589), then third year students 29,99% (n=470) and first year students 29,10% (n=29,10) while the least of them were students of master studies, if we take into account the total number of respondents which is 1567.

Table 1: Information of study participants

Year of study	n	%
First year of study	456	29,10
Second year of study	589	37,59

Third year of study	470	29,99
Master studies	52	3,32
Total	**1567**	**100,00**

Figure 4: Information of study participants

Table 2: Teacher survey results in the summer semester of the 2019/2020 school year by years of study and study programs - mean score

Year of study	**IT**	**EB**	**IS**	**CM**
First year of study (mean score)	4.26	4.41	4.72	4.65
Second year of study (mean score)	4.33	4.51	4.55	4.54
Third year of study (mean score)	4.68	4.70	4.88	4.43
Master studies (mean score)	4.72	/	/	/

Mean score starts from 4,26 to 4,88, in total (from 4,42 to 4,84 last year). When it comes to study programmes, there are differences in mean scores in all years of study, although the lowest score was on Electronic Business department (EB)- second year of studies (IT last year). There is also the biggest difference on Electronic Business department – first year (Computer Multimedia - CM the previous year). In the first year, the mean score ranges from 4,26 to 4,72 (from 4,56 to 4,79 last year), in the second year from 4,33 to 4,55 (from 4,50 to 4,84 the previous year), and in the third year from 4,43 to 4,88 (from 4,42 to 4,69 last year). The difference between the highest and the lowest mean score in the first and in the third year of studies is the same while the smallest difference is in the second year of studies that indicates steady quality of teachers. The difference in all study years was about the same in the previous academic year.

Mean score, on master vocational studies, ranges from 4,33 to 4,93 (from 3,44 to 5,00 last year). Mean score is 4,72 (4,67 the previous year). On the whole, it could be concluded that ITS has an excellent teaching staff (mean score 4,72) according to the student's grades.

By analyzing the grades given by the respondents to the associates, it could be concluded that ITS also has quality associates whose lower average grade was slightly lower compared to the teacher's grade (mean score 4,08 compared to 4,26).

Conclusion

There are numerous influences and achievements of different forms of e-learning during the Covid-19 pandemic in different countries. Some experts believe that the unplanned and rapid transition to online learning without preparation and insufficient coverage of the Internet has caused many bad experiences for users (pupils and student as well as educators), while the others believe that the whole experience will degenerate a hybrid model that will bring numerous benefits to all participants.

State of emergency due to the Covid-19 pandemic, epidemiological measures in terms of social distance and the ban on gatherings have affected various spheres of society in the Republic of Serbia, especially higher education institutions which have developed, in different ways at different times, some adequate responses regarding some ways of distance learning or only sending teaching materials to students. Unfortunately, in some cases, there was no communication with students. Deficiencies in the reaction of higher education institutions and teaching staff as well as the impact of the epidemic on students and on the study process itself have been proved by two independent researches.

During the state of emergency in the Republic of Serbia, for 52 days as well as after that with adherence to epidemiological measures and other recommendations of the competent ministry, ITS-Belgrade showed capability to rapidly accept the changes, thanks to a proactive approach, strategic management and perennial application of the online learning model as a general application of information communication technologies in daily functioning of the school, conducting lectures and exercises and communication with students. If we look at the mean score of the student satisfaction with the elements of the survey for the previous and the current year, it was clear that there are no discrepancies in the quality of service provided. ITS student satisfaction, expressed with high average individual grades of the elements of the quality of the pedagogical work of teachers and associates, proves that ITS successfully coped with the conditions of providing educational services during the Covid-19, as well as in regular business.

Abstract

In the last decade, scientific activities of large universities in Russia have been actively funded by the state. Universities are making attempts to implement one or several development models at once: a research university, a world-class university, an entrepreneurial university, a flagship university of the region, etc. The lack of a clear understanding of the strategy and model of the development of the university can lead to the formal fulfillment of the efficiency indicators set by the state and low real efficiency of spending budget funds.
A statistical study for open data of annual monitoring of the Russian universities let determine and analyze the models of the activities of Russian universities in the field of scientific research and innovative developments have been determined. The universities were identified that implement promising, from the point of view of world experience, models of scientific management. Differences in the development of the field of research and development in national research universities were revealed. It was shown that an increase in the share of extra-budgetary funds and in the share of funds of universities for research and development is not accompanied by an increase in the effectiveness of innovative activities in the regions. The performed classification of regions and the calculated values of the factors of the innovative activity efficiency and the financial conditions for the operation of regional flagship universities can be used to plan further support for flagship universities at the expense of the federal budget.

Keywords: Flagship University, Innovative Regional Development, National Research Universities.

Introduction and the Research Question

Till now Russian Federation mostly use direct government funding for supporting science. There is still a lack of interest in business to invest into research and development. The scientific activities of large universities in the country in the last decade have been actively funded by the state. The leading universities were supposed to overcome limits of routine educational activity. It is assumed that university staff should actively participate in scientific research with results brought to the market of innovative technologies and products. The activities of universities should be aimed at promoting innovations. This concept corresponds to the world practice of university-driven research and development. However, according to Eurostat [5], the present share of higher education employees in overall stuff conducting research and development is about 32% in European Union, 24% in Japan, and only 15% in Russia. In internal costs of research and development the share of higher education sector is less with 23% in EU, 12% in Japan and about 10% in Russia.

The Strategy for Innovative Development of the Russian Federation and other government documents of strategic planning [2, 3, 17] specify tasks of developing innovative activity, effective commercialization and implementation of scientific developments. Leading universities should become centers of regional innovation ecosystems. Since

Cite this Article as: Tatyana Maximova, Irina Sokolova, Dmitry Verzilin and Tatyana Kruglova "Conceptual Models for Development of Universities in Russia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2017, Russia has been implementing the priority project "Universities as centers of space for innovation creation" [12] aimed at making universities active participants in regional socio-economic and innovative development. Currently [11, 16] dozens of leading universities acquired special statuses providing for more autonomous educational policy and additional funding. Specifically, 29 universities got the status of national research universities (NRU) and 33 universities worked out approved programs granting the status of regional flagship universities.

Our express monitoring of universities' strategies in Russia allows us to conclude that universities are making attempts to implement one or several development models at once: a research university, a world-class university, an entrepreneurial university, a flagship university of the region, etc. The lack of a clear understanding of the strategy and development model of the university can lead to a formal implementation of indicators set by the state and to a low real efficiency of spending governmental funds.

The aim of the study was to determine through open statistical data the use of typical models specifying scientific research and innovative development in Russian universities.

Related Work

From the survey [7] we can sort out typical models specifying how universities do influence upon regional innovation strategies. The author identified four typical models that are most frequently encountered in publications on this topic. Namely, the model of an entrepreneurial university, aimed at the commercialization of research and development results; a regional innovation system (RIS) model, in which the university becomes a link between business and public administration; a model of an involved university, in which the university interacts with society and industry, sharing knowledge as a mutually beneficial resource, and a model of the university as a carrier of a social mission. The latter model is more dependent on leaders advancing the social mission. That survey analyzes the shortcomings in the implementation of the four models, specific to the United States. For example, universities are interested in being patent holders, rather than in selling licenses.

From [10] we can get conceptual models describing an influence of universities on innovative regional development in the UK, Sweden and Austria. Descriptions of the models are rather detailed and include conditions and results of their implementation in those three countries, such as the amount of funding, results of specific programs and projects, and the regulatory framework. In addition to the first three of four models mentioned above, there is a model of universities operating in the so-called "second mode" as carriers of new forms of knowledge production. Such universities combine interdisciplinary research, new scientific directions, new approaches to research and development management, and new applications of scientific results.

An analysis [14] of the model of an entrepreneurial university in Scotland provides for a conclusion that insufficient contribution of the private sector to research and development reduces the efficiency of entrepreneurial universities. Universities are unable to compensate for the insufficient contribution of the private sector, since their main priorities should lay in the reproduction of human capital and the conduct of fundamental research.

In some publications [1, 6, 7, 8, 10, 14, 19] on the influence of universities on regional innovative development there are conclusions that this influence is often exaggerated, and the actual results do not correspond to expectations. For example, there is a disconnection between the knowledge acquired at the university and its actual application in practice. The works [7, 10, 14] are quite typical in this area.

Analysis of publications shows how it is important when planning regional strategies for innovative development to determine the priorities of universities and maintain a balance between educational, scientific and entrepreneurial activities.

Materials and Methods

Our statistical study was carried out for open data from the annual monitoring of Russian universities [4]. We analyzed indicators of innovation and research activities, and the innovation infrastructure of universities in 2017 and 2018. Specifically, we observed activities of regional flagship universities and universities with the dominant development model of national research university (NRU).

The flagship university model assumes a significant impact of a university on the development of innovations in the region. So, to assess the state of innovative development of the regions in which the flagship universities operate, the data of Rosstat were used [18]. To level the random fluctuations in the values of the indicators, the data for 2017 and

2018 were averaged. We compared results obtained with the sub-indices of innovative development of regions and regional indices of innovative development for 2017 [13].

The methodology for determining the level of innovative development of regions described in [13, p.57-76] assumes the standardization of the initial statistical indicators and the calculation of summary subindices, which are sums of normalized indicators with equal weights. When normalizing, the transformation of indicators is used to compensate for the asymmetry of their distributions, then its average value is subtracted from each transformed indicator, then the resulting value is divided by the difference between the maximum and minimum values of the transformed indicator. The disadvantage of this technique is that it ignores possible correlations between the initial indicators. Therefore, it is not known in advance how certain aspects of innovative development will affect the final values of the indices. The indices themselves can have statistically significant correlations with each other. The integral index is the sum of five partial indices with weights proportional to the number of primary indicators included in each index. The use of a single integral index leads to the loss of a significant part of the information contained in the values of the initial indicators.

To overcome abovementioned shortcomings, when analyzing the multidimensional space of indicators characterizing the innovative development of regions, a factor analysis of the initial statistical indicators was used. In the factor analysis model (see, eg, [15]), the variance of each initial indicator is decomposed into the variance due to generality, that is, the existence of common, sometimes called latent, factors and into the variance due to specificity, that is, the variation of each initial statistical indicator. The technique of factor analysis is aimed at assessing factor loads (representing the values of the correlation coefficients of latent factors with the initial indicators), specific variances, determining the values of common latent factors for each object, and interpreting the selected factors according to the specifics of the initial indicators. Rotation methods are used to obtain an interpreted load matrix, so that each latent factor has high loads (correlation coefficients) for some initial indicators and low for others. In the present study, rotation was used according to the Quartimax method (see, eg, [15]). The obtained values of latent factors were used to classify regions using cluster analysis methods; analysis of variance was used to compare clusters (see, eg, [15]). A similar approach has been tested in the formation of strategic guidelines for state policy [20].

We used methods of descriptive statistics for the primary analysis of statistical indicators.

Results

Research universities as innovation centers

This study is a continuation of our research on the performance of scientific and innovative activities of national research universities.

In [8] we analyzed financial indicators of the scientific activity of universities in 2017. The article [9] presents the results of the data analysis for 2018. The patterns identified according to the data for 2017 were still valid in 2018.

In particular, we observed a constant elasticity of the share of income from R&D by the total volume of R&D in monetary terms (for the considered intervals of indicators). The change in the volume of R&D (x) by 1% led to a change in the share of income from R&D in the total volume of university revenues (y) by 0.45% -0.46%:

$y = 0.047x0.45$, $R^2 = 0.621$ (2017) и $y = 0.039x0.46$, $R^2 = 0.637$ (2018).

The indicators of financial support for scientific research in national research universities are subject to the following statistically significant patterns.

R&D revenues (y) per one scientific and pedagogical employee increase with an increase in the share of extra-budgetary funds in R&D revenues (x). The pattern was observed for 2017 and 2018, and there was an increase in average employee income for a given share of extra-budgetary funds:

$y = 31.849x - 187.93$, $R^2 = 0.552$ (2017);
$y = 34.149x - 162.41$, $R^2 = 0.592$ (2018).

The patterns obtained testify to positive trends in the implementation of scientific activities in national research universities.

An analysis of the structure of funding of universities in the context of budgetary and extra-budgetary sources showed [8] that in 2017 universities with lower total R&D funds had a higher share of extrabudgetary funds in R&D revenues.

The interval of the values of the indicator "the share of extra-budgetary funds in the total revenues of the university from R&D" was 22-100% for the analyzed universities. In 2018, the value of this indicator was in the range of 49-76%.
At the same time, the values of the indicator "total R&D in monetary terms" increased in 2018. This fact indicates an increase in the involvement of the elements of the innovation ecosystem in the financing of research and development.

At the same time, the values of the indicator "total R&D in monetary terms" increased in 2018. This fact indicates an increase in the involvement of non-government investors in the financing of research and development.

As a result of the analysis, we have identified universities that implement promising, from the point of view of world experience, models of scientific management. These are, first of all, those universities for which there is a positive relative increase in the target indicators, such as the total volume of R&D, the share of extra-budgetary funds in the revenues from R&D, and the share of R&D revenues in total revenues.

In [8] we presented an approach to identifying differences between national research universities in the field of research and development. According to the statistical data of 2017 and 2018, we identified nine leading universities with high practice-oriented scientific activity, but with an average levels of entrepreneurial innovation activity and of budget-oriented scientific activity.

Flagship universities as centers of innovative regional development

The main goal of creating the NRUs was to develop and commercialize innovative technologies [1]. The achievement of this goal also contributed to the training and employment of personnel with competencies in the field of research and development at the forefront of the world.

At the same time, the creation of the NRUs did not ensure innovative development of Russian regions of, since out of 29 NRUs, 19 are located in Moscow and St. Petersburg, another 4 are in cities with a population over one million and only 6 are in other regional centers. The need to educate and retain personnel in the regions of Russia, the creation of centers for regional innovative development, required additional support for regional universities at the expense of the federal budget [11, 12, 16]. To date, programs of regional innovative development have been supported with the aid of 33 flagship universities located in 31 regions (constituent entities) of the Russian Federation. During the period from 2016 to 2020, inclusive, each flagship university received subsidies from the federal budget in the amount of up to 150 million rubles annually. To determine the prospects for further support, it is necessary to assess the state of innovative development of the regions in which flagship universities operate. For these purposes, the factor analysis of the initial statistical indicators was used (Table 1). Factor loadings made it possible to interpret the first factor as a factor of the effectiveness of regional innovation activities, and the second as the financial conditions for the operation of flagship universities. The factors obtained explain more than 57% of the variance of the initial indicators. The values of the factors calculated for the regions in which the flagship universities are located were used to classify the regions using the k-means clustering method. Two groups (clusters) of regions have been identified. The values of the factors for the clusters are shown in Fig. 6. In the regions of the first cluster, there are higher values of the efficiency factor (the average values of the efficiency factor are, respectively: 0.75 units for cluster 1, -0.76 units for cluster 2). In the second cluster, on average, there are higher values of the financial conditions factor (the average values of the financial conditions factor are, respectively: -0.26 units for cluster 1, 0.13 units for cluster 2). The result obtained can be interpreted as the fact that an increase in the share of extra-budgetary funds and the share of university funds for carrying out research and development is not accompanied by an increase in the effectiveness of innovative activities in the regions.

Table 1 : Factor loadings (calculated by the authors according to UIISS data [18] for 2017 and 2018)

Initial indicators	Factor 1 (efficiency)	Factor 1 (financial conditions)
Internal current expenditures on research and development per one employee who performed research and development (excluding part-time workers and persons who worked under civil law contracts), thousand rubles	**0.64**	0.17
Share of extra-budgetary funds in internal expenditures on research and development, %	0.14	**0.80**
Share of the higher education sector in internal expenditures on research and development, %	-0.29	0.71

Share of costs for technological innovation in the total volume of shipped goods, work performed, and services in industrial organizations, %	**0.72**	-0.35
Share of innovative goods, work performed, services in the total volume of goods shipped, work performed, and services, %	**0.58**	0.06
Share of organizations implementing technological innovations in the total number of surveyed organizations, %	**0.81**	-0.24
Share of variance explained	0.34	0.23

Figure 1: Values of the factors for the regions where flagship universities are located (constructed by the authors based on the results of factor analysis).

In Table 2, for reference, we presented the regions included in each cluster, the values of the factors for the regions, the distances to the centers of the clusters, allowing us to conclude how a particular region is typical for the cluster.

Table 2 : The elements and characteristics of the clusters

1 cluster	Factor 1	Factor 2	Distance	1 cluster	Factor 1	Factor 2	Distance
Belgorod region	1.1	1.9	1.5	Kostroma region	-1.0	2.0	1.3
Vladimir region	0.3	-0.2	0.3	Oryol Region	-1.0	-0.2	0.3
Voronezh region	0.1	-0.5	0.5	Republic of Karelia	-1.6	-0.7	0.8
Tula region	1.3	-0.3	0.4	Komi Republic	-0.6	0.0	0.2
Yaroslavskaya oblast	0.7	-0.3	0.1	Vologda Region	-1.2	0.7	0.5
Novgorod region	0.5	0.1	0.3	Murmansk region	-0.6	-1.4	1.1
Republic of Bashkortostan	0.4	0.9	0.8	Pskov region	-0.1	1.4	1.0
Kirov region	0.0	-0.9	0.7	Republic of Kalmykia	-2.0	-1.8	1.6
Nizhny Novgorod Region	2.7	-1.3	1.6	Krasnodar region	-0.4	0.2	0.2
Samara Region	0.5	-0.4	0.2	Volgograd region	-0.3	0.2	0.3
Chelyabinsk region	0.4	-1.3	0.8	Rostov region	-0.3	0.0	0.3
Krasnoyarsk region	0.8	-0.7	0.3	Mari El Republic	-0.7	1.7	1.1
Omsk region	0.8	-0.2	0.0	Saratov region	-0.6	-0.3	0.3
Tomsk region	1.1	-0.4	0.2	Altai region	-0.6	0.1	0.1
Average	***0.75***	***-0.26***		Kemerovo Region - Kuzbass	-0.8	1.1	0.7
				Novosibirsk region	-0.5	-1.0	0.8
				Average	***-0.76***	***0.13***	

The resulting classification of regions can be used when planning innovative activities in regions based on flagship universities. When planning, it is necessary to take into account the identified differences between regions.

The results were compared with estimates obtained for the indices of innovative development of regions for 2017 [13]. It was found out that the values of the regional innovation index and four of the five sub-indices of innovative development of regions are statistically significantly different for the two identified clusters. The values of the total regional index of innovative development and sub-indices characterizing the socio-economic conditions of innovation, export activity and the quality of regional policy are higher for the first cluster. For the sub-index characterizing the regional scientific and technological potential, statistically significant differences were not observed. At the same time, this sub-index has a correlation coefficient with the highlighted performance factor of 0.45 ($p < 0.05$). Thus, the correspondence of the results of the factorial and cluster analysis to the results presented in [13] was established, which indicates the consistency of both approaches.

Conclusion

In the last decade, scientific activities of large universities in Russia have been actively funded by the state. Universities are making attempts to implement one or several development models at once: a research university, a world-class university, an entrepreneurial university, a flagship university of the region, etc. The lack of a clear understanding of the strategy and development model of the university can lead to the formal implementation of the efficiency indicators set by the state and a low actual efficiency of spending budget funds.

As a result of a statistical study for open data of annual monitoring of Russian universities, the models of the activities of Russian universities in the field of scientific research and innovative developments have been determined.

For national research universities, indicators of financial support for research and development are subject to the following statistically significant patterns. The elasticity of the share of R&D revenues in terms of the total volume of R&D in monetary terms (for the considered intervals of indicators) is constant. R&D revenues per one scientific and pedagogical worker increase with an increase in the share of extra-budgetary funds in R&D revenues. The established patterns testify to positive trends in the implementation of scientific activities in national research universities.

Universities with lower total R&D funds had a higher share of extra-budgetary funds in R&D revenues. The values of the indicator "total R&D in monetary terms" increased in 2018 compared to 2017. This fact indicates an increase in the involvement of the non-governmental elements of the innovation ecosystem in the financing of research and development.

We identified universities implementing promising, from the point of view of world experience, models of scientific management. These are, first of all, those universities for which there is a positive relative increase in the indicators of the total volume of R&D, the share of extra-budgetary funds in the revenues from R&D, and the share of R&D revenues in total revenues.

There are differences in the development of the field of research and development in national research universities. For nine leading universities, we note average levels of entrepreneurial innovation activity and budget-oriented scientific activity, as well as high practice-oriented scientific activity.

The flagship university model assumes a significant impact of such a university on the development of innovations in the region. To date, programs of regional innovative development have been supported on the basis of 33 flagship universities located in 31 constituent entities of the Russian Federation. To determine the prospects for further support, it is necessary to assess the state of innovative development of the regions in which flagship universities operate. For that we used data of Rosstat. The results obtained were compared with the sub-indices and indices of innovative development of regions for 2017.

The results of the factor analysis made it possible to single out two latent factors: the factor of the efficiency of regional innovation and the factor of the financial conditions of the flagship universities. For these factors, the regions in which the flagship universities are located were divided into two clusters. In the regions of the first cluster, higher values of the innovation efficiency factor were observed. In the second cluster there were, on average, higher values of the factor of financial conditions. The obtained result can be interpreted as the fact that an increase in the share of extra-budgetary funds and in the share of university funds for carrying out research and development is not accompanied by an increase in the effectiveness of innovative activities in the regions. The correspondence of the results of factor and cluster analysis with the results of determining the sub-indices of regional innovative

development has been established. To plan further support for flagship universities at the expense of the federal budget, it is advisable to use the performed classification of regions and the calculated values of the factors of the efficiency of innovative activities and the financial conditions of the flagship universities.

Abstract

The article analyses the situation on the market of the tourism industry in the context of the COVID-19 pandemic. The global crisis caused by the COVID-19 pandemic has radically changed the activities of the tourism industry around the world. Restrictions that have been implemented almost all over the world, especially the closure of interstate borders, caused significant damage to the tourism industry. The tendencies of losses of the tourist branch are determined and the attention is focused on the problems of significant decrease of tourist activity and level of employment in the tourism and related fields. The approaches of the governments of some tourist-attractive countries of the world are systematized for minimizing the consequences of the COVID-19 pandemic and stimulating the recovery of the tourism sector.

Practical proposals for overcoming the crisis are presented, its implementation will reduce the level of negative impact of the pandemic on the economy of the tourism industry. It is substantiated that there is a need of search of innovative models, introduction of new approaches, application of information technologies, improvement of the general model of communications in the conditions of tourists restriction on movement; all of that will promote access to tourist objects and will attract new audience, develop new skills and support transition to new conditions. Smart tourism is a catalyst for change that has significant potential, and it is a source of information for customers about the territory, in addition this is a quality communication channel with tourism service providers. Gamification is part of the modern information and communication infrastructure and is gaining popularity in the marketing activities of companies, using the best ideas borrowed from loyalty programs, game mechanics and behavioural economics and creating mechanisms for the participation of tourists in business processes.

Introduction

Tourism is one of the priority areas of economic and cultural development of many countries and an important factor in socio-economic development. Due to the functioning of tourism, the employment rate is growing (in 2019, the global tourism industry provided every tenth job - 330 million, which is equivalent to 10.3% of total employment) and creates 10.3% of world GDP, investment flows , state and local budgets are being filled (Travel and Tourism Economic Report 2019 – World, 2019). The development of tourism should become one of the strategic objectives of further stabilization and socio-economic growth of countries, individual territorial and administrative units, destinations.

The global crisis caused by the COVID-19 pandemic has radically changed the activities of the tourism industry around the world. According to the World Tourism Organization (UWNTO), as a result of the COVID-19 pandemic, the world tourism industry (compared to the same period in 2019) has been having negative consequences since the beginning of 2020: reduction of international tourist arrivals from 850 million to 1.1 billion people; the amount of unreceived export earnings from tourism - from 910 billion to 1.2 trillion US dollars; from 100 to 120 million jobs lost in the tourism sector (International tourism and COVID-19, 2020). During the COVID-19 pandemic, due to restrictive measures imposed by states on the movement of citizens, quarantine, air travel bans, etc., tourism became one of the sectors of the world economy that suffered the most, so it needs immediate effective action and ways out of the crisis. This means that the study is relevant and requires exploratory, analytical and practical developments.

Materials and Methods

The analysis of the latest researches and publications testifies to considerable interest of scientists of various branches concerning the sphere of the world tourist industry. In particular, such scientists as: Huliaieva V., Kabushkina M., Kvartalnoho V., Kyfiaka V., Liubtsevoi O., Malskoi I., Midltona V., Shapovala H. and others dedicated their works to the issues of world trends in tourism development. At the same time, the issues of assessing the current processes taking place in the world market of tourist services in the context of modern challenges and threats, in particular caused by the COVID-19 pandemic, remain insufficiently researched.

The following research methods and techniques were applied during the study: evaluation and data processing, statistical method, study of economic processes, determination of patterns and trends in their development, identification of areas of further improvement of these processes.

The analysis of the materials presented in the scientific literature allowed to comprehensively assess the problems of tourism business development and to conclude that it is insufficient to study the applied nature of the development of effective measures to overcome the crisis caused by the COVID-19 pandemic.

The aim of the study is to analyze the situation in the tourism industry and study the crises that have arisen as a result of the COVID-19 pandemic.

Given the purpose of the study, its task is to develop practical proposals to reduce the negative impact of the pandemic on the economy of the tourism industry.

Literature Review

Due to the spread of the COVID-19 pandemic, the tourism industry has found itself in a crisis situation, the negative consequences of which have a devastating impact on the world economy and employment. For each job vacancy directly created in the field of tourism, directly or indirectly produces about one and a half additional jobs. In 2020, before the COVID-19 pandemic, the labor-intensive hotel and restaurant industries alone employed 144 million people worldwide (COVID-19 and Labor (Issue 2), 2020). They include about 44 million self-employed workers and 7 million employers (COVID-19 and Labor (Issue 3), 2020). Most tourism enterprises are micro, small, and medium-sized enterprises with less than 50 employees. Approximately 30% of the total workforce is employed in companies with 2-9 employees.(ILO Bulletin, 2020).

According to the UNWTO World Tourism Barometer complete isolation, which was introduced in connection with the spread of the COVID-19 pandemic, led to a decrease in the number of international tourists in May 2020 by 98% compared to 2019 (pic.1-2). In the period from January to May 2020 compared to the same period in 2019, the number of tourists decreased by 56% or 300 million people, which led to a loss of revenues from world tourism in

the amount of 320 billion US dollars, which is more than three times the loss during the global economic crisis of 2009 (Impact of COVID-19 on global tourism made clear as unwto counts the cost of standstill, 2020).

In the Asia-Pacific region, first affected by the COVID-19 pandemic, the number of international tourist arrivals fell by 60% in January-May, by 58% in Europe, the Middle East by 51%, and in the USA and Africa by 47%.

However, it should be noted that during the summer months there is a slight trend towards a gradual change in tourism in the Northern Hemisphere, reflected in the gradual lifting of travel restrictions in some countries, the resumption of international flights, and the relaunch of some domestic and intra-regional markets (Market intelligence UNWTO World Tourism Barometer, 2020).

Fig.1: International tourist arrivals (YTD change,%)

Fig.2: International tourist arrivals (thousand)

Source: built by the authors based on materials International tourism and COVID - 19, 2020.

The significant negative impact is felt by all industries in which tourism has a significant multiplier effect, including aviation, manufacturing, agriculture, food and beverage supply. For example, the cancellation of flights and the closure of airports have led to the temporary loss of more than 10 million jobs in civil aviation. According to the latest estimates of the International Air Transport Association (IATA), the industry's losses could reach $ 113 billion. Overall, IATA estimates that international aviation business can be reduced by 19% (COVID-19: Resources for Airlines & Air Transport Professionals, 2020).

Results

The main factors that negatively affect the confidence and decisions of consumers of travel services are: travel restrictions and border closures that apply to most destinations, travel security issues, virus outbreaks and risks of new bans, the danger associated with lack of reliable information and deteriorating economic situation. The tourism industry needs a reboot. In the near future, the world is still facing serious challenges, from the indefinite duration of the pandemic period to restrictions on movement, all in the context of the global economic recession. Countries around the world are implementing a wide range of measures to minimize the effects of the COVID-19 pandemic and encourage the recovery of the tourism sector.

Table 1: Government measures taken by countries in a pandemic COVID-19

Budget stimulation as% of GDP	New loans and liquidity support	Deferral of payments on existing loans and bonds	Deferment of tax liabilities, their reduction or cancellation	Wage support
Germany				
23 %	€ 100 billion for direct recapitalization to ensure the solvency of companies; € 400 billion in	mostly through the European Central Bank and focused on stabilizing long-term interest rates that are lower or	Deferment of tax payments and reduction of advance tax payments, corporate taxes and trade taxes Cancellation of law	Extended access to short-term loss assistance Extended child support payments program for low-income parents

	guarantees that will help businesses confront liquidity problems; € 100 billion for refinancing	slightly lower than the market rate, depending on the rate and business	enforcement measures / fines in cases of late payment Advance tax payments, corporate income tax and trade tax have been abolished	Facilitate access to basic income support for non-employed people Expansion and simplification of social assistance compensation programs
Poland				
12%	PLN 25 billion (€ 5.65 billion) to support micro-enterprises in the form of interest-free loans PLN 50 billion (€ 11.3 billion) to support SMEs in the form of interest-free loans PLN 25 billion (€ 5.65 billion) to support large enterprises in the form of loans or bonds, purchase of shares or securities	Payment of principal and interest on the loan Extension of the grace period for an additional period of up to 6 or up to 12 months Reduction of the interest rate on loans to 0% for a period not exceeding 12 months Opportunity to discuss the terms of the loan for all entrepreneurs, regardless of the size of the business	Deferment of most taxes; Simplified forms and procedures for filing tax returns; The procedure of tax deductions has been accelerated	Payment of wage subsidies for employees of institutions affected by the pandemic and non-employees: 50% of the minimum salary - a drop in volume by 30% 70% of the minimum salary - a drop in volume by 50% 90% of the minimum salary - a drop in volume by 80%
Hungary				
9%	Providing soft loans and guaranteed loans; new export support through the state bank Eximbank; a grant of € 800,000 for investments in export companies; working capital loans on concessional terms; a new mechanism for providing guarantees and insurance.	Suspension of loan payments until the end of 2020 for all those who received a loan by March 18; extension of the term for obtaining short-term loans of business enterprises until July 30; annual interest rate (APR) for new loans increased to AP rate plus 5%	Mitigation of social protection for the sectors of the economy that are most at risk (travel, tourism, entertainment, etc.); new additional tax for credit institutions during 2020; a new additional tax for retail outlets (crisis tax) in favor of other important sectors; simplified taxation procedure and tax return procedures	Compensation of 70% of salary for three months for companies experiencing decline; significant reduction of various deductions from salary; 40% salary increase for people working in the engineering sector or in the field of research and development
Ukraine				
No data availab le	UAH 4 billion allocated to compensate the interest on existing loans for micro and small	Introduction of a zero declaration and tax on withdrawn capital; Abolition of total	The deadline for payment of taxes on land, land lease and real estate tax, which was due in April 2020, has been extended to	Temporary unemployment benefits for those who have lost their jobs as a result of the COVID-19 pandemic

	enterprises, as well as an expanded program of available loans (5-7-9%); UAH 24 billion to provide loans with state investment guarantees; UAH 1.6 billion in support of creative industries	fiscalization with full implementation of PPO software	June 30, 2020, and similar taxes for March 2020 have been abolished.	are paid in the amount of two thirds of the amount of salary for each reduced working hour, but not more than the fixed amount, namely the established minimum monthly salary (currently 4723 UAH or 150 €); increasing pensions and unemployment benefits

Source: International monetary fund policy, 2020; KPMG. Ukraine. Government and institution measures in response to COVID-19, 2020; International tourism and COVID-19, 2020; HDC Hotel&Destination Consulting, 2020.

Success in the resumption of tourism at the present stage and in the future depends on both interstate and public-private cooperation, on the efforts of all stakeholders in different regions and industries. The development and implementation of timely, large-scale efforts and agreed mechanisms will allow to level the consequences of the COVID-19 pandemic. Short-term, medium-term, and long-term measures should be developed on the basis of the International Labor Organization's response to the COVID-19 pandemic, which addresses four interrelated challenges (COVID-19 and Tourism, 2020).

Stimulating the economy and employment. It is necessary to develop and implement budgetary stimulus measures by providing new credit mechanisms, including sectoral ones. Micro, small and medium-sized enterprises of the tourism business are especially in need of credit resources, which at this stage are in an extremely difficult situation due to limited resources and problems with access to capital. It is advisable to use the approach of adjusting the terms of the loan on existing credit lines so that they become more accessible to these companies through guarantees and a reduction or fixed level of interest rates.

Support for tourism enterprises, jobs and income. Policies to support tourism enterprises, jobs and income can be provided by suspending or subsidizing taxes, fees and social security contributions. In many countries, tourism is seasonal, so there is a problem of informal employment in the industry, which is complicated by weak legal regulation and low level of organization of workers. Migrant workers, women and young people are most vulnerable to informal and temporary employment. Income support measures may include temporary wage subsidies and easing of tax and debt obligations.

Protection of employees of tourist enterprises. Effective measures include subsidies for paid leave for employees of enterprises that must be closed and assistance in cleaning and disinfecting workplaces before they are created. In many countries, workers who are experiencing deteriorating health or are in quarantine are granted paid leave.

Social dialogue as a source of decisions. Policies aimed at reducing the negative effects of the crisis should be formed on the basis of tripartite social dialogue.

It is obvious that measures aimed at supporting the tourism business and preserving jobs and sources of income are extremely important for the industry and its further development.

Restrictions on the movement of tourists require the search for innovative models, the introduction of new approaches, the use of information technology, improving the overall model of communication that will promote access to tourist facilities and attract new audiences, develop new skills and support the transition of tourists to new conditions. Continuous communication between the subjects of tourism and related activities at all stages of travel with existing and potential tourists is provided through various forms of marketing communications.

Intensive use and implementation of smart technologies in everyday life allow us to predict the transition from the traditional form of economic relations to the smart economy. Smart-tourism has features that have the characteristics of manifestation in the functioning of smart-cities and smart-destinations - the spatial aspect, as well as in the management of territorial-administrative units and destinations – a functional approach.

Research shows that smart tourism (sustainable, meaningful, actions that lead to responsible trips) is considered not as an industry, but as a catalyst for change that occurs when participants make constant, tangible actions that make travel responsible and modern.

Mobile information services demonstrate the presence of significant potential, both as a source of information for customers about the territory, and a quality channel of communication with tourism service providers. Creating information portals based on Internet services and software of modern gadgets today is one of the promising areas of development of the tourism industry. The development of the modern concept of using integrated information systems (IIS), combining Internet services and software applications of modern gadgets due to the need to synthesize information technology with Smart-method in urban cultural tourism by creating new information systems to control access to information flows. Development of smart tourism, constant and systematic use of smart elements leads to additional value of travels, rendering of additional services in the field of city cultural tourism (Kyryliuk, Lytvyn, 2019).

A new communication trend with consumers of travel services is gamification, which is part of modern information and communication infrastructure and is gaining popularity in the marketing activities of companies, using the best ideas from loyalty programs, game mechanics and behavioral economics and creating mechanisms for tourist participation in business processes.

Gamification is a kind of game technique, which provides a game form of any activity that increases the interest of participants to spend their time and energy on it, attracts and retains the consumer who is focused on the accumulation of unique bonuses and points. The gamification strategy is based on the reward for completed tasks in the form of points, honors or levels, indicators of progress and issuance of virtual currency to the performer. Gamification has effectively proven itself as a lever of influence on modern consumers, regardless of their age, social status and other characteristics.

The popularity of the concept of gamification is largely determined by the shift of generations in the age structure towards the young generation of millennials (born digital, digital natives, Net-Geners, Y-generation, MeMeMe-generation, millennials), who were born and socialized in a new information environment. Internet technologies, smartphones and games are an integral part of their lives, that stimulates the development of interactive tools to involve this category in the implementation of projects with the introduction of game elements. In 2017, there were approximately 1.7 billion millennials on the planet, this is almost 24% of the total population of the Earth. According to estimates of the experts, 75% of jobs in the world will be filled by this generation until 2025 (GBCSA, 2010).

The active penetration of game methods in marketing is explained by the following factors:

- significant coverage of adults with various game activities and monetization of these activities;
- constant availability of mobile devices and the Internet;
- falling efficiency of traditional types of advertising.

Gamification in marketing allows us to solve the following tasks: attracting users, retaining the attention of consumers, monetization of visits.

Gamification in tourism can take various forms, such as the use of auxiliary and virtual reality with the resources application, gamification of tours, games in theme parks, games between cultural heritage sites, websites, gaming experience in restaurants or accommodation, as an increase while on the plane, gaming in museums, the whole virtual tour in the game format of others (Tunic, 2017).

The implementation of gamification in the museum space contributes to its attractiveness and motivates guests to visit museums. The development of attractive museum programs, games, quests, interactivity of museum expositions allows you to dive in a certain atmosphere, to enliven the museum space. The trend of the game merging digital space with the real through the use of mobile applications allows you to combine electronic games with the space of reality, game-wise connecting digital space with the museum.

Modern multimedia capabilities combine a real environment and VR technologies. Open quests and mobile quest applications with augmented reality mechanisms create a new world for travelers and transform the journey into an exciting game. Mobile applications encourage more people to travel to explore new cities.

Elements of the game are introduced into the work of hotels and restaurants to effectively sell services and increase the number of consumers. Adaptation of these institutions to the use of game technologies, application of loyalty

systems, accumulation of points, which measure the achievements of users in the game, rewards for completed tasks or achieving a certain status (level, number of points) is economically viable for the company. The real benefits (free breakfast/lunch/dinner, additional meal, increase in the number of guests, decrease in the amount of the receipt of others) are effective with the help of virtual ones. Real rewards bring users closer to real institutions, allow him to appreciate all its benefits and as a result of its transformation from virtual to real loyal consumption of services.

The results of the implementation of innovative models to support the tourism industry are shown in table 2.

Table 2: Innovative models to support the tourism industry

Types of innovative models	Means of implementation	Result
Smart-technologies	Creation of new information systems to control access to information flows of the tourist services network. The constant and systematic use of smart elements.	1.Additional value of travel; 2. provision of additional services in the field of urban cultural tourism
Gamification in tourism	Development of interactive tools for attracting tourists to the implementation of projects with the introduction of game elements.	1. Attracting users; 2. retaining the attention of consumers; 3. monetization of visits
Gamification in the activities of museums	Attractive museum programs, games, quests, interactive museum expositions, mobile quest applications with augmented reality mechanisms	1. Motivation of visitors to visit museums; 2. the number of visitors increases
Gamification in the activities of hotels and restaurants	Use of game technologies; application of loyalty systems; accumulation of points, which measure the achievements of users during the game; rewards for completed tasks or achievement of a certain status (level, number of points).	1. The efficiency of sales of services increases; 2. the number of visitors increases

Accordingly, gamification is a marketing innovation in the field of tourism and is a competitive advantage of businesses and destinations. The use of the game format in travel services allows you to attract new, retain and motivate regular customers and becomes an integral part of most travel.

Conclusions

At the current stage, the crisis related to the COVID-19 pandemic has forced the tourism business to step out of its comfort zone and look for innovative ways to develop and operate. An important factor in the recovery of the tourism industry should be a strategic approach aimed at business continuity through interstate cooperation, public-private cooperation, public support for tourism and business initiatives, simplification of travel conditions, removal of barriers, mitigation of fiscal policy, incentives and application marketing innovations to restore trust among consumers of travel services. The use of modern marketing communications in the context of the COVID-19 pandemic will allow us to develop and promote tourist and cultural sites, to increase the potential for future travel. In order to successfully promote tourism products, it is necessary to create alliances of tourism and cultural facilities with technology companies and the private sector in order to build capacity after the resumption of tourism.

Abstract

The purpose of the present study is to compare the dynamics of 6 agricultural parameters (crop yield, employment rate, total GVA, the GVA of the agriculture sector, DP and LPA) in Romania and the countries within the Visegrad Group, between the years 2007-2013.Poland registered the highest GVA, GVA from agriculture and DP between the years 2007 and 2013. Romania scored the highest percentage of the employment rate between the studied timeline. Czech Republic registered the highest crop yield and LPA. Continuous monitoring of the European agriculture performance is needed in order to identify a long-term trend and develop prediction models, for future development of support strategies and legislation framework of the sector.

Keywords: agricultural sector performance, crop yield, employment rate, Visegrad Group.

Introduction

Agriculture refers to the extraction or harvesting of products from the earth and is part of the primary sector of the economy. Agriculture is the broadest word that can be used to indicate the methods in which crop plants and domestic animals support the human population by supplying food and other products(Harris and Fuller, 2014).In the European Union, agriculture is the main land user, accounting for more than 47% of the total territory

Cite this Article as: Ira A. SIMIONOV, Alina MOGODAN, Stefan M. PETREA, Aurelia NICA, Dragos S. CRISTEA, Sarina ROSENBERG and Victor CRISTEA "Comparative Study Between Romania And Visegrad Countries, Related to Agricultural Sector Performance" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(Giannakis et al., 2015).Since the expansion of the European Union (EU), significant funding under the Common Agricultural Policy (CAP) and structural funds umbrella has been allocated to ensure the renewalof agricultural machinery in the new EU Member States (Volkov et al., 2020).

The dynamic character of this sector has manifested during the past decade and can be attributable to a large variety of factors, such as disruption of production, distribution networks enhancement, climate change (there is no other economic sector as exposed to natural hazards), economical strategies and globalization or investments dynamics (Petrea et al., 2020).

From the total output value of the EU's agricultural industry,approximately 55.0 %was generatedby the next countries: France (77.2 billion €), Italy (56.9 billion €), Germany (52.7 billion €) and Spain (52.2 billion €). Other countries combined output such as the United Kingdom (29.8 billion €), the Netherlands(28.2 billion €), Poland (25.0 billion €) and Romania (18.6 billion €)accounted for approximately 23.4 % (Eurostat, 2018). In the last years, a small rise value of the EU's agricultural industry was observed, which is dueto the developments in the values recorded in Romania (+8.0 %), France (+5.6 %), Italy (+3.0 %) and Spain (+3.0 %) (Eurostat, 2018). At the opposite pole, a decline in the values of the agricultural industries was observed in countriessuch as: Denmark (-8.9 %), Sweden (-8.8 %), Germany (-6.3 %) and Poland (-2.4 %) (Eurostat, 2018).From the employment point of view, higher levels of salaried labor input were observed in Ireland (+5.0 % per year on average), Luxembourg (+3.9 % per year on average), Austria (+2.6 % per year on average) and Poland (+2.2 % per year on average). At the opposite pole, declines of the salaried labor input were observed were noted in Slovakia (-5.2 % per year on average), Greece (-3.6 % per year on average), Czech Republic (-3.3 % per year on average) and Romania (-3.2 % per year on average) (Eurostat, 2018). Low productivity of the agricultural sector is determined by the lack of investments, capital and available loan schemes (Shik et al., 2016; Petrea et al., 2020).

Quantifiable parameters can be used in order to assess the agriculture performance and productivity such as crop yield, employment rate, the gross value added (GVA), direct payments (DP) and labor productivity in agriculture (LPA). According to Giannakis et al., (2015), Eastern European countries exhibit the highest rates of decline in the number of farm holdings due to the restructuring process of privatization and redistribution of agricultural land. According to Petrea et al. (2020), GVA is strongly related to productivity as it measures the contribution tothe economy of an individual producer, industry or sector.

According to Baer-Nawrocka (2016), there was observed a transformation of the agriculture sector in the countries of Central and Eastern Europe, manifested through improved productivity over a long period of time. Therefore, the aim of this study is to compare the dynamics of 6 agricultural parameters (crop yield, employment rate, total GVA, the GVA of the agriculture sector, DP and LPA) in Romania and the countries within the Visegrad Group, between the years 2007-2013.

Materials and Methods

The agriculture activities in Czech Republic, Hungary, Poland, Slovakia and Romania are supported by the Common Agricultural Policy (CAP).

The following parameters were recorded and analyzed: crop yield (kg), employment rate (%), the total GVA (billion $), the GVA of the agricultural sector (billion $), DP and LPA (€/annual work unit), for each of the aforementioned country, and for each year within 2007-2013 timeline.

Results and Discussions

The crop yield is directly influenced by factors such as climate, irrigation, fertilizer use etc. As it can be observed in Figure 1, the lowest crop yield was registered in the year 2007 in all countries, except for Poland, which registered the lowest crop yield in the year 2008. In case of the highest crop yield, the production varied with the highest values in the year 2011 for Romania and Czech Republic, and in the year 2008 for Hungary and Slovakia. In all the studied years, the Czech Republic recorded the highest yield production, compared to the rest of the analyzed countries, except for the years 2008 and 2009, when Hungary recorded the highest crop yield.

Fig. 1: The crop yield in the analyzed countries

The employment rate in the analyzed countries was relatively constant within the studied timeline, for each country. As it can be observed in Figure 2, the highest employment rate was recorded in Romania (between 28.7–31.01%), followed by Poland (between 12-14.74%). The lowest employment rate was observed in the Czech Republic (between 2.99-3.03%) and Slovakia (3.08-4.21%).

Fig. 2: The employment rate in the analyzed countries

The total GVA in the analyzed countries (Figure 3) was constant between the years 2007-2013. The highest GVA was recorded in Poland, for all the studied years and the lowest GVA wasrecorded in Slovakia, for all studied years.

Fig. 3: The gross value added in the analyzed countries

The GVA generated from the agricultural activities (Figure 4) registered the highest values in Poland (between 10.93 and 15.07 billion $), followed by Romania (between 8 and 13.51 billion $). The lowest agricultural GVA was recorded in Slovakia (between 1.5 and 2.7 billion $).

The percentage of GVA agriculture from the total GVA, registered highest average value in Romania (6.29%), followed by Hungary (4.19%). This result emphasizes the significant importance of agriculture sector in these countries economy. However, in case of Czech Republic and Slovakia, the agriculture sector registers a low GVA percentage from the total GVA, fact that points out the potential of further development of the sector in the aforementioned countries.

Fig. 4: The gross added value from the agricultural activities in the analyzed countries

The direct payments granted by the European Union to the analyzed countries manifestedan upward trend between the years 2007-2013 (Figure 5). Poland registered the highest values of direct payments (between 1076.45 and 2769.5 €/ha), followed by Hungary (between 471.52 and 1203.4€/ha). The lowest values of direct payments were recorded in Slovakia.

Fig. 5: Direct payments in all analyzed countries

The LPA registered the highest values in the Czech Republic, followed by Slovakia (Figure 6), in all the studied years. The lowest LPA was registered in Romania and Poland (Figure 6), for all analyzed years.

Czech Republic and Slovakia assured the highest crop yield from the studied countries (Figure 1), with low employment rate (Figure 2), fact which reveals a superior degree of technical and technological abilities that are used in agriculture, although this sector is not majorly contributing to total economic performance of the country, compared to Romania, where the situation is opposite.

Considering that Hungary scored the second highest crop yield, a low percentage of employment rate and high value of direct payments, it is highlighted the intentions of this country to develop its agriculture sector, making it a key sector in the national economy.

The high investments in the agricultural sector in Poland, manifested through a high value of direct payments, indicate the intentions of this country to raise the productive performance of this sector. This was expected since Poland registered the lowest LPA compared to the rest of the Visegrad countries. Thus, the polish agriculture needs a consistent financial input (DP) for retechnologization, the development of new, economic sustainable growing technologies respectively.

Fig. 6: The labor productivity in agriculture in all analyzed countries

The status of Romania is similar to Poland, with the mention that the Romanian agricultural sector occupies a more important place in the national economy, considering the high employment rate percentage. Nevertheless, the Romanian investments in this sector are below the Polish investments, fact that determines the recommendation of a raise of these investments, through different instruments in European finances, and thus, raising the potential of national agriculture sector.

Conclusions

Poland registered the highest GVA, GVA from agriculture and DP between the years 2007 and 2013, compared to the rest of the Visegrad countries and Romania. Thus, it can be highlighted the high potential of this country to future development of the agriculture sector and its significant importance in the national economy.

Romania scored the highest percentage of the employment rate between the studied timeline, compared to the countries within the Visegrad group. This fact associated to the low crop yield of the country, indicates the need of an upgrade of the agricultural infrastructure.

Czech Republic registered the highest crop yield and LPA, compared to the rest of the Visegrad countries and Romania, fact that emphasizes the efficient development of the agriculture sector in this country.

Continuous monitoring of the European agriculture performance is needed in order to identify a long-term trend and develop prediction models, for future development of support strategies and legislation framework of the sector.

Abstract

The social, political and economic development of Russia in the 1920s was largely determined by the legacy of the Civil War and War Communism. Historians discuss the importance of the NEP (New Economic Policy) phenomenon, which is an extremely unyielding subject of research for a number of reasons.

Keywords: New Economic Policy, government investment, War Communism, Civil War, cooperative economy management.

The New Economic Policy ("New" in relation to the War Communism) is usually considered as a policy of transition from capitalism to socialism, implemented since March 1921 (10th Communist Party Congress) to the second half of 1920s. NEP was proclaimed in the context of a severe political crisis that arose during the country's transition to peaceful life (the Civil War in most of Russia and other Soviet republics ended by 1921).

The root cause of the political crisis of 1921 was the inability of the Russian communist party of the Bolsheviks to lead the country on the one hand, and the unwillingness of the population (especially the peasantry) to submit to the economic policy of War Communism in peacetime on the other hand.

The main reason of discontent of the peasantry was food surplus requisitioning (complete alienation of surplus agricultural production in profit of the state). This discontent was expressed in the rise of anti-Bolshevik riots in a number of regions of the country, including the "antonovschina" in the Tambov province, where the government had to use regular army units led by N. M. Tukhachevsky to pacify the peasants.
In early 1921, mass strikes began in Petrograd, and on March 1, Kronstadt sailors rose up in solidarity. Rebels demanded "power to the Soviets, not to the parties." The mutiny was suppressed on the night of August 16-17, 1921, by troops under the command of Tukhachevsky and Trotsky.

By the beginning of 1920, a crisis started within the ruling Bolshevik party due to so-called "discussion of trade unions".

In the midst of the crisis, 10th Communist Party Congress began to work in March 1921. The Congress put an end to factional activity in the Communist Party (resolution "On unity in the Party") and officially established the Central Control Commission (CCC), which was supposed to prevent the formation of factions, sort out personal conflicts, etc. During the Congress, Lenin first proposed replacing food surplus requisitioning with tax in kind, and peasants received the right to sell all surplus products on the market. The measures proposed by Lenin were fixed by the decisions of 10th Communist Party Congress (May 1921). Since that time, the transition to the NEP was finally proclaimed.

The NEP was finally established in 1923 (RSFSR) and in 1924 (other republics of the USSR).

1. Replacement of food surplus requisitioning with tax in kind (spring 1921)
2. Permission for private trade (May 1921)
3. Beginning of denationalization (autumn 1921)

4. Creation of a legal framework that meets the new economic conditions (1922)
5. Monetary reform (introduction of the gold ten-rouble coin) (1922-1924)

In October 1921, the State Bank was restored, which controlled the network of newly formed cooperative banks, credit and insurance partnerships. At the end of 1922, monetary reform began. Until March 1924, a stable (gold ten-rouble coin) and collapsing (Soviet bank note) currencies were simultaneously in circulation. The exchange ratio was 1 gold ten-rouble coin for 60 thousand Soviet bank notes. By February 1924, the State Bank bought the remaining Soviet bank from the people. The gold ten-rouble coin was a hard convertible currency and was worth about 6 USD until 1927.

Elements of long-term planning were also introduced into the NEP. The first such plan was prepared by the State Commission for Electrification of Russia and approved at the VIII Congress of Soviets in December 1920. In February 1921, the State Planning Committee of the USSR was established.

As a result of these events, the national economy has revived, and market relations have begun to improve. However, political regime hardened (censorship, one-party system, intraparty purges).

With the introduction of the NEP, a slow but steady economic recovery begins. 1925 was the year of maximum development of concessions: major contracts were signed with the Americans (manganese mining in Georgia) and with the British (gold mining in Siberia). As of 1926, 113 agreements with foreign companies were registered, but only 31 contracts were related to industry. Since 1923, rapid demographic growth began:

- 1923 – 134 million people
- 1926 - 147 million people (average annual growth of 2%).

The analysis of economic condition of the transition to the new economic policy suggests that commercial and industrial cooperation activities were carried out in extremely adverse conditions due to the economic devastation and outcome of famine (1921-1922), aggressive fiscal policy, lack of funds, and the low purchasing power of the population.

NEP improved the national economy, but it was not possible to avoid crises. The most sensitive crises were Scissors Crisis of 1923 (widening gap between industrial and agricultural prices) and the procurement crisis of 1927-1928. Unemployment has steadily increased due to competitive business environment. These facts became the political justification for the rejection of the NEP in the late 1920s.

Abstract

Each country, regardless of its territory, contains a certain number of administrative and territorial entities, therefore the state regional policy is implemented in all countries and is essential within the framework of the overall economic development strategy. In the Russian Federation, issues of regional development are constantly relevant. Currently, in accordance with the Order of the Government of the Russian Federation N 207-r "On approval of the strategy of spatial development of the Russian Federation until 2025" d/d February 13, 2019, the goals, objectives, mechanisms and methods of spatial development of the country are approved. In general, regional policy in Russia is fast-paced due to significant impacts of both external and internal factors.

Keywords: State Policy, Special Economic Zone, Priority Social and Economic Development Area, Regional Development.

Regional policy in Russia has undergone many changes in the process of evolution from decentralization and significant independence (1990s) to significant centralization and redistribution of a significant part of the accumulated funds in favor of the Federal budget of Russia and other centralized funds (since the mid-2000s). As a result, some researchers note that certain regions of the Russian Federation are subsidized due to the redistribution of a significant part of the accumulated funds in a benefit for the Federal budget of Russia and other centralized funds. In the end, many heads of government bodies of constituent entities of the Russian Federation point to a significant dependence on Federal authorities and the increasing importance of interpersonal relationships.

Recently, the state policy of regional development began to evolve in the field of granting greater independence to the governing bodies of the Russian regions. One of the main principles is the implementation of state support for regional and local authorities, provided that they independently exercise their powers established by the Constitution of the Russian Federation and Federal laws.

In accordance with the Decree of the President of Russia, constituent entities of the Russian Federation are funded with grants (inter-budget transfers) proportionally to their development ratings.

These days, EU shifts from equalization via compensations into stimulation of underused region capacity in order to provide competitiveness. China and USA apparently try to achieve balanced spatial development through the development of development of aggregated regions (macro regions). However, long-term balanced spatial development can't be achieved using direct economic incentives (fiscal balancing etc.) due to limited government resources. Due to this fact, federal authorities in the Russian Federation use indirect incentives in order to stimulate region competitiveness through the development of endogenous factors. It should be noted that these incentives cause certain government expenditures (tax and customs losses). According to the report of the Accounts Chamber of the Russian Federation, residents of special economic zones (SEZ) receive 28 billion RUB of benefits over 11 years (2005-2015). However, the development of SEZs and expansion of production volume will cause improvement in employment and increase in tax payments, increasing government revenues.

Creation of the territories with special legal status holds an important position among indirect incentives in Russia. First off, these are special economic zones (SEZs), most of which were created under the Federal Law No. 116-FZ

Cite this Article as: Vladimir KOVARDA, Elena BOLYCHEVA and Roman LAPTEV" Research of Dynamics of The State Policy of Regional Development of Russia In the Context of Stimulating Spatial Development" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

"On Special Economic Zones in the Russian Federation" d/d July 22, 2005. Residents of such territories have a number of benefits and preferences.

It should be noted that in 2016 the Accounts Chamber of the Russian Federation reported that many SEZs appeared to be ineffective. Due to this fact, there were a number of government decrees on termination of SEZs. Concurrently, in 2014, the federal law on creation of priority social and economic development areas (PSEDA) came into force. There are also benefits for residents of these territories (Figure 1).

Figure 1: Major exemptions and concessions for residents of SEZs and PSEDAs

At the same time, these indirect instruments of economic stimulation of regional development have significant differences and function in parallel and complement each other. These territories are characterized by different scheduled durations (49 years without extension for SEZ and 70 years with possibility extension for PSEDA), different goals and objectives, as well as different localizations. Thus, SEZs are created for the development of manufacturing industries, high-tech industries, tourism, health resorts, port and transport infrastructure, technology development, and the production of novel products. PSEDAs are created in order to create favorable conditions for attracting investment, ensuring accelerated social and economic development, and creating comfortable conditions for ensuring the human and societal life.

PSEDA can be created only within the constituent entity of the Russian Federation, while SEZ can occupy several constituent entities.

Thus, PSEDA is is more flexible and focused on regional development.

On July 1, 2019, Chapter 25 of the Federal Law No. 289-FZ d/d March 3, 2018 came into force allowing creation of free warehouse customs regimes with the possibility of placing goods under free warehouse customs treatment (i. e. reducing customs charges).

However, despite increasing use of indirect incentives, direct governmental funding for social and economic equalization of regions continues to grow. In 2017, developmental differences between 10 wealthiest and 10 poorest regions reduced from 5.7 to 2.6 times due to equalization transfers from federal budget. Total amount of inter-budget transfers is 1690.1 billion RUB.

Figure 2: Structure of inter-budget transfers in 2017, billion RUB

Figure 2 shows that grants amounted to 44.91% of all inter-budget transfers in 2017. Figure 3 shows that grants tended to grow in 2016-2018: granted amounts increased more than 1.5 times over two years.

Figure 3: Time course of grants as inter-budget transfers, billion RUB

Thus, constituent entities of the Russian Federation are still supported directly due to existing redistribution system. However, the use of indirect incentives gradually increases.

Nowadays, regional equalization still prevails in EU, however mechanisms of stimulation of endogenous factors of regional economic development are increasingly frequently used.

Conclusion

Nowadays, the state policy of regional development in Russia transforms from federal centralization into the stimulation in region competitiveness through the development of endogenous factors and increasing use of indirect incentives.

Factors of Bank Profitability: Empirical Evidence from Poland and Czechia

Wiktoria SLOMIANY

Heineken Global Shared Services, Poland wiktoriaslomiany0@gmail.com,

Marcin KĘDZIOR

Cracow University of Economics, Cracow, Poland, kedziorm@uek.krakow.pl

Abstract

The paper aims to identify the major factors which affect the profitability of banks in selected East European countries. The empirical analysis verifies the profitability factors in 40 listed banks in Poland and Czechia. The analysed factors comprise bank size, capital adequacy, loan loss provisions, liquidity, management efficiency, lending, revenue diversification, market concentration, economic growth and inflation. The factors regarded as the most significant ones include loan loss provisions, capital adequacy and management efficiency. The multivariate analysis is based on linear mixed models.

Keywords: banking, bank profitability, determinants of profitability, Poland, Czechia

Introduction

Banks are stated to be one of the most relevant financial institutions in the economy. Although objectives of every bank differ, there are some that are the same for each banking institution - profitability, liquidity and maximizing the value of the bank (Rose, 1996). Looking at a big picture, banks supporting the economy in financial terms determine the existence, functioning and development of economic entities, but also in a larger scope, is a key for development of different sectors of economy and economy as a whole (Kopiński, 2016).

The notion of profitability shows how banks manage their resources and how efficient is their performance. High or increasing profitability is the only way for banks to encourage investors for investment in shares or debt issues or to boost their operations in extended periods of time. Managers use profitability ratios to receive information about the bank, it is used for internal purposes, but also for attracting potential investors and keeping the current ones (Compton, 1989). Good level of profitability strengthens the position of banks, which encourages potential customers to use bank services (Kopiński, 2016).

The paper aims to verify profitability factors on the basis of banks from selected East European countries. The choice of this subject is determined by the actual scientific needs. The profitability of banks from Eastern Europe countries, as yet, has not been subjected to in-depth empirical verification. The only significant works in this field are as follows: Djalilov, Piesse (2016); Havrylchyk, Jurzyk (2011); Kopiński, (2016); Titko et al (2015). As yet, the factors impacting the profitability of Polish and Czech banks, verified in this work, have not been subjected to empirical verification. The work analyses the following factors which have an impact on bank profitability: bank size, capital adequacy, loan loss provisions, liquidity, management efficiency, lending, revenue diversification, market concentration, economic growth and inflation. The authors believe that relatively innovative factors include loan loss provisions and revenue concentration, in particular in the population of banks from Eastern and Central Europe.

The analysis, conducted in 2013-2017, comprises 40 banks from Poland and Czechia. The choice of banks from these two countries results from similarities between them in such areas as economic development, the development of banking sectors, as well as the institutional and legal environment. In the first part of the paper, several determinants of bank profitability are described and their relationship with profitability is analysed comparing various researches. In the second part of the article, an analysis of the statistical significance of the influence of various factors on the profitability of banks in Poland and the Czech Republic was carried out. Correlations between quantitative variables are evaluated using Spearman's correlation coefficient. Because the collected data is not independent, multivariate analysis is based on linear mixed models.

Cite this Article as: Wiktoria SLOMIANY and Marcin KĘDZIOR "Factors of Bank Profitability: Empirical Evidence from Poland and Czechia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Determinants of bank profitability

In the literature, the determinants of bank profitability are divided into internal (microeconomic) and external (macroeconomic) ones. In the article the following internal factors will be analyzed: bank size, capital adequacy, loan loss provisions, management efficiency, liquidity, lending, revenue diversification, market concentration, GDP growth, and inflation rate.

Bank size

Many research studies indicate bank size as a factor which influences bank profitability. However, one cannot clearly state whether bank profitability is positively or negatively influenced by this variable (Rose, 1996). A positive correlation was discovered in the USA before the crisis of 2008 - customers felt safe keeping money in big banks due to a simple reason - in case of economic turbulences, they believed that government would bail out the bank as it was "too big to fail" (Ding et al, 2017). According to I. Adelopo et al (2018) bank profitability before, during and after the financial crisis of 2008 was similar, but larger banks can easier overcome current financial problems with their resources and scale advantages.

It was noticed that large banks could benefit more from product and loan diversification possibilities (Smirlock, 1985). A positive relationship between bank size and profitability is also associated with economies of scale (Bourke. 1989).

However, as it was noticed in the evidence from Switzerland, the impact of bank size is not always clear cut (Dietrich, Wanzenried, 2011). The authors found out that during the crisis, large banks were less profitable than small or medium-sized banks. It was due to much higher loan loss provisions during the crisis.

Shehzad et al (2013) pointed out that expanding operations in different markets increases costs, which are far greater than profits. Such costs include product development, diversification and branch expansion. However, it was also noticed that during unsteady times, such as crisis, large banks have an advantage and they borrow on lower rates and lend at higher ones, enjoying monopolistic position (Allen et al, 2011).

Capital Adequacy

Capital adequacy is strongly associated with Basel Capital Accord. It is stated there that supervisors need to set minimum adequacy levels which are appropriate and prudent. Capital adequacy ratios are key ones in assessing the financial situation of a bank, its solvency or possibility of expansion (Lessambo, 2013). According to Tran et al (2016), if adequately capitalized banks raised more capital, there would be a negative relationship between capital and profitability, whereas for undercapitalized banks, the correlation would be positive.

In the previous research, the results concerning relationships between capital adequacy and profitability were mixed. Bourke (1989) found out that banks which are highly capitalized, also have better sources of financing on low cost and low risk level and they can enter markets with better quality assets, therefore they are more profitable. However, other researchers- like Altunbas et al (2007) claim that across Europe inefficient banks tend to be the ones that are highly-capitalized. It was also noticed by Kashyap et al (2010) that an increase in capital ratios also raises the cost of funding.

Dietrich and Wanzenried (2011) verified empirically that capital ratio does not have impact on Swiss banks' profitability before the crisis, however it is a significant and negative determinant during the crisis. The reason for that can be that safer banks in Switzerland received lots of deposits, but since the lending demand was decreased, income was not increased. The authors mentioned above also accomplished work concerning profitability in low, middle- and high-income countries (Dietrich, Wanzenried 2014). According to their research, capital ratio has a positive and significant impact on banks in high-income countries. Highly-capitalized banks are perceived as safer; thus their funding costs are lower. Similar results were achieved by Demirguc-Kunt and Huizinga (1999) and (Borroni et al, 2016).

Loan Loss Provisions

Credit risk is the likelihood of the deterioration in the credit standing of the borrower. In general, diversified portfolio of loans and credits is advised, as different likelihood of default is assigned to different types of assets and off-balance sheet activities. The highest risk is associated with loans, as they are mostly given for longer periods of time and the financial situation of individuals and companies can change (Casu et al, 2006)

If banks carry out their operations in unstable and risky environment, having troubles controlling their lending, they will probably have a higher loan loss provision ratio, which implies reduced credit quality, resulting in increased provisioning costs and decreased interest revenue. According to Menicucci and Paolucci (2016) European banks showed a negative relationship between the ratio and profitability. The same results were also validated in Swiss

research (Dietrich, Wanzenried, 2011). The authors also noticed that loan loss provisions have been increased noticeably during the crisis and it affected the profitability results.

In the study concerning profitability in transition countries, it was interesting to find out that in late transition countries (such as Armenia, Belarus, Moldova, Ukraine) the impact of credit risk was negative on profitability, whereas when it comes to early transition countries (including, among others, Poland, Czech Republic, Hungary, Lithuania), it was just the opposite - the relationship was positive (Djalilov, Piesse, 2016). Managers from early transition countries took longer time to work on the proper risk strategy and they were engaging in risky transactions whereas late transition countries chose risk-averse strategy. The negative relationship between the ratio of loan loss provisions and bank profitability was also validated by Croatian data (Pepur, Tripovic, 2017).

Management Efficiency

Efficiency of banks is necessary due to a competitive market and high expectations of the owners of banks. In the literature there can be found two approaches to efficiency – structural and non-structural one. Structural approach focuses on either cost minimization or profit maximization. Non-structural approach pays attention to achieved financial performance. Often performance is based on the market value of the firm (Berger et al, 2012).

A study carried out by Molyneux et al (1996) in European banks showed that small banks have higher chances of minimizing costs by using economies of scale than large banks. This changed in the first decade of the twenty-first century, though. It was also noticed by Altunbas et al (2007) that probability of attaining average cost saving is higher when operational inefficiencies are decreased or removed than when economies of scale are used. Empirical research carried out by (Borroni et al, 2016) proved that the higher cost-to-income ratio, the lower profitability. The same was noticed in the research assessing profitability in selected countries of Central and Easter European Countries (Petria et al, 2015). The correlation was much stronger for ROAE than for ROAA.

However, in the investigation of Spanish banks the outcome was opposite - the higher the efficiency, the higher the profitability (Trujillo-Ponce, 2013). The author noticed that since the early 1990s improvements in technology, information and communication have made banks perform in a more efficient manner, lowering their expenses while revenues were generated at a higher level.

Liquidity

As liquidity is one of the main objectives of a banking institution, it can greatly impact profitability. Liquidity is seen as an ability to repay obligations when they become due (Duttweiler, 2009). Vodova (2016) analyzed links between profitability and liquidity in the Polish banking sector. A positive correlation between liquidity and profitability was found among medium banks. The ones with a good level of liquid asset ratio show high profitability. Bordeleau and Graham (2010) discovered that keeping liquid assets makes profitability higher, however up to a certain point after which the relationship is reversed. It was also found that this relationship is dependent on the business model of the bank and risk of issues with the funding market.

However, other authors have noticed a negative relationship between liquidity and profitability (Adelopo et al, 2018; Petria et al, 2014).

Loans to Total Assets

Lending is the main activity of a bank, together with deposit taking. Lending provides funds for some period of time by a bank, the borrower is obliged to give back a borrowed amount together with interest in a specified period of time. Bikker and Vervliet (2018) noticed that a relationship between loans ratio and profitability might be difficult to be predicted because of the fact that on the one hand, big loan portfolio generates high interest income, but on the other hand, the credit risk exposure is greater as well. Greater loan portfolio increases profitability, but the credit risk can decrease profitability. (Trujillo-Ponce, 2013) also confirmed a positive relationship between lending and profitability for Spanish banks. The same results were obtained by Borroni et al (2016), but only when dependent variable was Net Interest Margin. Both Menicucci and Paolucci (2016) and Demirguc-Kunt and Huizinga (2000) confirmed an insignificant relationship between the loan ratio and profitability.

Revenue Diversification

Banks rely on both interest and non-interest income, however the proportion of non-interest income in net operating income varies, depending on the character of the bank. It is claimed that gradually non-interest income will have more impact on the bank's profitability (Koch, MacDonald 2010). Diversification was assessed inter alia by Demirguc-Kunt and Huizinga (1999). A negative correlation was noticed between non-interest income ratio and net interest margin. The authors found out that this relationship is stronger in rich countries than in poor ones.

In the research concerning bank profitability in the Euro Zone results depend on the dependent variable used Borroni et al (2016). Those results show that during the period of stabilized economy, banks increase profitability by engaging mainly in lending. In the times of crisis, other sources of income are necessary. Also, according to Dietrich and Wanzenried (2011), banks engaged mainly in traditional banking activities will have lower profitability.

GDP Growth Rate

According to Zampara et al (2017) – macroeconomic factors have big influence on the profitability as they can cause great opportunities or great threats. Higher GDP causes greater demand for bank services and also drop in the rate of bad credits. During economic growth, banks set the rates and fees to be higher and this is beneficial for profitability. In times of economic slowdown, there are more loan defaults, the quality of credit portfolio deteriorates and overall the profitability of the bank is hurt. It was also noticed that prosperous economy has positive impact on solvency of borrowers, encourages businesses and individuals to make investments and take more loans (Trujillo-Ponce, 2013). Adelopo et al (2018) and Pepur, Tripovic (2017) also observed positive impact of GDP Growth Rate on bank profitability.

Inflation

Another way of assessing the relationship between macroeconomic conditions and profitability is via inflation- usually described as annual inflation rate. Typically, increase in inflation is associated with higher loan rates and then raise in bank income. However, some authors notice that the fact if the inflation was foreseen or not, has some influence as well. If it was predicted, then the profitability can be increased. On the other hand, when inflation is sudden, borrowers are not prepared for it, and this can cause problems with loan repayments. There is also an issue that banks would not adjust their rates in accordance to inflation promptly. Then there is a threat that the costs would be higher than gains which would reduce profitability as well.

The research examining Chinese banking sector found out that the relationship between inflation and bank profitability is positive and significant (Tan, Floros, 2012). Authors concluded that the reason behind it is that during studied time period (2003-2009) the inflation was anticipated. Banks had time and could plan the adjustment of the interest rates to make the revenues higher than the costs

In another research Adelopo et al (2018) noticed that. during times with healthy economy, banks are predicted to be more profitable. Results show that the higher the inflation, the higher the profitability and this relationship is statistically significant. In case of more costs appearing, banks can effectively pass them on customers.

Positive results were also confirmed for Spanish banks (Trujillo-Ponce 2013). Author also underlined the point that if the inflation was expected, this information gave banks more time to prepare and to adjust their interest rates accordingly.

HHI Index

Hirschman-Herfindahl index is used for assessing concentration ratio in the particular industry. Negative relationship between the Hirschman-Herfindahl index and profitability was discovered by Borroni et al (2016). According to the authors this relation can be associated with strong competition that is a result of lowering interest margin and as an effect- profitability. The same results were confirmed by Petria et al (2015). Positive correlation was noticed in the research concerning Tunisian banks during the financial crisis which most likely was associated with the high quality of management of Tunisian banks (Rachdi 2013). Similar results are observed for Spanish banks (Trujillo-Ponce 2013).

The Results of Empirical Research

This study comprises listed banks from Poland and Czechia. The choice of banks from these two countries result from a number of similarities between the two nations with regard to the following areas: economic development, banking sectors, legal systems, and cultural and historical factors. In the first phase of the study the authors analyse the impact of selected factors on profitability using linear correlation coefficients, followed by regression analysis. Correlations between quantitative variables are analysed using Spearman's correlation coefficient. Because the collected data is not independent, multiple factor analysis is based on linear mixed models. The analysis comprises 40 banks from Poland and Czechia in 2013-2017. The analysis assumes a significance level of 0.05. Therefore, all p values below 0.05 are interpreted as confirming significant correlations. The analysis is conducted in R-3.6.2. The models were built on non-independent observations (40 banks, each evaluated in 5 consecutive years), a linear mixed model was used. Observations could be temporarily and spatially correlated. By temporal correlation, we mean correlation between data from the same bank but two distinct years. By spatial correlation, we mean correlation between data from two distinct banks in the same year. This led us to include two crossed random effects in our model: one for year and one for bank.

The definitions of dependent and independent variables are presented below.

Table 1: Dependent and independent variables

Symbol	Variables	Proxy	Expected relation
Dependent variables			
ROAA	Return on Average Assets	Net Income/Average total assets	
ROAE	Return on Average Equity	Net Income/Average total equity	
Independent variables			
Bank-specific determinants			
BS	bank size	natural logarithm of total assets	+
CA	capital adequacy	equity/total assets	+
LLP	loan loss provisions	loan loss provisions/total loans	-
ME	management efficiency	cost to income ratio	-
L	lending	total loans/total assets	+
RD	revenue diversification	non-interest income/operating revenues	+
LR	liquidity risk	loans/customer deposits	-
Industry-specific determinants			
MC	market concentration	hirschman-herfindahl index	+
Macroeconomic determinants			
EG	economic growth	gdp growth	+
I	inflation	inflation	+/-

Table 2 presents linear correlation analysis for variables ROAA and ROAE. ROAA is significantly correlated with bank size, capital adequacy, loan loss provisions and management efficiency. ROAA is most affected by capital adequacy, management efficiency and bank size. Therefore, banks with a large share of equity are expected to have a higher level of profitability. Also, the efficient management of the global conglomerates of costs and revenue has a negative impact on banks' profitability. Bank size, which usually indicates an impact on various market players including competitors and clients, is also strongly correlated with corporate profitability. As expected, loan loss provisions have a negative impact on profitability and, obviously, on banks' financial result. ROAE, in turn, is correlated with a larger number of variables, but the level of correlation is generally lower. The following variables are regarded to be significantly correlated with ROAE: bank size, capital adequacy, loan loss provisions, management efficiency, liquidity risk and HHI index. Management efficiency is a variable most negatively correlated with ROAE. The character of correlations (positive or negative) of particular variables with ROAA and ROAE is identical. Among new statistically significant variables, attention should be given to the mutual impact of liquidity risk and ROAE. It is in line with the theoretical assumptions which assume that all risk measures are significant for investors. Moreover, industry concentration increases profitability measured by ROAE. The following variables are most strongly correlated with ROAE: management efficiency, bank size, liquidity risk and HHI index.

Table 2: Linear correlation analysis between ROAA and ROAE profitability factors for Polish and Czech banks

Tables 3 and 4 present a linear mixed model for variables ROAA and ROAE. The significant factors affecting ROAA are as follows: capital adequacy, loan loss provisions, management efficiency, liquidity risk, loans to total assets and revenue diversification. The impact of the above factors on ROAA is as expected and negative (loans loss provisions, management efficiency, liquidity risk), and positive (capital adequacy, loans to total assets and revenues diversification). The greatest range of impact is found for loan loss provisions, capital adequacy and management efficiency. A significant impact of economic growth and inflation rates on the higher profitability of Polish and Czech banks is not recorded. The profitability of banks in the analysed countries is significantly affected by an appropriate level of equity, which mitigates risk and, consequently, reduces the cost of acquired capital. Proper capitalization also increases bank's trustworthiness, attracting potential customers. Same results have been confirmed by Bourke (1989). Financial liquidity also mitigates bank risk, but excessive liquidity can have a negative effect on maintaining high. This supports the findings of Vodova (2016), however it is worth to mention that the results of analysis of the relationship between liquidity and profitability are not uniform and vary from research to research. A significant role is played by appropriate lending policies and the analysis of clients' creditworthiness (Tan, 2016; Menicucci, Paolucci, 2016), as well as generating higher revenue dynamics in relation to cost dynamics (management efficiency). The study confirms the results obtained by Trujillo-Ponce (2013) and Borroni et al (2016) and shows that efficiency is connected with the profitability. It should be also noted that a large volume of loans has a positive impact on profitability, but of equal importance in this context is revenue diversification. Positive correlation of profitability with lending proves that the interest income coming from the loans is more important, than the credit risk coming from lending (also confirmed by Trujillo-Ponce, 2013). However, banks also noticed that having other sources of income can be advantageous and influence profitability in a positive way, which wasn't true for Eastern countries two decades ago (Demirguc-Kunt, Huizinga, 1999).

Table 3: Linear mixed model for ROAA for Polish and Czech banks

Table 4 presents a linear mixed model for ROAE in Polish and Czech listed banks. The impact of particular factors on ROAA and ROAE can be regarded as similar, which indicates the reliability of the obtained results. The impact of loan loss provisions, management efficiency, liquidity risk and revenue diversification on profitability is very similar for ROAA and ROAE. The impact of capital adequacy and loans to total assets on ROAE is less significant than on ROAA. Even though insignificance of capital adequacy with ROAE might seem unexpected, in the research concerning Euro Area the same results have been obtained (Borroni et al, 2016).

There is no impact of economic growth and inflation on the profitability of Polish and Czech banks. However, the most unexpected finding is a slight impact of bank size on profitability in light of the fact that bank size has frequently performed the function of a control variable in a number of empirical research studies of banks' financial management. Even though it is surprising result, it was confirmed also by Adelopo et al (2018). ROAE is most affected by loan loss provisions, it is also in line with results of Dietrich and Wanzenried (2011).

Concluding Remarks

Banks constitute a lifeblood of the economy, and they are commonly regarded as factors which have a great impact on a broadly understood socioeconomic environment. In the time of the economic slowdown caused by the Covid-19 pandemic, an analysis of banks' financial standing is of crucial importance to a number of market players and the

results can influence many decisions. Easter European countries were also severely hit by the pandemic and banks with stable financial foundations and with constant financial results have an important role to play in the period of the pandemic and post-pandemic, essential for the recovery of national economies. It seems that without financing of enterprises by the banking sector, the macroeconomic situation will not improve significantly. This work analyses listed banks in Eastern Europe countries and presents the empirical verification of such factors as bank size, capital adequacy, loan loss provisions, management efficiency, liquidity, loans to total assets, revenue diversification, industry concentration, GDP growth rate, and inflation rate. The authors verify a negative impact of loan loss provisions, management efficiency, liquidity risk, and a positive impact of bank size, capital adequacy, loans to total assets, revenues diversification and industry concentration. The major factors influencing the profitability of Polish and Czech banks include loan loss provisions, capital adequacy and management efficiency. It can be concluded that banks' most fundamental activities in the area of the quality of granted loans, capital adequacy and management efficiency have a major impact on the profitability of Polish and Czech banks. The obtained results are consistent with both return on assets and return on equity. A significant role from the perspective of banks' financial success is played by the supervision of EU and government institutions over bank security (capital adequacy), and supervision over management efficiency, exercised by supervisory boards, and the quality of loans. The results of the conducted research are significant for the banking sector of Eastern European countries, as well as governments, banking supervisory authorities and standard setters.

The limitations of this work result from a relatively small number of analysed countries and banks as well as a small number of variables. Further analyses should focus on broader verification of profitability factors for banks in West and East European countries, as well as the characteristics of banks' corporate governance systems.

Tomasz PALYS
Cybernetics Faculty, Military University of Technology, Warsaw, Poland, tomasz.palys@wat.edu.pl

Abstract

The paper presents the method of simultaneous identification of multiple commands encoded optically. The command encoding algorithm and the multiple command identification algorithm based on Extended Finite State Machine (EFSM) were developed. The method has been examined in a real and virtual environment. The method can be used in systems that implement the control of objects optically by using multiple commands issued by multiple operators.

Keywords: Laser Beam Coding, Augmented Reality, Extended Finite State Machine.

Introduction

The control of the system's objects by pointing them out at the (virtual) stage with a marker displayed by a laser pointer is the subject of the research and is used in many applications. The elements of such a system are: the stage, laser pointer - a manipulator that generates a command (e.g. by pointing out a specific element of the stage) and the camera - the sensor that registers specific elements of the stage in order to detect and identify the command generated by the manipulator. The command (the encoded optical signal generated by the pointer) has various forms and interpretation, e.g. the type of the command depends on: the object of the stage, which was pointed out (as reported by Pramit et al (2012) and Olsen and Nielsen (2001)), the color of the laser (Gu et al (2014)), the way the optical signal is encoded (Vogt et al (2003) and Palys et al (2017)). Pramit et al (2012) and Olsen and Nielsen (2001) described the results of the research consisting in inputting, into the operating system, commands, by pointing out certain elements of the user's graphic interface with the laser pointer's marker, were presented. The marker generated by the laser pointer is also used to mark SLAM (Simultaneous Localization And Mapping) system elements as described by Gu et al (2014), or in systems such as optical shooting ranges – it was shown by Soetedjo et al (2013) and Soetedjo and Nurcahyo (2011). Very interesting results were obtained in systems for controlling robotic manipulators, by using this system to point out objects subject to manipulations – it was described by Xie et al (2009), or to point out a point, to which the robot should move – as was mentioned by Fukuda et al (2009). Another direction of the research is the attempt to encode the commands in the optical signal emitted by the laser, which such signal manifests itself as a marker flashing in a specific way – as was described by Vogt et al (2003) and Palys et al (2017). Encoding commands can also consist of changing a laser color - as was shown in research conducted by Gu et al (2014). The differentiation of markers generated on the stage by several operators (by several laser pointers) may pose the another problem, which analyzed in research conducted by Gu et al (2014), Vogt et al (2003) and Palys et al (2017).

The paper presents the method and the results of the research on the implementation of this method consisting in the detection and identification of signals encoded optically, which are displayed in the form of markers flashing on the screen (on the stage). The markers are applied to the stage in the form of spots emitted by the laser pointer.

Motivation

Controlling the system by means of the signal encoded optically requires a method of generating single commands. If the number of commands is small, you can assign various colors to the commands. Another solution is the approach of encoding the laser signal in the form of a blinking, in a specific way, marker, whose source is a laser pointer. Such an attempt was made by Vogt et al (2003), where the laser signal was encoded according to the RS-232 standard. However, the results showed that the simultaneous detection and identification of multiple laser signals is complex and the method proposed by Vogt et al (2003) needs to be modified. The research conducted by

Cite this Article as: Artur ARCIUCH and Tomasz PALYS "Identification of Commands Encoded Optically" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the authors, among others, shows that the very method of encoding the optical signal generated by the laser pointer should be modified. In research conducted by Palys et al (2017) the method of laser signal encoding was proposed and examined in such a way that the interruptions, consisting in dimming out the marker during the exposure of the command, are short and their number does not exceed 2. The results of the command identification were obtained at the level of 98.86% (3600 attempts were made), which prompted the authors to carry out the research (a generalization of the research results is presented in this paper) evaluating the usefulness of the developed method for parallel detection and identification of multiple signals generated by the pointer (the laser pointers) emitting a signal of equal wavelength. Initial research results was described by Palys and Arciuch (2019).

Next chapters describe the encoding and command identification method and present the research results obtained in the proposed real and also simulation environment, and the conclusions. The simulation environment was presented in a research by Arciuch and Palys (2019).

The method to encode a command

The encoding of the signal generated by the laser pointer, into the form of commands, is based on activating and deactivating the marker on the stage in a strictly defined time. The command c_i, where $i = 1, ..., N$ and N is the number of commands, is saved as a binary vector, and the time of emission of one bit of the command is equal to T_W. It is assumed that the deactivation time of the marker, when exposing the command, is short, always equal to the exposure time of one bit, and their number does not exceed 2. Let Ω stand for a code table: $\Omega = [\omega_{rk}]_{L \times L} : \omega_{rk} = k+(r-1)(2L+2-r)/2$ for $r+k+1 \leq L \vee \omega_{rk} = \phi : r+k+1 > L$, where $r = 1, \ldots, L$; $k = 1, \ldots, L$; L – is the number of rows and columns and the symbol ϕ stands for an undefined (unimportant) element. In turn, by $B = [b_j]_{((L+1)*L/2)}$ the column vector was denoted, whose elements are binary vectors. Each element of the code table ω_{rk} is uniquely assigned the binary vector $b_j = [\alpha, 1, 1]$, where $j = k+(r-1)(2L+2-r)/2$. The last two numbers one of the b_j vector are the stop bit and the end frame bit respectively. If $r = 1$, then $\alpha = \rho$, where $\rho = \zeta(L+1-r)$, which corresponds to the notation of the index of the row r in the $L+2$ bit cold-one code (ζ) having an inverted bit order.

	k_1	k_2	k_3	k_4	k_5	k_6	k_7	k_8
r_1	**1**	2	3	4	5	6	7	**8**
r_2	9	10	11	12	13	14	**15**	ϕ
r_3	16	17	18	19	20	21	ϕ	ϕ

Fig 2. Example of encoding the commands

Otherwise, $\alpha = \rho + \kappa$; where $\kappa = \zeta(L+1-r-k)$. The parameter κ is equal to the sum of the index of the row r and the column k written in the cold-one code having an inverted bit order. An example of the code array for $L = 8$ is shown in Fig 1 and the examples of binary vectors in Fig 2.

After assuming that the emission time of a single bit is constant and equal to T_W, the way to encode commands with the following properties was obtained. Binary vectors are transmitted in series. The exposure time of the code is constant and equal to $(L+4)T_W$. The marker (the laser pointer) is being enabled i.e. activated only at the moment when the bit changes from "0" to "1" and the marker is being disabled i.e. deactivated at the moment when the bit changes from "1" to "0". One or two interruptions with the T_W length may occur during the code exposure. To encode N commands, a code array with $L = round(sqrt(2N))$ rows and columns should be built.

Identification of commands

Description of the method

The sequence of stage images obtained with the camera makes the input data for the method. Decoding the command is based on observations of markers detected in subsequent images. At the moment t (in a single image) you can observe no more than K markers, where K is the number of commands sent simultaneously or with an

offset less than the exposure time of the marker. The marker is represented by the Extended Finite State Machine (EFSM).

```
function [S', S] = Sequencing (t, O, S')
Input:
        t - detection time
        O = {oj, where j = 1, …, J}
        S' = {si, where i = 1, …, I}
Output:
        S' - active sequences
        S - inactive sequences
Algorithm:
IF J > 0 THEN                                   //STEP 1
        IF I > 0 THEN
                D = Distance (S', O);           //STEP 2
                Y = Inconsistent (D, S');
                D = Allowed Value (D, Y);
                WHILE IsAllowed(D) == true DO //STEP 3
                        [i, j] = MinAllowed(D);

Fig 3. Method of decoding messages

Fig 4. Algorithm for creating a marker observation sequence

The process of decoding the command takes place in the four phases, as presented in Fig 3. The first phase consists in detecting the marker, observing its position and writing the detection time in memory. In the second phase, based on the detection times, the observations of each marker are arranged in sequences. From the values of the parameters describing the sequence: the moment of activation and deactivation and the estimator of the average marker position are determined. This phase ends with dividing the sequence into active and inactive ones. Inactive sequences represent disabled markers and active sequences represent enabled markers. In the third phase, each inactive sequence is given to the input of the relevant EFSM machine, and the fourth phase of decoding takes place. In this phase, a recognition of commands is being performed. The marker disable time and the estimator of its average position, lastly assigned to the machine, are transmitted in the feedback path to the phase three. This provides the basis for organizing and linking the inactive observation sequences with the EFSM machine representing the marker observed.

Detection and sequencing of observations

The first phase (see Fig 2) is connected with determining the marker's observation on the basis of a sequence of images obtained with the camera. The method of marker detection is described in □. In the case of images in RGB format, the $R = [r_{ij}]_{W \times H} : r_{ij} \in \{0,...,255\}$ component is analyzed, where W x H is the resolution of the image (the authors conducted experiments for the R component of the image in RGB format and the V component of the image in HSV format). The R image is subjected to the contrast normalization operation: $r_{ij} = (r_{ij} - r_{avg}) / r_{max}$, where r_{avg} and r_{max} represent, respectively, the average and maximum value of the R matrix elements. Then the image is subjected to the binarization - the threshold value h is being selected experimentally, although e.g. in the paper □ this value was determined from the relation: $h = r_{max} / 1.1$. Markers detected in the image acquired at the moment t form the set $O = \{o_j\} : o_j = [x_j, y_j]$, where $j = 1, \ldots, J$, J represents the number of observations acquired at the moment t, and x_j, y_j represent the center of the marker. The set O and the moment of detection t make the input data for the second phase of the decoding algorithm. In this phase, a sequence is created from the acquired observations - the order in the sequence is being determined by the detection times (see Fig 3). The sequencing of observations is then being carried out. Let $S' = \{s_i\}$, where $i = 1, ..., I$ and I represent the number of sequences that represent the enabled markers, represent a set of active sequences. The first step of the algorithm consists in checking if the number of the observations J obtained is bigger than zero. If it's bigger than zero, go to step two, and if it's not bigger, go to step five. Additionally, in the first step, you should check if there are active sequences. If no active

sequences exist then the fourth step of the algorithm should be performed. If there are active sequences, the distance matrix (according to the Euclidean metric) $D = [d_{ij}]_{I \times J}$, between the obtained observations o_j, and the average values of markers' positions that represent sequences s_i should be determined and the coefficients' matrix for inconsistency of attaching observations to the sequence $Y_{ij} = (d_{ij} - avg(\{s_i\})) / std(\{s_i\})$ should be determined, where $avg(\{s_i\})$ means the average value between the adjacent elements of the sequence and $std(\{s_i\})$ means their standard deviation. The second step is ended with the designation, in the matrix D, of the prohibited values, for which the non-compliance factor $Y_{ij} \geq 4$. The third step of the algorithm is being repeated until all allowed values are exhausted. First, the smallest available d_{ij} distance is searched for. Based on the index of the row i and the index of the column j do the following steps. Attach the observation o_j to the S_i sequence and update its average position $p^{(i)}$ and initially assume that the moment of disabling $t^{(i)}_E$ is equal to t. Then remove the observation o_j from the set O, and the column j from the set D. After setting the elements of the row i as not allowed ones in the distances' matrix, repeat the third step of the algorithm. The fourth step consists in checking if there are any observations in the O set that were not attached to the sequence. If there are such observations, new sequences are created from them. The marker activation time should be assumed as $t^{(i)}_B = t$. The last, fifth step consist in dividing the sequences into active ones and inactive ones. Sequences, to which observations at the moment t were attached, are treated as the active sequences S' and others as the inactive sequences S.

Recognition of Commands

The third phase of the method (see Fig 2) consists in passing inactive sequences to the input of a proper EFSM machine. For each active machine, the average marker position and the time to disable the marker, is read. The procedure is analogous to that of attaching observations to the sequence. The difference is that in the third step, instead of the attachment operation, the selected sequences are passed to the input of a proper machine, and in the fourth step, instead of creating a new sequence, the sequence is given to the input of the machine that is in its initial state.

Fig 5: State diagram of EFSM

Transitions	Current state	Input symbol	Guard functions	Update functions	Output symbol	Next state
a_0	–	–	–	$k=0,\ r=0,$ $T_E=0,\ P=(0,0)$	ϕ	q_0
a_1	q_0	$s^{(i)}$	$f(t^{(i)}_E - t^{(i)}_B) \leq L$	$k=f(t^{(i)}_E - t^{(i)}_B),$ $T_E=t^{(i)}_E,\ P=p^{(i)}$	ϕ	q_1
a_2	q_1	$s^{(i)}$	$h(t^{(i)}_E - t^{(i)}_B) \leq L$ $\wedge\ f(t^{(i)}_B - T_E) == 1$	$r=f(t^{(i)}_E - t^{(i)}_B)+1,$ $T_E=t^{(i)}_E$	ϕ	q_2
a_3	q_2	$s^{(i)}$	$h(t^{(i)}_E - t^{(i)}_B) == L+1$ $\wedge\ f(t^{(i)}_B - T_E) == 1$	$T_E=t^{(i)}_E$	$g()$	q_3
a_4	q_1	$s^{(i)}$	$h(t^{(i)}_E - t^{(i)}_B) == L+2$ $\wedge\ f(t^{(i)}_B - T_E) == 1$	$T_E=t^{(i)}_E$	$g()$	q_3

a_5	q_1	$s^{(i)}$	$h(t-T_E)>L+2$	$k=0,\ r=0,$ $T_E=0,\ P=(0,0)$	ϕ	q_0
a_6	q_2	$s^{(i)}$	$h(t-T_E)>L+2$	$k=0,\ r=0,$ $T_E=0,\ P=(0,0)$	ϕ	q_0
a_7	q_3	-	-	$k=0,\ r=0,$ $T_E=0,\ P=(0,0)$	ϕ	q_0

where:

$f(t)=\ \mathrm{round}(t/T_W)$

$h(t)=\ f(t)+k+r$

$g()\ =\ k+(r-1)(2L+2-r)/2$

Fig. 6: Transitions set of EFSM

The last phase is related to the recognition of commands. The process is executed by an extended states' machine, which is defined as the 6-tuple EFSM = (Q, q_0, V, M, W, A). The interpretation of the operation of the states' machine and the meaning of the individual symbols is as follows. The set of the states of the machine is denoted by $Q = \{q_0, q_1, q_2, q_3\}$. The initial state of the machine is denoted by q_0. The state associated with the first activity of the marker, which such activity is associated with the column index of the code array, is represented by q_1. In turn, q_2 denotes the second activity of the marker, which such activity represents the messages below the first row of the code array. The state q_3 is equated with the last activity of the marker. The states can only be changed at the moment of the marker deactivation if a symbol being the member of the set of input symbols M appears at the input. Each input symbol is identified with a sequence of observations of the marker s_i. The change of a state is affected by the time of enabling the marker $t^{(i)}_B$ and the time of disabling the marker $t^{(i)}_E$. Additionally, the estimator of the average position of the marker $p^{(i)}$ is being written in memory. The finite machine of the states was extended by a set of variables $V = \{r, k, t, T_E, P\}$, where r stands for a row index and k for a column index of the code array and t for the current moment. After each change of a state, the disable time T_E and the estimator of the average position of the marker P is being written in memory. Transitions between states of the machine are defined as elements of the set $A = \{a_k: (q, s, guard, update(V), w, q')\}$, which means that if the machine is in the state q and the element $s \in M$, appears at the input, then the transition to the state q' will take place if and only if the logical expression *guard* is true. Only in this case the variables of the machine shall be updated and an element $w \in W$ shall be generated at the output, where W means a set of commands extended by the blank element ϕ (see Fig 1). The states' diagram of the EFSM machine is shown in Fig 5 and the elements of the set A (see Fig 6). Moving the machine from the initial state to the state q_1 means making an assumption about the start of the command transmission. The assumption is considered true if and only if the model reaches state q_3. Only in this case, the element w is generated at the machine output (based on the variables r, k). In other cases, the element ϕ is given to the output. Each rejection of the assumption (assumed in the state q_1) results in the model going to the initial state q_0.

Results of Research

The effectiveness of the command recognition algorithm was examined in two phases. The first phase in a real environment and the second one in a simulated one. In both phases, the commands c_i, where $i \in \{1,...,36\}$, were encoded by using the technique presented in chapter 3. In the real environment, the effectiveness of single command recognition was examined depending on the bit T_W emission time and resolutions of images, on the basis of which the marker detection was performed.

Fig. 7: Influence of a camera resolution and a time emission of the T_W bit on the effectiveness of commands' identification

In turn, the markers representing five commands were generated in the simulated environment and the influence of the distance between the markers on the efficiency of the system was examined. Additionally, the influence of marker vibrations and activation time delays on the recognition result was examined. The real workstation consisted of: the Manta G - 201 Allied Vision camera with a lens with a focal length of F = 8 mm, equipped with a mid-pass (λ_0 = 650 nm ± 10 nm) optical filter; the laptop computer; the laser pointer, that was shown by Palys et al (2017); the screen.

Fig. 8: Identification of the commend c_{35}

The examination was performed for the camera resolutions of: 640x480 *px*, 800x600 *px* and 1024x768 *px*. The frequency of acquiring successive frames of the image was respectively: 66.3 *Hz* (640x480 *px*), 55.7 *Hz* (800x600 *px*) and 45.1 *Hz* (1024x768 *px*), and the T_W time varied from 0.025s to 0.055s in 0.001s steps. During the experiment, if for the camera resolution of 640x480 *px* the images changed on average every 0.0151s, then the correctness of the command recognition was 90% (T_W = 0.0302 *s*). The results of the experiment are presented in Fig. 7. Additionally, in Fig. 8, the marker activation function and the obtained time relationships for the c_{35} command are presented.

To carry out the second phase of the experiment, the command generation and recognition system, in Simulink environment (Matlab by MathWorks) was built. The system made possible to recognize five commands simultaneously. Experiments were conducted for five scenarios. Each scenario consisted in generating the marker for the command c_3 at the point P_3 =[200, 200]*px* and the markers for the commands: c_1, c_2, c_4, c_5, at points with the

coordinates: P_1 = [135, 135]px, P_2 = [265, 135]px, P_4 = [135, 265]px, P_5 = [265, 265]px. Then the points P_1, P_2, P_4 and P_5 were moved towards the point P_3. Each scenario was repeated 100 times. In the first scenario it was examined how the distances between P_i: $i \in \{1, \ldots, 5\}$ affect the effectiveness of command recognition. For this scenario the recognition efficiency began to decrease after reaching the 11px distance from P_3. On the other hand it was examined in the second scenario how the marker vibrations affect the effectiveness of the system. Each coordinate, of each point, was changed by a random value (according to normal distribution) from the (-3px, 3px) range. For this scenario the effectiveness began to decrease after reaching the 35px distance from P_3. In the next three scenarios the activation time of the command marker was changed and the points' vibrations were simulated. The activation delay was T_W, $2T_W$ and $3T_W$. respectively. For the T_W delay, the efficiency of identification began to decrease after reaching a distance of 28px from P_3. For $2T_W$ and $3T_W$ delays, the identification efficiency began to decrease after reaching 26px from P_3. The results of the experiments are shown respectively in Fig. 9 and Fig. 10. The proposed method makes it possible to identify multiple commands emitted simultaneously and to identify commands having different start times. Moreover, the method takes into account the vibrations of the markers, which are the commands' carriers. The method can be used in systems that implement the control of objects optically by using multiple commands issued by multiple operators. The conducted experiments confirm the effectiveness of the method presented in the paper.

Malgorzata SOLARZ
Wroclaw University of Economics and Business, Poland, malgorzata.solarz@ue.wroc.pl

Abstract

The purpose of the article is to present the approach to the risk of using internet and mobile banking services and also the tools and activities aimed at reducing it by Polish representatives of the Baby Boomer, X, Y, Z generations. Based on the analysis and interpretation of the research findings conducted on a nationwide sample and covering the members of the distinguished populations, the following first research hypothesis was refuted: *the representatives of the analysed generations show both a diversified level of openness towards technological innovations and the acceptance of the related risk* (H I), whereas the following two hypotheses were verified: *the representatives of the analysed generations show a diversified use of internet and mobile banking services* (H II), and *the representatives of the analysed generations show a diversified approach to the activities reducing the risk of using internet and mobile banking services* (H III). The accuracy assessment of the formulated hypotheses was based on the identification of the respondents' attitudes to new technologies and the related risks, the declared use of internet and mobile banking services, as well as the tools and activities used by the people under study aimed at reducing the risks related to the discussed form of banking.

Keywords: internet and mobile banking, perceived risks, generational cohorts

Introduction

Technological innovations affect every dimension of human life, including the organization and transfer of financial services which cover the needs related to the broadly understood acquisition, collection and distribution of natural persons' funds, carried out through and with the use of online and mobile banking. Knowledgeable and rational use of internet and mobile banking services requires, on the one hand, the need to recognize the related risks and, on the other, to adopt an active attitude towards their causes and effects. These activities apply to both financial intermediaries and the consumers of their services. Scientific and practical importance should be assigned to the recognition of attitudes adopted by consumers of mobile banking services towards these risks and the actions taken to limit their potential. This knowledge creates, e.g., the premise of educational, cognitive or promotional activity focused on developing diverse, in the generational cross-section, attitudes and behaviours towards the emerging threats.

The purpose of the presented study is to show the approach to the risk of using internet and mobile banking services as well as the tools and activities aimed at reducing it by Polish representatives of the Baby boomer, X, Y, Z generations. The premise for preparing the article was the research gap noticed by the authors and concerning both the cross-generational perception of the risk associated with the use of internet and mobile banking services, and also the assessment of attitudes and actions related to its reduction undertaken by Polish members of population cohorts. The structure of the article is focused on the implementation of the adopted research goal and, apart from the introduction, it includes sections devoted to: a/risk and its perception in taking consumer decisions, b/characteristics of generational cohorts, c/methodology and findings of the conducted research, as well as d/conclusions resulting from the analysis and assessment of the research findings.

Risk and its Perception in Consumer Decisions

The risk of online transactions can be approached as one of the key elements explaining and influencing the appropriate purchase behaviour (Zhang et al 2012), (Chen et al 2015) of people who perform these transactions

Cite this Article as: Jacek ADAMEK and Malgorzata SOLARZ"The Risk of Using Internet and Mobile Banking Services from the Perspective of Polish Representatives of the Baby Boomer, X, Y, Z Generations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

(consumers). The perceived risk as a subjective vision of the threats associated with purchase decisions was conceptualized in 1960 by R. Bauer (1960). This optics is based on the assumption that any decision to purchase goods or services is associated with risk, whereas the perceived risk can be defined, e.g., as (…) *the nature and amount of uncertainty or consequences experienced by the consumer in contemplating a particular purchase decision* (Cox and Rich 1964) see (Guru et al. 2020, p. 138). The uncertainty associated with the achievement of the goals underlying the act of purchase remains the source of this risk. The perceived risk is a factor influencing the appropriate consumer behaviour, as they want to avoid making mistakes, and its level turns into a function (Mitchell 1999), (Cox and Rich, 1964):

- the importance of the goals pursued through the purchased good and
- the subjective significance of the consequences resulting from these failures.

The feeling of uncertainty and the perceived risk are also present during the purchasing decisions made via the Internet, including those associated with the purchase and use of the offer provided by internet and mobile banking services.

The perceived risk of purchase decisions can be analysed in many dimensions (Biswas and Biswas 2004), (Boksberger et al 2007), (Hong 2015), (Papas 2016), however, the risk dimensions most frequently associated with e-banking are as follows: Perceived performance risk, Perceived security risk, Perceived privacy risk, Perceived time loss risk, Perceived social risk (see Table 1).

Table 1: Dimensions of the perceived risk in purchase decisions combined with the use of internet and mobile banking

Dimension of perceived risk	***Content of perceived risk***
Perceived performance risk	It refers to working/functioning of the obtained product in a way that ensures meeting the expected needs/functions. It may result from a wrong choice being a consequence of the subjective inability to assess its quality. Information asymmetry and the absence of possibility to test internet banking services limit the consumer's ability to make a choice that meets his/her expectations, thus reducing confidence in the offered products/services.
Perceived security risk	It is associated with the risk of losing financial resources. The security of accumulated funds is treated as one of the most important factors determining the acceptance and use of online banking, while the gap between the expected and actual security of new technologies becomes a factor which determines the behaviour of potential and current clients of these institutions. Another dimension of this risk is, e.g., the probability that the price of the service/product is not in line with its subjective value perceived by the consumer.
Perceived privacy risk	It is connected with the subjective feeling of the risk related to losing confidential information regarding personal data, wealth, family, etc.
Perceived time loss risk	The use of online tools as well as acquiring skills to take advantage of these facilities results in the need of proficiency in appropriate techniques, learning which often requires devoting an extensive amount of time, primarily in the case of senior citizens. According to the consumers of internet and mobile banking services, this time may also be taken up by the need of repeating certain operations that were previously performed incorrectly.
Perceived social risk	It refers to the social environment and its approach to, e.g., new technologies, including the use of online banking as a form of access to financial services. For example, in the era featuring the dynamic development of social networks, the expressed opinions and the promoted attitudes if considered authoritative and desirable, on the one hand, may stimulate/influence purchasing decisions, whereas, on the other, constitute a platform for their evaluation and acceptance by the community members in which the consumer is functioning.

Source: authors' compilation based on: (Cunningham et al 2005) (Gerrard et al. 2006), (Littler and Melanthiou 2006), (Mihalcescu et al 2008), (Aldás-Manzano et al. 2009), (Kesharwani and Singh Bisht. 2012), (Li 2012).

It is natural that the actions performed by the potential and current consumers of financial services offered by internet and mobile banking, rationalizing purchasing acts (and their consequences), have to focus on identifying and recognizing these risks along with their potential, and also on adopting an active attitude towards the emerging risks. Such an attitude provides the basis for making knowledgeable purchasing choices, ultimately determining consumer satisfaction with the choices made.

Baby boomer, X, Y, Z generations and their characteristics

Observing the behaviour of individual consumer groups can be based on the generational cohort theory. In the opinion of X. Li et al (2013), this theory is a tool for learning and understanding the similarities and differences in the adopted attitudes, behaviours and preferences expressed by the members of individual generations. W. Strauss and N. Howe (1991) argue that a generation should be understood as a population of people born in the same period of time, characterised by similar geographic and historical locations, and therefore sharing a common identity. According to these authors, belonging to a given generation is compulsory and permanent. In addition, the individual generational cohorts experience (…) *the same national events, moods and trends at similar ages* (Strauss and Howe 1991, p. 48), which ultimately results in a state providing each generation with a collective personality. J. W. Smith, J. W and A. Clurman (1998) explain the term generation as a group of people sharing common life experiences, shaped by the worldwide events, natural disasters, politics, economic conditions and pop culture. In accordance with this optics, the similarity of experiences is a unique category, and therefore owing to them it is possible to distinguish one generation cohort from another. In turn, M. MacCrindle and E. Wolfinger (2014) approach the term generation as a group of people born in the same era, shaped by the same timeframe and under the influence of the same social factors. Ultimately it is *(…) a cohort united by age and life stage, conditions and technology, events and experiences* (MacCrindle and Wolfinger 2014. p. 3). These authors emphasize that the common characteristics of individual generations break through geographic, cultural or socio-economic boundaries, and thus become the determinants of these global communities.

Remaining beyond the dispute on the definition itself, it can be adopted that a generation is a group of people connected by a similar timeframe of birth and significant events at critical stages in the development of the social, economic and cultural environment in which they have to fulfil their functions and goals. This viewpoint allows concluding that currently four generations are identified and described from different perspectives in the source literature (Howe and Strauss 2000) (Jorgensen 2003), (Bejtkovský 2016), (Littrell et al 2005) (Schade et al, 2016) (Koksal 2019) (Yu and Miller 2005) (Reisenwitz and Iyer 2009), (Fishman 2016) (Sima 2016). They are as follows (the discussion on the differentiation of time intervals assigned to each of these generations is disregarded here): a/Baby boomer (Bb) (1946 – 1964), b/Generation X (X) (1965 – 1979), c/Generation Y (Y) (1980 – 1994) and d/Generation Z (Z) 1995 – present). Table 2 presents the basic characteristics of the aforementioned groups.

Table 2: The characteristics assigned to the representatives of the Bb, X, Y, Z generation

	Baby boomer	***X***	***Y***	***Z***
Knowledge sharing	Willingly, voluntarily	It is based on mutuality and cooperation	Only in cases of self-interest or if forced	On virtual level, easily and rapidly, no stake, publically
Teamwork	Unknown	Natural environment (multinational companies)	Belief in the success of common effort	On a virtual level (only if forced)
Aim	Solid existence	Multi-environment, Secure position	Rivalry for leader position	Live for the present
View	Communal, unified thinking	Self-centred and medium-term	Egotistical, short-term	No sense of commitment, be happy with what you have and live for the present
Relationship	First and foremost Personal	Personal and virtual Networks	Principally virtual, network	Virtual and superficial
Values	Patience, soft skills, respect for traditions, EQ, hard work	Hard work, openness, respect for diversity, curiosity, practicality	Flexibility, mobility, broad but superficial knowledge, success orientation, creativity, freedom of information takes priority	Live for the present, rapid reaction to everything, initiator, brave, rapid information access and content search
IT	It is based on self-instruction and incomplete	Uses with confidence	Part of its everyday life	Intuitive
Others	Respect for	Rule abiding,	Desire for	Differing viewpoints,

	hierarchy, exaggerated modesty or arrogant inflexibility, passivity, cynicism, disappointment	materialistic, fair play, less respect for hierarchy, has a sense of relativity, need to prove themselves	independence, no respect for tradition, quest for new forms of knowledge, inverse socialization, arrogant, home office and part-time work, interim management, undervalue soft skills and EQ	lack of thinking, happiness, pleasure, divided attention, lack of consequential thinking, no desire to make sense of things, the boundaries of work and entertainment overlap, feel at home anywhere

Source: (Bencsik et al. 2016)

One of the dimensions and areas of the research addressing the characteristics, preferences and attitudes presented by the representatives of particular generations is analysing their financial behaviour. They cover various issues, also the ones concerning the use of technological innovations, including internet and mobile banking (Bruce et al. 2019), (Boonsiritomachai and Pitchayadejanant 2017), (Tan and Lau 2016), (Cuong et al. 2015), (Rutecka and Bednarz 2017), (Shankar and Jebarajakirthy 2019), (Shams et al. 2020), (Munoz-Leiva et al 2017) (Koenig-Lewis et al. 2010). This research is primarily focused on the analysis and assessment of the importance regarding the intentions underlying the use of appropriate financial services, including those offered by the aforementioned banking services. At this point, it is worth adding that the authors of this study have also noticed a certain gap in the existing research concerning both the cross-generational perception of the risk related to using internet and mobile banking services as well as the assessment of attitudes and actions connected with its reduction.

Methodology and Research Results

In the context of the above considerations, the purpose of the article was: *to show the approach towards the risk of using internet and mobile banking services as well as the tools and activities aimed at reducing it by Polish representatives of the Baby boomer (Bb), X, Y, Z generations.* The adopted goal became the basis for the formulation of three following research hypotheses:

1. The representatives of the analysed generations show both a diversified level of openness towards technological innovations and the acceptance of the related risk (H I),
2. The representatives of the analysed generations show a diversified use of internet and mobile banking services (H II),
3. The representatives of the analysed generations show a diversified approach to the activities reducing the risk of using internet and mobile banking services (H III).

In order to carry out the purpose of the study and to verify the adopted hypotheses the authors provided their own, original answers to the following research questions:

1) What is the attitude of the representatives of particular generations to new technologies and the related risks?
2) What is the declarative level of using internet and mobile banking services among the representatives of the studied cohorts?
3) What is the approach of the representatives of the analysed generations to the activities reducing the risk related to using internet and mobile banking services?

The verification process of the adopted hypotheses was based on the results of surveys conducted by the authors in March 2020 using the CAWI method (*Computer-Assisted Web Interview*), on a nationwide sample covering 1040 respondents. These studies are a part of the research project entitled: *Self-exclusion from digital banking services in the light of the characteristics of X, Y, Z generations*. The research sample was selected in a random and quota manner. The structure of the sample was corrected using the analytical weight, so that it corresponded to the structure of Poles in terms of the key characteristics related to the subject of the study. When constructing the weight, socio-demographic variables were taken into account, such as: gender, age, education, income level and size of the place of residence (see Table 3).

Table 3: Research sample – characteristics

Generation *(n=1040)*

Source: authors' compilation based on the survey research.

The population represented by four generations included 53% of women and 47% of men. Gender analysis of the representatives within the surveyed generations indicates that the highest share of women is attributed to generation Bb (61%), whereas generation X has the highest share of men in the number of the studied cohort.

In the surveyed population, higher level of education was the dominant one, whereas secondary education was represented by 48% and 42% of its members, respectively. The university graduates accounted for as many as 60% of Y generation representatives. In turn, primary and vocational education was characteristic for 10% of the respondents. Among them the leading positions were taken by X and Bb generations. On average, every eighth person representing X generation and every ninth person from Bb generation was assigned the lowest level of education.

The vast majority of the analysed population (43%) earned net monthly income ranging from PLN 2001 to PLN 5000, while the net income of every tenth respondent was higher than PLN 5000. The highest percentage of the best earners was among X and Y generations (such income was earned by 13% and 12% representatives of these generations, respectively). The representatives of these generations also dominated in the group of people earning net income ranging from PLN 2001 to PLN 5000. The percentage of Y generation representatives reaching this level of income was 50% (X - 46%). One in five surveyed people declined to answer the question about their monthly net income.

39.00% of the respondents lived in a village, whereas the other lived in cities of various sizes. A village was the place of residence for as many as 47% representatives of the youngest of the analysed generations (Z), while the most numerous urban population was characteristic for the representatives of Bb generation, 70% of whom were city dwellers. A statistical picture of a typical representative of the analysed cohorts is shown in Table 4.

Table 4: Statistical characteristics of a typical representative of Z, Y, X, Bb generation

Z	**Y**	**X**	**Bb**
Gender			
Woman	Woman	Men	Woman
Education			
Secondary	Higher	Higher	Secondary
Net income (PLN)			
3001-5000	3001-5000	3001-5000	1001-2000
Place of residence village/city			
City	City	City	City

Source: authors' compilation based on the survey research.

The first part of the survey covered the respondents' attitudes to technological innovations and the related risk (see Table 5).

Table 5: Attitudes of the representatives of the surveyed generations to new technologies and the related risk

I am open to new technologies (n = 100%)				
	Z	Y	X	B
Yes	65%	54%	61%	52%
No	35%	46%	39%	48%
I treat technological innovations as highly risky				
Yes	10%	14%	9%	9%
No	90%	86%	91%	91%

Source: authors' compilation based on the survey research.

The analysis of the above presented information confirms that Z generation remains most open to new technologies (65% of its members show such openness), while the representatives of Bb generation are the least inclined to accept and use technological innovations (almost half of them present a sceptical attitude towards such innovations). This situation does not come as a surprise, taking into account the technical and technological environment and the pace of its changes, in which the representatives of these generations were and are fulfilling their social and professional functions. Interestingly, the low level of new technologies acceptance is shown by the representatives of Y generation (54%) which, in turn, can be explained, e.g., by the highest percentage of their ratings indicating high level of risk related to using such innovations. It is somewhat surprising that the level of risk assessment regarding technological innovations, presented by the representatives of other generations, i.e. Z, X and Bb, is evenly matched. On average, only one in ten members of these cohorts expressed an opinion about high level of risk related to technological innovations.

The assessment and ranking of the generational distribution covering people declaring openness to new technologies and those treating new technologies as highly risky, adjusted by the number of the studied cohorts, confirms the above conclusions allowing to indicate that the first group is formed by the representatives of Z generation (28%), X (26 %), Y (24%), Bb (22%), whereas the second one includes members of Y (33%), Z (24%), X (22%), Bb (21%) generations.

The second area of the conducted analyses was the declared level of using internet and mobile banking services by the members of the surveyed populations (see Table 6).

Table 6: Declared use of internet and mobile banking services in the analysed cohorts

I have an online bank account (n = 100%)				
Answer	**Z**	**Y**	**X**	**B**
Yes	63%	61%	62%	68%
No	37%	39%	38%	32%
I use mobile banking applications				
Yes	60%	48%	53%	37%
No	40%	52%	47%	63%
I use modern mobile payment systems (PayPal, PayU, BLIK, Google Pay, HCE)				
Yes	60%	45%	52%	45%
No	40%	55%	48%	55%

Source: authors' compilation based on the survey research.

The content of the above Table shows that an online bank account is the most popular service of the discussed forms of banking, used by the representatives of the analysed populations. Bb generation is the leading one in this area (68% of them use this financial service). The relative popularity of an online bank account does not match the use of mobile banking applications. In this case, the difference between the percentage of the representatives of the borderline generations assessed in terms of using mobile banking applications is as high as 23 percentage points (Z – 60%, Bb – 37%). In the case of Bb generation, this situation can be explained by, e.g., not having a smartphone or not showing the need to use it for such purposes. Another factor explaining the above situation may be the reluctance to use this distribution channel for banking services, influenced by the following factors:

- technical (e.g. having a mobile phone not adapted for this purpose),
- personal factor (e.g. subjective difficulty in operating a mobile banking application, concern about making mistakes resulting in financial consequences).

The level assessment of using modern mobile payment systems by the members of the surveyed populations remains consistent with their using mobile banking applications. Z population is the leading one in this respect, as 60% of its representatives take advantage of this type of payment systems. Y and Bb generations are placed at the other extreme. In the case of these cohorts, the systems are used by 45% of their members.

When assessing the distribution and generation ranking of people declaring the use of internet and mobile banking services discussed above, adjusted by the size of the surveyed populations, it is concluded that these groups are formed by the following percentage of the analysed cohorts:

- having an online bank account – Bb (26%), Z (25%), Y (25%), X (24%),
- using mobile banking applications – Z (31%), X (26%), Y (24%), Bb (19%),
- using modern mobile payment systems – Z (30%), X (25%), Y (23%), Bb (22%).

The final area of research presented in this study was the approach taken by the representatives of the analysed generations to the actions reducing the risk related to using internet and mobile banking (see Table 7).

Table 7: Declared approach of the representatives of the analysed cohorts to the activities reducing the risk related to using internet and mobile banking

I have an up-to-date antivirus software installed (n = 100%)				
	Z	Y	X	Bb
Yes	61%	47%	57%	66%
No	39%	53%	43%	34%
When logging into online banking I always pay attention to the correct address of the bank whose services I use				
	Z	Y	X	Bb
Yes	58%	51%	62%	69%
No	42%	49%	38%	31%
I read the content of all attachments to the incoming e-mails and/or text messages				
	Z	Y	X	Bb
Yes	39%	31%	38%	38%
No	61%	69%	62%	62%
I use mobile banking at school/work through the Wi-Fi network operating there				
	Z	Y	X	Bb
Yes	30%	27%	33%	19%
No	70%	73%	67%	81%
I believe that my daily limits for online transactions in mobile/internet banking set by the bank should be increased				
	Z	Y	X	Bb
Yes	23%	20%	19%	13%
No	77%	80%	81%	87%

Source: authors' compilation based on the survey research.

The assessment of this approach is based on the analysis of using appropriate services/activities indicating, on the one hand, the awareness of the emerging risks associated with the use of internet and mobile banking and, on the other, an active approach to their reduction. For example, Bb generation is the group whose members have the highest percentage of installed and up-to-date antivirus software (66% of the respondents from Bb generation have and use such protection), with the indication that more than half of Y population does not have such software). The analysis addressing behaviour of the representatives of the studied cohorts favouring the reduction of risk related to using internet and mobile banking also shows that:

- approx. between 51% (Y) and 69% (Bb) members of the analysed generations pay special attention to correct internet address of the bank whose services they use, with the highest percentage of these people referring to the oldest generations (Bb and X),

- representatives of the assessed generations are aware of the risks associated with the content of attachments to the received e-mail or text messages, including those addressed by their banks. The content of such messages is consciously unrecognized by 69% of Y generation, 62% X and Bb each, and 61% Z,
- members of the surveyed generations also show great awareness of the risks related to using public Wi-Fi networks, in the authors' opinion. In this case, using such access points is declared by 19 to 33% of the representatives of particular populations (19% Bb), (27% Y), (30% Z), (33% Y),
- a similar conclusion refers to the assessment of bank internet/mobile transaction limits. From the perspective of the vast majority representatives of all surveyed generations, their usually low level, set by the bank, is considered safe and not requiring any additional adjustment. This opinion is expressed by 87% of Bb generation, 81% X, 80% Y and 77% Z.

Research Conclusions

The conducted research presents a diversified picture of the approach to the risk related to using internet and mobile banking services as well as the tools and activities of its reduction by Polish representatives of the Baby boomer, X, Y, Z generations. The conclusions resulting from the interpretation of the collected answers can be approached as the picture of specific states and attitudes represented by the respondents towards technological innovations and the associated risks, and also their activities, which are assumed to be the response to the risks related to using the dynamically developing online banking based on the internet and mobile access channel and the distribution of its services.

In the opinion of the research authors the first hypothesis stating: *The representatives of the analysed generations show both a diversified level of openness towards technological innovations and the acceptance of the related risk* (H I) should be refuted. Such an interpretation of the obtained research results is supported by the situation of a clear difference in both acceptance and openness towards new technologies between the studied cohorts. The analysis of the percentage of people open to new technologies clearly shows its growing tendency related to the assessment of the representatives of the increasingly younger generations. This state seems to be natural, having adopted that the professional and social activity as well as everyday life of these populations' members was accompanied, to a varying degree, by the dynamic and profound changes created by technical and technological innovations. However, the differentiation in openness to new technologies does not go along with the differences in the perception of the related risks. In the authors' opinion, the low and relatively constant level of perceiving these innovations as risky can be explained in two ways. On the one hand, it may be a consequence of the assumption that the representatives of the analysed cohorts perceive these innovations as friendly, meeting the expectations and needs of their users, and therefore free from the risks of their application and, on the other, this result may be the consequence of insufficient knowledge and awareness related to the negative consequences of implementing technical and technological innovations.

The second hypothesis can be considered as verified, which says: *The representatives of the analysed generations show a diversified use of internet and mobile banking services* (H II) as well as the third hypothesis stating: *The representatives of the analysed generations show a diversified approach to the activities reducing the risk of using internet and mobile banking services* (H III).

Hypothesis II has been confirmed in the visible differentiation of using the services in question by the individual cohorts. In this case it is clearly visible that the younger generations, comparing to their predecessors, find it easier to use modern tools and techniques for accessing financial services. The only exemption from this conclusion is the leading role of the representatives of Bb generation in having online bank accounts comparing to other populations. At this point, it is worth adding that from the perspective of assessing this use, there is still an extensive space for the activities to be carried out by banking institutions and other financial market organizers focused on education and promotion of internet and mobile banking, predominantly among the representatives of older generations. Such activities are absolutely desirable in the current epidemic situation, as they favour the protection of people who make financial transfers and payments by accelerating them, refraining from cash payments or abandoning the need for their physical realisation in bank branches.

The conclusion regarding the verification of hypothesis III is a consequence of the situation, according to which the analysed populations show actual differences in using the discussed services and taking actions reducing the risks related to the analysed forms of banking. This difference, referring to, e.g., having and using the up-to-date antivirus software, verification of the correct bank internet address or using public hotspots can be explained by the different perception of the risk implied by accessing the web-based network and internet and mobile banking services, as well as the subjective assessment of the effectiveness of specific protective measures.

Regardless, however, of the reasons underlying the situation discussed in this article, it is important to emphasize the need for intensifying educational and cognitive activities characterizing: a/ the risks implied by using mobile and internet banking, b/ tools and desirable attitudes of their consumers reducing the related risks.

Polish Code of Professional Ethics in Accounting – A Survey Among Accountants and Other Professionals

Marek CIESLAK, PhD

Poznan University of Economics and Business, Poznan, Poland
marek.cieslak@ue.poznan.pl

Abstract

The need for a code of ethics to ensure equality for stakeholder groups is taken for granted. The Code of Professional Ethics in Accounting regulates the ethical behavior of people professionally involved in accounting. The conducted survey allowed for the formulation of a number of conclusions regarding the Code. Although the respondents considered the principles to be correct, they were less willing to support solutions binding the practice of the accounting profession with compliance with the principles contained in the Code. The largest number of respondents decided that the requirement for practicing the profession in accounting should be observance of the principle of professional secrecy, and the least that it should be compliance with the rules of conduct in the event of a conflict of interest.

Keywords: accounting ethics, accountants, code of ethics, Poland.

Introduction

Professional ethics develops with many users, as then they must make choices in the interpersonal sphere. It is the task of judging and compromising that requires ethical judgment and that develops the dynamics of service institutions. Hence, the profession must also develop its own value system in order to assess and influence the goals of the stakeholders' activities (Cieślak and Skoczek-Spychała 2006, 2007). Individual value systems of any group cannot provide an acceptable standard, and a relatively independent set of standard values is needed to drive the necessary choices. Service profession codes of ethics must mean costs for some users and benefits for others. Their establishment requires a relatively independent standard.

The aim of the paper is to present the results of the survey concerning the Code of Professional Ethics in Accounting, prepared and adopted by the Accountants Association in Poland, which is meant to be phase one of bigger research taking also other stakeholders into consideration. The presentation will be preceded by short considerations on accounting ethics and the characteristics of the Code. Due to the limited volume of this article, the research results will be presented in a shortened, synthetic form (without graphs showing the distribution of responses).

Ethics and its Codification as an Element of Accounting

The need for codes of ethics to maintain equality between different but valuable groups is usually taken for granted. However, an important question remains: how do leaders view and try to achieve equality? Is the term equality in the sense of the concept of justice too idealized and vague to serve as a practical standard? It is, of course, possible to adopt one of the competing groups' code of ethics as theirs, but it is an accepted practice to create collective value based on the needs articulated by all stakeholders and use it to evaluate individual sacrifices and benefits.

T.G. Higgins and W.E. Olson (1972, p. 33) stated that the code of ethics is the basic document creating professions, ethical concepts fill the body with spirit, and a consent to ethical concepts and adherence to them by the majority of practitioners changes the profession into a profession.

The code of ethics must be authoritative to be an effective tool of social control - it must also be credible to obtain effective power. While obviously the usual doubts about the notion of compliance and of possible consequences are

Cite this Article as: Marek CIESLAK "Polish Code of Professional Ethics in Accounting – A Survey Among Accountants and Other Professionals" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

important, the process of convincing parties affected by the code that this proposed code of ethics should be supported despite some undesirable consequences is equally important. (Preston et al. 1995, p. 530).

Codes of ethics are needed in accounting also because accounting standards (legal regulations, rules - which, of course, depend on the legal system in which the entity operates) instruct the accountant on how to proceed in a typical decisions in rarer but often far-reaching consequences, unusual situations.

Characteristics of the Code of Professional Ethics in Accounting

The Code of Professional Ethics in Accounting (hereinafter also referred to as the Code or Code of Professional Ethics) was adopted on June 23, 2007 by the 19th National Congress of Delegates of the Accountants Association in Poland (*Stowarzyszenie Ksiegowych w Polsce,* hereinafter also SKwP). The Code contains regulations of ethical conduct in the most important spheres of professional activity of people dealing with accountancy. The preamble states that the Code contains "patterns of ethical behavior that should be followed by accountants in their profession" and is intended to be the basis for resolving ethical disputes. Although it obliges "every person dealing with accounting to observe the principles of ethics and to act in accordance with the spirit of the development of the profession in the field of accounting and the global environment in which it is currently performed" (SKwP 2007, preamble), it is an honorary obligation, which actually apply only to the signatories of the Code, regardless of whether they are members of the SKwP, which in turn is not mandatory.

According to the Code, a person dealing with accounting is a natural person who performs accounting activities (nb. The accounting activities described in the Code are an adaptation of Art. 4 sec. 3 of the Accounting Act (Act 1994), however, a provision was added to perform financial analysis and popularize knowledge in the field of accounting), management support activities, tax settlements and other public-law settlements in the entity, as well as other persons related to accounting through teaching or other forms of accounting popularization.

The SKwP Code contains nine ethical principles applicable to people dealing with accounting, namely the principle of professional competence, the principle of high-quality work, the principle of professional independence, the principles of responsibility for the prepared and presented information, principles of conduct in relations with persons, entities and institutions professionally related to it, rules of conduct in cases of disputes and conflicts of interest, rules of conduct in special situations, rules of professional secrecy and the rule of properly offering services in the field of accounting. The authors of the Code also included a provision that the profession in the field of accounting is a profession of special importance, which should be seen in the macro- and microeconomic scale.

Results of the Conducted Research

As the Code has been implemented for a longer time, I have decided to survey the knowledge of its provisions on a sample of 316 respondents, employed mainly in accounting departments of the units. Among the respondents there were also people employed in the financial departments of enterprises, describing themselves as "members of the management of the entity", including chief accountants and financial directors, as well as people related to finances, working, for example, in tax offices or credit departments of banks, collectively included in the 'other' category.

Although only 5% of respondents declared membership in the SKwP, the awareness of the Code was declared by an average of 22% of respondents. The largest percentage of people (33%) who have read the Code in relation to those declaring that they know its existence are members of the management of economic units. A similar declaration was made by 14% of people who identify themselves as accountants. None of the other respondents read the document before completing the survey.

The respondents stated that the Code of Professional Ethics in Accounting is necessary. The opposite opinion was expressed by 18% of the respondents: the largest number among employees of financial departments, and the least among employees of accounting departments. Among the respondents who declared knowledge about the existence of the Code, the most opposed to it was among the members of unit management (17% of respondents declared that they had read this document and it is not needed), and the least among employees of financial and other departments (all considered its existence needed); 6% of employees in the accounting department admitted that they knew about its existence, but did not read it and considered it unnecessary. On the other hand, respondents declaring a lack of knowledge about the existence of the Code, this document has the most opponents among employees of financial departments (31%).

The respondents (85% in total) stated that the Code should apply to all people involved in accounting. Only 15% were of the opposite opinion. The first option gained the greatest support among the respondents declaring them-

selves as members of the unit's management, and the lowest among persons describing themselves as employed in the financial department.

When asked whether the enforcement of the provisions of the Code of Professional Ethics in Accounting should be left in the hands of the professional self-government or SKwP, or should it be handed over to the judiciary, the overwhelming majority of the respondents opted for the first option.

The next nine questions of the survey concerned the following rules contained in the Code of Professional Ethics in Accounting. The respondents were asked for their opinion on the validity of a particular rule, as well as for their opinion on whether compliance with the rule should be a requirement for the accounting (accountant) profession. Below I present the most interesting answers gathered in the survey.

The first question concerned the validity of the principle of professional competence, which 91% of respondents considered correct. The greatest number of supporters of making the performance of an accounting profession dependent on compliance with the principle of professional competence was among representatives of other professions, and the least among employees of the financial department. It is also worth noting that 58% of the accounting department employees answered "yes", which is a value lower than the weighted average for all respondents, which was 65%.

The second of the principles included in the Code of Professional Ethics in Accounting, the principle of high-quality work, was recognized as right by 88% of respondents. It was least accepted by employees of the accounting department, and only in the group of other employees this principle was assessed as highly as the principle of professional competence. Compliance with the principle of high-quality work as a requirement for the accounting profession was supported by only half of the respondents.

The principle of professional independence was recognized as correct by even fewer respondents than the first two principles (74%), but it is interesting that 86% of people who define themselves as members of the management of the unit had such an opinion. The responses of employees from other departments resulted in a low acceptance level compared to the first two principles.

The fourth question concerning the principles included in the Code of Professional Ethics in Accounting was intended by the respondents to indicate that the principle of responsibility for the prepared and presented information in the field of accounting is right or wrong. The answers show that this principle was appreciated by the respondents, and the fact that the practice of an accounting profession was dependent on compliance with this principle was much less accepted. Relatively the least convinced here were representatives of the management staff (56%), and the most convinced people of other professions (77%). Against the background of answers to a similar question regarding the remaining rules, the total score of 64% of the answer to "yes" should be considered quite high.

Another principle of the Code regulates the conduct in relations with persons and entities professionally associated with a person practicing accounting. Almost all employees of other departments in the units considered it correct (96%), and she found the most opponents among employees of financial departments (20%) and members of management units (74%).

The rules of conduct of a person dealing with accounting in the event of a dispute and conflict of interest were considered correct by 73% of the respondents; the employees of financial departments did so the most (84%). This rule found the greatest opponents among the management of units and employees of accounting departments (18% and 17%, respectively), and the most "I don't know" answers were given by employees of other departments of enterprises (21%). These principles were the only ones that received more "no" than "yes" answers to the question of whether compliance with them should be a requirement for accounting professionals (41% and 35% respectively). Responses to "yes" prevailed among the members of management of units and employees of other departments in enterprises, while answers to "no" prevailed among employees of financial and accounting departments

The principle of professional secrecy, which is not particularly surprising, turned out to be the principle most appreciated by people describing themselves as members of the management of the unit - everyone considered it correct, just like the respondents working in the accounting department (99% "yes"). In total, 98% of respondents agreed with its wording. Also, the largest number of respondents (77% in total) considered that compliance with this principle should be a requirement for the accounting profession. Again, it is not surprising that the most supporters of this approach were among the management staff (86% in favor, only 4% against).

The principle of professional secrecy, which is not particularly surprising, turned out to be the principle most appreciated by people describing themselves as members of the management of the unit - everyone considered it correct,

just like the respondents working in the accounting department (99% "yes"). In total, 98% of respondents agreed with its wording. Also, the largest number of respondents (77% in total) considered that compliance with this principle should be a requirement for the accounting professionals. Again, it is not surprising that the most supporters of this approach were among the management staff (86% in favor, only 4% against).

The last rule from the Code of Professional Ethics, i.e. the rule regulating the principles of properly offering accounting services, may be perceived as controversial, if only because it is unethical to offer accounting services by making any comparisons with other accountants, especially - in terms of competences and prices of services (SKwP 2007, point 8.1.5) The rule was assessed as correct by the respondents (78%), it gained the least supporters among employees of financial departments (67%), and the most among representatives of other professions (88%). However, the highest number of opposing votes was recorded among the management staff.

Conclusions

The survey conducted on a sample of over 300 people working in accounting departments, financial departments, unit management and other positions related, however, directly or indirectly to accounting, allowed for the formulation of a number of conclusions.

The awareness of the existence of the Code of Professional Ethics in Accounting is quite low among respondents, however, the vast majority of respondents recognize the need for a document regulating the ethical behavior of people working in the field of accounting. The respondents believe that the provisions of the Code should be binding on all persons dealing with accounting, and not only on the members of SKwP, which prepared the Code. According to the respondents to the questionnaire, the supervision over compliance with the provisions of the Code should be carried out by the professional self-government, and not by the state authorities through the administration of justice.

All the rules of conduct formulated in the Code of Professional Ethics in Accounting were considered correct by a significant majority of votes; the principles of professional secrecy (98%), professional competence (95%) and responsibility for the prepared and presented information in the field of accounting (93%) gained the greatest support. The smallest number of respondents (74%) considered the principle of professional independence and the rules of conduct of a person dealing with accounting as correct in cases of disputes and conflicts of interest.

The respondents supported the solution that requirements the performance of the accounting profession to a lesser extent than compliance with the Code. The highest number of respondents (77%) considered that the requirement of practicing the profession in the field of accounting should be observance of the principle of professional secrecy, and the least - the rules of conduct of a person dealing with accounting in cases of dispute and conflict of interest (35%) and proceedings a person dealing with accountancy in relations with persons associated with her professionally (38%). Such responses may or may not be caused by a lack of faith in one's own abilities and security ("what will happen, if it happens to me to break the rule"?).

The average assessment of the principles contained in the Code was similar in all professional groups (from 83% to 89% of the respondents considered them correct), the highest rated principles were assessed by representatives of the management staff, and the lowest - interestingly - by employees of accounting departments.

Abstract

This article presents a statistical analysis of road accidents, which happened in 2018 on Polish roads, with particular regard to the age group in which the highest number of injuries/fatalities from road accidents occurs. The research is based on the causal analysis of increased accident rates amongst the identified demographic group of drivers, as well as on external factors such as the national driver training system or legal and organizational solutions in the remit of road safety. This research article for the first time presents results and recommendations on the causes and effects of road accidents based on a detailed analysis of; the aggregate age of drivers, the current training regime and level of confidence in the rules governing specific road behaviour. This is an innovative approach, both from a theoretical and a practical safety sciences perspective, with a future impact on road safety.

Keywords: Road Safety, Road Traffic Accidents, Young Drivers, Driving Behaviour.

Introduction

The occurrence of road accidents is accompanied by many different factors, such as the type and condition of the road infrastructure, traffic congestion and its organization, the type and technical condition of vehicles, the development of scientific and technical facilities in the field of motoring, the involvement of administration in the implementation of tasks in the field road safety and many other elements more or less noticeable or palpable [11]. However, the most important reason influencing the occurrence of road accidents in the human-vehicle-road relationship is definitely the human factor [8]. Due to the fault of human, both as a vehicle driver and being an unprotected participant in traffic, a total of over 90% of all road incidents in a given calendar year occur. When analysing this factor, attention should be paid to the age of vehicle drivers, which for years indicates a certain age group in which the highest number of accidents and consequently victims. The study presents a statistical analysis of road accidents taking into account the age criterion of perpetrators. In terms of selecting the age group that is most often the culprit of road accidents, an attempt was made to identify and analyse the causes of the increased accident rate of a statistically selected group and to answer the following questions whether: is the fault caused by an inadequate training system and on drivers obtaining a driving license for the first time? What can be considered one of the main research problems? Or maybe not fully functional legal and disorganized solutions or even threatening road safety are the main cause of road accidents due to human factor? This question should also be treated as one of the equivalent research problems. There were also postulates de lege lata and de lege ferenda in the scope of improving the state of safety in road traffic, which should be treated as the main goal of research carried out using statistical and comparative methods as well as by means of analysis. This research study analyses the causes of road accidents and involves a comprehensive survey on a national scale. Indeed, there are similar studies conducted across other nations which have analysed the causes and impacts of road traffic accidents. This research

has been based on three main factors which have included previous world-wide analysis, respectively; 1) impact of driver speed as a cause of road accidents – based on research conducted by the Ci2N University of Strasbourg for the VINCI Autoroutes Foundation – 2017, 2) age of drivers – by the Ministry of Transport of Great Britain [10] and 3) training system – by "British School Motoring" (one of the most famous driving schools in Great Britain) [23].

The article uses statistical data from 2018. At the time of submitting the print material, the data for 2019 was not available, however, a comparative analysis of the last few years indicates that in percentage terms they change within the statistical error.

Age of Managers

Analysing the statistics of road accidents, their effects, circumstances and causes of occurrence, it can be seen that the source of the largest number of road accidents is human error (as a participant in road traffic) (Fig. 1). In 2018, this was responsible for 30 171 road accidents (95,3% of the total), in which 2 569 people were killed (89,8% of all fatalities) and 35 690 were injured, i.e. 95,5% of all victims.

Fig. 1: Report on the occurrence of road accidents in 2018. Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, *Wypadki drogowe w Polsce w 2018 roku,* Warszawa 2019.

For years, most road accidents have been caused by the fault of drivers, putting them in the first place of all statistics, reaching numbers exceeding ten times higher than the perpetrators of other accidents due to the fault of pedestrians and passengers (Fig. 2). As at 30 June 2018, the population of this age group was 2 922 156 people, a group between 25 and 39 year old – 8 903 584, people between 40 and 59 years old recorded 10 266 316, while there were 9 392 660 people in the age group over 60 [24].

Fig. 2: Road accidents in 2018 by agency. Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, *Wypadki drogowe w Polsce w 2018 roku,* Warszawa 2019.

In 2018, drivers of vehicles were the perpetrators of 27 556 road accidents, in which 33 261 people were injured and 2 177 were killed. Most accidents happened this year: in May (2,697), June (2,673), July (2 689) and October (2 699), and least in February (1 542). Most submissions about the events the police received on Friday (5 230), and the least on Sunday (3 681), while the most common hours of events were the so-called rush hour, i.e. between 4 p.m. and 6 p.m. (4 383), and least between 2 p.m. and 4 p.m., when 302 road accidents occurred.

Particular attention should be paid to the group of so-called "young drivers" between 18 and 24 years old, which has the highest rate of road accidents per 10 000 population (Fig. 3).

Fig. 3: Accident rate per 10 000 population by age group. Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, *Wypadki drogowe w Polsce w 2018 roku,* Warszawa 2019.

In 2018, 5 113 road accidents were caused by "young drivers" aged between 18 and 24 years old, which accounted for 18,6% of all accidents that were generally caused by the drivers. As a result of these events, 428 people were killed and 6 734 were injured. In addition, it should be noted that within the age group directing from 18 to 24 years of age there is also the largest number of fatal and injured victims (Fig. 4).

Fig. 4: Rate of deaths and injuries per 1 million population in 2018. Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, *Wypadki drogowe w Polsce w 2018 roku,* Warszawa 2019.

The highest number of fatal accidents, 379, in relation to the population, was also caused by this group of "young drivers", which accounted for 19,1% of all accidents caused by drivers. It was mainly a collision with a tree, a side impact, frontal collision and hovering on a pedestrian (Fig. 5).

Fig. 5: Type of road accidents with a fatal outcome caused by drivers of vehicles in the age range 18-24.

Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, Wypadki drogowe w Polsce w 2018 roku, Warszawa 2019.

The most common causes of accidents caused by drivers in this age group were: inadequate speed to traffic conditions, failure to give priority to crossings, and failure to give priority to pedestrians at a pedestrian crossing (Fig. 6).

Fig. 6: The main causes of fatal accidents caused by drivers in the 18-24 age group

Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, Wypadki drogowe w Polsce w 2018 roku, Warszawa 2019.

The main cause of road accidents for which drivers are responsible at 18 to 24 years old, is a mismatch of speed to traffic conditions, which in 2018, constituted, 35,6% of accidents, resulting in 53,3% of all fatalities in accidents caused by them.

Speed, as a source of road accidents depends on the class, function of the road, nature of traffic and development of the surroundings [16]. It can therefore be concluded that a factor threatening road safety is the lack of ability for young drivers to adapt their speed to the type of road, technical solutions and traffic solutions [4]. It should be noted that one of the reasons for drivers exceeding the speed limit is the vehicle manufacturers themselves, who are constantly working on increasing the speed of designed cars.

Research conducted on a group of young drivers shows that they achieve driving pleasure only after developing a significant speed and in conditions that allow for fast driving [5]. Studies conducted on a group of young drivers indicate that they achieve driving pleasure from excessive speeding and in conditions that allow for fast driving. Ergonomic studies show, however, that at speeds above 130 km/h. the driver of the vehicle decreases its level of perception and response time to external stimuli, i.e. road signals and other road users [17]. This is due to reaching the biological limit of mental fitness at this speed, and especially if excessive speed is accompanied by heavy traffic. The driver of the car is obliged to constantly make choices and actions regardless of the perception and assessment of the situation. At high speeds, the probability of making a mistake increases significantly, while the possibility of corrective actions decreases [6].

There are probably several sources contributing to "young drivers" exceed speed limits. Undoubtedly, one of them is the lack of appropriate practical knowledge and experience, which often results in faulty assessment of road conditions and inadequate speed adjustment to these conditions. For example, during heavy rainfall, in the fog or after dark, it is much more difficult to maintain control over a vehicle moving additionally at excessive speed. Lack of the right skills and the mentioned practical knowledge mean that young drivers in bad weather are not able to accurately assess the distance between vehicles, braking distance, or vehicle driver behaviour during a sudden cornering [15]. Acquiring such important manners of driving a vehicle as recognizing hazards on the road, maintaining a safe (not always allowable) speed, the ability to combat distraction or dealing with difficult or urgent road situations is the result of many years of practice. Preparation courses for driving tests are focused only on passing on basic knowledge about driving without the possibility (due to the limited number of hours) of meticulous and sufficiently to learn to react in very different and numerous situations on the road.

Another reason affecting speeding by young drivers is ignorance of their psyche and automotive skills. Negative factors of everyday life, or the desire to impress peers can cause the driver to be aggressive or bravado on the road. The driver's personality function manifests itself either in cautious driving or in excessive self-confidence. And it is this negative attitude of the driver towards the environment in connection with the lack of knowledge of his personality that is the hidden cause of road accidents, the source of which is excessive speed [7].

Failure to adapt speed to traffic conditions by young people is a problem present not only in Poland. For example, in 2015 Goodyear's tyre company commissioned a survey in Europe, the Middle East and Africa regarding speed limits and compliance with traffic rules [18]. The survey was addressed via the Internet to drivers under 25 years of age. Research results have shown that the speed in a given section is usually exceeded by young drivers in Poland, which 81% of respondents admitted. Slightly less in Africa – 79% and in Russia – 60%. The most responsible young drivers turned out to be residents of Great Britain (54%) and Spain (40% respondents admitted to speeding). Spaniards also much less often try to achieve the maximum speed of their vehicles. This state of affairs is probably explained by the effective enforcement of the law and the quite numerous number of speed cameras. However, young drivers from Russia (46%) and Germany (53%) admitted to testing their vehicle. The behaviour of the latter group is not surprising, however, as most German motorways, as few, do not have speed limits.

Statistics also indicate that the cause of road accidents caused by "young drivers" of vehicles was not only the failure to adapt speed to traffic conditions, but also incorrect overtaking, incorrect driver behaviour towards pedestrians, or failure to give priority to another traffic user [13]. Drivers in this age group, adopt these bad practices most often in urban traffic or in places with heavy traffic. Here the so-called thrill present at excessive speed gives way to bravado and a desire to impress, which is manifested in extreme overcoming the difficulties of city traffic, or the satisfaction of poor (sometimes imaginary) competition with other drivers. Research indicates that incorrect overtaking is the effect of rush or is dictated by the desire to show off the "young driver" of their skills, while slow and compliant with traffic rules for many of them means weakness and cowardice [14].

It is this improper and irresponsible approach to the basic principles of road safety that are the cause of a large number of road accidents with tragic consequences. The decisions made by drivers are, after all, an objective assessment of the situation and their own capabilities, which often – in the case of drivers up to 24 years old – are different than the reality indicates. In the absence of experience, there are various reasons for accidents causes in young drivers. These include: deciding to perform any manoeuver, in addition at excessive speed, lack of concentration (sometimes under the influence of alcohol or other stimulants) and cooperation with other road users (necessary e.g. when overtaking, passing, avoiding) very often inexperienced drivers mistakenly they assess the distance of another car, the possibility of their own vehicle or the prevailing road conditions, and are probably not aware of the fact that in such a situation they pose a threat not only to themselves but also to other participants using the roads properly [3].

Analysing the above behaviours and characteristics, it is possible to present a general profile portrait of the "young driver", which has the following features:

- treats his vehicle in a utilitarian way, which he only uses to travel quickly;
- extremely approaches the appearance of the vehicle, i.e. either does not show a clear interest in the car, or - in order to stand out and want to impress – unduly focuses his attention on various accessories and modifications (e.g. modernization, tuning, modernization, installation of equipment for loud listening of music, etc.);
- drives his vehicle carelessly, automatically and without proper concentration or attention to his driving style;
- while driving, often uses the telephone (sometimes also without the required hands-free kits), which focuses on conversation, instead of safety, smokes cigarettes, which in turn limits manual operations;
- shows constant rush resulting from permanent lateness;
- does not respect traffic regulations, which is due to lack of concentration, lack of involvement in driving and educational gaps;
- park the vehicle in a prohibited area with no parking (most likely out of convenience, laziness or as a result of thoughtlessness);
- behaves selfishly, e.g. by forcing priority, so-called driving on the road, or preventing drivers on subordinate roads from joining traffic, of which this manoeuver is sometimes only possible with the appropriate behaviour of another driver;
- derives satisfaction from dangerous driving, often above the speed limit, and in relation to properly moving drivers can be aggressive and rude;
- as a tendency to decide on performing risky ones and dangerous activities and behaviours, such as overtaking at excessive speeds in places with no overtaking.

The characteristics of "young drivers" indicated above are confirmed both by statistics on the road accidents caused by them and the results of numerous observations of their use of roads. Both should be a premise for reflection that will force all drivers to verify their driving style and complement this style with quality. This applies in particular to young drivers (not seniority) of drivers, because any vehicle they use is like a dangerous tool in the hands of the wrong person, because they lack the imagination and responsibility for themselves and for other road users (passengers, pedestrians, other drivers etc.) [12]. This is indicated by offenses with the participation of "young drivers", which in most cases have a tragic ending (Fig. 7).

Fig. 7: Structure of offenses committed by "young drivers" revealed by the Police in 2018.

Source: Authors own work based on Komenda Główna Policji Biuro Ruchu Drogowego, Wypadki drogowe w Polsce w 2018 roku, Warszawa 2019.

The offenses indicated proof that the existing preventive systems (fines, penalty points) used by the Police proved to be ineffective. In the present world, with deeply rooted democracy, in which there are no authorities, even police officers no longer give due respect. Society requires more rights, more privileges and more benefits from the state, without any obligations. This applies especially to young people, who are a group of people who respect the law the least (although you cannot generalize here, because it could be far from being harmful to honest and righteous younger people). Although this inexperience or behaviour is often explained by youthful enthusiasm, joy of life and independence, which is the receipt of a second (after ID card) important document - driving license, this law does

not justify neither vices nor offenses. However, information about road incidents, or tragic statistics in this area do not have causative power and are not able to influence the reason of some "young drivers". It is hardly surprising, because the source of all methods is psychological background. By submitting to smaller or greater temptations, we all feel free and we have the right to make various choices. However, this does not absolve anyone from responsibility, and motivation, reflection and analysis of their own conduct should be elements of teaching at a very early stage of life, and when referring to education of participation in road traffic - at the level of the first theoretical classes in the training centre. This approach to the issue of "young drivers" as road participants will probably make it more friendly and attractive, and thus – safer [9].

Training system for drivers obtaining a driving license for the first time

Research issues related to road safety are many areas of human activity related to such thematic groups as e.g. legal and organizational solutions, rescue systems, educational and preventive activity, psychological and medical problems, the impact of transport and road technology and technology, traffic supervision, gathering and grouping information, examining threats and their causes, analysing explanatory, preventive and repressive measures. However, referring to the criterion for assessing the causes of road accidents caused by drivers of vehicles, including groups of so-called "Young managers" can be identified in several areas in which to look for the reasons for such a high accident rate from the indicated groups. And these are, among others: a system of training candidates for drivers, a system of road marking using signs and signals, and control systems and the use of preventive and repressive measures against the so-called "young managers".

Based on Article. 26 of the Act of 5 January 2011 on drivers of vehicles [19] to conduct training for persons applying for permission to drive a motor vehicle (driving license) are entitled: driver training centres, as organizational units of the entrepreneur entered in the register of entrepreneurs operating training centres; military units in the scope of training soldiers for the needs of the Polish Armed Forces and organizational units of services subordinated to or supervised by the minister competent for internal affairs - in the scope of training people for the needs of these services. As you can see, the Act indicates the multitude of entities authorized to conduct courses, however, they differ in training methods and the level of assessment of effects, which in turn depends on the people running the courses, i.e. instructors. Remembering about the group of "young managers", about their agency, lack of experience and bravado while driving, the question arises whether one of the reasons for this is the proper preparation of teachers for conducting this type of education. Driving instructors play the most important role at the stage of training young drivers, because their knowledge, practice and training skills affect the driving safety of young drivers.

The cited act on vehicle drivers regulates the rules of admitting people to conduct training as a driving instructor. Article 33 indicates that it may be a person who has at least secondary education; has the same driving license category as the scope covered by the training for not less than two years; has a valid medical and psychological certificate about the absence of health contraindications to perform the duties of an instructor; has successfully completed a course for candidates for instructors and will provide a certificate of its completion, and has not been the subject of a court judgment for offenses against road safety. The paradox of this regulation is that it requires the instructor to only confirm the possession of a driving license, and not to document the driving practice.

In addition, conducting driving courses is usually an additional gainful occupation for instructors, and the duration of his work, according to the Act, may not exceed a total of 12 hours, so taking into account the fatigue of such a person with "regular" employment, the effectiveness of the work as an instructor should be questioned, which is responsible for the safety of not only driving, but also the student himself. In such a system and for such a limited time, he is unable to teach the student basic reflexes, develop desired responses, or put him under control of behaviour when moving a vehicle. The centres where the courses are conducted also leave a number of doubts. Often, their infrastructure is not adapted to the needs and training requirements.

In order to improve road safety and minimize (eliminate) accidents involving "young drivers", measures should be taken to improve the system of training candidates for drivers obtaining a driving license for the first time, in particular:

- increasing the competence level of instructors and lecturers, with particular emphasis on their training process, level of knowledge and experience,
- improving the quality of services provided by driver training centres by introducing operating restrictions and restrictions,
- imposing strict requirements on driver training centres and reliable standardization.

The introduction of suggested changes discussed below may significantly enhance the level of training for drivers, and consequently eliminate many threats to road safety arising from improper practices, particularly amongst young drivers.

Lack of trust in road signs as a cause of traffic incidents

An important factor influencing the occurrence of road incidents (collisions, accidents and disasters) is undoubtedly non-compliance of road traffic rules and law by vehicle drivers. The statistics cited above indicate that the largest number of road incidents occurs in the group of "young drivers" blamed for many negative behaviours, such as bravado, recklessness, lack of experience, or permanent non-compliance with traffic rules, including road signs and signals. All drivers navigating on known sections of roads are aware of traffic hazards existing in these places and set up various types of road signs. However, for even an experienced driver moves sometimes in an uncertain manner, while performing many activities, such as tracking the map, controlling traffic on the road and reading important information from road signs. However, if these signs are obscure or do not comply with accepted rules or their appearance goes beyond the norm, it is difficult not only to notice, but also to follow. Therefore, the driver is not always liable for causing cause a traffic accident.

In Poland, the issue of road signs and signals in road traffic, their significance and scope of validity was set out in the Regulation of the Ministers of Infrastructure and Interior and Administration of July 31, 2002 on road signs and signals [20]. In accordance with art. 3. on roads apply: 1) vertical signs in the form of shields, boards with inscriptions or symbols, which also appear in the form of illuminated signs; 2) horizontal signs in the form of lines, inscriptions and symbols placed on the road surface; 3) light signals transmitted by signalling devices; 4) signals given by authorized persons; 5) sound or vibration signals sent by devices placed on the road.

It is recognized that compliance to road signs: order, prohibition and warning are placed on roads to ensure orderly traffic organization and to maintain safe driving. Everything would be straightforward if road signs were set up for each threat or required information. However, on Polish roads you can meet many absurdities disorganizing this movement, or even affecting the emergence of threats. This is explained in the following six considerations:

- speed limit signs. As you can easily see, the antidote for every threat (although not always a threat) is speed limit (i.e. sign B-33 limiting speed to 40 km / h). However, the road situation does not always require road users to make such a decision. In Great Britain, for example, where drivers and other road users have to use their experience and judgement, there are many sections of winding roads with no speed limit, and yet statistics show that in this country there are fewer accidents and fewer number of victims
- marking errors can cause confusion. This problem particularly applies to drivers who, without knowing the map or making the area, are forced to perform dangerous manoeuvers, e.g. sudden stopping, turning back or reversing on busy roads, because road signs have been placed wrongly or are illegible. From road signs (especially those on express roads), information must be read by drivers quickly to be able to choose the appropriate response (e.g. change of lane).
- setting the B-20 signs, i.e. "stop" at closed or rarely used level crossings. Of course, maintaining special safety in such places is indisputable, but drivers ignore such restrictions, because in combination with a straight section of the road without special hazards, they consider the presence of such signs to be meaningless. Even patrolling policemen enforce compliance with regulations without thinking about the legitimacy of introducing restrictions. As a consequence, such situations result in a lack of respect for road signs on busy unguarded crossings where accidents are common.
- irremovable signs after completion of road works. The problem here is that despite the completion of construction works, road signs still restrict movement along this section of the road. In addition, having erected signs related to the repaired road section (e.g. speed limits), no reference signs are placed. Drivers become confused, resulting in slow driving, until the next intersection cancelling the restriction. Rarely do drivers follow orders and simply ignore this restriction.
- defective system solutions and lack of consistency due to municipalities or county pursuing their own road marking policy. The same threats are marked in different ways in different communes or counties. Ridiculous speed limits are simply ignored by drivers. In addition, positioning of traffic signs are often set too close to the danger or well in advance, which causes chaos and loss of orientation by the driver.
- clutter and excessive information compounded by additional banners placed and hung. Their appearance or setting rules have not been regulated in any legal act. Traffic signs are no longer visible or readable with bright, shining or even moving advertisements. An uninformed driver is not able to see a road sign important for road safety. Road signs informing about e.g. petrol stations (D-23), restaurants (D-28) or vulcanization (D-26a) are the biggest problem, which are replaced by the advertisement of a

given service provider (Irregularities regarding the setting of road signs where included In the post-audit statement of the Supreme Audit Office regarding the control of public road, in addition to roads manager by the General Directorate for National Roads and Motorways. In 77% of cases, the control revealed irregularities in vertical and horizontal markings, in particular they concerned the positioning of the marks in a way that did not meet the requirements set out in the regulations and not in accordance with the adopted traffic organization [25]).

These are examples of inadequate road marking causing misinformation and ignoring of important warnings by drivers, thus not complying with the law. This problem affects drivers of all ages, not just "young" ones. In addition, the excessive amount of information on the road for any driver makes it not possible to "register" even when travelling at the applicable speed. Traffic has the characteristic that it can change radically at any time and to prevent hazards drivers must constantly monitor the traffic situation (e.g. other moving vehicles or road users).

The method of setting road signs and signals is regulated by the Regulation of the Minister of Infrastructure of 3 July 2003 on detailed technical conditions for road signs and signals and road safety devices and conditions for their placement on roads [21].

Currently, the regulations indicate a large number of road signs and signals, both in type, size, colour and purpose, therefore their setting should be thought out, i.e. they should appear only where they are really necessary and in a manner appropriate to the prevailing conditions and situations

Conclusions

This research article for the first time presents results and recommendations on the causes and effects of road accidents based on a detailed analysis of; the aggregate age of drivers, the current training regime and level of confidence in the rules governing specific road behaviour. The author has analysed the general profile and common characteristics of the "young driver", attributed by typical behaviour of young people and reflected on the inefficient and inadequate training system for such challenges. The authors believe that a significant factor that has a negative impact on shaping the silhouette of a "young driver" are irregularities that occur in road signage and markings.

To improve the level of trust in road signs, focus on systemic solutions for:

- amendments to the rules on setting road signs and their regular updating in order to harmonize these rules across the country,
- designation and appropriate training of persons responsible for setting road signs and for designing traffic organization, since at present no qualifications or permits are required of these persons.

Currently, traffic signs can be erected by any employee in this position. Sometimes, they are arranged in a mutually exclusive way, or in excess. Road signs are set by road owners, i.e. the General Directorate for National Roads and Motorways, it can also be done by heads of provinces and communes, county executives, or presidents of cities with county rights. Railway workers and employees of road repair companies also have the right to set signs. According to the law, road signs can be set by any official who has been employed in such a position and there is no requirement for these individuals to have a driving license.

In addition, in order to improve the level of road safety and reduce risks in this traffic, you should focus on control systems and the use of preventive and repressive measures against a group of so-called "young managers" [1]. The effectiveness of these projects should be achieved by:

- selective approach to the application of penalties for the group of "young managers",
- introduction by the services responsible for maintaining road safety and order of the obligation to create detailed risk maps in the subordinate area,
- focusing on identifying groups of "young drivers" who frequently violate traffic law (e.g. organizing races on the road in built-up areas),
- creating a palette of educational measures.

It cannot be prejudiced that all drivers when driving a vehicle do so in a manner that is unreasonable or bypassing applicable law. Many of them do it wisely and properly, not only by taking into account traffic law, but through proper observation of the environment and the ability to predict the behaviour of other road users. An experienced driver is able to predict the behaviour of another driver and react early enough to the threat to prevent a traffic incident with various effects.

Among the "responsible" group of drivers, there are also road accidents due to, for example, improperly functioning road infrastructure limiting the possibility of proper driving on the road, as well as due to the lack of driving culture of other drivers, i.e. by non-compliance with regulations, lack of experience or recklessness. The aforementioned driving culture together with the broadly understood communication culture and with the entire legal and institutional system normalizing road traffic is part of the safe space surrounding the human being and the road [2].

In addition, driving culture (along with driving safety) should be part of the training process for candidates for drivers who for any reason have lost their driving license. Training tailored primarily among the "young drivers" will contribute to improving road safety and the entire management system, which will contribute significantly to reducing the risk of road hazards, i.e. collisions, road accidents or disasters that result in tragic events.

The research undertaken in this article will be further developed, both in terms of the proposed aspects and also through benchmarking with other countries, taking into account the analysis of the application of practical solutions which provide much better road safety statistics.

Covid-19 Impact on Banking Sector: Case of Latvia

Aija PILVERE-JAVORSKA and Baiba RIVZA

Latvia University of Life Sciences and Technologies, Jelgava, Latvia
apilvere@gmail.com

Abstract

Covid-19 pandemic first wave took place in second quarter 2020 in Latvia. Rapid reaction from the government imposing restrictions, resulted in medical "success" with few causalities. Impact on the economy is still to be evaluated, while the main indicators and predictions are in, Latvia is expected to face the largest GDP contraction among Baltic States. Banking is one of the main sectors securing funding lifeline to the companies, in order to produce goods and services, provide employment, thus to create value added for economy. The aim of the research is to assess the Covid-19 pandemic first wave impact on how banks operate and what is funding availability to enhance economic recovery possibilities in Latvia. Authors discovered that already after 2008 recession bank lending had an overall trend to decrease in Latvia, thus reducing available funding to the companies and households for recovery. Bank business model has changed already before Covid-19 pandemic, especially in the light of restructuring of banking sector by supervisory institutions. Covid-19 impact in banking sector has been to whom banks lend money, there are significant increase in lending to government, holding and lending money to Central Bank and other monetary financial institutions, while we saw even further reduction of lending to companies. Overall major banks' profits have seen a drop in Q22020, but they remained profitable, with exception one of the major banks experienced significant losses.

Keywords: Covid-19, banking sector, impact analysis, Latvia.

Introduction

Covid-19 pandemic, which at its beginning was not believable to reach Europe and let alone Latvia – a far Nordic European Union (EU) country, however in second quarter of 2020 (Q2 2020) the first wave of Covid-19 was unrolling across Europe and Latvia. This pandemic is different from the recession in 2008. Researchers Wojcik D. and Ioannou S. (2020), confirms it by stating that "whereas the global financial crisis on 2008 is sometimes referred to as the North Atlantic crisis, the COVID-19 pandemic is truly global, directly affecting almost every country in the world." It was a wave of unknown and seeing Italy battle with severe causalities, Government of Latvia took drastic measures and on 12.03.2020, declared emergency situation in Latvia. This move allowed Latvia to be called a "success" case with relatively few causalities in the medical terms in Q2 2020, and even allowed to end the emergency situation on June 09, 2020. There is a necessity to evaluate the impact of Covid-19 first wave, how the "success" and fighting with Covid-19 has affected economy in Latvia. As noted by Sheridan A., Andersen A.L., Hansen E.T., Johannesen N. (2020), that "in many countries, the introduction of social distancing laws in response to COVID-19 has occurred at the same time as a sharp contraction in economic activity, including consumer spending." On the other hand, economic impact has been seen also on financial and banking system in the world, this has been already recognized by Rizwan M.S., Ahmad G., Ashraf D. (2020) that "COVID-19 has slowed down the global economy. Consequently, financial institutions are facing elevated levels of liquidity risk, loan defaults, and loss of intermediation revenues. Interconnectedness among financial institutions can spread individual issues to the network of institutions resulting in an overall heating-up of the financial system." Similarly, the impact in the research has discovered also on other part of financial system – stock market by O. Erdem (2020), and Harjoto M.A., Rossi F., K. Paglia J.K. (2020). The global pandemic of Covid-19 has generated negative shocks on the equity markets across the globe.

Authors agree with Barnoussi A., Howieson B., van Beest F. (2020), who recognized "the COVID-19 pandemic is rapidly changing the economic environment, so banks will need to reassess whether it is still reasonable to consider credit risk to be low. Normally they can rely on their credit ratings, so they need to update the ratings to meet the new economic environment." They recognized that need to reassess, but have to recognize that the change cannot be stopped, are banking system and their supervisory institutions prepared for that - is one of the questions to answer yet in Latvia. Similarly, in the context of historical events Korzeb Z., Niedziółka P. (2020), emphasized that "as with

previous global crises, it is essential to learn lessons from the current situation, as pandemics are unlikely to be repeated in the future. The power of supervisory institution over banking system and its help to revive or defer economic recovery is important and is acknowledged by Podtserkovnyi O., Vozniakovska K. (2020), where they indicated that "the real powers of the national (central) bank in the economic system and the actual ability of governments to subordinate the decisions and actions of such banks to their current interests depend on this assessment, which may negatively affect confidence in the national currency and prospects for overcoming the economic consequences of the Covid-19 epidemic." The global impact and challenges of institutions were defined by Bryce C., Ring P., Ashby S., Wardman J. K. (2020) that "transboundary crises present a significant challenge for organizations, including businesses and public institutions. Established crisis management responses can be ineffective and business continuity can be severely disrupted as problems occur over multiple domains and manifest in unfamiliar ways. Often escalating and migrating risk quickly across political and social boundaries to affect society, businesses, and global financial markets". Similarly were elaborated by Flögel F., Gärtner S. (2020), that "still, the pandemic differs from the financial crisis as the real economy at large is in turmoil, which is likely to cause defaults on business loans and potentially also affect the much larger housing loan market." The issue is two folded – the health of existing issued loans and new loans to be issued are equality important, to drive economic growth and development. Without funding companies can only stagnate, especially if the country has weak stock market, thus companies have limited sources of funding available, as is the case in Latvia. Additionally banks can be grouped in the clusters in the Covid-19 based on actions, as discovered by Talbot T., Ordonez-Ponce E. (2020), that "in the COVID-19 pandemic… three clusters of banks are identified: sweeping actions, cautious actions, and wait & see, highlighting that while most banks are doing little to help their stakeholders, three of them have a proactive and strong commitment to their clients and communities in these times of need.". This is an interesting perfective of analysis, unfortunately the lack of available data of individual bank data on loan issuance in Latvia, prevents authors to assess banking system from this perspective. On other hand, there is one more dimension to evaluate the impact, which is discovered by Li X., Xie Y., Lin J.H.(2020) , their "…results show that (i) the COVID-19 explosion makes the bank more prong to loan risk-taking, thereby adversely affecting banking stability. (ii) Government capital injections make the bank more prudent to loan risk-taking, thus contributing to banking stability."

There are several ways to evaluate economic impact, authors are doing it through evaluating banking system and what impact Covid-19 has had on the availability of the funding to the economy, via loans available to companies and households and put forward recommendations to improve situation in Latvia. Topically on the issue has also been emphasized by J.W. Goodell (2020) "banks of course by their nature are vulnerable in times of economic downturns, because of the likelihood of nonperforming loans and the possibility in extreme cases of bank runs. It remains to be seen how COVID-19 will change the practices of financial institutions." Similarly, Korzeb Z., Niedziółka P. (2020), emphasized that "as with previous global crises, it is essential to learn lessons from the current situation, as pandemics are unlikely to be repeated in the future. Therefore, the biggest challenge facing the banking sector today is to reorient existing strategies to prepare for similar scenarios in the future. The scale of lending, which appears to be crucial for economy's recovery, depends on the extent to which capital will be consumed as a result of the crisis and to what extent capital requirements will be liberalized." Overall, when other researchers evaluate Covid-19 impact on economy and banking, they research how well are banks capitalized and their profit levels, but lack the research on how banks in pandemic help or hold back economic recovery. Thus, the ***research aim*** is: to assess the Covid-19 impact on the changes of how banks operate and what is funding availability to enhance economic recovery possibilities in Latvia.

Materials and Methods

Authors used scientific literature review, combined with analysis of Covid-19 legislative acts and available statistics from the Financial and Capital Market Commission (FCMC) Latvia. This research is structured in three main parts: pre-Covid-19 banking sector landscape in Northern EU: Finland (FI), Sweden (SE) and Denmark (DK) compared to three Baltic States (Estonia (EE), Latvia (LV) and Lithuania (LT), second part analyzes main indicators of overall banking system in Latvia on quarterly bases from 2018 until Q2 2020. This is done to be able to compare two non-Covid-19 second quarters of 2018 and 2019, in order to remove seasonal biases if any. Third part evaluates all 13 in Latvia operating and reporting banks on the individual bases to research their business model and to evaluate Covid-19 impact on individual bank level. In order to perform this research authors compiled annual data from 5 central banks of Denmark, Sweden, Finland, Estonia and Lithuania, as well as from FCMC in Latvia, for time period form 2003 until 2019, on the total lending (TL), and total deposits (TD). Authors used polynomial relationship trendline, to forecast and extrapolate potential development of various indicators.

Results and Discussion

Pre-Covid-19 Banking Sector in Northern Europe and Latvia

Authors assessed pre-Covid-19 pandemic landscape of the banking sector in Latvia in the context of the closest neighbors – Estonia and Lithuania and against well-developed Nordic EU countries: Finland, Sweden and Denmark, already since 2003. The intension was to compare the banking system development to and post 2008 recession and its development upon arrival of Covid-19. This resonates well also with researcher Piotrowski, D. (2020) that "criticism of the banks' actions has intensified especially since the global financial crisis initiated in 2007." This along with introduced overhaul or reorganization of the banking system by the supervisory institutions in Latvia, has set the impact on the banking system and loan availability already preceding Covid-19. As can be observed in Figure 1, it is almost obvious that in Sweden and Finland banking main indicators: namely lending and deposits growth had not experienced significant impact of 2008-2009 recession, while in Denmark those indicators' growth did have an impact and had experience modest drop and stagnated since then. On other hand deposits in Finland banks did not have any drop and had been slowly and steadily growing. In Sweden there had been a drop in bank deposits during the recession period, however it has recovered significantly and experienced steady increase since 2011. In Denmark similarly as with lending, deposits observed a mild drop and had not seen significant growth as in Sweden.

Fig. 1: Nordic EU Countries Total Lending (TL) and Total Deposits (TD) during 2003-2019.
Source: Authors' compiled based on the central banks of Finland, Sweden and Denmark data

The lending and borrowing situation in Baltic States banks presented similar trends, while deposits did not drop significantly, there had been an insignificant drop of deposits in banks of Lithuania and Latvia, while total lending in banks of Lithuania and Latvia encountered significant drop. In the meantime, in Lithuania banking sector lending by 2019 even exceeded pre-recession amount, while in Latvia as the total lending dropped in 2009, it had been declining until 2018, when only in 2019 saw a slight increase, reaching only 2006-year level. In Estonia banks saw a mild drop and steady recovery in total lending, as can be observed in Fig.2.

Fig. 2: Baltic States Bank Total Lending (TL) and Deposits (TD).

Source: Authors' compiled based on the central banks of Estonia and Lithuania, and on FCMC data of Latvia

As discovered by Pilvere-Javorska A. et al. (2020) the correlation results of GDP per capita with total bank lending, lending to the companies and households, there are strong correlations in Finland and Sweden in all 3 components, in Lithuania and Estonia in 2 out of 3 bank lending components, while in Latvia, there is no strong correlation, suggesting that there is need for further analysis. This has suggested that in Latvia there are other factors, besides main macroeconomic indicators, influencing bank lending. Authors discovered that indeed there are historical differences since 2008, while bank lending drops in 2008-2009 in all reviewed countries, it recovers along with GDP per capita growth, with exception in Latvia, where bank lending had started declining in 2008, and continues declining until 2018, while GDP per capita and deposits recovered post decline in 2008. This can be observed when looking closer to the bank sector lending development when compared to GDP per capita historical development in 2003-2019. As is displayed in Figure 3. authors decomposed total lending between lending to households, non-financial corporations (further term used companies) and other lending as residual, in order to determine to which lending segment the drop is attributed in Latvia. It is observed that GDP per capita despite the drop in 2009 and 2010, has recovered and in 2013 reached pre-recession year 2008. Other issue for analysis is what was observed above, that total bank lending decreases, as Figure 3 displays, the lending dropped to households and companies, while other lending (which includes lending to other Monetary Financial Institutions (MFIs) and government) has remain unchanged and even saw significant increase in 2019, which is before Covid-19 started in Europe. Thus, the lending increase mentioned earlier in Latvia is attributable to the other lending.

Fig.3: Bank lending and GDP per capita

Source: Authors' compiled based on FCMC Latvia and EC data.

Similar analysis in Latvia was done on the other part of the banking assets: deposits, Figure 4 reveals, that deposits from households has seen steady and stabile increase from 2003 to 2019, while deposits from companies dropped in recession 2008-2009, but recovered. However, deposits from companies, experienced again decline since 2015. In annual report on financial system the Bank of Latvia (2016) report notifies that weak lending has been for years and its further weakening would negatively impact economy. This together with this Bank of Latvia mentioned that parent companies of Banks operating in Latvia due to their situation weakening in Nordics, could use their subsidiary bank resources in the case of turbulence and relocate them to help their operation in their group headquarter countries, i.e. Sweden, Norway, Denmark. This combined with the capital restructuring initiated afterwards from Latvian government on the financial sector, as can be seen in the Figure 3 and 4, even more impacted lending and funding availability for the companies and from the companies.

Fig.4: Bank Deposits breakdown by origin, years 2004-2019, in Latvia

Source: Authors' compiled based on FCMC data.

In addition, in Latvia as has been stated by the FCMC, there has been taking place complete transformation of banking sector, initiated by the supervisory institutions. The transformation has even more slowed down lending to companies, as has been seen in Fig.3. and combined with already declining lending since 2008, combined with the way the transformation has been executed, has been having significant negative impact on the available funding and lending to the companies. This is especially complicated, since in Latvia bank lending is in many cases the only access to the companies and households for external funding for development. If that was not enough, early 2020 Covid-19 pandemic arrived. The impact of it is analyzed further in the research. Next issue to address, what impact has had Covid-19 first wave on banking sector and funding available to non-monetary financial corporations in Latvia?

Banking Sector in Latvia during Covid-19

In Latvia as of the Q2 2020 are operating 13 banks and 3 EU banking subsidiaries (Luminor Bank, previously was registered in Latvia, now a branch of Estonia registered bank) Bigbank Latvia branch (Estonia) and OP Corporate Bank Plc Latvia branch (Finland). As stated by the Latvia FCMC Chairwoman Santa Purgaile in April 2020, that "the overall banking performance in 2019 demonstrates stability", however, the important aspect which is not really discussed is what happens to funding availability to the companies and households, she hints that "over the past year, the total amount of assets in the Latvian banking sector did not change significantly" (Santa Purgaile: ……2020). While total amount of assets did not change significantly, as data shows in Fig.5., significantly changed where the assets are deployed. As can be observed in Fig.5. since Q2 2018 there has been observed decline of the proportion of loans to non-monetary financial corporations to total banking assets, as well as stagnation with decrease in Q2 2020 of loans to households to total assets. Since Q2 2019 until Q1 2020 is observed increase in banking assets held in Central Bank and lent to other credit institutions. If for the Covid-19 impact could be the jump of banks using their assets to purchase /invest in debt securities, it would be useful to analyses the information in which debt securities investments the jump is attributed, however no public information was found by the authors. This needs to be evaluated in which securities the holding had been increased, especially when looking at debt securities yield pattern, as euro area debt securities itself for AAA bonds are with negative yields for all maturities (European Central Bank…..), also in April 08, 2020 State state-owned Development Finance Institution "Altum" (further Altum) has issued 20 mill.EUR worth of bonds with 1.3% yield to maturity, what is notable, that the bond issue was organized by negotiating country Lithuania SEB Bankas.

Fig.5: Where bank money is invested, as % of total assets and trends in in Latvia from 2018 to Q2 2020

Source: Author's calculations based on Latvia FCMC data.

Authors to assess the future development, extrapolated data by adding 4 additional quarters to see if there are no changes, what development scenario can be expected. Using polynomial relationship trendline, which results in the highest with fit of the forecasted data to the trendline, Thus, if there are no changes in the existing status quo, the upcoming year will be tough for companies and economy as such, as banks most likely will continue "safe" policy holding its assets in central bank and lending to other credit institutions, as forecasted trend indicates with R square being 63% of upward trend, and invested in debt securities, while declining trend especially to loans to companies or R square being 77% and households. Now the companies who qualify for lending as indicated in "Financial sector future…" 2020 report, are following: cash flow is crucial, no lending for collateral, total equity above 25%, total

labilities against EBITDA less than 4-5 times, companies should have a reserve for at least 10-20% in cash flow, ability to service their liabilities, ability to repay loan principle. It should be noted that based on the aforementioned information, implied average loan term is less than 5 years. This length of loan maturities cannot provide financing of production expansion, investments into plants and factories, but it is typical maturities for leasing and equipment finance. There is needed an analysis how many of overall number of companies in Latvia qualifies for those criteria, and second issue for the companies which qualifies to this lending criteria, do they require lending at all.

Fig. 6: Where bank gets the money? Fraction of deposits as percentage of total assets, % in Latvia
Source: Author's calculations based on Latvia FCMC data.

Other side of banking system assets is where the money comes from, from available Latvia FCMC data, there has been decline as already noted since 2015 for the deposits by companies until 2019 beginning and stagnates further until Q2 2020, when measured as a fraction of total assets. When evaluating closer the source where banks obtain money, authors continued evaluating deposits as a fraction of total assets, there is one surprise in Covid-19 times or Q2 2020, that there is significant jump from 0 to almost 5% of total assets as a deposit from Central Bank of Latvia. This generates question, especially as further we will see in analysis of individual banks operating in Latvia have 30% of their assets held in Central bank or lent to other MFIs. This poses a question and need for more detailed evaluation why and in which bank(s) Central bank of Latvia has invested or deposited significant amount of the money?

Already Central Bank of Latvia in their Financial Stability Report, issued 21.07.2020, recognize that lending has contracted significantly, that is in 2014 ratio of loans to domestic non-MFIs to GDP was 27%, and in 2019 only 17.7%, which corresponds to the authors' research results already from 2008. Also, Central Bank of Latvia recognizes in 2020 that banks are well position to the upcoming Covid-19 crisis, which is also what Latvia FCMC has stated, however banks themselves yes, how about companies and availability of so needed funding?

Table 1: Assets of Banks in Latvia as of 27.09.2020 by Latvia FCMC reporting from 2018 until Q2 2020

Banking Assets		**Q22020/Q22019 (%)**	**Q22020/Q22018 (%)**	**Change, thsd. EUR Q2 2020 compared to Q2 2018**
Items				
Cash and cash balances at central banks		121%	92%	-449481
Claims on credit institutions		85%	62%	-496275
Loans to non-bank clients		96%	93%	-1023979
Incl.	General government	182%	220%	96998
	Other financial corporations	75%	126%	107612
	Non-financial corporations	94%	88%	-915509
	Households	100%	95%	-313080

Source: Authors' calculations based on Latvia FCMC data.

Thus, to evaluate Covid-19 impact on banks in Latvia, authors analyzed Q2 2020 against Q2 2019 and Q2 2018. The results are compiled in Table 1, analysis of where the banking assets are deployed and their change. When comparing Q2 2020 to both Q2 2019 and Q2 2018 – data showed the change in to whom banks lent amid Covid-19 pandemic

impact – that is lending to general government. Banks had issued in Q2 2020 compared to Q2 2019 to the central government significantly more loans an increase is by more than 82% over the Q2 2019 and even more by 120% more when compared to Q2 2018. It would be necessary to determine for what these loans are issued for, is it for the Covid-19 pandemic first wave impact lessening projects or other projects? As general government is 100% safe source of lending to banks, they are apparently more preferred compared to the financing of non-MFIs. Loans to companies, when calculating loans outstanding at Q2 2020 less Q2 2018, indicates that loans to companies outstanding amount has reduced by 915 mill.EUR. One of the reasons could be the government policy and fines by supervisory authorities to the banks within the scope of financial system restructuring, which has created situation when banks in fear do not finance regular companies and prefer lending to government. In the meantime, at no point authors consider to support or promote lending to the companies which are in poor shape or with bad business model, however the analysis reveals that there are several issues in the sector from the 2008 up to the Q2 2020, that worsens the availability of the loans to the companies. Also, AS SKDS survey of households and companies (2020) on the transformation of the banking system reported, that 20.4% of companies reported that their cooperation with banks has worsened or significantly worsened, while 15.1% of households report the same. Also 28.5% of companies who have taken loan or leasing within 2019 (only 15.2% of all companies), reported that they have observed increased reporting required by banks or rejection of their applications. Thus, it supports authors' earlier findings.

In line with the declining loan residual to companies, and to evaluated further concept in Latvia of theory that loan quality during pandemic deteriorates, authors calculated the impact of delinquent loans, non-performing loans as a percentage of total loans issued, where excluded were loans to the government, since loans to government usually are not delinquent or non-performing). Results are presented in Figure 7 and it is observed that since Q1 2018 non-performing loans have a decreasing trend with an increase in Q3 2019, and similar increase in observed for non-MFI corporation loans in Q2 2020, thus Covid-19 pandemic impact is slightly seen, especially for the companies' abilities and discipline to repay the loans.

Fig. 7: Delinquent and non-performing loans as % of total non-bank issued loans (excl. loans to government) in Latvia from Q1 2018 to Q2 2020

Source: Authors' calculations based on Latvia FCMC data.

Similar trend is seen in the Figure 8, where there is small increase in Q2 2020 in restructured loans as % of total non-bank issued loans (excluding loans to government). This increase in similar as observed also in Q1 2019 for loans to companies, which impacted also all restructured loans increase as % of total non-bank issued loans. Thus, the factors impacting restructuring of loans in Q1 2019 and Q2 2020 need be evaluated closer by the Latvia FCMC and Central Bank of Latvia, since they have detailed access to each bank's data on loans and restructured loans, to establish what fraction of the increase was attributed to the Covid-19 pandemic and what to the similar factors, which occurred in Q1 2019. Bank loan quality has not change significantly and thus, there has not been the Covid-19 pandemic effect observed, or the effect is coming with delay and will be seen more in coming quarters, thus analysis should continue once data becomes available.

Fig. 8: Restructured loans as % of total non-bank issued loans (excl. loans to government) in Latvia from Q1 2018 to Q2 2020

Source: Authors' calculations based on Latvia FCMC data.

Presented information, along with that in Latvia, the forecast of the expected GDP drop to be the largest among all three Baltic States in Latvia. IMF in October forecasted that Latvia is expected to have 2020 GDP to contract of 6.0%, while Lithuania 1.8%, and Estonia 5.2% (Regional Economic… 2020), presents the future struggles to the companies if status quo in banking sector resides, thus need to evaluate on the individual bank level the impact of Covid-19 pandemic.

Individual Banking Sector in Latvia during Covid-19 pandemic

As lending data is not available per each individual bank, it is impossible to determine, which banks have reduced or halted lending to companies, and who are main lenders to the general government and on what terms. Thus, authors attempted to evaluate the banking sector from available data on individual bank level, who report in Latvia. First need to rank banks based on their size; thus, banks were ranked based on their total assets, 93% of total assets or size of banking market in Latvia is comprises by five banks out of 13 reporting in Latvia: largest being Swedbank 37% of total assets, Citadele bank – 24%, SEB bank -21%, Rietumu Bank -8% and BlueOrange Bank – 3%, rest of the banks are only 1% if measured their size by their total assets.

First dimension that authors evaluated was what proportion of total assets are held in Central Bank of Latvia or have lent to other MFIs, overall average is 28% as presented in Fig.9. If at the first glance 28% seems significant, then compared to Q1 2018 average was 36%, thus there has been a decline. When evaluated two largest banks Swedbank and Citadele bank, they held 33% and 32% of their total assets in central bank or has lent to other MFIs, which is the same level for Swedbank and SEB bank when compared in Q2 2020 and Q2 2019, while a substantial increase for Citadele Bank in Q2 2020 when compared to Q2 2019 – it was 13%, and 18% in Q2 2018. Thus, Citadele Bank is the main bank which has switched large proportion of its assets to the hold in central bank or lend to MFIs. Large proportion of these funds could be rerouted to the companies and household in the form of lending.

Other dimension of analysis on the individual bank level, which indicate their business model, as defined by Berger A.N. et al (2016) that "commercial banks are typically defined as institutions that make commercial loans and issue transactions deposits." Thus, they pay interest for deposits and charge interest on issued loans, as well as charge fees for new loan issuance, for instance, account opening and servicing. As is compiled and presented in the Fig.10. average fee income as % of total fee and interest income was 47% in Q2 2018, 43% in Q2 2019, and 40% in Q2 2020.

Fig.9. Total assets held by each individual bank in central bank and other MFIs % of total assets in Latvia in Q2 2018, 2019, 2020

Fig.10. Bank fee income as % of fee and interest income in Latvia, at the end of Q2 2018, 2019, 2020

Source: Authors' calculations based on FCMC data.

On other hand, when issuing loans, the main and largest commission fee is loan issuance in Latvia banks, mainly ranging from 0.5%-2% of loan amount, and thus since we do not have data on the issued loans by each of the banks, then for the banks, where there is major drop and drop in general on commission fee income as a fraction of commission fee and income fee, could signal and confirm that loan issuance has diminished. For major banks in Latvia – Citadele, Swedbank, Rietumu Bank and BlueOrange Bank, especially in for later two, this confirms, while for SEB bank there is a small drop already in 2019 Q2 which is sustained in Q2 2020, these banks comprise 93% of total banking assets reporting in Latvia. Contrary is observed for Baltic International Bank and LPB bank, which are one of the smallest banks by total assets, each representing 1% in Latvia.

Third dimension, is weather Covid-19 pandemic in Q2 2020 has impacted individual bank profits, and to what level and which banks. Individual bank profits were compared and presented in Fig.11.

Fig.11: Bank Profits for Q2 2018, 2019, 2020 in Latvia, Thsd.EUR

Source: Authors' calculations based on Latvia FCMC data.

Citadele Bank, the second in size bank in Latvia has experience almost 30 mill. EUR loss in Q2 2020, which in large part is attributed to the write-off of 24.6 mill. EUR, or as explained in Latvia FCMC table as "Net profit or loss on financial assets and financial liabilities designated at fair value through profit or loss" It is unclear to what that loss

has been attributed to. It is very clear, that Covid-19 pandemic had significant impact on top 5 banks' profits, they have dropped when comparing to the second quarters in 2018 and 2019.

Conclusions and Recommendations

Overall banking sector in Latvia had experienced decline in lending already pre-Covid-19 pandemic, that is from 2009 until 2018, while for Estonia and Lithuania, as well as Sweden and Finland lending grew from 2009 until 2019. In Latvia lending showed an increase in 2019, but it was attributable to lending to government. On the other hand, deposits grew in all countries, also Latvia, as did GDP per capita. There declining trend in loan residuals persist also when comparing Q2 2018, 2019 with Covid-19 pandemic first wave Q2 2020, when banks increased lending to general government and even more by 915 mill.EUR decreased loans outstanding to companies in Q2 2020 compared to Q2 2018. Major change which can be attributed partially to Covid-19 pandemic is shift in lending to general government, which has increased significantly in Q2 2020.

Together with financial sector restructuring done by the supervisory authorities, banks are reluctant to lend to companies, as noted to criteria issued by Financial sector future…report in 2020, where main lending parameters are listed to whom banks are open to lend, thus the maturities are short and criteria is one to which unclear how many companies can comply with and if they do, then do these companies are in need for the funding. Thus, currently bank lending is hindering growth and recovery of the economy.

Individual bank data indicates that major part of main reporting banks in Latvia holds the assets in Central Bank of Latvia or has lent to other MFIs, while the proportion has decreased – still comprising almost one third of their assets, but it has decreased based on the lending to general government. Covid-19 pandemic first wave had significant negative impact on the banks' profitability, however major banks, except Citadele Bank who experienced major loss, have operated with profit in Q2 2020.

The reasons of the bank lending are also the financial sector restructuring, and thus authors suggest that in banking supervisory sector, there is need to issue more detailed information to the banks on the parameters of what is seen as acceptable clients and what is considered as risky clients. Commercial banks need to have motivation and confidence that when issuing loans or serving customers, they will not risk facing penalty or risk to be blacklisted or under strict supervision of supervisory institution.

Authors suggest also to FCMC to interview and work closely with local bank managers, what are hindering factors for loan growth and how together supervisory authorities with commercial banks can make lending landscape stronger, especially in the turn of Covid-19 pandemic second wave.

Abstract

Purpose: E-services provided by public administration are most often available through a web browser or mobile application. The development technique can directly affect use comfort and conformity with service and operating quality policy of the entire office. The quality of the application matters and should be monitored. It is valid for all tiers of public administration, also local governments. The purpose of the work is to perform a multi-criteria assessment of websites of local government units in Małopolskie Voivodeship. **Design/methodology/approach:** The study covered 182 websites of local government units. The results were normalised with zero unitarisation. This way, each website could be assigned a synthetic aggregate quality indicator, SQI. **Findings**: The attribute with the lowest score for the tested websites was the performance on mobile devices. It suggests that local governments should optimise their websites for mobile devices. **Research limitations/implications:** The study involved a limited number of website quality attributes and a limited number of test applications. **Originality/value:** The study pinpoints critical attributes of local government websites in need of optimisation.

Keywords: E-Administration, Quality, Usability, User Experience, Optimisations, Design Standards.

Introduction

E-administration develops thanks to IT systems. They are handled by administration personnel who need restricted-access privileges, usually through authorised access, identity check, or encrypted VPN to work with the system. The results of the use of such systems might, however, be available to the general public. Their primary user should be a citizen. Therefore e-services are most often provided through web browsers or mobile applications for two-way communication. The user is not required to install additional software.

End-user applications are built in various ways. Their development technique can directly affect use comfort and conformity with service and operating quality policy of the entire office [Qutaishat 2013, Sá et al. 2016, Ismailova and Inal 2017]. Therefore, the quality of the application matters and should be monitored. It is valid for all tiers of public administration, also local governments [Król and Zdonek 2020a]. Local governments often implement central-government regulations. They also solve problems of local communities and can use websites and mobile applications to this end. So these should be of high quality. The purpose of the work is to perform a multi-criteria assessment of websites of local government units in Małopolskie Voivodeship.

This paper is organised as follows. The second section presents issues relevant to the quality of websites, particularly multi-criteria quality assessment. Section three describes the methodological framework for the research. Key results and conclusions are presented next. Discussion analyses results of selected public administration website quality tests. The findings are provided in the summary, and research limitations are discussed in the final part.

Website Quality

In principle, a website can be built according to precise and easily available standards, such as the World Wide Web Consortium W3C standards regarding code correctness (HTML and CSS) and website accessibility. They contain guidelines for each part of a website. One can also choose from among myriads of content management systems (CMS) that conform to the standards. Note, however, that W3C standards are not normative. They are, nevertheless, respected and followed by creators of websites and web applications all over the world.

Design standards can be 'official' (recorded in the documentation) or come in the form of 'good practice'. Many universal attributes of IT system quality have been recorded in standards by the International Organization for Standardization (ISO). ISO/IEC 25010:2011* , for example, describes six main software quality characteristics: (1) functionality, (2) reliability, (3) usability, (4) efficiency, (5) maintainability, and (6) portability. According to ISO 9241-100** , usability is derived from (1) effectiveness; (2) efficiency, and (3) use satisfaction. Such standards as ISO 13406*** , ISO 14915**** , or ISO TR 16982***** apply to the usability of interactive systems and user interface ergonomics. They set required quality attributes to ensure sufficient use and human-machine interaction quality. It is not always the case that a list of guidelines and quality criteria is available. It is particularly true for website attributes that affect its place on the search engine ranking list. In such a case, it is the intuition, knowledge, and experience of the administrator/editor of a website that matter the most. High search result rankings are often achieved with trial and error. Moreover, the usability quality of websites is often measured with metrics formulated as good practices, such as Nielsen's heuristics [Huang and Benyoucef 2014].

Website Quality Assessment

Website quality is a complex issue [Lee-Geiller and Lee 2019]; hence it can be evaluated in different ways: with or without users, automatically (an algorithmic indicator score) or manually after a cognitive walkthrough. The approaches listed above can be successfully combined as well. What is more, website quality assessment is often subjective, based on original checklists, and hinging on the author's skills and knowledge to a large extent.

An indicator-based assessment usually comes in two forms. (1) A global aggregate multi-criteria assessment takes into consideration as large a number of numeric indicators describing website quality as possible. (2) A detailed assessment focused on a specific domain cross-validates a selected quality attribute, such as performance.

Website quality attributes include mobile readiness, content quality (content is king), etc. Mobile readiness can be verified in various ways, using test applications, CSS (Cascading Style Sheet) code exploration, or with specific mobile devices [Galvez and Youngblood 2016]. It is relatively easy to check whether a website changes its appearance to fit a mobile device, but to verify the usability (the comfort of use) of a website is more complicated and requires extensive testing [Garcia-Lopez et al. 2017]. The same applies to content quality assessment. It can be quantitative or qualitative. A qualitative assessment measures the ratio of code (HTML, CSS, JS) to the text content (the text to HTML ratio, THR). A qualitative assessment can measure the so-called semantic value or its ease of perception [Ojha et al. 2018]. Performance [Dickinger and Stangl 2013] and SEO [Giannakoulopoulos et al. 2019] are just as important. Website performance can be expressed with various scores, such as Yslow, PageSpeed Score, or measures of load time (in seconds): First Byte, First Contentful Paint, or Fully Loaded. Assessment of search engine optimisation can aggregate measurements of all of the attributes mentioned above.

Another design attribute determining the quality of a website is its accessibility. Relevant guidelines (Web Content Accessibility Guidelines, WCAG) are provided by the World Wide Web Consortium W3C [Ismail et al. 2018, Król and Zdonek 2020a]. Other factors of website quality are the number of backlinks and the quality of internal links [Król and Zdonek 2019] as well as global quality indicators such as Alexa Rank, Serpstat Visibility, or Open PageRank [Ziakis et al. 2019].

Materials and Methods

The study covered websites of all 182 local government units in Małopolskie Voivodeship, Poland (Fig. 1). The quality of the websites was measured with eight web applications run in a web browser (Table 1). The quality indicators and test tools were selected based on a literature analysis [Galvez and Youngblood 2016, King and Youngblood 2016, Garcia-Lopez et al. 2017, Giannakoulopoulos et al. 2019, Król and Zdonek 2020b].

Fig. 2: Małopolskie Voivodeship, Poland. Source: own work

The research was informal, quantitative, and carried out under normal use conditions. Each test gave a final score. The final scores were positioned in various ranges and resulted from the aggregation of various tests (Table 1).

Table 1: Test applications and scope of tests

Test scope	Test tool (URL)	Indicator (score scale)
Search Engine Optimisation (SEO)	ZadroWeb (zadroweb.com/seo-auditor)	SEO Score (0–100)
Mobile optimisation test	Mobile-Friendly Test: Bulk Testing Tool (technicalseo.com/tools/mobile-friendly/)	Mobile readiness (0–1)
Performance (desktop) PSI desktop	PageSpeed Insights (developers.google.com/speed/pagespeed/insights/)	Google PageSpeed Score (0–100)
Performance (mobile) PSI mobile	PageSpeed Insights (developers.google.com/speed/pagespeed/insights/)	Google PageSpeed Score (0–100)
Text to HTML ratio THR	Text to HTML ratio checker (prepostseo.com/code-to-text-ratio)	Text ratio (0–100%)
No. of backlinks	Backlink Checker (iwebtool.com/backlink_checker)	Backlinks (>0)
General website quality	Blink Audit Tool (audyt.blink.pl)	Quality indicator (0–100%)
Text semantics, marketing value evaluation	Blink Audit Tool (audyt.blink.pl)	Score (0–100%)
Accessibility (WCAG guidelines)	WebAIM WAVE Web Accessibility Evaluation Tool (wave.webaim.org)	Errors (>0)
Open PageRank	Open PageRank Online Tool (domcop.com/openpagerank)	Page Rank Value (0–10)

Research Process

The author first assessed the search engine optimisation of the websites using automatic algorithms. ZadroWeb generated the final summary score for SEO tests. The application evaluates such parameters as conformity with

W3C standards, complete metadata, performance, and values of Page Authority and Domain Authority. Mobile readiness was tested with the Bulk Testing Tool.

Website performance was tested in the desktop and mobile modes with PageSpeed Insights (Google Developers). The value of the Text to HTML ratio (THR) and the number of backlinks were verified. The semantic value of the text was assessed with Blink Audit Tool. Conformity with WCAG was verified using WAVE Web Accessibility, and global 'website ranking position' was evaluated with Open PageRank. The measurements were then standardised with Equation (1) for LTB characteristics and Equation (2) for STB values. An LTB diagnostic variable, larger-the better, should be as high as possible (SEO score, for example). An STB variable, smaller-the-better, should have the lowest possible value (such as syntax errors in HTML code). Standardised variables lie in the [0,1] interval.

$$zij = [xij - mini\{xij\}] / rj \quad (1)$$
$$zij = [maxi\{xij\} - xij] / rj \quad (2)$$

where $zij \in [0,1]$.
and:
zij – a standardised variable;
$zij = 0 \Leftrightarrow xij = mini\{xij\}$;
$zij = 1 \Leftrightarrow xij = maxi\{xij\}$;
xij – the value of the variable before standardisation;
mini{xij} – the minimum value of the variable before standardisation;
maxi{xij} – the maximum value of the variable before standardisation;
rj – the range for the j-th variable.

The standardisation found the common denominator for the diagnostic variables so they could be added up. This way, each website could be described with a synthetic aggregate quality indicator (SQI). The SQI value was used to group the websites into categories.

Results and Conclusions

Each of the websites could score 0 to 10 multi-criteria quality assessment points [0,10]. The website with the lowest score had 2.86 points (SQI value), while the website with the highest result had 6.68 points. All the investigated websites scored 865.9 points in total out of 1820, which is 47.6% of the available points (Fig. 1). It is a mediocre result at best, suggesting that most of the websites needed to be optimised. Characteristics most in need of optimisation included mobile performance (PSI mobile) and the number of backlinks. Still, desktop performance (PSI desktop) had plenty of room for improvement as well.

Figure 2: The general quality results for local government websites in Małopolskie Voivodeship. Source: own work

As many as 88 websites (a little over 48%) reached mobile performance up to 38 points (out of 100 maximum PSI mobile points). The poorest performing website scored only 2 PSI mobile points out of 100 (Table 2). Mobile performance of 33 websites was critical, with scores below 20. Such a low performance can significantly hinder browsing comfort or even prevent mobile use completely. Moreover, at least 41 websites (22.5%) required urgent desktop performance optimisation (PSI desktop).

Table 2: Descriptive statistics – SEO, performance, and THR tests

Attribute	SEO	PSI desktop	PSI mobile	THR
Mean	71.66	63.26	39.21	14.99
Median	72.9	63	38	16
Min.	52.34	10	2	2
Max.	85.05	99	93	33

Source: own research

The largest range was noted for the number of backlinks (Table 3). Note, however, that the quality of the pages the links came from was not verified, and this quality is important for search engine results page ranking. Values of a general quality indicator (according to the Blink Audit Tool) ranged from 36 to 82 percentage points (Table 3). Note further that there were relatively many websites with average or low Open PageRank values (below 2 points). In addition, many of the investigated websites required accessibility optimisation, in particular as regards the visibility of some content on the screen/display (Table 3).

Low values of Open PageRank are characteristic of unpopular websites, which are those with low visitor counts and few quality backlinks. It is somewhat puzzling as public administration websites are open to the public and need not attract visitors. Their audience comes 'ex officio'. Such websites are, therefore, predisposed to large visitor volumes and many backlinks.

Table 3: Descriptive statistics – link, content, accessibility, and other quality indicators

Attribute	Backlink	General quality score	Semantics	Accessibility	Open PageRank
Mean	215,184.16	61.38	63.54	20.47	2.97
Median	8,530.5	61	65	15	3.18
Min.	223	36	35	0	0.22
Max.	18,066,954	82	95	185	4.85

Source: own research

Most objects in the set of websites scored 'average' SQI values. This group constituted almost 77% of all the websites (type II and II websites combined). The mean quality score under the research design was from 4 to 6 SQI points (Table 4). Websites that demonstrated 'average quality' required optimisation, but no gross design errors were identified. Nevertheless, the multitude of minor flaws in many areas, including development technique and the way content was published, cumulated, which reduced their general score. Websites not optimised for mobile devices, with poor performance, few backlinks, and low values of other quality indicators had the poorest results.

Table 4: Typology of websites divided by the SQI value

Score range	0–2.99	3.0–3.99	4.0–4.99	5.0–5.99	6.00–7.00
Number of websites	1	30	81	59	11
Percentage (%)	0.55	16.48	44.51	32.42	6.04
Website type	V	IV	III	II	I

Source: own research

The investigated websites scored almost 72% of the maximum number of points for SEO, about 63% of points for PSI desktop performance, and a little over 39% of PSI mobile performance points (Table 5). Moreover, almost 80% of them 'reacted to display size'. They adapted their appearance (layout, content position, menu, etc.) to mobile devices (in various ways and to various extents).

Table 5: Quantitative statistics – SEO, performance, THR, and mobile readiness tests

Attribute	SEO	PSI desktop	PSI mobile	THR	Mobile readiness
The maximum score	18,200	18,200	18,200	18,200	182
Total scores	13,042.14	11,513	7,137	2,729	144
Percentage (%)	71.66	63.26	39.21	14.99	79.12

Source: own research

The websites scored high as regards search engine optimisation. It is a good result, but the measurement involved only one tool and does not provide a sound footing for an unambiguous SEO assessment. Algorithmic SEO measurements should employ complementary tests with several test tools.

Discussion

The quality of public administration websites is assessed comprehensively or in one dimension. One of the most frequently investigated attributes of such websites is accessibility [Kamoun and Basel Almourad 2014, Galvez and Youngblood 2016, King and Youngblood 2016, Paul and Das 2019, Król and Zdonek 2020a]. It is mostly because the accessibility of websites of institutions financed by the public budget is regulated in many countries, also in Poland [KRI 2012].

Kopackova et al. [2010] focused on the accessibility of local e-government websites in the Czech Republic (n=39). They looked into website accessibility from a wider perspective, taking into consideration the search engine results page visibility. The researchers employed selected computerised tools and techniques. The criteria defined for accessibility and findability testing were as follows: findability through Czech search engines, page rank, URL comprehensibility, observance of WCAG rules, comprehensibility of screen reader output, (X)HTML validation, display in a low-resolution browser, separation of content from the graphic part, and metadata usage. Kopackova et al. [2010] demonstrated that the websites they tested most often had to be corrected to conform to W3C recommendations, mostly as regards (X)HTML syntax and WCAG compliance. Furthermore, they noted a need to improve the content as regards SEO, including keywords and headers.

Galvez and Youngblood [2016] comprehensively assessed local e-government websites in Rhode Island. They evaluated development technique quality in terms of accessibility, usability, and mobile readiness. They used WebAIM's WAVE to investigate accessibility. Galvez and Youngblood [2016] demonstrated that local government websites in Rhode Island should be optimised, in particular, in terms of accessibility and mobile readiness.

Al-Soud and Nakata [2010] tested accessibility, usability, transparency, and responsiveness of thirty Jordanian government websites and their readiness to deliver government services online. They employed tools for automatic evaluation of selected website attributes, including SortSite (PowerMapper Software) in their research. They assessed such attributes as usability, conformity to W3C standards, link rot, and SEO. Their website evaluation revealed that the websites suffered from a lack of consistency in standards and features. Furthermore, they identified a lack of consideration of citizens' expectations and needs through the absence of various features which facilitate the user interaction process.

Most studies on public administration websites conclude that the websites require optimisation, especially regarding accessibility and mobile readiness. Generally, every website can be optimised, amended, or improved to a certain extent both as regards technical issues and content.

Summary

From the technical perspective, public administration websites, including those of local government units, should conform to the same design (quality) standards as other websites. Websites can differ in terms of content, for example, its arrangement and text or layout, but also function and functionalities.

The attribute with the lowest score for the tested websites was the performance on mobile devices (PSI mobile). The results indicate a real need to optimise websites of local government units for mobile devices. The importance of the matter rises with the rising number of users who browse websites on mobile devices. Moreover, desktop and mobile performance affect website rank in search engine results pages.

Research limitations

There is a risk that studies on large sets of websites can turn out to be superficial or relatively generalising because of a large number of tested objects and the complexity of the issue of 'website quality'. On the other hand, only a study on a representative (sufficiently large) sample can justify conclusions for the entire population. Such an approach inherently limits the number of assessed quality criteria and tools. It provides no room for in-depth quality assessment, which is the foundation of dedicated quality audits.

Quality assessment of a specific set of websites provides certain general insight mostly into global problems. Nevertheless, when upgrading their websites, local government units should focus primarily on the results of a detailed audit, which can pinpoint problem areas in need of intervention. One must not forget that the online ecosystem is a complex one, and each website is an individual specimen.

Why Does Tribalism Cause Corruption in Some Countries?

Dr. Yousif ABDELRAHIM
Assistant Professor, Department of Management
College of Business Administration - Prince Mohammad Bin Fahd University
P.O. Box 1664, Al-Khobar 31952, Kingdom of Saudi Arabia
yabdelrahim@pmu.edu.sa

Abstract

This research paper explores the relationship between tribal factors of gender inequality, ethnic fractionalization, indigenous population, group grievance, and the country's level of corruption and explains why tribalism causes corruption in 132 countries worldwide. I used the least-squares multiple regression analysis and secondary data from the Corruption Perception Index, the Global Economy, the Human Resource Development, Economic Commission for Latin America and the Caribbean and the World Bank Group, the Historical Index of Ethnic Fractionalization Dataset, and the Economist Study as evidence of corruption, group grievance, gender inequality, indigenous population, ethnic fractionalization, and political instability to test the four hypotheses. The results suggest that Group grievance, gender inequality, and ethnic fractionalization have a strong and significant relationship with the country's level of corruption. However, indigenous population appears to have no significant relationship with the country's level of corruption. The research theoretical and practical implications and future research have also been discussed.

Keywords: Tribalism Index, Corruption, gender inequality, ethnic fractionalization, indigenous population, group grievance.

Introduction

According to Transparency International (TI) (https://www.transparency.org/en/ pre ss/one-in-four-people-in-africa-pay-bribes-survey-says), approximately130 million Africans paid a Bribe in 2019 alone; either to get access to essential services or to escape penalty by the court and /or the police. The costs of corruption (i.e., the exploitation of power for personal gain) are evident and acknowledged. Recently, Global Financial Integrity (www.gfintegrity.org/) reported that $1.1 trillion lost to corruption in the world's developing countries in 2013. For example, $ 25.50 billion Lost to corruption in Iraq between January 2011 and December, 2014. What makes Many countries in the Middle East and North Africa (MENA) along with other African countries to be the most corrupt countries in the World is still in a dilemma. Since corruption impacts a country's economy, growth and the quality of life people live, scholars need to study corruption from different angles. Tribalism Index (TI), developed by the USF Global Initiative on Civil Society and Conflicts (http://usfglobalinitiative.org/tribalism-index/) has long recognized that tribalism (i.e., tribalism is the perceptions of gender inequality, perceptions of grievance, linguistic and ethnic fractionalization) is one of these angles that plays an important role in corruption. Previous studies such as Abdelrahim (2019, 2020) empirically found a positive relationship between tribalism and corruption which confirms the TI findings.

However, social science in general and the management field, in particular, have been Slow-moving to conduct meaningful research in the area of tribalism and corruption that explains why tribalism causes corruption. Tribalism and corruption issues have hardly been addressed in most of the management's top journals. Hence, it is critical for the management field to become involved in scholarship that may help academics and practitioners to better comprehend the many aspects of tribalism and a country-level of corruption. That leads to one research question; why does tribalism cause corruption? This study fills the gap in the literature by answering the above-mentioned question through examining the relationship between the critical factors (i.e., indicators/components) of tribalism (i.e., the perceptions of gender inequality, perceptions of grievance, linguistic and ethnic fractionalization) and corruption empirically (Figure1). The findings of this study could also benefit educators and policymakers to understand the dynamics of tribalism and focus on tailoring specific educational programs and policies that help reduce corruption.

Literature Review and Hypotheses Development

Figure1: The conceptual framework for the relationship between tribalism and corruption

Corruption

According to Transparency International (2020), corruption is the exploitation of power by government and nongovernment administrators, officers, and key employees for personal gain. The act of corruption includes illicit enrichment, misusing government property, bribery, hiring relatives and friends, embezzlement, etc. Researchers such as Seldadyo and De Haan (2005) have identified many reasons cultural, economic, and non-economic factors that cause corruption in countries. Corruption hinders economic growth, discourages foreign investors, employment, government spending on social programs, and harbors poverty (Šumah, 2018).

Tribalism

Consistent with the tribalism index, I define tribalism at a country-level as the perceptions of corruption (i.e., the extent to which government agencies are corrupt due to favoritism, nepotism, and bureaucracy); population demographics (i.e., how big indigenous population in a society is); gender inequality (i.e., to what extent women are actually equal to men in education, political empowerment, and health); perceptions of grievance (i.e., the extent to which groups in a society experience grieve); linguistic and ethnic fractionalization (i.e., the extent to which a society keeps its ethnic and linguistic patterns). I adopted tribalism definition from the tribalism index is the only quantitative measure at the country level that exists in the literature, and I need to be consistent with the TI scale. In addition, the tribalism index is a very valid scale with multiple indicators that capture all or most aspects of tribalism.

Tribalism Versus Corruption

The relationship between tribalism and corruption has long been identified by Jacobson and Deckard (2012) and the positive relationship between tribalism and corruption at the country-level has been empirically confirmed by Abdelrahim (2019, 2020). Many researchers have linked tribalism to corruption. Gullette (2007) has conceptualized tribalism as one kind of corruption due to kinship ties. Jacobson and Deckard (2012) relate tribalism to corruption because of kin networks that pressurize government personnel to practice nepotism and nepotism to help their tribe members get richer. Individuals' values, norms could significantly dictate corruption (Theron, 2013). For instance, African tribal officials usually accept gifts as gifts are considered a part of their cultural norms (Theron, 2013). In a tribal collectivistic culture, individuals are responsible to take care of their relatives and close family members. Social pressure created cultural norms and collective tribal life might cause tribe members to fulfill their cultural obligations through corrupt actions such as favoritism and nepotism.

Gender Inequailty Versus Corruption

Previous Research has claimed a positive relationship between gender inequality and corruption. For example, gender inequality is associated with a higher perceived level of corruption and differences in critical development outcomes in tribal countries (Branisa and Ziegler, 2013). Prior studies have examined the relationship between gender inequality, which measured on the basis of women representation at the workplace in a country) and corruption. The greater the representation of women in a country, the lower level of corruption in economic and political life (Swamy et al., 2001; Dollar, Fisman, and Gatti, 2001). In addition, gender differentiation in masculine cultures contributes to gender inequality and gender inequality contributes to corruption (Islam, 2004). Moreover, Swamy et al. (2001) found that men and women tolerate corruption differently as men are more tolerant to corruption than women do. Finally,

Rivas (2013) experimentally showed that men go for corrupt choices habitually more than women. Hence, I argue that gender inequality in countries is more likely to increase the level of corruption in a country and posit hypothesis 1 (H1) and hypothesis 1 (H1):

H1: Corruption in countries with a high level of gender inequality will be higher than corruption in countries with a low level of gender inequality.

Ethnic Fractionalization

Ethnic fractionalization is another factor of tribalism that relates to corruption. The relationship between ethnic fractionalization and corruption was articulated by Cerqueti et al. (2012). Cerquet noted the existing nonlinear relationship between corruption and ethnic fractionalization. Many researchers believe that Corruption is high in homogeneous countries and low in countries with intermediate ethnic fractionalization (Svensson, 200). Ethnolinguistic fractionalization seems to be accountable for different kinds of corruption-related phenomena (Shleifer and Vishny 1993). According to the study conducted by Mauro (1995), corruption is high in higher ethnic diverse societies due to the ethnic power structure that facilitate more bribery taking. Since bribery is a form of corruption and ethnic fractionalization causes more bribery, I expect that countries with high ethnic fractionalization to be highly corrupt and posit hypothesis 2 (H2):

H2: Corruption in countries with a high level of ethnic fractionalization will be higher than corruption in countries with a low level of ethnic fractionalization.

Indigenous Population (Population Demographic)

How big indigenous population in a society plays a critical role in corruption. Social identity theory has predicted traditional in-group bias (Tajfel & Turner, 1979). The theory also proposed that group members tend to favor the in-group to whom they belong over the out-group members for motives to be in line with group promotion and self-esteem. In addition, research on social cognition suggests that instinctive tendencies could significantly influence behavior without responsive recognition (Bargh, 1997; Perugini, 2005). The disadvantaged (low-status minorities) out-group minority people frequently show out-group favoritism because of the negative stereotypes among low-status minorities and their struggle for equal rights (Hinkle & Brown, 1990; Mullen et al., 1992). Since indigenous people live collectively is one group I suggest that the indigenous population practice in-group favoritism. Favoritism has been known for its relationship with corruption by prior research. Favoritism is a kind of corruption that based on mutual trust and long-term social relations and reciprocity (Lowe et al., 2008). According to Redlawsk, D. P. (2005), corruption is perceived as lawbreaking and corruption also understood as favoritism among Americans. Following the above discussion, I would argue that indigenous population is associated with corruption and propose hypothesis 3 (H3):

H3: Corruption in countries with a high level of the indigenous population will be higher than corruption in countries with a low level of the indigenous population.

Group Grievance (Perceptions of Grievance)

Perceptions of grievance (the extent to which groups in a society experience grieve). Grievances caused by indigenous marginalization in some countries such as Nigeria is often a fuel that fans violent conflict (Smith, D. J., 2014). That implies grievances could be one of the factors that motivate the outbreak of violent rebellion, civil war, and political instability in a country. For example, the main motivation for the Libyan violent rebellion is the collection of group grievances caused by economic grievances, the lifestyle of the former president family members, absence of political rights, and tribal grievances (Are, W. W, 2013). Rebellion can be explained by severe grievances (Collier, P., & Hoeffler, A., 2004). Violent rebellion causes civil war and civil war is an extreme form of political instability (Ghobarah, H. et al., 2003). Political instability has been known for its contribution to the high rate of corruption in the Economic Community of West African States (ECOWAS) (Lederman et al., 2005; Leite and Weidmann, 1999; Park, 2003). Based on the above I would argue that group grievance is associated with corruption and propose hypothesis 4 (H4):

H4*: Corruption in countries with a high level of group*

Methodology

Data Collection

I used the following general research model to collect secondary data from different resources and tested the four research hypotheses:

$$LOC=\beta_0+\beta_1*GI+\beta_2*EF+\beta_3*IP+\beta_4*GG \quad (1)$$

Where LOC, GI, IP, EF, GG, and PI refer to corruption, gender inequality, indigenous population, ethnic fractionalization, group grievance, and political instability, respectively. After testing the research hypotheses, the study of the specific model is shown below:

$$LOC=\beta_0+\beta_1*GI+\beta_2*EF+\beta_4*GG \quad (2)$$

PI*GR refers to the interaction between political instability and group grievance. EF2, IP2 and PI2 refer to the impact of ethnic fractionalization, the indigenous population, and political instability at higher levels of EF, IP and PI on corruption.

Dependent Variable

Corruption is the dependent variable measured at the country level. I used the corruption perceptions index as a proxy to measure corruption in 132 countries. The Corruption Perceptions Index (CPI) was developed by Transparency International (TI) researchers and experts rank 180 regions and countries based on perceptions of corruption captured by survey questions in the last two years in twelve different institutions. The CPI combines data from thirteen different sources that surveyed a country's business people and experts with their perceptions of the corruption level in the public sector. The CPI put together several dimensions of corruption to constitute an index that is available online at https://www.transparency. org/en/cpi/2019/ resu lts/table. Respondents who are experts and business executives answered the CPI survey questions that capture all forms of corruption in the public sector including nepotism, favoritism, bribery, etc. The CPI uses a scale of zero (highly corrupt) to 100 (very clean). For instance, Denmark ranks first with a score of 87 while Somalia with a score of nine ranks 180.

Independent Variable

Indigenous population, group grievance, ethnic fractionalization, and gender inequality are the study independent variables at the country level. Group grievance is measured by the group grievance index and the dataset for group grievance was borrowed from the Global Economy website at https://www.theglobaleconomy. Com /rankings/group_grievance_index/. Gender inequality is measured by gender equality index and the dataset was borrowed from the Human Resource Development at http://hdr.undp.org/en/data. Indigenous population is measured by indigenous population index and the dataset for indigenous population was borrowed from the Economic Commission for Latin America and Caribbean at https://www.cepal. org/ en/infografias /los-pueblos-indigenasen-america-latina and the World Bank Group / International World Group for Indigenous Affairs (IWGIA) at http://iwgia. org/ima ges/yearbook/2020/IWGIA_The_Indigenous_World_2020.pdf. Ethnic fractionalizat-ion is a variable that was measured by ethnic fractionalization index and the dataset for ethnic fractionalization was borrowed from the Historical Index of Ethnic Fractionalization Dataset at (HIEF)https://dataverse. harvard.edu/dataset. xhtml?Persi sten tId=doi:10.7910/DVN/4JQRCL

Control Variable

The literature review shows that a country's political instability could influence the country's level of corruption. Political instability increases the level of corruption in the long-term (Nurudeen, Abd Karim, and Aziz, 2015). Political instability is measured by the political instability index borrowed from the Economist Study at http://viewswire.eiu.com/site_info.asp?info_ name=social_unrest_tab le&page= noa ds&rf=0The Economist Study ranks countries at a scale ranges from zero to ten, where zero means a country is highly not corrupt and ten means a country is highly corrupt.

Hypothesis Test

In this research study I examined the influence of four factors of tribalism (i.e., group grievance, indigenous population, gender inequality, and ethnic fractionalization) on the national levels of corruption in 132 countries using the ordinary least-squares multiple regression analysis and controlling for controlling for political instability. The least squares regression analysis is used because the corruption variable dataset is normally distributed with appropriate variance. To test examine the influence of tribalism factors on levels of corruption, I controlled for the countries' political instability and entered all the tribalism factors simultaneously. I also thought carefully about indigenous population factor when entered the tribalism variables individually in the regression equations because of the data limitation on indigenous population. The number of tribalism variables in the regressions always kept one, two, or three variables at a time, keeping enough degrees of freedom. For other tribalism factors there was no need for limiting the number of tribalism factors entered in the regression equation since I have a dataset for 132 countries, and therefore, no concerns about the degree of freedom.

Results

Through the results of the least-squares multiple regression analysis, the study seeks to explain the dissimilarities across nations in the propensity to be corrupt. Table 1 shows the correlations between all the six variables included in the least square regression analysis. Table 2 shows the inclination of a nation to be corrupt versus tribalism factors and political instability. The cross-sectional data for corruption of all regions and countries under examination were measured as perceptions in all 132 nations.

The results from the ordinary least squares suggest group grievance to be the most powerful tribal factor that influences the level of corruption in many nations because it is significant in all of the three regression equations in which it was included. Group grievance appears to have a remarkable relationship with the country's level of corruption. Ethnic fractionalization is the second most important tribal factor because it has a significant relationship with the level of corruption in two out of four regression models. Gender inequality also has a significant relationship with the level of corruption in one of the three regression models. The tribal factor of the indigenous population appears to have no significant explanatory power in all of the four regression equations. Finally, political instability appears to be a significant control variable in one of the four regression

Table 1: Correlations between all the six variables

	EF	GG	GI	IP	LOC	PI
EF	1					
GG	0.199**	1				
GI	0.227**	0.278**	1			
IP	0.273*	0.406**	0.171	1		
LOC	-0.293**	-0.589**	-.298**	-0.202	1	
PI	0.015	-0.028	0.057	-0.101	-0.061	1

Note: **Correlation is significant at the 0.05 level (1-tailed). **Correlation is significant at the 0.01 level (1-tailed). EF= Ethnic Fractionalization; GG= Group Grievance; GI= Gender Inequality; IP= Indigenous Population; LOC= Level of Corruption; and PI= Political Instability.*

Table 2: Summary of the Least Square Regression Analysis for Variables Predicting Perceptions of Corruption (N=132)

	Model 1	Model 2	Model 3	Model 4
Variable	***β / sig.***	***β / sig.***	***β / sig.***	***β / sig.***
Constant	44.80 / 0.00***	76.34 / 0.000***	80.8 / 0.000***	80.11 / 0.000***
PI	13.09 / 0.00***	-0.45 / 0.37	-0.44 / 0.318	-0.38 / 0.377
GG		-5.01 / 0.000***	-4.75 / 0.000***	-4.53 / 0.000***
EF			-13.88 / 0.013*	-11.73 / 0.035*
IP				0.07 / 0.693
R^2	0.424	0.527	0.589	0.640
F for change in R^2	30.95***	22.78***	19.010***	17.33***

Note: p* < 0.05; p** < 0.01; p*** < 0.001
β = *Beta;* sig. = Significance; PI = Political Instability; GG = Group Grievance; EF = Ethnic Fractionalization; Indigenous Population; R^2 = R Square.

Conclusions

The least-squares regression analysis supported three of the four hypotheses. H1, H2, and H4 were supported. Gender inequality, ethnic fractionalization, and group grievance all have a significant effect on the country's level of corruption. The results showed no significant relationship found between the level of corruption and the indigenous population. Support for H1 and is consistent with Branisa and Ziegler (2013) who associated high levels of gender inequality with higher levels of corruption in countries. The relationship between indigenous population and the country's level of corruption was not support. Perhaps, could have no significant impact on the country's level of corruption since indigenous people are highly unemployed and even when they are in the workforce they are more likely to hold non key positions that will allow them to make important decisions and be corruption. For example, in Australia indigenous employment disparity is still an issue since the unemployment rate among indigenous people is 28% (Taylor, & Hunter, 1998).

Theoretically, research study findings may help scholars to explain why tribalism causes corruption in some countries. Researchers also could have a clear idea about which tribal factor contributes the most to levels of corruption in highly tribal communities and countries worldwide. Practically, the study findings could help educators to tailor specific training programs that focus on gender equality and gender differences, and therefore, incorruptness. The research findings might also layout guidance for policymakers to extra special attention to ethnic fractionalization with regard to socioeconomic distribution. Finally, the findings may help leaders to embrace new strategies that help overcome social instability and group grievance. Future research should investigate why political instability does not significantly impact the country's levels of corruption in all of the regression four models.

The Influence of the Presence of Art on Social Cohesion during COVID-19

Iuliana COMAN

Bucharest University of Economic Studies, Bucharest, Romania

iuliana.coman@csie.ase.ro

Abstract

The crisis generated by the Covid-19 pandemic brought major changes in the behavior of the society, on the freedom of movement, on the organization of events, on the program of schools and universities. The aim of this paper is the evaluation of the changes manifested in the behavior of art consumers with an accent on the influences manifested by art upon the social cohesion during the Covid-19 pandemic. The research considers macroeconomic indicators provided by the National Institute of Statistics, Eurostat, and a survey conducted in the first week of May 2020, during the Covid-19 crisis. The purpose of the survey was to analyses art consumer behavior during this pandemic, the presence of art in the lives of respondents, and the influence that art has on the life of society. The sample of the survey included 200 persons with high education in the South of Romania, being defined using demographic sampling rates. The results showed that art continued to be present in the life of society and participate in supporting the passage of this period, continuing to participate in the consolidation of the community.

Keywords: Art, Society, Community, Influences, Covid-19.

Introduction

Cultural Barometers carried out in Romania, France, or Canada during the last years, demonstrate that art has an important role in society, developing the independence of individuals, expanding the capacity of knowledge, developing the understanding and the ability to act. Art also participates in the construction of social cohesion and develops society by encouraging civic participation. (Croitoru and Becuț Marinescu, 2017).

Gombrich (2012) underline also that art was an important component of mankind since ancient times, participating in the construction of society.

Art participated in the creation of a detailed image of the different period in mankind history, with a special contribution during the period of crisis, creating an exhaustive picture of these periods (Demos, 2013) (McDonnell and Tepper 2014), but also participating in the development of solutions to overcome these periods difficulty (Linesch, 1994) or their prevention (Klingman et al., 1987).

The role of art in the construction of society starting with the beginning of human history, the different influences manifested by art during the crisis period were analyzed in different researches. This paper aims to present the specificity of the evolution of art consumers' behavior during the Covid-19 crisis, in Romania, considering also the macro economical context generated by the Covid-19 crisis. More than this the paper analyses the influences manifested by art on the life of society and the participation of art in the consolidation of society.

Literature Review

The utility of art was presented in a series of researches published during the last years. Gombrich (2012) underline the utility of art, art consisting in the construction of temples and houses, in the making of paintings and sculptures

Cite this Article as: Iuliana COMAN "The Influence of the Presence of Art on Social Cohesion during Covid 19" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

or the weaving of an ornamental motif, there are no peoples who have not developed an art form. Gabeaud (1930) reminds the role of art to express feelings or the spiritual dimension of art like contemplation and prayer.

The capacity of art to participate in social cohesion was also reflected by Muhammad et al. (2016) and by Otte (2019). De Arriba et al. (2019) present the capacity of art to present and to find solutions to contemporaneous problems.

Pantano (2011) shows that culture influences consumers' behavior, the cultural components influencing the process of product perception. Nissley (2010) presents the implications of the art presence in contemporary society: decoration, entertainment; as a tool for management/leadership development and strategic transformation when the business integrates arts in areas such as vision and values, creativity and innovation, branding and marketing.

The covid-19 pandemic brought massive changes in the behavior of art consumers and art producers, art being one of the most affected sectors (Danieli and Olmstead-Rumsey, 2020), but the segment of luxury products in the art market registered an increasing trend during this period (Puaschunder, 2020).

The Internet penetration registered high increases during last year (Internet World Stats). The evolution of the Internet transformed internet platforms into the most common solution for access to the different forms of art during the Covid-19 crisis. Li et al. (2019), Korstanje and Babu (2016), and Chung and Yun (2013) analyses important issues associated with the processes of disseminating information using Internet like the responsibility of the mass-media in the impartiality of the message broadcasted and the role of the media in not amplifying risk and in not politicizing the risk issue.

The influences between art and society are analyzed also by Biraglia and Gerrath (2020). In their research is analyzed the impact of museum sponsorship on the perception of consumers. Another influence analyzed during the Covid-19 crises is the influence of music upon patients and staff working in clinics (Giordano et al., 2020). At the same time, attention is paid to the impact that concerts during the COvid-19 pandemic can have on listeners but also on singers. (Helding et al., 2020).

Objectives and Methodology of Research

The objectives of the research included the presentation of the socio-economic context generated by the Coronavirus Crisis in the Romanian society, a short presentation of the art consumers behavior during the Covid-19 crisis, and analysis regarding the influence of the art presence upon the society and upon the conviction regarding the capacity of art to participate to the consolidation of community.

The presentation of the socio-economic context considers different macroeconomic indicators. For analyzing the influence of the presence of art upon society a survey was organized, during the first week of May 2020 on a sample of 200 people in the south of Romania. The data collection was organized using TalkOnlinePanel - a company specialized in online surveys.

The structure of the sample was defined using the next sampling rates: education - persons with university studies; gender - 50% men and 50% women; age - 35% of respondents with ages between 31 and 40 years old, 47% with ages between 41 and 50 years old and 18% others.

The sample included persons with higher education for assuring thus a consistent exposure of the respondents to art and therefore a more profound analysis of the impact of art in the life of individuals and the life of society. The influence of education on the behavior of art consumers was also confirmed by the Cultural Barometer 2018 where it is mentioned that people with higher education have the greatest participation in cultural consumption (Croitoru and Becuț Mariescu, 2019). In defining the questionnaire, different studies and statistical analyses carried out in recent years in the field of art were taken into consideration, allowing the identification of the main factors which are manifesting in this field. Among the factors analyzed are the next ones: consumption of art, the presence of art in the lives of the respondents, the convictions regarding the participation of the art in the life of individuals, and the consolidation the society.

The method used to identify the relationships between factors was the Chi-Square method and Cramer's V test. The test introduced by Karl Pearson allows the verification of the hypothesis of an association between the variables generated by answers obtained from two different questions.

For calculating the Chi-Square indicator, computed using EXCEL, contingency tables were organized by intersecting the answers to two questions: X - with the alternatives Xi, placed as rows of the table, and Y - with the alternatives Yj, placed in columns. (Mihaita, Stanciu-Capota, 2005).
The next steps were:

- The formulation of the null hypothesis H0, which states that between the two variables-segmentation questions there is no causal link or association
- Choosing the significance level or threshold α and calculating the number of degrees of freedom of the table according to the formula (r-1) (c-1); based on these data, one assumes from the table of distribution $\chi 2$ its value, theoretically (index t);
- Calculating the expected theoretical frequencies (expected, in case of a homogeneity test), according to the following formula:
  θij=(Total Line I x Total Line J) / Total = Ti. x T.j
- Calculation of $\chi 2$ index using the formula: $\chi 2=\sum ri=1\sum cj=1$ [(xij- θij)2/ θij]
- $\chi 2$ is compared with the one obtained from the distribution table $\chi 2$ as follows:
  • if $\chi 2$calculated > $\chi 2$teroretical, the null hypothesis is rejected and therefore there is an association or potential relationship between the studied segmentation variables;
  • if $\chi 2$calculated < $\chi 2$teroretical, the null hypothesis is accepted and therefore there is no association or potential relationship between the studied segmentation variables.
- After identifying the existence of the association between the segmentation variables, we used the Cramer's V test to verify how strong the connection between the two variables is.

$V=\sqrt{(\chi 2/[(N)Min (r-1, c-1))}$

The scale of values that Cramer's V can have is the following:

- ≤0.10 there is no association
- >0.10 and ≤0.30 weak association
- >0.3 and ≤0.50 moderate association
- >0.5 and ≤0.70 strong association
- >0.70 very strong association

Results

Art consumption in the Romanian society

The image of art consumption in Romania during the Covid-19 crisis is reflected by data obtained in the survey organized regarding the behavior of art consumers in southern Romania in the first week of May 2020.

The analysis of consumption frequencies was done considering the context generated by the Covid-19 crisis and the available platforms that offer access to different art forms and cultures.

The data obtained show that 75% of respondents consumed movies using internet platforms with a frequency of at least weekly and among men even 79% consumed movies at least weekly using Internet platforms.

In the case of theater consumption using Internet platforms, 44% of respondents consumed at least once a month. And in the case of theater, there is a higher consumption for men, 47% of men have consumed at least monthly theater using the various existing platforms. Music continues to be the art form consumed with the highest daily frequency, 57% of respondents consumed music daily using various forms of online broadcasting. In the case of Literature, 59% of the respondents read with a frequency at least weekly Literature in classical format or electronic format. The visual arts were also available online during this period, many museums exhibited their galleries in

virtual tours. Thus, the survey shows that 59% of respondents accessed various Internet platforms used to display works of art. It can also be mentioned that 16% of the respondents consumed other art forms besides the ones mentioned above. These other art forms include dance, culinary art, and photography.

In the survey the influence of art on society and the participation of art in community consolidation were analyzed, both topics were the subject of questions in the questionnaire.
Data obtained show that 55% of respondents expressed their total agreement regarding the influence of art upon the life of society and 12% of respondents expressed their partial agreement regarding the influence of art upon the life of society. It can also be seen that women are more convinced that art influences the life of society, 88% of women have expressed their agreement, and in the case of men 82% of them have expressed their agreement on the influence of art on society. If we consider education as a segmentation variable, it can be seen that people with postgraduate studies are more convinced of the ability of art to influence society, 86% of people with postgraduate studies have expressed their agreement concerning the influence of art on society, and in in the case of people with university degrees, 84% of them expressed their agreement on the ability of art to influence society.

Analyzing the capacity of art to participate in the consolidation of the community, the answers also showed the conviction of the respondents regarding the capacity of art to participate in the strengthening of the community. 90% of the respondents expressed their agreement regarding the participation of art in the consolidation of the society, 54% expressed their total agreement, and 36% the partial agreement. The differences between men's and women's beliefs are very small, 90% of women and 89% of men agreed. If we use education as a segmentation variable there are also small differences: 90% of respondents with university studies and 88% of respondents with postgraduate studies have expressed their agreement on the participation of art in the consolidation of community.

To analyze the influence of art on society, the influences generated by the following variables were also considered: the presence of art in the respondents' lives, the age, gender, and studies of the respondents.

Table 1: Influences upon the convictions regarding the capacity of art to influence the life of society

Variable 1	Variable 2	$\chi 2$	CRAMER V
Art influences the life of society	Arta was present in life	31.30	0.39 (Moderate association)
Art influences the life of society	Age	2.61	0.11 (weak association)
Art influences the life of society	Gender	1.43	0.08 (no association)
Art influences the life of society	Education	1.47	0.09 (no association)

Source: Author's own research

It has been observed that there is an association between the presence of art and the influence of art on society, as was expected. The presence of art influences the convictions about the ability of art to influence society but should be mentioned that also the convictions regarding the capacity of art to influence the society manifest influence upon the presence of art, generally in the social context, the existence of an association means to influence that manifests itself in both directions between the two variables.

Age also shows a weak influence on the convictions about the ability of art to influence society. (Craver's V is 0.11). The variables Gender and Education do not show influence, between them and the convictions regarding the capacity of the art to influence society there is no association.

Analyzing the influences that manifest on the capacity of art to contribute to the consolidation of the community, the following possible variables of influence were analyzed: the presence of art in the respondents' lives, age, gender, and education.

The association between the presence of art and the contribution of art to the consolidation of the community is strong. It is the strongest association identified in this analysis. Also, the ability of art to contribute to community building is weakly associated with age and education. Gender does not show any influence on the agreement on the ability of the art to contribute to the consolidation of the community.

Table 2: Influences upon the convictions regarding the capacity of art to consolidate community

Variable 1	Variable 2	$\chi 2$	CRAMER V
Arta participate in the consolidation of community	Arta was present in life	49.53	0.5 (Strong association)
Arta participate in the consolidation of community	Age	2.74	0.12 (Weak association)
Arta participate in the consolidation of community	Gender	0.32	0.04 (No association)
Arta participate in the consolidation of community	Education	3.78	0.14 (Weak association)

Limitations of the research

This communication is an academic lecture, an example of robustness a simple approach starting from the statistical instrumentation of the percentages of contingency tables of the dichotomous variables found in planes and hyperplanes of interaction or indifference.

The survey organized for surprising the image of the Romanian art consumption during the Covid-19 crisis has not statistical guarantees, the approach offered an image regarding the 200 respondents included in the sample.

One of the goals of this paper is to promote this subject, of the importance that the presence of art represents in the consolidation of the society, aiming to participate in the launch of the subject regarding the analyzes and discussions on this topic.

Comments

The influence of the presence of art on social cohesion

Art was one of the most affected sectors during the Covid-19 pandemic. Danieli and Olmstead-Rumsey (2020) mention that the related shutdowns are concentrated in just a few sectors like arts, entertainment, recreation.

Changes were necessary for the behavior of art consumers and art producers due to the movement restrictions, non-essential stores closed, and events stops. In the Romanian market starting with 17 March schools, universities, non-essential shops, and events were closed, and national and international movements and flights were restricted. The restrictions were removed starting with the 1st of June, and flights were partially restricted.

Looking to the evolution of the Romanian art market reflected by macroeconomic indicators calculated by the National Institute of Statistics, during the last 10 years we have an increasing trend for the number of spectators and auditors at artistic performances, concerts, cinema spectators, and visitors to museums and public collections. A fluctuating evolution was registered for the number of active readers in libraries, the number of printed books and brochures entered in the Legal Deposit of the National Library, and for the number of newspapers, magazines, and other periodicals.

ARTMARK, the biggest company in the sector of artwork auctions, released in 2020 a report regarding the perspectives of the Romanian art market in 2020 and 2021 in the context of the Covid-19 pandemic. The report presents the evolution of the Romanian art market in recent years and an estimation of the evolution for 2020. In Romania, the art market has experienced annual growth of 22% in the last five years, until the end of 2019. The year 2020 begins under the auspices of a positive end of 2019, signaling trends of moderate, organic growth in all directions.

Also, the data obtained in the survey conducted for this study show that art consumption continued during the period of the crisis caused by a coronavirus. Respondents to the study conducted in Romania continued to consume art in various forms using mainly internet platforms that helped consumers to have access to various art forms, from movies, theater, art exhibitions, music to museum tours. Although the study is without statistical guarantees, it aims

to launch a topic that may be of interest in contemporary society, namely the impact of art consumption on the lives of individuals and society.

The capability of art to participate in building society and consolidating the community was one of the conclusions of the latest Cultural Barometers conducted in Romania, as well as in other European countries or worldwide. (Croitoru and Becuț Marinecu, 2017).

This influence is also manifested in times of crisis, such as the one we are going through. Gupta (2020), shows how art, the act of viewing, making, and sharing music, street art, paintings, graphic art, cinema, and digital videos can serve as a therapeutic vehicle for empowerment, solidarity, and collective action as most human beings strive to adopt practices of extreme social distancing as the recommended community mitigation strategy to help save lives before a vaccine is developed.
The data obtained in the survey organized for this research show that the respondents are convinced that art influences the life of society and participates in the consolidation of society. We find this conviction among respondents regardless of age, gender, or education. There is, however, a set of variables that influence respondents' beliefs about the influence of art on society, namely the presence of art in the life of society. This influence was identified both in the period preceding the Coronavirus crisis (Coman and Mihaita, 2019) and is identified in the crisis period.

Recent studies also show the influence of variables such as convictions regarding art on the assessments of the usefulness of art or of the ability of art to influence society (Coman, 2020).

Published studies also show that art has an influence on society, and on consumer behavior in the periods before the coronavirus crisis (Croitoru and Becuț Marinecu, 2017) also influencing consumer perceptions (Pantano, 2011).

Music, in particular, influences the lives of listeners in general, but it is also used to go through difficult periods during the crisis, such as the one we are going through, being used in clinics. (Giordano et al., 2020).

The influences of art on society are also manifested by the role that art plays in building the urban landscape, in improving the quality of life (Muhammad et al., 2016), reaching the support that art can have in the educational process, such as in the development of creative pedagogy methods for teaching political economy (De Arriba et al., 2019).

Conclusions

The beginning of 2020 found Romania in a period of economic growth with an optimistic society, in which the Index of Consumer Confidence managed in December 2019 to exceed for the first time the European average of the consumer confidence index (European Commission). Art consumption was registering also an increasing trend for most indicators.

The Covid-19 pandemic brought a series of restrictions that the Romanian society and economy had not faced in the last decades: travel restrictions, flight restrictions, closing schools and universities, banning events, and closing non-essential stores. During this period generated by the Covid-19 crisis, art consumption continued, in different forms, adapted to the period, continuing to be present in the lives of people and society.

This paper offers a brief profile of art consumer behavior in Romanian society during the Covid-19 crisis, considering the influences that art manifests on society and the participation of art in building social cohesion. Through the Survey carried out, survey without statistical guarantees, the research participates in the presentation of this topic and aims to open it for further research.

According to the survey conducted in May 2020, 75% of respondents consumed movies using internet platforms with a frequency of at least weekly, 44% of respondents consumed theater at least once a month. Music continues to be the art form consumed with the highest daily frequency, 57% of respondents consumed music daily using various forms of online broadcasting. In the case of Literature, 59% of the respondents read with a frequency at least weekly literature in classical format or electronic format.

This research also shows that art continues to participate in the strengthening of the community, 90% of the respondents of the survey agreed on the ability of art to participate in community building, and 85% agreed on the ability of art to influence society.

The role of art in society during this period covers many other areas, exceeding the answer to people's esthetic needs. Art participate in the consolidation of communities, art offers the support of staff and patients in clinics, in the case of music, or provides an investment solution in these turbulent times, or art plays the role of support for solidarity and collective action in the sustenance of the community strategies such as social distancing during the Covid-19 crisis.

Abstract

Behavioural Finance as a field has been making an effort to elucidate a litany of heuristics, prejudices, inefficiencies to make sense of price moments of financial instruments. This paper is an attempt to study the factors influencing investment decisions among retail investors in Kerala. Data was collected from respondents through questionnaire. Personality traits indirectly impacts how we use we existing set of information this study shed light on the impact of personality traits on investment decision. It would help in better understanding even with near-universal access to information and necessary allied infrastructure the investment per capita remains low compared to the rest of India. It also attempts to observe the influence of extroversion and openness as personality traits on the perception of factors influencing investment decisions among investors. The significant factors that influence investment decisions are observed to make it easier for improving and getting more retail investors to invest in mutual funds.

Keywords: Mutual Funds, Kerala, Personality Traits, Investment Decision, Individual Investor

Introduction

The integration of the world economies has bought nations closer; this has made the economic future of any country interlinked that of other countries. The integration of the Indian economy with that of the world in 1991 which led to an increase in India's Gross Domestic Product from $303.056 Billion in 1991 to $451.573 Billion in 2001(World Bank) which represents a significant spike in growth between 1981-1991 when the GDP grew from $270.471 Billion to $303.056 billion (World Bank). The high growth had made more than 50% of the Indian Population (around 600 million) on account of better salaries and growth prospects be classified as middle class. (Krishnan, S., & Hatekar, N 2017). The vast part of the Indian populace who now made disposable income and a growing desire to improve their standard of living want to find avenues to park part of their savings in financial instruments, to earn better returns. This led to the populace of India investing in but not limited equity market, mutual funds, public provident fund, Fixed deposits in banks, Life insurance policies, post office saving schemes, debentures, treasury bills, options, derivatives, and savings bank account.

Significance of The Study

The mutual fund industry is the fastest-growing segment of the Indian financial sector even while being highly competitive and offering attractive returns on the corpus invested by the investors and providing operational flexibility (Reserve Bank of India,2017). There has been a 25% Compounded Annual Growth Rate increase in the Assets Under Manage during 2013-2018. "The growing formalization and financialization of the Indian economy, household savings have been shifting from physical assets to financial Assets, and within financial assets from bank deposits to securities" (Reserve Bank of India,2018). Retail Investors investment decision on investing in financial decisions are based upon variables including but not limited to Risk aversion, Prospecting, Anchoring, herding (Wamae, J. N., 2013), Neutral Information, accounting information, self-image/firm-image coincidence, advocate recommendation, personal financial needs (Mutswenje, V. S. 2009). The study of such factors is of great significance because conventional financial and economic theories such as Capital Asset Pricing Model, Efficient Market Hypothesis, Monetary Theory, etc which are based on a certain set of assumptions have at times been put to test due to financial market anomalies. Daniel Kahneman a psychologist who won the Nobel Memorial Prize in Economic Science in

Balasubramanian "Factors Influencing Investment Decision of Mutual Funds and The Role of Personality Traits in Their Perception Among Retail Investors in Kerala" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2002 along with Amos Tversky can be credited to inventing the topic of behavioral finance, which changed the way we expect financial instruments to behave in the financial market. Behavioural Finance as a field has been making an effort to elucidate a litany of heuristics, prejudices, inefficiencies to make sense of price moments of financial instruments (Hammond, R. C. 2015). The existing literature covers the factors influencing investment decision, but there exists a lack of papers on how the personality of an individual influences his perception of the factors. This paper is an attempt to fill this void.

Literature Review

Theoretical Review

Ajzen (1986,1991,2000,2002) introduced the theory of planned behavior, which is considered to be one of the preeminent social psychology theory that can be made use of to anticipate the behavior of humans. It was refined for a pre-existing theory known as the Theory of Reasoned Action (TRA) (Ajzen and Fishbein, 1980).

TRA considers the intention of the behavior as the direct motivator for individuals to perform the behavior. TRA even though widely accepted did not precisely predict the behavior of individuals who were constrained by a lack of opportunities or time etc, even when the individual would otherwise be socially urged and is favorable to perform it (Ajzen, 1991).

Global Context

Grinblatt, M., & Keloharju, M. (2000) observed that in the Finnish financial market foreign investors tend to trade with the market, whereas Finnish investors tended to trade against the market. Kaniel et al. (2012), and Kelley and Tetlock (2013) found that there exists an order imbalance of the ability to predict future returns or price movements by individual investors, signifying that some of the individual investors possessing price-sensitive information.

Dickason and Ferreira (2018) studied to identify the association of investment biases with that with the category the investor belongs to, and how they make their investment decisions. It was found that investors with low to average risk tolerances, in general, displayed to loss aversion bias and mental accounting bias. An impulsive decision making and self -control bias was observed among investors with a high tolerance to risk. Investors with moderate risk aversion were susceptible to anchoring, overconfidence, regret aversion, and availability biases. It was concluded that such studies would help create investment products that are attractive to investors.

Hossain, M. F., & Nasrin, S. (2012) studied to identify the factors that influenced the investment decision of retail investors in equity shares which were listed in the Dhaka Stock Exchange. The study arrived at the conclusion that investors had placed significant emphasis on share price, accounting information, specific attributes, and reputation of the business entity. It was found that demographic factors influenced how accounting information was considered significant in the investment decision.

Chen et al. (2015) attempted to identify herding among investors in Taiwan. It was found that large individual investors usually formed a herd, whose activities directly correlated to movements in the equity share price. The trading operations of small retail investors were indirectly related to present and future movements in equity share price and returns, which was attributed to the behavior of selling share before any positive price-sensitive information becomes public and buying shares before any negative price-sensitive information becoming public.

Phan, K. C., & Zhou, J. (2014) attempted to identify the factors that were influencing the investment behavior of investors in the Vietnamese Stock Market. The authors found a significant impact of subjective norm, psychological factors, investment attitude of the investor, and subjective norm on the individual's investment behavior. Gender has a statistically relevant moderation effect on the relation between investment attitude and psychological factors, between behavioral intention and subject norms and attitude of the investor and behavioral intention. East (1993) studied equity share investment decision in Britain, the study found that the theory of planned behavior was able to accurately predict investment decisions.

Gunathilaka, C. (2014) concluded that accounting information, self-image/firm image, and advocates recommendation has a significant influence on the selection of equity stocks in Colombo. Clark M. & Soutar, G. N. (2004) Concluded that recent share price moments and company management played a bigger role than price to earnings ratio and dividends (present and past) in the Australian Financial market.

Indian Context

There exists a significant relationship between the demographic factors and the capacity of an individual to bear risk, Respondents who regarded themselves as a conscientious, extravert, and agreeable were in general found to take more risk (Athira, and Kakkakunnan, 2020). This supports the interlinkage of investment decisions with the demographic and personality traits of the investor (Thomas and Rajendran 2012).

Joshi et al. (2011) attributed the investing behavior investors in Gujarat was significantly impacted by market expectations, market sentiments, and past performance. Bennet et al. (2011) observed a significant difference in investment decisions between gender.

Objectives

- To know a demographic profile of retail investors in Kerala.
- To analyse the factors that significantly affect the investment decision.
- To explore the role of personality traits in influencing investment decisions.

Hypotheses

- H_{0a}: All factors significantly associated with the influence investment decision
- $H_{0b:}$ Personality traits significantly associated influence how factors are perceived.

Research Methodology

The study focuses on the state of Kerala, the population of the study is the retail investors in mutual funds in Kerala. The sample size of 384 was selected as per Morgan's table, confidence interval was 95% and margin of error was at 5%. The data was collected with the use of a questionnaire. Out of the 384 filled questionnaire, 125 (33%) were considered for the study, the rest were rejected due to being incomplete or multiple selections being selected for questions. This research design uses a descriptive and analytical research design. The questionnaire was divided into two segments one enquiring about the demographic information of the respondent and the second segment enquiring about the respondent's perception of the economic factors in influencing their investment decision. The response was analyzed using the Statistical Program for Social Science by IBM.

Data Analysis, Interpretation and Conclusion

Demographic Profile

The demographic profile of the respondents is presented in Table 1. The table shows the demographic profile of the respondents based on the age of the respondents, gender of the respondents, education level, monthly income, and marital status of the respondent.

Table 1: Demographic profile of the respondent

		Count	Percentage
Age	Under 18	0	0.0%
	19-22	40	32.0%
	23-26	49	39.2%
	27-30	18	14.4%
	Above 30	18	14.4%
	Total	125	100.0%
Gender	Female	84	67.2%
	Male	41	32.8%
	Total	125	100.0%
Marital Status	Single	91	72.8%
	Married	30	24.0%
	Divorcee	4	3.2%
	Total	125	100.0%
Highest Education Qualification	Higher Secondary	0	0.0%
	Senior Secondary	0	0.0%
	Graduate	52	41.6%
	Post- Graduate	65	52.0%

	Others	8	6.4%
	Total	125	100.0%
Annual Household income	Under Rs.3,00,000	43	34.4%
	Rs.3,00,001- Rs.5,00,000	34	27.2%
	Rs.5,00,001- Rs.7,00,000	20	16.0%
	Rs.7,00,001- Rs.9,00,000	6	4.8%
	Above Rs.9,00,000	22	17.6%
	Total	125	100.0%

Source: Primary Data

It is observed that 39.2% of the respondents were between 23-26 years old, 32% where between the age of 19-22, and those aged between 27-30 and above 30 each accounted for 14% of the respondents. 62.7% were female and the rest where men. Singles accounted for 72.8% of the respondents, married 24%, and divorcees 3.2%. Postgraduates accounted for 52% of the respondents, graduates 41.6%, others at 6.4%. 34.4% of the respondents had an annual household income of under Rs.3,00,000., 27.2% household earned between Rs.3,00,001- Rs.5,00,000., 17.6% of the respondents had a household income in excess of Rs.9,00,000., Rs.5,00,001- Rs.7,00,000 by % and 4.8% Rs.7,00,001- Rs.9,00,000.

Cronbach Alpha

Cronbach Alpha is used to measure the internal consistency of a questionnaire. The value usually lies between 0-1. A high value denotes a set of items that are closely related to as a group.

Table 2: Cronbach's Alpha of questions on factors affecting investment decision.

	Cronbach's Alpha	N of Items
Overall (Investment Decision)	.912	30
Self-image and Firm Image	.652	9
Accounting Information	.905	7
Neutral Information	.616	6
Advocate Recommendation	.594	4
Personal Financial Needs	.712	4

A high Cronbach's Alpha denotes a set of items that are closely related to as a group. In this case, the questions on factors affecting investment decision are closely related to each other

Table 3: Cronbach's Alpha of questions on personality.

	Cronbach's Alpha	N of Items
Overall (Personality)	.770	10
Extroversion	.731	5
Openness	.551	5

A high Cronbach's Alpha denotes a set of items that are closely related to as a group. In this case, the questions on personality are closely related to each other.

Rescaled Communalities

Table 4: Rescaled Commonalities based on the personality trait

	Initial	Extraction (Extroversion)	Extraction (Openness)
Religion	1.000	.846	.845
Political party affiliation	1.000	.911	.909
The environmental record of the business entity	1.000	.785	.810
Perceived ethics of the firm	1.000	.768	.791

Firms involvement in solving community problems	1.000	.592	.636
Feeling about the firm's products and services	1.000	.835	.807
Ease of obtaining borrowed funds	1.000	.723	.806
Attractive of alternative investment avenue	1.000	.738	.675
Diversification Needs	1.000	.789	.801
Coverage in press	1.000	.689	.737
Opinions of the firm's majority shareholders	1.000	.704	.834
Friend or Co-worker recommendation	1.000	.759	.792
Statements from government officials	1.000	.683	.710
The reputation of the firm	1.000	.826	.805
Gut feeling about the economy	1.000	.825	.810
Information obtained from the internet	1.000	.746	.792
Getting rich quickly	1.000	.654	.689
minimizing risk	1.000	.676	.628
Fluctuation's in the stock market	1.000	.657	.654
Affordability	1.000	.776	.742
Broker Recommendation	1.000	.704	.653
Past performance	1.000	.795	.768
Current Economic Indicators	1.000	.778	.766
Firms Status in the Industry	1.000	.729	.726
Dividends paid in the past	1.000	.751	.644
Marketability of the instrument	1.000	.777	.712
Condition of Financial statements	1.000	.832	.805
Expected Corporate earnings	1.000	.718	.761
Expected Dividends	1.000	.769	.719

Communality measures the percentage of variance in a given variable under study which could be explained by all other factors conjointly and this value can be construed as the reliability of the indicator. Political affiliation has the highest variability in both cases whereas "Firms involvement in solving Community problems" has the lowest variability in the case of extroverts and "Minimizing risk" in the case of open-minded respondents.

Table 5: Total Variance explained based on extroversion.

Table 5 indicates the total degree of variance that can be explained by each component. Eight factors that together explained 75.501% of the total variability was extracted. These are orthogonal to each other. The cut-off was based on the condition that the eigenvalue should be at least 1. The first component explained 32.55% of observed variance, the second component 10.1722%, the third component 8.722%, the fourth component 6.310%, the fifth component 5.533%, the sixth component 4.435%, the seventh component 4.020%, and the eighth component 3.759%.

Table 6: Total Variance explained based on Openness.

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %

Table 6 indicates the total degree of variance that can be explained by each component. Eight factors that together explained 75.403% of the total variability was extracted. These are orthogonal to each other. The cut-off was based on the condition that eigenvalue should be at least 1. The first component explained 31.207% of observed variance, the second component 11.829%, the third component 9.467%, the fourth component 5.763%, the fifth component 5.079%, the sixth component 4.611%, the seventh component 3.938%, and the eighth component 3.509%.

Table 7 shows variables that make each variable influence on each component. Value is in the range of -1 to 1. A value of greater than 0.5 shows a significant influence on the corresponding component. It is observed in table 8 and table 6 that respondents show a significant difference in how they perceive factors that influence an investment decision.

Table 7: Rotated component matric based on the Personality traits.

Political party affiliation	125	1.776	1.1561	30

Friedman rank test assigns weights bases on the degrees of importance of factors in influencing the activity. Table 8 depicts the influence of factors and their degree of influence if investment decisions It can be seen that the first 12 factors greatly influence investment decision, 13-28 factors, and averagely important, and the last two are least influential.

Findings and Suggestions

The demographic profile of the respondents signifies that respondents irrespective of age, gender, marital status, education, and income invest money in equity mutual fund schemes. It was also seen that respondents perceive the variables differently based on personality traits. All the factors except for religion and political affiliation of the respondents play a significant part in influencing the investment decision of the respondents.

Conclusion

It is concluded that factors except for religion and political affiliation of the respondents play a significant part in influencing the investment decision of the respondents. The respondent's perception of factors is influenced by their personality and that people irrespective of age, gender, marital status, income, and education invest in equity mutual funds. This study could help asset management companies develop customized advertisements to prospective customers based on the personality thereby helping them convert leads into sales. It also sheds light on an indirectly influencing factor on which further study across geographical boundaries could be done and studied to find if similar impact is observed in other places.

Limitations and Scope for Future Study

The study is limited to thirty factors and the state of Kerala. There exist immense potential and value to study if the factors are similarly influenced in other places. Studies can also be done on how personality impacts their perception

among investors. The influence of personality is an invisible factor that brings forward other biases of the investor and is therefore of significance to study.

Abstract

The aim of present study is to evaluate the effect of 4 significant different feeding rates (V1 – 0.22%, V2 – 0.12%, V3 – 1.22%, respectively V4 – 1%) on koi carp rearing and economic sustainability performances in order to determine proper feeding technologies that addresses to certain technological scenario. The experimental trials were carried out during a 41 days experimental period. The experimental design was made in duplicate. The water quality parameters (water temperature, pH, and dissolve oxygen) were evaluated daily during the entire experimental trials. The average individual biomass was 28±1.2 grams and the average individual length was 11±0.5 cm. Considering the registered values of SGR, FCR and RGR, it can be stated that V1 and V2 feeding rates are recommended for koi carp stocking, during a longer period of time, while V3 and V4 feeding rates can be also applied for rearing purposes. From an economic point of view it is recommended not to use, on a long-term, the V1 and V2 technological scenario, since they do not offer economic sustainability. These scenarios are recommended to be used only during limited period of time, if certain dysfunctionalities develops during the fish rearing technological process. If koi carp rearing is targeted, the V4 scenario is identified as most suitable in order to be used for assuring the best results in terms of production (FCR value) and economical sustainability. However, the results of this present study are influenced by the PRAS performance to sustain a certain degree of production intensity, limited by the configuration and design of water conditioning units.

Keywords: Economic Sustainability, Feeding Rates, Intensive Aquaculture, Koi Carp.

Introduction

In recent years, the growth of fish in recirculating systems and partial recirculating systems has experienced a significant increase, more and more investors being attracted by the benefits of such a business. Recirculating and partial recirculating systems are controlled systems in which fish or other aquatic creatures can be intensively farmed, the technological water being recirculated through a series of filters and devices, thus removing unwanted substances from the water.

Considering the modern aquaculture sector, different types of aquaculture systems such as recirculating aquaculture systems (RAS), partial recirculating aquaculture systems (PRAS) or integrated aquaculture systems were established to conserve and minimize the water usage and to optimize the production. In a RAS and PRAS, a part of wastewater is reused after appropriate treatment and conditioning. It is one of the most intriguing strategies for intensifying aquaculture production while simultaneously reducing wastes. It provides a dual benefit of reducing water demand and minimizing effluent problem. The RAS and PRAS is designed to collect and remove waste products, uneaten feed and harmful bacteria from the fish tank and treated water can be recycled back into the system. (Nuwansi et al., 2019).

Ornamental fish culture is fast emerging as a major branch of global aquaculture. The koi carp is an economically important species of ornamental freshwater fish (Kumara et al., 2015). The Japanese ornamental carp (*Cyprinus carpio* var. Koi) is famous for multi various colors and patterns, making it commonly culture and trade across the world (Tian et al., 2018).

However, for the industrial ornamental fish sector five biological traits are considered as most important: growth rate, feed intake, feed conversion ratio, mortality rate and uniformity. These traits influence farm income and expense. Thus, fish that grow fast will attain market weight early which saves costs. When ensuring uniform products, famers can increase profit by selling more fish in the preferred price range (Omasakia et al., 2017). Also, low mortality rates will be achieved if achieving a proper balance between the production system design and the applied feeding technology.

In order to evaluate the economic sustainability of a fish farms, fixed and variable cost must be considered. Thus, feeding is a major factor that determines the production costs in aquaculture (Li et al., 2020). Feed cost depends largely on the crude protein content in the diet (Kabir et al., 2019). Also, the feeding intensity and fish diet crude protein content are influencing the design of aquaculture production system technical aspects and water conditioning capacity.

Feed represents the major cost of production, therefore, reducing feed intake by assuring low values of FCR will led to an increase farm profit. Feed conversion ratio (FCR), the ratio between feed intake and body weight gain, is of major interest for improving aquaculture sustainability through reduced feed costs and environmental impacts (Rodde et al., 2020).

However, in aquaculture, the feeding rate varies, according to the fish development stage, fish stocking density and production system water conditioning performance. As it is considered an economic activity, industrial aquaculture implies permanent financial inputs and outputs. Since financial inputs are required permanently, in order to sustain the proper application of fish rearing technology, the income is conditioned by ornamental fish sale. It is known that, during a production cycle, a series of scenarios can appear, as follows: fish feed shortages, shipping restrictions, working restrictions, financial shortages, water conditioning equipment failure. Thus, the fish rearing technology must be flexible in order to adapt, on short of long term, to each of these scenarios, without losing fish biomass. This can be possible by applying proper feeding rates that will be able to sustain fish biomass and prevent it for losing weight or, if possible, ensuring the best rearing performances with limited fish feed resources, ensuring also a proper economic sustainability.

The aim of present study is to evaluate the effect of 4 significant different feeding rates (V1 – 0.22%, V2 – 0.12%, V3 – 1.22%, respectively V4 – 1%) on koi carp rearing and economic sustainability performances in order to determine proper feeding technologies that addresses to certain technological scenario.

Materials and Methods

Experimental Design

The experimental trials were carried out at the Aquaculture Research Center of Food Science and Engineering Faculty – ''Dunarea de Jos'' University of Galati, Romania, during a 41 days experimental period. The koi carp exemplars were reared in 4 experimental variants, by applying different feeding rates, as presented in figure 1.

Fig. 1: Experimental variants

The experimental design was made in duplicate. The experimental partial recirculating production system (PRAS) consists in PVCL rearing units and water treatment modules composed of mechanical sponge filter and biological activated carbon (BAC) filter. For V1 and V2 a single filtration module was used, while 2 filtration modules were used for each of V3 and V4 experimental variants.

The following formula was applied for determining the hydraulic retention time (*HRT*) and hydraulic loading rate (*HLR*) in each of the four experimental variants: $HRT = (S \times h \times n) / Q$, (*hours*), where S – rearing units surface (m^2), h – water level within the rearing units (m), n – porosity of rearing units material, Q – inlet water flow (m^3/day) and $HLR = Q/S$ *(m/day)*. Thus, the HRT was evaluated at 5.27x10-4hours at V1 and V2 and 2.63x10-4 hours at V3 and V4, respectively. In terms of *HLR*, a 40 m/day value is attributed to V1 and V2, while 80 m/day is assured at V3 and V4 experimental variants.

A 40% daily water exchange rate was applied in order to assure optimum growth conditions for the biological material. The experimental fish groups were homogeneous at the start of the experiment. No significant differences ($p>0.05$) were registered between the variants in terms of both fish individual biomass and individual length. The average individual biomass was 28±1.2 grams and the average individual length was 11±0.5 cm.

The biological material from all four experimental variants was fed with pellets with a biochemical composition as presented in table 1.

Table 1: Biochemical composition of pellets

Parameter	Value
Crude protein	38%
Lipids	15%
Fiber	1.7 %
Ash	8.8 %
Phosphorus	1.2%

Methods for Water Quality Analysis

The technological water temperature, pH and dissolved oxygen (DO) were determined daily, using a WTW – 340pH meter, respectively a WTW Oxi 315 I temperature and DO meter.

Technological Indicators

Growth performance and feed utilization were calculated according to Petrea et al., 2019a:

1. Total biomass gain: IBG = Bf-Bi[g/fish], with Bf – final fish biomass; Bi – initial fish biomass;
2. Specific growth rate: SGR = 100 x (ln Bf - ln Bi)/t [% fish biomass/day], with Bf – final fish biomass, Bi – initial fish biomass, t- duration of the experiment;
3. Feed conversion ratio: FCR = F/IBG [kg feed intake/kg fish biomass gain], with F –feed intake, FBG – individual biomass gain;
4. Protein efficiency ratio: PER =IBG/(F*CP/100) [kg/kg], with FBG –individual biomass gain, F – feed intake, CP -crude protein.

Results and Discussions

Technological Scenario

Water Quality Parameter

The water quality parameters (water temperature, pH, and dissolve oxygen) were evaluated daily during the entire experimental trials. Thus, water temperature ranged from 18.5oC to 25oC at all experimental variants, with no statistically significant difference (p>0.05). The pH ranged between 6.1 – 6.8 (figure2), while dissolved oxygen (DO) ranged between 4.2 – 6.8 mg/L (figure 3). The results reveal low pH values for the variants where higher feeding rates were applied (V3 and V4), compared to V1 and V2. However, no statistically significant differences were observed between the experimental variants (p>0.05) in term of pH, although the average value registered in V3 is lower compared to the pH average values registered at the rest of the experimental variants. Most probably, the feeding rate applied in V3 is closed to the maximum water conditioning limit of the PRAS system, fact revealed also by the low DO concentrations registered during the experimental period at this experimental variant. Also, in terms of water DO, the V3 registered significant (p<0.05) lower concentrations, compared to the rest of experimental variants (V1, V2, V4). The dynamics of both pH and DO are closely related to water exchange rate. Thus, the ups and downs are mostly influenced by high water exchange rate (40% per day), since the production systems is a PRAS.

Fig. 2: The pH dynamics, for each variant, during the entire experimental trial

Fig. 3: The DO dynamics, for each variant, during the entire experimental trial

Growth Parameters

The growth performance indicators (table 2) revealed no mortalities during the trial, therefore confirming the good results registered in terms of water quality.

Table 2: Growth performance indicators for each of the experimental variants

Technological parameter	V1	V2	V3	V4
Experimental period (days)	41	41	41	41
Survival (%)	100	100	100	100
Individual biomass gain (g)	0.72	0.17	7.66	7.68
Feed protein (%)	38	38	38	38
Daily feeding ratio (% BW)	0.22	0.12	1.22	1
Initial fish stocking density (kg/m3)	3.78	3.78	3.79	3.85
Final fish stocking density (kg/m3)	3.89	3.81	4.89	4.95
Relative growth rate (g/g/day)	0.66×10^{-3}	0.15×10^{-3}	7.04×10^{-3}	6.94×10^{-3}
Specific growth rate - SGR (%BW/day)	0.07	0.02	0.62	0.61
Feed conversion ratio – FCR (g feed / g biomass gain)	3.30	5.62	1.73	1.44
Protein efficiency ratio - PER (g/g)	0.80	0.61	1.52	2.19

In aquaculture, several models applicable to the concave portion of the growth curve have been used. The formula most used is the ″instantaneous growth rate″ or ″specific growth rate″ (SGR) and is based on the natural logarithm of body weight (Bureau et al., 2000). The average specific growth rate indicates a superior fish production at V3 (0.62 %BW/day) and V4 (0.61 %BW/day), compared to the rest of the experimental variants (V1 - 0.07 %BW/day and V2 - 0.02 %BW/day, respectively).

The FCR indicates the technological efficiency of feeding strategy (Petrea et al., 2020) in each of the tested experimental variants. Thus, the FCR indicator reveals better values, as expected, mostly dependent on the applied feeding ratio. The V4 registered the best technological efficiency emphasized by a FCR value of 1.44, followed by V3 (1.73). However, it is important to mention that all FCR values are positive, situation which emphasizes that fish gain in biomass during the 41 days experimental period, although a low feeding rate were applied both in V1 and V2. Related to other similar studies, it must be emphasized that Safari and Sarkheil (2018) analyzed the growth performance of koi carp with an initial individual weight of 7.42 g, reared during a 63 days experimental trial by administrating feed with 34% crude protein and applying a feeding rate of 0.56%BW and recorded an average FCR value of 2.88 g/g. Also, Nuwansi et al. (2019) registered FCR values between 4.13 – 5.59 g/g for koi carp with an individual weight of 4.04 - 4.05 g, by applying a feeding rate of 2% BW.

Regarding the individual and total RGR recorded values, no significant differences ($p>0.05$) were recorded between V3 and V4 experimental variants, while statistically significant differences ($p<0.05$) were recorded between V2 and the rest of experimental variants. The highest RGR value is registered at V3 while the lowest is associated to V2 (table 2).

Considering the registered values of SGR, FCR and RGR (table 2), it can be stated that V1 and V2 feeding rates are recommended for koi carp stocking, during a longer period of time, while V3 and V4 feeding rates can be also applied for rearing purposes, especially in production systems with limited possibility to maintain the water quality parameters within an optimal range throughout the entire experimental period.

A highest protein efficiency ratio (PER) is recorded at V4 experimental variants, followed by V3. Also, V2 registered the lowest PER value, in accordance with the daily feeding rate applied at this experimental variant throughout the trial (0.12% BW).

The FCR and PER results emphasize that 1% feeding ratio is most suitable to be applied if koi carp rearing technological sustainability is targeted, considering the present PRAS.

However, if PRAS water treatment capacity will be improved or water exchange rate will be increased over 40%, the optimal feeding rate will also exceed 1% BW.

Economic Scenario

The economic sustainability for each of the four scenarios, described by the experimental variants (V1, V2, V3, V4) tested in present trial, is important to be considered since aquaculture is an economic industrial activity and all the technological decisions must be justified, also, by their economic impact. Thus, since koi carp price varies, depending not only on size, but on a series of factors as genetic lineage, coloration pattern, provenance or methods of selling (bulk of individually), it is difficult to estimate an income.

However, considering the differences related to water treatment design and the various technological performances obtained for each of the four scenarios, it can be concluded that the economic sustainability can be estimated by evaluating the operational costs related to electricity and fish feed.

Also, according to other studies (Petrea et al., 2016; Petrea et al., 2019b), costs related to electricity and fish feed have the highest percentage from total variable costs.

For the evaluation of electricity costs, the electricity consumption was determined, considering the design of the PRAS, described in the material and methods section, as follows: V1 – 797.22 KWh per kg fish produced, V2 – 3416.67 KWh per kg fish produced, V3 – 155.20 KWh per kg fish produced and V4 – 154.90KWh per kg fish produced.

Table 3: Feeding and operational costs per one kg of koi carp, in different scenarios

Operational costs (€)	**Economic scenario**			
	V1	**V2**	**V3**	**V4**
Electricity cost per one kg of koi carp produced	117,86	505,13	22,95	22,90
Feeding costs per one kg of koi carp produced	19,82	33,74	10,37	8,65
TOTAL	137,68	538,87	33,32	31,55

It can be observed that both V1 and V2 presents a very high electricity consumption per kg koi carp produced, mostly due to low values of biomass gain, registered during the experimental trial as a direct consequence of low feeding rates applied. This situation is also encountered in both feeding and electricity costs, presented in table 3.

Thus, it is recommended not to use, on a long-term, the V1 and V2 technological scenario, since they do not offer economic sustainability. These scenarios are recommended to be used only during limited period of time, if certain dysfunctionalities develops during the fish rearing technological process.

Conclusions

Appropriate feeding strategy for each technological scenario is fundamental for assuring the economical sustainability of the aquaculture activity. The V2 scenario is considered to be most suitable for stocking koi carp during limited period of time if resource limitations (fish feed shortages) occur. However, if the fish stocking periods are longer and the resources availability is less limited, the V1 scenario can be applied, improving therefore the economic sustainability.

If koi carp rearing is targeted, the V4 scenario is identified as most suitable in order to be used for assuring the best results in terms of production (FCR value) and economical sustainability. However, the results of this present study are influenced by the PRAS performance to sustain a certain degree of production intensity, limited by the configuration and design of water conditioning units.

Circular Business Model For Granulated Carbonated Volatile Fly Ash From Fluidized Beds In Underground Mining Techniques

Jadwiga PROKSA

Central Mining Institute, Plac Gwarków 1, 40-166 Katowice, Poland

jproksa@gig.eu

Abstract

Circular business models are one of potential ways for industry to profitably achieve radical gains in resource efficiency. This article presents the concept of a closed-loop business model on the example of the management of fly fluidized ash in synergy with power plant and mine. The developed model consists of recycling by-products from the power industry by using them in underground mining technologies. Designing a business based on usage of granulate material produced according to the new method of processing fluidized fly ash was presented on the Lean Canvas model.

Keywords: Circular Business Models, Lean Canvas, industrial synergy, Cradle-to-Cradle, carbonatizated granulate.

Introduction

Zero waste, circular economy, industrial synergy are popular concepts nowadays. In order for these slogans to be followed by actions, a comprehensive knowledge of designing circular business models is needed. The essence of the circular economy is to remain in the economy of products, raw materials and materials as long as possible, along with minimizing waste generation, at all stages of the product life cycle. To do this, new business models based on industrial cooperation should be developed (Bocken N., Snihurc Y., 2020; Lewandowski M., 2016). Circular concept means pursuing and creating the opportunities for a shift from an "end-of-life" concept to "Cradle-to-Cradle". The circular economy becomes a new vision of resource processing, value creation and entrepreneurship. Companies need to consider how to close material loops, reduce resources, and keep materials and products in the loop for as long as possible. This may result in the necessity to reconsider the values offered and the necessity of industrial cooperation.

A review of business models supporting the circular economy (CE) is described in a research study by Lewandowski (2016), examining various cases of the model's transition to a closed loop. Classic models are not enough - they have gaps, they are not consistent with the CE concept, and their success often depends on the specifics of the business. The application of CE guidelines in business models is complicated, the economy may have great difficulties in not generating waste, probably 100% circular business models do not exist (yet) (Van Renswoude K., Wolde A.T., Joustra D.J., 2015).

This article presents the concept of a closed-loop business model on the example of the management of fly fluidized ash in synergy with power plant and mine. The proposal fits in the business model of recovery and recycling, linked to the production and consumption system, where everything that was considered waste is reused.

The developed model consists of recycling by-products from the power industry by using them in the mining structures. The solutions included in the patents developed at the Central Mining Institute prove that combustion by-products subjected to the carbonation process can be returned to the mine in the mine-power plant system, in accordance with the concept of a circular economy. The proposed model of mine and power plant synergy is based on the interaction of these two sectors (Proksa J., 2017). The research on carbonation of these ashes, carried out with use of technical carbon dioxide, lead to the reduction of free calcium content below 1%. Such product meets the requirements of the application in underground mining technologies. The fly ash from the Łagisza Power Plant was carbonated as described in the work (Łączny M.J., et al., 2015) and in the patent PL 410867 ("Method for

Cite this Article as: Jadwiga PROKSA" Circular Business Model For Granulated Carbonated Volatile Fly Ash From Fluidized Beds In Underground Mining Techniques" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

processing volatile ashes from the use of the energy producing fuels for the product with controlled content of free calcium oxide"). The resulting carbonated fluidized ash then was used in a simultaneous three-phase granulation process in the system: solid - liquid - gas carried out in the granulator - intensive counter-rotating mixer (Proksa J., Bzowski Z., 2020). The result of the research is a patent application in Poland No. P.431864 ("Method of obtaining carbonatizated granulate on the basis of fly ash"). The possible applications of the granules in selected underground mining technologies were initially determined, e.g.: sealing of goafs, filling voids and unused workings, liquidation of shafts, construction of explosion-proof dams. The article presents the Lean Canvas approach for the above case - a business model was developed for the management of processed fluidized fly ash for use in underground mining technologies.

Concept of the Buisness Model

Business Model Canvas (BMC) is a tool that allows to effectively control the approach to business. It allows to gather extensive knowledge and necessary information and enter them into one model, which can be flexibly corrected if necessary. BMC, created by Alexandr Osterwalder, is mainly used in companies that are already on the market and looking for improvement. Based on this model, a variation was created - Lean Canvas (LC), developed by Ash Maurya. This model is targeted at new businesses, products and technologies. LC, as opposed to BMC, focuses on: problem understanding, solution, key metrics, and unfair advantage. It is characterized by a view on uncertain and risky activities in business (Sire P., Prevost E., Guillou Y., Riwan A., Saulais P., 2019).

The business model consists of nine elements that allow to define value and profit. LC proposes an iterative approach to process management. The Ash Maurya template fields should be filled in the following order (Maurya A., 2012; York J.M., 2020):

1. Problems - the most important problems to be solved should be indicated,

2. Customer segmentation - the target customers for whom the product or service will be delivered should be determined. It is closely related to the problems,

3. Value Proposition - the benefits that customers will have from the product or service provided should be established. This is the value promised to be delivered,

4. Solution - the solutions (and their most important features) to the previously established problems should be provided,

5. Unfair advantage - the advantage over the competition that is unique and cannot be copied should be considered. An unfair advantage can help in finding of partners and investors,

6. Structure of revenues - all elements related to the company's revenues should be determined,

7. Cost structure - all operating costs related to the introduction of the company/product to the market, maintaining customer relations and generating revenues should be determined,

8. Channels - all possible methods of reaching customers should be established,

9. Key indicators - indicators to monitor performance should be determined. This constitutes a feedback from the market about the product or service.

Table 1: Maurya's lean canvas.

Due to the innovative approach to the fluidized fly ash processing and the development of a new product, the Lean Canvas model has been used in the research.

Designing circular business models

The concept of a circular economy is based on the main principles of the new approach to economics: design out waste/design for reuse, build resilience through diversity, rely on energy from renewable sources, think in systems, waste is food/Think in cascades/Share values - symbiosis (Ellen MacArthur Foundation). Circular business models are one of potential ways for industry to profitably achieve radical gains in resource efficiency. An interesting direction may also be the adaptation of risk management to innovation in CBM (Linder, M .; Williander, M., 2015).

Designing a business based on usage of granulate material produced according to the new method of processing fluidized fly ash was presented on the Lean Canvas model. The analyzed case is characterized by the Circular Economy approach and industrial synergy. To make the transition from a linear business model to a circular business model possible, value proposition should be treated as a key element (Osterwalder, A., Pigneur, Y., Bernarda, G., Smith, A., 2014). Table 2 presents the results of the research.

Table 2: Lean Canvas for power plant and mine synergy.

1.Problem ▪ Development of fluidized fly ash ▪ Carbon dioxide disposal ▪ Waste prevention at source ▪ Dusting in transport of fluidized fly ash ▪ Closing the loop in the synergy of the mine-power plant system ▪ Trends towards industrial symbiosis ▪ Power plant - mine cooperation ▪ Effective waste management in a power plant	**4.Solution** ▪ Loop closure ▪ A new way of managing fly fluidized ash ▪ A new way of carbon dioxide management **8.Key metrics** ▪ Efficient technology ▪ Waste management ▪ Placing the processed waste in the mine	**3.Unique value proposition** ▪ Innovative zero waste technology in the process of energetic coal combustion ▪ Economical technology, energy-saving, highly effective, environmentally friendly ▪ Easy transport of the product due to the absence of dusty substances ▪ Industrial symbiosis ▪ Extending the product life cycle ▪ Circular products enable product-life extension	**5.Unfair advantage** Simultaneous carbonation and granulation of the fly ash with addition of CO_2 **9.Channels** ▪ Business-to-Business ▪ Networking ▪ Seminars ▪ Fairs ▪ E-mais	**2.Customer segment** ▪ Polish coal industry ▪ Raw materials and mineral wastes companies. ▪ Polish waste operators
7.Cost structure ▪ Logistics ▪ Production line ▪ Transport line ▪ Product testing			**6.Revenue streams** ▪ Efficient waste management ▪ Circular Economy ▪ Waste-free power engineering ▪ Power Plant – Mine cooperation ▪ Industrial synergy	

Conclusions

The aim of CE is designing products in non-waste technologies and extending the product life cycle. Waste-free energy in cooperation with the mining industry has a chance to create industrial synergy in order to close the cycle. Carbonation of fluidized fly ashes with the use of carbon dioxide appears to be a promising way of processing them for the recovery and use of this waste. It is an innovative technology developed at the Central Mining Institute. This opens up new perspectives in the use of carbonated fluidized fly ash in various types of mining technologies. This approach is an opportunity to close the loop in this industrial synergy. The developed concept was modeled in Lean Canvas.

The solutions to the problems defined in the model are presented in the solution position. The solution for the formation of fly ash is the process of simultaneous carbonation and granulation, which gives the possibility of using these products in the mine and closing the loop. Additionally, this process eliminates the problem of dust release during transport. The presented unique value proposition is in line with the Circular Economy concept.

Abstract

As announced in our previous works, this paper is part of a larger research that deals with sustainable development and environmental protection in extractive industry. In this respect, this paper is aiming to identify the relationship that may exist between externalities and economic efficiency in terms of market failure. We begin our analysis of externalities by discussing the forms that externalities can take in terms of consumption and production. Then we shall move on by explaining the links between externalities (as source of market failure) and economic efficiency. In the end, by looking at three sorts of pollution problem – a consumer-to-consumer case, a producer-to-producer case, and a case where the unintended effect is from a producer to consumers – we shall bring out all of the essential features of pollution as a market failure problem.

Keywords: Consumer, Efficiency, Externality, Market Failure, Pollution, Production Function, Producer, Property Right, Utility.

Introduction

An external effect, or an externality, is said to occur when the production or consumption decisions of one agent have an impact on the utility or profit of another agent in an unintended way, and when no compensation/payment is made by the generator of the impact to the affected party. Some authors leave out from the definition of an externality the condition that the effect is not paid or compensated for, on the grounds that if there were payment or compensation then there would be no lack of intention involved, so that the lack of compensation/payment part of the definition as given in the text here is redundant [Barber and Markandya, 1990; Mäler, 2011; Howarth, 2012; Brown *et al.*, 2015].

As we shall see, there is something in this. However, we prefer the definition given here as it calls attention to the fact that lack of compensation/payment is a key feature of externality as a policy problem. Policy solutions to externality problems always involve introducing some kind of compensation/payment so as to remove the unintentionality, though it has to be said that the compensation/payment does not necessarily go to/come from the affected agent [Perman *et al.*, 2003; Common, 2004; Petri, 2004].

In our analysis thus far [Neagu *et al.*, 2019], we have excluded the existence of externalities by the assumptions that were made about the utility and production functions. But in practice consumption and production behaviour by some agents does affect, in uncompensated/unpaid for ways, the utility gained by other consumers and the output produced, and profit realised, by other producers [Redclift, 1992; Pezzey and Toman, 2002; de Man, 2016].

Economic behaviour does, in fact, involve external effects. The stated definition of an external effect is not perhaps very illuminating as to what exactly is involved. Things will become clearer as we work through the analysis. The two key things to keep in mind are that we are interested in effects from one agent to another which are unintended,

and where there is no compensation, in respect of a harmful effect, or payment, in respect of a beneficial effect.

Classification of Externalities

In our two-person, two-(private)-commodity, two input economy we have worked with:

$$U^A = U^A(X^A, Y^A)$$

$$U^B = U^B(X^B, Y^B)$$

as utility functions, and:

$$X = X(K^X, L^X)$$

$$Y = Y(K^Y, L^Y)$$

as production functions.

Note that here the only things that affect an individual's utility are her own consumption levels, and that the only things that affect a firm's output are the levels of inputs that it uses. There are, that is, no external effects. External effects can, first, be classified according to what sort of economic activity they originate in and what sort of economic activity they impact on. Given two sorts of economic activity, consumption and production, this gives rise to the six-fold classification shown in Table 1. The first column shows whether the originating agent is a consumer or producer, the second whether the affected agent is a consumer or producer, and the third provides an illustrative utility or production function for the affected agent. In Table 1, we are concerned only to set out the forms that unintended interdependence between agents could take. Some examples will be provided shortly.

Table 1: Externality classification

Arising in	Affecting	Utility/production function
Consumption	Consumption	$U^A(X^A, Y^A, X^B)$
Consumption	Production	$X(K^X, L^X, Y^A)$
Consumption	Consumption and production	$U^A(X^A, Y^A, X^B)$ and $Y(K^Y, L^Y, X^B)$
Production	Consumption	$U^A(X^A, Y^A, X)$
Production	Production	$X(K^X, L^X, Y)$
Production	Consumption and production	$U^A(X^A, Y^A, Y)$ and $X(K^X, L^X, Y)$

Source: Authors own assumptions.

In the first row in Table 1, an example of a consumption externality is where agent B's consumption of commodity *X* is an argument in A's utility function – B's consumption of *X* affects the utility that A derives from given levels of consumption of *X* and *Y*. In the second row, A's consumption of *Y* is shown as affecting the production of *X*, for given levels of capital and labour input. The third row has B's consumption of *X* affecting both A's utility and the production of *Y*. In the fourth row the amount of *X* produced, as well as A's consumption of *X*, affects A's utility. The fifth row has the production of *Y* determining, for given capital and labour inputs, the amount of *X* produced. Finally, in the sixth row we have a situation where the level of *Y* affects both A's utility and the production of *X*.

The unintended impact that an external effect involves may be harmful or beneficial. As such, table 2 provides examples of both kinds. If an individual has a vaccination that protects them, which is their intention, it also has the unintended effect of reducing the probability that others will contract the disease.

Table 2: Beneficial and harmful externalities

Effect on others	Originating in consumption	Originating in production
Beneficial	Vaccination against an infectious disease	Pollination of blossom arising from proximity to apiary
Adverse	Noise pollution from radio playing in park	Chemical factory discharge of contaminated water into water systems

Source: Authors own assumptions.

An individual playing their radio loudly in the park inflicts suffering on others, though that is not their intention. In these two cases, the external effect originates in consumption and affects individuals. A beneficial externality originating in production, and impacting on production, is the case where a honey producer's bees pollinate a nearby fruit orchard. Pollution, in the bottom right cell, is a harmful externality which most usually originates in production activities. It can affect consumers, or producers, or both.

Another dimension according to which external effects can be classified is in terms of whether they have, or do not have, the public goods characteristics of non-rivalry and non-excludability. While external effects can have the characteristics of private goods, those that are most relevant for policy analysis exhibit non-rivalry and non-excludability. This is especially the case with external effects that involve the natural environment, which mainly involve pollution problems. Why this is the case will become clear in the analysis that follows here. All of the examples in Table 2 involve non-rivalry and non-excludability.

Externalities and Economic Efficiency

Externalities are a source of market failure. Given that all of the other institutional conditions for a pure market system to realise an efficient allocation hold [Guesnerie, 1989], if there is a beneficial externality the market will produce too little of it in relation to the requirements of allocative efficiency [Howarth, 2012; Bulearca and Popescu, 2019], while in the case of a harmful externality the market will produce more of it than efficiency requires. Since we are concerned with the application of welfare economics to environmental problems [O'Connell, 1982; Bernham, 2008; Feldman, 2008; Deardoff, 2014], and the main relevance of externalities there is in regard to environmental pollution, we shall look in any detail only at harmful externalities here.

We shall now produce an important example that concerns a harmful externality pollution problem. We will demonstrate that the market, in the absence of corrective policy, will 'over-supply' pollution by looking at three sorts of pollution problem – a consumer-to-consumer case, a producer-to-producer case, and a case where the unintended effect is from a producer to consumers. These three cases bring out all of the essential features of pollution as a market failure problem. In our demonstration we shall use diagrams and partial equilibrium analysis [Grandmont, 1977; Geankoplos, 1987; Black, 1995; Eaton *et al.*, 2009] to make the essential points (this analysis method may be reviewed in a previous paper [Bulearca and Popescu, 2019].

Evidence now suggests that the accumulation of tropospheric ozone in urban areas poses serious threats to human health, and also leads to agricultural crop damage in surrounding areas. Note that this accumulation of ozone in lower layers of the atmosphere is completely distinct from the destruction of the ozone layer in the earth's upper atmosphere (the stratosphere). The latter phenomenon – often known as 'holes in the ozone layer' – causes different problems (this issue will be largely addressed in a future work).

A major source of tropospheric ozone is road vehicle exhaust emissions. Because vehicle emissions have real effects on well-being through our utility and production functions, these emissions can be termed 'goods' (although it may be preferable to label them as 'bads' as the effects on utility are adverse). However, with no individual private property rights in clean air, in the absence of government intervention, no charge is made for such emissions. With no charges being made for damaging emissions, resources will not be allocated efficiently. An efficient allocation would involve lower exhaust emissions, implying one or more of: lower traffic volumes, change in fuel type used, increased engine efficiency, enhanced exhaust control.

How such objectives might be achieved is considered in this paper, and in more detail in a future paper, but it should be clear at this stage that one method would be through the use of a tax on the emissions that cause ozone accumulation [MacGillivray, 1994]. As such, an efficient emissions tax would impose a tax rate equal to the value of the marginal damage that would occur at the efficient level of emissions. In arriving at this conclusion, we do not explicitly consider the time dimension of pollution. But note that if ozone accumulates over time, and damage is dependent on the stock of ozone rather than the flow of emissions in any particular period, then we need to consider the accumulation of the

pollutant over time. As we shall demonstrate in a future work, where emission flows lead to accumulating stocks of pollutants, it may be efficient to impose a tax rate that rises over time.

Hence, before getting into these cases in a little detail, at this stage we can make a general intuitive point that covers both beneficial and harmful externalities. The basic problem with external effects follows directly from the definition in regard to un-intendedness and lack of payment/compensation. These two features of the externality problem are directly related. The lack of intentionality follows from the fact that the impact involved does not carry with it any recompense, in the case of a beneficial effect, or penalty, in the case of a harmful effect. External effects arise where an agent's actions affecting other agents do not involve any feedback – benefit is conferred which is not rewarded, or harm is done which is not punished.

Given the lack of reward/punishment, which in a market system would be signalled by monetary payment, an agent will not take any account of the effect concerned. It will be unintended and 'external' to their decision making. Where it is a beneficial effect, it will not be encouraged sufficiently, and there will not be enough of it. Where it is a harmful effect, it will not be discouraged sufficiently, and there will be too much of it. The key to dealing with the market failure that external effects give rise to, is to put in place the missing feedbacks, to create a system which does reward/punish the generation of beneficial/harmful effects, so that they are no longer unintentional.

Consumption–Consumption Externality

Suppose that A and B live in adjacent flats (apartments). A is a saxophone player, who enjoys practising a lot. B does not like music, and can hear A practising. The utility functions are:

$$U^A = U^A(M^A, S^A)$$

$$U^B = U^B(M^B, S^A)$$

where M represents wealth and S^A is the hours that A plays the saxophone each week, with $\partial U^A/\partial M^A > 0$, $\partial U^B/\partial M^B > 0$, $\partial U^A/\partial S^A > 0$ and $\partial U^B/\partial S^A < 0$.

In Figure 1 we show, as MB, the marginal benefit of playing to A, and, as MEC for marginal external cost, the marginal cost of playing to B. Marginal benefit is the amount that A would pay, if it were necessary, to play a little more. Conversely, MB is the amount of compensation that would be required to leave A as well off given a small reduction in playing. Marginal external cost is the amount that B would be willing to pay for a little less playing. Conversely, MEC is the amount of compensation that would be required to leave B as well off given a small increase in M (hours of A's saxophone playing).

Given that A does not in fact have to pay anything to play her saxophone in her flat, she will increase her hours of playing up to the level M_0, where MB is equal to zero. At that level, A's total benefit from playing is given by the sum of the areas of the triangles a, b and d, and B's total suffering is measured in money terms by the sum of the areas b, d and c.

Figure 1: The bargaining solution to an externality problem

This is not an efficient outcome, because at M_0, MEC > MB. The efficient outcome is at M^* where MEC = MB. At any M to the left of M^*, MB > MEC, so that for a small increase in M, A would be willing to pay more than would compensate B for that increase. At any M to the right of M^*, MEC > MB so that for a small decrease in M, B would

be willing to pay more for a small decrease in M than would be required to compensate A for that decrease. The inefficient level of saxophone playing at M_0 comes about because there are no payments in respect of variations in M, no market in M, so that the effect on B is unintentional on the part of A.

At the level of principle, the solution to this problem of inefficiency is fairly obvious. The problem is that A does not compensate B because B does not have any legal right to such compensation, does not have a property right [Bulearca and Popescu, 2019] in a domestic environment unpolluted by saxophone music. So, the solution is to establish such a property right, to give B the legal right to a domestic environment that is not noise polluted.

Such legal arrangements would support bargaining which would lead to M^* as the level of M. The argument that establishes that M^* would be the outcome under a legal regime where B can claim compensation from A exactly parallels the argument that establishes that M^* is the efficient outcome. To the left of M^*, with MB > MEC, A will be willing to pay more in compensation for a small increase in M than B requires, so will pay and play more. A will not increase M beyond M^* because the compensation that it would be necessary to pay B would be greater than the worth to A of the small increase thereby attained.

The Coase Theorem

The idea that, given a suitable assignment of property rights, private bargaining between individuals can correct externality problems and lead to efficient outcomes is generally attributed to the Nobel prize winning economist Ronald Coase, and the result discussed above is often referred to as the *'Coase theorem'* [Coase, 1960]. In fact, the result discussed above is only half of the Coase theorem. The other half says that an efficient outcome can also be attained by vesting the property right in the generator of the external effect. In that case, the generator would have the legal right to play, for this example, as much saxophone as she liked. The point is that given that right, it could be in the interests of the victim to offer money to the generator not to exercise their right to the full. Just as the absence of a clear property right vested in the victim inhibits one kind of bargaining, so does the absence of a clear property right vested in the generator inhibit another kind of bargaining.

Suppose then, that in our saxophone-playing example a law is passed saying that all saxophone players have an absolute right to practise up to the limits of their physical endurance. Legally A can play as much as she wants. But, a legal right can be traded. So, the opportunity now exists for A and B to bargain to a contract specifying the amount that A will actually play. That amount will be M^* in Figure 1. To the right of M^*, MEC > MB, so B's willingness to pay for a small reduction is greater than the compensation that A requires for that small reduction. Starting at M_0 and considering successive small reductions, B will be offering more than A requires until M^* is reached where B's offer will exactly match the least that A would accept. As such, A and B would not be able to agree on a level of M to the left of M^*, since there B's willingness to pay is less than A requires by way of compensation.

So, what the Coase theorem actually says is that given this kind of externality situation, due to incomplete private property rights, one solution involves creating property rights for either the victim or the generator, and that either assignment will lead to an efficient outcome. It needs to be explicitly and carefully noted here that there are two things that are not being claimed. First, that it is not being said that the outcome will be the same in both cases. Second, that it is not being said that either way of assigning property rights necessarily promotes equity.

In regard to the first point here, note that considering the move from M_0 to M^* in our saxophone music example consequent upon the establishment of the property right and the ensuing bargaining we have:

- For the case where B gets the property right – there is an M reduction of $(M_0 - M^*)$ and A pays B an amount equal to the area of triangle b, the money value of B's suffering at the efficient outcome M^*.
- For the case where A gets the property right – there is an M reduction of $(M_0 - M^*)$ and B pays A an amount equal to the area of triangle d, the money value of A's loss as compared with the no-property-rights situation.

Clearly, which way the property right is assigned affects the wealth of A or B. To be granted a new property right is to have one's potential monetary wealth increased. In case (a), B experiences less saxophone hours and an increase in wealth by virtue of a payment from A, so that A's wealth goes down with her pleasure from playing. In case (b), B experiences less saxophone hours and a decrease in wealth by virtue of a payment to A, who gets less pleasure from playing. As we have drawn Figure 1, in neither (a) nor (b) does the increase in wealth affect the receiving individual's tastes. In case (a), that is, B's willingness to pay for less music hours is not affected by becoming wealthier – the slope of the MEC line does not change. In case (b), A's willingness to pay for more music hours is not affected by becoming wealthier – the slope and position of the MB line do not change.

While these assumptions may be plausible in this example, they clearly are not generally appropriate. They were

imposed here to produce a simple and clear graphical representation. If the assumption that tastes are unaffected by wealth increases is dropped, then with the case (a) assignment MEC would shift and with the case (b) assignment MB would shift. In neither case then would M^* as shown in Figure 1 be the bargaining outcome, and the outcomes would be different in the two cases. Both outcomes would be efficient, because in both cases we would have MB = MEC, but they would involve different levels of M.

So, the first point is that the Coase theorem properly understood says that there will be an efficient outcome under either assignment of property rights, not that there will be the same efficient outcome under either assignment. The second point, concerning equity, is simply that there is no implication that either assignment will have any desirable implications in terms of equity. This follows directly from our earlier discussions of the relationship between optimality and efficiency [Bulearca and Popescu, 2019]. In the case of our saxophone example, we have said nothing about the initial wealth/income situations of the two individuals.

Clearly, our views on which way the property right should be assigned will, unless we are totally uninterested in equity, be affected by the wealth/income of the two individuals. Given that efficiency criteria do not discriminate between the two possible assignments of property rights, it might seem natural to take the view that the assignment should be on the basis of equity considerations. Unfortunately, this does not lead to any generally applicable rules. It is not always the case that externality sufferers are relatively poor and generators relatively rich, or vice versa.

Even if we confine attention to a particular class of nuisance, such as saxophone playing in flats, it cannot be presumed that sufferers deserve, on equity grounds, to get the property right – some may be poor in relation to their neighbour and some rich. Given the simple and compelling logic of the arguments of the Coase theorem, the question arises as to why uncorrected externalities are a problem. If they exist by virtue of poorly defined property rights and can be solved by the assignment of clearly defined property rights, why have legislatures not acted to deal with externality problems by assigning property rights? A full answer to this question would be well beyond the scope of this paper, but the following points are worthy of note.

First, as we have seen, the case for property rights solutions is entirely an efficiency case. Legislators do not give efficiency criteria the weight that economists do – they are interested in all sorts of other criteria.

Second, even given clearly defined property rights, bargaining is costly. The costs increase with the number of participants. While expositions of the Coase theorem deal with small numbers of generators and sufferers, typically one of each, externality problems that are matters for serious policy concern generally involve many generators and/or many sufferers, and are often such that it is difficult and expensive to relate one particular agent's suffering to another particular agent's action. This makes bargaining expensive, even if the necessary property rights exist in law. The costs of bargaining, or more generally 'transactions costs', may be so great as to make bargaining infeasible.

Third, even leaving aside the large numbers problem, in many cases of interest the externality has 'public bad' characteristics which preclude bargaining as a solution. 'Public bad' is a term often used for a public good that confers negative, rather than positive, utility on those who consume it. As such, in the remaining part of this paper we shall discuss this last point in the context of producer-to-consumer externalities.

Production–Production Externality

For situations where numbers are small, this case can be dealt with rather quickly. Consider two firms with production functions:

$$X = X(K^X, L^X, S)$$

$$Y = Y(K^Y, L^Y, S)$$

where S stands for pollutant emissions arising in the production of Y, which emissions affect the output of X for given levels of K and L input there. As an example, Y is paper produced in a mill which discharges effluent S into a river upstream from a laundry which extracts water from the river to produce clean linen, X. Then, the assumption is that $\partial Y/\partial S > 0$, so that for given levels of K^Y and L^Y lower S emissions means lower Y output, and that $\partial X/\partial S < 0$, so that for given levels of K^X and L^X higher S means lower X.

Note that we are guilty here of something that we cautioned against in a previous paper [Neagu *et al.*, 2019] in our discussion of the materials balance principle – writing a production function in which there is a material output, S, for which no material input basis is given. We do this in the interests of simplicity. A more appropriate production function specification may be given to show that the essential point for present purposes is not affected by our shortcut

in the interests of simplicity. As such, a more satisfactory production function for the polluting firm would be:

$$Y = Y(K^Y, L^Y, R^Y, S\{R^Y\})$$

where R^Y is the input of some material, say tonnes of coal, and $S\{R^Y\}$ maps coal burned into emissions, of say smoke, and $\partial Y/\partial R^Y = Y_R > 0$, $\partial Y/\partial S = Y_S > 0$ and $\partial S/\partial R^Y = SR^Y > 0$. We shall now show that while this more plausible model specification complicates the story a little, it does not alter the essential message.

This externality situation is amenable to exactly the same kind of treatment as the consumer-to-consumer case just considered. Property rights could be assigned to the downstream sufferer or to the upstream generator. Bargaining could then, in either case, produce an efficient outcome. To see this simply requires the reinterpretation and relabelling of the horizontal axis in Figure 1-5.13 so that it refers to S, with S_0 replacing M_0 and S^* replacing M^*.

For profits in the production of X we have:

$$\pi^X = P_X X(K^X, L^X, S) - P_K K^X - P_L L^X$$

where $\partial \pi^X/\partial S < 0$.

The impact of a small increase in S on profits in the production of X is, in the terminology of Figure 1, marginal external cost, MEC.

For profits in the production of Y we have:

$$\pi^Y = P_X Y(K^Y, L^Y, S) - P_K K^Y - P_L L^Y$$

where $\partial \pi^Y/\partial S > 0$.

The impact of a small increase in S on profits in the production of Y is, in the terminology of Figure 1, marginal benefit, MB.

With these reinterpretations, the previous analysis using Figure 1 applies to the producer-to-producer case – in the absence of a well-defined property right S will be too large for efficiency, while an efficient outcome can result from bargaining based on a property right assigned to either the producer of X or the producer of Y.

An alternative way of internalising the externality would be to have the firms collude so as to maximise their joint profits, thus this would produce an efficient outcome. The matter is, however, quite intuitive. The externality arises because the Y producer does not take account of the effects of its actions on the output for given inputs of the X producer. If the Y producer chooses its levels of K^Y, L^Y and S in the light of the consequences for the output of X for given K^X and L^X, and hence on the profits arising in the production of X, then those consequences will not be unintended.

On the contrary, the two firms will be operated as if they were a single firm producing two commodities. We know that a single firm producing a single commodity will behave as required for efficiency, given all of the ideal conditions. All that is being said now is that this result carries over to a firm producing two commodities. For the firm that is producing both X and Y the ideal conditions do apply, as there is no impact on its activities the level of which is unintentionally set by others.

While joint profit maximisation can internalise an externality as required for efficiency, there appear to be few, if any, recorded instances of firms colluding, or merging, so as to internalise a pollution externality. Collusion to maximise joint profits will only occur if both firms believe that their share of maximised joint profits will be larger than the profits earned separately. There is, in general, no reason to suppose that cases where there is the prospect of both firms making higher profits with collusion will coincide with circumstances where there is a recognised inter-firm pollution externality.

Production–Consumption Externality

The key feature of the case to be considered now is that the external effect impact on two agents, and with respect to them is non-rival and non-excludable in consumption. As is the case generally in this paper, 'two' is a convenient way of looking at 'many' – the two case brings out all the essential features of the many case while simplifying the notation and the analysis. Putting this key feature in the context of the production-to-consumption case aligns with

the perceived nature of the pollution problems seen as most relevant to policy determination. These are typically seen as being situations where emissions arising in production adversely affect individuals in ways that are non-rival and non-excludable.

So, in terms of our two-person, two-commodity economy we assume that:

$$U^A = U^A(X^A, Y^A, S) \text{ with } \partial U^A/\partial S < 0$$

$$U^B = U^B(X^B, Y^B, S) \text{ with } \partial U^B/\partial S < 0$$

$$X = X(K^X, L^X)$$

$$Y = Y(K^Y, L^Y, S) \text{ with } \partial Y/\partial S > 0$$

Emissions arise in the production of Y and adversely affect the utilities of A and B. The pollution experienced by A and B is non-rival and non-excludable. A concrete example, bearing in mind that 'two' stands for 'many', would be a fossil-fuel-burning electricity plant located in an urban area. Its emissions pollute the urban airshed, and, to a first approximation, all who live within the affected area experience the same level of atmospheric pollution.

Given our earlier discussion of the supply of public goods, we can immediately conclude here that private bargaining based on some assignment of property rights will not deal with the externality problem. And, the joint profit maximisation solution is not relevant. In this kind of situation, correcting the market failure requires some kind of ongoing intervention in the workings of the market by some government agency. As we shall consider at some length and in some detail in a future paper, there is a range of means of intervention that the government agency, call it an environmental protection agency (noted as Agency), could use. Here, we shall just look at the use of taxation by the Agency, so as to bring out the essential features of the situation where the externality has the characteristics of a public bad. Here we shall use partial equilibrium analysis based on Figure 2.

Figure 2: Taxation for externality correction

It introduces some new terminology. PMC stands for private marginal cost. Private costs are the input costs that the Y producer actually takes account of in determining its profit-maximising output level, that is:

$$C = P_K K^Y + P_L L^Y = C(Y)$$

so that PMC = $\partial C/\partial Y$.

We introduced the idea of MEC (marginal external cost) in considering the consumer-to-consumer case, as the amount that the sufferer would be willing to pay to reduce suffering by a small amount. In the present case there are two sufferers and MEC is the sum of the willingness to pay of each of them, as consumption of suffering is non-rival and non-excludable. We define social marginal cost as:

$$SMC = PMC + MEC$$

Figure 2 shows PMC increasing with *Y* in the usual way. The SMC line has a steeper slope than the PMC line, so that MEC is increasing with *Y* – as *Y* production increases, *S* output increases. To maximise profit, the *Y* firm will produce at Y_0, where PMC is equal to the output price P_Y. This is not the *Y* output that goes with efficiency, as in balancing costs and benefits at the margin it is ignoring the costs borne by A and B. Efficiency requires the balancing at the margin of benefits and costs which include the external costs borne by A and B. The efficient output level for *Y* is, that is, *Y** where SMC equals P_Y. In the absence of any correction of the market failure that is the external costs imposed on A and B, the market-determined level of *Y* output will be too high for efficiency, as will the corresponding level of *S*.

To correct this market failure the Agency can tax *S* at a suitable rate. In Figure 2, we show a line labelled PMCT, which stands for private marginal cost with the tax in place. This line shows how the *Y* firm's marginal costs behave given that the Agency is taxing *S* at the appropriate rate. As shown in Figure 2-5.14, the appropriate tax rate is:

$$t = SMC^* - PMC^* = MEC^* \tag{1}$$

that is, the tax needs to be equal to marginal external cost at the efficient levels of *Y* and *S*. As such, we may show that another way of stating this is:

$$t = P_X \left[MRUS_{XS}^{A} + MRUS_{XS}^{B} \right] \tag{2}$$

Comparing equations (1) and (2), we are saying that:

$$MEC^* = P_X \left[MRUS_{XS}^{A} + MRUS_{XS}^{B} \right] \tag{3}$$

This makes a lot of sense. Recall that MRUS stands for marginal rate of utility substitution [Bulearca and Popescu, 2019]. The *XS* subscripts indicate that it is the MRUS for commodity *X* and pollution *S* that is involved here. Recall also that the MRUS gives the amount of the increase in, in this case, *X* that would keep utility constant in the face of a small increase in *S*. Equation (3) says that MEC* is the monetary value of the extra consumption of commodity *X* by A and B that would be required to compensate them both for a small increase in *S*, from the efficient level of *S*. In saying this we are choosing to use the commodity *X* as the compensation vehicle. We could equally well have chosen the commodity *Y* for this purpose and derived:

$$t = P_Y \left[MRUS_{YS}^{A} + MRUS_{YS}^{B} \right] \tag{4}$$

and

$$MEC^* = P_Y \left[MRUS_{YS}^{A} + MRUS_{YS}^{B} \right] \tag{5}$$

Taxation at the rate MEC* is required to bring about efficiency. Note that the tax rate required is not MEC at Y_0, is not MEC in the uncorrected situation. In order to be able to impose taxation of emissions at the required rate, the Agency would need to be able to identify *Y**. Given that prior to the Agency intervention what is actually happening is Y_0, identification of Y* and calculation of the corresponding MEC* would require that the Agency knew how MEC varied with S, i.e. knew the utility functions of A and B. It is in the nature of the case that this information is not revealed in markets. The problems of preference revelation in regard to public goods were discussed above.

Clearly, those problems carry over to public bads such as pollution. The implications of this for feasible policy in respect of pollution control by taxation shall be discussed in a future paper.

Finally here we should note that the basic nature of the result derived here for the case where just one production activity gives rise to the emissions of concern carries over to the case where the emissions arise in more than one

production activity. Consider a two-person, two-commodity economy where:

$$U^A = U^A(X^A, Y^A, S) \text{ with } \partial U^A/\partial S < 0$$

$$U^B = U^B(X^B, Y^B, S) \text{ with } \partial U^B/\partial S < 0$$

$$X = X(K^X, L^X, S^X) \text{ with } \partial S/\partial S^X > 0$$

$$Y = Y(K^Y, L^Y, S^Y) \text{ with } \partial Y/\partial S^Y > 0$$

$$S = S^X + S^Y$$

Both production activities involve emissions of *S*, and both individuals are adversely affected by the total amount of *S* emissions. In this case, efficiency requires that emissions from both sources be taxed at the same rate, t = MEC*.

Conclusions

As this paper is part of a larger research that deals with sustainable development and environmental protection in extractive industry, in this article we identified the relationship existing between externalities and economic efficiency in terms of market failure. An external effect, or an externality, is said to occur when the production or consumption decisions of one agent have an impact on the utility or profit of another agent in an unintended way, and when no compensation/payment is made by the generator of the impact to the affected party.

As demonstrated, there is something in this because we preferred the definition given here as it calls attention to the fact that lack of compensation/payment is a key feature of externality as a policy problem. Hence, policy solutions to externality problems always involve introducing some kind of compensation/payment so as to remove the unintentionality, though it has to be said that the compensation/payment does not necessarily go to/come from the affected agent.

While in our previous analysis we have excluded the existence of externalities by the assumptions that were made about the utility and production functions, in practice consumption and production behaviour by some agents does affect, in uncompensated/unpaid for ways, the utility gained by other consumers and the output produced, and profit realised, by other producers. Economic behaviour does, in fact, involve external effects. The stated definition of an external effect is not perhaps very illuminating as to what exactly is involved. The two key things to keep in mind are that we are interested in effects from one agent to another which are unintended, and where there is no compensation, in respect of a harmful effect, or payment, in respect of a beneficial effect.

We began our analysis of externalities by discussing the forms that externalities can take in terms of consumption and production. As such, external effects can, first, be classified according to what sort of economic activity they originate in and what sort of economic activity they impact on. Given two sorts of economic activity, consumption and production, in this paper we were concerned only to set out the forms that unintended interdependence between agents could take.

Another dimension according to which external effects can be classified is in terms of whether they have, or do not have, the public goods characteristics of non-rivalry and non-excludability. While external effects can have the characteristics of private goods, those that are most relevant for policy analysis exhibit non-rivalry and non-excludability. This is especially the case with external effects that involve the natural environment, which mainly involve pollution problems.

Externalities are a source of market failure. Given that all of the other institutional conditions for a pure market system to realise an efficient allocation hold, if there is a beneficial externality the market will produce too little of it in relation to the requirements of allocative efficiency, while in the case of a harmful externality the market will produce more of it than efficiency requires. Since we are concerned with the application of welfare economics to environmental problems, and the main relevance of externalities there is in regard to environmental pollution, in our analysis we focussed only at harmful externalities.

As such, where it is a harmful effect, it will not be discouraged sufficiently, and there will be too much of it. Therefore, the key to dealing with the market failure that external effects give rise to, is to put in place the missing feedbacks, to create a system which does reward/punish the generation of beneficial/harmful effects, so that they are no longer unintentional. The idea that, given a suitable assignment of property rights, private bargaining between individuals

can correct externality problems and lead to efficient outcomes is often referred to as the 'Coase theorem'.

So, what the Coase theorem actually says is that given this kind of externality situation, due to incomplete private property rights, one solution involves creating property rights for either the victim or the generator, and that either assignment will lead to an efficient outcome. As we demonstrated in this paper, there are two things that are not being claimed: first, that the outcome will be the same in both cases; and second, that either way of assigning property rights necessarily promotes equity.

Given the simple and compelling logic of the arguments of the Coase theorem, the question arises as to why uncorrected externalities are a problem. If they exist by virtue of poorly defined property rights and can be solved by the assignment of clearly defined property rights, why have legislatures not acted to deal with externality problems by assigning property rights? A full answer to this question would be well beyond the scope of this paper, but the following points are worthy of note.

First, as we have seen, the case for property rights solutions is entirely an efficiency case. Second, even given clearly defined property rights, bargaining is costly; the costs increase with the number of participants, as the costs of bargaining, or more generally 'transactions costs', may be so great as to make bargaining infeasible. And third, even leaving aside the large numbers problem, in many cases of interest the externality has 'public bad' characteristics which preclude bargaining as a solution. 'Public bad' is a term often used for a public good that confers negative, rather than positive, utility on those who consume it.

Hence, in the remaining part this paper discussed this last point in the context of producer-to-consumer externalities analysis through consumption-consumption externality, production-production externality and production-consumption externality, all considered to be essential features of pollution as a market failure problem.

In our discussion of market failure thus far we have assumed that just one of the ideal conditions required for markets to achieve efficiency is not satisfied. Based on the main findings of this paper, our future works will address issues regarding the second-best theorem that welfare economics implies in discussing harmful externalities generated by firms, meaning a package of government interventions that do the best that can be done given that not all sources of market failure can be corrected.

Finally, as many of the services that the environment provides involve some kind of market failure, the levels of provision in a market system will not be those corresponding to allocative efficiency. Much of resource and environmental economics is about devising ways to intervene in the market system so as to promote efficiency in the use of environmental services. In our next papers we shall look at the problem of pollution, building on our previous researches of that problem under the externality issue.

Restructuring of Energy Sector Enterprises as An Emitter of Environmental Pollutants in The Face of New Ecological Standards

Renata ŻABA-NIERODA

Department of Finance for Sustainable Development
Cracow University of Economics, Cracow, Poland
E-mail address: zabar@uek.krakow.pl

Abstract

An attempt was made to present the plant as a company producing significant amounts of particulates, CO2, SO2 and NO2. The guidelines for the size of these pollutants for the power industry have been stricter and will be even more stringent. The need to adapt to standards that will be reflected in standards will increase the amount and cost of implementing environmental standards. Power plants have been struggling to adapt to environmental requirements in the past, with further constraints requiring substantial investment to meet growing environmental requirements. Ecological standards reduced to pollutant emission standards were very difficult to achieve. In the future, severe emission standards will be even more severe for the power industry. The ways to adapt to the standards can be different forms of power plant activity. This will require increased investment.

Keywords: Pollution, Ecological Standard, Power Plant, Power Industry.

Introduction

The civilizational development of the world is connected with an increase in energy consumption for the developing industry, construction, transport, communications, agriculture, trade and service networks, and the growing social needs of the population. The needs of the economy and the inhabitants for energy are met mainly by the energy sector. The European Union's policy on environmental protection is assessed as restrictive. The defined ecological goals are socially desirable quality standards in terms of the condition of the basic components of the natural environment that should be provided by power plants. Numerous and rigorous ecological standards for the power sector in the form of European Union directives must be implemented. Polish power companies are taking adjustments in this area. The adaptation of the Polish power industry to the more stringent ecological requirements has a large impact on the formation of electricity prices. There will also be differences in the prices of energy offered by individual producers. The costs of implementing EU directives vary for different manufacturers, depending on the scope of modernization and carried out by them in previous years.

The aim of the article is to present new ecological standards applicable to Polish power plants and ways of adapting power plants to more and more stringent environmental requirements. A crisis situation occurs both in an enterprise struggling with maintaining financial liquidity and in an entity that has so far functioned as healthy, but the environment has fallen ill. Thus, crisis factors occur inside the enterprise - they are endogenous factors, but also outside - exogenous factors (independent of the individual). Management is making decisions, what to change to make it better? - and therefore - change or what and how to restructure? Restructuring is most often associated with a bad situation that threatens to go bankrupt. This is a corrective restructuring. But it should be remembered that there is also development restructuring. It involves introducing changes at every stage of the company's life - not only when the entity loses liquidity and begins to fall into crisis. Each change should be a change for the better, it should have the features of development restructuring, the types of which are very different.

The common feature of the definitions of restructuring contained in the literature is that all authors agree that it is a change, and the change is thorough (radical), covering important areas of economic activity. In the literature, restructuring is defined in many different ways due to the variety of areas of changes that may concern: the economic system of the state, its individual sectors, regions or specific enterprises or their groupings. However, all these definitions have a certain point of contact - that is the purpose of change. This goal is to improve the rationality and

efficiency of resource and production factor management, giving the economic structure the features of modernity, flexibility, innovation and adaptability.

The essence and systematization of environmental protection standards

In the economic theory and practice of environmental protection policy, there are two basic groups of methods for regulating environmental protection activities [Fiedor et al. 2002, p. 280]:

- direct (direct coercion), administrative and legal methods, based mainly on technological standards (norms) of permissible levels of pollutant emission, these are orders or prohibitions regulating the manner (intensity) of using environmental resources,
- indirect (indirect coercion), economic and market methods, based mainly on the theoretical premise, leading, through appropriate legal, institutional and economic solutions, to internalization of the negative effects of production (consumption) activities, which may reduce the social costs of achieving the desired level of pollution.

Business entities are regulated by direct methods - standards. A standard is a commonly agreed criterion that determines the common, usually most desirable characteristics of something, such as a manufactured object or human behavior. The standard is also called the basic, simplest version of the product. In a technique, a standard is a set of parameters, usually with a name, that provides the appropriate level of quality, safety, comfort or compatibility with other products. Standards can be defined as a typical value of any variable that characterizes the behavior of an economic system [Kornai 1983], they constitute the average value of a variable of the analyzed system. The standards are useful in situations where there is a risk of irreversible changes in the environment, they can be regarded as effective preventive measures. There are four categories of standards [Folmer, Gabel, Opschoor 1996, p. 222]: immission, emission, technical, product.

Immission standards characterize the desired state of the environment and constitute ecological goals. It is an acceptable level of concentration of pollutants in the environment (immission) or an acceptable dose of these pollutants for humans, fauna and flora, or for environmentally noxious interactions. They are to ensure health, ecological safety and an adequate standard of living. Defining the limits of interference in the environment limits economic losses and ecological externalities [Famielec 1999, p. 32]. Environmental quality standards are requirements that must be met in a given time by the environment as a whole or its individual natural elements [Act of 27 April 2001]. In the Polish legal system, the immission standards have been regulated for: atmospheric air, surface water, soil, noise.

Emission standards may be introduced in the form of a legal act, binding throughout the country, or in the form of an administrative act that applies to a specific economic entity (the sum of standards for individual entities may not exceed the standards applicable in a given area). They take the form of emission limit values. Emission was defined by the Environmental Protection Act [Act of 27 April 2001] as introduced directly or indirectly, as a result of human activity, into the air, water, soil or soil: substances, energy, such as heat, noise, vibration or electromagnetic fields . The amount of emission is understood as the type and amount of substances or energy released into the environment at a given time, as well as the concentration or levels of substances or energy, in particular in waste gases, introduced sewage and generated waste. [Act of April 27, 2001].

The emission standards are the emission limit values specified in the Regulation of the Minister of the Environment [Regulation of the Minister of the Environment of 4 November 2014] and are binding standards. On their basis, the emission limit values for installations are determined. The emission limit values are such additional emission standards that may not be exceeded by installations requiring an integrated permit.

Substances are chemical elements and their compounds, mixtures or solutions occurring in the environment or resulting from human activity. Pollution is an emission that may be harmful to human health or the state of the environment, may cause damage to material goods, deteriorate the aesthetic value of the environment or interfere with other, justified ways of using the environment. Emission is a broader concept than pollution. This definition differs from the common understanding of the term issue. It means a substance or energy introduced into any component of the environment, and not the phenomenon of introducing them into the environment. Emission is often identified primarily with air pollution, while, according to the definition of environmental law, emissions are also waste or sewage discharged into the environment. This interpretation and definition is of fundamental importance for environmental legislation, as it always defines emission limit values and not pollutants in the permit.

Technical standards define the type of production process or abatement equipment that the polluter plant has to install (e.g. a specific type of scrubber, stack or water purification). The condition for their determination concerns the technological possibilities of complying with the standard (otherwise, they cannot be enforced). The expression of feasibility is the concept of the best BAT technology achieved (Best Available Technlogy) or a best possible technique

that is not excessively expensive BATNEEC (Best Available Techniques Not Entailing Excessive Costs). Technological conditions can be used in the process of defining norms (standards) in several ways based on technologies:

- existing, used and generally available,
- the best achievable (BAT or BATNEEC), available only to some entities - their dissemination requires additional investment or organizational effort,
- at the experimental stage.

The standard is set as the desired level, but achieving it requires undertaking technological research. It is used when the available technology does not guarantee the appropriate quality of the environment. Government agendas impose standards on companies and leave time for them to achieve them through technological adjustments. For many enterprises, regulations of this type will pose a specific threat to their development and as such will become a motivation to take appropriate actions [Kobyłko (ed.) 2000, p. 17]. Technological considerations mean adapting the standards to the best available technique. In this regard, a solution can be selected from among five possible standards. These standards are [Górka ((ed.) 1999, p. 45]:

- average,
- model,
- experimental,
- not having the appropriate technology,
- economically sensible.

Technology-based standards are not free from flaws and ambiguities resulting from the failure to adapt technological progress to development, the imbalance between the stability of industry operating conditions and technological innovations, and the emergence of different technological and financial incentives. It is necessary to adjust standards and other regulations to the evolution of the technology of increasing the requirements of the social environment (as to the quality of the natural environment). They should favor the development of technology and respond to innovation.

Product standards define the features of potentially polluting products that have a negative impact on the natural environment or its individual components. They define the permissible content of ecologically hazardous substances in a given product, as well as the permissible levels of impurities that may arise when using a given product. Product standards include technological standards used in the power industry and relating to the requirement to use specific materials and raw materials. They define the minimum level of energy efficiency of various primary energy carriers (sometimes they have a rather specific form of an indicator, such as: maximum emission of a given gaseous or dust pollutant per one gigajoule of energy generated with the use of a specific energy fuel).

The standards system is associated with legal and administrative permits (licenses) for the use of specific environmental resources or the pollution of its individual components. These are: administrative decisions (planning and regulatory), concessions, licenses, permits, consents [Fiedor et al. 2002, p. 285].

Planning decisions concern building conditions and land development, and regulatory decisions concern the scope of permitted but harmful use of the natural environment (e.g. water-legal permits for special use of water or the permissible amount and type of pollutant emission). Administrative acts also include decisions on imposing fines for violating environmental protection requirements and decisions on temporary suspension of operations.

The standards are combined with do's and don'ts (including the choice of technology) and environmental recommendations. The orders force subjects to certain behaviors, most often they concern the choice of the type of technology, cleaning or production device. The bans define which solutions cannot be applied or which activities cannot be undertaken. Theoretically, these instruments are characterized by a very low degree of environmental risk, but the costs of controlling their compliance are high (transaction costs). Ecological recommendations are of a different nature, as well as tips about the possibilities of a given entity if it wants to improve the sphere of ecological and economic activity or contribute to the implementation of a specific ecological goal. They are used in the ecological policy of the European Union countries in connection with the increase in environmental awareness, favoring the implementation of recommendations in practice, and acceptance of proposals by economic entities caring for their ecological image. The application of ecological recommendations may be connected with the use of a specific non-monetary and non-fiscal instrument of moral pressure, the existence of which, with the ecological awareness of the society, makes recommendations an effective instrument of environmental protection policy. Effective management

of a company is impossible without taking into account the aspects of environmental protection [Mikołajczyk (ed.) 2006, p. 26]. Nowadays, enterprises not only eliminate the damage caused to the environment, but most of all they implement pro-ecological activities [Burzyńska, Fila 2007, p. 39].

Ecological standards in selected power plants may be achieved by such groups of investment and organisational enterprises as liquidation of the existing sources, abandoning or reducing energy production, modernisation of the existing sources with various applicable technologies, building new sources of energy production with various technologies limiting emission of pollution into air (eco-innovative solutions in this respect), application of new types of raw materials for energy production, emission trading [Żaba-Nieroda 2011, s. 180]. The identified methods and enterprises of implementation of ecological standards in the electrical power engineering sector have been grouped into 6 blocks and all of them result in financial consequences typical of operational, financial and investment activities. The consequences of protection activities are not directly isolated and apparent in the accounting and financial reporting of companies. Work is still in progress on creating the so-called ecological accounting, initiated, among others, by the Ministry of Environment and the Ministry of Economy [Famielec J., Stępień M, 2005, p. 52]. They allow naming and measuring financial consequences of protection activities, including implementation of ecological standards. Typical financial categories related to ecological enterprises include: investment expenditures (expenses) and the resulting assets, current costs (expenses), proceeds from sales, equity, obligations (as a source of financing).

The natural environment as an element of power plant operations

The natural environment is an indispensable element of every human activity. The resources and forces of the environment are used as production factors, it creates the conditions for production activity and consumption. The use of the environment should be carried out in a way that allows to maximize the net benefits of economic development while protecting and ensuring the recovery of the usefulness and quality of natural resources in the long term.

Depletion of natural resources and reduction of resilience and the ability to regenerate the environment must affect the results and conditions of running a business, and in the long term it leads to a serious limitation of the development opportunities of future generations [Kryk 2003, p.15].

The state's ecological policy and actions for sustainable consumption and production take into account two principles:

1. The polluter pays principle - meaning placing full responsibility, including material responsibility, for the effects of pollution and other threats to the environment on individuals using environmental resources. This rule also applies to the nuisance caused by the consumption process, especially when the consumer has the option to choose consumer goods that are less harmful to the environment.
2. The principle of prevention - assuming that counteracting the negative effects on the environment should be undertaken at the stage of planning and implementation of projects based on the possessed knowledge, implementation of the procedure of environmental impact assessment and monitoring of ongoing projects. This means that when choosing preventive measures and methods of eliminating the effects of specific processes or events, as well as the distribution of available resources for environmental protection, preferences will be given to activities that will prevent pollution, develop recycling, and enable an integrated approach to reducing and eliminating pollution and threats. and will favor the introduction of pro-environmental systems for managing production processes and services.

In the production of electricity, the emission of air pollutants is particularly burdensome for the environment, mainly concerning combustion of fuels in conventional fuel power plants (hard coal and lignite, heating oil, natural gas). Due to the amount of emissions and their nuisance, the most important emissions are: SOx, NOx, CO2 and dust [CIE ZE 1997].

Data on these emissions from individual production technologies are presented in Table 1. Dust from fuel and waste landfills is an additional source of pollution. Ashes intensively dusty during unloading and handling (when they are not yet compacted) and ashes stored in dry, above-level landfills. The emission of ashes from the surface of furnace waste dumps may exceed 10 Mg per year from 1 ha of the landfill [Kucowski, Laudyn, Przekwas 1993, p. 285].

Table 1: Average emissions of pollutants from conventional fuel power plants in the world

Type of fuel	Air emissions			
	SO_x	NO_x	Dusts	CO_2
	[1000 Mg/Gwe] rocznie			
Carbon (3% content) sulfur				
Conventional boilers				
- no emission reduction	205	32	252	8013
- with emission reduction	23	23	1	-
Fluidized bed boilers with dust extraction	38	10	3	-
Lignite (0.6% sulfur content)				
- no emission reduction	54	44	284	8393
- - with emission reduction	16	23	1	-
Heating oil				
- no emission reduction	84	28	6	6577
- - with emission reduction	9	14	0,4	-
Natural gas - no emission reduction	0,02	25	0,3	4461

Source: Own study based on: [Graczyk 2005, s.102].

The amount of pollutant emission depends on a number of factors, mainly [Kamiński 2006, p. 98]:

- type and quality of fuel: content of chemically pure coal, sulfur, nitrogen and mineral substances, calorific value,
- type of technology: type of installation (conventional boilers, fluidized bed boilers, industrial furnaces, turbines, gas etc.),
- type and location of the burner, size and age of the device as well as its technical condition, etc.,
- operating conditions: excess temperature load, excess air, admixtures, emission abatement method used.

This paper focuses on the standards for air pollution caused by the power industry. Compliance with the standards requires the reduction of gas and dust emissions, in particular SO2, NOx and CO2 gases, the development of energy generation in renewable sources and the development of combined heat and power generation, which allows for obtaining electricity with significant energy savings in primary fuel. Actions in this area force the creation of restructuring solutions in power plants, but also in the entire sector.

Ecological Standards and The Need to Restructure Power Plants

Poland has relatively large reserves of solid fuels (hard coal and lignite), small reserves of natural gas, scarce oil reserves. Renewable energy sources are dominated by biomass and geothermal water energy. Poland has no uranium ores with a significant concentration of this element, whereas significant amounts of uranium are in diffused form [Soliński 2012, p. 62]. Electricity is mainly produced by professional thermal coal- and lignite-fired power plants. Some of the electricity comes from industrial power plants and gas-fired power plants. Hydroelectric power plants, wind turbines, biomass-fuelled power plants and biogas combustion plants play an inconsiderable part in the generation of electricity. An analysis of the data presented in Figure 1 shows that primary energy consumption decreased during the period under examination. Energy consumption decreased in the first analysis period until 1995, only to increase in the following year and decrease again.[Famielec, Kijanka Żaba-Nieroda 2019, 13] The increase in energy consumption is visible in 2010 and 2011 followed by a further decrease in energy consumption.

Fig. 1: The dynamics of primary energy consumption in Poland in 1990-2015 (1990 = 100)

Source: Compilation and own calculations based on the IEA statistical base.

The structure of primary energy consumption also changed during the period under examination. The main source of final energy in the period analyzed was coal and crude oil. Since the beginning of the 1990s, the share of coal had systematically decreased and the share of consumption of oil, natural gas and renewable energy had increased. Figure 2 shows the structure of primary energy consumption in 1990 and 2015.

Fig. 2: The structure of primary energy carrier consumption in the year a) 1990 and b) 2015

Source: Own compilation based on the IEA statistical base.

The key ecological environmental policy objectives have been curtailed to a reduction of CO_2 emissions by 2020 as compared to 1990. Table 2 presents the EU Member States' greenhouse gas emission reduction targets by 2030.

Table 2: The EU Member States' greenhouse gas emission reduction targets by 2030

Grounds for setting the target	Target year of reduction	EU Member States' greenhouse gas emission reduction targets	Achieved CO_2 emission reduction targets in the period under examination a. actual b. on the basis of an annual average target
Kyoto Protocol to the United Nations Framework Convention on Climate Change	up to 2012	by 6% compared* to the 1990 level	for 2012 a. - 15.55 % b. - 6.00%
European Union climate and energy packet – 3x20	up to 2020	by 20% compared** to the 1990 level	for 2015 a. - 16. 83% b. - 16.6 %

Climate and energy policies up to 2030	up to 2030	by 40% compared to the 1990 level	for 2015 a. - 16.83% b.- 25.0 %

As shown in Table 2, Poland has met the guidelines contained in the Kyoto Protocol and the measures taken to reduce greenhouse gas emissions in the field of CO_2 have been implemented above the assumed limits. The action programme for all EU countries, called the climate and energy package, or 3x20% by 2020, endorsed by the European Council in March 2007 and implemented in April 2009, set out three key objectives, which were, at the same time, the objectives of the Europe 2020 strategy for smart, sustainable and inclusive growth [Famielec, Kijanka Żaba-Nieroda 2019, p. 16]:

1. Reducing greenhouse gas emissions in the European Union by 20% by 2020 compared to the 1990 levels.
2. Increasing the share of renewable energy to 20% of final gross energy consumption in the European Union in 2020.
3. Increasing energy efficiency in the Union by 20% as compared to forecasts for 2020, as well as increasing the share of biofuels in total transport fuel consumption to 10% by 2020.

As part of the climate and energy policy up to 2030, adopted by national leaders in October 2014, the EU is in pursuit of three main objectives, which include:

1. Reduction by at least 40% of greenhouse gas emissions as compared to the 1990 levels.
2. Ensuring that at least a 27% share of renewable energy sources in total energy consumption is achieved.
3. At least a 27% increase in energy efficiency.

By achieving the first of these objectives, the European Union will be able to undertake cost-effective measures to attain the long-term goal of reducing emissions by 80-95% by 2050 in the context of the necessary reductions that should be achieved collectively by the developed countries, and to provide a fair and ambitious contribution to reaching the Paris Agreement.

However, in order for it to be implemented, the sectors covered by the EU Emissions Trading Scheme would have to reduce emissions by 43% compared to the 2005 levels, which necessitates the reform and strengthening of the ETS; sectors not covered by this scheme would have to reduce emissions by 30% as compared to the 2005 level, which requires the setting of individual binding targets for individual Member States.

The European Commission is seeking cost-effective ways to make the European economy more climate-friendly and more energy-efficient. The improvement of energy efficiency is perceived as the most cost-effective way of reducing greenhouse gas emissions and the largest source of energy available to the world [Cullen and Allwood 2010, pp. 2059-2069]. The EU's road map for moving to a low-carbon economy indicates that by 2050 the European Union should have reduced its greenhouse gas emissions by 80% as compared to the 1990 levels only through national emission reductions. The key steps in achieving this objective would be to achieve a 40% emission reduction by 2030 and a 60% emission reduction by 2040. It is assumed that all sectors must be involved, to the extent appropriate to their technological and economic capacity, but it should be borne in mind that there are differences in the size of the reductions to be achieved between sectors [Famielec, Kijanka, Żaba-Nieroda 2019, p. 18].

According to the European Investment Bank, the investment needs of the electricity sector by 2020 will amount to almost EUR 70 billion (approximately PLN 300 billion). Of this, the renewable part will amount to EUR 12 billion, the nuclear part - EUR 6 billion, and the CO_2 capture and storage systems (CCS) - as much as EUR 25 billion. The main problem is that CO_2 emissions can be reduced mainly by building gas power plants or renewable energy. Until 2020, the CCS technology to be installed in coal-fired power plants will not be applicable. The cost of building a coal-fired power plant with CCS will be one-third higher than a traditional one, and the cost of producing electricity by up to two-thirds. The reduction of CO_2 in Poland will have a much greater impact on slowing GDP growth than in other EU countries. It is estimated that by 2030 we will lose 1 percentage point on average annually. GDP. In the EU, growth is expected to amount to 0.6 percentage points. Rising costs of energy investments will translate into higher electricity bills. Construction of nuclear and wind installations is associated with high investment outlays for this purpose.

The construction of a nuclear power plant per 1 MW of capacity costs about - PLN 15 million. The outlays for wind farms are much lower, but due to the limited time of their use, they actually amount to several times more than for nuclear installations. In the case of a gas-fired power plant, the cost of building 1 MW of capacity is approx. PLN 2-3 million, depending on the technology, and in the case of coal, it is PLN 5.5-6 million. Fuel for the latter is relatively cheaper. However, it is the combustion of gas that produces less CO_2 emissions. This is important from the point of view of Poland in the context of the EU climate package and the tightening of regulations on CO_2 emissions.

Polska Grupa Energetyczna announced that the planned new unit at the Dolna Odra power plant will be fired with coal, alternatively the use of gas technology in the construction of this unit was also considered. A few months later, information was released that the opposite would be the case - a gas unit would be built instead of the previously planned hard coal-fired unit. Experts believe that in the case of Dolna Odra, located near Szczecin, a gas unit will be more economically viable, which would not be profitable in Silesia, where coal is transported over short distances (and state energy companies are prohibited from importing this fuel). Gas from Norway is to flow to the vicinity of Szczecin via the planned Baltic Pipe pipeline via Denmark [Baca-Pogorzelska 2017].

It is possible to introduce emission limits for conventional technologies in the EU in conjunction with the reform of the CO_2 emission allowance trading system (the so-called EU ETS). The current stage of the project for the construction of a new unit in Dolna Odra, planned by the end of Q2 2018, will include the development of a feasibility study for the investment, as well as launching other administrative proceedings aimed at obtaining a decision on environmental conditions for this task. The company is considering selecting one of the three technologies: a simple cycle gas unit, a simple cycle gas unit prepared for a possible extension to a gas and steam unit (CCGT ready) or a gas and steam unit. Due to the specific location conditions of the Dolna Odra Power Plant, located in an area characterized by high demand for power balancing the power system, the new unit should be highly flexible. Consultations with Polskie Sieci Elektroenergetyczne have shown that the gas block is able to meet these requirements.

Costs of adapting electricity producers to new standards

Adapting to EU regulations will cost electricity producers PLN 140 billion by 2030, which means that the price of electricity may increase by about 20%. The energy sector will have to spend about PLN 100 billion on investments in gas and coal (or nuclear) blocks, and these are not all the huge expenses of the Polish energy sector planned in the coming years. The next planned expenses of PLN 130 billion are fees for CO_2 emissions in 2021-2030, additional costs are at least PLN 6 billion for adapting the power plant to the so-called BAT conclusions - lower emissions of sulfur and nitrogen compounds, chlorine and mercury by 2021. The presented investment outlays may cause that in the perspective of 2030 the average electricity bill may increase from the current approx. PLN 100 per month to PLN 120.

Poland relies on the production of energy from coal, its share in the energy generation structure is approx. 86%, in 2030 it is to be 60%. The Polish energy system is based on well-worn installations. On July 31, 2017, the European Commission made a formal decision to initiate the entry into force of the so-called BAT conclusions for power plants, which will apply from 2021. It is estimated that the adjustment costs in this respect will amount to approximately PLN 15 billion necessary for the modernization of energy installations so that they emit less SO_2 and NOx as well as Hg and Cl compounds. The five largest Polish energy companies controlled by the State Treasury estimate their expenses at approx. PLN 6-9 billion [http://serwisy.gazetaprawna.pl (10/09/2017)]. For the Energa concern, this means the need to modernize the Ostrołęka B Power Plant and the Elbląg and Kalisz CHP plants. In the case of Tauron, assessments are ongoing regarding the need to adapt the installation to changing requirements. PGNiG Termika believes that its Siekierki CHP plant is adapted to the new regulations (similarly to the Wola heat plant), the company is considering turning off two steam boilers and turbine sets. In Żerań, most of the old devices will be dismantled, they will be replaced by a new steam and gas unit, the cost of which will amount to PLN 1.5 billion. Boilers in the Kawęczyn Heat and Power Plant and the Pruszków Heat and Power Plant require adjustments. In the case of Kozienice Power Plant, adjusting the generating units to the BAT conclusions costs about PLN 150 million. In the case of Połaniec Power Plant, approximately PLN 300 million. The estimated expenditures of the Enea concern will amount to approximately PLN 500 million.

Although the principle promoted by the European Commission is technological neutrality, it is not respected in this case. The limit of 550 g CO_2 / kWh covers all available technologies with the exception of coal. Even the most modern coal units currently emit 700 g of CO_2 per kWh of energy produced. The most modern coal-fired power plants in the world achieve an efficiency of 43%. To fit within the 550 g limit, they would have to work with 65-70% efficiency - it is technologically unattainable. The draft winter package proposes a maximum emission of new power plants at the level of 550 g CO_2 / 1 kWh, the EU ETS project goes further, assuming the threshold of 450 g CO_2 / 1 kWh. The most modern coal-fired power plants do not go below 700 g CO_2 / kWh. Poland requests that these numbers be

averaged not for a given gym, but for the entire country. Such a solution would allow the construction of coal units, e.g. assuming the construction of a nuclear power plant that does not emit CO_2.

On July 31, 2017, the European Commission adopted an implementing act on new standards tightening emission standards for industry, including coal-fired power plants. This is another step limiting air pollution, but also a considerable challenge for the Polish energy sector. The new regulations concern the so-called large combustion plants, i.e. power plants and combined heat and power plants, which are responsible for almost one third of industrial air pollutants in the EU. All installations that are subject to these regulations, and there are about 3.5 thousand of them in the EU, will have four years to reduce emissions of harmful substances into the atmosphere. By mid-2021, power plants and large heating plants have to adjust their emissions to BAT requirements. These standards are to be the basis on which the relevant environmental protection authorities will issue permits for enterprises. This is not about CO_2 emissions, but about gases such as SO_2, NO_x (and dust). Additional substances such as Hg, HCl, HF and NH_3 were also covered by the emission limit values. The limits apply to all large combustion plants with a capacity of 50 MW or more, except for those that benefit from previous derogations from some of the regulations. The Directive on industrial emissions [Directive of November 24, 2010], according to which BAT requirements are the benchmark for pollutant emissions, provides for the possibility of granting derogations from the limits. A company that wants to use such a solution will have to indicate that the costs of compliance with the standards are disproportionate to the environmental benefits they bring

Conclusion

The presented study is a methodological approach in which an attempt was made to present the power plant as enterprises generating significant amounts of dust pollution, CO2, SO2 and NO2. The guidelines for the size of these pollutants for the power sector have become more stringent and will be even more stringent. The necessity to adapt to the norms which are the expression of the standards will increase the outlays and costs of implementing ecological standards. Power plants made an effort to adapt to environmental requirements in the previous years, and subsequent restrictions require significant investment outlays to adapt to the growing environmental requirements. The state of the environment is largely determined by what we introduce into it. Ecological standards reduced to pollutant emission standards were very difficult to achieve. In the future, strict emission standards will be even more severe for the power sector. The level of standards has risen sharply since 2020. Various forms of power plant activity may be ways to comply with the standards. This will require increased capital expenditure and an increase in costs related to compliance with the standards. Electricity prices will also rise as a result of rising costs.

Knowledge Management in The Context of Service Companies

Rober Balcerzyk

Dr., Assistant Professor at the Faculty of Management of the General Tadeusz Kościuszko Military University of Land Forces in Wrocław, email: robert.rb@interia.pl
ORCID: 0000-0002-5462-6901

Abstract

The main objective of the research presented in the article was to diagnose the Knowledge management in organization. The conducted research was of a pilot nature. This article attempts to define the term *„knowledge management"* based both on the literature on management sciences and on the respondents' opinion. There is also described a model concept of *„knowledge management"*. In the described studies, the factors determining the *„knowledge management"*. Factors affecting knowledge sharing in the respondents' opinion were presented. Barriers in the development of companies were presented. Problems related to data acquisition and processing were described. Based on the analysis of research results, conclusions have been formulated that can be used in the design of *„knowledge management"* programs.

Keywords: Knowledge Management, Knowledge, Information.

Introduction

The development of a knowledge-based economy and globalisation have led to a revolution in management concepts. In modern organisations, the importance of intellectual capital as a significant part (component, determinant) of the total value of the organisation is appreciated. A special role in organisations is assigned to employees. It is the employees who, to a large extent, constitute the „*added value*" of the company. It is easy to purchase new technology, however the preparation and motivation of employees is a capital that is built up for a relatively long time and cannot be copied.

Full implementation of development programmes within the framework of *knowledge management* requires the involvement of the company's top management, the entire management staff and the employees themselves.

Knowledge currently becomes a commodity, has a measurable form and creates *„added value for the company"*. Knowledge workers determine the strength of the enterprise and create the *intellectual capital* of the organisation. Nowadays, knowledge management is recognised as a concept of organisation management, which emphasizes the role of the intellectual capital of employees in building competitive advantage. It makes it possible to improve processes and react to changes in such turbulent environment.

In today's computerised world, in the era of innovation, an overwhelming amount of data and information is encountered. As a result, they do not always constitute useful and sought-after knowledge which can be applied anywhere in the organisation management. In short, we should know what we are looking for, for what purpose, and what this knowledge is supposed be used for as well as how to use it in order to achieve expected results in our organisation.

The concept of knowledge management in the literature on management sciences.

In the literature of the problem, the concept of knowledge management is defined in various ways. There were attempts to define knowledge as early as in ancient times (Galata 2004). Greek philosophers, such as Plato and Aristotle, were the first ones to try to define what knowledge was. Socrates, Plato and Aristotle stressed that the measure of wisdom was the ability to show surprise (I know that I know nothing). Attempts to explain this concept

were also made by the supporters of idealism (Descartes, Kant), empiricism (Locke, Hume) and the 20th century philosophers (Ryle, Macmurray).
M.J. Stankiewicz (2006) states that „knowledge is a changing mixture of experience, contextual information values and expert insight, providing a framework for assessing and connecting new experiences and information. It is created and used in the consciousness of its owner".

P. Drucker (2002) believes that „knowledge is always connected to a person, is carried, created, justified and perfected by that person and applied, taught and passed on to others and used by a person for good or bad purposes". P. Drucker defines knowledge as an effective use of information in action and is the first to appreciate the importance of knowledge in the economy.

L. Kowalczyk (Drucker 1999) believes that „knowledge remains to be closely correlated with skills (often considered more important than knowledge itself) and competences (the essence of which is the ability to solve professional problems in a specific work environment). Competences, like knowledge, become relevant when they are used to achieve specific goals, but this requires a combination of competence, motivation and the working environment".

A. Sopińska, P. Wachowiak (2006) devised the following model of knowledge management in a company (Figure 1).

Figure 1: Model of knowledge management in an enterprise

Source: A. Sopińska, P. Wachowiak, 2006

The first stage of knowledge management is the acquisition of explicit knowledge. It consists in obtaining all information from various sources. At this stage an important role is played by the analysis of the company's information needs and data collection. In the next stage - the processing of explicit knowledge - the information collected is subject to preliminary arrangement and storage and then analysis and interpretation. These activities are followed by the sharing of explicit knowledge. In consists in disseminating the collected and processed information, reaching out to parties interested in the results of the analyses conducted. They provide new insights into the interpretation of events, phenomena or objects. They can influence the behaviour and judgment of the recipient.

Another kind of knowledge in hidden knowledge. Its acquisition mainly consists in improving the competences of employees. Its processing (second stage) consists in the assessment of the degree of assimilation of knowledge acquired by the employee, verifying the usefulness of knowledge from the point of view of the objectives to be achieved by the employee and the organisation itself. The next stage is the sharing of hidden knowledge consisting in passing the knowledge on to other employees.

The last stage of knowledge management is the joint use of explicit and tacit knowledge used to make managerial decisions. It is important to link explicit and tacit knowledge since they intersect with each other. It leads to the rational use of knowledge resources in the organisation.

Authors of the described concept of knowledge management attribute a special role to the organisational culture in this process. It should be oriented towards innovation, openness to the environment and pragmatism.

Knowledge is divided into explicit and tacit knowledge. Explicit and tacit knowledge are not completely separate. During the creative activities of individuals and groups, there is interaction and interpenetration between the two types of knowledge. Explicit knowledge turns into tacit knowledge and vice versa. In literature, it is indicated that the basis of knowledge is data and information, which become knowledge only after being processed (Figure 2).

Figure 2: Hierarchy of knowledge

Source: M. Kłak, 2010

Data are a component of the information (Brdulak 2005). They include raw and unanalysed facts, figures and events. Nowadays, they are most usually saved and stored in the form of data sets. These should be understood as sets of single facts about a certain event. Processed data constitute messages and shape information. In an organisational context, data constitute a formalised record of the transactions made.

Collected, organised and properly interpreted data constitute information essential in the decision-making process. In the context of information, both the sender and the recipient are concerned. Thanks to the message, it is possible to obtain answers to the questions: who?, what?, where?, when?

S. Galata treats information as all events (real or conceptual), recorded, collated, grouped, interpreted and generalised from the point of view of the adopted goal (Galata 2004).

The characteristic feature of knowledge is that it is usually of qualitative nature.[1] Data and information are perceived differently. Rather, they are of quantitative and formal character. Other characteristics of knowledge are:

- dominance - knowledge takes precedence over all other resources;
- inexhaustibility - the value of knowledge increases with the frequency of its use;
- simultaneity- the use of knowledge resources by many people in different places at the same time is possible;
- multidimensionality - considers knowledge management in functional, process, instrumental and institutional terms.

Methods and characteristics of the research sample

[1] M. Klimczok, A. Tomczyk, *Zarządzanie wiedzą – współczesna koncepcja zarządzania przedsiębiorstwem*, Zeszyty Naukowe Wyższej Szkoły Humanitas. Zarządzanie, Sosnowiec 2012, nr 2, s. 166.

The research presented in the article uses the triangulation of research methods such as:

- analysis and criticism of literature (literature on knowledge management, innovation management, employee development);
- secondary source analysis (reports, research reports on knowledge management in enterprises);
- a diagnostic survey with company employees in the area of „knowledge management".

A **diagnostic survey was adopted as the leading method in the conducted research.** This allowed for an acquisition of an objective context of the examined phenomenon and ensured high quality of the research. The diversity of methods was aimed at achieving a consistency of the empirical basis for the inference.

The **questionnaire** was developed on the basis of a literature analysis in the field of knowledge management. The questionnaire was intended for students (part-time students) of three Universities of the Lower Silesian Voivodeship. In the research, the following variables were set as independent variables: gender of the respondents, age of the respondents, size of the company (workplace), place of residence.

The respondents are part-time students at three Universities in Wroclaw and nearby municipalities. A total of 356 students were examined. The studied group was evenly divided on the basis of gender. Women constituted 51% of the surveyed group and men constituted 49% of it. The gender of the respondents is presented in Figure 3.

Figure 3: The group studied according to gender.

*Source***:***own research*

About 69% of the respondents were young people aged 19-29. 19.7% of the respondents were aged 30 to 40. The least numerous group were students over 40 years of age (11.2% of respondents). During the analysis of the structure of the group examined in terms of age, it should be noted that the respondents are young people at the stage of preparation for a career or early professional career, during which a crystallisation, the narrowing of the field of exploration and finalisation of the choice of profession take place. They recognise the need for continuous improvement and learning. They want to build their own intellectual capital to ensure their competitiveness on the labour market. It consists primarily of acquired knowledge, skills and experience, which are used in the work performed. They invest in themselves while simultaneously having higher requirements regarding career and professional development. The age of respondents is shown in Figure 4.

Figure 4: Group examined in terms of gender.

Source: own research

About 35% of the respondents are employees of companies employing more than 100 people. Over 21% of the students were employed in medium companies (21 to 50 employees) and the same percentage of students were employed in organisations employing 6 to 10 employees. Only 10.1% of respondents were employed in companies employing 51 to 100 employees. Respondents are mainly employees of small and medium companies due to the fact that they live in the surrounding villages. The employment of respondents in terms of the size of the company is shown in Figure 5.

Figure 5: Employment of respondents due to the size of the company

Source: Own research

Two of the examined Universities were located in poviat towns in the Lower Silesian Voivodship. Therefore, 43% of the respondents are inhabitants of small municipalities with up to 50,000 inhabitants (Figure 6). Almost one third of the respondents are rural residents (over 28%). A relatively small group of respondents are inhabitants of municipalities with up to 10,000 inhabitants (7.3%). Only 1.1% are residents of larger cities. Therefore, the respondents are employees at small and medium companies.

Figure 6: Respondents' place of residence.

Source: Own research

Acquiring information and developing knowledge management

In one of the first questions the respondents were asked for their opinion on the understanding of the term "knowledge" (Figure 7).

Figure 7: Understanding of the term "knowledge" by respondents

Source: Own research

More than half of the respondents (50%) are aware of the importance of knowledge in today's economy. Approximately 21% believe that knowledge is an investment and another 29% of respondents say that knowledge is a building block of intellectual capital. They understand the importance of knowledge in broadening competences, improving effectiveness and efficiency in an organisation. It can therefore be assumed that they treat knowledge (or rather acquiring it through participation in courses, trainings, workshops or studies) as an important component of the intellectual capital of an organisation. It can be argued that they treat the financial resources used by the organisation to obtain knowledge as an investment rather than a cost. Nearly 33% of respondents believe that knowledge is a development stimulus and 8% define knowledge as a generator of wealth. More than 6% treat knowledge as a competitive asset and only 2% treat it as a production asset. It is worth noting that no one interprets knowledge as an element of products, and yet it is knowledge that determines their creation.

Respondents' opinions allow for concluding that knowledge is the basic resource of an organisation determining its intelligence. Knowledge is a property of the employees and not the organization. It determines the market value of the company at the same time. Knowledge is the art of creating the value of intangible assets of an organization. The success of a company is determined by the ability to acquire, accumulate and share the knowledge with co-workers. Knowledge is the foundation for the functioning of a modern organization. It should also be stressed that knowledge is of a qualitative nature.

The next question asked to the respondents was meant to determine whether the examined students actively participate in the process of knowledge sharing (they share with other co-workers). Their opinions are shown in Figure 8.

Figure 8: Respondents' views regarding active participation in knowledge sharing

Source: Own research

Almost all respondents (81%) confirmed their active willingness to share knowledge by ticking "yes" or "definitely yes". Only 9% of the respondents gave a negative answer. This proves that the respondents are very aware of the impact of the knowledge sharing process on the functioning of an organisation. It can be assumed that the companies employing the examined group have an appropriate "climate" in the organisational culture conducive to knowledge sharing. It is likely that these companies also have an appropriate incentive system in place to encourage their employees to share knowledge. It also shows that the employees identify with the organisation and are emotionally attached to it. They are loyal employees and they identify the trajectory of their career path with the development of the company. It can also be presumed that they have the proper competences to establish desired interpersonal relations, communication or teamwork. Knowledge sharing is not only about passing it on, but also about assimilating it.

These organisations probably have the proper technical infrastructure to support knowledge management in a company. It should be remember that having appropriate information technology tools facilitates and accelerates the process of obtaining information that makes problem solving and managerial decision-making easier.

Respondents were asked for opinions regarding the functioning of organisational units in the company directly responsible for knowledge management in the organisation. This is shown in Figure 9.

Figure 9: Respondents' opinions regarding the functioning of organisational units directly responsible for knowledge management in the company

Source: Own research

More than 82% of respondents are of the opinion that the company should have special organisational units responsible for knowledge management. About 6% of the respondents have no opinion on this subject and only 10% are against it. It means that employees want to have access to the company's information resources that make their work easier. This may also indicate that they want to share knowledge "in a safe manner". On the one hand, they want to receive confirmed (verified) information and on the other hand, they want the information provided to co-workers to not be used in any undesirable way. Research confirms that employees demand people responsible for knowledge sharing in their structures. It can be assumed that these tasks are currently performed by middle and line management. They recognise the importance of knowledge in such a competitive economy. Despite the fact that the majority of respondents are employed in companies employing up to 100 employees, they see a need to establish "knowledge management" units. This, in turn, shows that the respondents are also aware of the problems in creating efficiently functioning "knowledge networks". It should be expected that these companies probably have a relatively simple organisational structure that is conducive to communication between employees anyway.

Research also shows that information technologies are a determining factor in the knowledge management process. Respondents' opinions on this subject were shown in Figure 10.

Figure 10: Opinions regarding the perception of information technology.

Source: Own research

The vast majority of employees (89%) claim that the knowledge management process is determined by information technologies. Only 9% of respondents are of the opposite opinion. It should be remembered, however, that the tools

used in the process of knowledge management are intended only to support it. They are intended to ensure that relevant staff receive information in good time. They also provide access to information (knowledge) and lead to material prosperity. The results show that economic, social, scientific and technical progress and globalisation caused the Polish society to be increasingly more informative. Complex processes require the use of a growing number of new techniques and tools for data collection, processing and delivery to users. Respondents recognise that information is a cornerstone of knowledge development and innovation. Information is the basic and most significant "resource" in the organisation.

The research has attempted to determine what constitutes the greatest barrier to knowledge sharing. The results are shown in Figure 11.

Figure 11: Opinions regarding barriers to knowledge sharing

Source: Own research

The main factor constituting a barrier to knowledge sharing in the opinion of respondents is the lack of self-confidence, underestimation of oneself and one's ideas (31%). It should be remembered that low self-esteem is the result of excessive self-criticism, lack of self-confidence and low self-value. One may think that the respondents are characterised by low self-esteem (avoiding ambitious goals, new tasks, and strong reaction to criticism from co-workers). The reason may be insufficient knowledge of oneself and receiving unfavourable (somewhat biased) messages in the past from superiors, teachers, parents. Therefore, it is necessary to create an organisational climate in which comparison of employees with others and making an assessment based on the assessment of others are avoided.

Respondents mention the fear of losing their position, the manifestation of the "knowledge is power" syndrome as the second factor (barrier) (26%). In the opinion of respondents, possessing unique knowledge grants power to the employee. It should be remembered that power is a social relationship between individuals in which one party imposes their will on the other. It exists wherever there are superiors and subordinates. Therefore, in the opinion of the respondents, sharing knowledge makes the employee (in terms of their professional competences) unattractive for the organisation.

Lack of recognition and bonuses encouraging to share the knowledge with other employees is considered to be a barrier by approximately 15% of respondents. This proves that there is a lack of incentive systems supporting the development of employee competences, increase of involvement and employee satisfaction. Lack of incentive systems complicates the building of competences within organisations that are difficult to obtain on the external labour market. Thanks to the implementation of such solutions, the company becomes a more attractive workplace for new employees.

One in ten respondents believes that the barrier is the lack of a "higher-up" example from management (9%). The same number of respondents is characterised by a lack of trust in the recipient (fear of improper use of the knowledge shared) (8%). Respondents also mention the lack of time for knowledge sharing itself (6%) and lack of trust in the source of knowledge (3.3%).

The results show the problem in knowledge sharing is not the lack of adequate IT infrastructure, but people (employees). Psychological traits, behaviour and motives for action constitute the main problem.

Conclusions

Summing up the problem of "knowledge management", it should be stated that this process is determined by many different factors. These include mainly the organisational culture (favourable conditions for cooperation), employee competences (establishing interpersonal contacts, communicating, teamwork skills) and information technology infrastructure (appropriate preparation and equipment of workstations, possession of appropriate information technology tools, access to information technology networks).

The main determinant of an organisation's intellectual capital is the knowledge and skills of its employees. They are the ones who create the added value of the company. They are the ones who provide the competitive advantage. The financial resources allocated to their development and vocational training should be treated as investments rather than costs.

Employees recognise the importance of knowledge in the functioning of the company. They postulate the appointment of persons in organisational structures responsible for "knowledge management" in the company. Such a solution may be to appoint managers or coordinators of "knowledge management" in the company. These persons would also play an important role in initiating changes in the organisation.

Thanks to the use of information technologies, it is possible to obtain information which in turn becomes a key strategic resource of the organisation. Information is essential to coordinate production, sales and intercontinental marketing in the age of globalisation. Modern computers and communication technologies create an information technology infrastructure that enables acquisition, processing and storage of information. Information in the modern world is intensively used in economic, social and political life. All this in turn leads to the creation of an information society.

The use of new information technologies in the organisation streamlines and increases the effectiveness of the company thanks to the acceleration of management and decision-making procedures.

In a learning organisation it is important to create an organisational culture based on openness, cooperation and knowledge sharing in a way that enables the implementation of new ideas and concepts. Research shows that encouraging people to share knowledge is not an easy task. Promotions are not only a privilege for people who have this knowledge, but also for those who are able to share it with their co-workers.

At the stage of selection of employees for the organisation (when preparing the employee's competence profile) particular attention should be paid to the psychological traits, behaviour and attitudes of candidates in the intellectual, emotional and behavioural spheres.

Abstract

Corporate Social Entrepreneurship (CSE) emerged as an approach derived from the evolution and discussion around corporate social responsibility. It is not intended to be another form of corporate social responsibility (CSR), but rather a process for invigorating and advancing the development of CSR. It implies a global and disruptive change within organizations (Austin & Reficco 2009). This paper is part of a broader research that is being developed within the scope of *EMBRACE - European Corporate Social Entrepreneurship curriculum*, a project funded by the European Union. It aims to present the main results from the first Phase of the project focused on the review of CSE programmes in Higher Education Institutions (HEIs) in Europe, giving particular emphasis to the Portuguese context. In order to develop the state of art of Corporate Social Entrepreneurship (CSE) programmes in HEIs a qualitative methodological approach was defined, using three complementary tools for data collection: desk research, interviews and focus group with key-informants. This preliminary study shows a weak awareness presented by Portuguese experts, regarding the CSE approach. It also stresses the lack of CSE programmes and trainings taking place at Portuguese HEIs, even though there are several courses related to corporate and social businesses and management. It became evident the strong rooting of the concept and practices of corporate social responsibility, as well as social entrepreneurship, and at the same time the need to work towards raising awareness for the CSE approach, aimed at the simultaneous creation of economic and social value.

Keywords: Corporate Social Entrepreneurship; Higher Education Institutions (HEIs); Portuguese CSE educational programmes

ALEGRE "The state of Corporate Social Entrepreneurship (CSE) in Higher Education Institutions (HEIs): the Portuguese case" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The EMBRACE Project: Main Aims and Outputs

EMBRACE aims to promote CSE in HEI educational programmes and improve students' competences, employability and attitudes contributing to the creation of new business opportunities dealing with social change inside companies as well as promoting collaboration among companies.

By fostering the engagement of central actors as Academia (namely, students, researchers, *alumni* (graduates), teachers, managers of CSE programmes in HEIs, experts on education/training on CSE) and Enterprises (namely, entrepreneurs, managers, experts on promotion of social intrapreneurship, experts on CSR processes), the central aim of EMBRACE project is to co-design, co-create, co-develop and co-implement an innovative, multidisciplinary European Corporate Social Entrepreneurship Curriculum (ECSEC) to be incorporated into HEI educational programmes across all disciplines.

The project's design includes different phases (Work Packages) each one with specific outputs (Deliverables) and associated operational objectives (Figure 1).

The current paper is based on the main results of the first research Phase - "Review of Corporate Social Entrepreneurship (CSE) Programmes in HEIs". Firstly, it is made a brief review of literature, focused on a key concept - Corporate Social Entrepreneurship. Secondly, it is presented a description of the methodological design defined for this specific phase, followed, thirdly, by the presentation and discussion of the main findings considering the Portuguese context.

Fig. 1: Project´s design: main phases, main outputs, operational objectives

Corporate Social Entrepreneurship: An Emergent Concept

Corporate social entrepreneurship is a specific concept and concerns new practices, which justifies why there are still ambiguities and discussion around the term and its meaning.

Corporate Social Entrepreneurship emerged as an approach resulting from the evolution and discussion around corporate social responsibility (Bowen, 1953; Azevedo & Carlos, 2015: 63). According to Austin and Reficco (2009) CSE embodies elements and criteria of *corporate entrepreneurship*, in a classic assumption as defined by Say, Schumpeter, Drucker and Stevenson, and of *social entrepreneurship*, most recently affirmed with the proposals of Dees (2001).

CSE is comprised as "the process of extending the firm's domain of competence and corresponding opportunity set through innovative leveraging of resources, both within and outside its direct control, aimed at the simultaneous creation of economic and social value" (Austin, Reficco, Wei-Skillern, 2006). Considering Austin and Reficco perspective, CSE it is not another form of CSR, but rather a process for invigorating and advancing the development of CSR. CSE aims to provide an approach that will accelerate the CSR journey. The fundamental purpose is therefore to

accelerate companies' organizational transformation into more powerful generators of societal betterment (Austin & Reficco 2009: 2-3).

The authors identify 5 key-elements of CSE, as presented in Table 1.

Table 1: Key-elements of CSE (Austin & Reficco, 2009)

Dimensions	Definition
1. Enabling environment	Entrepreneurial mindset and entrepreneurial culture enabling fundamental organizational transformation, in order to achieved of economic and social value generated both in vision and strategy, and in the organization structure and processes. This entrepreneurial environment promote economic and social values.
2. The Corporate Social Intrapreneur	Individuals within the enterprise who are focused on fostering and bringing about the internal organizational transformation and innovation that moves the organization to a more advanced state of CSR. This means, coexistence of social entrepreneur and corporate entrepreneur advocating integration of social and business values using of new resources, configurations, actions and relationships, stakeholders. This integration is communicated externally and internally in order to show how changes and social action are fundamental for enterprise needs and interests.
3. Corporate purpose: values-based organizations	Creation of social, economic and environmental value are structural of the organization identity, as well as ethical actions and innovative and disruptive solutions. Compliance and sharing values within the organization to promote work across departmental lines.
4. Value creation and double return	Optimization of returns to stakeholders and other external actors affected by social and economic values. Transparent accountability focus on complementary and synergistic rather than competitive.
5. Co-generating value	Collaboration with external organizations in order to establishment of strategic alliances to create innovative solutions and leverage the resources outside their direct control to solve economic and social problems and to promote the success of innovative business

Aligned with the Harvard approach by Austin and Reficco (2009), the consortium of EMBRACE project defined CSE as «'a way of doing business' so that all staff in any given organisation (public, private or third sector) are fully aware of their role, responsibility and contribution to the sustainable socioeconomic enhancement of their organisations and the communities in which they live and work. The CSE process includes: creating an enabling entrepreneurial environment, fostering corporate social intrapreneurship, amplifying corporate purpose and values as well as building strategic

alliances in order to solve economic and social problems and to promote the success of emerging innovative business strategies».

Data and Methodology

As mentioned before, the Phase 1 operational objective was to analyse the delivery of Corporative Social Entrepreneurship programmes in HEIs in the nine European countries involved in the project (Germany, Greece, Hungary, Ireland, Lithuania, Portugal, Romania, Spain and The Netherlands) in order to define the gaps and obstacles of the implementation and use of CSE, especially in the academic context. The current paper is focused on the main results regarding the Portuguese context.

In order to develop the state of art of Corporate Social Entrepreneurship (CSE) Programmes in Portuguese HEIs a qualitative methodological approach was defined. We have used three complementary tools for data collection: (i) desk research, (ii) interviews, (iii) focus group.

Concerning the desk research, we have analyzed the institutional websites from 51 HEIs (out of a total of 119 HEIs in Portugal), in order to encounter 20 to 25 courses of CSE or related terms (such as, Corporate Social Responsibility (CSR), Social Entrepreneurship, Corporate entrepreneurship, Intrapreneurship, Social innovation).

In terms of interviews, we have conducted a set of 7 interviews to relevant actors from Academia in this field, from different Regions of Portugal (North - Porto, Center - Coimbra and Lisboa and South – Algarve), identified through the desk research, namely managers of programmes for CSE in HEIs (3), experts on education/training on CSE (2), experts on promotion of social intrapreneurship and CSR processes (2).

Regarding the focus groups, 2 were carried out in order to have a broader knowledge of the representations of CSE, needs in terms of demand of CSE courses/modules/programmes, ways of involving different actors (industry, government organisations, businesses in general, Civic Society Organisations) in the co-development and co-design of such modules/ courses/ programmes. The focus groups participants' profiles were equal to the ones defined for the interviews.

Findings and Discussion

The state of Corporate Social Entrepreneurship (CSE) programmes delivery in Portuguese Higher Education Institutions (HEIs)

Considering the desk research carried out it was possible to identify 41 CSE (or related terms) courses and programmes in the Portuguese HEIs. In terms of scientific area, most of these courses and programmes are delivered at faculties and schools of Management, Economics and Business (25 courses). These programmes are mainly connected with the classic corporate entrepreneurship approach (containing disciplines as "business plan", "leadership", "innovation management" and "business management").

Nevertheless, it was also possible to identify courses and programmes delivered at faculties and schools of Sociology, Political Sciences, Human Sciences, Arts and Humanities, Psychology and Educational Sciences (11 courses). These programmes are closer to the social entrepreneurship approach (incorporating disciplines with topics as "collaborative work", "impact on business and society", "social economy", "social responsibility", "social intervention" and "social innovation").

It is important to highlight that more than a half of these CSE programmes (28) are delivered at post-graduation level, namely at Master Level (17) or Executive & MBA level (11). This means, that there is a lack of CSE approach in prior levels of higher education (Bachelor).

The interviews and focus group carried out provided important inputs concerning the state of awareness and knowledge regarding the concept of CSE in the Portuguese Academia.

Prior Awareness and Knowledge of The CSE Concept in The Portuguese Academia

The key informants were unfamiliar with the concept. It is indeed an emergent concept in the field. The reflections shared by experts during the interviews and focus groups show that there are different CSE understandings: i) for most of them, there are no relevant differences between CSR and CSE; ii) others consider that CSE is a new designation for

the phenomenon of social entrepreneurship; iii) and only a minority of experts positioned the CSE concept at the heart of the business model and refers that CSE opens a new model and establishes a new contract with society.

Main actors identified as key elements for the co-design and co-implementation of European Corporate Social Entrepreneurship Curriculum (ECSEC)

According to experts' perspectives about entities that should participate in the co-design and development of CSE training programmes, courses or modules, a heterogeneous and wide set of stakeholders should be involved on this, namely private companies, not-for profit and public organizations, cultural entities, governmental institutions from different levels (European, national, regional and local).

Considering the experts shared perspectives, moving towards initiatives and practices that explore the model proposed by the concept of CSE implies the shift to an integrated approach with different stakeholders and not particularly focused on just one entity. This means creating articulated and heterogeneous alliances.

General Pedagogical Strategy

In order to have a comprehensive and integrated CSE approach, experts advocated the need of having a mixed approach: that would include the contribution of a theoretical framework plus "field work" in businesses and organizations. In other words, this mixed approach should combine a theoretical dimension with a practical part, namely trough an internship (of short duration e.g.) in different types of organizations (public, private and nonprofit).

Final Remarks

More than taking place outside the logic of the activities of the companies, CSE presents itself as a proposal to conciliate both economic and social mindsets and aims to transcend corporate social responsibility practices (Austin & Reficco, 2009). This approach has direct consequences in the way that organizations are managed and organize their internal and external practices and how the different stakeholders are involved.

This preliminary study shows the lack of CSE programmes and trainings taking place at Portuguese HEIs – even though there are several courses related to corporate and social businesses and management.

It also stresses the lack of knowledge/awareness presented by Portuguese experts reflecting the inexistence of practices that seek to reconcile (intra) entrepreneurial action throughout a double approach: economic and social. Indeed, no organizations and companies with CSE practices were referred or identified while conducting the interviews and focus groups (even though there is a strong use and implementation of corporate social responsibility concept and practices).

The hegemony of a classical economic thinking can create obstacles for new entrepreneurs to become early-adopters of CSE practices. The involvement and comprehension, since early, by teachers, researchers, students, alumni, (future and current) entrepreneurs can be important in order to develop and implement CSE approach and its specific business models. In order to achieve this goal, it seems important to design CSE courses, programmes and trainings in HEIs.

Abstract

Professionals in all fields are indispensable to make the economy work when societies go through public health crises, natural disasters or catastrophes. Analyzing the studies conducted by various specialists, we notice that a large part of these workers are not willing to work in such conditions. In this paper we wanted to find out what can motivate a person to work in conditions of stress, fatigue and risk of illness, which motivational tools may be applicable in an economy in crisis. The COVID 19 pandemic is one of the biggest challenges humankind has met so far. The population is going through a period of continuous stress that creates many problems and mental health. The category most affected by this problem is the medical staff, who are reluctant to continue their activity.

Our desire is to find out how we can best motivate workers to respond to the call for help in the event of disasters and pandemics and to continue economic activity, thus avoiding blockages and recessions.

Keywords: The employee motivation, the pandemic COVID 19, human resources

JEL Classification

Introduction

Motivation can be the flame one can have in order to finish a job. Motivation is a part of human resources domain and it is studied in the past 20 years in different sectors and in the last years in health sector (Papathanasiou, 2014).

Prithwiraj Choudhury, professor at Harvard Business School, said" the virus could act as a game-changer for remote work (…). This is an opportunity to essentially restructure organizations."

The COVID-19 pandemic highlighted deficiencies in the health system that are still unaware, such as the lack of medical equipment or protective equipment for employees. In this context, human resources management had to face this new challenge and the priority was to ensure sufficient staff for the proper conduct of hospital activities. The U.S. Bureau of Labor Statistics estimates a need for about 11 million nurses, given that the pandemic has caused a drastic drop in the number of hospital volunteers to be covered by new employees, while also affecting health care costs. The difficulty faced by human resources management in hospitals in terms of staff recruitment and training is even greater in this pandemic context, one of the current solutions being to use virtual methods of recruitment (Rice, 2020).

As a result of the global pandemic, health systems mobilized, creating new hospitals specially built to treat patients with COVID-19, an example being Huoshenshan Hospital, which required the recruitment of more than 10,000 medical staff. Another measure taken by the human resources management department was to call on retired staff due to their experience and the ability to train newcomers. Another measure taken during this pandemic period was to use the internet to conduct basic consultations through video conferences with patients, in order to provide time from

Cite this Article as: Andreea Daniela Tudor, Agata Laura Țoc, Alina Georgiana Petre, Aurora Cosma and Andreea Stoica " Workplace Motivation: Engaging Employees During A Pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

specialists and space in hospitals for patients with serious health problems affected by this new virus. Management standards have been implemented regarding the online health sector, among which we mention: Internet hospital management measures, Internet diagnostic and therapeutic measures and Remote medical service management (Thoughts on healthcare management in an epidemic, 2020).

With the gradual reopening of companies and the resumption of activity during the pandemic, human resources management has encountered a number of difficulties on the part of employees regarding the minimum number of employees required for business activities, safety at work, and also employee motivation and reduction their stress during work hours. That is why the Organization for Economic Co-operation and Development has offered a series of solutions to support the management of human resources of organizations and public sectors.

In order to ensure the minimum number of employees needed to carry out the activity, it can be proposed as a solution for certain employees to increase office overtime so as to cover the time for colleagues who work remotely, introduce special bonuses for those employees or increase overtime pay, or hiring temporary employees, postponing the retirement of experienced and available employees to physically work in the office. In order to ensure safety at work, solutions involve modifying the work schedule by introducing a flexible schedule chosen by the employee, ensuring a well-sanitized and disinfected work space, encouraging the replacement of public transport with walking, cycling, etc.

Regarding the motivation of employees and the reduction of stress, some of the proposed measures would be to maintain a very close relationship with the staff, to communicate a lot and to constantly transmit the measures taken to protect them. The trainings are also proposed especially for managers, to supervise their teams and to support them emotionally, to provide adequate work equipment, to support employees to form a new work routine in this pandemic context (OECD, 2020).

A recent study conducted at West China Hospital of Sichuan University found that human resource management played an important role in providing management training for medical staff, both front-line and offline-related patient screening and security measures, in establishing a strict management of the working environment, imposing strict rules to be followed regarding the development of the activity inside the hospital, such as the disinfection of all objects, the ventilation of the rooms, as well as restoring working hours for medical staff so that the duration of exposure to patients with COVID-19 is as short as possible, and also restoring working shifts (Zheng etal., 2020).

Motivation of medical staff during the pandemic

The medical staff is the main component in a medical unit, they are the ones who provide care for the sick. During pandemics, the amount and complexity of health care increases greatly. In general, the need for medical staff is never satisfied, there is always a shortage of staff in this field, at this time we face a future in which there is too much work and too few workers.

The Dublin Declaration on Human Resources for Health estimated that we will need about 40 million health workers, with the risk to exist only 18 million, urging countries to increase funding for health and for the recruitment, development, training and retention of health workers (BRITNELL, 2019).

In order to have enough staff in the medical units it is important to have motivation, also performance and well-being are two other very important things for the employees. So managers need to find new tools to reinvigorate their teams and empathetically help employees solve their problems (Oak, 2020).

Many employees will get sick and unfortunately some will die. Those with symptoms will need to be quarantined. Studies show that quarantined staff feel guilty for colleagues left alone at work and for contaminated families, and because health work is done in a team, they suffer from loneliness, end up with mental health problems, become anxious and refuse to return to work (Walton, 2020).

Image1: The most important factors that influence your employees' experience and, therefore, motivation and productivity. (Martic, 2020)

One of the most important problem is lack of staff with influence over the morale of the working staff especially in the health system. Shortage of staff leads to uneven quality of care in hospitals. Health care workers need more communication with management regarding atmosphere at the work place and the resources they use (Aiken, 2001). Studies show that empowerment of the employees using autonomy and collaboration increases job satisfaction and lowers the number of sick leave days and with less burnout. Another observation is that competence is associated with lower levels of anxiety and insomnia. Higher levels of competence and meaning were associated with lower levels of depersonalization and emotional exhaustion (Hochwalder, 2005).

Emergencies are defined by highly demanding tasks with many obstacles that requires prompt resource allocation. Physicians do not have the ability to react in these situations in the first years and they have to learn step by step (Hershkovich, 2016).

Internal motivation of the employees depends on the level of confidence between them and the employer that arises from knowledge and correlation between information and experience (Rousseau, 1999).

In 2010 Hissei Imail & his collaborators conducted a study in Japan. They analyzed the absence rate of the medical staff during a real H1N1 pandemic. The goal of the study was to assess the availability of the medical professionals to work during a pandemic and the factors that influence the professional activity of the hospital employees during a real pandemic infection.

Workplace stress factors among healthcare professionals

Coronavirus is impacting our lives and we can admit it's a situation that put a lot of pressure on the professionals from the healthcare system. They may feel overwhelmed because of the amount of work that they have to do because

of the current situation. This might cause physical and mental exhaustion, insomnia, a general low mood, sadness or even depression.

In the graphic below we included the most present factors that currently have an impact and decrease the level of motivation among the medical staff. We want to add that the factors may differ depending on each person. Also, the intensity of each factor might differ. Therefore, when some peoples are stressed, they are almost on the verge of a breakdown while others are managing the stressful periods a lot better.

Image 2: Workplace stress factors among healthcare professionals

In addition to all the factors mentioned above, another component that could contribute to the stress level of the medical staff, is the possibility of people avoiding them, thinking the posibility of being infected is very high. That's not always true because currently the hospitals are offering protection measures against the virus. Perhaps this is an asumption caused by the beginning of the panteminc when the medical staff was not having enough protective clothes and equipment to avoid the infection.

The feeling of protection are providing trust among the medical professionals. Protection includes taking all reasonable precautions to prevent the infection of the medical staff, caring for those who become ill and reducing threats of malpractice for those working in high-risk emergencies.

The data from the scientific research shows that some factors can increase both motivation and hesitation in the same time. Giving workers the feeling that they are protected by the local government and the hospital is especially valuable because it increases their motivation and decreases their hesitation at work (Imai, 2010).

A study by Tommy Nichols and Christine D. Valdez conducted in 2013 showed that other factors that may determine and motivate health workers not to be absent during pandemics are also related to basic needs: food, shelter, water, rest. Assuring the basic needs may reduce the absenteeism. High concerns were also shown for the pets while at work or in case of quarantine. A way to increase the motivation might be by providing pet care services.

Financial motivation can be accomplished by providing financial support for the families of employees who died as a result of the exposure and also by offering financial incentives. Regarding non-finacial motivation ways to keep the employees engaged are verbal messages of gratitude and encouragement or merit recognition awards. (Nichols,T., ; Valdez, Ch., d., 2013)

The most important reason in keeping balance in a pandemic is devotion to the profession, followed by helping others despite the risk of getting sick. Appropriate protection supply like respiratory masks for medical personnel and families give confidence and willingness to work. (Valdez, 2013)

Research Methodology

The present article includes an analysis of the documentation found in various publications and scientific articles in order to illustrate the potential advantages of our country. Therefore, we conducted a comprehensive research into numerous sources of secondary data, such as articles, reports and books from the following areas: " the employee motivation, the pandemic COVID 19, human resources ".

For the research, we also used electronic databases, such as PubMed, Academia. EDU, BRILL and Wiley Online Library. Other sources were the archives of different journals.

The method used is a descriptive and quantitative one, given the fact that the subject is very widely discussed.

Results and Discussions

The current pandemic has managed to highlight the important role of human resource management in organizations but especially in health systems, becoming one of the key elements when it comes to business continuity and its development in optimal conditions. The adaptation to a new style of carrying out the activities within the job, the motivation and retention of the employees was possible through a good human resources management that was revolutionized through new technologies and new strategies, to correspond to the current needs.

Government programs to reduce deliberate absenteeism during disasters must first ensure the basic needs of employees, provide food and water during work, provide rest and breaks and secondly to ensure the safety of employees and their families, financial rewards, recognition of merits and psychological support.

On 28 September, the European Council - the Council of the European Union, approved financial support of 87.4 billion EUR under SURE (a temporary EU instrument to mitigate unemployment risks during the COVID-19 crisis).

Image 3: Financiar support SURE

It is a temporary support tool for mitigating unemployment risks in an emergency, millions of workers across Europe benefit from this aid, and is part of the tools to motivate employees through policy decisions taken at EU level (Scholz, 2020).

Conclusions

It is essential that organizations have a plan for the likelihood of a crisis, either a public health emergency or a large-scale disaster. The biggest problem is ensuring a workforce that will be willing to work, that will ensure the continuation of the organization's activity, because the loss of this workforce and voluntary absenteeism can have serious repercussions for the victims of the crisis.

Analyzing the evolution of the COVID-19 pandemic, it is concluded that it will be long-lasting, so we must take breaks, we must take leave days to "reset", we must also have rest periods. It is essential to enjoy normal and simple things like food, drink, sleep and play sports, think positively and be grateful for the good things in ones life, for example family and friends.

The health leader should create adaptable, short term and flexible plans that include rotating of personnel, solutions to new problems and flexibility in group structure. Team leader should not work alone and communication and collaboration is essential to team cohesion (Kreiss, 2010).

Abstract

The article presents selected decision-making problems concerning the actions of the Police in search of missing persons and proposes methods of *machine learning* (ML) to support decisions concerning the level of service activities (so-called *search level*). The problem of determining the scale of operations in searching for missing persons is extremely important, because the health and life of a missing person (often children or elderly people with illnesses) depends on the effectiveness of the search. In this issue, the time from the moment of disappearance to the moment of making a decision should be as short as possible. Equally, decisions taken with limited knowledge, should be appropriate to the situation and risk. A model of the decision-making situation is presented, including a description of information that is processed at all stages of proceedings. Due to the size of the detailed data vector, aggregation functions were proposed, which reduce the size of input data in ML methods. The analysis of historical data allowed to develop and calibrate several ML methods. Moreover, on the basis of formal documents (government act and other regulations), a decision tree was developed for cases which are qualified according to formal regulations. The article contains results of the tests performed on a set of anonymised data from the reality and synthetic data generated to increase the volume of information. In order to identify the most appropriate method of classification, the quality of classification and decision support was studied, which was then presented in the conclusions.

Keywords: machine learning, searching for missing persons, multiresolution modelling

Introduction

Every year about 15 thousand people go missing in Poland. The reasons for these disappearances vary and regardless of the cause, the most important thing is to find the missing person before any life-threatening event occurs. A significant part of the disappearances are minors, who are often unable to survive alone in hostile conditions. Depending on the age of the person, their ability to live independently, and other key factors, the search for persons must be adapted and planned accordingly. Due to the organization of the search the most important aspect is to determine the threat to the life of the missing person and the urgency of the search. Police statistics show that during the first 24 hours about 30% of all missing persons are found, during the first 48 hours about 54%, during the first 7 days about 77% and during the first 30 days after the police accepts the report more than 90% of all missing persons are found, this shows the need to prioritize the search activities for missing persons. The percentage of people found within specific time frames since the disappearance is presented on Fig 1.

Fig 1 : The percentage of found missing people within specified times range. Source: https://www.policja.pl/pol/aktualnosci/115830,Zaginiecia-osob-w-Polsce-Fakty-i-mity.html

For every registered missing person case by the Polish National Police a search level is defined. The definition and description of three search levels is presented in the Chief constable Ordinance number 48 adopted on 28 June 2018. The ordinance defines three different search levels – I, II and III. The levels define the degree determining the urgency and scope of the search activity depending on the identified risk of threat to a person's life, health or freedom. The levels are assigned to reported cases of people who, as a result of an event that makes it impossible to determine his or her whereabouts, needs to be found to protect her life, health or freedom. The lower the number of the level, the more actions are taken in order to find the person. The ordinance specifies basic situations that allow for assignment of each of the levels.

The first level is assigned to a case of a person whose disappearance is related to a real, direct occurrence of a threat to his life, health or freedom, for whose rescue required direct and immediate search with the involvement of considerable forces and resources. The second level applies to a person whose disappearance is connected with a reasonable suspicion of risk to her life, health or freedom. The third level is assigned for a person whose disappearance is not directly and reasonably related a threat to her life, health or freedom.

In Poland, a project called "Developing a database and tools for semantic information and knowledge management in the area of disappearances and searches for people", financed by the National Center for Research and Development is coming to an end. The result of the project will be an IT system enabling, among other things, collection of data regarding completed and currently ongoing searches. Historical cases will be the basis for calibration of ML methods used to draw conclusions about: the level of searches, predicting the cause of the disappearance, building behavioral models of different types of missing persons, developing standard operating procedures for the police, indicating normative documents and searching from the database, documents related to the disappearance cases, similar to the currently implemented ones. A separate functionality is a GIS module supporting the field search process.

The subject of this article is the use of ML methods to suggest the search level of the missing person based on the data collected during the search process. It is sometimes difficult for unexperienced policeman to determine which level should be assigned and it is crucial in planning the search activities and decision making regarding the case. It may help indicate the places of search, appropriate operational activities and predict the behavior of the missing person. The prediction of the search level for newly defined cases is based on a hybrid approach, the ML methods learned using previously reported cases and a set of rules based on the ordinance in the form of a decision tree. In this article we present a method for both practical and new problem regarding a recommendation of “search level”. The novelty of the proposed method consists in combining the known ML algorithms with the generation of rules based on the law.

The rest of the work was divided into five parts. In the "Related work" section there will be an overview of missing persons' search methods, ML methods and GIS systems. The "Data description" section contains the definition of the data model describing the disappearances and the aggregated model and relations between the models. Aggregate model is used directly in ML methods. The real data available for the time being covers 717 cases. The section "Classification methods" reviews the ML methods that have been used to infer the cause of the disappearance. The "Multiclass methods validation" section discusses methods of quality assessment for classification methods when objects are classified into more than two classes. At the end, a section presenting the results of a computational experiment performed on data containing a large number of cases is presented.

Related Work

The search level (strictly speaking), defined by the Chief constable Ordinance, has not been found in any research work. However, plenty of research has been conducted in the area of searching for missing persons, this research includes general studies that focus on the statistics usage for analysis of current cases, "Search and rescue - SAR" issues and most importantly the usage of ML for searching missing persons.

The research conducted by NCA (2017) focuses on describing the problems of missing persons, it “provides key statistical data regarding missing people and unidentified individuals/remains reported to Great Britain police in 2015/16”. The report is based on data collected in the fiscal years 2012/2013 to 2015/2016 broken down by gender, age, reasons for the disappearance and the duration of the search. Collected results may help in prediction of the distance between the point of disappearance and the place of finding, the duration of the search from the moment of reporting the disappearance to finding. The handbook published by Morewitz et al. (2016) contains statistics data regarding missing persons, but also provides tools and methods that might help in finding the person, these methods are based on solutions taken from biology, genetics, anthropology, and archaeology. However, the Handbook does not include works on the use of IT systems, including artificial intelligence methods, ML or GIS.

A lot of research has been conducted in the area of search and rescue (SAR), named after military action of searching for missing ships or pilots of planes shot down or landed as a result of an accident in an unknown area. Out of the found research on the topic, the most interesting and most frequently quoted is the book by Koester (2008). It provides many types of disappearances, elements of behavioral models of persons missing in the field, tips and rules that help plan the search and schedule the performed activities in order to find the person. Another good quality research regarding practical guides for planning and conducting the search has been published by Bownds (2013).

Research also has been done in the area of finding missing persons using face recognition algorithms. Facial recognition systems based on deep learning methods such as convolutional neural networks are one of the approach to the problem. Bharath et al. (2019) used Convolutional Neural Network (CNN) for calculating face embeddings and then Support Vector Machine (SVM) algorithm to try to match missing person face in the database. Chandran et al. (2018) proposed similar architecture as in previously mentioned paper. Their system purpose was to find missing children. Model was composed of pre-trained CNN model with SVM classifier.

Delahoz-Dominguez et al. (2019) approached the problem from an angle of including personal and geographical information about the missing person. They used machine learning methods for predicting status of the missing people based on vector consisting of 20 variables. Random forest method performed better than decision trees and k-nearest neighbours.

The previously described work does not mention the utilization of machine learning methods in order to aid the process of finding the person. Detecting criminal activity using artificial intelligence and ML methods has been described by Larose (2015) and in the paper by Nath (2006) which presents the use of clustering methods to identify patterns of crime with regard to the spatial location of crimes. The usage of CCTV cameras to discover and track criminal activity has been mentioned in the article by Chackravarthy et al. (2018). Automatic detection of crime has also been presented by McClendon et al. (2015), he used regression algorithms to detect and compare crime patterns identified in two different crime data sets and by Wang et al. (2013), presenting a tool that can analyse different crimes to find which of them were committed by the same person.

Although the research regarding finding missing persons using machine learning methods have relatively numerous literature, the main problem (strictly speaking) of “search level” has not been widely published. One of the few studies on the topic have been conducted by Blackmore et al. (2002, 2003a,2003b,2005). They contain a precise description of research aimed at building an inquiry system to support police work in searching for missing persons. The research was commissioned by the New South Wales State Police in Australia and focused mostly on predicting the possible reason for disappearance using 357 cases. A complete and very inspiring study are outcomes of the ChildRescue Project (2019) - co-funded by the Horizon 2020 EU Programme. Authors examine a set of methods and algorithms for predictive analytics, aiming to enhance the techniques of profiling. The profile of missing person is conceptually quite close to our proposition related to data description - a vector of features.

The problem considered in this paper has not been described in any research yet, the main reason for this is the local character of the search level (it was defined in the Polish Chief constable Ordinance). The data being the basis for the analysis came from the archives of the Polish Police. In order to identify the best method of classification, several selected methods were studied: decision trees and random forests, naïve bayes classifier and multilayer perceptron.

Data Description

In consideration of the amount and diversity of information collected in the process of searching for missing persons, the police and other support services should rely on templates and schemes for describing case information. These

are the so-called questionnaires, which are readable to humans, however for the purposes of computer support methods (including machine learning) they must have a structured form. The formal model for the description of collected information about the missing person and his/her surroundings (including the circumstances of the disappearance, weather conditions, relations with other people) will ensure consistency and completeness of data in decision support, especially in regard to the search level.

Hence, we will further assume that:

- S – a set of "missing persons" cases;
- F^1 – non-empty and finite set of possible "detailed" features describing the case (first-order features). This is information collected in the course of the investigation;
- L^1 – number of features in set F^1;
- F^2 – non-empty and finite set of possible "aggregated" features describing the case. This is "the secondary" information, determined on the basis of the values of the features in set F^1;
- L^2 – the number of attributes in the set F^2;
- $F=F^1 \cup F^2$ – non-empty and finite set of all possible "aggregated" attributes describing the case;
- $f \in F$ – feature *f*, defined by the ordered pair $<id_f, D_f>$, where:
    - id_f – identifier of feature *f*,
    - D_f – domain of values for feature *f*;
- $D = \bigcup_{f \in F} D_f$ – domain of values for features describing the case.

Each case $s \in S$ is described by a feature vector consisting of two subvectors $s=<S^1, S^2>$, where:

- the vector of "detailed" features:
    - $S^1 = <s^1_1,\ldots, s^1_i, \ldots, s^1_{L1}>$, $s^1_i \in F^1$, $i=1..L^1$;
- vector of "aggregate" features:
    - $S^2 = <s^2_1,\ldots, s^2_i, \ldots, s^2_{L2}>$, $s^2_i \in F^2$, $i=1..L^2$.

The value of each feature of vector S^1 in the case *s* at the moment *t* – this is the so-called "information on the case" established at the moment *t*:

- $v: S \times F^1 \times T \rightarrow D$,
- $v(s,f,t) \in D_f$, $f \in F^1$, $s \in S$.

If the information is not time-dependent, a fixed value may be assumed:

- $V: S \times F^1 \rightarrow D$,
- $V(s,f) \in D_f$, $f \in F^1$, $s \in S$.

The value of feature *f* defined by the domain D_f might be:

- nominal - domain is an unordered set (i.e. for two values it is possible to define only the relationship of equality or difference);
- ordinal - domain is an ordered set (i.e. for attribute values it is possible to specify the relationship of equality, difference, minority or majority);
- numerical - domain is defined on numerical measurement scales: interval or ratio (on these scales, as opposed to ordinal scales, arithmetic operations are also possible).

The following are selected features from F^1 collection, constituting "information on the case":

- s^1_1: Gender of the missing person:
    - id_{s11} = "sex"
    - D_{s11} = {0: "male, "1: "female" }
- s^1_2: Previous suicide attempts:
    - id_{s12} = "suicide_attempts"
    - D_{s12} = {0: "Unknown",1: "Not registered ",2: "Simulated", 3: "Real"}
- s^1_3: Somatic illnesses:
    - id_{s13} = "somatic_illness"
    - D_{s13} = { 0: "hypertension", 1: "chronic coronary artery disease", 2: "cancer", 3: "chronic respiratory diseases", 4: "diabetes", 5: "life-threatening", 6: "non-life-threatening" }

- s^1_4: Traumatic events/experience:
  - id_{s14} = "traumatic_events"
  - D_{s14} = { 0: "abandonment by someone", 1: "death of a relative", 2: "unforeseen situations difficult to handle", 3: "rape of a person", 4: "violence against a person", 5: "formal/legal problems", 6: "change of marital status", 7: "birth of a child", 8: "a disappointment to sb./sth." }
- s^1_5: Relationships to other people:
  - id_{s15} = " relations_to_other_people "
  - D_{s15} = { 0: " conflict in the relatives ", 1: " conflict in the relatives ", 2: "conflict at work ", 3: " conflict in the environment ", 4: "rebellion against the family", 5: "rebellion against another person", 6: "rebellion against the situation", 7: "participation or cooperation with a criminal group", 8: "threat from a criminal group", 9: "contact with addicts", 10: "contact with sects", 11: "rejection by the environment", 12: "problems in many relationships", 13: "persecution", 14: "imaginary relationship with someone", 15: "abuse or blackmail", 16: "broken relationships with the environment"}

The data constituting "case information" are collected during the investigation of missing persons at different stages and therefore at different moments in time. This means that at a given point in time *t* not all of the features of the S^1 vector in case *s* have to be fixed and this can be considered, in simple terms, to be non-existent. In the proposed model we use a complete set of features with the length L^1, i.e. the vector S^1, and the presence of features' values in the vector will be evaluated by function *E*:

- $E: F^1 x T \rightarrow \{0,1\}$
- $E(f, t) = \begin{cases} 1, & when\ the\ i-th\ feature\ is\ determined\ at\ t \\ 0, & otherwise \end{cases}$, $f \in F^1$.

Aggregated Data Model

The number of features in the set of F^1 contains more than 30 "detailed" features describing the case ($L1 \approx 30$), with different levels of detail - they represent qualitatively different values. The domains of the features' values are relevant to the type of data collected in the case - they can be numeric, enumerated, ordinal or nominal. Most methods of data analysis require sets with a large amount of data - assuming that L^1 is the largest possible number of different "detailed" features, the number of all potential combinations of features can be determined as "2^{L1}-1".

It is obvious here that we reject the empty set as irrelevant, because it means no 'information on the case'. For L^1=30, and assuming that the features have at least 2-value domains, the number of all possible combinations of data is so great that in practice it would be difficult to develop algorithms for effectively recommending the cause of the lost/missing. The dimensionality is a significant problem for the effectiveness of all algorithms of data mining and machine learning - it has a negative impact on the quality of prediction, exceeds the requirements for computing power, worsens the response times of the implemented methods. In the literature, this problem is called the curse of dimensionality. In order to reduce the length of the features' vector, it is possible to (1) select significant features and discard excessive ones, and (2) apply aggregation of detailed features into generalised ones.

The first step is the selection of traits - in the proposed model we have selected a subset of mandatory features from set F^1, ensuring the consistency and completeness of the information collected in the case. For this purpose, we define the *O* function, which specifies the features necessary for the correct functioning of machine learning methods:

- $O: F^1 \rightarrow \{0,1\}$
- $O(f) = \begin{cases} 1, & when\ the\ i-th\ feature\ is\ mandatory \\ 0, & otherwise \end{cases}$, $f \in F^1$.

According to the *O* function a set of rule restrictions for GUI and database have been implemented.

The next step is to aggregate the "detailed" characteristics into "aggregated" characteristics. For this purpose, we specify a set of functions corresponding to methods, which for each case $s=<S^1, S^2>$, $s \in S$ determine the values of attributes in the S^2 vector (of length $L^2 < L^1$) on the basis of values of attributes in the S^1 vector:

- $X = \{X_i: (F^1)^{L1} \rightarrow F^2, i=1..L^1\}$

The idea of aggregation is illustrated in the figure below:

$$S^1 = \langle s^1_1, \ldots, \mathbf{s^1_3}, \ldots, \mathbf{s^1_{14}}, \mathbf{s^1_{15}}, \ldots, s^1_i, \ldots, \mathbf{s^1_{20}}, \ldots, s^1_{L1} \rangle,\ s^1_i \in F^1,\ i=1..L^1$$

$$\mathbf{X_3} \downarrow$$

$$S^2 = \langle s^2_1, \ldots, \mathbf{s^2_3}, \ldots, \mathbf{s^1_8}, \ldots, s^2_i, \ldots, s^2_{L2} \rangle,\ s^2_i \in F^2,\ i=1..L^2,\ L^2 < L^1$$

Fig. 1. The idea of determining the values of "aggregated" features from "detailed"

The aggregation function for characteristic s^1_3 ("Somatic diseases") is presented below:

- $X_3: (F^1)^{L1} \rightarrow F^2$;
- $X_3(s^1_1, \ldots, s^1_i, \ldots, s^1_{L1}) = \begin{cases} 0, & when\ s^1_3 = 0 \vee s^1_3 = 2 \vee s^1_3 = 4 \vee s^1_3 = 5 \\ 1, & when\ s^1_3 = 1 \vee s^1_3 = 3 \vee s^1_3 = 6 \end{cases}$.

Other aggregation functions concern the following characteristics are as follows: age, ability_impl, life_threat, adjustment, suicides, medication, health_condition, temporary_hardness, relations_to_other_persons, traumatic_events, higher_mood, negative_self, negative_others, behaviour_change, leave_preparation, weather, terrain.

To conclude, the applied functions for selection and aggregation of features let reduce a problem "curses of dimensionality".

Table 1: Examples of values of the aggregated features

sex	***suicides attempts***	***somatic illnesses***	***traumatic events/experience***	***relations to other persons***
male	real	no	abuse against a person	threat from a criminal group
male	no	cancer	difficult situations	no
male	simulated	no	death of a relative	conflict at school
male	no	no	abandonment by somebody	unknown
female	no	diabetes mellitus	no	unknown
male	no	no	unknown	no
male	no	hypertension	no	unknown
male	no	no	no	conflict at school
female	no	hypertension	unknown	conflict in the relatives
male	unknown	no	abuse against a person	threat from sects
female	no	no	difficult situations	conflict in the relatives
male	no	diabetes mellitus	formal/legal problems	conflict in the relatives
male	no	hypertension	no	conflict at school
female	no	no	yes	unknown
male	no	cancer	unknown	no
female	simulated	no	abandonment by somebody	conflict at school

Classification Methods

Decision Trees

Decision trees described by Sathyadevan & Nair (2015) are widely used classifies in problems where the rules for the classification must be easy to understand and should be possible to be visualized. Even though they are not the best classifiers, they are selected because of their comprehensiveness. In predicting the search level they play a very important role. Based on the examples defined in the Chief constable Ordinance (Table 2) a set of rules have been identified that allow to assign search levels in some cases with 100% certainty.

Table 2: Examples of cases defined in the ordinance that fit into the definition of three search levels

Level I	Level II	Level III
A minor under the age of 10 years	A person declaring once again an intention to commit suicide, or whose declaration of intent of committing suicide was considered real	A person expressing the desire to break off contacts with family, loved ones or the environment in which he last stayed
A minor between 11 and 13 years old, missing for the first time		
A person unable to exist independently	A minor between the ages of 14 and 18 missing for the first time	A person who moved away from his place of residence as a result of family disagreements
A person that requires continuous use of medication and failure to take them is life-threatening	A person capable of independent existence, but requiring care and constant intake of life-saving medication	A person for whom it is not possible to determine the causes or circumstances of the disappearance
A person missing due to a real suspicion of committing a life threatening crime against him	A person missing abroad, for whom there is a justified need to provide help to protect her life, health or freedom	A person with whom there is no contact, and declared a desire to leave or its disappearance is connected with departure or visit abroad
A person whose behavior in a real way indicated a direct intention to commit suicide if the immediate undertake of actions will most likely contribute to the prevention of a suicide attack		A person not requiring constant medical care or continuous medication that has willfully left the care facility, treatment facility, or other institution
A person lost in weather conditions threatening his life		A minor between the ages of 11 and 13 years missing once again

These rules have been joined together to form a decision tree that allows to predict the search level using the rules. The decision tree is presented on Fig. 2, it uses the rules identified for levels I and II. Some of the leaves contain the value ‘Unknown’, in this case an additional ML method is used for prediction the search level, the additional method is trained using 717 cases defined in the database.

Fig. 2 : Decision tree built using rules extracted from the ordinance

One of the additional methods that can be used are Classification and Regression Trees (CART) provided by *scikit-learn*. They would be used only in situations of ending in the 'Unknown' leaf of the decision tree based on the ordinance. For generating the splits, usually, the Gini impurity or information gain ware. To reduce overfitting each of the trees was pre-pruned by limiting the number of leaves.

Random Forest

Random forests are an example of an ensemble ML method, which bases its prediction on decision trees (Sathyadevan & Nair (2015)). It usually provides better results than a single decision tree and reduces the chance of overfitting because each of the trees is smaller and concentrates only on a subset of training data. When the trees are learning each of them can choose the splitting feature from only a subset of the defined features in the training vector, this allows each of the trees to focus on different aspects of the training data, resulting in trees which are very different. During the classification process each of the trees is used separately for the classification and based on the chosen leaves from all of the trees the final result is determined.

The random forests chosen for predicting the recommended search level are built of CART trees with the Gini impurity or information gain as the splitting criteria.

Naïve Bayes Classifier

The naive Bayesian classifier is a special case of the Bayesian network. Its structure has a form (Jensen (2007, p.59)):

Let the possible cause of missing be collected into one hypothesis variable H with prior probability $P(H)$:

- For all information variables I, acquire the conditional probability distribution $P(I \mid H)$ (the likelihood of I given H).

- For any set of observations $f_1, f_2, .., f_n$ on the variables $I_1, ..., I_n$, calculate the product $P(f_1, f_2, .., f_{1n} \mid H) = P(H)\prod_{i=1}^{n} P(f_i)$. This product is also called the likelihood for $f_1, f_2, .., f_n$ given H.
- The posterior probability for H is then calculated as

$$P(H \mid f_1, f_2, .., f_n) = \mu P(H) P(f_1, f_2, .., f_{1n} \mid H) =$$

$$= \mu P(H) \prod_{i=1}^{n} P(f_i)$$

where: $\mu = 1 / P(f_1, f_2, .., f_{1n})$ is a normalization constant.

Multilayer Perceptron

Multi-layer perceptron (MLP or Artificial Neural Network) consists of layers, where first using a non-linear transformation, transforms and projects the input data into next layer, to a space where it becomes linearly separable. This next layer (referred as hidden layer) makes MLP a universal approximator which means that it finds any mathematical function $y = f(x)$ that can map features x to outputs y. In our paper inputs of neural network are missing persons reports (which can contain missing data) and outputs are disappearance reasons. In a paper published by Hornik, K., Stinchcombe, M. and White (1989) authors shows Universal Approximation Theorem which says that MLP can solve classification task for arbitrarily complex function $f(x)$ for any number of inputs and outputs.

In our system we used Multi-layer perceptron implementation provided by *scikit-learn.*

Support Vector Machine

SVM (Support Vector Machine) – described in a study by Cortes and Vapnik (1995) - is a non-probabilistic, binary linear classifier that performs supervised learning for classification or regression of data groups. After processing training examples, SVM can perform unsupervised learning. The method leads to achieve the best separation of data with the boundary around the hyperplane being that differentiates the two classes. The known 'cons' is that it doesn't perform well for large data set because the required training time is higher. Also, it cannot perform very precise if the data set has too much noises (i.e. target classes are overlapping).

Case Study

In this paper we conducted a study to see the usefulness of machine learning methods for predicting a search level. Dataset on which methods were learnt and tested consisted of 717 real life cases of missing persons reports. Distribution of classes in dataset is imbalanced which means that there is unequal number of classes within dataset. Table 3 shows the division of search levels in the dataset.

Table 3: Results of classification for various methods

Search level	Number of cases (%)
I	312 (43,5%)
II	334 (46,6%)
III	71 (9,9%)

Table 4 presents results of the conducted experiments. Best results were achieved by Decision Trees and Random Forest algorithms.

Table 4: Results of classification for various methods

Method	Fit
Decision Trees	0.81
Random Forests	0.83
Naive Bayes	0.52
Support Vector Machines	0.51
Multi-layer Perceptron	0.47

Confusion matrices for those two methods are being presented respectively in Table 5 and Table 6.

Validation method for all examined algorithms was k-fold cross validation where original dataset was randomly partitioned into four subsets.

Table 5: Confusion matrix for Decision Trees

		Assigned Class		
		I	II	III
Actual Class	I	204	49	8
	II	35	284	15
	III	12	7	52

Table 6: Confusion matrix for Random Forest

		Assigned Class		
		I	II	III
Actual Class	I	271	39	2
	II	40	287	7
	III	9	13	49

Conclusion

The issue of determining the scale of operations in search for missing persons is extremely important, because the health and life of a missing person (often children or elderly people with illnesses) depends on the effectiveness of the conducted activities. On the other hand, the amount of force and resources involved is important both economically and in terms of the safety of people in other areas from which the security services are redirected. In this issue, the time from the moment of disappearance to the moment of making a decision should be as short as possible. Equally, decisions taken by the police, with limited knowledge, should be appropriate to the situation and threat. Therefore, computer methods are necessary to support decisions made by police officers - the article proposes the use of machine learning methods. The solution we proposed allows to predict the search level regardless of the disappearance reason what is important considering: the planning of search activities, their timing, territory and the extent. To achieve that goal, the machine learning methods have been used.

For ML methods, dimension reduction is a key issue which determines the quality of classification results. In the proposed solution, the reduction of data volume was achieved by selecting features and aggregating retail features to generalised ones. This has reduced the complexity of the classification tasks, including the space of possible vectors of feature value combinations.

In the article, the methods were explored: Decision Trees, Random Forests, Naive Bayes, Support Vector Machines, Multi-layer Perceptron.

As a result of the conducted analyses, it was found that the most questionable results were obtained using the Multi-layer perceptron and SVM methods - this is probably due to the lack of an algorithm for selecting optimal parameters of the method. The value of the Fit factor obtained in the Decision Trees and Random Forests methods indicates their best adaptation to classified information. The weakness of the considerations presented in the paper is the small number of real cases, which is the basis for teaching ML methods. It is planned to carry out further verification of the methods used along with increasing the content of the missing persons database. It seems that the use of a combination of ML methods and rules generated under the law to inference for the level of the search is a significant improvement in the accuracy of the inference. This hypothesis will be verified in further research.

Abstract

Many statistics about websites and their structures and used resources are available. But those numbers are not clearly placed in web-performance context which can gives a closer notion about best-practices in web development.
In this paper, websites from the Moz Top 500 list have been used for the empirical research. The structure of each site was examined. It includes exploring of metadata about DOM and utilization of CSS. This gathered data has been combined with available web-performance statistics.
Observed values are visually presented and give a brief image about the current state of the web. With usage of statistical tools relationships in DOM structures have been found. The research also showed that, utilization of served CSS definitions is very low. This fact can directly influence user-experience, because unnecessary data is downloaded. The next part of the research outputs show the impact of website complexity on web-performance.

Keywords: Web performance, Web analysis, Dead-Code analysis, Core Web Vitals

Introduction

During the last decade, websites completely changed their purposes. From websites with static content, their utilization has moved to highly interactive web applications. Nowadays, usage of web applications is practically unlimited. Smaller desktop applications are moving to the web, because development for desktops is highly connected to a specific platform, needs installation, and not available everywhere. In comparison, web-applications which are available almost every which means availability on almost every device and without any installation. Noteworthy, are platforms for watching videos such as Netflix or YouTube (market leader in video streaming category) which, in many households, has replaced traditional TV. Another such example is Photopea which is a web-based replacement for Adobe Photoshop. They can be considered as proof of moving from desktop application to the web environment. Increased usage of web-applications requires adaption of user-interface for smooth interaction. The related visual appearance is highly related to web-design and user-experience (UX) which takes care of UI adaption. Each adaption usually adds a few lines of code. During the time of improving user-experience, the code-base size is increasing, and specific CSS styles rules are not applied. The "dead-code" can be marked as wasting of data-bandwidth which can be used for more useful data. The next side effect of the unused code is its impact on source code quality.

According to HTTP Archive ((HTTPArchive, 2020), median web-page size in 2011 was 600KB, now in 2020 it is more than 2MB. Thus, it has more than tripled during nine years. From that size, 26 KB is HTML and 71 KB is external CSS. The rest of the size is images, scripts, fonts and etc. From a performance point of view, each byte is counted.

Text 'Structural Profiling of Web Sites in the Wild' was the inspiration for this paper (Chamberland-Thibeault and Hallé, 2020). The aim of their text was to create a reference point for other studies which use samples of web pages for their own research. This paper follows up the idea and includes similar and different metrics.

To be more specific, this paper is focused on empirical research of website structure, usages of CSS and its overall impact on performance. The next aim of the research is awareness of responsive design impact in code bases.

The following sections describe the process of gathering metadata about websites and gathering data from public data-sets. Combination of the data is composed into detailed result sections which are followed by discussion about the causes and effects.

Methodology

Typically, the research begun with gathering of a website collection to analyze. When the representative websites had been collected then processing occurred. The results of processing are gathered metadata about each website. With each type of metadata, it is possible to distinguish two types. The first type is data about the website structure itself. The second one is data about performance. With combining of data, a unique data-set has been created. The new data-set has been evaluated with a statistical method. Selected observed data has been compared with http-archive stats which serves as validation of gathered data.

The analysis is done only on website homepages. In the following sections, each step is described in more detail.

Input Data

As the input websites for this research, Moz500 (Moz, Inc, 2020) has been selected. The list contains the most popular sites in the world which are based on link metrics that models how Google ranks websites. From the website collection, duplicates of country specific version of same websites were removed. After data set cleaning 337 websites for analysis remain.

Website Structure Exploration

For scraping of websites and their contents, JavaScript script has been developed. To be more specific, NodeJs (Node.js, 2020) has been used which allows to user third-party libraries. It makes gathering of data easier and it allows reuse of invented works. One of the most important used libraries is Puppeteer (Puppeteer,2020). Puppeteer is a NodeJs library which provides a high-level API to control Chrome web-browser over the DevTools Protocol. In summary, it allows opening of the web browser in a programmatic way (in headless mode without GUI) and investigates the structure each element on the web page.

For each website gathering of following data has been made.

- Count DOM elements
- Count classes and ids attributes
- Deepest node of the DOM
- Transfer size, decoded size and number of resources
- CSS coverage (used and unused CSS styles)

For getting CSS coverage, build-in Google Chrome analysis have been used.

Data acquisition was performed with following parameters:

- UserAgent: Mozilla/5.0 (X11; Linux x86_64) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/84.0.4147.105 Safari/537.36
- ViewPort: 1920x1080 (known as FullHD)
- Cache: disabled

For validation of the data, a screenshot of each website has been captured. Then each screenshot has been validated for correct data obtained.

Performance Information Gathering

For gathering of objective performance data, PageSpeed Insights API (Google, 2020) has been used. The tool is written by Google for testing web-performance and its API provides real-world data from the Chrome User Experience Report (CRUX) and data from the Lighthouse tool. In the CRUX, data from millions of real web-users

are gathered. From that data, a public data-set of key user-experience metrics for popular web-sites is created. Practically it means, for each visited web, it is possible to obtain the available user-experience metrics, and then send it to Google. The data can serve the website maintainer as tools for improving websites which helps to improve user-experience.

As the most useful performance metrics is possible to consider:

- Largest Contentful Paint (LCP) – metric represents render time of the largest object visible within view-port.
- Cumulative Layout Shift (CLS) – is calculated score of unexpected layout shifts. In the real world, it can cause issues when user has decided to interact with elements and the elements are shifted. This can lead to a very unpleasant situation for user.
- First Input Delays} (FID) – gives information about delay between user first interaction and time to start processing of the interaction. This metrics is useful for JavaScript based websites which are built mostly on the client side. This leads to a big delay between user first interaction and its processing.

Those metrics are known as Core Web Vitals (Walton, 2020) and they will be part of Google Ranking Factor in nearly future (Shepard, 2020). There are more available metrics but for the research, this brief introduction is enough.

For gathering data from the API, an existing automated online spreadsheet has been used (McNulty, 2019). The spreadsheet has been improved to gather other important information such as metric proportions. Each metric has three categories (slow, average, fast) with set limits. Data for each category represents percentage proportions allocated to it.

Data Post Processing

When both data have been gathered, joining and cleaning is required.

The final data-set has been processed in the R-studio which provides a very effective way to analysis data. For finding and proofing of the relationship between metrics, correlation has been used.

Results

HTML structure

In the order, the first data exploration is focused on metadata about the whole website collection. On figure 1, the chart of cumulative distribution of count elements across analyzed websites is shown. From the chart is possible to observe that 90% of websites have less than 3000 elements.

Fig. 1: Cumulative distribution of HTML elements on websites

The figure 2 shows distribution of element counts across researched websites, which describes distribution of values in more detail. Each line represents 50 elements. For better readability, extreme values have been omitted.

The next figure 3 shows usage of CSS class attributes against DOM length. Here, it is possible to see linear dependency between those metrics.

Fig. 2: Distribution of HTML elements on websites

Fig. 3: CSS Classes on the DOM length

Fig. 4: Distribution of DOM depth elements

DOM depth may indicate increased source code complexity of the web-page. In the top three websites with deepest DOM, are placed yandex.ru (43 depth), twitch.tv (41 depth), and eventbrite.com (38 depth). The figure 4 describes whole data (bin width is 1).

Selected cases have been picked up in following list:

- translate.google.com – uses class attribute for almost every element. The ratio of usage class per HTML element is 96%.

CSS usage

Figure 5 shows distributions of CSS style usage across all tested websites. The metric of loaded CSS styles is composed from external and internal styles. In average number, it means that the total loaded CSS styles for the main page is 420 KB. From that size, only 40 KB is used and 380 KB is unused.

Fig. 5: Distribution of CSS styles usage on websites

The average size of downloaded CSS definition per HTML class attribute is 1 KB. The style definitions are not related only to class attributes, but also to HTML elements.

The selected CSS style definition has been investigated in more detail due to the high ratio of unused CSS code. The following reasons lead to non-utilization of all CSS styles:

- Media queries – is the main block for building websites with responsive design. This kind of CSS definition is activated only when conditions for displaying are met.
- CSS Frameworks – are very powerful and make website development much easier because they provide many predefined definitions which are immediately ready to use. They also contain the aforementioned media queries. For example, one of the most common used CSS frameworks is Bootstrap, which has 160 KB (Otto, et al., 2020).
- Too specific and repeating styles – is probably caused by generating of CSS.

Selected cases have been picked up in following list:

- apple.com – It is representative from the category of "Too specific and repeating styles". The CSS styles contain language variants which are not negligibly repeated. For improvement, it is possible to load only a country-specific version of the web. The dead-code ratio is 93%.
- espn.com – website targeted on sport which contains one of the longest CSS definitions which are more than 30000 lines long (formatted), takes more 650KB, and CSS dead-code ratio is 94%.

Some observed websites duplicates CSS directly to DOM optimizing (Jovanovski and Zaytsev, 2016).

Analysis has been done only on the website homepage, and it does not mean the CSS styles cannot be used on other pages of the website.

Performance Impact

As was mentioned before, performance values have been combined with gathered HTML statistics data for correlation evaluation. Even in variety and uniqueness websites, weak correlations between performance and DOM structure has been observed. Figure 6 shows selected results of the correlation analysis.

Fig. 6: Performance correlations

The first input delay proportion metrics are correlated with maximal DOM depth. The FID (0-100) represents the proportion of users who have First Input Delay under 100 milliseconds. It is similar with FID (100-300) and FID (>300).

The maximal DOM depth is negatively correlated with FID (0-100) and conversely, FID (>100) is weekly positive correlated. It means that websites with lower shallow DOM structure are faster. The DOM depth and length implicates more complex DOM structure.

Conclusion

In this paper, empirical exploring of HTML website structures, coverage of CSS definitions, and its impact on performance has been done. Selected properties of web-pages have been observed and described in more detail, such as DOM length, and usage of class attribute. Gathered values has been visualized in plots which better illustrate the whole situation. An interesting facts can be the perceived ratio of usage class attribute per HTML elements which is 15%.

As one of the most important gathered knowledge is utilization of loaded CSS code at homepages, around 40% of page use has only 10% of loaded CSS styles. This definitely has an impact on user-experience, because unnecessary code is downloaded and parsed to user's devices. The main impact will be observable especially on portable devices which are very often limited by available data (FUP). The results of this research should alert web-developers about the dead-code factor which causes downloading of unnecessary code and its parsing. Approach for reducing size of CSS is explored and ready to use (Mazinanian, et al., 2014).

The future work will be dedicated to exploring of subsequent web properties and their impact on web-performance.

Abstract

Technology ceased to be an exclusivity in the world, its current use is necessary and fundamental in the industrial field. In such a competitive and globalized world, technology optimizes the production processes of organizations. In the agri-food sector, exporting companies need to improve their processes of categorization and homogenization of their products based on the uniformity of its physical characteristics, such is the case of the Peruvian green lemon. Therefore, it is necessary to save time, cost and human effort in carrying out this process. Therefore, this research aims to implement an artificial vision system for the classification of the dimension of lemons. The artificial vision system consists of the processes of image capture, pre-processing, segmentation, description and recognition and interpretation. Where algorithms compare the characteristics of the lemon to obtain an optimal result. As a result, after using the artificial vision system, an efficiency of 85.1%, a sensitivity of 84% and a specificity of 100% were obtained. It is concluded that the detection of the caliber of the lemons works optimally allowing the number of hits to meet the objective of the investigation. The implementation of this system provides a solution to the problems of product homogeneity.

Keywords*:* Machine Vision, Selection of Green Lemon, Time.

Introduction

Today, the creation of increasingly fast, expert and autonomous computers is the trend in computer companies that provide computers with the ability to relate to their environment, just like the human being through the senses [1]. We are currently immersed in a technological revolution for computing that is based on access and information processing capacity.

A difficulty found in computers is providing sensory capacity since there are complementary elements such as sensors, signal adapter cards or environmental noise. Despite these drawbacks, there is great interest in giving computers one of the senses, which is the ability to see. [2]. Computers are currently capable of looking at and recognizing images in a way similar to how humans interpret a photograph, having a profound impact on the health, distribution and agriculture sectors.

Artificial vision reproduces the visual processes of man, analyzing and improving the quality of the image, such is the case of agriculture where there is a high interest in evaluating the quality of agri-food products [3]. This technology is based on simulating human vision for the classification and recognition of products in agriculture. Artificial vision has also been used to detect the size and color of a product in real time, positioning itself as an understandable and accessible technology [4]. The application of artificial vision contributes to 100% quality control in real time.

Cite this Article as: Alex PACHECO, Consuelo ESPINO, Marco AÑAÑOS, Elizabeth MENDOZA and Liz PACHECO "Artificial Vision System for the Classification of Green Lemons (Citrus latifolia)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In companies in the agri-food sector, the requirements for the export of Peruvian lemons are increasingly uncompromising in quality and presentation of products. The companies that export this product carry out the selection process manually, in which the lemons go through a metal grid of various sizes to specify their diameter and then the operators are in charge of classifying and selecting them visually [5]. The classification of lemons visually causes a greater demand for labor, generating a margin of error of 20% [6]. Visual recognition of agri-food products is a field where this technology is implemented and has spread rapidly, specifically in the automatic classification of fruits and vegetables [7], [8]. Therefore, this research aims to implement an artificial vision system for the classification of the size of lemons, which will provide a comprehensive solution to companies dedicated to the export of lemons.

Theoretical Background

Artificial vision: called computational vision that encompasses the processes of obtaining, characterizing, and interpreting information from images taken from a three-dimensional world. These are divided into 5 processes (capture or acquisition, preprocessing, segmentation, description, recognition, interpretation) and due to the complication of implementation they are grouped into 3 levels of vision which are: under acquisition and preprocessing processes, middle segmentation processes and description, high recognition process [9]. Artificial vision processes are fast and simple, capable of improving an image in the same way that human vision does.

Figure 1: Procesos de la visión artificial.

Digital image: or digital graphic is a two-dimensional representation f (x, y), of an image from a numerical matrix, often in binary and is made up of a finite number of elements with a particular value and position, called pixels [10].

Digital Image Processing (PDI): Processes the images digitally by means of a computer, to do this, knowledge of physics, mathematics, and computation is applied. Its objective is to improve the images and make evident details that are not noticeable to the naked eye [11].

PDI Digital Image Processing Processes

1) Capture or acquisition: In this first stage, the image is captured and digitized from the physical to the digital by means of an image capture device such as the camera [12].

Figure 2: Acquisition phase.

2) Pre-processing: At this stage we use techniques to reduce noise, contrast brightness, or enhance features. which facilitates later stages, eliminating parts of the image that are not taken into account [13].

Figure 3: Pre-processing phase.

3) Segmentation: Pixels can be selected based on their RGB or HSV values. RGB, for its acronym in English Red, Green, Blue is a type of color that allows to represent all colors based on the primary colors of light and it is possible to highlight an object of a defined color [14].

Figure 4: Segmentation phase.

4) Description: this process is where objects with common characteristics are classified within 3D space and the space is restricted by triangulation techniques so that a single image is selected and it can be interpreted [15].

Figure 5: Description phase.

5) Recognition and interpretation: it is the process that associates a motive with a group of recognized objects such as an apple, a house and tries to imitate knowledge [16].

Figure 6: Recognition phase.

Materials and Methods

For the lemon classification tests, each process of the digital imaging technique was taken into account [17].

Table 1: Diameter of the lemons according to their classification.

Gauge code	Diameters (mm)
1	58 -67
2	53 – 62
3	48 – 57
4	45 – 52
5	42 - 49

The evaluation of the processes is based on a scale from 1 to 4.

Table 2: Device and algorithm rating measure.

1	2	3	4
Bad	Regular	Normal	Good

Phases of Image Processing

1. Capture or acquisition. A digital camera or a smart cell phone are ideal for capturing the images necessary for our project.

Table 3: Contrast chart of devices for image capture.

	Devices	
Criteria	Nokia 3.1 plus camera	Ultra compact sony rxo digital camera
Resolution	3	4
Memory	4	4
Transfer system	4	4
Capture speed	4	4
Total	15	16

Preprocessing

A.- Contrast enhancement: Histogram transformation is the most suitable and a transformation will be applied to HSV channels, to have a better image in contrast, saturation and brightness.

Table 4: Contrast chart between contrast enhancement techniques in the preprocessing stage.

Criteria	**Transformation of**	**Edge accent**	**Detection of**
	histogram		contours
Computational complexity	4	1	1
Uniform distribution of Gray levels in the image			
	4	2	3
Pixel enhancement of interest	2	2	4
Total	10	5	8

B.- Noise reduction: The Gaussian Filter is the most suitable to minimize noise in the image and segment correctly.

Table 5: Contrast chart between noise reduction techniques in the pre-processing phase.

Criteria	Opening (erosion, dilation)	Median filter	Gaussian filter
Preserves edges	3	3	2
Reduces impulsive noise	2	2	4
Smooth smoothing	3	2	4
Total	8	7	10

3. Segmentation. The threshold is considered low cost and the region technique is not necessary since the object is analyzed by image.

Table 6 : Contrast chart of the techniques of the segmentation phase.

Criteria	By threshold	By characteristics of regions
Threshold selection	4	3
Analytical equations	4	2
Total	8	5

4. Description: We have chosen the region description since the figure of the lemon in its composition contains many green pixels.

Table 7: Table of contrast between techniques of the description phase.

Criteria	Outline descriptors	Region descriptors
Pixel quantity dependency on the target	3	4
Using clustering	3	3
Object homogeneity	1	2
Total	7	9

5. Recognition and interpretation: the theoretical decision technique was chosen for recognition since the adaptation by correlation varies greatly and you must have a database to be able to use it.

Table 8: Contrast table between techniques of the recognition and interpretation phase.

Criteria	Theoretical decision for recognition	Correlation adaptation
Descriptor comparison	3	3
Search by proximity	4	1
Total	7	4

Results

The solution achieved through the software based on the algorithms indicated in the methodology To check the software activity, experiments were carried out each with 272 lemon figures, these figures were captured in different scenarios, resulting in the following:

True positive (VP):

At the moment that the lemon image is recognized by the artificial vision system (with the dimensions that comply with the standard) it is classified correctly. PV = 77.4%, equivalent to 211 lemons.

True negative (VN):
When the image of the lemon is recognized by the artificial vision system (with dimensions that do not meet the standard), VN = 6.5%, equivalent to 18 lemons, is not correctly classified.
False positive (FP):
At the moment that the lemon image is recognized by the artificial vision system (with dimensions that do not meet the standard), it classifies it correctly. FP = 0%, equivalent to 0 lemons.
False negative (FN):
At the moment that the lemon image is recognized by the artificial vision system (with dimensions that meet the standard) it is not classified correctly. FN = 16.1%, equivalent to 44 lemons.

Table 9: Representative table of the sensitivity analysis.

Criteria	Correct classification	Incorrect Classification
Lemons that meet standards	Vp	Fn
Lemons that do not meet standards	Fp	Vn

Table 10: Results in quantities of sensitivity analysis.

Quantities	True	False
Positive	211	0
Negative	18	44

Table 11: Results in percentages of sensitivity analysis.

Percentage	True	False
Positive	77.4%	0%
Negative	6.49%	16.1%

it was determined that, if possible, a machine vision system can perform a uniform selection of lemons. The selection time is 0.33 seconds per lemon, the effectiveness of a number of hits (true positives and true negatives) that the artificial vision system has, applying the software, resulting in 83.9% of a total of 272 lemons.

Discussion

This research aims to determine a uniform classification of lemons based on the use of artificial vision, processing the images and analyzing the results, the following was obtained:

The classification of lemons that were correctly detected through artificial vision is sensitivity, showing 84%, which represents 211 images of lemons out of a total of 272. After comparing the results of the software with a manual measurement, we can affirm that the difference Gauge ranges from ± 2 millimeters which can cause a lemon to rank to another gauge, automatically turning a true positive into a false negative. This is 11.40% lower than the automatic pattern recognition software for the discrimination of polished rice grains based on image processing [18].

When the image of a lemon does not meet the stipulated standards, it should not be assigned a size. In this work, the specificity is a true negative whose value is 100%, while in the research [19], a specificity of 91.91% was obtained, finding a difference of 9.09% in image processing.

The correct classification of lemons made up of true positives and true negatives in the efficiency of the imaging process is 85.1%. While the classification of wheat seed varieties is slightly more than 1% higher using computer vision [20].

Compared to the function that a worker performs in the classification of the lemon, the artificial vision system takes 0.33 seconds to classify each image.

Abstract

The article examines the legal responsibility of artificial intelligence, identifies problematic aspects, suggests ways to solve them. It is concluded that it is impossible to talk about the possibility of recognizing its full legal personality. In our opinion, the legislator should not go along the path of creating the possibility of bringing artificial intelligence systems to justice, but on the path of ensuring more detailed control over the actions of their developers and operators, and the development of appropriate standards.

Keywords: Artificial Intelligence, Crime, Responsibility, System, Intellectual Activity.

Introduction

As stated by Vasil'ev, A. A., Shpopper, D. and Mataeva, M. H. (2018), The National Strategy for the Development of Artificial Intelligence for the period up to 2030 defines artificial intelligence as a set of technological solutions that allow simulating human cognitive functions, as well as obtaining high-quality results when performing specific tasks comparable to performing at least the results of human intellectual activity.

Methods

General and special scientific methods, traditional for theoretical and applied legal research, were used, such as formal-legal, system-structural, content analysis of various publications, comparative legal method.

Results and Discussion

Today, artificial intelligence is considered as a technology with the possibility of multifaceted use, for example, for civil, military, legal purposes. But due to the fact that the artificial intelligence system is capable of independent actions without direct impact on a person, a number of questions arise in the legal regulation of relations with the participation of artificial intelligence, including questions of legal responsibility.

The development of artificial intelligence creates new threats associated with minimizing the human factor, so, for example, with the correct formulation of the primary task for this system, it will be able to both block hacker attacks and create them independently.

Social engineering is being automated, an example of which is the so-called "bots" - programs that can perform certain actions in accordance with a specific algorithm through interfaces intended for people. Tirranen, V. A. (2019) provides example, stating that they can conduct a dialogue with forum visitors or answer questions on social networks.

It is worth noting that the state of criminal policy in the field of combating crimes committed using artificial intelligence algorithms leaves much to be desired.

Cite this Article as: Andrey BAYBARIN, Alexander GREBENKOV, Anton BAUMSTEIN and Maria SINYAEVA“ Artificial Intelligence as a Subject of a Crime” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

It is obvious that technologies based on artificial intelligence, their algorithms can be a tool for a wide range of crimes, including attacks on people, property, environmental safety, public and state interests. An example is the technology of "deep fakes", the use of which allows the creation of reliable video images. So, the technology of subject-independent face replacement and face reconstruction called Face Swapping GAN (FSGAN), regardless of the object, can be applied to any pair of faces. As a result, as stated in Red'kina, A.I. (2016), we can observe how famous people allegedly take part in provocative interviews, etc.

From a legal point of view, the production and distribution of such video fakes can be qualified as defamation. But in this context, the experience of Texas is interesting, when, on the eve of the 2020 elections, lawmakers criminalized the creation of political deepfakes, establishing punishments up to 1 year in prison.

Ponkin, A. V. and Red'kina, A. I. (2018) note that a new cyber-physical system is emerging, which is designed to solve the fundamental problem of modern society, namely, the inability to process the increasing amount of information.

Note that the very use of artificial intelligence systems causes the emergence of new problems and difficulties within the framework of existing models of responsibility, which are mainly based on the concept of a causal relationship between an action and its consequences.

In the case when the use of such machines led to the commission of a serious mistake, the question arises as to what exactly caused this: the original complexity of the equipment or its incorrect programming and training?

For example, in recent years, the use of unmanned vehicles is gaining more and more popularity. In this connection, the question also arises, in the event of a fatal traffic accident, who will be the direct culprit of this accident? A similar precedent already exists, namely, in August 2019 in the state of Arizona, an unmanned vehicle owned by Uber hit a pedestrian who died on the spot. It follows from the circumstances of the case that the driver was nevertheless present in the cabin, but did not have time to take control of the car. It should be noted that in this situation the driver was found guilty, and not the unmanned vehicle. However, in our opinion, this situation cannot be used as a sustainable practice. Since in most cases of using artificial intelligence, it is reasonable to hold the developers of this system accountable for mistakes made by it. But not in situations where the artificial intelligence system begins to function in a way that could not have been predicted earlier, especially, as Cukanova, E.Yu (2018) states, if such a system interacts with other agents. The essence of the autonomy of an artificial intelligence system just means that the introduction of some data and the programming of such a system in a certain way leads to a specific result in response to given circumstances.

Conclusion.

The complex and polymorphic nature of such systems makes it impossible to clearly define responsibility for the failures of such programs. In addition, if we talk, for example, about complex equipment, then decision making by such equipment is likely to be distributed among several different programs (developed, possibly, by different programmers unfamiliar with each other) and processors, based on data received from sensors of different types. Decision making with such equipment will also depend on the environment in which it is used, the context, and the tasks assigned to it. In this case, it is inappropriate and incorrect to assign responsibility to designers and developers. In addition, there is a serious problem related to the vulnerability of artificial intelligence systems to hacking, which can complicate the identification of the person responsible for the harmful actions of such a system.

Summarizing the above, we note that today there is an active development of artificial intelligence technologies and at this stage it is impossible to talk about the possibility of recognizing its full legal personality. In our opinion, the legislator should not go along the path of creating the possibility of bringing artificial intelligence systems to justice, but on the path of ensuring more detailed control over the actions of their developers and operators, and the development of appropriate standards.

Abstract

The article proposes a conceptual approach to the study of the problems of building engineering and technical means of security and supervision (TMOSS) in the context of implementing the tasks of ensuring the safety of facilities and employees at the modern stage of the development of the penal correction system in the context of the application of various forms of innovation: information, organizational, social, technical and technological and co-responsible settlement at the legislative level. The conclusion is made that in the special conditions of the pandemic, the effectiveness of the activities of penitentiary institutions is largely determined by the competence of the penitentiary staff and the effectiveness of the use of modern TMOSS.

Keywords: Penal Correction System, Institution, Employee, Research, Technology, Means, Protection, Supervision, Threat, Safety, System, Analysis, Method, Factor, Program, Concept, Concept, Conceptual Scheme, Development.

Introduction

The conceptual approach to the study of the problems of building innovative TMOSS in penal institutions involves a comprehensive study of the results of the rapid introduction of modern information, organizational, social, technical and technological forms of innovation into the practical activities of the penal correction system and the corresponding changes in the basic provisions of criminal enforcement legislation and other regulatory legal acts, as the main factors for achieving the main goal - ensuring the safety of facilities and employees of the penal correction system.

Methods

This article, based on a conceptual approach, highlights an integrated set of provisions constituting a methodological framework for research into the problems of building innovative TMOSS in penitentiary institutions while differentiating them. The methodological basis of such a study is a systematic multi-vector factor analysis of information set forth in modern regulatory acts, scientific materials, official statistics and analytical documents, which provide the results of a study of emerging problems in the use of modern technical means of security, communication and information protection systems, organization of security and escorting.

Based on the conclusion of G.V. Nazarenko (2016) that... «the movement of scientific thought comes from the concept (initial idea) to the conceptual scheme (developed idea), then to the conceptual system (completed scientific theory)», we believe it appropriate in the course of the study to use such categories of conceptuality introduced by the author as a concept, conceptual scheme, conceptual system, concept and con-ceptualism.

At the legislative level, we consider the concept of building modern TMOSS in the penal correction system as a set of conceptual schemes, each of which represents a comprehensive set of criminal regulations (concepts) of the current editions of penal enforcement legislation and other regulatory legal acts, as means of designing criminal law norms,

Cite this Article as: Andrey BAYBARIN, Alexander GREBENKOV, Vladimir TARYKIN and Gennady PLOHIH" Conceptual Approach to Construction of Engineering and Technical Means of Security and Supervision in the Penitentiary System at Present Stage" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

institutions and other regulatory blocks. In our view, it is precisely such a concept as a defining idea (strategy) that systematizes all the ideas (views) developed to understand the direction of the development of TMOSS in the penal system, provides an answer to the question of how to achieve the intended goal.

Results and Discussion

The main purpose of the concept of building modern TMOSS in the penal system is based on the priority of the constitutional norm on ensuring the rights and freedoms of the individual, which forms the basis of the State's criminal policy, as enshrined in federal legislation and other normative legal acts. In particular, the rights to personal safety of convicts, employees of penal institutions and members of their families are enshrined in the Criminal Enforcement Code (CEC) of the Russian Federation (CEC of the Russian Federation - FL of 08.01.1997 № 1-FL). At the same time, the practical bodies of the penal system should ensure: the humanitarian orientation of their activities, adherence to international norms and standards for the execution of criminal penalties, including on the construction and use of TMOSS.

As safety of penal correction system is an important component of public safety of Russia, and the concept of construction modern an TMOSS in penal correction system has to be formed also on the basis of «The strategy of national security of the Russian Federation» approved by the Decree of the President of the Russian Federation of 31.12.2015 № 683 and also provisions of Acts of the Russian Federation: «About the institutions and bodies executing criminal penalties in the form of imprisonment» of 21.07.1993 № 5473-I (an edition of 02.12.2019); «About detention of suspects and the crimes accused of commission» of 15.07.1995 № 103-FL (an edition of 27.12.2019); «On State Protection» from 27.05.1996 № 57-FL (ed. From 27.12.2019); «Criminal Code of the Russian Federation» dated 13.06.1996 № 63-FL (ed. from 18.02.2020); «Criminal Enforcement Code of the Russian Federation» dated 08.01.1997 № 1-FL (ed. from 27.12.2019); «On Safety» dated 28.12. 2010 № 390-FL; «On administrative supervision of persons released from places of deprivation of liberty» from 06.04.2011 No. 64-FZ (ed. from 01.10.2019) and other regulatory legal acts.

For example, article 12 of Act №5473-I of 21 July 1993 on institutions and bodies carrying out criminal sentences of deprivation of liberty discloses the general requirements for the organization of the security of penal institutions, and article 32 of the Act guarantees the protection of the State, both for personnel of penal institutions and for members of their families.

Article 83 of the CEC of the Russian Federation defines the rights of using TMOSS by the administration of the penal correction system to prevent escapes and other crimes, violations of the established procedure for serving a sentence and in order to obtain the necessary information on the behavior of convicts.

In this context, R.Z. Useev (2015) justifies the need to prepare a state paradigm for the security of the penal system and shows that «the central element of the study of the security of the penal system should be its facilities: people (personnel, convicts, suspects, accused and other persons) and his vital interests; the range of relationships and processes in the penal system; facilities and objects for ensuring the activities of the penal system; institutions and bodies (subdivisions) of the penitentiary system as structural units of the Federal Penitentiary Service of Russia, institutions of the territorial body of the Federal Penitentiary Service of Russia, subdivisions of a separate institution».

A.V. Kudryavtsev and A.V. Senatov (2014) bring the problem of ensuring the security of employees of the penal system and their relatives to the state level and note that... «the protection of employees of the penal system involves the implementation of a unified state policy in the field of security through a system of measures of an economic, political, organizational and other nature, adequate threats of vital interests».

Concepts (innovative ideas containing creative meaning) and conceptual schemes (systems of concepts interconnected according to certain rules) of building modern TMOSS in the penal system are determined today by current legislation and other regulatory legal acts of federal government bodies that form the penal policy of the state.

The basis of the conceptual scheme (system of concepts) for the construction of modern TMOSS in the penal system in the organizational and legal aspect at the legislative level are the concepts of «protection» and «supervision»? which at the level of conceptual knowledge - the most significant components in the area of knowledge under consideration - are disclosed in the relevant norms of articles of the current editions of the laws of the Russian Federation and other by-laws in all kinds of practical use in various types of institutions of the penal system for various situations.

In the «National Security Strategy of the Russian Federation», approved by Decree of the President of the Russian Federation dated 31.12.2015 № 683, the concepts of «protection» and «supervision» are disclosed:

- in paragraphs 45, 49 of the section «State and public security»;

- in paragraph 54 of the section «Improving the quality of life of Russian citizens»;

- in paragraph 62 of the section «Economic growth»;

- in paragraph 86 of the section «Ecology of living systems and environmental management».

The concepts of «protection» and «supervision» are also disclosed in articles of current federal laws:

Articles 2, 12, 37, 215.4, 274 of the Criminal Code of the Russian Federation;

Articles 1, 10, 12, 24, 60, 60.4, 60.6, 60.11, 60.18, 60.19, 81, 82, 83, 85, 101, 103, 104, 121, 129, 133, 156, 164, 173.1, 179, 184 of the Penal Enforcement Code of the Russian Federation;

- Articles 5, 12, 12.2, 13, 28, 30, 31.2, 32 of the Law of the Russian Federation «On Institutions and Bodies Executing Criminal Penalties in the Form of Deprivation of Liberty»;

Articles 7, 34, 42, 48, 49, 51 of the Federal Law «On the Detention of Suspects and Accused of Crimes».

The norms of the articles of these Laws served as the basis for the adoption of a number of targeted programs and concepts aimed at improving and developing the penal system in matters of ensuring the safety of their facilities and employees, and approved by resolutions and orders of the Government of the Russian Federation.

Today, the conceptual approach of building modern TMOSS in the penal system is being implemented within the framework of the main directions of the Concept of the federal target program «Development of the penal system (2017-2025)», approved by Order of the Government of the Russian Federation of December 23, 2016 № 2808-r.

At the executive level, conceptual diagrams of requirements, tasks and measures for the equipment of TMOSS facilities of the penitentiary system are established by the approved Order of the Ministry of Justice of Russia dated 04.09.2006 № 279 (ed. from 17.06.2013) the corresponding Manual, which was developed and approved in accordance with legislative and other regulatory legal acts of the Russian Federation and European penitentiary rules. In the sections, articles and annexes of this Manual, conceptual schemes (systems of concepts) of building modern TMOSS in the penal system are described in detail, the basis of which in the organizational, legal and engineering and technical aspects are the concepts of «protection», «supervision», «engineering» and «technical».

The manual (para. 4) contains a conceptual chart of 18 main tasks (concepts), the implementation of which should be provided by TMOSS in the penal system.

The manual (item 5) contains a conceptual diagram of 9 main organizational measures (concepts) that ensure the fulfillment of the main tasks by creating appropriate TMOSS in the penal system.

In general, the TMOSS complex (item 6. Instructions) is a set of fences, engineering barriers and structures for security and surveillance purposes, technical means for collecting and processing information, technical means for security alarm, security television, access control and control, operational communication and warning, as well as uninterrupted power supply and security lighting installed and used at the facility of the penal system. At the same time, together with the TMOSS complex, equipment can be used at the security facility to counter the unauthorized use of cellular communication devices, search and inspection and other special equipment that does not reduce the efficiency of using TMOSS.

Depending on the purpose, place of installation and tactical tasks solved by units and services of institutions of the penal correction system, the general conceptual scheme «TMOSS Complex» in the context of the essence of the concepts «protection» and» supervision» can be divided into two components:

a) the conceptual scheme «Technical Means of Protection» (TMP) includes 8 concepts of constructions, designs, the equipment and means of engineering arms which are established on object perimeter for ensuring performance of tasks of its protection and requirements imposed to access control on an object (from an object);

b) conceptual scheme «Engineering and technical means of supervision» (ETMS) includes 6 concepts of technical means, systems and devices for collecting and processing information, security alarm, video surveillance, access control and control, operational communication and notification, monitoring and inspection, which are installed on the internal territory of the facility, as well as in special buildings and premises to ensure the established regime for the detention of convicts and persons, Detainees and their supervision tasks.

In the context of the concept of «engineering» and «technical» general conceptual scheme «TMOSS Complex», depending on the physical and mechanical properties of the elements, the principle of operation and materials for the manufacture of devices, can be divided into engineering means of protection and supervision (EMPS) and technical means of protection and supervision (TMOSS).

P.M. Nikolaev (2018) in his study uses a system-wide approach to modeling the application of TMOSS and names three factors that can have a significant impact on the effectiveness of protection and supervision in institutions of the penal system, these are: 1) technical characteristics of TMOSS; 2) methods and tactics of using TMOSS; 3) types and number of TMOSS used. At the same time, the author of the study shows that... « improper tactics of using or insufficient TMOSS reduces the effectiveness of supervision and protection, as well as creates prerequisites for escaping or violating the regime. On the other hand, the excess of TMOSS leads to an overexpenditure of funds for their purchase, installation and operation, while the effectiveness of supervision and protection remains unchanged.

Let us consider the influence of socio-economic factors and criminal policy of the state as a whole on the development of institutions of the penal system on the basis of a decrease/increase in quantitative indicators. A comparative analysis of the dynamics of changes in the main indicators given in the analytical certificates «A Brief Description of the Penal Correction System» for 2013 and 2020 (as of March 01) of the Statistical Data section of the official website of the Federal Penitentiary Service of the Russian Federation showed the following results.

1. The total number of special continents held in all penal institutions decreased by 183509 (26.14%) from 701900 in 2013 to 701900 people as of March 1, 2020. At the same time, the number of women of the special continent decreased by 15,966 (27.67%) from 57,700 to 41,734 women, the number of children's houses remained unchanged (13 units), and the number of children in them decreased by 294 (41.18%) from 714 to 420 children.

2. **The total staff of all penal institutions** decreased by 42,533 people (12.57%) from 338,500 (2013) to 295,967 (2020), while the number of convicts per 1 full-time employee decreased by 15.39% from 2.07 to 1.75, respectively. Including the number of certified employees decreased by 21,216 people (8.61%) from 246,500 to 225284, and the number of convicts per 1 certified employee decreased by 18.98% from 2.84 to 2.30.

3. The number of correctional colonies (CC) decreased by 39 units (5.28%) from 739 to 700. At the same time, the number of special continents decreased by 166,566 (28.47%) from 585,000 to 418,434 people, the specific load on average by 1 CC decreased by 194 (24.49%) from 792 to 598 people.

4. The number of CCs for life sentences increased by 2 units (40.00%) from 5 to 7. At the same time, the number of special continents increased by 174 (9.57%) from 1819 to 1993 people, and the specific load decreased by 79 (21.78%) from 364 to 285 people on average per 1 CC.

5. The number of settlement colonies (SC) decreased by 9 units (6.92%) from 130 to 121. At the same time, the number of special continents decreased by 6,702 (16.97%) from 39,500 to 32798 people, the specific load on average per SC decreased by 33 (10.84%) from 304 to 271 people.

6. The number of pre-trial detention centers and premises in the pre-trial detention center mode decreased by 90 units (22.78%) from 395 to 305. At the same time, the number of special continents decreased by 15924 people (14.02%) from 113600 to 97,676, but the specific load on average on 1 institution increased by 32 people (11.20%) from 288 to 320.

7. The number of prisons increased by 1 unit (14.29%) from 7 to 8. At the same time, the number of special continents increased by 274 people (30.44%) from 900 to 1174, the specific load on average on 1 institution increased by 18 people (13.76%) from 129 to 147.

8. The number of educational colonies (EC) decreased by 23 units (50.00%) from 46 to 23. At the same time, the number of special continents decreased by 1093 people (49.68%) from 2200 to 1107, the specific load on average per 1 EC remained unchanged - 48 people.

9. The number of institutions of the Criminal Executive Inspectorate with branches decreased by 1,031 units (41.93%) from 2,459 to 1,428. At the same time, the number of special continents decreased by 20,319 people (4.36%) from 465,700 to 486019, the specific load on average per 1 EC increased by 151 (125.17%) from 189 to 340 people.

10. The number of penal correction facilities decreased: a) state unitary enterprises - by 22 (41.51%) from 53 to 31; b) centers of labor adaptation of convicts - by 18 (3.07%) from 587 to 569; c) production workshops - by 22 (23.66%) from 93 to 71; d) evening general education schools - by 52 (16.30%) from 319 to 267; e) training and consulting points (branches) - by 39 (7.10%) from 549 to 510; e) vocational schools - by 48 (14.41%) from 333 to 285.

11. The number of penal correction facilities increased: a) separate structural units - by 140 (46.36%) from 302 to 442; b) objects for religious ceremonies and ceremonies - by 289 (22.99%) from 1257 to 1546; c) healthcare institutions - by 11 (19.64%) from 56 to 67.

It should be noted that the decrease//increase in these indicators is determined not only by socio-economic factors and the criminal policy of the State as a whole, but also by the implementation of the requirements of legislative and other regulatory legal acts of the Russian Federation, the European prison rules approved by Recommendation Rec (2006) 2 of the Committee of Ministers of the Council of Europe, and the introduction of modern TMOSS in the penal system.

The characteristic features of the modern stage of development of institutions and organizations of the penal system are the dynamic introduction of «breakthrough» technologies into their practical activities, which S.I. Rodzin and I.N. Titarenko (2014) in their study denote the term «NBIC» (NBIC - acronym: N - nano; B - bio; I - info; C - cogno). Based on a systematic approach to the study, the authors showed that nano-, bio-, info-, cognitive technologies do not develop in isolation, but actively influence each other in a single complex of NBIC technologies, while the purpose of each component they disclose as follows:

- nanotechnologies radically change the possibilities of producing substances with pre-programmed properties;

biotechnologies manipulate the biological parameters of humans, living systems and plant organisms;

- information technologies, implementing the input, storage, processing and output of information of various levels of semiotic valence, ensure the functioning of complex man-machine complexes and the organization of social systems;

- cognitive technologies change the mental parameters of a person, transforming the states, properties, qualities of individual and social consciousness.

Today, the responsible for the integration trends of the components of the NBIC complex are information technologies and artificial intelligence technologies, which are beginning to be actively used in the creation of modern TMOSS in institutions of the penal system.

Consider the impact of the introduction of modern technologies in TMOSS on the reduction/increase of quantitative targets for the prevention and suppression of crimes and violations of the established regime of detention of convicted and detained persons.

To this end, we will carry out a comparative analysis of the dynamics of changes in the main indicators given in the statistical tables of the Statistical Data section of the official website of the Federal Penitentiary Service of the Russian Federation, which reflect changes in the characteristics of persons detained in various institutions of the penal system. The analysis of indicators for 2013 and 2019 showed the following results.

1. Remand centres and prison facilities. According to FSIN statistics for the period from 2013 to 2019, the number of special continents decreased from 134142 to 99948 people (by 25.49%).

The total number of crimes committed has increased - from 78 to 151 (by 93.59%) and the level per 1000 people - from 0.57 to 1.50 (by 163.16%). Of these, the following decreased: murders (st.105 of the Criminal Code of the Russian Federation) - from 4 to 3; intentional infliction of grave bodily harm (part 1-4 of article 111) - from 8 to 6; shoots (Art. 313) - from 8 to 1, of which attempts at shoots - from 2 to 0; hostage-taking (art. 206) - from 1 to 0; the number of convicted persons wanted (as of December 31) decreased from 18 to 6, and the number of criminal acts disorganizing the work of the penitentiary (part 3. Art. 321) increased from 0 to 1.

The total number of crimes prevented has decreased from 45,227 to 91. Including the number of: crimes against the person from 34,799 to 0; shoots - from 3192 to 0.

2. Adult correctional colonies. According to FSIN statistics for the period from 2013 to 2019, the number of special continents decreased from 559938 to 423825 people (by 24.31%). Of these, the number of persons sentenced to imprisonment decreased: for the first time - from 245546 to 195810 (by 20.26%), for the second time - from 129024 to 75117 (by 41.78%), three or more times - from 559938 to 423825 (by 24.31%).

The total number of crimes committed increased from 865 to 1015 (by 11.73%) and the level per 1000 people - from 1.23 to 2.34 (by 90.24%). Of these, the number decreased: murders - from 13 to 5; intentional infliction of grave bodily harm - from 43 to 27; shoots - from 138 to 110, including attempted shoots - from 8 to 1; hostage-taking - no. The number of actions that disorganize the work of the IU increased from 7 to 17. The number of convicted persons wanted (as of December 31) decreased from 133 to 75 (by 77.33%).

The total number of crimes prevented has decreased - from 59810 to 268. Including the number of crimes against the person - from 54361 to 0 and the number of escapes - from 2133 to 0.

The number of seized: money - from 5.06 to 1.38 million rubles; industrial and artisanal spirits - from 52666.3 to 29081.0 liters; narcotic drugs, psychotropic substances and their analogues - from 84504.199 to 65505.447 grams; cutting objects - from 7758 to 7363 units.

3. Juvenile Education Colonies. According to FSIN statistics for the period from 2013 to 2019, the list of convicts in the EC at the end of the reporting period decreased from 1974 to 1155 people (by 70.91%).

The total number of crimes committed decreased from 7 to 5 (by 40%), but the level per 1000 people increased from 3.46 to 4.26 (by 23.12%). Of these: no murders; actions that disorganize the IC operation - from 1 to 0; intentional infliction of grave bodily harm - from 1 to 1; hooliganism - from 1 to 0; escapes and attempts at escapes - no; hostage-taking (art. 206) - no.

The number of crimes prevented has decreased - from 1058 to 1.

The number of seized: money - from 35,000 to 0.00 rubles; industrial and artisanal spirits - from 57.7 to 0 liters; cutting objects - from 25 to 1 units. However, the number of seized narcotic drugs, psychotropic substances and their analogues increased from 1.2 to 8.84 grams.

4. Criminal and executive inspections. According to FSIN statistics for the period from 2013 to 2019, the number of persons registered in the reporting period increased from 947656 to 1003165 (by 5.86%).

The number of crimes committed increased from 16046 to 19413 (by 20.98%), and the level per 1000 people increased from 16.93 to 19.35 (by 13.51%).

Conclusion

It should be assumed that the increase in some of the above indicators is determined not only by the insufficient effectiveness of the implementation of modern TMOSS in institutions of the penal system, but also by the corresponding professional competence of their employees.

The conceptual approach to the study of the problems of building innovative TMOSS in penal correction institutions involves a comprehensive study of the results of the prompt introduction into the practical activities of the penal correction system of modern information, organizational, social, technical and technological forms of innovation and the corresponding changes in the main provisions of penal enforcement legislation and other regulatory legal acts, as the main factors for achieving the main goal - ensuring the safety of facilities and employees of the penal correction system. The results of the study were obtained in the context of a realistic scenario for the development of the penal policy of the Russian Federation, which is characterized by the relative stability of the current system of internal and foreign policy, economic, social, legal and spiritual factors.

On 30 March 2020, the Chief State Medical Officer of the Federal Penitentiary Service issued Decree № 29 «On the introduction of additional sanitary and anti-epidemiological (preventive) measures aimed at preventing the emergence and spread of a new coronavirus infection (COVID-19)». In connection with the continuing spread of a new coronavirus infection and in accordance with the requirements of article 48 of the Federal Law of 15.07.1995 № 103-

FL «On the detention of suspects and accused of committing crimes», a regime of special conditions has been introduced from 31.03.2020 to special instructions in pre-trial detention centers located in Moscow and the constituent entities of the Russian Federation. The operational headquarters of the Federal Penitentiary Service of Russia has been established, the tasks of which are to coordinate the activities of all units of the penal system on issues of prevention and timely detection of this disease.

The declared pandemic and measures taken in the state to combat coronavirus will inevitably lead to a deterioration of the economic component, a sharp and deep aggravation of foreign policy relations, a tightening of domestic policy: state borders, enterprises are closed, mass events are canceled, the authorities call on citizens to a regime of self-isolation and impose penalties for its violation. In the context of the pandemic, the State's penal policy will evolve under the influence of significantly changed key factors in the pessimistic scenario.

The results of the activities of institutions of the penal system in special conditions will largely be determined by timely changes in the penal policy of the State, the competence of the personnel of the penal system and the effectiveness of the use of modern TMOSS, including in the field of medical care.

Abstract

Cyber security risks and threats have increased in recent years, causing significant economic and social losses to public and private organisations as well as individuals. Discourses around these problems have driven government initiatives and academic research in Malaysia to focus on protecting critical national information infrastructure (CNII), the public and governments. In contrast, there has not been much attention given to the impact of cyber threats on business organisations, especially in the digital economy era. The recent data from Cyber Security Malaysia (CSM) stated that in the year 2019 alone, more than 10,700 cyber security attacks on corporations, business organisations and individuals nationwide for incidents such as ransomware, malicious attacks, data breaches were recorded, indicating that cyber-threats are together growing in digital ecosystems. There has not been much attention given to the impact of exposure of Malaysian businesses to high levels of cyber-attacks, especially those related to the digital economy era. The lack of attention to this research area indicates that cyber security management in this new age economy is an uncharted territory and requires further investigation. The objective of this paper is to discuss the comprehensive landscape of cyber security management in Malaysia's business context. Particularly, the aims of this paper are to propose on how organizations can develop a comprehensive defence system, incorporating situational awareness systems, threat intelligence analysis, and effective security operation platforms and trust technology for digital economy.

Keywords: Cyber Security, Digital Economy, Security Analytics, Blockchain, Digital Business

Introduction

In digital economy, business organisations must be able to innovate and guarantee competitiveness by leveraging the opportunities of the Fourth Industrial Revolution (IR 4.0), in which IR 4.0 are characterized by a convergence of technologies to support competitiveness in doing business (Schwab, 2016). The technological convergence and digitalisations are the state-of-art strategy to work in digital economy. Wider adoption of digital technology in Malaysia's business organisations implies the importance of cyber security in business setting. As reported by IDC Malaysia International (IDC Malaysia, 2019), it is predicted that by 2023, around 70% of all IT spending in Malaysia's business organisations will be on computing platform technologies. It is expected that over 50% of all enterprises will build "digital-native" IT environments to thrive in the digital economy, expecting an estimated RM 5bn investment by the Malaysian Government. It is also estimated that millions of devices will be connected to this digital ecosystem that will encourage the pervasive use of information and communications technology (ICT) in all aspects of the Malaysian economy. Technology applications in this ecosystem are promising, indicating that many business organisations are going to benefit from this digital ecosystem.

However, recent data from Cyber Security Malaysia have indicated more than 10,700 cyber security attacks on corporations and individuals nationwide through various security incidents in 2019 alone (MyCERT, 2019). This trend has suggested that cyber-threats are growing in such ecosystem and that organisations are required to improve their defence and strengthen their security posture in this new economy settings. The objective of this paper is to

discuss the comprehensive landscape of cyber security management in Malaysia's business context. Particularly, the aims of this paper are to investigate how organizations can develop a comprehensive defence system, incorporating situational awareness systems, threat intelligence analysis, and effective security operation platforms for digital economy.

Malaysia and the Digital Economy

The "digital economy" is a term for all those economic processes, transactions, interactions, and activities that are based on digital technologies. In specific, the digital economy refers to a broad range of economic activities that use digitized information and knowledge as key factors of production. According to World Bank Group (2019), from 2010 to 2016, the digital economy grew by 9 percent per year in value-added terms and is expected to approach 20 percent of the economy by 2020 and continuously expected to grow in years to come. The digital economy which is based on adoptions of disruptive technologies to new business models and delivering products and services in a convenient manner, presents a huge opportunity for companies of all types and sizes. In Malaysia alone, e-commerce businesses are growing particularly quickly, and is expected to exceed RM 110 billion by this year, comprises nearly 40 percent of the digital economy. Interconnected capabilities of disruptive technologies are enabler for digital economy.

However, although interconnected capabilities of disruptive technologies bring many benefits, it also introduces a host of new vulnerabilities with far reaching implications. Disruptive technologies also have the potential to increase vulnerabilities to cyber-attacks which can lead to financial losses and disruptions to essential digital business and services. As the next generation of information technology is driving the digital economy, data has become a key asset as well as a new target for hackers. In 2017, cybercrime cost the global economy $600 billion. In 2018, the global financial damage exceeded $1 trillion, a 50% annual increase. Recent study by Microsoft in collaboration with Frost & Sullivan 2018 reveals that the potential economic loss in Malaysia due to cybersecurity incidents can hit a staggering US$12.2 billion, and indeed shows the potential impact on economic cost of cybersecurity breaches (Dashika Gnaneswaran, 2018).

This scenario emphasized that as the digital economy expands, so does the threat landscape. More efforts are needed to construct a comprehensive defence system at the early age of informatization, build the situational awareness systems, threat intelligence analysis and security operation platforms. In a digital world where cyberthreats are constantly evolving and attack surface is rapidly expanding, cybersecurity is becoming a compelling opponent against cyber-attacks, making it an increasingly vital element of any organizations' strategy. As the interconnectedness in the modern business environment has become more complex, digitally fuelled innovation has outpaced the ability to introduce adequate safeguards against cyber-criminals. This scenario lead to a real risk in which lack of safeguards could reduce the growth of the entire digital economy, hurting both individual companies and the economy.

In the context of this study, cyber security risk originates from the deep infiltration of IT systems and devices into business activities. Given the increased dependence on technology and the number of information and cyber-security breaches happening around the globe, organisations need to implement strategies to respond to security incidents accordingly. Therefore, cyber-security management must become an integral part of organisations' business strategies to scrutinise risks that may be associated to the business and ensuring that organisations are prepared to prevent or mitigate cyber security risks and breaches in their business environments. In this view, proper establishment of cyber security components will help protect organisations and reduce risks from both internal and external security threats.

Cyber security exposure on Malaysian businesses

Cyber security monitoring in Malaysia is proactively done by Malaysia The Malaysia Computer Emergency Response Team (MyCERT). MyCERT, one of Cybersecurity Malaysia's departments, serves as a benchmark for the country's Internet community in dealing with security incidents. MyCERT works closely with law enforcement agencies like the Royal Malaysian Police, the Securities Commission and Central Bank of Malaysia. MyCERT also collaborates closely with Internet Service Providers (ISP), network security response teams and numerous information security projects around the world (MyCERT, 2020).

For the recent year, the largest number of cyber-threatening incidents reported to Cybersecurity Malaysia were online frauds, with a total of 7,774 reports, followed by intrusions and intrusions attempt with 1,463 reports (MyCERT, 2019). The sources of incidents reported to MyCERT came from various parties in Malaysia and

abroad, including home users, private sectors, government sectors, industries, and cyber security organizations pro-active monitoring. The high dependence on the use of ICTs for the social, political, and economy spheres, has vulnerably increased the array of cyber threats around the world. Including Malaysia, as it is progressively pacing into becoming a global economic force, so thus its economy which is gradually transiting into a digital one. The danger that it is very rampant in the world that every digital economy faces cyber-assail threats or vulnerabilities, where cyber-criminals try to get involved in the intrusions of vital information belong to the government and private companies for fraud activities (Bakri Mat et al., 2019).

In this modern age, cyber-related fraud became the most prevalent form of cybercrime (Adnan Rizal Harris et al., 2017). In Malaysia cyber security exposure, online fraud cases mainly involves scams, phishing, or social engineering to mislead and obtain sensitive data and also intrusions which includes hacking or data breach attempts for personal and illegal economic gain is reported to high in numbers for the year 2019 (MyCERT, 2020). In accordance with the top cases in Malaysia cyber security landscape, the definitions of these cyber related to both threats are discussed as follows:

Table 1: Definitions of cyber intrusion and fraud

Threats	***Definition***	***Motives***
Intrusion	*Any kind of unauthorised activities that cause damage to an information system (Khraisat et al., 2019). This means intruder is gaining unauthorized access to a system- access to information belongs to particular individual or organization.*	*-political, personal, and economic gain.* *-to monetize stolen data on underground black markets.* *-impersonate someone financially.* *-competition - IP, blackmail, competitive intelligence, sabotage.* *-financial greed* *-financial difficulties* *-targeted data repositories (e.g., banks, retail companies, health care, cryptocurrency wallets and systems) that can be monetized*
Fraud	*An act of deceit by IT-experts/skilled person who use their expertise and computer resources to fulfil their selfish desires (Faisal Alanezi, 2015)* *For example, e-commerce frauds that are concerned more generally with fraudulent financial transactions linked to online retail sales, where businesses and clients are both victimized.*	

All these activities fall under Malaysia's COMPUTER CRIMES ACT 1997. Cyber Crime, also known as 'Internet Crimes' or 'Computer Crimes,' is any criminal activity that uses a computer as an instrument, target or means of perpetuating further crimes or offenses or offenses under any law (Binitha et al., 2007). According to Maziah Mohd Ali (2016), there are four major categories of cyber-crimes, such as cyber-crimes against individuals, cyber-crimes against property, cyber-crimes against organisations, and cyber-crimes against society. All these crimes ranges from individual attacks such hacking, email spoofing, spamming, cyber defamation and harassment, cyber stalking, to cyber-attacks on property such credit card fraud, intellectual property crimes includes software piracy, illegal copying of programs, distribution of copies of software, copyright infringement, trademarks violations and theft of computer source code. Apart from that, it is further recognized that cyber-crime against society can be in the form of forgery by computers and high-quality scanners and printers in currency notes, revenue stamps, mark sheets (Cybersecurity Malaysia, 2004).

While in digital economy the ecosystems require secured operating environment, the rising of cyber security challenges and its effect on-line digital businesses will be a major concern in the Malaysian digital economy climate. Based on this concern, a comprehensive discussion on strengthening a more inclusive landscape of cyber security management in Malaysia's business context for digital economy are exceedingly crucial. Particularly, needs for holistic view on how organizations can develop a comprehensive defence system, incorporating situational awareness systems, threat intelligence analysis, and effective security operation platforms and trust technology for digital economy is worthy and beneficials. This effort is in alignment to support the pervasive use of digital technology for National Digital Economic Initiative (Digital Malaysia) that eventually will allow a prosperous, sound, and safe economy for the nation.

Developing A Comprehensive Cyber Defence System for Digital Economy

As the Digital Economy takes the centre stage around the world, so thus the risk of cybersecurity threats. With threats becoming increasingly sophisticated, the need to handle it have grown exponentially and requires a very strong focus. Developing a comprehensive cyber defence system is an essential element to protect and enable digital economy. As reported in the Accenture 9th Annual Cost of Cybercrime Study 2019, the impact on organizations, industries and society from these cyber-attacks is significant (Bissell et al., 2019). In tandem with the growing amount of security breaches, overall cybercrime expenses for the business have been raised to a record peak of US$ 13.0 million in 2019, from US$ 11.7 million in 2017, an arise of 12% accumulatively for two consecutive years.

On the other hand, Asia Pacific (APAC) are also facing growing rates cybercrime and in recent years there have been instances of serious cyber security incidents reported in this region. According to a report by Marsh and McLennan companies (2017), Asia is 80 percent more likely to be targeted by hackers than other parts of the world. According to the report, the reasons for the comparatively higher cyber threat in APAC are twofold: one is because of the growing pace and scope of digital transformation, and second because the rising of vulnerabilities from the of growing IoT technology in businesses. Several recent high-profile cyber-attacks affecting several countries and industries throughout the region have highlighted the problem. The Figure 1 below exhibit some of the infamous APAC cybersecurity cases as highlighted in various sources for the past five years.

Fig. 1: Recent Cyber security cases in APAC
(source: Marsh and McLennon Companies Survey 2017)

From the reported cases, most were found to be financially motivated and economy related by its perpetrators. In this view, incidents in cybersecurity as illustrated in the APAC infamous cases may have very negative effects on numerous levels (individual, institutional, organizational, corporate, and national), causing direct financial damages at all levels. Based on the cases above, it is obvious that intrusions and data theft were among highly reported cases in APAC and has high impact on monetary and reputations of the organizations.

To combat cyber security, various approach has been discussed respectively at various levels. For example, administrative and coordinated approach such as international collaboration in protecting nation and defending against cybercrime, development of National Cybersecurity Strategy (NCSS), improvement of legal framework encompassing cyber security elements, enhancing cyber security investigation capabilities were all now globally implemented to battle security threats.

On the technical perspectives this study strongly implies that main root of cyber security incidents is often due to the poor management of information systems within the organization and lack of strong encryption mechanism in place for protecting critical data belong to the organization. In this view, a lower cyber security risk can be ensured

by having an effective and advance controls that has the capability to detect and cyber threats within the organization. According to Spremić & Šimunic (2018), security controls should be applied to detect and/or prevent unwanted events (unauthorized use, inaccurate data, ineffective processes, wrong algorithms or faulty system inputs etc.) or problems from external environment (external attacks, faulty data transmission, natural disasters, etc.). Application of emerging technology as part of logical security controls in this area is vital. New data encryption technology for example, could assist in preventing data breach and theft incidents that could cost millions of dollars to businesses.

Ability to analyse security events before it could happen is crucial. Detecting and analysing cyber security threats in real time for example could support business organizations in combating cyber security. Apart from that some new and emerging financial technology (fintech) such as Blockchain also can be considered as to offer a stable and efficient approach for cyber security and privacy protection (Schutzer, 2016). All organizations could benefit from the reduction in cybercrime cost enabled by further investment in advanced controls and technology in cyber security. Among technological approaches in combating cyber threats are Security analytics with big data and machine learning for threats detections and preventions, as well as Blockchain for fintech applications and anti-fraud. The Fig 2 below illustrates the proposed cyber defence systems for accommodating security needs of digital economy.

Fig. 2: Proposed layers of Cyber defence systems for digital economy

Security analytics with big data and machine learning

At its core, analytics entails the discovery, interpretation, and communication of meaningful data patterns. Relative to IS/IT, security analytics refers to the collective process by which a set of collected data, data aggregate, and analytical tools (software) are used for security monitoring and threat detection (Oprea et al., 2018). Ancient cybersecurity struggled to keep pace with attacker's new methods of penetration, and this is because it was difficult to predict threats of intrusion that was attributed to the then level of technological advancement (Cavelty, 2015). However, the case is different today, with modern day tools and techniques, Machine learning (ML) and Artificial Intelligence (AI) have greatly improved information security and cybersecurity in general (Das & Morris, 2018). ML is the application of AI that empowers systems to automatically learn and improve through experience as well as adapt to new patterns without intentional programming.

Big data is indeed one of the top reasons leading to improvements in the way decisions and transactions are made. The use of large-scale data and technologies available has contributed to innovation growth, an enhancement in delivery quality and value added across industries. In addition, the introduction of big data analytics and ML have revolutionised information security at an organizational and national level. Computer algorithm are used by these security tools to observe any abnormality or adjustment in data and their patterns. Because of the large data that is impossible to be manually analysed, ML uses algorithm to observe alterations in network traffic, endpoint and user behaviour data, cloud resources, business applications, Non-IT contextual data, Identity and access management

data, and external threat intelligence sources. Among other reasons, the goal of this is to fuel consistency in information monitoring and to be able to identify the slightest threats in real-time (Ford & Siraj, 2014).

Digital economy is focused on the interrelation between data, business value and business decision-making. With this digitization, more data will be consumed in the ecosystems offering more opportunities for business, human well-being, and the economic environment itself, if used effectively. Application of big data and business analytics within these ecosystems are significant and can pave the way towards digital economy (Pappas et al., 2018). Such ecosystems could facilitate competition, coordination, and co-operation between the various players to generate new possibilities for businesses and to fulfil the needs of customers. Additionally, it can also contribute to new market opportunities for entrepreneurs, innovators, and companies to build innovative digital based solutions, and are capable to assists in transforming agile and sustainable business model in this setting.

Despite advantages, with dependency upon internet-enabled business models, companies are more vulnerable to a wider array of cyberattacks and business disrupting events. Within that setting, the integration of cyber security into the given context will secure business data, which in turn creates trust in stakeholders, customers, and partners. For digital economy, security analytics that allow split-second insights into cyber risk in business environments is important for the organisation to rapidly eliminate it. With this technological paradigm of security intelligence and analytical platforms, organisations are able detect and analyse cyber security threats in real time, thus assists in a proactive ways of handling threats under a frequent changing business environment. This enables organisations to maintain their competitiveness and function in agile ways to success in the digital economy (Zaini et al, 2020).

Blockchain application to support technology trust in digital economy

Not literally, a blockchain is simply a chain of blocks that contains information. The term blockchain went wild after the renowned publication of Satoshi Nakamoto's bitcoin in 2008 (Nakamoto, 2008). In computer terms, a blockchain is a distributed database on multiple computer systems. Data is stored in series of blocks, hence the name (Sarmah, 2018). On the chain, each block is cryptographically identified with a unique alphanumeric that referred as "hash." Each block also retains the hash of the previous and next block on a chain, this creates timeline order for when each block is created and enables the sequential arrangements of the blocks (Ajao et al., 2019; Khairuddin and Sas, 2019). Today, blockchain transcends beyond the world of cryptocurrency down to cybersecurity. In the context of data and information security, blockchain provides a decentralised database with multiple nodes (servers and systems). In blockchain, data is stored in a form of ledger on all nodes, but it is presented as single copy and every node on the network has real-time access to it. Although there are studies highlight that blockchain could be threaten by the selfish miner's attack (Eyal & Sirer, 2018; Sapirshtein et al., 2018). There is however limited empirical evidence to proof that the chain is successfully breakable. This makes it near-impossible to delete or tamper with any data because all the nodes on that network will reject the tampered data and restore the original copy from over 50 percent of the nodes. Therefore, to successfully hack into a chain of blocks, a hacker must manually access more than 50 percent of the nodes on a network and make the same changes on a data. This, however, is impossible as there are thousands of nodes on a chain (Taylor et al., 2019).

The main keys that lured cybersecurity to adopt the cryptocurrency's blockchain are its decentralisation, transparency, and immutability. Decentralisation enables a single copy of to be stored on multiple databases but appear to all its users as a single entity. Any authorised alteration of a copy of the data on the network will be implemented on the whole node. Decentralisation eliminates the risks of data loss or inefficiency in an event where system upgrade is necessary. Blockchain transparency lies in the ability of the blockchain's mining work to timestamp each transaction (data creation and alteration), identify the user who initiated the transaction, present a prior state of a block before alteration, and then match the new chain against others on the network (Khairuddin and Sas, 2019). This makes it difficult for hackers to gain access to the blocks as each transaction must have a registered node before it can be validated. Immutability is believed to the strongest capability that a blockchain has. For each data or information stored in a block, a hash is created to identify the block, the hash determines the position of a of block on a chain, an addition or deletion of a data in a block automatically changes the hash code, thus crumbling the whole chain (Puthal et al., 2018)

In digital economy, application of blockchain is foreseeable to act as a platform to facilitate the exchange of digital assets and service over the internet via decentralized and transparent ledger. In e-commerce sector for instance, the C2C or consumer to consumer concept of purchase is mostly supported by the trusted escrow service with extra fee to the buyer and seller to ease the payment and exchange of goods. However, with the strong characteristics of blockchain including transparent, decentralized and ease of use, the application of this technology could eliminate the function of third party between those transaction (Sas and Khairuddin, 2017). Blockchain allow seller and buyer to make peer to peer transaction by creating a digital token embedded with a smart contract with the agreed terms

on its' transparent ledger for them to trace and track the movement of payment as well as goods (Khairuddin, 2019; Hu, et.al, 2019). Hence, it does not require both parties to pay any extra fee for the transaction as well as promote trusted exchange in digital economy. In this case, any sorts of fraudulent can be eliminated when both parties doing their businesses online.

Implications and Conclusion

This work addresses the needs for a comprehensive, coherent, and empirically tested study to be conducted to assess the requirement of new and emerging cybersecurity technology to fit into digital economy framework. As there is a dearth of research on the status and perception of cybersecurity management by digital business organizations, particularly in developing countries, such study is considered timely and could add an empirical evidence to Cybersecurity research. As a country that is moving towards digital economy, the findings of subsequent study are especially important as they may greatly empower the nation towards sustainable development and better economy. Cybersecurity management must be an integral part of this. Consequently, it allows this nation to improve economic growth and become a highly developed nation in 2050 through the competitiveness of business entities and organisations locally and globally. Future works on exploring the suggested cybersecurity technology; security analytics and blockchain as part of cyber defence layer for digital economy is vital and require urgent deliberation by researchers in this area.

Abstract

The article represents the issues of systematizing various factors of the region scientific and technological development, as the basis of scientific technological and social economic development of individual regions and the country as a whole. The research significance is determined by improving the tools of strategic planning and management decision-making at the regional level in accordance with the requirements outlined in the "Strategy for scientific and technological development of the Russian Federation" approved by the Decree of the Russian Federation President.

Keywords: Scientific and Technological Development, Scientific and Technological Potential, Development Conditions, Development Outcomes, Factors of The Region Development.

Introduction

The globalization of the economy and markets, increased competition result in reducing the life cycle of products, increasing their technical complexity and demanding requirements for the level of quality; it necessitates the adaptation of economic entities at all levels to the rapidly changing macroeconomic conditions through the continuous development of science, technology and introduction of innovations. The fast digitalization of all spheres of human activity contributes to rapid spreading new products and technology, shortening the stages of the innovation cycle, developing international cooperation and integration in the field of technological innovation.

Effective innovation activity is the basis for reproducing scientific and technological potential, creating conditions for the formation and development of high-tech production, increasing the competitiveness and investment attractiveness of entities, both at the level of enterprises and at the level of countries or their individual territories (Gulin, K. A., Mazilov, E. A., Kuzmin, I. V., Alferyev, D. A., Ermolov, A. P. (2012)).

Approved by the Russian Federation President Decree dated 01.12.2016 No. 642, the strategy of scientific and technological development in the Russian Federation determines the necessity to focus on an innovative way of development to ensure long term sustainable, dynamic and balanced development and competitiveness in the world market of Russia. The document defines scientific and technological development as "the transformation of science and technology into a key factor in the development of Russia and support of the country ability to respond to major challenges effectively" (Putin. V. V. (2016)). An important role in this process is assigned to the regions, since their socio-economic, scientific and technological development determines the level of economic and innovative development of the state as a whole. Therefore, at present the issues of scientific and technological development of

Cite this Article as: Marina DMITRIEVA, Yuri ERYGIN , Marina SAVELYEVA and Galina YURKOVSKAYA " Region Scientific and Technological Development: Main Factors and Their Systematization" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the regions are becoming more and more urgent (Belyakov, G.P, (2020), Oveshnikova, L.V.a, Sibirskaya, E.V.a, Tenetova, E.P.a, Kuznetsova, N.P.b, Grigoryeva, M.O.a, (2020)).

Systematizing factors of the region scientific and technological development

The research considers scientific and technological development to be "qualitative changes in the technological background of the territory economy, leading to economic growth, based on the development of science, the creation and use of advanced technology, the production of high-tech products" (Belyakov, G.P, Kochemaskin, A.N. (2014)). The definition highlights the region scientific and technological development as a part of its innovative development forming in the sphere of science and high-tech product manufacture.

Currently there are 85 regions in Russia, where the scientific and technological development is at different rates. This is influenced by natural climatic conditions, the availability of natural resources, demographic characteristics, industry specialization, the level of development of industrial production and digitalization, the provision of transport and energy infrastructure, the level of scientific and technological development, the level of education, the degree of integration of the industrial sector and innovation infrastructure inside the region and beyond, the population standard of living and many other factors (Gokhberg, L. (2020)).

The factor arrangement resulted in three main interconnected factor groups having an impact on the region scientific and technological development (fig. 1). The selected factor groups are:

– region scientific and technological potential;
– conditions to use the region scientific and technological potential;
– effectiveness to use the region scientific and technological potential.

Fig. 1: Interrelation of factor groups of scientific and technological development

The scientific and technological potential (STP) of a region is a combination of various types of resources: human, material and technical, non-economic, information, organizational, managerial and financial used by the subjects of innovative activity - enterprises and organizations, within the framework of certain types of economic activities of the region at the stages of creation (field of science: fundamental and applied research, experimental design) and use (field of production: introduction and commercial transfer) of technology. The range and effectiveness of the use of the scientific and technological potential of a region depends on the conditions created in this territory for its implementation.

The conditions to use the scientific and technological potential of a region are determined by the combination of external and internal factors that contribute or hinder implementing the scientific and technological potential of

certain areas in a given territory. These factors can be grouped into the following terms: natural and climatic; market-based; institutional; general infrastructure; innovation infrastructure.

Some of the factors determining the conditions are objective in nature and they are taken for granted, since they cannot be influenced, or the range of influence could be insufficient; other factors are influenced by the regional development management system. Well-coordinated and effective work of the federal and regional authorities will contribute to the transition to a qualitatively new level of regional scientific and technological development as well as the involvement of the private sector in this process through interest in innovations and advanced technology. The better the conditions to develop innovations, the higher the innovative activity, investment attractiveness, intensity and efficiency of the use of the regional scientific and technological potential, both within individual territories and the region as a whole.

The effectiveness of the use of the regional scientific and technological potential reveals the results obtained due to the efforts by all subjects of innovation activity, as well as federal and regional authorities to ensure their effective interaction, to create favorable conditions to develop technological innovations. The main outcomes of using the regional STP are the created volumes of GRP and GDP. The nature of this group factors lies in the formation of the basis for the subsequent scientific and technological development, both of individual subjects of innovation activity, and of the region as a whole.

Therefore, the research proposes systematization of the factors influencing the scientific and technological development of the region; it is based on a number of provisions:

1. Scientific and technological development (STD) of a region is determined by the scientific and technological development of certain types of the region economic activities (hereinafter referred to as directions) and is reflected in the results of using the region scientific and technological potential (STP).

2. Each direction corresponds to the type of economic activity according to OKVED2, carried out by economic entities of the region in the field of science and the manufacture of high-tech products.

3. STD of each direction is influenced by three groups of factors related to:

– scientific and technological potential of the direction (STPd);
– terms of STPd use;
– the effectiveness of STPd use.

4. Scientific and technological potential of the direction is formed at the following stages of the technology life cycle:

– development, including the stages of fundamental and applied research, research and development;
– use implying the introduction of a new technology into manufacture and its commercial transfer.

5. At the stages of developing and using new technology, the scientific and technological potential of a direction is formed by the subjects of innovative activity, functioning within the framework of this direction. As a result, the following can be distinguished as separate elements of the assessment:

– scientific and technological potential of innovation subjects in the scientific sphere;
– scientific and technological potential of the innovative activity subjects in the sphere of manufacture of high-tech products.

Figure 2 illustrates the provisions of the proposed approach.

Fig. 2: Approach to the systematizing groups of factors of the scientific and technological development of the region.

The proposed systematization includes factor decomposition based on two features:

– on the selected factor groups related to the scientific and technological potential of a region, the conditions to use scientific and technological progress, the effectiveness of the use of scientific and technological potential;

– on the character of impact: external and internal.

The more detailed research proposes the groups of factors influencing the scientific and technological development of a region; table 1 demonstrates individual factors identified and systematized.

Table 1: Factors of region scientific and technological development

Group	Factors	
	External	Internal
Scientific and technologcal potential of a region (STP)	– global and national level of technological innovation development; – the degree of cooperation and integration of subjects of innovation in the global and national markets	– level of the material, technical and technological base of the regional industrial complex; – availability of joint ventures with foreign companies; – provision and of qualification level of managers, engineers and workers at scientific and industrial enterprises; – internal costs for research and development; – digitalization level at scientific and industrial enterprises; – patent and inventive activity in a region; – commercialization level of technological innovations.
Conditions of using STP of a region	*Natural and climatic:* – features of natural and climatic conditions of a country. *Market-based:* – demand for technological innovations nationally and globally; – national investment climate; – global and regional private sector interest in technological innovations. *Institutional:* – government policy in the sphere of scientific and technological development; – strategy of the national scientific and technological development; – government support of innovative and scientific and technological activity. *General infrastructure:* – structure of the national economy; – geographical location of a country. *Innovative infrastructure:* – national development and efficiency of the innovation infrastructure.	*Natural and climatic:* – natural and climatic conditions in a region; – availability of natural resources in a region. *Market-based:* – demand for technological innovations in a region; – investment potential of a region; – private sector interest in technological innovations in a region. *Institutional:* – regional policy in the innovation development; – strategy of the regional scientific and technological development; – regional support of innovative and scientific and technological activity. *General infrastructure:* – specialization and cooperation of enterprises of the industrial complex in a region; – cooperation range of scientific organizations, centers and universities; – availability of scientific organizations, centers and universities; – development and efficiency of the financial and credit system, transport, energy and social infrastructures in a region; – educational level of the employable population of a region; – personnel motivation system for the development of technological competencies. *Innovative infrastructure:* – development and efficiency of the region's innovation infrastructure; – integration of innovative infrastructure range in a country and a region.
Effectiveness of using STP of a region	– total GDP; – GDP per capita; – national salary level.	– total GRP; – GRP per capita; – regional salary level; – value of the additional cost from the creation and use of technological innovations; – export effectiveness of high-tech products and innovative technology; – publication activity in the sphere of technological innovation in a region.

Presented in the table, the factors demonstrate that the scientific and technological development of a region can be represented as a system complex of interrelated subjects and the conditions of their interaction; together they form the outcomes of the region scientific and technological development. To create a stable positive trend in the scientific and technological development of a region, the dynamics of changes in factors amenable to influence must be uniform, progressive and homogeneous, since it is almost impossible to compensate for the lack of other resources and conditions with an excess of individual resources and conditions in a region.

Conclusion

The identified and systematized factors are the key to understanding and formulating the fundamental principles to evaluate the scientific and technological development of a region. The principles could become the basis to form an indicator system and to develop evaluation methodology for the scientific and technological development of a region in the authors' further research.

Abstract
Based on fractal theory and the provisions on fractal structuring concerning socio-economic systems, the essence of the restaurant business has been defined as a complex, unstable, self-similar, fractal production and service system that seeks for self-development; a conceptual model of the system of the restaurant industry functional fractal determinants (range, technology, management, marketing, development dynamics and hierarchy) and a fractal model of the restaurant industry by organizational approach have been developed (person, position, unit, enterprise, merger of enterprises (network, cluster) restaurant services market). On the basis of the basic evolutionary principles system (necessity, sufficiency, controllability, self-organization, variability, structural-functional systematic, unity and infinity), a hierarchy of enterprises fractal determinants in the restaurant industry was formed.

Keywords: Fractal Theory, Strategic Management, Hierarchy, Determinants, Development.

Introduction

Fractal as an independent structural unit of the enterprise in the process of functioning set and formulate their tasks. Fractals can change, reappear and disintegrate. The peculiarity of fractals is their self-organization, which results in clusters occurrence. The clustering condition is the absence of external pressure and the formation of a common goal for the cluster as a higher-level organization system. Fractals also have centralized functions that are related to the special data that cannot be stored permanently in subfractals. An important point in demonstrating the feature of fractal self-organization is that good ideas come true no matter where they came from. Therefore, one of the most important requirements for an official, unit or enterprise within a merger, as a "fractal factory", is their ability to entrepreneurial thinking and activity.

Fractal does not always remain in the superfractal system, it can also become completely independent. Thus, the closely related companies occurs.

Literature Survey

Modern scientists distinguish separate rigid self-similarity regarding invariance of large-scale transformations and non-rigid (covariant) (Aguinis, H., Edwards, J. R., & Bradley, K. J. (2017)). That is, we are talking about linear and nonlinear fractals. The first is characterized by absolutely accurate adherence to the principle of self-similarity. In nonlinear fractals, the affine principle is maintained with less intensity.

Analysis of the literature allows us to formulate the major feature of fractals - self-similarity, which can be traced at any level of the functional hierarchy (Arsenyev, Y., et al. (2019); Drobyazko, S., et al. (2020)): striving for optimal organization of functional relationships; setting boundaries; formation of central structures; maintaining the fractal structures integrity; ensuring a certain defined development time (cycle); formation of periphery and formation of attractive goals.

The study of socio-economic processes should be based not on the geometric concept of self-similarity (fractality), but on its structural and essential content, that is, rather, on the fractality principle (Hitt, M., & Duane Ireland, R. (2017)). In this case, fractality can be viewed from two interrelated positions: the fractality of the systems (their

Cite this Article as: Svetlana DROBYAZKO and Yuliia MELNIKOVA "Formation of A Strategic Management Model for Enterprises on The Basis of a Fractal Approach" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

structures, elements) involved in the process, and the fractality of the processes that determine the level of enterprise development.

Identifying self-similar structures gives new opportunities to manage the ability of choosing priorities based on the concordance of internal and external resources with the influence of environmental factors, of the external environment, which determines the scientific task of finding effective mechanisms for strategic management of the development processes and self-development of restaurants (Meyer, G. D., Neck, H. M., & Meeks, M. D. (2017)).

An important feature of fractals is their small dimension, the value of which for economic units is determined the following ways (Durmanov, A., et al. (2019)): the area of dimensional resources; functional and structural features of production and service; the goals and tasks of the enterprise, as well as it`s history.

At different hierarchical levels (region, enterprise, part of enterprise) it is possible to identify self-similar dimensional socio-economic structures and self-constructing ones, which have similar trajectories and elements of development (production, service, sales, cash flows, social, cultural, etc.) (Trigeorgis, L., & Reuer, J. J. (2017)).

Methods

The following set of general scientific and special research methods is used in the work: logical analysis - when constructing the logic and structure of work; systematization and comparison - to clarify and order the conceptual apparatus for strategic management of restaurant business; methods of data grouping and generalization - in the calculation of strategic development indicators by the group of selected enterprises for the restaurant industry; systematic and process approach - to substantiate methodological support for assessing the level of strategic management effectiveness of enterprises and its components.

Results

Based on the taxonomy method, it becomes possible to construct a generalized assessment of a complex entity, such as restaurant business or process, such as strategic management.

Relevant indicators are selected for assessment and further usage in the process of strategic management of the restaurant business according to the proposed fractal structure (Table 1).

Table 1: Fractal structure of the indicators system for assessment of strategic management effectiveness (author's development)

Fractal level	Fractal determinants of the enterprise	Strategic task	Indicators
Higher potential	Competitiveness	Ensuring the competitiveness of the enterprise and the effectiveness of strategic management	Effectiveness of the strategic management
Hierarchy	Hierarchy	Obtaining and consolidation of the enterprise in a certain hierarchical place in the industry and inter-branch space (type, network, format, cluster)	Profitability
Evolution	Dynamics of development	Providing the necessary dynamics of the enterprise	Rate of the turnover change
System composition	Marketing	Ensuring maximum compliance between supply and demand	Turnover Turnover in place
Information (energy information)	Management	Ensure maximum compliance between the subject and the object of management	Labor productivity Completeness of strategic management functions implementation

Energy	Technology	Optimization of service technologies and production of goods, as well as effective functioning of providing structures	Quality of service Production quality
Elements	Assortment	Optimization of the assortment, improving the quality of restaurant products	Menu compliance with customer expectations Quality of restaurant products

Assessment of the strategic management effectiveness, which is carried out using taxonomic analysis by defined indicators, makes it possible to rank enterprises.

The fractal approach allows to distinguish the rates at six fractal levels and to gain a fractal profile of the strategic management effectiveness in the field of restaurant business.
An important step in the strategic management process is to determine further directions of the enterprise`s development. In order to achieve this goal, the environment changes are forecasted in an optimistic, realistic and pessimistic scenario. Based on the evaluation of the strategic management effectiveness and the determination of the enterprise`s rank, it becomes possible to determine the optimal boundaries of the forecasted goals.

The major indicators in solving this problem are the indicators of the strategic management of the in the group within the companies under study, the outsider, as well as the enterprise that is the object of research. Goals due to the realistic prediction may lie between the levels of the research entity and the enterprise-leader. According to optimistic forecasts, fractal effectiveness indicators will exceed the level of the leader. According to the pessimistic forecast fractal effectiveness indicators will be lower than those achieved by the enterprise - the object of study (Table 2).

Table 2: Opportunities of fractal levels strategic development in the field of restaurant business according to different forecasts (author's development)

Forecast	Fractal levels of the enterprises in the field of restaurant business					
	1 Assortment	2 Technology	3 Management	4 Marketing	5 Development dynamics	6 Hierarchy
Optimistic	Exceeding the leader level by a certain group of enterprises or reaching the level of a leader by a certain group of enterprises					
Realistic	Reaching the leader level for a specific group of enterprises or maintaining the existing level of a company in a specific group					
Pessimistic	Maintaining an existing enterprise level by a specified group or reducing an existing enterprise level by a specified group					

However, this applies to indicators whose values are largely depend on consumer preferences. No one will reduce the quality of products, services and strategic management by the law of self-preservation. Strategic enterprise management includes the process of forming aim system. Achieving (maintaining) a certain level of competitiveness is a higher level aim.

Analysis of research regarding goal setting and strategic planning shows the diversity of approaches and classification systems of goals. In our opinion, the goals of the second hierarchical level should be grouped in three directions: improvement of structure and quality of goods, improvement of market relations, as well as optimization of internal resources.

For each direction, the goal is specified by the certain parameters - the nature and pace of change in the quality or amount of the object. Thus, for restaurant products, the technical and economic characteristics of quality are determined, as well as the period of its achievement. Target consumers, volume and specific weight are important for the market.

The second level goals are specified in the third level of the "goal tree". Thus, the direction of improving the "status" of a product is specified by improving product`s quality in accordance with the changed norms and

determining an adequate price. The direction of work concerning the market is specified by the work on market research and measures of influence on the market (advertising).

With regard to internal resources, it is advisable to clarify the obtaining methods of all types of resources (raw materials, equipment, information, finance, personnel, organizational and management resources, etc.), as well as establish their interaction within technological processes, and organize a strategic management system.

Personnel should be distinguished as a separate third-level aim due to it`s special nature. The created hierarchy of goals regarding the restaurant business becomes an important condition for choosing an effective algorithm of actions. The interaction of these elements is basic for a system (person, unit or enterprise) to achieve a high level of competitiveness.

Discussion

Taking into account the multidimensionality of the enterprises activity, as well as the fulfillment of special basic and additional functions, a conceptual model of the system of functional fractal determinants in the restaurant industry has been developed. Its essence lies in the hierarchical organization of fractal determinants (assortment, technology, management, marketing, dynamics of development, hierarchy), united on the basis of evolutionary principles, and a fractal model of the restaurant business by organizational approach (person, position, unit, enterprise, organization) merger of enterprises (network, cluster), restaurant services market).

Based on the strategic management analysis, it is proposed to define it as an activity that aims to create competitive advantages, achieve sustainability and flexibility of the enterprise in the long run due to human potential with the predominance of proactive management style, development and implementation of effective strategies that provide not only necessary reaction, but also capable of influencing the environment, based on the vision of the enterprise future image and due to the high dynamic organizational capabilities of fractal determinants to self-development. Taking into account the structure of the strategies as well as the main content and types of strategic activities, a list of strategic functions to be implemented by the restaurants is proposed.

Conclusion

Using fractal theory, the decomposition of the restaurant management system into main components was performed, which made it possible to form a system of qualitative (quality of restaurant products, concordance between menus and consumer expectations, quality of goods and service) and quantitative (completeness of strategic management functions, productivity, turnover, turnover per 1 seat, rate of change in turnover, profitability) strategic management performance evaluation indicators.

Taking into account, the high degree of uncertainty and variability of the environment, it is recommended to formulate an impact forecast of business environment factors using an optimistic, realistic and pessimistic scenario. In order to respond adequately to the environmental impact, for each variant of the forecasted scenario, expedient strategic development boundaries were outlined, which focus on the enterprise's own achievements and the achievements of the leader of the respective restaurant enterprise group.

Abstract

It is stated that investment is a factor of economic growth only if the financial system and real sector of economy interact closely, when financial flows of a cumulative, speculative, short-term nature gradually turn into long-term business investments. Financial markets development of the world countries and strengthening the role of in the global investment process has a complex nature and requires addressing many issues in the process of further economic transformations. Determining innovative direction of investment activity in the world countries is realized through the calculation of the relationship between the volumes of high-tech goods export and volumes of net portfolio investments at current prices for the period 2010-2016 in 130 countries.

Keywords: Economic Growth, Investment Market, Global Transformations, Net Portfolio Investments, Institutional Environment.

Introduction

The problem of financial markets further development of the world countries and strengthening the role in the global investment process has a complex nature and requires addressing many issues in the process of further economic transformations. Creating a favorable investment climate, building an effective financial market model, providing conditions for transforming savings into investments and moving investment capitals to the real sector of economy should be considered as components that will reverse negative trends in the national economies development and allow the country to enter the path of sustainable economic growth, despite unfavorable external factors and global environment at the same time.

The link between the economies of individual countries is growing in the context of globalization of the world economy, both in the field of production and dependent movement of capitals in the form of foreign investments, increasing rapidly and leading to the transformation of the world investment market, in the process of which becomes more urgent the need for the development of an institutional environment that supports a highly liquid and transparent market and provides opportunities for free and effective international movement of capitals.

The purpose of this work is to deepen the theoretical and methodological bases of research on the development of the global investment market in the context of global transformations.

Literature Survey

Global transformations lead to certain transformations that affect the entire planet. These transformations may be independent of humanity, objective nature or may be caused by subjective purposeful actions of certain participants in these transformations (Nur'ainy, R., & Adipati, N. M. (2018, October)). So, the process of globalization is a rather contradictory phenomenon in the world space (Nurianto, R. S., & Fata'al Chuzaibi, A. (2019)).

Cite this Article as: Henryk DZWIGOL and Mariola DZWIGOL-BAROSZ "Determinants of The World Investment Market Development in The Context of Global Transformations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The essence of the process is expressed within the limits that contribute to improving the efficiency of the world economy, economic and social progress of humanity (Dollar, D. (2017)).

But from another point of view, the forms of manifestation of these borders can sometimes infringe on the interests of the general population of the whole world, as well as individual countries that are not members of the states "club" of the "Golden billion" (Thede, S., & Gustafson, N. Å. (2017)).

The study of the processes of international capitals movement is of the greatest interest in the context of financing the world economy. Indeed, with the development of society, the relationship between the economies of individual countries increases, both in the field of production and dependent movement of capitals in the form of foreign (foreign) investments increase rapidly (Morris, M., & Staritz, C. (2017)).

Today, industrial capital is actively developing the world economic space through investments, that express the immanent flexibility of capital, the ability to combine or consistently use various forms and methods of foreign economic financial expansion, the ability to adapt to variable economic, socio-political and legal conditions in different countries and groups of countries(Perraton, J., & Spreafico, M. R. (2019)).

Investments are the most important resource source for the development of the country socio-economic system, determine the process of economic development in general, and affect the deepest bases of economic activity, the scales, structure and effectiveness determine the state, prospects and competitiveness of a country's economy (Chen, P., Karabarbounis, L., & Neiman, B. (2017)).

Investments with different national origins are intertwined and interact with each other (McSparren, J., Besada, H., & Saravade, V. (2017)).

They form international flows and develop into global investment resources that function in the global investment space (Sondermann, D. (2018)).

The development of market relations, the formation of a new ownership structure, change in the management system, the expansion of economic independence and other manifestations of global transformations of the world economic system require the search for and application of new methods and approaches to regulating the economy (Lee, T. K., Cho, J. H., Kwon, D. S., & Sohn, S. Y. (2019)).

Thus, the distinctive features that form the market approach to understanding the essence of investments are considered:

First, linking investments and generating income that acts as a motive for investment activity (Cho, S., & Kurtz, J. (2018));

second, consideration of investments in the relationship of two aspects: resources (capital values) and investments (expenses) (Capolupo, R. (2018));

third, the analysis of investments in dynamics, which allows to combine within the category "investments", on the one hand, resources, investments, and on the other – the return of money invested as a motive for this association (Somer, M., & McCoy, J. (2019));

fourth, the inclusion of any investments that give an economic or other useful effect in the investment objects (Tsai, I. C. (2017)).

Recognizing the significant contribution of scientists to the development of economic researches on this issue, it can be stated that the global determinants of the world investment market development as an immanent feature of the world economy functioning and the basis of spacial asymmetries in the world economy system remain poorly studied direction of modern economic science.

Therefore, despite the depth of contemporary research issues associated with complex generalization of preconditions, reasons and factors of asymmetric development of the global investment market, which define special influence on the state of the world economy, imperfect formation practice of balanced investment policy of the country, the investment attractiveness and conditions of full integration into the global investment space indicate the need for further developments in this direction.

Methods

Scientific statements, conclusions and recommendations are fully justified, which confirm the existence of a logical relationship between the formulated tasks and obtained results, reasonableness of theoretical conclusions, the use of a wide volume of statistical material and methods of scientific research.

The information and statistical bases of the study were results of the researches, monographic and other publications of scientists, official statistical and analytical materials of international organizations (groups of World bank, WTO, IMF, UNCTAD), expert valuations of rating agencies, materials of international information agencies, legislative and regulatory documents, statistical data of the European Commission.

Results

It is being formed industry 4.0- the era of innovations, when advanced technologies are radically changing entire sectors of economy at astonishingly fast rates at the present stage.
One of the most tangible aspects of the fourth industrial revolution is the idea of "service-oriented design". It can range from users who use factory settings to produce the products, to companies that deliver customized products to individual consumers.
However, when implementing the industry 4.0 concept are envisaged key issues – standardization, labor organization, availability of technologies and sufficient funding.

So, for a smooth implementation of" Industry 4.0", it is necessary to take the following measures:
providing affordable services in the network infrastructure and supporting them with international standards and policy- both national and global;
gradual replacement of old static, non-dynamic systems with new ones that work in real time and are service-oriented.;
creating new business models;
attracting employees from the beginning of modernization processes, improving the skills and technical development.

Institutional, spacial and structural transformations of the economic environment stimulate investment processes of development in an innovative direction. Innovation activity of countries in open economy is determined by the direction of global development and the desire to accumulate competitive advantages for long-term economic growth. Knowledge and information technologies form the environment for the formation of a post-industrial society and the corresponding level of production of knowledge-intensive goods and services. This process is accompanied by the emergence of fundamentally new management systems and contributes to the spread of network forms of organizational interaction of economic structures, including the Internet space. Policy to support the competitiveness of countries that set goals for sustainable socio-economic development based on the systematic use of investment factors and uniform special placement of innovation infrastructure.

The relationship between investment activity and scientific-technological progress has several aspects. The most important of them is to consider investments as a kind of catalyst for scientific researches, which is especially important in the conditions of turning science into a direct productive force of society. In this regard, it is necessary to form a model of financing economic growth based on innovations, which creates the possibility of developing the real sector of the economy on the basis of the latest achievements of the STP and forming an optimal structure of social production.

Investment activity currently plays a crucial role in ensuring sustained and high-quality economic growth. In this regard, we believe that the important moment is the country's ability to mobilize not only the internal but also external investment opportunities and resources.
Innovative activity is an engine of economic progress, a catalyst for economic growth and development. Today, the increasing factor of resources efficiency and business based on SRRCW and innovations has taken the first place, which has led to the formation of concepts of the innovative type of economic growth. This type of growth, to which developed countries have moved, is based not on the production and consumption of material goods, but on the creation and consumption of information products, that is, high-tech products. This means that this type of growth is not related to the "cost-output "problem and determined by the degree of information consumption. The main sources of such economic growth are innovations and accumulation of human capital.

Therefore, investments in innovation activity can be considered as one of the most important factors of the country's economic growth, the formation of an innovative economy.

Three fundamental measures can be attributed to the set of measures necessary for the formation of an innovative economy in the country: a) increasing the volumes of SRRCW financing and investment, improving the mechanisms; b) active use in practice of indirect methods of financial support for the innovation environment – tax incentives, customs preferences, targeted lending, leasing, state guarantees; c) formation of innovative clusters with subsequent targeted funding from the state and foreign investors.

There is a need to prioritize measures that serve as the basis for the development of innovative technologies in the context of global transformations of the world economy. Thus, investments in innovations is a central priority and main means of developing new technologies, which in turn is a catalyst for increasing activity in the global investment market.

We should consider such indicators as the volumes of venture investments in innovative technologies according to the rating of global investment index, the volumes of international investments in scientific-research and research-construct industries, that is, those that are based on knowledge ((R&D); global trends in global venture investments in innovation by sectors to study the innovative component of the global investment market.

The volume of investments in other innovative technologies, such as commercial services, recreation services were not stable during the study period 2013-2018. High volumes of investment in this industry were recorded in 2015 (21 % of total investments in innovation), 2018 showed a two-percent investment decline to 17.6 %.

Thus, the software remains the leader among the industries of innovative technologies in the global investment market, which consistently receives a share of venture investments in the amount of 35 to 47 percents. The main directions that are developing, are energy and media technologies, which together account for 12.6 % of global venture investments in 2018. Negative trend is observed in the investment of developments related to computer fitment: venture investment of such projects in 2018 decreased by half compared to the relatively high indicators of 2013 (up to 6.3 %).

We calculate the relationship between such indicators as to determine the innovation direction of investments in world countries:

export of high-tech goods, mil.dol USA, 2010-2016;
net portfolio investments at current prices, mil.dol USA, 2010-2016.
The results of the calculation are shown in Table 1.

Table 1: The results of correlation analysis*

**it is calculated by the author*

Let's analyze the results in more detail.

It is possible to identify countries (8) that have a strong correlation between the volumes of high-tech export and volumes of net portfolio investments for the period from 2010-2016, Fig.1 based on the results of the analysis.

Romania (0.796-0.78), Finland (0.809-0.8-0.82), Moldova (0.814-0.8-0.82), Spain (0.834- 0.82-0.84), Bolivia (0.853-0.84-0.86), Lesotho (0.879- 0.88), Luxembourg (0.883-0.88), Israel (0.911- 0.9-0.92).

Figure 1: Group of countries with a high dependence between volumes of high-tech export and volumes of net portfolio investments, 2010-2016. *

We can make a conclusion that the definition of innovation area of investment activity in the world countries is possible through calculation of the relationship between the volumes of high-tech goods export and volumes of net portfolio investments at current prices based on the results of determining innovative investment area in the world countries.

Our correlation analysis for the period 2010-2016 for 130 countries allowed to identify 4 groups of countries:

8 countries (including Finland, Israel) that have a strong correlation between indicators, which indicates a high degree of portfolio investments efficiency in innovative sectors of economic development;

22 countries (including the United States and France) that are characterized by an average correlation between indicators, which may be the result of a significant diversification of financing sources for innovative sectors of economic development;

53 countries (including Germany, Japan, UK) where the financing level of high-tech industries of economy is not sufficient, which is the gradual reorientation of the countries on the strategy of industrialization by attracting foreign investment and requires significant development of science and the funding to other development strategies, in which the financing of innovative sectors of the economy requires much lower volumes and is not a priority;

46 countries (including Sao Tome and Principe and Saint Vincent and Grenadines) that have an inverse relationship between the volumes high-tech export and volumes of net portfolio investments, which may be the result of offshoring the economies of these countries.
In the world practice of financing innovation and investment activities is actively used venture financing, which is an effective mechanism that allows to implement advanced ideas, encourage business to move to an innovative path of development, and improve the efficiency of economy as a whole.

Discussion

Thus, the study of foreign experience in financing and stimulating innovative processes in the economy shows the leading role of the state, this role does not always involve direct financing. India and China pay great attention to international cooperation to attract foreign capital for the systematic development of a number of industries over the decades. Private companies and foreign investments have rapidly changed the economic systems of both countries, which have become important suppliers of high-tech products and services in the global market as a result of foreign technologies and know-how.

Thus, it is possible to determine the following global trends in stimulating innovative and investment processes on the basis of the conducted research:

Economically developed countries (USA, Europe) actively used financial incentives of stimulating, including the activity of financial development institutions (development banks, venture and investment funds), combining them with economic support for economic entities (in particular, applying tax incentives);

countries with developing economy(India, China) successfully use non-financial development institutions (free economic zones, techno-parks and techno-polises, business incubators and clusters), thus creating conditions for the development of high-tech industries.

Conclusion

Determining innovative direction of investment activity in the world countries is realized through the calculation of the relationship between the volumes of high-tech goods export and volumes of net portfolio investments at current prices for the period 2010-2016 in 130 countries. The correlation analysis allowed to identify 4 groups of countries: 8 countries (including Israel, Finland) which are characterized by a strong relationship between indicators, which indicates a high degree of portfolio investments efficiency in innovative sectors of economic development; 22 countries (including the United States and France) that are characterized by an average correlation between indicators, which may be the result of a significant diversification of financing sources for innovative sectors of economic development; 53 countries (including Germany, Japan, UK), where the financing level of high-tech industries of economy is not sufficient, which is the gradual reorientation of the countries on the strategy of industrialization by attracting foreign investment and requires significant development of science and the funding to other development strategies, in which the financing of innovative sectors of the economy requires much lower volumes and is not a priority; 46 countries (including Sao Tome and Principe, Saint Vincent and Grenadines) that have an inverse relationship between the volumes of high-tech export and volumes of net portfolio investments, which may be the result of offshoring the economies of these countries.

Abstract

Due to the changes taking place in all spheres of public life, the emphasis in the issues of staff's education and advanced training and their professional development is transferred from the national to the institutional level. Accordingly, the issue of creating, on the one hand, an effective system of education and advanced training, and on the other - an in-house system of methodical work becomes important. The set of components of the system of scientific and methodological support of the managers' professional development has been separated. The criteria for the classification of the forms and methods of managers training were systematized and substantiated, in particular: activity of the adult student; number of participants; place of study, time and duration of the study. Forms and methods of diagnosing the needs of managers, forms and methods of training, forms and methods of evaluating learning outcomes were structured and analyzed in detail.

Keywords: Business Education, Corporate Education, Transnational Company, Vocational Training, Human Resources.

Introduction

Scientific search is specified by the managers' professional development, because, as practice shows, the level of their professionalism, competence and personal qualities depends on the effective activity of the organization as a whole and, in particular, its competitiveness in the market Statistics demonstrates (Akinbola, O., Solomon, K., & Ibidunni, S. (2018)) that 10% of the companies annually fail due to the lack of management staff training, in particular because of they do not spend money on training their own managers or do not have the money to hire highly qualified professionals in the field.

A high level of professional qualification, as well as a well-structured and structured system of training and development for managers play a crucial role in the German management culture. Considering the costs for training managers as strategic investments, transnational corporations are at the same time developing a system of measures

aimed at retaining trained professionals. There is a high level of corporate loyalty among German managers: the average length of work in one organization is 8 years, while it is 3 years in the US (Mizikaci, F. (2019)).

The purpose of the research: based on the system, personally oriented, competent, process and situational approaches to carry out a comprehensive scientific analysis of the systems of managers' professional development in transnational corporations of Germany and Poland, to identify constructive ideas of these countries' experience and to substantiate the possibilities of their creative use in the modernization of the system of professional education.

Literature Survey

A thorough analysis of the current state of its research in the philosophical, psychological and pedagogical, socio-economic scientists' achievements is important for the development of conceptual, theoretical and methodological foundations of this problem. (Zhaoqun, W., & Haiqing, H. (2017)).

Therefore, we consider it's expediently to carry out this analysis in the following areas:

philosophical and conceptual foundations of the personality development in the context of civilizational transformations (Jamali, D., Karam, C., & Blowfield, M. (2017));

fundamental provisions of professional development in the system of continuing adult vocational education in accordance with the concept of lifelong learning (Chen, Y., Xu, Y., & Zhai, Q. (2019));

organizational and pedagogical aspects of corporate training (Deering, D., & Sá, C. (2018));

methodological and didactic features of training, retraining and advanced training of managers (Avidov-Ungar, O., & Reingold, R. (2018)).

In general, the problem of professional and personal development of specialists is not new. Throughout human history, it has been and continuing to be the subject of research by philosophers, scholars, educators and practitioners (Milner, J., McCarthy, G., & Milner, T. (2018)).

Based on content analysis, we can distinguish the components of the staff's professional development in general and managers in particular, these are:

1) basic professional education obtained from educational institutions (Rubens, A., Schoenfeld, G.A., Schaffer, B.S., & Leah, J.S. (2018));

2) corporate training (Boiral, O., Raineri, N., & Talbot, D. (2018)):

a) short-term compulsory training, both at the enterprise and in specialized educational institutions and based on the problems solution specific to a organization with the involvement of its own or external lecturers, which is a system of educational, attestation and certification measures provided by the production system (da COSTA, F.R., Pelissari, A.S., & Gonzalez, I.V. (2018)):

school of young specialist in order to get acquainted with the specifics of professional activity and traditions of the company;
mentoring for the purpose of its quick and successful preparation for the execution of work duties and mastering the traditions of the labor collective;
school of production management, its aims is formation of the managerial competence of managers' enterprise;
learning a foreign language;
advanced training caused by the need to support the technological processes of the modern enterprise;
professional retraining caused by the need for production in connection with intensively changing techniques and technologies;

b) short-term additional training carried out out of the company related to the strategic objectives of the enterprise and provides only additional education that the manager receives in accordance with the area of work in which the company is going to use him in the future (Garber, R. (2017)):

temporary rotation as a form of self-study in order to acquire new skills (used in enterprises requiring polyprofessional competence);
professional retraining with assignment of additional qualification "manager of the specific specialty";
MBAs and Executive MBAs for managers of the highest level and personnel reserve;

3) long-term compulsory education for managers providing obtaining the second higher education, caused by the requirements of the enterprise due to the mismatch of the diploma of the first higher education to the company profile (Gunawan, J., Aungsuroch, Y., & Fisher, M.L. (2018));

4) post-professional education of managers, the difference from additional education is the following: it does not necessarily have system nature and may have nothing similar with the strategic tasks of the enterprise (postgraduate, doctoral studies, business education) (Padley, W., Long, J., Welyczko, N., Dowsett, D., Salter, N., Ford, K., ... & Brown, J. (2019));

5) post training accompaniment covering (Kangas, M., Kaptein, M., Huhtala, M., Lämsä, A.M., Pihlajasaari, P., & Feldt, T. (2018)):

organization and coordination of production, innovation, inventive, scientific and creative activities of young professionals;
organization and holding of the corporate thematic scientific and technical exhibitions;
participation in the corporate conferences;
individual consultancy and coaching;
organization of communities by professional interest, etc.

6) self-education and self-development (Choi, E.H., Kim, E.K., & Kim, P.B. (2018)).

Methods

The concept of the study is based on the position that the managers' professional development as a purposeful process, covering a set of interrelated components and has a continuous and adaptive nature, gains efficiency and effectiveness on case of the system approach to its organization, implementation of the holistic analysis of interacting mechanisms, related to theoretical and methodological, psychological and pedagogical, programmatic and methodological, legislative and regulatory support.

There are three interrelated concepts to implement this idea:

- theoretical and methodological, it substantiates a general methodological approach, covering the system and closely related synergistic approaches; personally oriented, its semantic field is expanded and specified directly related to it culturally, with acmeological and axiological components, and indirectly related to it of the subject-subjective and sociological-managerial, as well as competence, process and situational ones;
- theoretical, taking into account the leading theories, concepts and models of personnel management, first of all, from the standpoint of situational and process approaches and provides for the separation of components, stages, content and identification of features of managers' professional development in the corporate education system;
- practically oriented, aimed at revealing constructive ideas of the developed countries' experience and their creative use in the domestic practice of Ukrainian realities.

Results

Therefore, each transnational corporation can now be regarded as a learning organization, that is, a kind of educational institution which, on the one hand, provides employment and, on the other hand, provides its employees with the necessary educational opportunities for their professional development.

In order to effectively transfer these intangible assets, companies organize their own training centers, their tasks are to create supportive learning environment in which all employees can develop both professionally and personally. Obviously, there is not enough one specialist in the training department to implement such a large-scale activity.

It is necessary to create a separate structure with own mission, goals and objectives, regulatory base. This structure can be an internal training center. Its mission is to form and develop system staff training, which enhances the company's competitiveness.

Therefore, we consider it expediently to analyze the activity of the corporate training centers as a pedagogical phenomenon, according to the following logically constructed algorithm (Fig. 1).

Figure 1: The algorithm of the activity analysis of corporate training centers (author's development)

Assessing the effectiveness of the corporate training center for business can be done by influencing business (ie, achieving the goals set for the corporation), adjusting to business processes (opportunities to make operational changes and improvements taking into account business development); ensuring the effectiveness of training (reducing costs through innovative combined education and training methods, and through continuous optimization of training costs); implementation and support of graduation business projects focused on the technology of the corporation.

The criteria for the effectiveness of the corporate training center can be: increase in sales and revenues of the company; cost reduction, including through the unification of management processes, introduction of unified technologies; increase of customer satisfaction; improving the quality of products and services; optimization of the order cycle time; waste reduction; improving safety indicators; increasing employee satisfaction; reduction of staff turnover. Instead, the priorities of corporate training centers are to fill the widespread shortage of mid-level managers and to establish a new management culture at a TNC. This is a key to qualitative changes, without them strategic development and success are impossible.

As we can see, all of the above components are interconnected and mutually reinforcing. This is explained by the fact that the corporate training center in the modern sense is a system of corporate training and personnel development, which is inextricably linked with the strategy of the organization's development. It should be emphasized that the basis of any corporate training center, like all classical universities, is a system approach to the learning process. However, the reasons for their emerging are different: the first were due to the need for knowledge of the world, systematization and transfer of knowledge, and the second one is due to the acceleration of the pace of life, the need to adjust to the constant growth of scientific and technological progress, although the prerogative of both are education itself.

Accordingly, there are two main trends in existing programs:

"individual" programs designed exclusively for company's employees (closed system);
special purpose programs open to employees of other companies (open system).
The first type of programs focuses not only on educational goals related to the provision of specific knowledge relevant to the organization, but also on their integration. In such programs, much greater importance is attached to the acquired knowledge which is consistent with the strategic goals of a particular company. Often part of the course is to increase the internal motivation and identification with the company, which allows the staff formation with high levels of intra-group cohesion.

The second type is experience-oriented. The company that wants to distribute it organizes programs (usually certified) where knowledge on a specific topic is available to all comers. The first option is more widespread as it is the cheapest and easiest way to create your own training center.

However, it should be emphasized that since the idea of corporate training centers began to appear in the personnel departments of different organizations, so before the model of their functioning has changed significantly. Initially, these were development centers located in large departments, over time they became autonomous centers of idea formation, creation of new concepts and initiation of changes.

Starting from the essence of the corporate training center, its purpose is to create the internal corporate knowledge system, the educational process should be directed by the company, and as many internal specialists as possible should participate (as trainers). The educational alliance with commercial and government institutions is usually not limited to the provision of textbooks and premises to the company. In this case the external training companies or other providers of training programs are needed to provide the company with a standard set of training aimed at familiarization and expanding of standard competencies. Identification, formalization and dissemination of THK's unique competencies should be carried out by the company itself.

Therefore, the main idea of the corporate training center is to create the corporate system of knowledge. That is why the training process should be coordinated by the company and internal specialists of the company (as trainers) should participate in it. In this case, the cooperation of the educational institution and the company must consist in mutual enrichment of knowledge. Those profile specialists of the company, who will conduct trainings and classes, transfer knowledge and experience to the next generation, receive the approved training method. Educational institutions, in exchange for the knowledge, provide the premises, get access to the information accumulated by the company.

Although interaction with traditional educational institutions is a good option for employee training, the formation of independent educational structures within the enterprise itself has become increasingly popular in recent years. If a company has multiple training programs for different categories of employees, if training and development programs are repeated and massive, if the proportion of unique training programs is large, and their relationship to the achievement of strategic goals is obvious, then it should be focused on creating an independent educational structure with internal trainers and training specialists.

Figure 2: Components of the system of manages' corporate training (author's development)

Now there are separate corporate training centers considered as independent businesses entities and have educational licenses (such as Global Learning, created by IBM). After studying at this corporate university, students are issued certificates.
Due to the changes taking place in all spheres of public life, the emphasis in the issues of staff's education and advanced training and their professional development is transferred from the national to the institutional level. Accordingly, the issue of creating, on the one hand, an effective system of education and advanced training, and on the other - a corporate system of methodical work becomes important.

We proceed from the traditional understanding of methodological support as a professional interaction between the subjects of the pedagogical activity, which covers methodological support (curricula, programs, educational and methodical, normative, special literature, manuals, reference books, working materials, methodological recommendations, etc.), it assumes constant interconnection of all subjects of the educational process, taking into account the dynamics of specialists' professional development, flexible response to this process through the use of control and corrective procedures.

We propose to summarize a number of components of scientific and methodological support of the corporate training and managers' professional development in TNC (Fig. 2).

There are two main types of education for TNC:

criteria for economic effectiveness characterizing contribution of the program to the economic development of TNC on the whole, including both direct and indirect effects;
criteria for social effectiveness taking into account the expected contribution of the program to social development, its indicators cannot be expressed in the cost estimate.

We can distinguish the following two types of corporate training programs: the first ones are focused on enhancing external adaptation, the second ones are focused on internal integration. They can be specified thematically:

1. Specialized training programs by the areas of TNC activities (sales training, negotiations, etc.).
2. Team building programs (active group and intergroup activities with subsequent reflection, business and role play, problem analysis).
3. Programs for the development of interpersonal and intercompany communication, formation of conflict resolution skills (sensitivity training, role-playing games, imitation business games).
4. Programs of corporate culture design.
5. Management training programs (lectures, seminars, practical classes, educational business games).
6. Programs for preparation for organizational innovation (organizational mind games, project development, analysis of organizational situations).

Discussion

However, in our opinion, the main reason why major corporations spend money to build a corporate university is to introduce continuous improvement mechanisms in the company, to increase the return on project transformation, and in the context of our research, that is, directly for managers - to promote personal and professional development throughout life.

In addition to the above, there are several accompanying reasons:

interest of the corporation's management in the strategic development of its company;
need of the company for innovative and initiative employees;
need not only to acquire new knowledge from the outside, but also to translate it with their own experience in all branches and units in different countries or cities for the most effective learning;
necessity to train staff not only to solve urgent problems, but also to achieve medium- and long-term goals.

Instead, the primary purpose of creating a corporate training center is to provide system strategic staff training, that is, training enabling the company to solve strategic objectives and achieve strategic goals. It follows that the corporate training center should influence the competitiveness of TNC, assist in the implementation of its long-term strategy and plan its work in accordance with a single ideology that follows from the basic strategy of the company for the future.

The need for organizational changes and changes in the principles of personnel development management in the conditions of increasing competitive struggle implies increase of personnel productivity, quality of goods, improvement of customer service, creative and innovative attitude to business. But first, management should be aware of the benefits of corporate training, including:

creation and improvement of the system of experience transfer within the company;
training of "narrow" specialists of the specific direction of activity (cleaning, work with software products);
continuous advanced training for all employees;
dissemination of the best practices of divisions within the company;
decreasing the number of errors by thoroughly reviewing the procedures of current activity;
reducing the cost for expensive external training (in case of a well-developed corporate training system, it will be enough to send 1-2 employees who will share their knowledge with colleagues), etc.

It should be emphasized that these are not all the benefits of corporate training. Many problems can be solved by using a variety of low-budget methods of internal learning; through the development of intangible factors of stimulation of mentors, trainees, training project managers, the use of competitive schemes between structural units in the implementation of the training system; development of criteria and methods of evaluation of the training effectiveness by branch, evaluation of the training program in post-program support by trainees, managers (lecturers); team work, development of organizational culture, oriented to the development of the corporate training system.

Analysis of the well-known TNC activities in the organization of staff training enables us to find out which conditions are the most appropriate for work of the training system. The most important ones among them are:

when there is a close connection with the company's strategy, its goals, objectives, mission;
there is a real, not far-fetched, need for training: the staff sense very much "pseudo-education";

formed motivation: in order to fruitfully learn, one desire of the manager is not enough, employees' motivation is required;
the company has been created training environment, there is a positive internal PR training;
there is support from the company management at different levels;
environment was created for implementation (application), consolidation and continuous updating of knowledge;
knowledge bank was created enabling regular updating of knowledge;
the learning process is system and continuous.

Conclusion

The main directions and forms of managers' professional development within the corporate training centers can be: training within the company, distance learning in a computer network, participation in open seminars and conferences, internships in the company's departments, project management, mentoring, coaching, etc.

Scientific and methodological support, as professional interaction of subjects of pedagogical activity, involves considering the dynamics of specialists' professional development and constant interconnection of all subjects of the educational process. The components of scientific and methodological support for the managers' professional development at TNC are: defining goals and developing training policies; diagnostics of the existing level of personnel development, diagnostics of need and readiness for training, identification of expectations; selection and formation of training content; drawing up individual training and development plans; coordination of individual plans, drawing up the general corporate training plan; development of training and development programs; selection of types of training forms and methods; selection of trainees; logistical support; conducting training; post-study support (introduction of acquired knowledge, adaptation of new knowledge to real practice); a control system, tracking changes and evaluating the effectiveness of training, identifying gaps, which are both diagnostics at a new level; adjusting training plans and programs; staff motivation.

The study does not exhaust the problems of managers' professional development in multinational corporations. Issues of managers' cross-cultural training in the corporate education system, training of andragogues (trainees, instructors, coaches, tutors, etc.) for effective activity in corporate training centers remain relevant.

Perspective directions of further research are also theoretical, methodological and didactic substantiation of talent management and development of their creative potential, development of tools for stimulation and retention in the organization of managers who have been trained, study of experience in the development of the individual's leadership potential. The problem of formation managers' ethical behavior as a set of actions, social responsibility of management at the international level deserves special attention.

Abstract

The factors influencing the formation and management of international teams of project managers in a multicultural environment are analyzed. The main problems in managing communications in international projects that are directly related to the human factor are identified and the existing approaches to solving such problems are analyzed. The set of key competences of project managers of international teams in a multicultural environment, which distinguish successful project managers, is defined. An approach to the development of project managers working in international teams in a multicultural environment has been developed taking into account the development of competences that determine a successful project manager.

Keywords: sustainable development, competence, manager, team, communication management.

Introduction

When forming and managing the team of project managers, these differences have a direct impact on the communication processes and interactions of the project team. As a result, this can negatively affect the success of the project as a whole, as well as the satisfaction of team members since errors and misunderstandings in communications, lead to a low level of trust and motivation in the project team.

Humanization involves increased attention to the individual as a whole, the creation of the most favorable development of its abilities, physical, and moral qualities.

Modern education aims to form an ecological and economic responsible person, ready for the conscious activity on the basis of acquired knowledge and established standards and rules of behavior in relation to the environment in the conditions of sustainable development.

Forming and managing the international team in a multicultural environment require harmonization of the competences of team members both cross-culturally and professionally, based on scientific methods and approaches. All this determines the relevance of the research topic.

Cite this Article as: Olena KOTYKOVA, Oksana KOMAROVSKA, Oksana MATVIICHUK, Maryna RADCHENKO,and Tetiana HOLINSKA "Methods of Modeling of Managers' Competences in The Context of Sustainable Development" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The purpose of the research is to develop models and methods based on competences aimed at the cross-cultural development of the project managers of international teams in a multicultural environment and balancing disagreements and misunderstandings in cross-cultural communications, ensuring the success of the project.

Literature Survey

The application of the competence-based approach is becoming increasingly common in project management practices, in particular, professional standards, since project managers are increasingly paying attention to the importance of this concept (Meng, X., & Boyd, P. (2017)).

The competence language is used in many organizations as the basis for personality characteristics (Putri, K. D. C., Sari, M. M. R., Ramantha, I. W., & Budiasih, I. G. A. N. (2019).

The concept of the competence is used and formed in accordance with the role that the individual performs; and is also considered useful for improving staff productivity when used for assessment, training, and other processes related to staff (Ahmed, R., & Anantatmula, V. S. (2017)).

Competences are key elements in the following cases: high-quality job descriptions, development of methods and criteria for selecting employees; staff productivity management; development of methods and tools for personnel assessment; description of processes for assessing individual competence and results; elaboration of staff development programs (Engelbrecht, J., Johnston, K. A., & Hooper, V. (2017)).

In general, the use of competence modeling as a method for assessing, training, and developing competences is a common practice in the field of Human Resource Management (HRM), science, which studies recruitment, distribution, development, leadership, retention, and dismissal of staff (Medina, R., & Medina, A. (2017), Rasnacis, A., & Berzisa, S. (2017)).
In the so-called competence models, competences are structured in a hierarchy or grouped in clusters with descriptors (Aragonés-Beltrán, P., García-Melón, M., & Montesinos-Valera, J. (2017)).

There are three types of sources for obtaining data for creating the so-called competence models: panel discussions and focus groups with experts in this field (Gunawan, J., & Aungsuroch, Y. (2017)); interviews about significant events with highly qualified specialists (Banihashemi, S., Hosseini, M. R., Golizadeh, H., & Sankaran, S. (2017)); general competence dictionaries (Maqbool, R., Sudong, Y., Manzoor, N., & Rashid, Y. (2017)).

There are a number of behavioral competences, or the so-called soft or flexible skills, which allow applying innovative approaches in situations where people have their own solutions to existing problems (Pinto, JK, Patanakul, P., & Pinto, MB (2017)).

Interpersonal competences are a trend of the future and part of the path to success.
Project management is an area where professional standards are actively used, in particular: ICB, PMBOK, PRINCE2, P2M, AIPM, and the like. Let's consider the concepts of "competency" and "competence" in these standards and the approaches available for managing international projects in a multicultural environment (Varajão, J., Colomo-Palacios, R., & Silva, H. (2017)).

ICB (Individual Competence Baseline) is a standard on the basis of professional knowledge and a system for assessing the competence of project managers (Radujković, M., & Sjekavica, M. (2017)), which is issued by the International Project Management Association (IPMA).
The authors summarize the analysis of the competence-based approach used in professional standards for project management. A competence-based approach is also experiencing fundamental difficulties.

First of all, it is necessary to clearly define a common understanding of each competency that needs to be developed and implemented between different departments or even organizations (for competences independent of organizational structure) (Artz, B. M., Goodall, A. H., & Oswald, A. J. (2017)).

Secondly, at the technical level, the various systems and services involved in personnel management, training and knowledge management must be semantically aligned so that competence-based approach es can meet their holistic expectations (Davis, K. (2017)).

Finally, compensation is crucial in competence modeling: more accurate, realistic, and well-defined competences become more complex management and control tasks (Ha, T. P. T., & Tran, M. D. (2018).

Methods

The theoretical basis of the study includes the scientific works of scientists in the management of international projects and programs. Theoretical research was based on the use of system analysis methods, set theory methods, as well as the methodological base of standards for project management, and international management and cross-cultural communications theories.

To verify the obtained methods and models and practical confirmation, pilot training for teams of young project managers originating from different countries and cultures was conducted in Germany and Belgium.

Results

Successful management of multicultural projects requires solving numerous challenges: legislative and political environment, security issues, economic factors, infrastructure limitations, and the like, which are unique for each country.

However, the human factor and communication management are the most important factors affecting the success of such projects. In general, cultural misunderstandings are caused by the fact that a message is composed, or “encoded” in one cultural context, sent, and then received or “decoded” in another cultural context.
Cultural beliefs and rules lead to behavioral differences. For example, in some countries, a certain model of behavior may be considered a manifestation of politeness, while in others it is quite the opposite.

There are also various cultural beliefs about informal communication at work. Some cultures tend to exclude informal communication, and some cultures view informal communication as part of business ethics. Various measurements of behavior such as space, touch, and eye behavior, form another cluster of cultural patterns that can cause conflicts and misunderstandings.
Hierarchical structure is a common tool in project management practice, which are used to distribute the logical components of large arrays of project elements to be managed. For example, common breakdown structures are the project work breakdown structure or the hierarchical structure of the project’s organization (English, “organization breakdown structure”).

The competence breakdown structure method is based on the generally accepted project management approach, which allows structuring a complex system into smaller manageable elements. The competence breakdown structure method allows detailing the concept of the competency, despite the approach to the use and determination of the concepts of "competency" and "competence".

The competence breakdown structure is a method that decomposes the concept of cross-cultural competence into smaller elements in their original form. In other words, competences related to cross-cultural development, are divided into sub-competences in several approaches to the desired degree of detailing. When applying this method, an international project team led by a specialist independently determines important competences and sub-competences, which are referred to cross-cultural relations and communications, enriching with specific finds, formalized during interactive discussions in cross-cultural training. This method helps to visualize the competences that will be developed by the project teams during the introductory phase of the project (cross-cultural training).

Figure 1: Cross-cultural profile of the manager competences (author's development)

Thus, the competence breakdown structure method provides the basis for self-reflection and focused development. The structure of breaking down the competences into subcompetences is also an approach to visualizing problems and suggestions that can be discussed on a virtual social platform.

The competence breakdown structure method offers a communication strategy for project team members on the basis of their own personal qualities and advantages, which is also the cause of misunderstandings in international teams. Thus, a basis for the joint contribution of the project team members, which is aimed at mitigating and preventing conflicts, is formed.
Given this statement and analysis of the literature conducted within the framework of this scientific work, a method that is called the cross-cultural profile of competences (Figure 1) for the formation of cultural consciousness and interpersonal interactions in international project groups has been developed.

The competence profile, that is, the set of competences of an individual, is tailored to predefine personal and organizational goals and has a unique form in each international project team.

The cross-cultural competence profile reflects the goals of the project team development, which are aimed at the results of individual development, motivating team members to change their behavior, attitude and development of self-esteem and motives that are more difficult to train. It offers a common language and a basis for self-reflection and self-improvement; provides a point of reference for team building, trust management, prediction of cross-cultural misunderstandings and motivation for personal development of cross-cultural competences.
The proposed sample of cross-cultural competence profile (Figure 1) aims to encourage project managers to plan and facilitate the process of cross-cultural development within multicultural groups.

However, this list may be expanded or reduced depending on the team characteristics (size, cross-cultural background) and the amount of time that can be devoted to the cross-cultural development of the project team, etc.
The cross-cultural competence profile is subject to further breakdown. Each element of the cross-cultural competence profile contains sub-competences that explain the effectiveness detail.

Figure 2 shows sub-competences that contain specific examples (A, B, C, ..., N, M, N, etc.) that are relevant to the project team. Sub-competences are flexible elements that are initially prepared by the project manager, project office, or cross-cultural experts.

Figure 2: Model of sub-competences of international manager profile
(author's development)

During the kick-off meeting, the project manager can initiate a discussion and update elements and sub-competences based on project members' proposals. Thus, the cross-cultural profile of competences serves as a reference point for developing basic rules based on the multicultural specifics of the project team. During the implementation of the project, an updated and documented cross-cultural profile of competences should be disseminated and, in the future, serve as a point of discussion for identifying and updating cross-cultural differences and compromises. At the final project stage, the cross-cultural competence profile can be easily documented in the form of lessons learned from the project.

The main advantage of the cross-cultural competence profile is that it serves as one of the main success factors for each project, that is, the satisfaction of interested parties. The implementation of this method is aimed at predicting cross-cultural misunderstandings, preventing incorrect communication, and delaying information flow in the project.

The disadvantages of applying the cross-cultural competence profile can be, for example, cases when, in task-oriented teams, people do not want to waste time using such tools.

Moreover, the concept of the competency and competences can lead to some confusion when introduced for the first time. In conflict situations, people do not know what exactly they do not know if it is not presented in such a way that it causes a free and conscious choice. In other words, the international competence profile should highlight not the prescriptions in emergency cases but a combination of features and capabilities that it is desirable to strive for. The results of the introduction of this method by the author for the preparation of multicultural teams of project managers have confirmed its practical value.

Discussion

The introduction of cross-cultural training can take place in the following forms.

When carrying out an international project, the teams of which consist of three or more significantly different cultures in the project team, as part of the first project meeting and/or events to create the project team;
When implementing international project programs, whose teams consist of three or more significantly different cultures in the project team;
As one of the functions of the Project Management Office (PMO), which organizes training;
By inviting consultants who are specialists in conducting cross-cultural training;
In the program of events for team building both as a separate cross-cultural training and as one of the topics proposed to the project team during the kick-off meeting;

As a measure of summarizing the results of the project, formalizing the lessons of the project and the "emotional close-out" of the project. It is important to ensure the presence of positive emotions since when closing a project a "burn-out syndrome" quite often occurs when stress from the project ends. Conducting cross-cultural training, which concludes cross-cultural projects and emphasizes new discoveries and shared cultural traits.
As measures to prevent or resolve conflicts;
As part of the training on project management in a multicultural environment;
As part of the training program for undergraduates with a degree in Project Management or related subjects (for example, International Business).
During the implementation of cross-cultural training, the following challenges and problems are possible that may impede the effective establishment and functioning of this method:
Disagreement on the part of the project team members;
Disagreement from the management of the organization or experienced project managers;
The need to learn often causes resistance;
Conducting the first training without further monitoring and/or conducting the final training;
Insufficient budget in the project;
Lack of time, especially for intermediate and final training;
Force majeure circumstances.

Conclusion

High-level communications are built and structured in such a way that they help minimize and/or avoid unexpected delays and misunderstandings, warn applications of redoubled efforts, learn about problems in advance, and apply preventive measures.

According to the analysis of competences related to the management of international teams of projects in a multicultural environment, the existing classifications and approaches to formalizing and defining cross-cultural competences should be in-depth taking into account the specifics of the multicultural environment and the challenges associated with the human factor and problems in international communications.

Multicultural project managers must have a set of key competences. These competences constitute the asset of the project, ensuring its success. An analysis of world literature and scientific research indicates that the use of soft skills is the main tool that is used to solve problems and challenges related to the human factor and communications in international teams of project managers in a multicultural environment.

Therefore, when a project team is formed in a multicultural environment, it is necessary to formalize special requirements for the soft, in particular, cross-cultural competences of the project team members. In other words, the success of the project depends on the harmonization of the cross-cultural awareness and skills of the project team members. The manager of such a team should convey to the team members that one of the tasks of the team is to work with the existing team members and, accordingly, with the cultures involved.

The competence breakdown structure method is based on the generally accepted project management approach, which allows structuring a complex system into smaller manageable elements. The competence breakdown structure method allows detailing the concept of the competency, despite the approach to use and definition of the concepts of "competency" and "competence".

The proposed method was developed as part of scientific research and conducting cross-cultural trainings for international graduate students and masters who perform tasks for work or assignments in multicultural groups. However, further research and development are required to contribute to the field of competence management of international groups in a multicultural environment.

Abstract

The introduction of the unified technology platform for the deployment of the cloud-based educational environment in higher education institution helps to solve numerous problems of unifying the architecture of the environment, integrating the technological infrastructure of learning on a single basis, providing wider access to better samples of electronic resources and services. When designing a cloud-oriented learning environment, it is advisable to use a hybrid service model of its structure, its content covers electronic resources of educational and scientific purpose. The holistic model of specialist training in the cloud-oriented environment contains levels and components of competence that are inherent for the process of training scientific and pedagogical staff of the education informatization trained in a high-tech environment. The integration of different subsystems of the environment into a single training system ensures the integrity of this process through the separation of invariant factors inherent in different branches of education.

Keywords: Holistic Model, Electronic Resource, Environment Architecture, Hybrid Service Model, Educational Informatization.

Introduction

Formation and development of educational and scientific environment of higher education institutions on the basis of cloud computing technology is an actual direction of modernization of pedagogical systems of modern higher education. It is associated with the spread of more convenient, flexible, scalable systems for organizing access to electronic resources and services, facilitating teamwork with software applications, removing geographic and time constraints, mobility of all learning subjects using cloud technologies and other factors.

Prospective information and communication technologies (ICT) are an instrument for implementing the principles of human-centricity, equal access to education in pedagogical systems of higher education. The cloud technologies mostly meet the needs of solving urgent socio-economic, educational and cultural problems of modern society, the main of them are increasing the level of accessibility and quality of education, interconnection of processes of scientific research and training of scientific and pedagogical staff, improving the design, formation and provision of functioning of educational and scientific environment (OSE) of higher education institutions.

Cite this Article as: Lyudmila PET'KO, Vanda VYSHKIVSKA, Liudmyla OVSIIENKO, Olena KULYK and Oleksandra SHYKYRYNSKA "Formation of The Virtual Educational Environment of The University in The Conditions of Education Informatization" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The development of OSE is characterized by increasing requirements for the quality of electronic resources for scientific and educational purposes, expansion of more flexible, personalized, open organizational systems, which becomes possible with the use of cloud services.

The involvement of higher education institutions in cloud-based open information and educational space can also play a leading role in: deepening the links between education, science and production; expansion of cooperation between educational and scientific institutions; creation of various corporate structures, supported by cloud technologies, aimed at developing closer interaction with the higher education sector; solving urgent social and economic problems; improving the intensity of the scientific search and training process, etc.

Literature Survey

The current stage of society is characterized by the emergence and expansion of the digital market, which is constantly covering all new industries. Trends in the development of this market are largely determined by the progress not only of the technology sector itself but also penetration of advanced ICT into other fields of production and social activity (Feldman, J.D., et al. (2018)).

In particular, education is a prospective area for the introduction and application of new technologies. It will stimulate productivity and efficiency of activity in this field, make graduates more competitive, promote their professional realization, business development, economic growth (Pegalajar, M. C. (2018), Li, S. C., et al. (2006)). The dynamism of production processes, caused by the rapid change in technology, leads to the emergence of new areas of specialization, which may not have existed a few years ago, creation of new jobs.

The world's leading companies and governments are investing in advanced digital technologies such as mobile communications, social media, big data analytics, intelligent devices that control connected objects and sensors, and others (Idris, M.Y., et al. (2017)).

Among them cloud technologies using organizations around the world play a special role, and this growth is at an impressive rate (Wong, E. M. L., & Li, S. C. (2006)). The issue moves from a plane of competitive advantage to a plane of avoidance of backlog and overcoming a technological gap in comparison with more developed subjects of business in all spheres of economic and social development.

Global trends in cloud computing are characterized by data from leading market research companies in the IT sector.
Digital technologies are being introduced in education and education systems to make the learning process more efficient and up-to-date (Taylor, S. (2018)). Prospective learning systems are based on intellectual and interconnected environments.

But the existence of high-tech systems (infrastructures, environments) does not improve the quality of education yet. A key element in this process is the teaching staff (Paradarami, T.K., Bastian, N.D., & Wightman, J.L. (2017)). The lecturers and teachers should possess sufficient skills ICT use in order to become leaders of changes and to activate the processes of modernization of educational systems.

Methods

To solve the tasks set in the work scientific methods were used: theoretical - analysis of psychological and pedagogical, philosophical sources on the research problem to clarify the status of the issue development of formation and development of cloud-oriented educational and scientific environment of higher educational institutions, identifying research areas, principles and approaches to the environment design; analysis of current standards and regulations regarding the use of ICT in the process of education and informatization of educational institutions; generalization of domestic and foreign experience of using cloud services and technologies in higher education institutions to determine trends in development, to clarify the basic conceptual and terminological apparatus, establish conceptual bases of research; theoretical analysis, system analysis, systematization and generalization of scientific facts and patterns for the development and design of models of cloud-oriented environment, substantiation of the main conclusions and provisions.

Results

The design of electronic educational resources (hereinafter referred to as EER), which are elements of meaningful content of the environment, can be considered to some extent, regardless of the system means and resources of their

supply, which are also "in the cloud". Thus, the provision of system tools for network configuration, as well as the design of the filling itself, its quantitative and qualitative composition appear to some extent as separate tasks, separate stages of this activity. Therefore, the issues of justifying the ways of selecting and classifying the necessary electronic resources, ensuring the proper level of their quality play a more important role.

Electronic resources appear at the same time as objects and means of learner's activity, thus, they perform certain functions implemented in the process of mastering the subject area. It is expediently to characterize the types of activities conducted for ICT services in a cloud-based system which serve as its educational services. Obviously, not all functions that can be performed within a particular system are necessary, that is, not all of them need to be converted to services.

It will be necessary to determine the components of its content filling for the design of educational services on the basis of a hybrid model of the educational and scientific environment of a higher education institution. The components are electronic resources of educational and scientific purpose.

Electronic resources to support learning activities can be further classified according to the types of activities, including acquisition of theoretical material, consolidation of knowledge (tasks, exercises execution, skills development, and knowledge assessment (Table 1).

Table 1. Electronic learning resources in the cloud-oriented environment (copyright development)

Electronic resources	ACTIVITY		Electronic resources
	Essence of the activity	Type	
Resources for e-journal systems, e-libraries, information retrieval networks, collections, multimedia libraries, EOP reference and additional, text, editors of tables, images, presentations, EOP creation tools	Preparation of demonstration and printed materials, educational and reference literature processing	Preparation and search of learning material	
Resources of e-journal systems, e-libraries, information search engines and social networks, collections, multimedia libraries, EOP reference and additional, electronic textbooks, manuals, electronic training courses, linguistic analysis programs, educational expert systems, e-thesaurus	Processing of texts, formulation of statements, concepts, conclusions, syntactic and semantic texts processing, multimedia demonstration	Theoretical material processing	
Electronic text-books, tutorials, electronic training courses, learning expert systems on tasks solution, electronic tasks, activity environments, subject packages of applied programs (PAP), PAP modeling, simulator programs, training lab workshops	Tasks, exercises solving, skills development, execution of practical, laboratory work, modeling, data analysis and processing, construction, calculations, mathematical transformations	Consolidation of knowledge, formation of practical skills	
E-testing systems, automated knowledge assessment systems	Assessment, monitoring of educational activities	Evaluation of learning outcomes	

It is possible to suggest further detailing the types and varieties of electronic resources for educational purposes, which are a component of the educational constituent of the educational institution environment, by the criterion what place these resources occupy in the organization of the learning process.

Research pedagogical activity is an important component of practically all branches of education, where it is necessary to introduce modern innovative approaches, tools and technologies. Because of this identification of its

structure and functions, forms and levels of organization, processes and constituents becomes an urgent issue for the professional development of not only scholars, but also teachers-practitioners, lecturers and educators of many links.

Particular interest in this context is the issue of the activity aspects of the experiment organization, concerning the application of modern facilities and technologies, in particular means of informatization, to support certain stages of the process of scientific and pedagogical research, their role and place in the implementation of research activities, ways of their optimal selection and use.

Identification and systematization of different types of actions, as well as their corresponding forms of thinking is one of the areas of the activity approach application in the field of research of problems of scientific and pedagogical cognition.
In case of consideration of scientific and cognitive activity, the concept of cognitive action becomes a priority. It is an action with forms of thinking aimed at the realization of a function or correspondence. This approach assumes understanding of cognitive activity as a sequence of cognitive actions. Theory as a system of scientific knowledge (a system of various forms of thinking) in this sense can be considered from the point of view of the activity results fixed in thinking.

Consideration of scientific and pedagogical activity as a form of cognitive research activity involves the identification of the pedagogical knowledge of various structures and cognitive processes associated with them, which have a complex and multilevel structure. Such processes include, for example, hypothesing and their testing, scientific data collection and analysis, formulation and justifying conclusions, etc. It turns out that the isolation of certain types of activities and their procedural components often arises rather nontrivial methodological issues, because scientific theory provides in its structure a complex, multifaceted and hierarchical system of actions aimed at performing functions of various types.

Discussion

Identification and systematization of sets and systems of cognitive actions, their descriptions and conditions of implementation is an important area of analysis of the structure and functioning of pedagogical theory as a system of scientific knowledge. One of the ways to accomplish this task is to identify the types, varieties and levels of hierarchy in the structure of scientific and pedagogical activity and their systematization.

In order to successfully develop a procedure and technology for the implementation of a scientific and pedagogical activity of a certain type, it is necessary firstly to find out what kind of actions and in what sequence they will occur.

Technology and procedure, in this case, are a constructive description of a particular activity. An important element of technology research is the implementation of activities which also require typology in order to be able to organize their description, selection and place in the technology. Thus, systematization of types of activities in the structure of scientific and pedagogical activity is a prerequisite for the formation of technology of scientific and pedagogical research.

Conclusion

Pedagogically sound and appropriate introduction of cloud technologies into the educational process of the university, formation and development of educational and scientific environment on this basis is a factor of increasing access to electronic educational resources, increasing the efficiency of the use of ICT. An important prerequisite for it is the improvement of the ICT competency of researchers, teaching staff and students in the use of cloud technologies.

It is necessary to take into account the educational and scientific criteria for the formation of this competence, characterized by a number of indicators on the organization and effectiveness of scientific research, implementation of scientific results, forms and types of educational activities.

While designing the cloud-oriented educational and scientific environment of the university OSE, it is advisable to apply a methodological system for its formation and development, which is based on the use of certain methodological principles, methods and approaches, aimed at increasing access to electronic resources, using state-of-the-art tools and technologies, enhancing participants' ICT competencies, educational and scientific process.

The methodological system encompasses a number of techniques that are combined by a system-forming factor, which is a cloud-based approach that relies on relevant baseline characteristics and service models. The system includes: methodology of using the scientific-educational cloud of scientific / educational institution, aimed at improving the organization and increasing the efficiency of scientific research, implementation (publication, dissemination and use) of their results; techniques for using cloud-oriented components for educational purposes based on AWS hybrid cloud and a specialized service (SageMathCloud), focused on increasing the ICT competency of lecturers and students, improving learning outcomes.

Identifying and classifying different types of educational activities is a prospective subject of our research. It is consistent with the tendency to study the problems of technologicalisation of various aspects of pedagogical research. At the same time, identifying the types of activities and their procedural components within each stage is an important object of elucidating the structure of the study. These issues require further development and systematization, especially in the informatization aspect.

Abstract

It is proposed methodological approach to assessing the impact of the external environment on the implementation of this process, which is based on general and specific principles of the system, process, value-oriented approaches and involves the use of a sound system of indicators of factors characteristic of global, national, sectoral and regional levels and formal methods of valuation, which increases the objectivity and decisions validity level in the process of achieving and retaining competitive advantages of trade entities based on an integral approach to the formation of competitive advantages. It is made implementation of the proposed methodological instruments, which used the results of internal possibilities valuation, realized the influence valuation of external factors and set a favorable factors impact of all given levels, as well as negative impact some of them.

Keywords: competitive advantage, internal possibilities, business processes, international trade, external factors.

Introduction

The formation of an effective system of enterprise competitive advantages of economic activity certain type requires concretization of the content and identification of features taking into account industry specifics. The significance of the study these issues in relation to trade activity can be explained by the fact that the competitive advantages of all participants in the reproduction process (suppliers, manufacturers, trade entities, etc) are considered if they are recognized as consumers, that is, at the final stage of commodity circulation, where retail trade operates. It is no coincidence that the emergence and formation of competitive advantages theory occurred in the context of the formation and development of international trade theory. Features of competitive advantages are also related to the ability of trade enterprises to form them due to the quality characteristics of goods. The absence of production processes does not allow trade enterprises to directly affect the quality of goods.

Retail entities exercise indirect influence on the quality characteristics of ware through purchasing, cooperation in creating and developing a trade mark, forming a range of products with high quality, etc.

Literature Survey

Significant number of scientists consider competitive advantages based on the competence approach (Trigeorgis, L., & Reuer, J. J. (2017)).

The essence of this category is highlighted through the following characteristics (Zhao, E. Y., Fisher, G., Lounsbury, M., & Miller, D. (2017)): degree of development and efficiency of using competitive potential; combination of existing potential with experience of using and image; the function of resources and competencies; the consequences of having key and distinctive competencies; the set of competencies with internal and external capabilities, etc.

Proponents of this approach (Durmanov, A., et al. (2019)) as sources of forming competitive advantages distinguish not only internal capabilities and competencies in different areas of activity, but also external; note such integral features as the comparative, dynamic, effective nature and strategic orientation.

The developments of Ogunsiji, A. S., & Ladanu, W. K. (2017), who consider competitive advantages from the point of view of competencies and capabilities, mainly refer to the carriers and sources of formation, which somewhat blurs the essence of this category at the same time.

Scientists interpret competitive advantages from the point of view of an innovative approach as:

scientific-technical potential, new technologies and knowledge, any innovations that create an advantage over competitors, thereby focusing on modern sources of the formation (Caurkubule, Zh. L., et al. (2020); Zeibote, Z., et al. (2019));

innovative approach to business strategy and tactics, which is more in line with approach to forming competitive advantages (Meyer, G. D., Neck, H. M., & Meeks, M. D. (2017)).

Thus, while emphasizing the leading role of innovative factors in creating competitive advantages, the authors do not, in our opinion, fully disclose the meaning and nature.

Methods

Theoretical and applied aspects of the work were studied using the following methods: content analysis – for the development of conceptual and categorical apparatus; morphological analysis; scientific abstraction; analysis, synthesis, comparative analysis- to determine the features of competitive advantages of retail enterprises and the systematization, classification of influence factors the formation of competitive advantages; graphoanalytic, matrix- the effectiveness valuation of competitive advantages formation; graphic- for schematic display of a number of theoretical and practical provisions, etc.

Results

The process of forming the competitive advantages of a retail company is proposed to be carried out in a number of successive stages based on the basic approaches, principles and components of the applied bases.
It is the formation of maximum possible set of ideas about competitive advantages in all types (operational, financial, investment), areas of activity of enterprise retail trading, and sources – external (favorable legal framework, geographical location, etc) and internal (internal business processes, management, resources, etc) at the first stage.
The second stage is devoted to creating information base for the formation of competitive advantages of retail enterprises based on the use of both external and internal sources.
There are determined internal enterprise capabilities to ensure the implementation of individual ideas from the first stage formed by evaluating the set of potential and realized competitive advantages of the trading company according to appropriate criteria at the third stage.
Competitive advantages are identified depending on the stage of the life cycle or stated the absence based on the results of the evaluation. Accordingly, there are formulated targets regarding the nature of actions to form competitive advantages (Fig.1).

Identification conditions	Competitive advantages	Goals
$N_i K_j \to 1$	Generated and implemented	Support and development
$N_i \to 1, K_j \to 0$	Generated but not implemented	The maintenance, improvement and implementation
$N_i K_j \to 0$	Absent	Generation of new

Figure1: Identification conditions and goals of forming competitive advantages of retail trading enterprise (author's development)

Note. N_i *- areas of competitive advantages;* K_j *- positions of competitive advantages.*

It is carried out the valuation of the favorable conditions and environmental factors of retail trading enterprises for the implementation of competitive advantages with the set of ideas and behavior's type formed at the first stage (Fig. 2) at the fourth stage.

Figure 2. Type of behavior of retail trading enterprise depending on the impact nature of the external environment (author's development)

The fifth stage involves the creation of a set of relevant ideas of competitive advantages in various types\directions and sources of formation, which can be implemented by a retail trading enterprise due to internal opportunities and favorable factors of the external environment.

It is done by establishing the correlation of capabilities of the existing competitive potential and conditions of the external environment correspond to the implementation of certain ideas. Work is being carried out to form the competitive advantages of a retail company based on a set of current ideas identified at a previous stage, at the sixth stage.

Discussion

The issues of forming internal information, the competitive potential valuation and efficiency of forming competitive advantages are discussed in the previous sections. The next stages are related to the study of determinants of creating competitive advantages by retail trading enterprises and the influence of external environment on the process of the formation.
In our opinion, this approach is debatable, since the proponents identify the sources of competitive advantages with the factors of production, i.e. the resources necessary for the production of goods or services.

But we believe that the formation of competitive advantages is determined not only by sources, but also by the complex influence of numerous multidirectional factors that can both strengthen and weaken certain advantages. Enterprises can be provided with the same factors of production, but do not have competitive advantages.

This position is based on the generally accepted interpretation of terms. Thus, the source is defined as the basis, the initial beginning, that which gives rise to something, on which something is based, while the factor is the cause, the driving force of any process.

Our research, accordingly, is aimed at studying, identifying and systematizing factors that influence the formation of competitive advantages. Factors of competitive advantages are characterized not only by a significant number, but also are different depending on the scope of manifestation, attitude to the company, the nature and strength of the action, etc. Wide range of factors is due to the scale, multi-level, complex environment of business entities, as well as versatility of the competitive advantages and the specifics of the formation, implementation and development processes. Under such conditions the effective implementation of these processes on the basis of various factors requires the classification according to the directions and signs.
It is recommended type of behavior of the enterprise depending on the favorability of the external environment based on the influence valuation of external factors that occurred at the 4th stage.

It was revealed the adverse impact of information technologies development as a part of the innovation environment and the reduction in the number of market participants due to the overall positive influence of all levels of the external environment.
Adaptive behavior to the actions of competitors and decrease in the level of information technologies development was chosen to be adequate in the formation of competitive advantages in relation to these factors. The enterprise is recommended innovative and reproductive types of behavior in relation to the favorable influence of other factors.
Coordination of goals, directions, type of behavior, and measures for creating competitive advantages are shown in Fig. 3.

Competitive advantages \ Formation recommendations	Generated and implemented	Generated but not implemented	Absent
Goals	Support and development	The maintenance, improvement, implementation	The generation of new
Directions	The skill level of staff	The level of management competencies	Availability of commodity resources and capital
Type of behavior depending on the influence factors of external environment	Innovative. Reproductive. Adaptive to the competitors behavior in the industry and regional markets, to reduce the level of information technologies development	Reproductive on an innovative basis. Adaptive to the competitors behavior in the industry and regional markets, to reduce the level of information technologies development	Innovative (search and implementation of favorable opportunities). Adaptive to the competitors behavior in the industry and regional markets, to reduce the level of information technologies development
Formation activities	Increasing the level of staff abilities. Encouraging lower circulation costs. Creating conditions to optimize of circulation costs	Introduction of modern technologies in the trading process and customer service. Expanding additional services and price incentives for consumers	Expansion and revision of the assortment in the direction of forming assortment varieties of different price segments, improved quality and environmental characteristics, introduction of innovative products . Stimulation of consumers. Customization of the loyalty programs. Merchandising. The expansion and differentiation of the trade marks

Figure 3: Formation of competitive advantages based on the "internal business processes" projection (author's development)

Therefore, the proposed methodological instruments for the formation of competitive advantages of retail trading enterprises allowed to solving complex this problem, identify narrow spaces and critical conditions in comparison with the subjects of strategic group, as well as to determine measures for further actions to form competitive advantages and improve the competitive position in the strategic group and in the market.

Conclusion

Comprehensive methodological support for the formation has been developed, takes into account industry specifics, based on general and special principles of system, process and strategic-oriented approaches, the results of internal capabilities valuation and the pressure of external environment and provides for the sequential implementation of stages based on the conceptual provisions of creating competitive advantages of retail trading enterprises.

Scientific views on the allocation of environmental factors of retail trading enterprises are systematized and the classification is improved by: identifying features – directions and sources of competitive advantages, the role in providing competitive advantages; the company's response to changes in the external environment and directions of the development; details of specific factors in relation to retail enterprises by attributes- specialization of retail enterprises and the functional purpose of the range, organizational forms of trade and formats, components of business activity of retail enterprises based on the study of modern approaches to the classification of factors for the formation of competitive advantages.

It is developed a scientific-methodological approach to assessing the impact of the external environment on the implementation of this process, which unlike existing, based on a set of general and specific principles of the system, process and value approaches; involves the use of an integrated system of indicators characterizing the external environment of retail enterprises of world, national, sectoral and regional levels; focuses on the specifics of retail trading enterprises based on the conceptual foundations of competitive advantages formation.

As indicators, we selected indexes that are integral characteristics of factors in the relationship and calculated by authoritative international and national organizations, which increases the objectivity of the evaluation results and allows the use of formalized evaluation methods.

Abstract

The analysis and systematization of scientific and practical experience has made it possible to determine the following: requirements of the pedagogical and student community to the learning environment of an educational establishment are constantly increasing, which is caused by intensive development and active use of information and communication technologies both at educational establishments for solving educational problems and beyond. It is recognized that development of the Internet, transition of the general secondary education to various services contributes to rapid introduction of cloud-oriented learning environment for improving organizational and educational activities of subjects of education, which in the future may lead to improvement of the general secondary education system.

Keywords: cloud-oriented learning environment, information and communication technologies, educational establishment, competence, virtual learning environment.

Introduction

The relevance of the study is due to the fact that the requirements are growing for organization and quality of the educational process by the society, new opportunities emerge for comprehensive development of a student in the XXI century, new and more effective information and communication technologies (ICT) are rapidly developing, including cloud oriented learning environments (COLE), introduction of which into the general secondary education system will create the kind of management and training structures that will provide not only unrestricted access to e-learning resources, but also innovative conditions for communication and collaboration to those educational establishments that do not have relevant strong IT divisions, material and technical resources.

In a modern society open to everyone and aimed at development of general secondary education, the key role belongs to the teacher, who is entrusted with a comprehensive development of students, discovery of their potential and formation of a successful person. In addition, it is essential that professional and competent teachers with a high level of motivation work in schools, always ready to help their students. Professional activity of the teacher becomes more complex: new pedagogical technologies are introduced, the content of education is changing, new

Cite this Article as: Ganna TURCHYNOVA, Tetiana ALIEKSIEIENKO, Stanislav KARAMAN, Svitlana KUSHNIRUK and Tetiana HLADUN "Simulation of A Cloud Oriented Learning Environment at An Educational Establishment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

activities are emerging, which in turn requires a systematic development of the IC competence of all subjects of learning.

In recent years, interest in education has considerably improved and educators increasingly turn to the Internet to use ICT to communicate, collaborate and organize corporate work, and rapid development of cloud services has become a leading trend in addressing the educational mobility challenges of all educational process participants.

Solving these problems are socially important tasks of the pedagogical science.

Therefore, the basis of the cloud oriented learning environment is a series of scientific findings reflecting implementation of ICT in general educational establishments.

Literature Survey

Research on development of the learning environment of a general educational establishment is still relevant.

Interpretation of the concept of "learning environment", specifics of formation and development of learning environment, the importance of this concept for development of education is reflected in the works of scientists: Alsaadani, S., Bleil De Souza, C. (2019); Becker, L. R., Hermosura, B. A. (2019).

In the 21st century, the problem of environmental impact on development and formation of a student's personality becomes relevant, which is associated with implementation of personally-oriented learning.

In accordance with development of informatization of educational establishments, updating of the material and technical resources, emergence of computer classes, opinion of scientists regarding the term "learning environment" develops, and appear varieties characterizing its certain aspects (Yang, D., et al. (2018)).

Thus was defined the term "information and learning environment". The information and learning environment refers to a system-organized set of means of data transmission, information resources, interaction protocols, hardware, software and organizational-methodological software, focused on meeting the educational needs of users (Luo, N., Zhang, M., & Qi, D. (2017)).

Information and learning environment is defined as a set of conditions that contribute to emergence and development of processes of informational-educational interaction between students, teachers and means of new information technologies, as well as formation of a cognitive activity provided components of the environment are filled with proper content of a specific educational course (Raspopovic, M., Cvetanovic, S., Medan, I., & Ljubojevic, D. (2017)).

There are three main aspects of the "information environment": activity, communication, infrastructure (Huda, M., et al. (2017)).

The first aspect is participation of a person in the communication process, who, upon perceiving information, transforms it again into his personal knowledge.

The second aspect is communication, in which the level of education, awareness, human development is coordinated.

The third aspect is the infrastructure that enables communication activities (Internet, publishing, electronic libraries, information centers).

Scientists have identified the main types of learning environment (Machado, M. C., et al. (2018)): dogmatic learning environment (promotes development of passivity and dependence of a child); creative learning environment (promotes free development of an active child); career learning environment (promotes activity and dependence of a child); carefree learning environment (promotes free development and determines a passive life position of a child).

Some scholars (Cebrián, G., Palauand, R., Mogas, J. (2020), Lamb, R. L., Annetta, L., Firestone, J., & Etopio, E. (2018)) emphasize that the network (the Internet) led to emergence of the "network learning environment" concept. Such an environment is characterized by creating connections between people through the use of communication

technologies to achieve learning-related goals. Network learning involves storing and providing various information, email, message boards, software for organizing educational conferences, etc.

The advent of online learning games and simulators led to emergence of the concept of "virtual learning environment" (VLE) - a software system designed to support the process of distance learning with the emphasis on learning, as opposed to a managed learning environment, which is focused on managing the learning process. To create such an environment, it is typically necessary to use the Internet which provides assessment tools (in particular, an automatic assessment, e.g. a multiple-choice task), communication, downloading materials, returning assignments to students, peer evaluation, managing student groups, collecting and organizing assessment of students, surveys, etc.

Methods

To solve certain problems, a number of methods were used, in particular theoretical, methods of systematic and comparative analysis of pedagogical, psychological, philosophical, sociological scientific references, methodical, specialized literature to determine elaboration of the problem of designing a cloud oriented learning environment of a general educational establishment; legislative and regulatory documentation on development of general secondary education; analysis of pedagogical experience of using cloud oriented learning environment in education; synthesis, generalization and conceptualization for formulation of main provisions of the research; designing and modeling of cloud-oriented learning environment of a general educational establishment as a set of related components.

Results

To ensure functioning of education as a basis for sustainable development of a country, its competitiveness at the international level, it is necessary to ensure creation of new forms of organization of educational activities, transformation of organizational and educational practices, technical adaptation to new conditions of existence and activity.

An effective cloud oriented learning environment is developed on the basis of relevant policy of a general educational establishment, which defines basic aspects of comprehensive development of a student's personality and provides educational activity, is pedagogically balanced, creates conditions for educational mobility, develops IC competence, forms 21st century skills with the subjects of education and relies on both general scientific and specific principles and approaches.

Cloud computing is a progressive and promising solution, one of the elements of the revolutionary third IT platform. Its rapid spread is now a key trend that in the coming years will significantly affect the global development of education in general and secondary education in particular.
Today, it is obvious that even compared to the grid systems, not to mention the previous generation "hardwired" networks, the cloud service architecture is much more concise, more productive and less expensive.

First, cloud computing can significantly reduce capital costs for building data centers, purchasing server and network equipment, hardware and software. Most of these costs are borne by the cloud service provider. Additionally, a user saves on keeping IT staff and administration.

Second, cloud technologies provide the ability to quickly change configuration of the corporate IT infrastructure based on current needs, consuming (or buying) as many resources as needed at a given time. Cloud resources are usually enough to order a virtual "supercomputer" or infrastructure for a large corporation, and there are no problems with software updates (the latest versions are always available), compatibility of different operating systems.

Figure 1: Space-semantic component of cloud oriented learning environment (COLE) (author's design)

Third, cloud services literally allow to "carry one's workplace with oneself" – if a proper gadget is available and there is access to the Internet, a user, regardless of his location, always has access to his own virtual computer, corporate networks, databases.
Fourth, the range of services offered by manufacturers and providers of cloud solutions is constantly expanding. Usually, their range is fully in tune with the ever-increasing capabilities of modern computer technology.

Significant cost savings for software acquisition; availability of resources regardless of location, type of computer hardware, and operating system; increasing opportunities for collaboration and communication; reducing data storage and backup issues – all this takes secondary education to a new level of development.

Along with the widespread adoption and development of cloud technologies, there is a problem of pedagogical design and development of a cloud oriented model of a learning environment for a general educational establishment and the use of Office 365 capabilities to ensure educational mobility of all participants in the educational process.
In the process of designing a cloud oriented learning environment, its structure and components play one of the most important roles and determine its internal organization, interconnection and interdependence between components, which determines its further use by subjects of educational activities of different ages, with different levels of educational achievements and IC competence.

Designing such COLE component as space-semantic (Figure 1) is aimed at taking into account capabilities of the above components, which will ensure functioning of the learning environment of a general educational establishment and create conditions for universal access to objects.

Discussion

Such components include a training content repository that is filled with electronic educational resources and can contain a number of elements:

electronic textbooks that include theoretical material, a glossary, as well as topics of laboratory and practical works, sample control questions;
lesson plans and practical assignments;
assignments for an independent work;
assignments for a final academic assessment;
various instructions for laboratory works;
electronic data bank of test forms;
mini-tutorials and reference notes;
links to online resources and additional services;
additional training materials (textbooks, manuals, journals, etc.).

Conclusion

At the present stage of development of general secondary education, it is necessary to ensure functioning of the learning environment, which makes it possible to implement conditions for educational mobility, communication, collaboration and cooperation between the teacher and the students. It is necessary to introduce such models of learning environment that would allow to satisfy the needs of teachers for organizing and conducting lessons of a new type, activating students' learning activities, forming IC-competence and comprehensive development of creative personality. Such opportunities are provided by the use of a cloud oriented learning environment.

Creation of cloud oriented offices for subject teachers and filling of information repositories is a means of managing normative-methodical, didactic provision of activity of a regular school, contributes to mobility of all participants of the learning process, improving quality of education.

The model of integration of various services allowed to analyze directions of prospective development, forms of combination of various services and methods of their integration in COLE.

A necessary prerequisite for learning by means of COLE is implementation of a personally oriented educational paradigm. It doesn't need to absolutize standard teaching methods. Specifics of planning subjects' activities in COLE are determined by different aspects of the learning process and by three frames of access (shared, group, personal).

Abstract

The article contains proposals for the creation of a system for managing territorial tourism based on a tourist organization with a developed structure of departments and certain management functions and the creation of a specialized information and tourist portal of the region in the Internet with a system for monitoring the tourist resources of territories in real time. A range of factors influencing on the tourist potential of the area is determined.
A methodology for short-term planning of the development of domestic tourism has been developed and tested based on optimization of regional budgets investments. Research lies in clarifing and expanding the interpretation of the concept of "tourist territory", taking into account the rationale for the creation and maintenance of a management system, the construction of a factorologic model of tourism potential, including the coefficients of significance of the main factors of tourism development.
The developed proposals and recommendations allow the regional authorities to objectively assess the level of development of domestic tourism in the region, analyze processes and determine trends in domestic tourism, as well as the directions and scale of its development, rationally and effectively spending budgetary funds.

Keywords: enterprise of tourist complex, maximization of tourist potential, tourist territories, investments, management.

Introduction

Tourism in all its forms and types is recognized as one of the most promising sector of the economy. The multiplicative effect of tourism is enormous: the income received from one tourist exceeds the amount of money spent at the place of stay on the purchase of services and goods in the range from 1.5 to 4 times. Countries known as world centers of tourism have made it their state policy, taking on the functions of forecasting, coordination and control.

Cite this Article as: Valentyna SHAPOVAL, Tetyana HERASYMENKO , Iryna KYRYLIUK, Tetiana BERBETS and Oksana LYTVYN " Planning of Sustainable Development of Tourism in Ukraine (On the Example of The Dnepropetrovsk Region)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In the international rating of the competitiveness of countries in the tourism sector, published by the World Economic Forum, Ukraine ranks only 76th out of 140 countries (Burnashov, 2015). This indicates a serious lag in the competition for the tourism market, especially since Ukraine has a rich cultural, historical and natural heritage, which is the primary factor in the development of tourism to the European level. For this, it is necessary to improve the legal framework, establish infrastructure, carry out various marketing activities and the like. Together, these and other measures will make it possible not only to integrate into the European community, but also to intensify the development of the domestic tourism industry, which can become one of the main directions of economic development. Improving the conditions for conducting tourism business will also provide an opportunity to establish closer relations with the member states of the European Union.

The integration process is aimed at introducing European norms and standards in education, tourism, dissemination of our own cultural, scientific and technological achievements at the EU. Ultimately, such steps will be aimed at increasing Ukraine's European cultural identity and integration into the European intellectual, educational and scientific and technical environment (Mal's'ka, 2009).

In Ukraine, with a huge tourism potential, there is practically no state support for tourism development. The competitiveness of Ukrainian organizations in the field of tourism depends directly on the state approach to this issue, and the course taken in Ukraine – accession to the European Union – is another reason for changing attitudes for the tourism. We need a theoretical understanding of new forms and principles of interaction both between executive authorities of different levels, and their interaction with organizations whose activities are related to tourism; development of laws and regulations governing the activities of all enterprises and organizations of the tourism industry; improving the methods of activity of all participants in the market of tourist services that meet the requirements of the modern stage of socio-economic development.

Discussion

Many theoretical aspects of the development and functioning of enterprises of the tourist complex were reflected in the works of foreign and domestic scientists, in particular, (Burnashov I/, 2015, Mikhailichenko G., 2012 and Tkachenko T., 2009) studied the problems and prospects of the tourism industry. Deferent aspects of assessing the investment attractiveness of tourism enterprises were considered in works by (Andrash O., 2012), problems in the management in tourist areas were studied by (Malskaya M., 2009, Muzychenko-Kozlovskaya O., 2012, Byrkovich V., 2007) etc. Despite the significant achievements of the aforementioned authors, it should be noted that researchers do not pay sufficient attention to the management of tourism development in tourist areas and also do not use the system and methods of tourism management as part of the overall strategy for the development of the territories. The need for a comprehensive study of the mechanisms for the creation and operation of tourism management systems in tourist areas determined the choice of the research topic, the formulation of its goals and objectives.

Material and Methods

The purpose of this study is to develop theoretical and practical recommendations for improving the planning system for sustainable tourism development at the regional level (on the example of Dnipropetrovsk region).

As practice shows, the development of tourism can lead to both positive and negative consequences for the tourist area. The main positive results of tourism development include:

– creation of new objects of the tourism industry, modernization and increasing the efficiency of the objects of tourism and related infrastructure (medicine and health care, transport, utilities);
– attraction of tourists' savings when they spend expenses during travel, recreation, etc. (multiplier effect);
– strengthening of the consumer market;
– increasing the well-being of the local population due to an increasing of its employment, improvement of living conditions due to care for tourist resources and social infrastructure, improvement of social protection by increasing the budgetary self-sufficiency of the region.

However, there are also negative consequences of tourism development, in particular:

– structural change in the traditional economic system (complete cessation or transfer to other areas of entire sectors of the national economy;
– direct change in the economic conditions of the local population (change in the capacity of the local consumer market and the level of income of the population under the influence of the factor of tourist seasonality);

– formation of a weak economic system in the future (the territory cannot offer to the market anything other than its own tourism product).

Overcoming the aforementioned negative and increasing positive consequences of tourism development within a tourist territory can be provided by a tourism management system, which is a certain structure of interactions between all stakeholders, which may include various institutional elements (Andrash, 2012; Tkachenko, 2009). It serves as the basis for sustainable and long-term development of tourism in the tourist area due to:

– selection of directions for the influence of tourism on the natural, cultural and social spheres;

– ensuring equal distribution of expenses and incomes, creation of jobs directly in the local tourism sector and related sectors of the economy;

– stimulation of increasing the efficiency of accommodation facilities functioning, catering establishments, transport, excursion facilities;

– ensuring investment in the regional economy and its diversification;

– stimulation of the basic infrastructure of the territory modernization;

– assistance in the creation of recreational facilities, search for new sources of funding for the preservation of excursion facilities;

– formation of national identity among the local population and ensuring deeper mutual understanding;

– assistance in supporting the tourist area at the domestic and international levels.

Results

To clarify the concept of "tourist territory", we have identified a number of relevant functions performed by the territories (Fig. 1), and also presented its classification (Fig. 2).

Fig. 1: Functions of the tourist area

Source: compiled by the authors.

Number of tourist arrivals and inhabitants of the territory	• the largest; • large; • medium; • small.
Significance of the territory in the field of tourism	• world significance; • national significance; • regional significance; • local significance.
Dynamics of tourist profit on the territory	• seasonal; • year-round.
The state of development of the territory	• highly developed; • sufficiently developed; • has potential for development.
Tourist resources available on the territory	• suitable for mass recreation; • suitable for holidays and vacations; • limited.

Fig. 2: Varieties of tourist areas

Source: compiled by the authors.

Consider the functions of the department of tourism and resorts development in Dnepropetrovsk region (Fig. 3).

Department of Tourism and Resorts Development in the Dnipropetrovsk Region

Environment, natural and cultural heritage (promoting the rational use of natural resources, financing protection measures and restoration works, maintaining a register of tourist resources in the Dnipropetrovsk region.

Infrastructure (regulation of the placement of facilities, planning of infrastructure development, investment).

Population (stimulating the population for recreation in the Dnipropetrovsk region, promoting the creation of jobs in the field of tourism, standardization and certification of the tourism activities).

Educational institutions (assistance in ensuring continuous training of personnel for the tourism sector, assistance in organizing advanced training courses for staff in the tourism sector).

Tourism enterprises (licensing, standardization, certification of enterprises, promotion of achievements in the field of tourism, support of priority areas of tourism activities, collection of indicators of enterprise performance, their calculation and forecasting).

Other subjects involved in the tourism sector

Population (stimulating the population for recreation in the Dnipropetrovsk region – advertising, information support).

Tour operators, non-governmental organizations in the tourism sector (participation and organization of their own exhibitions, forums and conferences on tourism topics, organization of advertising tours for representatives of organizations.

European countries

Population (stimulating the population for recreation in the Dnipropetrovsk region - advertising, information propaganda, reporting tourists).

Tour operators, non-governmental organizations in the tourism sector (participation in international exhibitions, forums, conferences on tourism topics, organizing promotional tours, monitoring new trends in tourism, monitoring the international competitiveness of regional tourism products, creating representative offices and branches abroad).

Fig. 3: Functions of the Department of Tourism and Resorts Development in Dnipropetrovsk Region

Source: compiled by the authors.

Groups of factors: external (exogenous);
internal (endogenous).

Possible impact – positive / negative.
The kinde of the impact – extensive / intense.

Types of factors: natural and climatic, cultural and historical, financial, social, political and legal, scientific and technical, logistical, personnel, information, market, management, time factor.

Fig. 4: Factors, which influence on the development of tourism and resorts in the tourist area

Source: compiled by the authors.

The authorities of the Dnipropetrovsk region for the development of tourism and resorts should be provided with reliable information about the territory and the external environment in various aspects in order to support the adoption of correct decisions on organizing the tourism sector as an effective sector of the economy, which allows the rational use of the natural and cultural heritage of the region, increase employment and income of the population, to provide an inflow of investments (Muzichenko-Kozlovs'ka, 2012).

An effective tourism and resorts management system will contribute to the elimination or reduction of the constraining influence on it, both external and internal factors (Fig. 4), strengthening their positive influence in key areas (Fig. 5).

Trends of tourism	Directions of activity within the tourism management system
Preservation and reproduction of tourist resources	Suporting of tourist resources of the territory in proper condition for further reproduction, environmental protection
Planning the allowable environmental burden from tourism development	Analysis and assessment of all components of the environment to determine the requirements for tourist infrastructure of the territory
Interaction with the population	Involvement of the local population in the process of tourism planning with the aim of to develop the most profitable directions for the population
Creation and promotion of a quality tourist product	Ensuring the appropriate ratio of price and quality of the tourist product of the territory, attracting tourists to the territory while preserving the conditions of the environment
Obtaining economic and social benefits from tourism development	Increasing the value of financial and social capital per capita

Fig. 5: Directions of achieving the development of tourism and resorts in Dnepropetrovsk
Source: compiled by the authors.

The interaction of business and the government is the key to economic development, especially when it comes to cooperation with local authorities, which is well aware of the problems and economic interests of entities operating on its territory (Andrash, 2012). This thesis is fully and completely confirmed by many examples of successful interaction of the tourism business with government authorities.

The authors of the article analyzed the total tourism potential of the Dnipropetrovsk region (table 1).

Table 1: Quantitative assessment of the total tourism potential of the Dnipropetrovsk region

№	Components of subpotential	Quantitative and qualitative indicators of objects
Historical and cultural potential		
1.	Monuments of history, culture and architecture of regional and local significance	over 750
2.	Historically populated places of national and local significance	8
3.	Theaters / museums	13 / over 100
4.	Folk crafts and handicrafts	over 100
Tourist resource potential		
1.	Lakes and ponds	approximately 200
2.	Rivers and streams	over 1000
3.	Natural heritage monuments (reserves / nature parks)	approximately 200
4.	Deposits of natural mineral waters / therapeutic muds	15/4
The potential needs of tourists		

1.	Accommodation (number of rooms)	over 10000
2.	Organizations of sanatorium profile	approximately 30
3.	Transport infrastructure, including: international airport railway stations in Dnipro bus station in Dnipro	 1 2 1
4.	Travel companies (per 100 thousand population)	over 8
5.	Catering companies	approximately 2000
	Economic potential	
1.	Place by volume of output and small business development	in 5 regions
2.	Density in the formation of the total gross product of Ukraine	over 25%
3.	Number of partner countries	over 100
	Ecological potential	
1.	Place among the regions of Ukraine by the level of environmental impact / (by the activity of environmental protection)	high and exceeds the average in Ukraine almost in 1.5 times

Source. Compiled by the authors from [10].

As a result of the performed analysis, it was concluded that certain components of the aggregate tourism potential of the Dnipropetrovsk region (management and informational potential in the field of tourism) are weak, which is shown in the following aspects:

– lack of a system for monitoring the state of tourist resources;
– lack of information database about objects of tourism infrastructure (accommodation, tourists' leisure, meals);
– lack of a clear marketing strategy for promoting the region's tourism product on the international and Ukrainian markets;
– lack of a tourist image of a significant tourist territory by Ukrainian standards;
– lack of a clear system of tourism planning, which allows to ensure a long-term perspective in the direction of tourism development;
– non-participation in the management of tourism activities of tourism organizers in the region,
– lack of due attention to cooperation with specialized higher educational institutions of the region;
– irregularity of activities aimed at the development of tourism;
– uncertainty about the role and place of tourism in the economic system of the region, as well as from the possible benefits from its development.

Proposals for the application of an integrated approach to tourism management of tourist territories in the Dnipropetrovsk region provide for decision-making in the main directions.

1. Creation and implementation in the future of a tourism development program for tourist areas, which will allow:
– to create conditions for the effective development of tourism in the region;
– to form a competitive regional tourism product;
– to develop a system for promoting the region's tourism resources in the Ukrainian and international tourism markets;
– to form a modern regulatory and legal regional base for tourism;
– to develop measures of supporting small and medium-sized businesses in the field of tourism;
– to ensure the development of tourism infrastructure, as well as support for new tourism resources.

The structure of the program should include the following sections: content of problems and justification of the need to solve them by program methods, aim and objectives, system of program activities, timing and stages of implementation, implementation mechanism, resource provision, organization of management and control over the progress of implementation, assessment of efficiency.

2. Creation of a territorial organization for the development of tourism with a certain structure, which will consist of various units and which should eventually become the main authority of tourism management in the Dnipropetrovsk region (Fig. 6).

The structure of the territorial organization for the development of tourism will be composed of various units with a certain set of functions:

– expert and analytical center of tourism: identification and study of changes and trends in the structure and processes of the external and internal tourist environment, research of topical problems of tourism in the territories, analysis of factors that contribute or hinder the achievement of goals set for the territorial organization for the development of tourism;

– scientific and methodological center of tourism development: development of tourism scientific foundations in tourist areas and generalization of the existing experience of its development; search and formation of mechanisms for solving tourist problems;

– marketing center: promotion of the regional tourism product, management of the region's tourism brand;

– information and logistics center: dissemination of tourist news, creation and support of a data bank on tourism, distribution of tourist flows for the most efficient use of tourist facilities, consultative and reference work with tourists and the local population;

– support center for small and medium-sized businesses in tourism: providing support for the most promising types of tourism and local manufacturers of tourism goods, works and services;

– coordination council for tourism development.

Fig. 6: The structure of the territorial organization for tourism development

Source: compiled by the authors.

Representatives of tour operators for inbound and domestic tourism, specialists in tourism development, scientists from specialized universities, representatives of tourism industry enterprises can and should enter into various structural divisions of the territorial organization for tourism development.

A self-regulatory organization can become a form of their interaction within a territorial organization for the development of tourism.

3. Creation of a unified information and tourist portal of the Dnipropetrovsk region on the Internet, which should contain the following sections:

– information about available tourist resources with their detailed descriptions and characteristics, as well as indication of locations, obtained through monitoring of tourist resources in real time;

– detailed information about accommodation facilities, transport infrastructure, catering establishments;

– a program of tourism development in the Dnipropetrovsk region, which highlighting the key activities, terms and status of implementation;

– information about the territorial organization of tourism development, its structure and main areas of activity;

– a list of the most interesting excursion routes to the settlements of the Dnipropetrovsk region with a detailed description;

– a detailed description of the proposed regional tourism product with its particular features and unique characteristics.

The creation of the portal will increase the popularity of the region in the tourism market, attract new tourists, strengthen the information potential, and at the same time provide the tourism management system with the necessary information. In the future, the sections of the portal can be modified and supplemented depending on the needs of tourists and the territorial organization for the development of tourism.

Evaluation of the effectiveness of each of the directions for improving the tourism management system of tourist areas can be carried out according to a number of indicators. The most difficult is to analyze the possible effects of the development and implementation of an information and tourist portal at the Dnipropetrovsk region (table 2).

Table 2: Criteria for assessing the effectiveness of recommendations for improving the tourism management system of tourist territories in the Dnipropetrovsk region

Direction of improvement of the tourism management system	The name of the performance evaluation criterion
Development and implementation of information and tourist portal of Dnipropetrovsk region at the Internet	The total number of visitors and the number of repeated visits to the portal over a period of time
	Increase the flow of tourists
	Increasing the popularity of Dnipropetrovsk region as a tourist area
	Strengthening the competitiveness of the tourist product of the region
	Development of interest in travel around the area among locals
Implementation of the program of tourism and resorts development	Increase in tax revenues
	Investment income growth
	Reduction of resource costs
	Achieving performance indicators within the program
Creation and functioning of the territorial organization of tourism development	Increasing the degree of satisfaction of the needs of tourists
	Increasing the volume of provided tourist services
	Increasing the profitability of tourism enterprises
	Increasing the equability of tourist infrastructure using

Source: compiled by the authors.

Note the possible indicators of the effectiveness of the portal functioning, namely:

– the total number of portal visitors and the number of repeat visits within a certain period of time;
– increasing the flow of tourists through the portal;
– increasing the popularity of the Dnipropetrovsk region as a tourist territory;
– improving the competitiveness of the region's tourism product;
– development of interest in travel by the region among local residents.

Moreover, the information of the portal should help in the work of various divisions of the territorial organization for the development of tourism due to constantly updated information and be updated with news on the development and state of tourism resources and the tourism market.

Initial (design and software development, purchase of the necessary equipment, etc.) and operational (equipment modernization, Internet connection, financial support, etc.) costs of suporting the portal functioning should be included in a long-term tourism development program in the direction of the center of marketing activities of the territorial development of tourism organization or the center of information and logistics.

The interaction between business and government is the key of the economy development, especially when it means cooperation with local authorities, which is well aware of the problems and economic interests of entities operating on its territory. This thesis is fully and completely confirmed by many examples of successful interaction of the

tourism business with government authorities [9]. Analysis and generalization of this experience allowed the authors of the article to formulate a model of such interaction.

According to this model, at the previous stage of planning, a factorological model is formed that reflects the priority directions of development of the tourism business at the moment. Then, taking into account the approximate indexes for the planned capital investments in the industry, accumulated from various sources, their optimal distribution is carried out. As a result of this task, the optimal structure of investments is determined, ensuring the maximum growth of the tourism potential of the region.

At the next stage, specific investment projects are considered within the framework of capital investments allocated in the areas of tourism development. And here an important role belongs to the system of indicators of the effectiveness of these projects: on its basis, targeted allocation of funds from the regional budget is carried out, the return of these funds and the amount of income that should come to the budget as a result of the project are estimated.

Such indicators, which perform such functions in the best possible way according to the authors, include:

– the volume of services provided by the subjects of the tourism market, expressed in monetary units (as the multiplication of the size of the tourist flow and the average amount spent by one tourist);
– the income of the local (regional) budget from the tourism industry (expressed in monetary units);
– the profitability of the tourism sector (the ratio of budget revenues to expenditures, %).

The range of indicators proposed by the authors is formed as a result of analysis and aggregation of project data and is used in the process of their selection and formation of investment projects portfolio.

The formation of the project-investment portfolio is an iterative procedure due to the fact that:
– a shortage of funds is possible;
– insufficiently developed infrastructure for project implementation;
– individual projects are complex in formation and cover several areas of tourism development, requires a combination of the planned structure of financial resources.

In this case, the authorities at the regional level take a set of decisions to eliminate the problem:
– change in funding by fundraising from both internal and external sources, including by appealing to the highest echelons of power;
– solving infrastructure problems and developing industries related to the tourism business.

As the deficit of budgetary resources is a typical situation, in the process of solving these problems the main burden lays on the interaction with the business sector. This interaction is iterative-negotiable and is built on a mutually beneficial basis: entrepreneurs involved in the development of tourism are provided with various benefits (tax holidays, deferred payment of loans, favorable orders, preferences for the distribution of land and other scarce resources, etc.). And the problems that have arisen are solved by the regional authorities, as a result of which the tourist potential of the region increases as a basis for future revenues [On approval of the State Strategy of Regional Development 2020 from, 2014).

The modern methodical base of substantiation of any standard decisions provides use of economic and mathematical methods. Thus, the problem of choosing investment projects can be solved on the basis of the well-known classical problem of discrete optimal programming on the criterion of regional budget revenues maximizing and by limiting the amount of investment allocated to each of the areas of tourism development.

At the same time, the task is formulated in a variant setting, depending on the results of interaction between the authorities and other participants in this process, and restrictions on investments change depending on the volume of additionally attracted financial resources.

The authors of the article also formalized the task of assessing the distribution of capital investments in the main directions of tourism development. The corresponding optimization model has the following form:

$$\begin{cases} \sum_{i=1}^{n} a_i x_i \leq I^r + I^b + I^g \\ x_i \geq 0, \\ \sum_{i=1}^{n} c_i x_i \to max \end{cases},$$

where x_i (16 variables) – the intensity of the i-th factor (direction) use of tourism: 1) saturation with monuments; 2) the frequency of traditional mass events; 3) the degree of popularity of the monuments; 4) the level of development of transport infrastructure; 5) the degree of orderliness of the municipal infrastructure; 6) the level of development of the entertainment sector; 7) the level of development of the sports sector; 8) the level of development of the public catering network; 9) security level; 10) the level of development of the trading sector; 11) the level of development of the banking sector; 12) the level of development of the hotel fund; 13) the level of socio-economic development of the territory; 14) geographical location; 15) the level of development of health care and resort business; 16) the level of communication development;

a_i – specific capital intensity of the i-th factor;

I^r, I^b, I^g – capital investments allocated at the previous stage of planning by regional authorities, business, government target programs;

c_i – significance of the i-th factor according to the model;

$\sum_{i=1}^{n} c_i x_i$ – target function of tourist potential maximization.

According to the target function, investments will be distributed in the most attractive directions of tourism development, the structure of supply and demand for tourism services will become more balanced, which will ensure a more complete satisfaction of the needs for these services and will lead increasing in the tourism potential of the region.

Within the framework of this aspect of the work, two series of calculations were carried out, tested on the example of the Dnipropetrovsk region:

– the optimal structure of financing for the tourism industry has been established in accordance with the task that was determined at the previous planning stage;

– an assessment of the effectiveness of potential investment projects for the tourism development in the territory of the Dnipropetrovsk region was carried out.

Estimated calculations to determine the optimal structure of financing the tourism industry are based on the above scheme. Its practical implementation presupposes the need for output data: specific capital-intensive of i-th factor – a_i; the volume of capital investments allocated at the previous planning stage – I; c_i – the significance of the i-th factor in accordance with the existing model.

At the same time, if the volume of investments is set based on specific conditions (consolidation of various sources of financing for the tourism industry of the region under consideration), and the significance is already set by the model, the specific capital intensity of various factors requires a separate definition.

The system is solved as a classical linear programming problem after substitution of the calculated values of capital intensity and other initial data into the scheme. The simplex method was used in this work, and the choice of this method was determined by its high efficiency precisely for performing the tasks of finding the extremum of a linear functional in a multidimensional space under given constraints. Since in our case the task contains of 16 variables, it was possible to perform it using standard Excel tools without using more complex software packages.

According to the results of calculations on the distribution of capital investments, the areas can be divided into three groups:

1) with intensive financing;
2) with reduced funding;
3) while supporting the level of funding.

In particular, it is necessary to make larger investments in such areas as landscaping, preservation of monuments, providing comfortable access to them. Considerable attention should also be paid to the entertainment and sports sectors, ensuring the transport accessibility of monuments.

These areas are very important not only for the tourism industry, but also for the development of the territory as a whole. The thesis that the tourism industry can be organically integrated into the economy of the Dnipropetrovsk region and is an indicator of the potential of its attractiveness as a comfortable place to live is confirmed.

Other areas are planned to be financed in approximately the same amounts as before. These areas of tourism, such as security, development of banking services, development of the hotel fund, testifies to the sufficient amount of their financing in earlier periods.

As for such areas as holding mass events, development of communication infrastructure, public catering, investments in these spheres are reduced by 45.58 and 12%, respectively. This is due to the fact that today in the Dnepropetrovsk region the communication infrastructure is already formed, and the catering network has a tendency to rapid capital turnover and expansion through domestic resources.

Conclusion

The effect of the implementation of the tourism development program in the Dnipropetrovsk region can be assessed by indicators of the expected and received usefulness of program activities. Performance indicators of the program can be divided into three groups: direct (the result of the program), indirect (the result of the impact of the program on related areas) and general (the sum of performance indicators of the first and second groups) indicators.

Assessment from the effect of the creation and operation of a territorial organization for tourism development can be based on performance indicators (qualitative or quantitative), characterizing the degree of compliance of the desired status of the tourism system with the actual at a particular time. These include the degree of satisfaction of the needs of tourists, the volume of provided tourist services, the amount of income from investments, the profitability of tourist enterprises and the possibility of their development, etc.

The authors calculated the optimal structure of the sphere of tourist services for the Dnipropetrovsk region. The proposed procedures are universal and can be used for any region of Ukraine. Calculations show that all projects pay off, therefore, it is not only a contribution to the development of the tourism business, but also the provision of taxes to the revenue side of the regional budget.

Thus, it is recommended to cooperate with the business community in the implementation of strategically important local government projects. However, this cooperation must go beyond passive subsidies, providing for full participation in tourism activities based on public benefit and pragmatic calculation.

Abstract

In this paper, we consider the following problem - what affects the Nash equilibrium amount of investment in knowledge when one of the complete graph enters another full one. The solution of this problem will allow us to understand exactly how game agents will behave when deciding whether to enter the other net, what conditions and externalities affect it and how the level of future equilibrium amount of investments in knowledge can be predicted.

Keywords: Network Game; Nash Equilibrium; Externality; Productivity.

Introduction

The processes of globalization, post-industrial development and digitalization of the economy make studying of the role of innovative firms in the world economic development extremely significant. In papers [1, 3] mathematical models of the international innovative economy are constructed, on the basis of which the behavior of innovative firms is analyzed. In particular, authors of this article consider an important topic: how do firms realize their investment strategy in the development of knowledge, including outside their own region or country. The behavior of agents is determined by various externalities, which can have a completely different nature. Description of secondary effects is one of the most important directions in network game theory that authors of different articles try to analyze (for example, [8] and [7]).

There is also another aspect of the question: how to structure and organize their behavior in the best way in constantly changing economic and social conditions. In [2], the authors of the article try to take a new look at the system of organizing the actions of agent-innovators. It is important to take into account the impact (externalities) that influence agents by the environment, including other network entities. The article [4] shows the necessity of creation of regional innovative systems based on clusters. From this follows the relevance of the model description of the process of creating more extensive innovative clusters based on existing ones.

In addition, there is a need to model the process of changing the Nash equilibrium investment values, as well as the search for new internal or angular ones.

This article continues the study of Nash equilibria and its changes in the process of unification complete graphs. However, this paper contains a number of new elements in comparison with previous studies.

To begin with, we study dynamic behavior of agents, not only by generalizing the simple two-period model of endogenous growth of Romer with the production and externalities of knowledge (as in paper [10]), but also by using difference equations, which makes possible not to limit research to two time periods.

Secondly, our article describes all possible and impossible equilibria after the unification of two complete graphs. This simulation allows us to create a base, which has the potential for its complication and improvement in order to increase the applied nature of the model, for mathematical description of the game behavior of agents.

Thirdly, we show that at different levels of productivity and sizes of the united networks, the equilibrium investment values also change.

Fourthly, our article considers both internal equilibria and corner ones, which in studies, for the most part, were ignored by researchers.

In this article, we consider the case of unification two complete graphs with a single connection agent, which tends to another network for a number of different reasons: increasing the receiving externalities, the level of productivity, etc.

The main content of the article is focused on the analysis of changes in the Nash equilibrium investment values, as well as the description of angular solutions. We study necessary and sufficient conditions, and possible limitations for the appearance of new different equilibria.

The content of the article is as follows. Section 2 describes a two-period growth model, characterize new internal Nash equilibrium investments, and analyzes the behavior of network agents. Section 3 describes the following situation. There are two clicks with n_1 and n_2 edges respectively, with the same agents' productivity A and exists the agent of the first network, which connected to the all agents of the second network. Both the clicks are initially in inner equilibrium. Section 3 compares the inner equilibria in united networks with initial inner equilibria in both networks. Section 4 analyzes all possible and impossible equilibria in united network with the formulation of the conditions for their existence or absence. Section 5 defines adjusting dynamics in networks and dynamic stability of equilibria. Section 6 analyzes dynamic stability or instability of all possible equilibria in united network with the formulation of the conditions for their stability or instability. The section 7 describes the network dynamics model of net unification and the section 8 graphically depicts the results. Section 9 summarizes, and lists possible directions for future researches.

Two-Period Model

Model Description

There is a network (undirected graph) with *n* nodes, $i = 1, 2, \ldots, n$; each node represents an agent. In period 1 each agent *i* possesses initial endowment of good, *e,* and uses it partially for consumption in first period of life, c_1^i, and partially for investment into knowledge, k_i:

$$c_1^i + k_i = e, \;\; i = 1, 2, \ldots, n.$$

Investment immediately transforms one-to-one into knowledge which is used in production of good for consumption in second period, c_2^i.

Preferences of agent *i* are described by quadratic utility function:

$$U_i\left(c_1^i, c_2^i\right) = c_1^i\left(e - ac_1^i\right) + b_i c_2^i,$$

where $b_i > 0$; *a* is a satiation coefficient, b_i is a parameter, characterized the value of comfort and health in the second period of life compared to consumption in the first period . It is assumed that $c_1^i \in [0, e]$, the utility

increases in c_1^i, and is concave (the marginal utility decreases) with respect to c_1^i. These assumptions are equivalent to condition $0 < a < 1/2$.

Production in node *i* is described by production function:

$$F(k_i, K_i) = B_i k_i K_i, \;\; B_i > 0$$

which depends on the state of knowledge in *i*-th node, k_i, and on *environment*, K_i, B_i is a technological coefficient. The environment is the sum of investments by the agent himself and her neighbors:

$$K_i = k_i + \tilde{K}_i, \; \tilde{K}_i = \sum_{j \in N(i)} k_j,$$

where $N(i)$ – is the set of neighboring nodes of node *i*.

We will denote the product $b_i B_i$ by A_i and assume that $a < A_i$. Since increase of any of parameters b_i, B_i promotes increase of the second period consumption, we will call A_i "productivity". We will assume that $A_i \neq 2a, i = 1, 2, ..., n.$ If $A_i > 2a$, we will say that i-th agent is *productive*, and if $A_i < 2a$, we will say that i-th agent is *unproductive*.

Three ways of behavior are possible: agent i is called *passive* if she makes zero investment, $k_i = 0$ (i.e. consumes the whole endowment in period 1); *active* if $0 < k_i < e$; *hyperactive* if she makes maximally possible investment *e* (i.e. consumes nothing in period 1).

Let us consider the following game. Players are the agents $i = 1, 2, \ldots, n$. Possible actions (strategies) of player *i* are values of investment k_i from the segment $[0, e]$. *Nash equilibrium with externalities* (for shortness, *equilibrium*) is a profile of knowledge levels (investments) $\left(k_1^*, k_2^*, \ldots, k_n^*\right)$, such that each k_i^* is a solution of the following problem $P(K_i)$ of maximization of *i*-th player's utility given environment K_i:

$$U_i\left(c_1^i, c_2^i\right) \xrightarrow[c_1^i, c_2^i, k_i]{} \max$$

$$\begin{cases} c_1^i \le e - k_i, \\ c_2^i \le F(k_i, K_i), \\ c_1^i \ge 0, c_2^i \ge 0, k_i \ge 0, \end{cases}$$

where the environment K_i is defined by the profile $\left(k_1^*, k_2^*, \ldots, k_n^*\right)$:

$$K_i = k_i^* + \sum_{j \in N(i)} k_j^*$$

The first two constraints of problem $P(K_i)$ in the optimum point are evidently satisfied as equalities. Substituting into the objective function, we obtain a new function (*payoff function*):

$$V_i(k_i, K_i) = U_i\left(e - k_i, F_i(k_i, K_i)\right) = (e - k_i)\left(e - a(e - K_i)\right) + A_i k_i K_i =$$

$$= e^2(1 - a) - k_i e(1 - 2a) - a k_i^2 + A_i k_i K_i. \qquad (1.1)$$

If all players' solutions are internal $(0 < k_i^* < e, \; i = 1,2,...,n)$, i.e. all players are active, the equilibrium will be referred as *inner* equilibrium. Clearly, the inner equilibrium (if it exists for given values of parameters) is defined by the system

$$D_1 V_i(k_i, K_i) = 0, \; i = 1, 2, \ldots, n, \qquad (1.2)$$

or

$$D_1 V_i(k_i, K_i) = e(2a - 1) - 2a k_i + b_i K_i, \; i = 1, 2, \ldots, n. \qquad (1.3)$$

Let us introduce the following notations: $\tilde{A}$ - diagonal matrix, which has numbers A_1, A_2, …, A_n on the main diagonal, I – unit $n \times n$ matrix, M – network adjacency matrix. In this matrix $M_{ij} = M_{ji} = 1$, if there is the edge of the matrix, connecting vertexes i and j, and $M_{ij} = M_{ji} = 0$ – otherwise. It is believed, that $M_{ii} = 0$ for all $i = 1, 2, \ldots, n$. The system of equations (1.3) takes the form:

$$\left(\tilde{A} - 2aI\right)k + \tilde{A}M\,k = \overline{e}\,, \tag{1.4}$$

where $k = \left(k_1, k_2, \ldots, k_n\right)^T$, $\overline{e} = \left(e\left(1-2a\right), e\left(1-2a\right), \ldots, e\left(1-2a\right)\right)^T$.

Theorem 1.1. ([12], Theorem 1.1). The system of equations (1.4) for a complete network has only decision.

In this way, the system of equation (1.4) for a complete network has only decision k^s, components of which we will call stationary investment values, for the internal equilibrium - $k_i^* = k_i^s$, $k_i^* = k_i^s$, $i = 1, 2, \ldots, n$.

Characteristic behavior of agent

We introduce the following notation. Regardless of agent type of behavior the equation root

$$D_1 V_i\left(k_i, K_i\right) = \left(A_i - 2a\right)k_i + A_i\tilde{K}_i - e\left(1-2a\right) = 0$$

will be denoted by $\tilde{k}_i^s$. Thus,

$$\tilde{k}_i^s = \frac{e(2a-1) + A_i\tilde{K}_i}{2a - A_i}\,,$$

where $\tilde{K}_i$ – pure externality of agent i. It is obvious, that if agent i is active, then his investments will be equal to $\tilde{k}_i^s$ in equilibrium. To analyze equilibriums we need the following statement

Statement 2.1. ([12], Lemma 2.1 and Corollary 2.1) A set of investment agent values $\left(k_1, k_2, \ldots, k_n\right)$ can be an equilibrium only if for each $i = 1, 2, \ldots, n$ it is true that

1. if $k_i = 0$, then $\tilde{K}_i \le \dfrac{e\left(1-2a\right)}{A_i}$;
2. if $0 < k_i < e$, then $k_i = \tilde{k}_i^S$;
3. if $k_i = e$, then $\tilde{K}_i \ge \dfrac{e\left(1-A_i\right)}{A_i}$.

Lemma 2.1. ([12], Lemma 2.2) In equilibrium, the agent i is passive if and only if

$$K_i \le \frac{e\left(1-2a\right)}{A_i}\,; \tag{2.1}$$

the agent i is active if and only if

$$\frac{e\left(1-2a\right)}{A_i} < K_i < \frac{e}{A_i}\,; \tag{2.2}$$

the agent i is hyperactive if and only if

$$K_i \ge \frac{e}{A_i}\,. \tag{2.3}$$

In complete network there is the same environment for all agents, so we get the following consequence.

Corollary 2.1. *In equilibrium in a complete network, agents with the same productivity make the same investments. If all agents in the full network have the same productivity, then there is homophilia, that is, all agents behave identically.*

Remark 2.1. In a complete network, there cannot be situations when in equilibrium an agent with a high production value is active or passive, and an agent with a lower productivity is hyperactive, or when an agent with a higher production value is passive, and an agent with a lower productivity is active or hyperactive.

Speaking of a complete network, we will omit the index in the designation of the agent environment, since in a complete network the environment for all agents is the same. Thus, K is denoted the amount of investment of all agents of the complete network.

Corollary 2.2. ([12], Corollary 2.3) *The equilibrium, in which all agents are passive, is possible in a complete network if and only if*

$$K \le \frac{e(1-2a)}{\max\limits_i A_i} .$$

The equilibrium, in which all agents are active, is possible in a complete network if and only if

$$\frac{e(1-2a)}{\min\limits_i A_i} < K < \frac{e}{\max\limits_i A_i} .$$

The equilibrium, in which all agents are hyperactive, is possible in a complete network if and only if

$$K \ge \frac{e}{\min\limits_i A_i} .$$

Corollary 2.3. *Equilibrium, in which all agents are hyperactive, is possible in a complete network, if and only if*

$$\min_i A_i \ge \frac{1}{n} .$$

Equilibrium, in which all agents are passive, is always possible.

Unification of innovative nets

Let us consider the following situation. There are two clicks with n_1 and n_2 edges respectively, with the same agents' productivity: A.

There are three types of agents in the united network. The actors of the first type are all the agents of the first network, besides the agent of the first network, which connected to the agents of the second network. Actors of the second type are all agents of the second network. The third type of actors is only one agent – this is the agent of the first network that connected to all actors of the second network. Since all agents of the same type will have the same environment, they will behave in the same way, not only in equilibrium, but also in dynamics. Therefore, the investment of each agent of the type *i* will be denoted k_i, and the environment of each agent of the type *i* will be denoted K_i.

Both the clicks are initially in inner equilibrium. It follows immediately from (1.3) that the initial investment of agents is the following

$$k_1^0 = k_3^0 = \frac{e(1-2a)}{n_1 A - 2a} , \tag{3.1}$$

$$k_2^0 = \frac{e(1-2a)}{n_2 A - 2a} . \tag{3.2}$$

The system (1.3) for inner equilibrium in joined network is

$$\begin{cases} \left((n_1-1)A-2a\right)k_1+Ak_3=e(1-2a), \\ (n_2A-2a)k_2+Ak_3=e(1-2a), \\ (n_1-1)Ak_1+n_2Ak_2+(A-2a)k_3=e(1-2a). \end{cases}$$

Solving this system by Kramer method we obtain for inner equilibria new equilibrium investment amount:

$$k_1^*=\frac{2ae(1-2a)(n_2A-2a)}{(n_1-1)n_2A^3+2a(n_1-1)n_2A^2+8a^3-4a^2(n_1+n_2)A}, \qquad (3.3)$$

$$k_2^*=\frac{2ae(1-2a)\left[(n_1-1)A-2a\right]}{(n_1-1)n_2A^3+2a(n_1-1)n_2A^2+8a^3-4a^2(n_1+n_2)A}, \qquad (3.4)$$

$$k_3^*=\frac{e(1-2a)\left[(n_1-1)n_2A^2-4a^2\right]}{(n_1-1)n_2A^3+2a(n_1-1)n_2A^2+8a^3-4a^2(n_1+n_2)A}. \qquad (3.5)$$

Now we can analyze the difference between initial and final amount of investments. We will start from the first type agents. By directly comparing (3.1) and (3.3), we obtain the following lemma.

Lemma 3.1.

1) If $A<2a\frac{n_1n_2-n_1+1}{(n_1-1)n_2}$, then $k_1^0<k_1^*$.

2) If $A=2a\frac{n_1n_2-n_1+1}{(n_1-1)n_2}$, then $k_1^0=k_1^*$.

3) If $A>2a\frac{n_1n_2-n_1+1}{(n_1-1)n_2}$, then $k_1^0>k_1^*$.

We denote the factor from of Lemma 3.1 $\frac{n_1n_2-n_1+1}{(n_1-1)n_2}$ by *C*.

Remark 3.1. Note that $C=\frac{n_1n_2-n_1+1}{(n_1-1)n_2}=1$ if and only if $n_1=n_2+1$.

Corollary 3.1.

1. If $n_1=n_2+1$, then $C=1$, so

- $k_1^0<k_1^*$ if and only if $A<2a$, i.e. if and only if agents are unproductive;
- $k_1^0=k_1^*$ if and only if $A=2a$, i.e. if and only if there is a boundary case between non-productivity and productivity;
- $k_1^0>k_1^*$ if and only if $A>2a$, i.e. if and only if agents are productive.

2. If $n_1<n_2+1$, then $C>1$, so

- for all non-productivity agents, agents with the boundary value of productivity and a small part of productive agents, namely for the case

$$2a\le A<2a\frac{n_1n_2-n_1+1}{(n_1-1)n_2},$$

  it is true, that $k_1^0<k_1^*$;
- for productive agents, for which

$$A = 2a\frac{n_1 n_2 - n_1 + 1}{(n_1 - 1)n_2},$$

it is true, that $k_1^0 = k_1^*$;

- for all productive agents, for which

$$A > 2a\frac{n_1 n_2 - n_1 + 1}{(n_1 - 1)n_2},$$

it is true, that $k_1^0 > k_1^*$.

3. If $n_1 > n_2 + 1$, then $C < 1$, so

- for all productivity agents, agents with the boundary value of productivity and a small part of non-productive agents, namely for the case

$$2a\frac{n_1 n_2 - n_1 + 1}{(n_1 - 1)n_2} < A \le 2a,$$

it is true, that $k_1^0 > k_1^*$;

- for non-productive agents, for which

$$A = 2a\frac{n_1 n_2 - n_1 + 1}{(n_1 - 1)n_2},$$

it is true, that $k_1^0 = k_1^*$;

- for all non-productive agents, for which

$$A < 2a\frac{n_1 n_2 - n_1 + 1}{(n_1 - 1)n_2},$$

it is true, that $k_1^0 < k_1^*$.

Remark 3.2. Thus, if $C > 1$, then part of the productive agents (and the more *C*, the greater part) behaves as well as the unproductive agents, i.e. for them $k_1^0 < k_1^*$.

If $C < 1$, then a part of unproductive agents (and the less *C*, the greater part) behaves similarly to productive agents, i.e. for them $k_1^0 > k_1^*$.

Let us now consider the second type agents

Lemma 3.2.

1) If $A < \frac{2a}{\sqrt{(n_1 - 1)n_2}}$, then $k_2^0 < k_2^*$.

2) If $A = \frac{2a}{\sqrt{(n_1 - 1)n_2}}$, then $k_2^0 = k_2^*$.

3) If $A > \frac{2a}{\sqrt{(n_1 - 1)n_2}}$, then $k_2^0 > k_2^*$.

Remark 3.3. If $n_1 = n_2 + 1$, then $\sqrt{(n_1 - 1)n_2} = n_2$.

Corollary 3.2.

1) for all productivity agents, agents with the boundary value of productivity and a part of non-productive agents, namely for the case

$$\frac{2a}{\sqrt{(n_1 - 1)n_2}} < A \le 2a,$$

it is true, that $k_2^0 > k_2^*$;

2) for all non-productive agents, for which

$$A = \frac{2a}{\sqrt{(n_1 - 1) n_2}},$$

it is true, that $k_2^0 = k_2^*$;

3) for all non-productive agents, for which

$$A < \frac{2a}{\sqrt{(n_1 - 1) n_2}},$$

it is true, that $k_2^0 < k_2^*$.

Finally, consider an agent of the third type.

Lemma 3.3.

1) If $A = \frac{2a}{n_1 - 1}$ (i.e. if $n_1 = 2$, $A = 2a$), then $k_3^0 = k_3^*$.

2) If $A \neq \frac{2a}{n_1 - 1}$, then $k_3^0 < k_3^*$.

To sum up, we can make several conclusions.

Firstly, agents with very high and very low efficiency will increase and decrease the amount of investments respectively after the unification.

Furthermore, it is very important for the first net how large or small network will connect it.

Finally, the actor, which wants to join another net, should be prepared for increasing its investment expenditures for knowledge because of different externalities.

Adjusting dynamics in networks and dynamic stability of equilibria

After the description of two-stage model equilibria, we can go to adjusting dynamics. We introduce adjustment dynamics which may start after a small deviation from equilibrium or after junction of networks each of which was initially in equilibrium. We model the adjustment dynamics in the following way.

Definition 4.1. Each agent maximizes her utility by choosing a level of investment; at the moment of decision-making she considers her environment as exogenously given. Correspondingly, if $k_i^n = 0$ and $D_1 V_i(k_i, K_i)\big|_{k_i=0} \leq 0$, then $k_i^{n+1} = 0$, and if $k_i^n = e$ and $D_1 V_i(k_i, K_i)\big|_{k_i=e} \geq 0$, then $k_i^{n+1} = e$; in all other cases, k_i^{n+1} solves the difference equation:

$$-2ak_i^{n+1} + b_i K_i^n - e(1 - 2a) = 0.$$

Definition 5.1 implies that the dynamics in model under consideration is described by the system of differential equations:

$$\begin{cases} k_1^{p+1} = \frac{(n_1 - 1)A}{2a} k_1^p + \frac{A}{2a} k_3^p + \frac{e(2a-1)}{2a}, \\ k_2^{p+1} = \frac{n_2 A}{2a} k_2^p + \frac{A}{2a} k_3^p + \frac{e(2a-1)}{2a}, \\ k_3^{p+1} = \frac{(n_1 - 1)A}{2a} k_1^p + \frac{n_2 A}{2a} k_2^p + \frac{A}{2a} k_3^p + \frac{e(2a-1)}{2a}. \end{cases} \quad \text{where } p = 0, 1, 2\ldots \qquad (5.1)$$

Characteristic equation for this system is

$$\begin{vmatrix} \frac{(n_1-1)A}{2a}-\lambda & 0 & \frac{A}{2a} \\ 0 & \frac{n_2A}{2a}-\lambda & \frac{A}{2a} \\ \frac{(n_1-1)A}{2a} & \frac{n_2A}{2a} & \frac{A}{2a}-\lambda \end{vmatrix} =$$

$$= -\lambda^3 + \lambda^2 \frac{(n_1+n_2)A}{2a} - \lambda \frac{(n_1-1)n_2A^2}{4a^2} - \frac{(n_1-1)n_2A^3}{8a^3} = 0. \qquad (5.2)$$

Definition 4.2. The equilibrium is called *dynamically stable* if, after a small deviation of one of the agents from the equilibrium, dynamics starts which returns the equilibrium back to the initial state. In the opposite case the equilibrium is called *dynamically unstable*.

Lemma 4.1. In any network, a corner equilibrium, in which all the agents are passive, is stable.

Proof. As follows from (1.3), for any agent i the inequality $D_1V_i(k_i, K_i) \le 0$ holds as strict: $D_1V_i(k_i, K_i) = e(2a-1) < 0$. □

Lemma 4.2. In any network, an inner equilibrium is unstable.

Proof. Let the network consist of n nodes, and all agents have the same productivity A. Let M be the $n \times n$-matrix of difference equations system , describing the dynamics in the network. Then the matrix M has the form $M = \frac{A}{2a}(\mathrm{A} + I)$, where A – the adjacent matrix of the network, I – identity $n \times n$-matrix. In this way, the matrix M is symmetric and therefore has orthogonal basis of eigenvectors. Let $v_1, v_2, \ldots, v_n$ be an orthogonal basis, and x be arbitrary real n-dimensional vector. We expand it in terms of the basis:

$$x = \sum_{i=1}^{n} c_i v_i .$$

Then:

$$\frac{x^T M x}{x^T x} = \frac{\sum_{i=1}^{n} c_i v_i^T M \sum_{j=1}^{n} c_j v_j}{\sum_{i=1}^{n} c_i v_i^T \sum_{j=1}^{n} c_j v_j} = \frac{\sum_{i,j=1}^{n} c_i c_j \lambda_j v_i^T v_j}{\sum_{i,j=1}^{n} c_i c_j v_i^T v_j} = \frac{\sum_{j=1}^{n} c_j^2 \lambda_j}{\sum_{j=1}^{n} c_j^2} \le \frac{\sum_{j=1}^{n} c_j^2 \lambda_1}{\sum_{j=1}^{n} c_j^2} = \lambda_1, \qquad (6.1)$$

where λ_1 means the greatest eigenvalue. Choosing as a x vector, all components of which are equal to 1, we get:

$$\lambda_1 \ge \frac{A}{2a} \cdot \frac{2m+n}{n}, \qquad (6.2)$$

where m means the number of edges in network, and n means the number of nodes.

Let h be the number of node, having the greatest degree $d_{\max}$. Consider the vector x, the components of which are given in the following way:

$$x_i = \begin{cases} \sqrt{d_{\max}}, & \text{если} \quad i = h, \\ 1, & \text{если} \quad \mathrm{A}_{ih} = 1, \\ 0, & \text{иначе.} \end{cases}$$

Then

$$\sum_{j=1}^{n} M_{ij} x_j \geq \frac{A}{2a} \left\{ \begin{array}{ll} \sqrt{d_{\max}} + d_{\max}, & \text{если} \quad i = h, \\ \sqrt{d_{\max}} + 1, & \text{если} \quad M_{ih} = 1, \\ 0, & \text{иначе} \end{array} \right\} = \frac{A}{2a} \left(\sqrt{d_{\max}} + 1 \right) x_i . \qquad (6.3)$$

Multiplying both sides of (6.3) by x_i and summing over *i*, we obtain the inequality

$$x^T M x \geq \frac{A}{2a} \left(\sqrt{d_{\max}} + 1 \right) x^T x ,$$

and, applying (6.1), we get

$$\lambda_1 \geq \frac{x^T M x}{x^T x} \geq \frac{A}{2a} \left(\sqrt{d_{\max}} + 1 \right). \qquad (6.4)$$

Similarly to (6.1), we get

$$\frac{x^T M x}{x^T x} = \frac{\sum_{i=1}^{n} c_i v_i^T M \sum_{j=1}^{n} c_j v_j}{\sum_{i=1}^{n} c_i v_i^T \sum_{j=1}^{n} c_j v_j} = \frac{\sum_{i,j=1}^{n} c_i c_j \lambda_j v_i^T v_j}{\sum_{i,j=1}^{n} c_i c_j v_i^T v_j} = \frac{\sum_{j=1}^{n} c_j^2 \lambda_j}{\sum_{j=1}^{n} c_j^2} \geq \frac{\sum_{j=1}^{n} c_j^2 \lambda_n}{\sum_{j=1}^{n} c_j^2} = \lambda_n , \qquad (6.5)$$

where λ_n means the least eigenvalue of matrix *M*. We now consider the vector *x*, which components are given as follows:

$$x_i = \left\{ \begin{array}{ll} -\sqrt{d_{\max}}, & if \quad i = h, \\ -1, & if \quad \mathrm{A}_{ih} = 1, \\ 0, & otherwise. \end{array} \right.$$

Then

$$\sum_{j=1}^{n} M_{ij} x_j \leq \frac{A}{2a} \left\{ \begin{array}{ll} -\sqrt{d_{\max}} - d_{\max}, & if \quad i = h, \\ -\sqrt{d_{\max}} - 1, & if \quad M_{ih} = 1, \\ 0, & otherwise \end{array} \right\} = \frac{A}{2a} \left(-\sqrt{d_{\max}} - 1 \right) x_i . \qquad (6.6)$$

Multiplying both sides of (6.6) by x_i and summing over *i*, we obtain the inequality

$$x^T M x \leq \frac{A}{2a} \left(-\sqrt{d_{\max}} - 1 \right) x^T x ,$$

and, applying (6.5), we get

$$\lambda_n \leq \frac{x^T M x}{x^T x} \leq -\frac{A}{2a} \left(\sqrt{d_{\max}} + 1 \right). \qquad (6.7)$$

So, in the case when all agents have the same productivity and there is at least one edge in the network, the largest eigenvalue of the equation system, describing the dynamics, according to (6.4), is always greater than unity. If the network does not have any edges (all agents are isolated), then an internal equilibrium is possible only if all agents are productive

($A > 2a$), but then according to (6.4) the largest eigenvalue is greater then unit. □

Network dynamics model of net unification

To find the eigenvalues of difference equations (5.1) in general we need to impose the restrictions: $n_2 = n_1 - 1 = n$. Then the equation (5.2) takes the form

$$\begin{vmatrix} \frac{nA}{2a}-\lambda & 0 & \frac{A}{2a} \\ 0 & \frac{nA}{2a}-\lambda & \frac{A}{2a} \\ \frac{nA}{2a} & \frac{nA}{2a} & \frac{A}{2a}-\lambda \end{vmatrix} = \left(\frac{nA}{2a}-\lambda\right)\left(\lambda^2-\lambda\frac{(n+1)A}{2a}-\frac{nA^2}{4a^2}\right)=0,$$

hence

$$\lambda_{1,2}=\frac{(n+1)A}{4a}\pm\sqrt{\frac{(n+1)^2A^2}{16a^2}+\frac{nA^2}{4a^2}}=\frac{A}{4a}\left(n+1\pm\sqrt{n^2+6n+1}\right),$$

$$\lambda_3=\frac{nA}{2a}.$$

In this case inner equilibrium in joined network will be

$$k_1^*=k_2^*=\frac{2ae(1-2a)}{nA^2+2a(n+1)A-4a^2},$$

$$k_3^*=\frac{e(1-2a)(nA+2a)}{nA^2+2a(n+1)A-4a^2}.$$

Let us find the eigenvectors

$$\begin{cases} \left(\frac{nA}{2a}-\lambda\right)x_1+\frac{A}{2a}x_3=0, \\ \left(\frac{nA}{2a}-\lambda\right)x_2+\frac{A}{2a}x_3=0, \\ \frac{nA}{2a}x_1+\frac{nA}{2a}x_2+\left(\frac{A}{2a}-\lambda\right)x_3=0. \end{cases}$$

Thus, if $\lambda\neq\frac{nA}{2a}$, then $x_1=x_2=x$, $x_3=\frac{\left(\lambda-\frac{nA}{2a}\right)x}{\frac{A}{2a}}$, and if $\lambda=\frac{nA}{2a}$, then $x_3=0$, $x_1=-x_2$. Hence we may choose

$$e_1=\begin{pmatrix} 1 \\ 1 \\ \frac{1}{2}\left(1-n-\sqrt{n^2+6n+1}\right) \end{pmatrix}, \text{ corresponding to } \lambda_1=\frac{A}{4a}\left(n+1-\sqrt{n^2+6n+1}\right)$$

(we supposed $x = x_1 = x_2 = 1$, then $x_3 = \dfrac{\dfrac{A}{4a}\left(n+1-\sqrt{n^2+6n+1}\right)-\dfrac{nA}{2a}}{\dfrac{A}{2a}} =$

$= \dfrac{1}{2}\left(n+1-\sqrt{n^2+6n+1}\right)-n = \dfrac{1}{2}\left(1-n-\sqrt{n^2+6n+1}\right)$),

$e_2 = \begin{pmatrix} 1 \\ 1 \\ \dfrac{1}{2}\left(1-n+\sqrt{n^2+6n+1}\right) \end{pmatrix}$, corresponding to $\lambda_2 = \dfrac{A}{4a}\left(n+1+\sqrt{n^2+6n+1}\right)$,

$e_3 = \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}$, corresponding to $\lambda_3 = \dfrac{nA}{2a}$.

Thus, dynamics in joined network is described with following vector equation

$$\begin{pmatrix} k_1^n \\ k_2^n \\ k_3^n \end{pmatrix} = C_1\lambda_1^n e_1 + C_2\lambda_2^n e_2 + C_3\lambda_3^n e_3 + \begin{pmatrix} k_1^* \\ k_2^* \\ k_3^* \end{pmatrix}.$$

The constants C_1, C_2, C_3 can be found from initial conditions. Before unification the both networks were in symmetric inner equilibria:

$$k_1^0 = k_3^0 = \frac{e(1-2a)}{(n+1)A-2a},\ k_2^0 = \frac{e(1-2a)}{nA-2a}.$$

Hence by $n = 0$ we receive the following equations

$$\begin{cases} \dfrac{e(1-2a)}{(n+1)A-2a} = C_1 + C_2 - C_3 + \dfrac{2ae(1-2a)}{nA^2+2a(n+1)-4a^2}, \\ \dfrac{e(1-2a)}{nA-2a} = C_1 + C_2 + C_3 + \dfrac{2ae(1-2a)}{nA^2+2a(n+1)-4a^2}, \\ \dfrac{e(1-2a)}{(n+1)A-2a} = \dfrac{1}{2}\left(1-n-\sqrt{n^2+6n+1}\right)C_1 + \dfrac{1}{2}\left(1-n+\sqrt{n^2+6n+1}\right)C_2 + \\ \qquad + \dfrac{e(1-2a)(nA+2a)}{nA^2+2a(n+1)A-4a^2}. \end{cases} \tag{7.1}$$

We add first two equations of the previous system. We receive the following system of two equations to define C_1 and C_2:

$$\begin{cases} C_1 + C_2 = \dfrac{e(1-2a)\left[(2n+1)A-4a\right]}{2\left[(n+1)A-2a\right](nA-2a)} - \dfrac{2ae(1-2a)}{nA^2+2a(n+1)-4a^2} > 0, \\ \dfrac{1}{2}\left(1-n-\sqrt{n^2+6n+1}\right)C_1 + \dfrac{1}{2}\left(1-n+\sqrt{n^2+6n+1}\right)C_2 = \\ \qquad = \dfrac{e(1-2a)}{(n+1)A-2a} - \dfrac{e(1-2a)(nA+2a)}{nA^2+2a(n+1)A-4a^2} < 0 \end{cases} \tag{7.2}$$

It is easy to check, that the right side of the first equation is positive, and the right side of the second equation is negative. It is clear, that λ_2 is the largest eigenvalue in absolute and it is positive as all the components of eigenvector e_2. Hence, the nature of transitional process will be determined with the sign of constant C_2. Further, the sign of C_2, is defined by sign of the following expression

$$\tilde{\Delta}_2 = 2\left(k_3^0 - k_3^*\right) + \left(\sqrt{n^2+6n+1}+n-1\right)\left(k_1^0 + k_2^0 - k_1^* - k_2^*\right),$$

where k_1^0, k_2^0, k_3^0 – initial investment values.

If $\tilde{\Delta}_2$ is positive, then after transition process the network pass to corner equilibrium, where all the agents are hyperactive ($k_i = e$). If $\tilde{\Delta}_2$ is negative, then after transition process the network pass to corner equilibrium, where all the agents are passive ($k_i = 0$). It is easy to see that in considering case when both networks were in inner equilibria with any parameters if $n > 1$, then $\tilde{\Delta}_2 > 0$ and the network pass to corner equilibrium, where all the agents are hyperactive. If $n = 1$ (dyada connects to single agent), then the nature of network behavior in transitional process depends on ratio of *A* and *a*. Namely, if $\frac{A}{a} \geq \sqrt{96+32\sqrt{2}} - 4$, then the network pass to corner equilibrium, where all the agents are hyperactive. If $\frac{A}{a} < \sqrt{96+32\sqrt{2}} - 4$, then the network pass to corner equilibrium, where all the agents are passive.

So it is obvious (with Kramer formulas), that $C_1 > 0$. Comparing first equation of system (7.1) and first equation of system (7.2) it is obvious that $C_3 > 0$.

Let us check that corner solution, where $k_1 = k_2 = k_3 = e$, is equilibrium:

$$D_1V_1(k_1, K_1)\big|_{k_1=k_2=k_3=e} = -2ae + Ane - e(1-2a) = Ane - e \geq 0, \text{ if } A \geq \frac{1}{n},$$

$$D_1V_2(k_2, K_2)\big|_{k_1=k_2=k_3=e} = -2ae + Ane - e(1-2a) = Ane - e \geq 0, \text{ if } A \geq \frac{1}{n},$$

$$D_1V_3(k_3, K_3)\big|_{k_1=k_2=k_3=e} = -2ae + A2ne - e(1-2a) = 2Ane - e \geq 0, \text{ if } A \geq \frac{1}{2n},$$

corresponding to Corollary 2.4 in [12].

4. Graph visualizing

We can visualize this dynamics with graphs. To begin with, we need to set several restrictions. Firstly, the number of first net agents is one more than the amount of the second cluster actors. Secondly, $A > \frac{1}{n_1}$. Thirdly, initial reserve *e* is equal to 1 for all agents.

We will distinguish agents between their productivity and measure of saturation of initial good consumption.

4.2 First example.

In this case we will consider efficient and low saturated agent. The value of *a* is $\frac{1}{6}$, coefficient A=$\frac{1}{3}$>2a, $n_1 = 4$.

Figure 1: Investment change of efficient and low saturated agents

As Figure 1 provides, in the first period connected agent starts investing all its initial reserve of good in knowledge. It can be explained with large number of links with all other actors. Further, the second type agents start to invest all initial good and, finally, the first net actors become hyperactive.

4.3 Second example.

In this case we will consider efficient and high saturated agent. The value of *a* is $\frac{49}{50}$, coefficient A=2>2a, $n_1 = 4$.

Figure 2: Investment change of efficient and high saturated agents

The conclusions are the same, except the number of time periods that are need for agents to become hyperactivity. It can be explained that increasing utility of initial good consumption decrease the motivation for investment in producing new knowledges.

4.4 Third example.

In this case, we will consider non-efficient and low saturated agent. The value of a is $\frac{}{50}$, coefficient A=$\frac{2}{3}$<2a, $n_1 = 4$.

Figure 3: Investment change of non-efficient and low saturated agents

4.5 Forth example.

In this case we will consider non-efficient and high saturated agent. The value of a is $\frac{49}{50}$, coefficient A=1<2a, $n_1 = 4$.

Figure 4: Investment change of non-efficient and high saturated agents

We can make several conclusions by comparing efficient and non-efficient agents: the increasing speed of investment amount is higher for productive actors than for non-productive ones.

Conclusion

In this paper, we have described the process of change in game equilibrium during graphs unification using two-stage and dynamics models. We have highlighted the significance of the productivity role that influence the agents' behavior. Moreover, we determined the importance of graphs sizes, which also effect on agents' decisions that they take during unification process.

Then we visualize dynamic process using different parameters to depict a change in low-productivity and high-productivity actors. In addition, we have listed all possible and impossible equilibria to identify necessary restrictions for its existing.

We believe that this article offers the base model of game equilibria change that can be improved with increasing the amount of parameters and modification graphs' type to incomplete nets or non-oriented graphs.

Distributed Ledger Technology in Financial Sector – KYC/AML Aspect

Karol STRZALA

Lazarski University, Warsaw, Poland
k.strzala@lazarski.edu.pl

Abstract

New challenge to the AML/CFT and KYC was introduced by the technological developments and the emergence of cryptocurrencies. It became obvious that financial markets must become aware of currency based on distributed ledger technology. One of the key challenges for the financial system in terms of Blockchain technology development are the typical financial procedures related to AML and KYC. The paper aims to present the system of distributed ledger technology, show the impact it might have on the development of the financial system, show the problem of verification of clients that trade cryptocurrencies, and the threats related to money laundering using Blockchain technology. The paper also describes the method to fight money laundering by adopting the 5th AML Directive by the European Union.

Keywords: money laundering, know your customer, cryptocurrencies, blockchain, distributed ledger technology

Introduction

With the technology development, especially Internet banking, digital payments, and the creation of cryptocurrencies, it became clear that Anti-Money Laundering (AML) regulations have been lagging behind the technology development and the flow of money in the digital world. What is more, numerous terrorist attacks in Europe have pointed to the need to combat the financing of terrorism (CFT), which is closely linked to money laundering.

Financial market entities must become aware of Bitcoin and other cryptocurrencies based on Blockchain technology. Their daily market turnover is progressively increasing. At the time of writing the paper, the daily trading volume on the cryptocurrency exchanges amounted to $35,191 billion.[i] The development of Bitcoin gave rise to other cryptocurrencies. This diverse system of virtual assets has led to the emergence of numerous cryptocurrency exchanges and platforms for users to trade cryptocurrencies and exchange them for fiat money.

Distributed ledgers, smart contracts, consensus protocols, and cryptography allow for secure, transparent, and frequently less expensive transactions, which can be made in the financial system (Tschorsch and Scheuermann, 2016). As a result, there is an array of digital platforms and start-ups that implement Blockchain technology in their systems e.g., when it comes to micropayment, data storage, intellectual property, supply chain and logistics, and storage of financial assets (Davidson *et al*, 2018). Aside from i.a. determining the legal nature of cryptocurrencies (Hacker and Thomale, 2017), or security problems (Atzei *et al*, 2017), one of the key challenges for the financial system in terms of Blockchain technology development are the typical financial procedures: Know Your Customer (KYC), which allows for effective verification of identity of a cryptocurrency market participant, and (ii) Anti-Money Laundering, which is a set of procedures combatting money laundering using cryptocurrencies. In the Blockchain system, it is required that some proper access control systems ascertain who is allowed to access data and services. The security requirements change in distributed systems of different organizations that have their own independent access control capabilities (Ao and Minsky, 2003).

The paper aims to present the system of distributed ledger technology, show the impact it might have on the development of the financial system, show the problem of verification of clients that trade cryptocurrencies, and the threats related to money laundering using Blockchain technology. The paper also describes the method to fight money laundering by adopting the 5th AML Directive by the European Union.

Distributed Ledger Technology – Introduction

Distributed ledger technology or Blockchain is directly linked to Bitcoin digital currency. In 2008, an unidentified person, or a group of people named Satoshi Nakamoto came out with the paper "Bitcoin: A Peer-To-Peer (P2P) Electronic Cash System". The paper describes that Bitcoin is a digital currency that allows for the peer-to-peer transaction, without any intermediaries (Nakamoto, 2008). Bitcoin remains a system that processes transactions without a central regulatory institution. That is why it needs to have mechanisms that would prevent data forgery, duplication of payments, and any cyberattacks. In order to achieve this, Bitcoin uses many technologies, such as cryptography, digital signatures, hashing, public key, P2P, and Proof of work (Low and Mik, 2020).

Blockchain can be characterized as a decentralized database to store information. The database is distributed across all the nodes, which makes it a decentralized network. All the nodes adopt a certain set of rules that define what is allowed and not allowed in the network as well as the structure of the information stored. The set of rules determines the goal and Blockchain functionality (Narayanan *et al*, 2016). Blockchain was designed so to keep the entire content it stores unchanged. Any piece of information saved in the Blockchain network can only be changed or deleted with a good deal of work (depending on the size and network integrity) (Bradbury, 2013). Immutability allows to create a ledger, which tracks particular assets. Due to the rules enforced by the network, it is guaranteed that the resources do not come at the request and cannot be duplicated. A distributed ledger allows for the creation and use of cryptocurrencies. Accordingly, Blockchain is often synonymously referred to as distributed ledger technology (DLT) (Walport, 2016).

Blockchain might be used in various ways. There are two groups that can be distinguished – users who supervise the network and the network public. There are three types of directing execution (Kruijff and Weigand, 2017): (i) decentralized, which means that Blockchain is managed by all users, (ii) hybrid, which means that the supervisors are pre-selected, and (iii) centralized, meaning that one entity establishes the rules and supervision over the network. Moreover, Blockchain may be public and private: (i) a public one means that anyone can obtain access to the network and read the information it contains, (ii) a private one implies that there is limited access to the network. Blockchain technology makes it possible to carry out transactions between clients without their having bank accounts. It is enough for people to have their own wallets.

How blockchain can change the financial system

The financial system relies on a network of interlinked financial institutions, markets, and other financial system elements. The current infrastructure comprises a large number of intermediaries who are in charge of registering and settlement of payments. The transactions are settled by the entities that are able to identify the owner of the assets and all the parties of the transaction at any given moment. Intermediaries fulfill their functions which all together facilitate concluding contracts and making transactions in a low trust environment. Intermediaries play a key role in the functioning of the financial system. They are nearly everywhere and are guarantors of trust. Banks, investment funds, insurance companies, pension funds are intermediaries, too, and the majority gets profits from the money they charge for each transaction. The model of incomes based on charges is typically slow and expensive for consumers (Sangwan *et al*, 2020), and contributes to the exclusion from primary access to financial service. Furthermore, a centralized system, which is the one with the intermediaries, is prone to crashes and attacks (Hua *et al*, 2018). According to the 2020 PwC company's research 47% of organizations that participated in the research, suffered some form of economic crime within the last 24 months.[ii] Most crimes were related to misappropriation of property, cybercrime, corruption, accounting fraud, and money laundering. Despite the flaws, right from the start, the financial system was based on centralization and financial intermediaries.

The invention and further development of blockchain and its technology initiated a transformation in the way the financial system works and will develop in the future. Blockchain technology provides a new kind of storage, use, control, and transfer of value in the financial system. The system changes the perception and functioning of the financial system as a whole. No individual and no organization manages the network and is responsible for its operation and crashes (Walch, 2015). Features such as decentralization and the perception of Blockchain technology as an anonymous one raised the interest of criminal organizations, which use cryptocurrencies as a financial instrument to conduct illegal activity, e.g., money laundering.

Blockchain and Money Laundering

Client identification and authentication is the primary responsibility of financial institutions. They must implement KYC and AML procedures. Financial institutions must identify a client in conformity with existing regulations. It is typically a time-consuming and complicated process as it is required to verify if people are who they say they are.

Blockchain technology can support the process of client identification because there is identity management in its structure. The entity signs each transaction in the system with the private key, which only they know. All the entities may verify a transaction by using a public key that is visible in the network. The combination of a private and a public key might be perceived as an identity, which expresses its will in the network e.g., by carrying out a transaction. The primary protocol is not linked to the actual user identity, and with a pair of keys, the users remain pseudonymous. Due to Blockchain it is possible to make a decentralized connection between real-world identity and a pair of keys (Fromknecht et al. 2014; Civic Technologies 2018). Currently, there are many projects that deal with client verification issues in Blockchain technology.[iii]

Cyberlaundering

Cyberlaundering is a type of money laundering in which mechanisms available on the Internet are used to hide the true source of funds in order to make law enforcement less suspicious. A new type of money laundering was invented along with the soaring "electronic" finance at the end of the 1990s. (Kellerman, 2004).

The Internet is widely recognized as a valuable source of information and communication channel (peer-to-peer communication). One can almost immediately contact from one place in the world to another. Initially, the Internet was a very limited source of information, however, in the era of technology development and ease of using the benefits of www resources, it is currently the largest source of information and the fastest way of communication between users. In 2019, more than 4.5 billion people worldwide have access to the network and use the Internet. The development of technologies and communication routes, such as mobile telephony and the Internet, significantly influenced the way of doing business and revolutionized the economy, trade and other aspects of life.

In the era of the Internet criminals are becoming more and more creative when it comes to money laundering. Fake book sales via the Internet (Flood, 2018), shopping in games (Carole, 2018), renting places via Airbnb (Cox, 2017a), shopping on auction sites (Maramont, 2017) or even fake Uber rides(Cox, 2017b) are just a few examples of new methods for legalizing unlawful funds. As AML/CFT regulations currently rely heavily on banking transactions, criminals are becoming more and more creative. It is estimated that currently 10% of all laundered money is laundered via the Internet annually. At the same time, according to research, due to the fact that economies are becoming more and more cashless, by 2020 the percentage of funds digitally transferred compared to traditional methods of money laundering will have been doubled (Bromium, 2018).

Along with the development of technology, there have been the development of e-commerce. Due to electronic platforms the trade between entrepreneurs (B2B) and between entrepreneurs and consumers (B2C) has improved. Ease of searching for goods, availability and quick transactions have made e-commerce one of the milestones in the global economy - it is estimated that e-commerce sales will reach around USD 4.5 trillion in 2021 (Orendorf, 2017).

The development of electronic commerce has forced the need to introduce new "electronic" payment methods. Traditional ones are not suitable for fast settling of payments, which is necessary in e-commerce. One of the most popular electronic payment systems is undoubtedly the PayPal platform, an intermediary portal that allows electronic transfer of funds through a virtual wallet. It is worth noting that cash flow intermediaries are under constant supervision and subject to applicable AML regulations. Traditional money transfers, payments by credit or debit cards and payments via intermediary portals have begun to be replaced by increasingly popular virtual currencies that are not under the supervision of another entity.

Virtual currencies, called cryptocurrencies, are a type of financial means that can be used to buy real goods and services. The use of cryptocurrency is decentralized because there is no authority that issues and controls these currencies. Cryptocurrencies also allow their users to remain completely anonymous. The creation of cryptocurrencies was the aftermath of the financial crisis in 2008, which significantly reduced confidence in financial institutions and the services they provide. There is currently no universally accepted legal definition of cryptocurrency. One of the definitions of cryptocurrencies was created by the European Central Bank in 2012, which is: „ *a type of unregulated, digital money, which is issued and usually controlled by its developer, and used and accepted among the members of*

a specific virtual community." (European Central Bank, 2012) Another definition was presented by the US Department of the Treasure: *„medium of exchange that operates like a currency in some environments, but does not have all the attributes of real currency.*" (FinCEN, 2013)

Currently, the best-known cryptocurrency is Bitcoin, with market capitalization of USD 152.5 billion[iv]. This is the first cryptocurrency created by an anonymous person or group of people, called Satoshi Nakamoto. Bitcoin transactions can occur between any two parties, and since there is no third party, no bank account is required. The transaction has no fees or limits. The technology used in this system, called Blockchain, works without central computers and does not have a centralized place to store data, used to record individual transactions, payments or accounting entries. It is encoded using cryptographic algorithms. It is based on cryptographic ciphers (Nakamoto, 2008).

The use of cryptocurrencies is becoming more common due to the ease and the swiftness of their use compared to traditional payment methods. Nevertheless, despite the advantages of cryptocurrency, they pose a serious threat to the financial system in terms of money laundering and terrorist financing. The system is not resistant to this risk due to greater anonymity than traditional electronic payment systems because it is not controlled by any authority. Payments through anonymous digital wallets allow the "launderers" to hide sources of illegally obtained funds and hinder the control of money flows. Additionally, the ease of transferring funds between countries accessible via the Internet, poses a significant risk in terms of money laundering and terrorist financing.

Digital Currencies, Virtual Currencies and Cryptocurrency

At this point it is also worth paying attention to the distinction between digital currencies, virtual currencies and cryptocurrencies. Digital currencies is a general term used to describe all virtual currencies as well as cryptocurrencies. They can be both regulated and unregulated. Unlike banknotes, they are immaterial and exist only in digital form. Digital currencies can only be stored and issued using electronic wallets or designated connected networks. No need of the third party means that transactions are usually immediate and do not entail high fees.

Virtual currencies are also a type of digital currencies, which are usually controlled by their creators and used by members of a specific virtual environment such as a payment platform or an online game. It is important that all virtual currencies are digital currencies, while not every digital currency is virtual currency, because they operate outside a strictly defined virtual environment. Virtual currencies represent a specific value, they are issued, managed and controlled by private issuers and used for peer-to-peer payments. Unlike fiat money, virtual currencies are not issued by a bank. They are therefore prone to price fluctuations. The use of virtual currencies is registered by network administrators.

Cryptocurrencies are distinguished by the fact that they use many encryption algorithms and cryptographic techniques to ensure their security on the network. This level of security also makes it more difficult to fake them. Cryptocurrencies are digital currencies because they exist on the Internet as well as virtual currencies created using cryptographic algorithms.

One of the most popular platforms that generate their own virtual currencies are WebMoney[v] and Perfect Money[vi]. Both platforms were associated with cybercrime and money laundering (Emerging Technology from the arXiv, 2013). However, according to the Europol report (Europol, 2018: p. 59). Bitcoin is currently the most popular virtual currency used on the Internet to exchange funds between criminals.

Bitcoin has already been used to finance terrorism in the past. In June 2015, an American court convicted a teenager for providing ISIS support on social media. A teenager used Twitter to advise others on how to use Bitcoin to support ISIS in an anonymous way (United States Department of Justice, 2015). Moreover, also in 2015, cyber security analysts identified an ISIS supporter who ran a website to raise funds for terrorist activities. At that time, he managed to gather about USD 1000 for criminal operations (Harman, 2015). Bitcoin can be used to exchange funds on both the WebMoney and Perfect Money platforms, as well as on virtual game-based currencies. This possibility leads to illegal activities. Criminals exchange cryptocurrencies for virtual currencies e.g. in games, and then again for cryptocurrencies in order to hide the real source (Town, 2018).

V AML Directive

Virtual currencies pose a serious threat in terms of money laundering and weaken the financial system of the European Union. The V AML Directive aims to reduce this risk by, among others, introducing the definition of virtual currency in EU legislation. The AML Directive defines virtual currency as „*a digital representation of value that is not issued or guaranteed by a central bank or a public authority, is not necessarily attached to a legally established currency, and does not possess a legal status of currency or money, but is accepted by natural or legal persons, as a means of exchange, and which can be transferred, stored and traded electronically"*.(European Parliament, Directive 2018/843) The definition does not explicitly refer to any distributed registries' technology, and therefore may also include centralized payment schemes not based on blockchain technology, such as e.g. currencies used in computer games, like Warcraft Gold in the game World of Warcraft, released by the private company as a game platform operator.

In accordance with the V Directive, providers of virtual currency accounts began to be subject to AML regulations. It imposes on them, among others such obligations as accurate identification and verification of clients, as well as supervision of transactions carried out through their services. V Directive contains definitions of virtual currency account providers that goes as follows: „*an entity that provides services to safeguard private cryptographic keys on behalf of its customers, to hold, store and transfer virtual currencies*" (European Parliament, Directive 2018/843). It is worth noting that the providers of virtual currency accounts have been recognized as obliged entities, even if they do not offer the conversion of virtual currency into fiat money and vice versa. The definition is limited only to providers who store private credentials. Therefore, the entities that offer programs enabling the saving of credentials on local devices will not be classified as obliged institutions.

The European legislator has considered the identification and verification of clients together with the supervision of transactions to be sufficient for effective and adequate prevention of money laundering in the European Union. However, taking into account the technical aspect of blockchain technology, due to the frequent lack of involvement of third parties in transactions using cryptocurrencies, this may be a more demanding task. One of the biggest values of cryptocurrencies and blockchain technology is undoubtedly the option that transfers can be made without third parties that process transactions. Users can transfer funds directly in a peer-to-peer style. Given the anti-money laundering context, this means that criminals can continue to make transactions for money laundering and terrorist financing or other criminal activities without any third party. It will undoubtedly be difficult for the EU legislator to solve this problem in the coming years.

Conclusions

Despite the fact that the market capitalization of cryptocurrencies is still little contrasted with conventional money, the innovation can bring key change to capital business sectors and the manner in which organizations raise, use, and disperse esteem. Money laundering is a phenomenon that has crossed national borders and has become a global problem long ago. Although a number of actions have been taken so far to prevent and combat money laundering, this problem has not been resolved. It is impossible to completely eliminate money laundering, but it can be reduced. One way to reduce money laundering is to adopt legal solutions that, on the one hand, prevent money laundering and, on the other hand, help combat it.

The economic boom and the development of new technologies, and in particular the creation of the internet network in 1990, have caused the world to become smaller, and thus money laundering and terrorist financing are becoming an increasingly important problem on an international scale. The cross-border nature of these crimes, combined with the anonymity provided by the Internet, and transactions carried out through virtual currencies, as well as the lack of relevant legislation and specialized knowledge in law enforcement, mean that cybercrime is still developing.

The current approach of the European legislator to enact the provisions of the V AML Directive in relation to virtual currency exchange services and virtual currency account providers, raises a number of serious doubts as to its effectiveness and adequacy, as transactions in cryptocurrencies do not necessarily include the participation of the third party in the payment or any other third party at all. At present, however, no better approach has been found to regulate anti-money laundering for cryptocurrencies. However, there should be further research and political discussion on this issue in the future. However, the application of traditional AML/CFT rules to providers of virtual currency trading services should not necessarily be considered as a step in the right direction, mainly because the traditional money laundering approach may not be the most appropriate. Virtual currencies are a rapidly growing and boundless technology that creates a number of threats. That is why it is extremely important that the European Union creates a regulatory framework that is effectively implemented today and will remain effective in the future.

Moreover, due to the cross-border nature of money laundering and terrorist financing, it would be desirable to create universal standards in this respect in jurisdictions outside the European Union.

Abstract

This article examines the impact of the economic crisis caused by the COVID-19 pandemic on the structure of the regional economy (using the example of five subjects of Central Russia). As a result of the study, opposite trends were identified, namely, the growth of industrial production of basic food products (meat, milk, bread) in large agricultural organizations and a reduction in the total effective demand of the population of these regions due to a decrease in real disposable income (due to inflationary processes in the economy). The most realistic scenario for the development of the current situation in the regional economy is stagnation and an increase in the decline in the welfare of the population.

Statement of the Problem

As a result of the pandemic caused by the COVID-19 epidemic, almost all States faced crisis phenomena in the economy. The most obvious consequences of the crisis were a drop in aggregate demand (due to falling incomes); reduced employment and increased unemployment, primarily in the segment of the economically active population; limited availability of financial resources (due to higher interest rates by credit institutions. For Russia, the impact of these factors was quite significant, since up to 60% of the state budget is formed as a result of the sale of hydrocarbon raw materials (oil, gas) to the foreign market. As the global level of industrial production declined, the demand for hydrocarbons decreased, which led to the need to find reserves to cover the state budget deficit. The complexity of the situation in Russia is also determined by the fact that forecasts of prices for hydrocarbons do not allow us to expect growth. Since Russia's financial structures cannot get loans from international credit organizations (due to sanctions), the economic situation in the country remains extremely tense.

Since the Russian Federation is a large Federal state, the impact of the crisis on different regions of the country was different. This article attempts to analyze the impact of the crisis on the Central regions of the country (Central-

Chernozem economic region), which mainly have an agricultural profile of the economy. The volume of production of basic food products (meat, milk, bread), which are produced at large agricultural enterprises, was analyzed. The calculations did not use the production volumes of small farms and households, since their share in the structure of total agricultural production is not large (which allows them to be ignored).

Analysis of recent research and publications.

The problem of economic recovery after economic crises has always interested researchers. Most often in the scientific literature you can find studies that reflect the recovery of the economy after the global financial crisis of 2008/2009. Recent world events (the COVID-19 virus pandemic) have led to an increase in economic research on this topic. Researchers are interested in various aspects of the functioning of both the national economy [1-4] and the relationship of the national economy with global economic processes [5-8].

Studies on the impact of the global pandemic on the regions of the Russian Federation have appeared in the press. The paper [9] presents an analysis of indicators that describe the economic factors that cause a reasonable trend. The authors refer to economic factors that stabilize the decline in exports and imports in the Sverdlovsk region: reduced purchasing power and import substitution rates selected in a number of countries. Among the identified factors that provide a downward trend, the authors highlight the features of establishing and maintaining business contacts with business representatives from South Asian countries. The authors consider the competitiveness of regional products as a significant factor in stabilizing the decline in exports. The study concluded that taking into account positive and negative factors and further monitoring their impact can significantly reduce socio-economic losses in the region's economy.

The paper [10], which reflects the impact of the pandemic on the processes of interstate cooperation within the ASEAN countries, proves the need to expand interstate cooperation to level the threats of crisis phenomena in the economy.

In [11], the impact of the pandemic on the regions of the United States was investigated, while the issues of changes in the structure of the labor market in different States were investigated. It was proved that in those regions where telecommunications technologies are developed, the economic recovery was faster and the labor market recovered more dynamically.

In the study [12] focused on the problem of recovery of Pakistan's economy due to the pandemic proved to speed the recovery of aggregate demand in a country depends on factors such as infrastructure, degree of development of the health system, the system of social compensation. The more active the state provides direct financial injections into the economy, the faster the economic balance will be restored.

The paper [13] analyzes the effectiveness of government measures to contain the economic crisis in Africa. Conclusions are drawn about the important impact of decisions made by state structures and their impact on the economic processes of integration in the region.

In General, we can conclude that the pandemic, provoking the global economic crisis, led to the need to find new solutions to the existing problems. In particular, what are the most effective methods of state support for the economy? how should interregional unions be built to reduce the negative consequences of economic crises? what is the role of digital transformation of the economy in leveling the consequences of economic crises caused by various causes? Some of these questions are answered by this work because it was analyzed the production processes in several regions before the introduction of the pandemic and after the pandemic. The results show that production at large agricultural enterprises was practically not affected, production volumes increased during all nine months of 2020, but the decline in the purchasing power of the population led to the fact that some of the products produced simply cannot be purchased due to the depreciation of the income of the majority of the country's population.

Purpose of the article

The purpose of this scientific article is to demonstrate how unpredictable stress factors of the world economy (in this paper, we will consider the pandemic caused by the COVID-19 virus as such a factor) affect regional socio-economic systems.

Research Methods

The research methodology was based on both general scientific methods of cognition: analysis and synthesis, and specific economic methodology: index method (used to analyze the dynamics of production of basic food products in five subjects of Central Russia), graphic method (used to build graphs that reflect changes in the dynamics of basic economic indicators), factor analysis (used to determine the degree of impact of the pandemic on the structure of the regional economy).

The statistical data used in the study were obtained from open sources, in particular, the online platform unified interagency information and statistical system (EMISS) was used (https://www.fedstat.ru/).

The study period was five full years (from 2015 to 2019 inclusive) and nine months in 2020 (since only these data are available in statistical databases).

The aim of the study was to demonstrate how the pandemic affected the production of key food products in five regions of Central Russia (Belgorod region, Voronezh region, Kursk region, Lipetsk region, Tambov region).

Main Results of The Study

The Central Chernozem economic region consists of five subjects of the Russian Federation located in the historical center of the country and having a predominantly agricultural economic profile, which is explained by favorable natural conditions for the development of agriculture (high soil yield). This study analyzed the indices of industrial production of basic food products in all five regions of Central Russia. The General conclusion can be as follows: all five subjects are characterized by a General trend in the dynamics of industrial production indices. The trend is that by the end of 2019, the volume of production of basic food products in all the regions under consideration was the same. The variability in industrial production indices is small. However, since January 2020, the values of industrial production indices begin to fluctuate strongly and in some regions there is a downward trend in food production (although not very pronounced) (Fig. 1-4).

Figure 1. Production indices, % of the previous period. Belgorod

Figure 2. Production indices, % of the previous period. Voronezh

Figure 3. Production indices, % of the previous period. Kursk

Figure 4. Production indices, % of the previous period. Lipetsk

The greatest variability in the indices of industrial production of basic food products is typical for the first months of 2020 (January, February, March). In the second quarter (April, may, June) of 2020, the volatility of industrial production indices slows down, which is particularly evident in the Belgorod and Voronezh regions. The rate of stabilization of industrial production is determined by the fact that it is in these regions that the level of industry is most developed compared to the Kursk and Tambov regions (where the volume of industrial production is not high). In other words, the regional economic systems of the Belgorod and Voronezh regions were more resistant to the impact of the economic crisis caused by the COVID-19 epidemic, since the structure of the regional economy of these regions is dominated not only by agricultural sectors, but also by industrial ones. This is a very important conclusion, because within one economic region we can see a difference between regions. the more balanced the economic structure of the regional economy (with a predominance of all industries), the less the impact of the economic crisis on the region will be.

Regions such as the Kursk and Tambov regions are characterized by a high degree of volatility in industrial production indices, and during the first two quarters of 2020, there was a slight downward trend in production volumes.

In order to demonstrate the trend that is developing on the eve of the economic crisis and immediately after the COVID-19 pandemic, we will display in figure 5 the dynamics of changes in milk production (for meat and bread, the trend is similar).

Figure 5: Milk production by agricultural enterprises, thousand tons

The figure clearly shows that up to the end of 2019, milk production volumes are increasing in all five regions of Central Russia (in this case, production is considered only by large agricultural producers). The largest production volumes are typical for the Voronezh and Belgorod regions, since the level of industrial development of these regions is the highest. And since the first months of 2020, there has been a sharp decline in production, which may seem to indicate a crisis. In fact, we used monthly data on output in 2020, and these values are less than the annual data that we used for the period from 2015 to 2019. We made this decision only because the year 2020 is not over yet and there is no data on the annual production volume yet. However, if we analyze the monthly production data for the first nine months of 2020, we can conclude that they fully correspond to the average (monthly) production volumes of 2019.

This allows us to draw a somewhat paradoxical conclusion that despite the restrictions imposed and the decline in business activity in large-scale industrial production, there is no clear trend towards a decrease in the volume of products produced. Monthly production data for the first months of 2020 correspond to monthly production data for 2019. Large industrial enterprises are the least affected by the economic crisis and the decline in business activity, restrictions on the movement of the population in General did not affect the producers of basic food products.

Despite the fact that large industrial enterprises were not affected (in terms of production) by the crisis caused by the COVID-19 pandemic, the population of the studied regions of Central Russia suffered significantly, as the real disposable income of the population decreased (Tab. 1, Fig. 6).

Table 1: Real monetary income of the population, % of the corresponding period

Regions	2015	2016	2017	2018	2019	1 quar 2020	2 quar 2020	3 quar 2020
Belgorod region	99.3	100.8	99.1	98.7	101.3	101.1	97.5	92.9
Voronezh region	101.1	93.6	97.4	100.0	101.5	101.5	89.3	76.1
Kursk region	100.4	93.2	99.1	100.1	101.3	101.2	95.6	87.8
Lipetsk region	96.1	96.8	100.1	100.1	103.0	102.3	90.1	77.9
Tambov region	98.5	95.8	97.0	98.8	98.0	97.8	87.5	73.2

Figure 6: Real monetary income of the population, % of the corresponding period

From the numerical data in table 1 and figure 6, it is clear that the real disposable income of the population in all five subjects of Central Russia decreased to the values of 2019. This indicates that the population is getting poorer and can afford to buy less and less food per individual family member. Thus, we have identified two completely different (oppositely directed) trends. On the one hand, the volume of industrial production of basic food products (meat, milk, bread) is increasing, since enterprises have the opportunity and reserve to increase output, and on the other hand, the population cannot afford to buy food, since the monetary income of the population is decreasing. At the same time, the aggravating factor (in the context of the identified trend) is the increase in food prices, which is explained by the increase in production costs. This will further aggravate the already difficult economic situation of the population.

Conclusions

In the medium term, the most likely trends for the five subjects of Central Russia will be the following:

a) a significant decrease in the effective demand of the population caused by a decrease in real disposable income due to inflationary processes. For the regional economy, this factor is of the greatest importance, since the aggregate demand of the region's population is a stimulating factor for the development of the regional economy;

b) reducing the revenue side of regional budgets with a simultaneous increase in social expenditures and thereby increasing the gap between the expenditure and revenue parts of regional budgets;

c) liquidation of small and medium-sized enterprises, since they cannot compete with large producers in terms of production scale. Production volumes in large agricultural enterprises did not decrease even during the crisis.

Factors Affecting Mergers and Acquisitions in A Changing Environment

Andris DENINS

Dr.oec., Professor, Departament of Management Sciences, University of Latvia, Latvia
denins_a@yahoo.com

Abstract

The purpose of this article is to set the main factors impecting the process of companies mergers and acquisitions. There are results of research explaned in this article. The research contents is arising from detailed wellknown scientists opinions review concerning companies mergers and acquisitions. On the bases of mathemacical statistics the author has set relationship between companies gained financial results and factors affecting process of mergers and acquisitions Statistical models have been elaborated by wich the efficiency of mergers and acquisitions is avaiilable assesed.

Keywords: mergers, acquisitions, verticsl integration, horizontal integratin, mathematical statistics, regression analysis.

Introduction

Companies in the world compete with each other, and there are always companies that are more successful than others. Businesses take every opportunity to succeed. Mergers and acquisitions are a form of restructuring that plays a significant role in the corporate finance world. Nowadays, companies, when choosing the type of merger, want to assess the potential benefits. In assessing the synergies it is necessary to determine not only the synergies that can be obtained, but also those that can form another merger case. That was the subject of author's research.

The terms merger and acquisition (takeover) are very vague. In practice, they are usually used explicitly. However, their terminology is different. A wide variety of definitions can be found in the extensive literature and on the internet. An acquisition is defined as the acquisition of one enterprise by another and the combination of assets of two enterprises of equal size. A merger requires the cooperation of the management of the target company to combine assets, whereas an acquisition does not. A merger is inherently friendly, while an acquisition can be both friendly and unfriendly. Merger of two or more independent market participants in a merger to become one of the market participants, or to obtain a decisive influence over other market participants. A merger can be when two separate companies decide to continue their activities in a single organisation. Whereas a business transfer is a transaction consisting of the purchase transaction, with one company taking over another company towards full management with the objective of making the second a subsidiary or incorporating it into the company's current business.

Literature Survey

The takeover process of a company's shares or assets of a sale to move another company owned. Effective acquisition strategy provides significant growth of the company (Ashon, Cook, Schmitz, 2003).

Mergers or acquisitions can be achieved by: horizontal integration; vertical integration; related or unrelated diversification. Horizontal integration merger transaction sector companies that are direct competitors of production and the market segment in the field. Horizontal takeovers may lead to increased productivity, especially if companies are similar, but some of them use different resources that complement each other (Kapoor, Lim, 2007). Vertical integration merging the customer and the manufacturer or the supplier and the manufacturer. This can happen by the merger of two or more undertakings or company launching new directions. Vertical integration is the acquisition of one or more suppliers or distributors of a company's goods and services (Gabrielsen, 2003). Vertical integration is used to increase and get more power to the market. Companies often use vertical and horizontal acquisitions in order to gain additional market power within it (Haleblian, Dever, McNamara, Carpenter, Davison, 2009).

Cite this Article as: Andris DENINS "Factors Affecting Mergers and Acquisitions in A Changing Environment" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

There is also the opportunity to join with a company that operates in another sector that is not related to the current activities of the company - this is diversification. Such transactions do not provide companies the opportunity to capture new clients or to control a larger market share - they can take this action to reduce risky activity income volatility with relatively stable income that provides courses of action.

If the synergies that can be obtained in the company are smaller than those which can be competitors, then the company will be the loser in this situation. The expected synergies may take various forms. Traditionally, companies are planning to get synergy to reduce headcount; achieve high volume efficiency; the acquisition of new technologies; better access to markets, control over the industry. Merger of companies also improves financing opportunities.

P. Drucker shows that mergers and acquisitions will only be successful if the purchaser knows it is sure to be purchased in order to promote the company (takeover of the object) operation. Mergers and acquisitions targets can be divided into business, investor, and shareholder business objectives include business development and ensure the increase in business diversification, the faster acquisition of new markets, disposal of competitors by buying competitors and by taking market share; the aim of investors is investing free funds, participation in profitable business and undervalued asset purchase; general objectives of the association (co-operation) or the establishment of strategic investor attraction of company shares in the sale, the willingness to sell the business as well as financial resources for this (Colliens, 2017).

M. Martynova, S. Oosting and L. Renneboog studied the results of mergers and acquisitions (profitability) in Europe; they found that the combined turnover significantly outperformed the average company in their performance industry before the merger, but the merged entity's commercial profitability dropped significantly after the takeover (Martynova, Oosting, Renneboog, 2007).

R. Noe observed that 60-80% of all mergers are financially unsuccessful, as measured by the results of the stock market or by profit growth. In turn, A. Fridman concluded that 58% of mergers do not reach the set goals. M&A success rate is very low - only about 30-50% (Martynova, Oosting, Renneboog, 2007). Therefore many researchers in the field of business strategy attempt to identify the variables that influence the success or failure rate. Integration speed is referred to as a success factor (Bauer, King, Matzler, 2016).

Methods

Researching the issue of merger failures, the author came to the conclusion that each mergers and acquisitions transaction is different, because each company involved in the process, is unique and different from others. However, the method used is similar. Used several methods to find a "winning formula" by which to predict the joint and the acquired company's results.

However, the fact is that until now, such a solution has not yet been found and the percentage of errors continues to be high. One of the reasons for the success or failure of the company's mergers and acquisitions lies in the way the integration is carried out between the companies. The author believes that the key factor for success of the company's mergers and acquisitions is to create and motivate the management team that will focus on new business objectives.

Results

Company managers are responsible for the achievement of corporate goals of performance and the methods chosen. In order for companies to implement their chosen development strategy through mergers and acquisitions, it must be based on mergers and acquisitions to evaluate the results - should try to calculate the company's results and the expected effectiveness both before and after the transaction.

Researchers and practitioners have carried out several studies on the results of mergers and acquisitions. Different sources of literature over the past three decades, describe a number of methods. The author became acquainted with a number of international studies, dominated by the company's purchasing activities and research merger results. Research findings vary depending on the chosen performance evaluation and methods, which is an important factor in both researchers and practitioners drawing conclusions on the success or failure of mergers and acquisitions. Some authors recommend the use of mergers and acquisitions in the evaluation method based on public research and direct such to corporate profitability check, stock market awareness or the efficiency aspect. Various methods used in one country may not work in another (Sethi, Krishnakumar, 2010). Earlier studies indicated that the impact of the transferred research can be measured by observing the reaction of the stock market or changes in the company's efficiency, at the same time looking at the accounting dynamics (Tang, 2015). Most researchers have

used profitability (gross and commercial profit margin, equity and assets profitability, EBITDA) performance data. By analysing and identifying the reasons for the balance sheet, changes can be identified in the company's financial stability improvement or deterioration. It is not always the case that the sales increase is positive, so this change must be analysed in the context of cost and profit changes in volume. Company's financial stability assessment of the financial statements in changes to be analysed in the context of the amount of profit and changes in equity for the assessment of the impact of the most important items on profit.

Mergers and acquisitions (M&A) represent a popular strategy used by companies for many years. In fact several reviews have shown that, on average, companies create little or no value by making acquisitions (Hitt, King, Krishnan, Makri, Schijven, Shimizu, & Zhu, 2009). Economists and venture capitalists are predicting an increase in M&A as nowadays organizations want to grow their market share and presence by building synergies (Jain, 2014). M&A in a broad sense can mean a number of different transactions ranging from buying and selling companies, the concentration between companies, alliances, cooperation and joint ventures in the formation of companies. Schuler and Jackson (2001) argued that a broad definition of M&A could be used confusion and misunderstandings, because it covers everything from pure merger to strategic alliance. In this paper the definition of M&A will be used in the narrow sense as purchases as purchases of shares or assets on another company to achieve full management and operational impact. M&A of the company is in particular because the relevant information about the target company is not available to the acquirer (Very & Schweiger, 2001). Although the M&As are motivated by the expected synergy between the target and the acquiring firms, some mergers are successful while others are not (Canina, Jin-Young, Qingzhong, 2010). In the last years, markets are characterized by disruptive changes as well as M&A activities (Kernstock, Brexendorf, 2012). M&A are undertaken on the assumption that the combined company will have a greater value than the two companies alone (Vazirani, 2013). M&A processes are complex processes with many challenges in the pre-deal and post-deal phases.

In the present context of the European Single Market and the globalization among economies, mergers and acquisitions represent the means by which companies increase their competitional capacity (Banulescu, Popescu-Cruceru, Leuciuc, 2012). A representative review of the extant research on M&A over the last 15 years produced a list of the most common value studied. The review of the academic literature consisted of computerized and manual questions about the published research reports.
The value of the company will reflect the contents of the solution for the various parameters that are evaluated for its operation:

• market share and competitive position stability;
• income;
• investment need;
• operational efficiency;
• the tax burden;
• cash flow management;
• the degree of risk.

The company is in the process of evaluating a company's or individual's direction value. Most often, the aim of evaluation is the determination of the market value. To successfully plan the further development of the company, merger of the whole or part of the company, buying and selling, capital injections in new directions of activity, new investment in the current transaction, as well as in other cases, the company carried out the evaluation. Company rating as it also helps entrepreneurs, potential investors to evaluate the financial situation and make the right investment decisions. Company evaluation process results in the entire company or its separate actions in terms of value for money. An organization can have multiple values depending on the scoring target.
There are different types of evaluation:

• market value;
• the value of an investment;
• the value of company workers;
• salvage value;
• balance sheet value, etc.

The value of the company is composed of several factors. The first – the ability of a company to make money, the second – company assets that belong to the company, i.e., the material base, the third – goodwill: the word, the technology used, a market where it's working, staff. Results also suggest that the asset specificity discount in the target return is more pronounced if target firms are financially distressed. Asset specificity of a firm is an important determinant of the firm's value (Kim, 2018). Operating cash flow increases the company's turnover and other revenue associated with the core, but it reduces production, administration, sales and other operating costs. The

difference between revenue and the cost is the company's profit before depreciation deductions, interest payments and taxes (EBITDA), so the higher the EBITDA is obtained; the higher cash flow from operating activities the company is obtained. This variable directly affects the company's turnover and costs. Developing and directing profitable products and running costs, the company increased cash flow from EBITDA. In Latvia, to determine the value of the company, also uses EBITDA factor. EBITDA is the base business profitability, which usually take into account the buyer (Pratt, Reilly, Schweih, 1996). Financial analysis of the company's important role in the M&A process management. Analysis tasks: to determine the effectiveness of the company's activities; identify potential business development directions. Analysis of economic activities is a prerequisite for planning. So the company can plan their actions in the future, it is necessary to analyse the results of the previous operation. Nowadays, more and more business owners and managers understand that company's evaluation is a tool used to assess how successful the company implements its strategy, and what are the main elements of its competitiveness.

From a theoretical point of view, due diligence process is largely in line with the prospect organizational learning theory (Barkema & Schijven, 2008), more explicitly teaching (March 1991). Under this perspective, the company learns with each of them and can transfer this learning effect to future M&A. Challenge the M&A process is such that the process is more complicated than the operating company, for example, production, pricing, distribution, etc. Traditional legality checking process is primarily focused on tangible assets or documents relating to the operation of the company resulting in a legal, accounting and tax issues (Harvey & Lusch, 1995). Consequently, the main legality checks are still financial and although the results of M&A transactions show a lack of traditional credibility testing approach (McGrady, 2005). Business consultants are based on regular experiences based on best practices, using experience and feedback from projects with your customers. Look for factors that are mostly simplified and suitable for a large number of M&A. The main role of the due diligence process for M&A is to evaluate the benefits and responsibilities of M&A of the company with the analysis methods relating to the company's past, present and future are expected to purchase business. An in-depth examination of business process occupies a significant role in the M&A. If this process is missing, there is a great possibility that in the future it could cause bad financial indicators of the company. It is important to create a management team that will make due diligence process, a team that evaluated the company systematically both before and after M&A. Due diligence process see the problems that must be resolved in the company's M&A to be successful. The due diligence includes: financial risk analysis, the financial position of the company and the determination of the value, legal risk analysis, tax risk analysis and evaluation, financial indicators for conditions where reliable information is difficult to obtain, risk analysis staff. Often M&A require the national regulator or another third-party authorization. Restrictions may be imposed by the competition law; the transaction may be required for other government agencies to agree. Due diligence indicates the existing and potential liabilities. With an in-depth exploration of the company is evaluating whether the agreements contain specific restrictions or obligations.

Due diligence is in the process of acquiring the company, which is testing a company takeover object for determining whether the proposed transaction, the justification is based on the financial and strategic indicators. Need to define questions, which is acquiring a company must establish a plausibility check (Cullinan, Roux, Weddigen, 2004). The operation and development of the company is associated with future prospects, opportunities, risks and uncertainties, the company's performance depends on the skills to use modern business management techniques and tools. The findings suggest that identifying and prioritizing relevant fields in the context of integration would improve the resource allocation decision and the effectiveness of post-integration evaluation (Chang, Chang, 2014). Most existing research on M&A of the results of the study results on the company's profitability, which is based on stock prices. However, there are studies that use information about the company's accounting results in annual reports. D. Mueller was one of the first to use accounting data analysis of mergers and acquisitions for evaluation. He analysed the merger transactions of 247 from 1962 to 1972 for the coming three years after the merger.

D. Mueller studied the return on assets, equity capital profitability. Similar studies on enterprise's accounting data after the merger was also D.Ravenscraft and F. Scherer (Ravenscraf, Scherer, 1989), A. Seth, P.M.Healy, A Ghosh who studied the profitability of the company, which is 315 merged during the period from 1981 to 1995 (Ghosh, 2001). Most of the risk factors mentioned in the practical studies have already been studied academic literature. Business consulting studies mainly focus on overcoming practical obstacles learning process and highlight the area in which the involvement of consulting companies provides added value. They are also regards the execution of operational transactions as the decisive criterion for success, which determines the potential impact on performance after the acquisition stage. Therefore, partial vertical integration is profitable since it constitutes a strategic device to relax competition (Fiocco, 2016).

Vertical integration brings better coordination within the integrated firm, which boosts its investment incentive at both upstream and downstream levels (Liu, 2016). An extensive body of research supports that firms acquire other firms in order to innovate and/or become more sustainable (Park, Krishnan, Chinta, Lee, 2017). The type of

knowledge is a critical distinction for the value of M&A implementation (Ranucci, Souder, 2015). When organizational leaders can no longer achieve their goals through internal growth engines, they often embark on a M&A (Recardo, Toterhi, 2015). M&A are the important mechanisms through which companies can achieve growth, gain access to new markets and diversify their activities (Savovic, 2017). Companies use mergers to increase their stability and improve economic parameters (Sobolev, 2015).

Most M&As fail to meet the expectations of the purchasers. It is clear that the due diligence, valuation analysis, and negotiation that precede the closing of a transaction cannot guarantee its success. Instead, the synergies and assumptions that supported the decision to acquire a target business will be realized only if the purchaser effectively integrates the target. Unfortunately, many purchasers either fail to plan the integration of the target adequately or conduct the integration process too slowly (Venema, 2012).

Mergers and acquisitions over the past 40 years have generated considerable interest and generated demand for strategic literature, focusing on the strategic and organizational compatibility of companies as well as the management of mergers and acquisitions themselves. Despite the popularity and visibility of this type of transaction, one of the most interesting findings of merger and acquisition studies is that the merger has not delivered the expected result. The outcome of a merger or acquisition can be evaluated from various perspectives, such as whether the transaction has resulted in a profit for the company's shareholders. One of the calculation criteria is profitability, which can be measured and measured in the short or long term.

The measurement of the business of a merged or acquired entity is carried out by comparing the accounting data before and after the transaction (for a period of at least 3 years) and by comparing the accounting data on turnover and profits. Process of mergers and acquisitions has identified an important aspect to consider in order to establish a successful merger and acquisition.

Today's business strategy is based on plans and actions designed to help companies compete successfully in their industry. Its mission is to help companies achieve and exploit their competitive advantage. Strategic planning, on the other hand, must ensure the long-term development of the company and high economic growth rates. Company strategy is an important element that helps to focus the efforts to achieve goals and has a long-term character. In turn, in the process of strategy planning, the company develops possible actions and receives an answer on how to move forward.

Scientific papers analyzed by the author show that financial statements data can be used to determine the activities of a company by calculating, comparing, combining and interpreting various absolute and relative indicators. One of the simplest methods of financial analysis for assessing financial stability is the horizontal method of analysis - studying changes in the absolute ratios of a company's financial statements (balance sheet, profit and loss statement, cash flow statement). Significant changes in the key financial statement items have a significant impact on the financial stability of the company. In order to carry out due diligence of the financial ratios of Latvian companies, as well as to reasonably select the variables of the model to be used, the author considers it necessary to calculate and investigate the correlation of indicators showing the closeness of correlation between two related variables. In order to determine the correlation between the company's financial performance, the author calculated the correlation coefficients, and in order to obtain a statistically significant rating interval for the correlation coefficient, both variables must correspond to the normal distribution. However, as mentioned in the previous section, this is not the case. Therefore, these ranges were not calculated and the correlation coefficients only give insight into the possible relationships and trends of the cash flow.

Regression analysis was used to show the regularities of these parameters. The obtained data were processed with Microsoft Office Excel and SPSS programs. Multivariate regressions were performed on data processing using the standard least squares (Ordinary Least Squares) method. This method minimizes the sum of the squares of distance in the observed measurements. In total, 21 regressions were performed: one for each firm over several years of operation. Note that there are only 21 measurements in total, which is the minimum number of observations to ensure a normal distribution. Accordingly, due to the limited amount of data, regressions may not produce statistically significant results. In addition, it is also noted that the models that will be used in the regression analysis are not specifically designed to explain all fluctuations in the psychological factor, but to find correlations and to provide an overview of the performance of physical tasks.

Due to the large number of variables, a list of financial variables with potentially 22 variable ratios was used for the study. Based on the results of the study, it was concluded that several financial ratios indicate the performance of the company. The result of the detection model depends on the choice of indicators, so the correct choice of indicators provides the possibility to form a precisely working model. Various financial ratios were selected for analysis. All analyzed financial ratios were divided into four groups according to their importance:

1. Liquidity;
2. Profitability;
3. Solvency;
4. Activity.

The M&A model is modeled on the principle that at least one factor is selected from each set of ratios that exhibits the most significant difference between related and unrelated companies in the merger process. The following procedures were performed to arrive at the variables in the equation:

1. Observation of statistical significance for various alternative functions, including each independent variable;
2. Evaluation of the correlation between the relevant variables;
3. Accuracy of observation forecasts between different profiles.

The author believes that it is important to find out what factors affect company merger and acquisition results, how high the company's EBITDA is, and how companies with high and low levels can be classified according to a regression function.
The following indicators are used in the following study:

• y - EBITDA / turnover;
• x1 - gross profit margin ratio;
• x2 - profitability before interest payments;
• x3 - profitability ratio of taxable profit;
• x4 - commercial profitability indicator;
• x5 - return on assets ratio;
• x6 - return on equity;
• x7 - return on equity;
• x8 - turnover of assets;
• x9 - turnover of fixed assets;
• x10 - current assets turnover ratio;
• x11 - total liquidity ratio;
• x12 - current liquidity ratio;
• x13 - absolute liquidity ratio;
• x14- EBITDA / assets;
• x15 - equity / liabilities;
• x16 - Turnover / Assets.

By performing a correlation analysis of the raw data, the dependent variable y - EBITDA / turnover with the independent variables analyzed is statistically significant with significance levels of 0.05 and 0.01, resulting in a correlation coefficient matrix in which the correlation coefficients for the dependent variable with the relevant independent variables excluded are statistically significant.

The measurement of the financial results of a business combination is closely linked to the assessment of the significance of financial ratios. If the variable is EBITDA / turnover, there is a strong positive statistically significant relationship between the pre-interest profit margin, the after-tax profit margin and the commercial profitability ratio, the return on assets ratio and the EBITDA / assets valuation.

Higher EBITDA / Turnover Ratio is associated with higher average financial ratios for profit before interest, taxable profit and commercial profitability, Return on Assets, and EBITDA / Assets as evidenced by Pearson correlation coefficient values, which are statistically significant probability.

Multivariate regression analysis was used to assess the dependency of the financial results of M&A. There is a correlation between the selected factors, which may influence the accuracy of the solution, but estimation of the correlation coefficients using inequalities: roi> rij; roj> rij; rock> rik; rock> rjk; where o - performance indicator (EBITDA / turnover ratio estimate), i, j, k - factorial indicators (significance of profit before interest, taxable profit and commercial profitability, return on assets and significance of EBITDA / assets), Since the correlation of the factorial features with the performance trait is closer than the correlation between the factors, therefore, it is useful to include the selected factors in the regression model, there is no multicollinearity between the factorial features.

Selecting only those variables for which the EBITDA / Turnover correlation coefficient is statistically significant with significance level 0.05 and 0.01, the following result is obtained: In the Model Summary block of Model Summary, the author found that the coefficient of determination (R Square) equals 0.862, indicating that 86.2% of

the variance in the performance attribute is explained by the factors included in the regression equation (profit before interest profit margin (x2), taxable profit margin (x3) and commercial profitability (x4), Return on Assets (x5) and EBITDA / Assets (x14),

Thus, the linear regression model by which to forecast EBITDA / Turnover values looks like this:

$$y_t = 0.956x_{2,t} + 0.108x_{14,t} + 0.011 \quad (1)$$

where yt - EBITDA / turnover at time t;
x2, t - profitability ratio before interest payments at time t;
x14, t - EBITDA / assets at time t.

The linear regression analysis included all 17 variables, of which the dependent y was EBITDA / turnover. In the linear regression analysis, the following results were obtained in the SPSS program: In the first statistical block of Model Summary we find that the resulting linear regression model - 89.5% of the variance of the result variable is explained by the factors included in the regression equation (gross profit margin (x1) profitability ratio (x2), taxable profit margin (x3) and commercial profitability (x4), return on assets (x5), return on equity (x6), return on equity (x7), return on assets (x9), working capital ratio (x10), total liquidity ratio (x11), current liquidity ratio (x12), absolute liquidity ratio (x13), EBITDA / assets (x14), equity / liabilities (x15) and turnover / assets (x16) () R Square = 0.895).Analyzing the parametric statistics of the optimized models, the author concludes that the best model with as many variables as possible and without the problem of multicollinearity (VIF <5) is as follows:

$$y_t = 0.932x_{2,t} + 0.001x_{7,t} - 0.012x_{12,t} + 0.074x_{14,t} + 0.007 \quad (2)$$

EBITDA / Turnover (y) is impacted by profitability before interest payments (x2), return on equity (x7), current liquidity ratio (x12) and EBITDA / assets (x14). The gross margin ratio (x1) does not participate in any optimized model.

Discussion

As a result of the merger, the EBITDA to turnover ratio is increasing. Based on the above analysis, it is possible to formulate a number of factors affecting a company's EBITDA:

1. Net Turnover Growth: Turnover growth rate, usually expressed as a percentage of the prior period, is one of the first things that creditors, executives and professional financial analysts pay attention to when evaluating a company's business. The reason is simple - sales revenue affects virtually all other metrics. If the other variables remain constant, significant changes in net turnover will have an impact on both the company's balance sheet and profit and loss account.

2. Profitability before interest payments: Profit before interest payments is the sum of the profitability of an activity, excluding interest payments and taxes.

3. Return on Equity: Shows the return on each euro invested by the owners in the equity of the company. This way you can compare returns with other potential types of investment.

4. Current Liquidity Ratio: Reflects the ratio of the company's current assets (excluding inventories) to current liabilities. A higher ratio indicates a higher level of liquidity (greater ability to meet a company's current liabilities). A ratio of 1.0 indicates that the carrying amount of current assets is exactly the carrying amount of the present liability.

5. EBITDA / Assets: Return on total assets is the ratio that measures EBITDA on a company’s total net assets. The ratio is considered as an indicator of how effectively a company uses its assets to generate income.

Conclusion

The company is responsible at the European Commission's position is in unity with the success of the company. If the company's activities comply with the social aspects that contribute to customer requirements, the ability to provide a parallel to the other community members such as employees, suppliers, local communities are respected. This in turn means that a positive force in society can bring direct benefit and ensure long-term competitiveness. Today's requirement is that businesses and organizations need a sane, professional manager. The driver, also a businessman, professional skills not only to work with the company's economic information (financial records,

analysis, control, forecasting). The driver must also be able to take decisions in the management of human resources, which the absence of economic and legal information is also necessary psychological, pedagogical, ethical and social basis. As the surveys show, the acquirer should consider using a consistent and scalable process evaluating such typical risks associated with M&A. This means giving the same meaning checking the legality of reputation as a legal, financial, operational and other traditional credibility check. Move to the next level of due diligence needs to be improved more than replacing the traditional credibility test activities. However, every M&A has its own personality and thus the process of expanding legality may vary depending on the situation.

Abstract

The expediency of taking into account the dynamics of financial state of an enterprise and a competitive strategy at the present stage of strategic price management is substantiated. A matrix of situational price management at an industrial enterprise is developed, in which the choice of strategic guidelines is based on two approaches: the first is based on the needs of customers, the second is based on the technological capabilities of the enterprise itself. The matrix allows to identify a situation where it is appropriate to apply a particular approach. The article focuses on the importance of the monitoring function of industrial marketing management, which provides a specially organized systematic observation of the compliance of the results of industrial marketing management with the defined goals in order to make the necessary corrective management decisions in the modern competitive conditions of enterprises functioning and deepening crisis situations in the external environment.

Keywords: Monitoring, Industrial Marketing, Management Mechanism, Management Decisions, Strategic Management.

Introduction

In the industrial sphere, the situation is complicated by the specific features of production systems of enterprises and products, which increases the risk of their entry into the markets. Accordingly, in such circumstances, the role of marketing activity is growing significantly, but not as an independent function that can be observed in the practice of most manufacturers, but as one of the main systems of the enterprise, which provides communication with the external environment in close interaction with its production subsystem. Therefore, there is a need to develop an effective industrial marketing management mechanism at the enterprise, which will ensure implementation of its competitive strategy, closely coordinated with its production subsystem.

The purpose of the work is a scientific substantiation and development of theoretical and methodological foundations, scientific and methodological and practical recommendations on development of the mechanism of industrial marketing management for enterprises.

Literature Survey

In the conditions of constant increase of the cost of material resources, the main direction of increasing competitiveness of products is to reduce its material intensity (Rinallo, D., Bathelt, H., & Golfetto, F. (2017)).

Therefore, from our point of view, it is advisable to consider the process of managing the material consumption of products on the basis of marketing as one of the components of the process of managing competitiveness of the manufactured products (Anees-ur-Rehman, M., Wong, H. Y., Sultan, P., & Merrilees, B. (2018)).

According to the goal of the study, one of the tasks that is solved in this paper is theoretical substantiation of the modern concept of marketing (Iankova, S., Davies, I., Archer-Brown, C., Marder, B., & Yau, A. (2019)). Since this concept is implemented in the field of production in the form of a management system of the enterprise and its units, it is necessary to define the essence of marketing as a system of management of production and marketing activities and to define the functions that it performs (Drobyazko, S., et al. (2019)).

However, according to experts, not all businesses, organizations, firms that declare or profess the marketing concept, put it into practice (Adrodegari, F., & Saccani, N. (2017)).

Such businesses are limited to the formal elements of marketing: introduction of positions of Vice President (Deputy Director) on marketing, product manager, development of marketing plans or implementation of its individual functions, such as market research (Payne, A., & Frow, P. (2017), Gummesson, E. (2017)).

In comparison to other types of marketing, industrial marketing has received insufficient attention in Ukrainian marketing science, although the industrial marketing is one of the most complicated and requires special attention and specific approaches at all stages of the enterprise activity: development, production and delivery of industrial products to the consumer (Wieland, H., Hartmann, N.N., & Vargo, S.L. (2017). Therefore, the importance of industrial marketing is explained by specific features of the industrial sphere itself.

Summarizing, we should note that in the current conditions of globalization of economic activity, which is often accompanied by economic and socio-political instability and uncertainty, it is impossible to ensure effective functioning of industrial enterprises without industrial marketing on the basis of a clear and modern system of managing their marketing activities (Kienzler, M., & Kowalkowski, C. (2017)).

Problems of managing competitiveness of production of an enterprise on the basis of marketing are sufficiently studied by many scientists-economists (Hallberg, N. L. (2017)).
However, they still require considerable effort in many scientific and practical fields. In particular, this concerns development and production of new competitive products, that is, the innovative activity of the company, as well as its promotion on the market, improving marketing strategies, i.e. using innovative marketing (Yang, M., & Gabrielsson, P. (2017)).

Insufficient use of marketing is caused, on the one hand, by a lack of full understanding of the needs and capabilities of marketing tools, and on the other hand, by lack of qualified specialists in this area (Bankvall, L., Dubois, A., & Lind, F. (2017)).

Analyzing various sources of information, it is safe to say that in most companies marketing is limited mainly by promotional activities and methods of promoting products or services (Cortez, R. M., & Johnston, W. J. (2017), Felix, R., Rauschnabel, P. A., & Hinsch, C. (2017)).
Excessive use of marketing is observed in those organizations that, for simple tasks, involve highly skilled professionals who should solve the problems, which leads to excessive marketing costs, impossible to compensate by business activities (Malshe, A., Johnson, J. S., & Viio, P. (2017)).

That is why, before deciding on the use of marketing principles in the activities of enterprises and organizations, it is necessary to determine the required level of application of marketing (Efrat, K., Gilboa, S., & Yonatany, M. (2017)).

Marketing activity is particularly important for industrial enterprises, which usually sell their products far beyond their location. In case of a boundary region, marketing is transformed into a regional and / or international (Cambra-Fierro, J. J., Centeno, E., Olavarria, A., & Vazquez-Carrasco, R. (2017)).

Methods

To solve the set problems, the following methods of scientific research were used: abstract-logical approach - for theoretical generalization of research results and formation of intermediate and final conclusions based on them; graphic-analytic method - for providing material clarity and schematic representation of a number of theoretical and practical provisions; experimental - for testing scientific and methodological approach to assessing effectiveness of marketing activities in industrial enterprises.

Results

The main goal of strategic price management is to establish the best price level, the level that will maximize profit, that is, provide rational marketing price management from a strategic perspective, integrate existing techniques and methods of price management when using marketing tools, and therefore creating a long-term competitive advantage.

Accounting totality of the last two components will allow to determine the most appropriate of the available alternative directions of competitive strategy for the enterprise. These three reduced variables - the dynamics of the financial state of the enterprise, strategic orientation and type of competition - are the axes of the matrix in Figure 1.

<table>
<tr><td>I. Dynamics of financial state</td><td rowspan="2">I
Improvement of basic, auxiliary, servicing production processes</td><td colspan="2" rowspan="2">IV
Improvement of existing products (marketing commodity policy) and production processes</td></tr>

<tr><td>Technological</td><td>Marketing</td><td>II. Strategic orientation</td></tr>
<tr><td>Price</td><td>Innovative</td><td>III. Type of competition</td></tr>
</table>

Figure1: Situational price management matrix for an industrial enterprise (developed by the author)

In the proposed matrix, when selecting strategic guidelines, two main ones were used. The first guideline is technological, when both the well-established production of goods and search for new goods are based on available technologies that are inherent in the activity of the enterprise on the market. The second guideline is marketing, when all resources of the enterprise are focused on meeting the needs of consumers.

Traditionally, a product competitiveness indicator is a function of two variables: price (and, accordingly, its costs both for production of goods and its operation) and quality. It is established that in assessing competitiveness of a product it is also necessary to take into account another its parameter - maintenance, which means the whole range of branded services provided by the supplier to the consumer during the entire operational cycle.
In its turn, quality should include the technical and functional state of the product, uniqueness, environmental safety and innovation. Innovation should be understood as a set of new product features introduced at the enterprise for the first time.

Thus, the success of goods on the market is determined by a combination of three parameters - price, quality, service. Finding the right combination of these parameters is a promising way to manage prices.
In this connection, the author introduces a new concept of "space of product competitiveness", characterized by indicators of price, quality, service. Once in this space, the product will be sold to the benefit of the enterprise, provided the highest level of consumer satisfaction. Description of the parameters that form the space of product competitiveness are presented in Table 1.

Table 1: Description of parameters that make the space of product competitiveness (the author's research)

Parameters	Description
Minimum price level	The minimum acceptable price below which production of the goods at a given level of profitability is impossible at this stage of development of equipment and technology
Maximum price level	Characterizes the threshold price, the excess of which will dissatisfy buyers
Maximum quality level	The highest level of quality, exceeding which is impossible at this stage of development of equipment and technology
Minimum quality level	The lowest level of quality beyond which a product cannot be used for its intended purpose
Maximum level of service	Higher level of service beyond which it becomes intrusive for the consumer and not cost-effective (high-cost, unjustifiably expensive) for the manufacturer
Minimum level of service	The lowest rating of service beyond which goods cease to be attractive to consumers

Summarizing it should be noted, that modern economics and marketing do not have a versatile toolkit and methodology that would have allowed to predict optimal market prices for industrial products, while taking into account the impact on the pricing process of the entire spectrum of external and internal factors that simultaneously affect it.

Discussion

It remains problematic to ensure systematic monitoring in some areas, including marketing. Vulnerability of industrial enterprises to complex changes of the internal and external environment is largely explained by the lack of certain management tools for the enterprises, namely organizational and economic, information support of industrial marketing management monitoring.

The block diagram of monitoring in the system of innovative development process management of an industrial enterprise is shown in Figure 2.

Figure 2: Industrial marketing management monitoring algorithm for an enterprise (developed by the author)

Industrial marketing management monitoring system is an information-analytical system of providing process of industrial marketing management of enterprise with timely qualitative and quantitative data for regulation and correction of organization of its marketing activity, effective management of current state of innovative activity and prospects of further innovative development.

Management accounting data are used to form the monitoring information-analytical base. An information-analytical monitoring base is a system of indicators that reflects a given state of marketing activity, which is determined by goals of industrial marketing management. It can vary in both quantity and composition of indicators according to adjustments to the goal and performance indicators of marketing activities, which can be conducted to eliminate the effects of factors and bring the object to the balanced state.

In modern economic crisis conditions, the system of monitoring performance of marketing activities of the enterprise should be dynamic, because changing external environment causes constant corresponding changes in the internal environment, and therefore, the indicators that form its basis require constant revision.

Conclusion

It is substantiated that vulnerability of industrial enterprises to the complex changes of the internal and external environment are largely explained by the lack of certain management tools for enterprises, namely organizational and economic, information support of industrial marketing management monitoring. Monitoring means a specially organized systematic surveillance of the compliance of the results of industrial marketing management with the defined goals in order to make the necessary corrective management decisions in modern conditions of functioning of enterprises and deepening of crisis phenomena in the external environment.

Organizational and economic support of industrial marketing management monitoring is aimed at creation of a special monitoring service and realization of the following complex tasks: organization of the process of gathering, accumulation and transfer of information; organization of information support of problem solving; control over implementation of management decisions in the mechanism of industrial marketing management.

Monitoring information support is its important component, enabling timely acquisition of reliable data on the current state of the enterprise, which is determined by the goals of industrial marketing management, and the prospects of its change taking into account the impact of the external environment.

Abstract

In increasing share of IT in the public finance sector institutions' activity makes the assurance of information security by the institutions one of the most important challenges. One of the tools aimed at ensuring the meeting of the information security requirements in public finance sector institutions is the information security auditing.
The main purpose of the paper is to define, systematise and operationalise the principles of internal information auditing in public finance sector institutions in Poland as well as to determine the methodology of conducting it.
An analysis of the current normative acts on internal auditing allowed for the statement that the Polish legislator developed a formalised internal auditing procedure constituting the bases for isolating a multi-stage information security auditing methodology in public finance sector institutions, which due to their strategic importance for the state require applying special measures on broadly understood safety.

Keywords: Internal Audit, Units of The Public Finance Sector, Information Safety.

The paper presents the personal opinions of the authors and does not necessarily reflect the official position of the Opole University of Technology or the WSB University in Wroclaw or the University of Opole

Introduction

According to the Polish rules of law, the basis for information security system auditing in public finance sector institutions may include two sets of criteria: the criteria specified in the Polish Standard PN-ISO/IEC 27001 Information Technology - Safety Techniques - Information Security Management Systems – Requirements (hereinafter: Polish Standard PN-ISO/IEC 27001) for institutions in which the information security management system was incorporated based on the Polish Standard PN-ISO/IEC 27001 or, in the case of other institutions, the criteria specified in § 20 paragraph 2 of the Regulation of the Council of Ministers of 12 April 2012 on the National Interoperability Framework, the minimum requirements for public registers and exchange of electronic information and the minimum requirements for IT systems (Uniform text: Polish Journal of Laws; Dz. U. of 2017, item 2247, hereinafter: NIF Regulation).

Due to the elaboration's framework, the deliberations included in this paper will concern the principles of information security auditing in public finance sector institutions, conducted based on the latter set of criteria and do not cover auditing conducted based on the regulations of the Polish Standard PN-ISO/IEC 27001. The thesis of this elaboration is the statement that the Polish legislator developed adequate bases as well as formal and legal solutions, the purpose of which is to exercise adequate information security auditing in special organisations, such as the public finance sector institutions in Poland. The scientific methods used by the authors include the analysis of sources and individual in-depth interviewing of a representative of the head tax inspection office in Poland, i.e. the National Revenue Administration.

Internal auditing. Definition Approach

The improvement in managing a public finance sector institution is reflected in the internal auditing institution. It was introduced into the Polish legal system in 2001 as result of amending the Act of 26 November 1998 on public finances (Act of 27 July 2001 on amending the act on public finances of 26 November 1998, Polish Journal of Laws; Dz. U. no. 102, item 1116). Over the years, action has been taken to adapt the regulations adopted in 2001 to the regulations developed by international auditing organisations (Sojka 2017). This also applied to the definition of internal auditing.

When deliberating on the definition issues, it is necessary to start with the statement that the definitions specified in the Act on public finances as well as in domestic and foreign doctrine items do not directly refer to the concept of information security auditing in public finance sector institutions, but generally to the concept of internal auditing. There are however no formal obstacles against transposing these definitions to the concept of internal information security auditing. A specific feature of the currently applicable formal and legal definition of internal auditing is the close correlation of auditing with management control. Article 68 paragraph 1 of the Act on public finances, management control in public finance sector institutions covers all activities taken to ensure the execution of objectives and tasks in a legal, effective, cost-efficient and timely manner. According to Article 272 (1) of the Act of 27 August 2009 on public finances (hereinafter: PFA), an internal audit is an independent and objective activity, the purpose of which is to support the minister in charge of the department or institution's head in the execution of objectives and tasks through systematic evaluation of management control and counselling activities. The auditing allows for obtaining an evaluation of the adequacy, effectiveness and efficiency of management control in a government administration department or institution (Article 272 (2) of the PFA). The internal audit definition most commonly cited in the doctrine is the definition quoted by the Institute of Internal Auditors (IIA), which specifies the basic objective, nature and scope of internal auditing (Eulerich and Eulerich 2020), (Dzikrullah et. al. 2020), (Turetken and al. 2019), (Chojna-Duch 2012), (Czerwiński 2002). The Institute of Internal Auditors defines an internal audit as "an independent and objective activity, the purpose of which is to provide the organisation with value and streamline its operating activity. It is based on systematic and orderly evaluation of processes: risk management, organisational governance and control, and contributes to their improvement. It helps the organisation to achieve its objectives by assuring the effectiveness of the processes, also through counselling" (IIA 2020; IIA Poland 2020).

Information security auditing obligation in public finance sector

Information security auditing is strictly related to the information security management systems (hereby: ISMS) established and incorporated in the institutions. Auditing is one of the obligations of the institution's management, related to the systems' functioning. In scientific discourse, when defining the ISMS, authors most often refer to the definition included in the Standard ISO/IEC 27001:2017 (Szczepaniuk et al. 2020), (Mirtsch et al. 2020), (Tatiara et al. 2018) (Lidermann 2017), (Grenda et al. 2017), (Górny 2016), (Banasikowski 2011), (Liderman 2006). According to its guidelines, the ISMS is treated as part of a complete management system based on a business approach to risk with the aim to establish, introduce, act, monitor, review, maintain and improve information security.

According to § 20 point 1 of the NIF, entities performing public tasks are obliged to develop and establish, introduce and operate, monitor and review as well as maintain and improve an information security management system ensuring information confidentiality, availability and integrity with consideration of such attributes as authenticity, accountability, incontestability and reliability. According to § 20 point 1 of the NIF, the main purpose of establishing and introducing the ISMS should be an adequate security of the information collected, possessed and processed with special consideration of security with maintenance of their confidentiality, availability and integrity. Information security management in a public finance sector institution related to the ISMS implemented in the given institution takes place by the institution management's assurance of conditions enabling the execution and exercise of the activities specified in § 20 paragraph 2 of the NIF regulation. According to § 20 paragraph 2 (1)-(13) of the NIF regulation, the scope of information security management in an institution covers thirteen activities:

1. ensuring the updating of internal regulations on the changing environment,
2. maintaining an up-to-date inventory of equipment and software intended for information processing, including their type and configuration,
3. conducting periodic risk analyses on loss of information integrity, availability or confidentiality and taking action minimising the risk according to the analysis' results,
4. taking action ensuring that persons engaged in information processing have relevant permissions and take part in the process to a degree adequate to the tasks carried out by them and duties aimed at ensuring information security,

5. prompt change of permissions in case changes in the tasks of persons specified in point 4,
6. ensuring the training of persons engaged in information processing with special consideration of the following issues: information security threats; effects of infringing the information security principles, including legal liability, use of means ensuring information security, including devices and software minimising the risk of human error,
7. ensuring the protection of the processed information against theft, unauthorised access, damage or interference, through the following: monitoring access to information, activities aimed at detecting unauthorised activities related to information processing and ensuring means preventing the unauthorised access at the level of operating systems, network services and applications;
8. establishment of basic principles guaranteeing the safe work on mobile processing and teleworking;
9. securing information in a manner that prevents its unauthorised disclosure, modification, deletion or destruction;
10. inclusion in service agreements concluded with third parties of provisions guaranteeing adequate information security;
11. establishment of principles of handling information, ensuring minimisation of the risk of information theft and information processing means, including mobile devices;
12. ensuring adequate security in IT systems, especially based on the following: care for software updating; minimising the risk of information loss due to failure; protection against errors, loss, unauthorised modification; use of cryptographic mechanisms in a manner corresponding to threats or legal requirements; ensuring system file security; reduction of risks resulting from the use of published technical vulnerabilities of IT systems; prompt action after detecting undisclosed IT system vulnerabilities to security breaches and controlling IT systems' compliance with relevant standards and security policies;
13. prompt reporting of information security breaches in a pre-determined manner enabling quick implementation of corrective action.

§ 20 paragraph 2 (14) of the NIF Regulation, which makes it obligatory to conduct internal auditing on the security of information processed in an IT system at least once a year, entered into force on 31 May 2012. The practice of its application featured numerous doubts related to the unclear phrases used by the legislator in the NIF Regulation, therefore the Computerisation Department of the Ministry of Administration and Digitalisation (MAiC) as well as the Public Finance Sector Auditing Department of the Ministry of Finances (MF) established a common position and guidelines concerning information security auditing (Common position of the MAiC and MF on ensuring internal information security auditing; guidelines on information security auditing by the internal auditing unit; hereinafter: Common position of the MAiC and MF; Guidelines of the MF on security auditing). The documents specify two methods of meeting the obligation of ensuring information security auditing. The first method concerns units in which the basis for developing and incorporating an information security management system are the regulations of the Polish Standard PN-ISO/IEC 27001. In this case, the information security requirements specified in § 20 paragraph 2 of the NIF Regulation were deemed met, because the establishment of securities, risk management and auditing takes place based on the Polish Standards related to Standard 27001. This results in the lack of obligation to conduct additional internal audits, because auditing constitutes one of the already functioning elements of the information security management system specified in the standards (Common position of the MAiC and MF). According to § 20 paragraph 2 (14) of the NIF Regulation, the obligation to conduct internal information security auditing at least once a year applies to institutions in which the information security management system was not incorporated based on the Polish Standard 27001.

Methodology of information security auditing in public finance sector institutions

The detailed method of executing an internal audit is specified in the Regulation of the Minister of Finances of 4 September 2015 on internal auditing and information about the work and results of this auditing (hereinafter: MF Regulation of 2015 on internal auditing). In the Ministry of Finances' opinion, an information security audit should be conducted in the form of assurance tasks. This should take place with consideration of the requirements included in the Act on public finances, MF Regulation of 2015 on internal auditing and information on the work and results of the audit as well as international internal audit standards (MF Guidelines). The "International internal audit standards for the public finance sector institutions" developed by The Institute of Internal Auditors as internal auditing standards for public finance sector institutions were published in the Announcement of the Minister of Development and Finances of 12 December 2016, in which three internal auditing standard groups were distinguished: attribute standards specifying the features of organisations and persons dealing in auditing; operating standards specifying the nature of internal auditing activities and qualitative criteria aimed at their evaluation as well as the incorporation standards developing them and describing the requirements on assurance (.A) or counselling (.C) services (Polish Journal of Laws; Dz. U. of 2016, item 28, hereinafter: Internal Auditing Standards). The international standards for internal auditing should constitute the basis for each internal audit, regardless of its subject. Their application constitutes the condition for meeting the internal auditor's obligations

and contributes to a uniform approach to internal auditing (Umaralievich and Temirkhanova-Mutabar 2020), (Aloudat et. al. 2020), (Jablonski, Robak 2019), (Burt 2016).

If the internal information security auditing is entrusted to an internal auditing unit, despite the lack of a binding nature, it is necessary to keep note of the MF Guidelines on security auditing. The institution's head, when making the decision on entrusting the information security auditing to an internal auditing unit, should take into account the fact that the designation of a fixed risk area for the annual assurance tasks may contribute to the limited execution of the assurance tasks in other risk areas due to the internal auditing unit's resources (MF Guidelines on security auditing). Furthermore, he should take into account the fact that the internal auditing unit's employees possess adequate competencies, experience and knowledge on the information security auditing methodology (MF Guidelines on security auditing).

The rules of law do not specify a separate methodology of internal auditing in this special scope of information security auditing. An audit is a multi-stage process, therefore, based on the regulations of the Act on public finances and the rules of the MF Regulation of 2015 on internal auditing, four stages of the information security auditing methodology were distinguished for the purpose of these deliberations. Diagram 1 presents the methodology of information security auditing in public finance sector institutions

Diagram 1: Methodology of information security auditing in public finance sector institutions

The first stage covers the specification of the objectives, scope and audited units. This stage mainly features the specification of the task's objective, i.e. evaluation of the timeliness, diligence and correctness of the risk analysis on loss of information integrity, availability or confidentiality and the evaluation of action taken to minimise the risk. A risk is the probability of occurrence of any event, action or negligence that may lead to damage in the institution's property or image.

The assurance task's second stage covers the audit planning and specification of the research area. The area constitutes a starting point for conducting research and may include, e.g. in relation to area there of the information security auditing specified in the rules of the NIF Regulation related to conducting periodic risk analyses on loss of information integrity, availability or confidentiality as well as taking action minimising the risk according to the analysis' results, the following areas:

1. Introduction of regulations on information security risk analysis,
2. Acquaintance of employees engaged in the risk analysis with regulations on information security risk analysis,
3. Conducting the information security risk management analysis,
4. Categorisation of the risk effects in terms of information integrity, availability, confidentiality and accountability,
5. Specification of the acceptable risk,
6. Specification of the method of reacting to the analysed risk,
7. Specification of activities minimising the information integrity, availability, confidentiality and accountability loss risk.

The second stage of the assurance task during information security audit planning features six types of activities. A preliminary review in the information security audit comes down to the internal auditor's collection of information on the audited field. It includes a preliminary acquaintance with the documentation on information security in the institution without conducting a detailed analysis. It especially includes the following: getting acquainted with the objectives and field of the institution's activity in which the assurance task is executed; risk identification and evaluation after taking into consideration the existing control mechanisms and making arrangements with the audited institution or, in case of lack of such arrangements, with the institution's head, control mechanisms' evaluation criteria in the institution's field of activity subject to the task (§ 14 paragraph 1 of the MF Regulation of 2015 on internal auditing).

Risk analysis concerns the identification of potential risk in the research area and classification of results in the context of events. With consideration of the regulations of the Act of 27 August 2009 on public finances and the rules of the MF Regulation of 2015 on internal auditing and information on the work and results of the audit, the potential risks in the studied field of the institution's information security were identified for the purpose of these deliberations. An example of the method of classifying the results of information security auditing according to the audit's findings was determined. Two types of risks were distinguished: risk of failure to act or delayed action aimed at minimising the risk of loss of information integrity, availability or confidentiality. Table 1 presents an example of the method of classifying the results of information security auditing according to the audit's findings.

Table 1: Method of classifying the results according to the audit findings

Relevant	Average	Irrelevant
Findings that substantially affect the correct organisation of the information security management system – high relevance and/or non-compliance with the regulations (**high risk**).	Findings that affect the correct organisation of the information security management system – average relevance and/or non-compliance with the rules of law or procedures (**average risk**).	Findings that do not affect the correct organisation of the information security management system – low relevance and/or non-compliance with procedures (**low risk**).

The task's program and schedule constitute a specification of the audit task's stages distributed over time. It is developed after the preliminary review of the information security field to which the audit applies and especially includes the following: preliminary review result; institution head's and the audited entity's comments; resources required to execute the task, including possible need to obtain expert aid and the expected task duration (§ 15 of the MF Regulation of 2015 on internal auditing). According to § 16 paragraph 1 of the MF Regulation of 2015 on internal auditing, the auditor especially specifies the following in the assurance task's program: task topic constituting an answer to the identified and estimated risk; task objective constituting the starting point for designating the scope of the subject and object task as well as planning the method of executing the task in a manner that guarantees achieving the assumed objective; substantial risks in the institution's field of activity covered by the task; method of executing the task, especially a specification of the research sample and research techniques; agreed evaluation criteria as well as the date of task commencement and conclusion. The authorisation to execute the audit is a document issued by the head of the auditing unit. The authorisation to execute the information security audit includes: data identifying the auditor, i.e. his or her first name and surname; data

identifying the audited entity - the audited entity's name or the institution's name; date of expiry and signature of the institution's head (§ 4 paragraph 2 of the MF Regulation of 2015 on internal auditing). The preparation of auditing tools covers the development of internal audit questionnaires for the audited units, draft tests and a checklist completed by the internal auditor. Internal audit questionnaires is a document featuring questions concerning the management control system. The auditor uses the questionnaire by asking open-ended and multiple-choice questions to the audited unit's management and employees. Multiple-choice questions are formulated in a way that prevents answering them with yes or no, while open-ended questions allow the audited entity to freely describe the audit. The questionnaire can also be used during the initial stage of the audit to understand the control system's functioning principles. The auditor completes the questionnaire based on the answers provided by the audited entity or is completed jointly. Draft tests are use to determine the facts. We distinguish the following types of tests used by the auditor:

- roll-forward tests – used prior to the commencement of the audit activities. They are based on repeating specific control mechanisms that enable checking the process from start to finish,
- compliance tests – conducted to obtain sufficient evidence that the researched area operates in accordance with the rules of law and whether control mechanisms are applied,
- (real) reliability tests – they rely on checking whether the information specified in the documentation are complete, accurate and whether they reflect the facts. The tests can be conducted along with the compliance tests.

Checklist is a document that has a wide range of applications and can be used at each stage of carrying out the assurance task. It helps to unify the obtained information and ensures a standard approach to the conducted test.

Third stage of the task covers the execution of auditing activities. Their proper execution allows the institution's head to become sure that all information security processes taking place in the institution are proceeding well, i.e. that: the institution's objectives are achieved accordingly; the principles and procedures deriving from the current rules of law are implemented, complied with and incorporated by the institution's head and that the adopted control system is adequate and efficient, which enables a correct evaluation of the institution's activity (Szymańska 2012). The audit activities are executed based on the developed auditing tools. The main auditing tools include the internal audit questionnaire, tests and checklist. The internal audit questionnaire is aimed for audited units, which in an information security audit is the Data Protection Inspector or IT Specialist. Table 2 presents an example of the internal audit questionnaire for the Data Protection Inspector/IT Specialist.

Table 2: Example of an internal audit questionnaire for the DPI/IT Specialist.

Internal Audit Questionnaire for the DPI/IT Specialist				
	Scope of issue	**yes**	**no**	**Not applicable**
1.	Were regulations on information security risk analysis introduced, including: - designation of risk owner, - specification of team(s) to conduct risk analysis, - persons responsible for conducting the risk analysis.			
2.	Are directors at each organisational level engaged and do they support the information security risk analysis?			
3.	Was an inventory on the information security threats and vulnerabilities carried out?			
4.	Did the period covered by the audit include an information security risk analysis during the introduction of the IT system or public register?			
5.	Did the period covered by the audit include an information security risk analysis during the operation of the IT system or public register?			
6.	Did the risk evaluation include categorisation of the threat effects in terms of information integrity, availability, confidentiality and accountability?			

7.	Did the period covered by the audit include a risk evaluation? If so, please specify the dates.			
8.	Were acceptable risk (level) criteria specified? If so, please specify the date and name of document.			
9.	Was the method of reacting to risk higher than the acceptable risk specified? If so, please specify the date and name of document.			
10.	Were activities minimising the information integrity, availability, confidentiality and accountability loss risk specified? If so, please specify the date and name of document.			
11.	Are the activities minimising the risk specified in point 10 monitored and who is responsible for the monitoring?			
12.	Were regulations on risk analysis and business impact analysis (BIA) in terms of business continuity introduced, including: - designation of risk owner, - specification of team(s) to conduct risk analysis, - persons responsible for conducting the risk analysis.			

The second auditing tool is the test. The auditor is obliged to conduct the tests on a selected random population sample. The sample size depends on the given institution's population size. To ensure the result's reliability, it is recommended to test at least 50% of the population. Sample testing based on the collection of random samples with the use, among others, of the following sample selection methods:

- systematic sampling **–** requires estimating the fixed sampling interval. The interval is designated by dividing the population by the planned sample size. The first unit for the sample is selected randomly from 1 to the interval value. If the interval is marked as "i", the first sample unit as "p" and the sample size as "n", then the sample will include the following units: p, p+i, p+2i, p+3i,.....p+(n-1)i;
- random sampling – based on the internal auditor's selection without any conscious bias, i.e. without taking into account any reasons to include or discard a given element in/from the sample. It is applied when it is difficult to apply other sampling methods;
- stratification – the population is divided into two or more layers with specific features from which the sample is selected independently. When dividing into layers, it is possible to take into account, for example, the size of elements or risk to which the population elements are exposed – the same layer should include elements exposed to similar risk.

Table 3 presents the scope of the test on the specification of the correct low/average/high risk estimation

Table 3: Specification of the correct low/high/average risk estimation

Risk estimation correctness		Low/ average/ high risk						Identification of possible risks not taken into account in the risk analysis
Number of incidents	Procedure Yes / no	Incident	Number of incidents	Is there a procedure and is it applied	Actual risk estimate	As it should be	Incident	

The third auditing tool is the checklist completed by the auditor. In the checklist, the auditor specifies the information from the internal audit questionnaire for the Data Protection Inspector and IT Specialist as well as from the conducted tests. Table 4 presents the draft checklist completed by the auditor.

Table 4: Draft checklist completed by the auditor

Checklist completed by the auditor				
	Scope of issue	**yes**	**no**	**Not applicable**
1.	Were regulations on information security risk analysis introduced, including: - designation of risk owner, - specification of team(s) to conduct risk analysis, - persons responsible for conducting the risk analysis.			
2.	Are directors at each organisational level engaged and do they support the information security risk analysis?			
3.	Was an inventory on the information security threats and vulnerabilities carried out?			
4.	Did the period covered by the audit include an information security risk analysis during the introduction of the IT system or public register?			
5.	Did the period covered by the audit include an information security risk analysis during the operation of the IT system or public register?			
6.	Did the risk evaluation include categorisation of the threat effects in terms of information integrity, availability, confidentiality and accountability?			
7.	Did the period covered by the audit include a risk evaluation? If so, please specify the dates.			
8.	Were acceptable risk (level) criteria specified? If so, please specify the date and name of document.			
9.	Was the method of reacting to risk higher than the acceptable risk specified? If so, please specify the date and name of document.			
10.	Were activities minimising the information integrity, availability, confidentiality and accountability loss risk specified? If so, please specify the date and name of document.			
11.	Are the activities minimising the risk specified in point 10 monitored and who is responsible for the monitoring?			

In addition, during the execution of the audit task, it is possible (if necessary) to use methods such as analysis based on studying the audit documentation and verification based on breaking down the studied documentation. It is based on the comparison of data deriving from various sources to identify atypical situations or deviations from the desired state. Furthermore, during the test, in case of ambiguities, it is possible to ask the audited unit to file a statement confirming the correctness of the area's functioning. It is also possible to conduct a talk/interview, i.e. technique aimed at obtaining clarification and information from employees, the application of which must feature consideration of the basic principles applicable to the talk, i.e. specification of the talk's purpose and documentation of its important results, as well as the method based on graphical process analysis (chart), i.e. using a graphical mesh to develop a chart or scheme of activities that must be executed in order to complete the given task or activity. The purpose of preparing a graphical presentation is the better understanding of the process itself and identification of important control points and/or risks related to the audited process. Notes, i.e. auditor's notations on the executed audit activities are very often used by auditors. Calculations are used when the auditor breaks down various information requiring calculation.

The essence of stage four is the development of a report and evaluation on the research area. At this stage, the auditor develops the audit's initial results, which are agreed upon in writing with the audited entity. In case of failure to agree upon the initial audit results, the audited entity can file written reservations within the time specified

by the internal auditor of no less than 7 calendar days from the date of the audited entity's receipt of notification about the initial results (§17 paragraph 3 of the MF Regulation of 2015 r. on internal auditing). The report must include the following information: task topic and objective; task's subjective and objective scope; date of the task's commencement; findings and evaluation according to the criteria adopted in the assurance task program; recommendations; the auditor's response to objections; general evaluation of management control adequacy, effectiveness and efficiency in the institution's field of activity covered by the audit; date of the report's development as well as the first name and surname of the internal auditor executing the task and his or her signature (§18 paragraph 1 of the MF Regulation of 2015 r. on internal auditing).

Conclusion

Ensuring information security constitutes one of the biggest challenges faced by the public finance sector institutions. The strategic importance of the state's financial sector institutions requires the legislator to take special care to ensure their security. Aside from IT systems which in contemporary times are an absolute priority, it is also important to ensure information security in the institution's every day functioning. In each public finance sector institution we are dealing with various information and data which in principle are subject to protection by the power of law or due to the institution's important interests. Aside from technical and IT security, the information require an efficient administrative apparatus based on people. In Poland, thanks to the formal and legal changes, the recent years featured an introduction of effective tools and methods that substantially facilitated the issues of information security auditing. Thereby, thanks to the introduced changes, it became easier to execute audits and ensuring correct control over information security was expanded.

Abstract

Households tend to increase their spending as income increases which could have significant impact on inflation in any economy. Millions of households have lost and made incredible wealth in the stock market; however, economic and finance literatures have not focused on how changes in stock prices which influence household wealth and spending behaviour could be useful in forecasting inflation. Therefore, this study investigates stock prices and inflation in Nigeria between 1985 and 2018. It employs a Cross Correlation test to establish the cyclical relationship between market capitalization (a proxy for stock prices) and inflation. The study found that inflation tends to rise when stock prices are falling and inflation falls when stock prices are rising. Based on the findings of this study, it was recommended that monetary policy makers may choose to use its control of the discount factor to influence stock prices movements and indirectly control future inflation through stock market cycles in both the short run and long run. Such that by extending stock market cycles, inflation could decline for an extended period of time.

Keywords: Cyclical relationship; Stock prices; Inflation; Market capitalization, Discount factor

Introduction

Economists have argued that there exists a theoretical link between stock prices and inflation; however, there is no consensus interpretation of the relationship existing between both variables. The Fed model according to Asness (2003) posits that the average earnings yield on the stock market yield must be greater than the average bond yield for an equity risk premium to be generated, thereby suggesting the existence of a highly positive correlation between both variables. While inflation moves with nominal bond yields for reasons explained by Fischer effect theory (which describes the relationship between inflation, real and nominal interest rate), the observed positive correlation between expected inflation and equity yields has long puzzled economists (Bekaert & Engstrom, 2009; Okunlola, F.A., Babajide, A., and Isibor, A.A. (2020). Stock & Watson (2001) explained that the positive relationship between equity yields and expected inflation stems from the fact that current stock prices are valued using forward-looking economic variables, therefore the stock prices themselves could be useful in forecasting future inflation and economic growth.

The inflationary problem in Nigeria is quite startling. In the 32-year period between 1985 and 2017, Nigeria suffered double digit inflation in 24 out of the 33 observations which led to a severe erosion of the value of Naira in the last 3 decades according to data compiled from CBN Statistical Bulletin (2017). The singular inflation objective for CBN during the period always remained to achieve single digit inflation in the country; however, this was only a reality in just 9 of the 33 inflation observations, translating to a low probability chance of 27.2 percent that CBN will achieve single digit inflation in Nigeria in any given year (CBN, 2017). The average inflation during the 32-year period was as

Cite this Article as: Alexander OMANKHANLEN, Felicia OLOKOYO, Emeka UCHEAGA and Areghan ISIBOR "Understanding the Cyclical Relationship between Stock Prices and Inflation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

high as 19.9 percent, up to 11 percentage point higher than the current single digit target band of 6-9 percent the Central bank is currently seeking to achieve (CBN, 2018).

An obvious challenge CBN has struggled within the last 32 years is: understanding the inflation dynamics enough to predict its direction and use monetary policy to steer inflation closer to its monetary target (Omankhanlen, 2011; Achugamonu, Adegbite, Omankhanlen, Okoye, and Isibor, 2019). Economists point to the fact that when monetary forecasts turn out to vary widely from reality in most situations is proof that the economic model used in prediction may be grossly inadequate by way of omission of certain important variables (Kurotamunobaraomi & Ebiware, 2017; Omankhanlen, Senibi, and Senibi, 2016; Omankhanlen, Senibi, and Senibi, 2018). One of the most important variables often left out in inflation prediction models is stock market performance as monetary economists are often confused with how to integrate stock market performance into monetary prediction models (Gali & Gambetti, 2014; Isibor, Olokoyo, Arogundade, Osuma, and Ndigwe, 2018). Since a significant portion of household wealth in any country is held in the stock market, it ought not to be strange that volatility in stock prices could influence inflation outcomes through a wealth transmission mechanism.

Although numerous empirical studies have shown the relationship that exists between the Nigerian Stock Exchange All Share Index (an index which tracks change the stock prices of all publicly listed companies on Nigerian Stock Exchange) and inflation, the extent to which the market capitalization ratio to gross domestic product will be useful in predicting future inflation is yet to be fully understood or well researched by economists and financial experts. This study therefore seeks to investigate the cyclical association between prices of stock and inflation.

Literature Review

Stock prices can provide useful guidance in predicting economic growth or cycles and this has long been established empirically by numerous authors. For example, Farmer (2015) found that the stock market decline in 2008 was the primary reason for the great recession that followed between 2008 and 2009 after establishing that there existed a granger causal relationship between the stock market and unemployment rate in America. After showing that stock prices Granger causes unemployment rate in America, the study went on to show using a vector error correction model, that absent of monetary intervention by Central Bank, a significant crash in stock prices could lead to a spike in unemployment rate over the next one to four quarters.

Empirically, higher unemployment in a country could lead to an economic recession which is only the occurrence of two consecutive declines in economic output. This phenomenon may explain the occurrence of the great recession in 2008 when unemployment figure almost doubled, and the country entered its biggest recession since the great depression of the 1930s. This was not the first time Farmer had established a link between stock market cycles and economic cycles in the country.

In an earlier paper, Farmer (2012) had shown that changes in stock market wealth can also lead to changes in unemployment rate. Since a change in household wealth could lead to variation in the level of aggregate demand which then causes labour to be hired (or retrenched) in order to meet increase (or decrease) production levels to match effective demand. The link between stock market wealth and unemployment was recognized by Fama & Schwert (1977) who observed that during the 1990s, growth in stock market capitalization was accompanied by growth in employment rate in the country and vice versa in America.

Philips (1958) had earlier developed the popular “Philips curve” which explains that there is a negative relationship between unemployment rate and inflation rate such that an increase in unemployment rate should lead to a decrease in inflation as aggregate demand level contracts. The theory has now been improved upon after the stagflation of the 1970s which discarded the Philips curve with professional views on the relation between unemployment and inflation now in its third stage of evolution (Friedman, 1977). However, economists agree that a theoretical and empirical link exists between the unemployment rate and inflation rate. Since Farmer (2015) posits that stock market wealth is useful in forecasting unemployment rate and Friedman (1968) explains that a link exists between unemployment rate and inflation, it seems rational to anticipate a Vector Error Correction Model (VECM) in which stock market wealth could be useful in forecasting future inflation which could prove useful for monetary policy and investment decisions. Since the direction of the stock market performance could then provide hints of future inflationary pressure in the economy.

According to Bernanke & Gertler (2001), changes in asset prices could lead to changes in Central Bank's forecast of inflation, ultimately pointing to a link existing between current asset prices and future inflation in the country such that stock (asset) prices could be useful in monetary policy analysis in predicting future inflation. According to Tripathi & Kumar (2015), there exist philosophies on stock returns and inflation.

One philosophy lies in Fisher's hypothesis as explained by Irvin Fisher in 1930. Fischer effect defines some form of capital asset pricing model in which the actual return on stocks will be modelled as the real return compensations for both assumption of risk and inflation. This idea therefore flows from the belief that equities act as a hedge against inflation.

According to Boons, Duarte, de Roon & Szymanowska (2018), high inflation beta stocks demand higher inflation risk premium that lower inflation betas stocks, making lower inflation beta stocks the best hedge for inflation during periods where the nominal-real covariance is positive, meaning that a positive shock to inflation implies good news for future consumption. Inflation beta is derived by analyzing the sensitivity of the stock returns to variation in inflation.

Boons et al (2018) argued about inflation being priced into returns of stock and that inflation varies over time. This further gives credibility to the theoretical argument that stock prices inherently contain information about market expectation on future inflation and can therefore provide guidance for policy decision making since variation in interest rate will also affect the market's opinion on the direction on inflation which again will then feed into stock prices in a continuous feedback cycle.

Methodology

This study adopts the monetary transmission mechanism framework proposed by Olufisayo (2013) wherein inflation could be determined by variations in monetary variables such as money supply, credit, interest rates, exchange rates and asset prices. Theoretically, movement in inflation is stimulated through the monetary transmission channel, as changes in any of the monetary variables holding others constant can lead to variations in inflation. However, economists differ in the weight or importance placed on any of the monetary variable to independently explain changes in inflation as their influence on inflation tends to evolve over time and differ among countries.

According to Olufisayo (2013), the monetary transmission mechanism is the process through which monetary policy decisions are transmitted into changes in inflation and real GDP over time. For the purpose of this empirical analysis, the influence of monetary policy decisions that leads to changes in inflation will be the core focus as we seek to determine the extent to which variation in asset prices (particularly, stock prices) is useful in predicting changes in inflation over time in Nigeria. The study expects that including stock prices into the econometric model will help explain changes in inflation not only from a money market perspective which focusses heavily on changes in money supply but also from a capital market perspective which includes performance of the capital market which impacts on the investment income of households.

Model Specification

Based on Olufisayo (2013), the original model is stated in its implicit form as follows:

CPI = f (M2, DC, EXR, MPR, MCAP) …… (1)

Where:

CPI represents the consumer price index

M2 represents the broad money supply

DC represents the total domestic credit

EXR represents the exchange rate

MPR represents the monetary policy rate

MCAP represents the stock market capitalization

From the above stated model, we can see that there exists a theoretical link between stock prices and inflation. We therefore use this model as a guide to deciphering the cyclical relationship between market capitalization which is the proxy for stock prices and inflation.

Findings

To achieve the first objective which is to examine the short run relationship between stock prices and inflation, this study employs the contemporaneous correlation test. The Market capitalization (MCAP) is used to represent stock price while Inflation rate is represented by the Consumer Price Index (CPI). To address the objective, the business cycle approach used to separate the time series data into cycles and trends. This is achieved by employing a filtering procedure referred to as the Hodrick-Prescott (HP) (Alege et al., 2017; and Agenor et al., 2000).

A process involved in carrying out this technique is as follows: The series will be transformed into their natural logarithm form; the stationary properties of the series will be tested; detrending the series by obtaining the cyclical element; obtaining the autocorrelation statistics and also the cross correlation of the series (Alege, 2008; Isibor, Felicia, Maria, Godswill, and Chisom (2018). A good business cycle filter is one that can eliminate unit roots, remove phase shift and also isolate business cycle frequencies (Baxter and King, 1999).

The HP filter is useful as it helps to account for volatility in the time series variables. Secondly, it can measure whether there is a change in the variable before or after the output changes and finally, the cross-correlation coefficient measures the contemporaneous correlation of the variables. This will ascertain if a series is pro-cyclical or countercyclical.

Table 1 presents the contemporaneous correlation between stock market and Inflation. The results show that the degree of contemporaneous correlation between inflation and stock market is −0.0305 showing countercyclical relationship. This means inflation tends to rise when stock prices are falling and inflation falls when stock prices are rising.

The cross-correlation test can show which variable leads of lags the cycle. Therefore, it can reveal whether stock price is a leading or lagging indicator to inflation rate. When the maximum value of the cross-correlation coefficient between stock price and inflation falls on the left-hand side (lag), it means that stock price is the lagging indicator. On the other hand, if the maximum value of the cross-correlation coefficient between stock price and inflation falls on the right-hand side (lead), it means that stock price is the leading indicator. From table 1, the maximum cross correlation coefficient is 0.3723 suggesting that inflation lags stock prices. This means that changes in inflation rate happen after changes or fluctuations in stock prices.

Discussions from the Contemporaneous Cross Correlation result

The first objective of the study is to examine the cyclical relationship between stock prices and inflation. From the result shown in Table 1, and as confirmed in both figure 1 and figure 2, it was observed that inflation tends to rise when stock

prices are falling and inflation falls when stock prices are rising. A major explanation for the result is that investors would want to take advantage of rising stock prices to invest in the stock market and this would reduce inflation because any excess money in circulation will be used to increase investment positions rather than to increase consumption. However, when stock prices decline, most investors would quickly sell-off their securities and hold on to cash rather than invest. This could increase the money in circulation and result in higher inflation. Therefore, if the expected future return on investment is less than households desire, they will retreat to cash which could cause a problem of excess cash holdings and increased spending.

Empirically, this relationship between stock prices and inflation is evident in the past behavior of inflation and stock prices. For instance, in 2007, inflation had fallen to about 6.6 percent its lowest point in almost a decade which corresponds with when stock prices were most elevated in Nigeria. Rising stock prices had pushed market capitalization to GDP to about 30.9 percent which is the highest value of market capitalization to GDP ever recorded in the history of Nigeria.

This shows that higher stock prices led people to invest more in the stock market, which eventually reduced inflation. However, at the wake of the global recession, Market Capitalization went down from 30.9% in 2007 to 17.8 per cent in 2008. Simultaneously, inflation increased from 6.6% in 2007 to 15.1% in 2008. The recession which occurred in Nigeria in 2016 also shows this trend. Total Market Capitalization decline from 10.5% in 2015 to 9.1% in 2016 and resultantly, inflation increased from 9.5 per cent in 2015 to 18.55 percent in 2016. This result was confirmed by the study of Albulescu, Aubin and Goyeau (2017), Marx and Struweg (2015) and Fama (1981) where a countercyclical relationship was observed between prices of stock and inflation.

Summary

From the result of the contemporaneous correlation, the result provided evidence that there is a countercyclical relationship between stock prices and inflation rate. This implies that inflation tends to rise when stock prices are falling, and inflation falls when stock prices are rising. This therefore shows that stock prices is useful in forecasting inflation and market capitalization should be included in critical variables used in evaluating and forecasting inflation to achieve price stability.

Conclusion

This study proves that changes in household wealth as proxied by variations in stock prices overtime has a stronger influence on inflation than all other monetary factors. This means that spending behavior in the country has very little to do with the rate of interest in the market or rate of growth in the supply on money but rather on the promise of high future expected return from investing household wealth in capital market. In cases when market return on equities is high, households tend to invest more and reduce consumption whereas when market return on equities is negative, households tend to respond by selling their equity investments, returning to cash and increasing consumption.

This study goes further to prove that the trickle-down effect that Central Bankers have longed believed occur when household wealth increases that this tends to lead to an increase in their marginal propensity to consume is wrong. Rather the marginal propensity to save and invest tend to increase as households become richer and aggregate demand tends to suffer, thereby causing inflation to drop during periods of high stock market gains. Apparently, the promise of more returns in the stock market far outweighs the desire to consume today. So if Central Bankers wish to control household spending and inflation, their best bet will be to offer returns in the market so high that there is low or almost no liquidity preference for households to prefer to hold cash instead of financial assets.

Recommendations

Based on our empirical findings, the following recommendations were suggested:

1. Monetary policy makers may choose to use its control of the discount factor to influence stock prices movements and indirectly control future inflation through stock market cycles in both the short run and long run. Such that by extending stock market cycles, inflation could decline for an extended period of time.
2. Investors may recognize that stocks may not be a good hedge for inflation since we show that it is stocks that drive changes in inflation rather than the reverse.
3. Policies should be put in place to develop the local industries to boost local production and reduce import dependence.

4. The Central Bank could set the monetary policy rate in such a way that ensures that the natural rate of interest is equal to the market rate of interest which keeps inflation low and stable, thus, encouraging economic growth, price stability and domestic investment.
5. Both fiscal and monetary policy makers must set up policies that will support a stable exchange rate.

Resumen

El objetivo del trabajo presentado fue la determinación de la calidad del servicio prestado al turista médico como una oportunidad para el fortalecimiento del sector hotelero. Se determinó la calidad del servicio hotelero y para evaluar su nivel de satisfacción se seleccionaron turistas médicos durante su estancia de pos tratamiento. El análisis de los resultados mostró que el servicio recibido por el turista médico es deficiente. Este comportamiento se corresponde con el modelo de negocio que posee el sector hotelero en Barranquilla (orientado a la atención de turistas de negocios). Con base en los resultados del estudio, se sugiere que el sector hotelero podría introducir mejoras en su modelo de negocio, a través de una propuesta de valor diferenciadora dirigida a brindar atención al turista médico, constituyendo esto una alternativa para fortalecer su competitividad en el mercado.

Palabras clave: Calidad Del Servicio, Hotelería, Turismo Médico, Negocios.

Abstract

The objective of the work presented was the determination of the quality of the service provided to the medical tourist as an opportunity for the strengthening of the hotel sector. The quality of the hotel service was determined and medical tourists were selected during their post-treatment stay to assess their level of satisfaction. Analysis of the results showed that the service received by the medical tourist is poor. This behavior corresponds to the business model that the hotel sector has in Barranquilla (oriented to the attention of business tourists). Based on the results of the study, it is suggested that the hotel sector could introduce improvements in its business model through a differentiating value proposition aimed at providing care to the medical tourist, making this an alternative to strengthen competitiveness in the market.

Keywords: Quality of Service, Hospitality, Medical Tourism, Business

Introducción

Desde su génesis el turismo ha comportado cambios significativos a nivel de crecimiento y variedad, al punto que para el 2028 se proyecta que la industria de viajes y turismo sea uno de los segmentos económicos de mayor significancia a nivel mundial esperando un incremento del 11,7 % en el Producto Interno Bruto (PIB) global, según lo expuso la presidenta y CEO del Consejo Mundial de Viajes y Turismo (WTTC), Gloria Guevara Manzo en una sesión de medios en Madrid (Noguera, 2019). En este sentido, la predicción realizada por diversos organismos e instituciones internacionales estima un incremento sostenido a nivel mundial de los movimientos turísticos por el orden de 1.800 millones de viajes para el 2030 (OMT,2011).

En consecuencia, esta es una actividad que indiscutiblemente contribuye con el desarrollo económico de las localidades que lo adoptan como eje primordial de su dinámica comercial (Castro, Molina & Pablo, 2013). Adicional a ello, involucra en su cadena de servicio una serie de grupos de interés que generan diversas fuentes de empleo

(Schenkel, 2019) de orden temporal o fija, lo cual abona al logro de los Objetivos de Desarrollo Sostenible (ODS), en especial aquellos orientados a promover el trabajo decente como un significativo impulso para el crecimiento inclusivo (Ribeiro, 2017). En la actualidad, las necesidades de las personas han impulsado el surgimiento de otros tipos de turismo, originado a su vez nuevos nichos de negocio, ejemplo de ello es el turismo médico el cual es muy solicitado por un segmento de la población cada vez más interesado en cuidar su salud, abriendo enormes posibilidades para la elaboración de bienes y servicios, mediante una técnica distintiva emparejada con un proceso sinérgico que apunte a la construcción de clústeres entre las empresas del sector turístico y el sanitario.

En este orden de ideas, Fetscherin & Stephano (2016), produjeron un índice para determinar los destinos de turismo médico más demandados por la población a nivel mundial, el cual denominaron Índice de Turismo Médico (ITM). Para su cálculo se basaron en 4 dimensiones: a) Entorno del país, donde evaluaron elementos como similitudes culturales y lingüísticas, estabilidad económica y niveles de corrupción; b) Destino turístico, estudiando entre sus indicadores el atractivo, popularidad, exotismo y condiciones climáticas del destino; c) Costes del turismo médico, considerando aspectos como asequibilidad de las tarifas aéreas, costes del viaje, costes del tratamiento y costes de la estancia; y e) Instalaciones y servicios, evaluando el entrenamiento, la experiencia y la reputación de los médicos, los estándares de calidad en los cuidados y los servicios, reputación del servicio médico, las recomendaciones de familiares y amigos, entre otros. Todo ello dio como resultado el Top 30 de los destinos de turismo médico a nivel mundial, el cual es liderado por Canadá (76,9); seguido por Reino Unido (74,8) y en tercera posición Israel (74,8), mientras que Colombia (67,4) alcanzó el décimoctavo lugar siendo antecedido en Latinoamérica por Costa Rica (72,8) en sexto lugar, Brasil (67,9) decimosexto lugar y Jamaica (67,7) en el decimoséptimo lugar (Sánchez-Vergara,2017).

Ante este panorama, es interesante destacar que las investigaciones en el campo del turismo se enfocan hacia el turismo habitual, ya sea asociado al servicio hotelero o destinos más demandados (Akbar, Wadood y Alzaidiyeen, 2010), mientras que desde la perspectiva del turismo médico enfatizan el servicio que presta el sector salud, (Heung, Kucukusta, Song, 2011; Chuang, Liu; Yachi, 2014, Lovelock & Lovelock, 2018), y son escasos los que lo asocian al sector hotelero y el turismo médico (Sadeh y Garkaz, 2018) es por ello que la presente investigación se orienta a determinar las oportunidades de fortalecimiento del sector hotelero mediante la calidad de servicio que ofrece al turista médico. Para ello se procedió a entrevistar a diferentes actores y grupos de interés involucrados en ambos ámbitos salud y turismo con el fin de tener su percepción sobre este tema.

Para el grupo de hoteles se aplicó el instrumento diseñado por el MinCit, denominado Guía Estándares de Evaluación para la prestación del servicio de turismo de Salud, y para el grupo de turistas de salud o médicos se seleccionó el instrumento diseñado por Parasuraman, Zeithaml y Berry, 1991 denominado SERVQUAL, debido a que ha demostrado su fiabilidad y validez para medir la calidad del servicio desde las expectativas y percepciones que tienen los usuarios.

El producto alcanzado permitió determinar que el modelo de negocio de la mayor parte de los hoteles estudiados, no contempla una propuesta de valor orientada a satisfacer las demandas de este creciente segmento de la población turística, por lo cual la calidad del servicio percibido por los clientes no le genera la satisfacción esperada.

Calidad de servicio en el sector hotelero

Hablar de calidad de servicios turísticos, sin tomar en cuenta la opinión de los turistas sería inadmisible, ya que lo que está fuera del control de la empresa es imposible medirlo y sin este proceso de evaluación es inviable conocer el estado en el cual se encuentra la empresa que la lleve a emprender estrategias de mejora (Morillo,2007).

Es por ello que diversos autores han dado su aporte para definir la calidad de servicios, unos la plantean como la medida en que un producto o servicio responde a los requerimientos de quien lo adquiere o utiliza (Montgomery, 2009). Mientras que para otros es la brecha existente entre las expectativas o deseos de los clientes (servicio esperado) y sus percepciones (servicio recibido), agregando que la calidad del servicio es calificada por el cliente como la excelencia del servicio o producto al comparar las expectativas del servicio a obtener con la percepción de las acciones de las empresas proveedoras del mismo (Parasuraman *et al*.,1991). Desde la posición de Martin (1986), citado en Ruiz, Vázquez y Díaz 1995, p.21)

> La calidad de servicio es una combinación de dos dimensiones, la relativa al procedimiento, que es la que depende de los sistemas técnicos utilizados para prestar el servicio y la relacionada con la sociabilidad, asociada con la habilidad del proveedor para relacionarse con los clientes y captar sus necesidades.

Esta correlación entre procedimiento y sociabilidad aporta a la dilucidación de lo que se pretende evaluar para dar una aproximación a la calidad del servicio más coherente al sector hotelero de hacia dónde debe enfocar las mejoras

que contribuyan a elevar dicha calidad y con ello abonar a la satisfacción del cliente. Es así que varios estudiosos han desarrollado investigaciones destinadas a evaluar la calidad del servicio desde diversas vertientes como el estudio de Akbar, Wadood, y Alzaidiyeen (2010) en Malasia con el fin de establecer la relación entre las fallas del servicio que presenta el hotel y los factores como el valor percibido, la satisfacción del cliente y la lealtad en la industria hotelera. Los resultados arrojaron que el valor percibido y la satisfacción del cliente son las dos variables principales para obtener la lealtad del cliente, mediando y redirigiendo el efecto de la calidad del servicio.

Por su parte, Kuei y Lu (2013), analizaron la necesidad de implementar políticas de calidad en entornos donde la demanda es variable, como en el caso de los turistas, quienes cuentan ahora con múltiples vías para obtener información sobre las propuestas que los lleven a contratar el servicio o producto, siendo estas formas de acceder a la información sumamente distintas a las utilizadas en años atrás, aun cuando este estudio se perfila hacia el marketing, variable que no fue considerada en esta investigación, es significativo por cuanto las expectativas del cliente están vinculadas a la oferta que hace el alojamiento.

Mientras que, Aznar, Bagur y Rocafort, (2016), buscaron relacionar percepción de calidad por parte de los clientes de los establecimientos hoteleros con los resultados económico-financieros de los hoteles. Con el fin de determinar si la percepción de mayor calidad por parte de los usuarios se traduce en mejores resultados empresariales. Encontrando que estos no se relacionan significativamente, lo cual es consecuente con otras investigaciones publicadas donde pueden destacarse como posibles agentes causales el sesgo en las respuestas de los internautas o la no existencia de motivaciones internas en la implementación de sistemas de calidad.

Finalmente, Wu, Qomariyah, Sa & Liao, (2018) se propusieron investigar sobre la integración entre el valor del servicio y la recuperación del servicio en la industria hotelera mediante la adopción de un enfoque de Despliegue de la función de calidad (QFD) que integra el método del Proceso Analítico de Red (ANP)al servicio. Los resultados permitieron identificar cinco grupos de fallas en el servicio hotelero, que los clientes clasificaron de mayor importancia como a) la habitación; b) la llegada, facturación y salida; c) restaurante, comida y bebida y d) instalaciones y otros servicios. Mientras que por el lado de la recuperación del servicio los medios más efectivos para tratar las fallas fueron: “Corrección inmediata del problema”; “Disculpa”; “Reemplazo”; “Descuento”.

Cada uno de estos estudios, arroja elementos que el sector hotelero debe interpretar para tomar decisiones conducentes a la intervención de su modelo de negocio, con mejoras que conlleven a corregir las falencias encontradas en su servicio elevando así su calidad, sin embargo ello demanda involucrar en cualquier ecuación la opinión de quienes la han recibido, permitiendo pulsar el nivel de satisfacción que ha experimentado cada cliente al recibir el servicio, como lo esperaba, o como se lo ofrecieron, pudiendo hasta superar su nivel de expectativas. Esta condición óptima (Sorensson y Friedrichs, 2013), se asocia con la percepción que los viajeros tengan del destino donde la calidad de los servicios ofrecidos es fundamental. Por otra parte, no puede pensarse la calidad como un concepto único (Zeithaml y Bitner, 2000), ya que es necesario que lo hoteles den respuesta a las aspiraciones y demandas de los usuarios de turismo que cada vez son más diversos (Izquierdo, Lazo, Andrade, 2018).

Es por ello que, en la actualidad, el sector hotelero no puede garantizar la eficiencia del negocio basado únicamente en las condiciones de infraestructura de alojamiento, ya que el turista exige también encontrar un tratamiento personalizado, amigable, accesible y agradable a la vista, lo cual revela que la calidad del servicio se basa en las percepciones que el cliente obtuvo acerca de los servicios (Gadotti and França, 2009). Esto es compatible con lo expresado por Monfort, Defante, de Oliveira and Mantovani (2013, p 279).

> Si las necesidades básicas no fueron satisfechas, es decir, si la habitación no estaba limpia, los empleados no eran serviciales o hubo fallas en la comunicación, las instalaciones no van a ayudar. Se trata de un conjunto dinámico que debe ser trabajado.

Ahora bien, el punto neurálgico para cualquier establecimiento es determinar, con la mayor objetividad posible, la calidad del servicio que presta, hecho que engloba muchas dimensiones lo cual implica ampliar su nivel de complejidad, por esta razón las dimensiones y su medición han generado instrumentos que permiten la evaluación del constructo. En este sentido, destacan dos escalas que han sido representativas, una basada en el modelo propuesto por Parasuraman *et al.* (1985-1988-1991) y la otra por el modelo propuesto por Cronin y Taylor (1992).

En este momento, es propio fijar posición sobre lo que es la calidad de servicio visto desde el Modelo SERVQUAL, la cual es entendida como la opinión que tiene un cliente sobre la excelencia del servicio percibido (Parasuraman, Berry y Zeithaml 1991), esta calidad es medida mediante la escala del mismo nombre constitutiva de 22 ítems distribuidos en cinco dimensiones, ya que los clientes no distinguen la calidad del servicio como unidimensional sino que discriminan la información para llegar a una valoración sobre el servicio recibido (Zeithaml y Bitner, 2000).

El modelo de Parasuraman es conocido como el modelo SERVQUAL (Quality Service), este abarca el estudio de las expectativas del cliente sobre el servicio a recibir y las percepciones sobre el servicio recibido, esto lo hace a través de cinco dimensiones de la calidad del servicio (en principio eran 10 que fueron redimensionadas producto de las críticas recibidas) las cuales denominaron tangibilidad, fiabilidad, capacidad de respuesta, seguridad y empatía. Por su parte el modelo de Cronin y Taylor es denominado SERPERF (Service Performance) debido a que su enfoque se centra en evaluar solo las percepciones por considerar que la escala debía enfocarse en medir el desempeño de la empresa o servicio prestado, determinando así su efectividad. (Cronin y Taylor, 1994)

Sin embargo, es de destacar que ambos modelos se generan a partir de los aportes de Grönross (1984) conocido como modelo nórdico, basado en dos dimensiones: la calidad técnica asociada al servicio que recibe el cliente y la calidad funcional asociada con la forma en que el cliente recibe el servicio, estas dimensiones a su vez se hallan mediadas por la imagen corporativa, la cual actúa como un tamiz de la apreciación de la calidad, es decir, mientras más positiva sea esta imagen menor significancia tendrán los errores y el cliente estará más satisfecho.

Auge del Turismo médico

Para entrar en este tema cabe hacer una distinción pertinente entre turismo de salud y turismo médico, ya que el primero es incluyente, es decir, constituye las diferentes intenciones de las personas que se trasladan a otro lugar, para mejorar las condiciones de su salud (Ross, 2001), lo cual involucra no solo la parte médica sino también la de bienestar, como se desprende de la definición propuesta por Yu and Ko (2012) el turismo médico implica no solo viajar por tratamientos médicos sino buscar aquellos destinos que involucren la competencia técnica asociada a precios mucho más competitivos combinando los servicios médicos con la industria del turismo.

Mientras que para el Programa de Transformación Productiva (PTP) (2013, p. 13) son "Viajes con el objetivo primordial de recibir tratamientos curativos, estéticos o preventivos (enfermedades, dolores o intervenciones quirúrgicas).". Por parte de la Organización Mundial de Turismo (OMT) el turismo médico representa una variedad turística asociada al sector salud abarcando tratamientos de orden invasivo o no invasivo de carácter empírico, es decir, va desde el diagnóstico hasta la rehabilitación (OMT, 2018). Para efectos de la presente investigación se tomará en consideración la definición propuesta por Yu and Ko (2012) por considerar que esta aglutina los aspectos fundamentales para que el turista médico opte por un destino en particular.

A nivel mundial, el auge que ha tenido el turismo médico es producto de cambios sustantivos que se han producido para darle atención a las personas que presentan algún trastorno de salud o quieren practicarse alguna intervención quirúrgica en el extranjero (Poveda y Gallegos, 2018) abriendo oportunidades que pueden ser aprovechadas por los hoteles, con miras a fortalecerse en el mercado. Este aporte proveniente del turismo médico estaría permeado por una propuesta de valor diferenciadora en su oferta de servicios. Por consiguiente, el turismo médico representa una modalidad turística en la cual se enlazan diversos sectores interesados, dándole carácter de transdisciplinariedad cuyo involucramiento tributa elementos sustantivos tales como organización, desarrollo y ejecución haciendo que cualquier destino turístico incluya en sus paquetes de oferta los servicios donde cada grupo de interés es experto. (Martínez, 2016).

Este auge global ha guiado el interés de los turistas médicos marcando preferencias por algunos destinos de África y Asica como: Sudáfrica, Tailandia, Mongolia, Hong Kong, Barbados, India, y Corea del Sur (Yang, Hu, Sun and Chen, 2018). Mientras que, en Latinoamérica, destacan Estados Unidos, Canadá, Costa Rica, Brasil, Colombia, Jamaica (Sánchez-Vergara, 2017), teniendo en cuenta algunos criterios asociados tecnología, reconocimiento de los profesionales médicos, certificación de los centros de salud, asequibilidad en costos de procedimientos y tratamientos, entre otros.

Sin embargo, este tipo de turismo sigue creciendo en Colombia siendo preferidas las ciudades como Bogotá, Medellín, Cali y Barranquilla, como bien lo refleja el estudio de Triviño, Ovalle y Díaz-Solano (2018), cuando exponen que la ciudad de Barranquilla es uno de los polos objetivo para el progreso de la Costa-Caribe colombiana debido a su posición geográfica tan cercana a las ciudades turísticas de Cartagena y Santa Marta, que coadyuva a que Barranquilla se convierta, turísticamente hablando, en un entorno competitivo ligado al proceso de transformación tanto urbanística como económica que ha comportado en las últimas décadas. Este progreso se complementa con varios factores como la buena conectividad nacional e internacional, las diversas opciones de tratamientos médicos asequible que ofrecen los centros de salud y la variada oferta hotelera que hacen de esta ciudad un destino atractivo para el turista médico.

Entre los estudios realizados en materia de turismo médico destacan el De la Puente, 2015, donde analiza la dinámica del turismo de salud para el caso colombiano hallando como principal impulsor el aporte de los actores privados a partir del aprovechamiento de ventajas competitivas asociadas a costos, facilidades de acceso al país y colaboración de oficinas nacionales para la promoción de este tipo de turismo. Aunque por el otro lado, se hallaron falencias que

limitan el desarrollo del mercado, destacando el bajo nivel de bilingüismo, escasa información entre paciente-médico desde el país de origen hasta el de destino generando sobrecostos al turista internacional.

Otro estudio significativo fue el desarrollado por Yan et al, 2018, orientado a dar respuesta a uno de los problemas más importantes que presentan los turistas-pacientes, la selección de un destino óptimo donde realizarse su procedimiento médico. Para dar respuesta a esta problemática presentaron una nueva forma de tomar decisiones grupales con criterios múltiples (MCGDM) permitiendo evaluar y clasificar destinos de turismo medico con vaga información. Acompañado del enfoque de las relaciones de preferencias difusas neutrosóficas (NFPR) dando como resultado que los turistas- pacientes que no contaban con información, tiempo o paciencia pudieran expresas su incertidumbre sobre la valoración de sus preferencias.

Finalmente, se presenta el estudio desarrollado por Triviño, *et al.* (2018), quienes se propusieron caracterizar y tomar el turismo médico como diagnóstico para la conformación de un clúster. Los resultados caracterizan la capacidad y calidad de los tres centros de salud acreditados en la ciudad de Barranquilla, de un total de 390, que se encuentran habilitadas para prestar este servicio. Adicional a ello detectaron el nivel de individualismo en la cultura del tejido empresarial del sector y las falencias en cuanto al manejo de una segunda lengua como elemento sustantivo para el servicio de turismo médico. En consecuencia, plantean la necesidad de incorporar un número significativo de empresas acreditadas en el sector salud, así como adoptar una visión turística de región que facilite la vinculación de servicios complementarios de turismo.

Este estudio, abre la posibilidad de incorporar el sector hotelero como actor complementario en la prestación de servicios acorde a los requerimientos, necesidades y condiciones del turista médico, quien tiene limitadas posibilidades de hallar un alojamiento que le brinde un espacio de confort y los servicios específicos para poder culminar su fase de recuperación con calidad. Como pudo observarse, la mayoría de los estudios tratan por separado el turismo médico y el hotelero, brecha que aspira disminuir esta investigación, sin embargo, ambos conforman un binomio que abre múltiples oportunidades de negocio para dar respuesta a este segmento, lo cual permitiría contribuir aún más con la economía de la región. Máxime cuando al sector hotelero se han incorporado diversas trasnacionales que le han dado vivacidad a este importante sector, demostrando con ello que la ciudad cuenta con la capacidad para afrontar volúmenes considerables de turistas incluyendo a los que vienen por motivos de atención médica.

> Durante la última década, en el sector salud en Barranquilla se ha dado paso a la modernización de estructuras, actualización tecnológica y creación de nuevas instituciones, fortaleciendo la oferta de servicios. Ha sido un cambio significativo que ha impulsado en la ciudad el desarrollo económico en diversos sectores —afines o conexos— en las instituciones de salud, el sector hotelero y gastronómico (Triviño, et al. 2018, p.144).

En este sentido, cabe destacar que Barranquilla registró el 3.4% durante el 2017 representado por un ingreso de 113.809 turistas en comparación con los 72.519 reportados durante el 2016. (Migración Colombia, 2017, p. 22). Ahora bien, son muchos los estudios orientados a evaluar, determinar y analizar la calidad del servicio prestado al sector turístico, sin embargo, todos convergen en el turista convencional, evidentemente es el mayor segmento del sector, pero en los últimos años el turismo médico ha entrado de manera firme en el espectro del mercado y requiere de elementos diferenciadores al momento de acceder a un alojamiento, búsqueda que regularmente no es exitosa.

Ante este panorama, se hace necesario que la industria hotelera conozca las necesidades de los turistas médicos en cuanto a infraestructura, recursos humanos, requerimientos alimenticios y demás, prestándoles un servicio que deje satisfechos a sus visitantes, dado que muchos de estos turistas requieren de alojamientos apropiados a su condición, es decir, con ciertos requerimientos que le colaboren en su recuperación de manera armónica e integral. Adicional a ello, es menester considerar, que este tipo de turista nunca viaja solo, por lo regular viene acompañado de algún familiar o amigo cercano que también requiere de un servicio de alto confort que le ayude a manejar la carga de estrés físico y mental generado por la atención a un paciente, para cumplir con su rol de acompañante eficientemente.

Si bien el sector hotelero no es una institución de salud, el turista médico tampoco es un turista convencional, por lo cual su condición de paciente está presente, y sus necesidades y requerimientos se enfocan en desarrollar un proceso de rehabilitación adecuado. En este sentido los alojamientos deben estar conscientes que el servicio que se le presta a este tipo de turistas debe ser especial, tratando de articularse de manera sinérgica con los centros de salud de donde provienen estos turistas, para lograr prestar un servicio de calidad. (PTP, 2013). Sin embargo, es de destacar que el sector hotelero en Barranquilla, tiene centrado su foco de interés en el turismo de negocios, indicando este comportamiento que no hay un aspecto diferenciador hacia el segmento del turista médico que la selecciona como destino turístico para sus tratamientos o procedimientos de salud.

Metodología

El estudio tiene un enfoque cuantitativo, determinándose como descriptivo, por cuanto se analizaron las variables de manera individual para establecer, a la luz de las teorías y los datos la calidad del servicio prestado a los turistas médicos como una oportunidad para el fortalecimiento del sector hotelero en Barranquilla. De acuerdo a su línea en el tiempo, fue transversal con diseño no experimental debido a que los datos fueron recolectados sin que hubiese modificación alguna de ellos. El procedimiento para la recolección de información se realizó en campo. El hilo investigativo estuvo distribuido en 3 fases, la primera basada en la revisión de diferentes bases de datos tanto físicas como electrónicas para dar soporte teórico al estudio, en consecuencia, se tomaron libros, artículos científicos completos, tanto en inglés como en español, memorias de congresos y conferencias, informes de organismos e instituciones, entre otros.

En la segunda fase se aplicó un instrumento denominado Guía Indicativa de Estándares para la prestación de servicios de Turismo en Salud por parte del Sector Hotelero (PTP, n.d.) a los gerentes hoteleros que aceptaron ser parte de la población objeto de estudio, 15 en total, cabe mencionar que esta fase se desarrolló durante los meses de marzo-abril del 2018. En la tercera fase se aplicó la escala SERVQUAL (Parasuraman, *et al*.,1991) a los turistas, a través de sus médicos tratantes, por cuestiones de confidencialidad de datos. Fueron entregados en total 300 instrumentos, esta fase se desarrolló durante los meses de julio-noviembre de 2018. Cabe destacar que solo fueron devueltos 200 instrumentos debidamente diligenciados conformando la totalidad a analizar.

Guía Indicativa de Estándares para la prestación de servicios de Turismo en Salud por parte del Sector Hotelero

Esta guía es la herramienta propuesta por el PTP, que permite a los establecimientos del sector hotelero identificar su forma de participación en la oferta de servicios de turismo en salud. Como se desprende de esta especificación, la guía es de carácter exploratorio, ya que indica a los gerentes de hoteles aquellas áreas que requieren mejoras para poder prestar servicio a los turistas médicos.

El instrumento constó de 7 dimensiones agrupadas en 93 ítems, el direccionamiento seis (6), el talento humano seis (6), la infraestructura veinticuatro (24), atención al turista de salud treinta (30), comunicación con los turistas médicos cuatro (4), medición, análisis y mejora cinco (5) y, por último, sustentabilidad con dieciocho (18) ítems. Las alternativas fueron diseñadas bajo escala Likert que fueron de 0 a 5. Los datos se organizaron por dimensión en una hoja Excel y fueron exportados al programa SPSS para su cálculo descriptivo expresado en frecuencias y porcentajes. Para su valoración se elaboró un baremo de criterios.

Tabla 1: Escala de Criterios

Rango	Criterios
0-19	Sin estándar
20-39	Escaso estándar
40-59	Bajo estándar
60-79	Mediano estándar
80-99	Alto estándar
100	Excelente estándar

Modelo SERVQUAL (Quality Service)

Con este instrumento se midió la calidad del servicio hotelero dado al turista médico, se realizaron algunas adaptaciones simples orientadas a contextualizar los planteamientos al sector hotelero. Para utilizar este instrumento se obtuvo autorización del Dr. Parasuraman, uno de los autores de la escala SERVQUAL La misma consta de cinco (05) dimensiones que miden la calidad del servicio ofertado desde dos vías, la primera las expectativas que tienen los clientes (turistas médicos) sobre las condiciones que esperan encontrar durante su estancia en el hotel y la segunda las percepciones de estos mismos clientes, sobre el servicio recibido durante su estancia. Las dimensiones corresponden a: elementos tangibles (mobiliario, equipos e instalaciones, apariencia personal y alimentación); fiabilidad, asociado a la forma como el hotel presta el servicio a los clientes primando un servicio cuidadoso y confiable; capacidad de respuesta, que engloba el cuidado y asistencia que el hotel da a sus clientes de manera oportuna y sin dilaciones, manejando la disposición y voluntad para colaborar con ellos.

La dimensión seguridad, mide los conocimientos, habilidades y respeto, que se lo ofrece al cliente y por último la dimensión empatía, mide la conexión con el cliente al ponerse en su lugar, interpretando y entendiendo su situación, sus necesidades y sus conflictos, todo ello con el fin de darle una atención personalizada. Este cuestionario utiliza la escala de diferencial semántico (Osgood, Suci y Tannenbaum, 1957) que va de 1 a 7, donde el 1 representa, en la escala de las expectativas, el criterio de muy insignificante y el 7 muy importante. Mientras que, en las percepciones, el 1 representa el criterio de totalmente insatisfecho y el 7 totalmente satisfecho. Como puede notarse, tanto las expectativas como las percepciones se estimaron por el grado de importancia que le conceden los sujetos a cada una de las 22 afirmaciones o ítems del cuestionario.

Los valores de la escala que miden la calidad del servicio esperado y recibido por los clientes se obtiene calculando la diferencia entre las medias obtenidas por cada uno de los 22 ítem, tanto de las expectativas como de las percepciones, en las cinco dimensiones. Mientras que para determinar el valor de la brecha definitiva que arroja la opinión sobre la calidad del servicio recibido, se procede a restar el valor medio de la percepción al valor medio de la expectativa (P-E), si este es positivo (P > E) entonces la percepción superó la expectativa del cliente, considerando un alto nivel de calidad recibido. En caso contrario, si lo valores son negativos (P < E) se estaría en presencia de un bajo nivel de calidad percibido, ahora bien, si hay igualdad entre ambas (P = E), se estaría en presencia de un modesto nivel de calidad del servicio recibido.

Resultados Y Discusión

Los datos del instrumento denominado Guía Indicativa de Estándares para la prestación de servicios de Turismo en Salud por parte del Sector Hotelero, se reflejan en la tabla 2 con los porcentajes de las frecuencias estadísticas arrojadas para los siete factores evaluados, en ella se evidencia que los factores con mayor estándar fueron la comunicación con los turistas médicos y la medición, análisis y mejora de los estándares para prestar un servicio de salud, ambos con un 100% cada uno, correspondiente a excelente estándar, seguidos de la sustentabilidad con un 89,87% , y el direccionamiento con 85,3% ubicándose todos en el criterio de alto estándar, según el baremo, lo cual representa una gran fortaleza. Sin embargo, al comparar los porcentajes generales de las frecuencias (73,94), con el baremo diseñado, los mismos se sitúan en el criterio de mediano estándar, situación está que pudo verse afectada por los valores alcanzados, en el talento humano (29,31%) e infraestructura (35,55%) de los alojamientos, ubicándolos en el criterio de escaso estándar.

Estos resultados son consecuentes con lo que plantean Triviño, *et al*. (2018) donde una de sus conclusiones evidenció las falencias en del Talento Humano en cuanto al manejo de una segunda lengua como elemento sustantivo para el servicio de turismo médico, coincidiendo igualmente con la opinión De La Puente (2015) donde se evidenciaron falencias que limitan el desarrollo del mercado, destacando el bajo nivel de bilingüismo, escasa información entre paciente-médico desde el país de origen hasta el de destino generando sobrecostos al turista internacional. Como se desprende de estos resultados, el talento humano del sector hotelero estudiado muestra no estar a la altura de las responsabilidades que implica la atención a un turista-paciente, muchos de estos clientes provienen de países de habla inglesa en consecuencia no solo el personal de check in-check out o customer service debe demostrar dominio de una segunda lengua, hace falta que todo el personal que esté en contacto con el cliente, además este personal debe estar capacitado para la atención de usuarios de servicios de turismo en salud, que incluya, formación en primeros auxilios, identificación de señales de alarma, reanimación cardiopulmonar básica (RCP) o curso de primer respondiente.

En correspondencia con lo anterior, la industria hotelera requiere conocer lo que necesitan este segmento de la población turística y darle la atención adecuada, en cuanto a infraestructura, recursos humanos, alimentación, entre otros para prestar este tipo de servicio y dejar satisfechos a sus visitantes. (Portafolio, 2014), lo cual corrobora que los clientes no distinguen la calidad del servicio desde la unidimensionalidad, sino que discriminan la información para llegar a una valoración sobre el servicio recibido (Zeithaml y Bitner, 2000)

En cuanto a los resultados generales de la escala SERVQUAL, que contemplan las brechas entre expectativas y percepciones denotadas por los turistas médicos encuestados se presentan en la tabla 3, donde se observa claramente que todas las dimensiones comportan valores negativos, lo cual evidencia que las expectativas de los turistas médicos no fueron superadas por el alojamiento, traduciéndose desde la interpretación de los datos en un bajo nivel de calidad del servicio recibido, es decir, el cliente no fue satisfecho.

Siguiendo con el análisis, los resultados arrojan que la mayor distancia se ubica en la dimensión elementos tangibles con una amplitud de -0,637 lo cual representa el más bajo nivel de calidad percibido, es decir, los turistas médicos, en líneas generales, no quedaron satisfechos con la apariencia del alojamiento, la modernidad de los equipos, la alimentación recibida, ni la apariencia del personal que los atendió. Es probable que la apariencia del hotel no haya sido un factor determinante, por cuanto la mayoría de ellos cuentan con instalaciones modernas, sin embargo, el hecho de no contar con habitaciones mínimamente acondicionadas para la atención del turista médico, así como el servicio de alimentación especializada, pudo haber afectado su percepción. En este sentido se ratifica que los huéspedes de hoteles son exigentes con la calidad de las instalaciones, es por ello que algunos alojamientos confunden, el nivel de las instalaciones con la calidad del servicio, pero si las necesidades básicas no fueron satisfechas (ejemplo si la habitación no estaba limpia, si los empleados no fueron serviciales, si el servicio fue tardío, entre otros), las instalaciones no van a ayudar. "Se trata de un conjunto dinámico que debe ser trabajado". (Monfort *et al.*, 2013, p. 279)

De igual manera, la dimensión seguridad comportó un valor de -0,542 lo cual representa que el servicio asociado con una conducta de respeto, tranquilidad, confidencia y privacidad en la atención al cliente, no fueron lo suficientemente cubiertas por el hotel, lo cual se tradujo en un bajo nivel de satisfacción para el turista médico. Si bien la mayoría de los hoteles cuenta con caja de seguridad para salvaguardar las pertenencias de los clientes, el turista médico requiere de otros mecanismos que le permitan el resguardo de los insumos médicos necesarios para su tratamiento de recuperación durante sus salidas, esto se afianza aún más cuando el personal que está en contacto directo e indirecto con el cliente no le inspira confianza. Acá se pone en relevancia el papel que juega la gerencia como cabeza principal, para dar la importancia requerida a las necesidades y requerimientos de los turistas de salud, debido a que la calidad se fundamenta en las percepciones que el cliente tiene sobre los servicios recibidos (Gadotti y França, 2009). Así las cosas, el valor percibido y la satisfacción del cliente son las dos variables principales para obtener la lealtad del cliente, mediando y redirigiendo el efecto de la calidad del servicio. (Akbar *et al.*, 2010).

Como se desprende de los resultados, el sector hotelero no está brindando a los turistas médicos un servicio diferente al que acostumbra a ofrecer al resto de turistas, lo cual corrobora lo expresado por Monfort *et al.* (2013) la calidad va más allá de un buen alojamiento siendo los huéspedes de hoteles muy rigurosos con esta, ya que la calidad del servicio es sistémico e integral y solo bastará con que alguna de las expectativas no sean satisfechas para que el alojamiento no sea bien valorado, como se evidencia en la tabla 3 de resultados,

Tabla 3: Brecha Integral Resultados de la calidad del servicio prestado a turistas médicos

	Expectativas		Percepciones		
	Media(e)	Desv. Estándar	Media(e)	Desv. Estándar	Brecha
Elementos tangibles	6,500	0,000	5,863	0,252	**-0,637**
Fiabilidad	6,280	0,274	5,790	0,220	-0,490
Capacidad de respuesta	6,600	0,250	6,075	0,264	-0,525
Seguridad	6,280	0,214	5,738	0,263	**-0,542**
Empatía	6,380	0,274	5,910	0,174	-0,47

Conclusiones y Recomendaciones

Colombia y en particular Barranquilla, siguen posicionándose en el radar de muchos turistas de salud, son muchas las características que la hacen un destino tentador en este ámbito, la facilidad de conexión, la tecnología de avanzada en las diversas disciplinas, la calidad probada y reconocida internacionalmente de sus médicos y centros de salud, la planta de hoteles de talla mundial, la competitividad en los costes de procedimientos quirúrgicos y de tratamientos de menor complejidad, entre muchos otros, sin embargo, se ha puesto en evidencia algunos aspectos que limitan el aprovechamiento de las oportunidades que se derivan del turismo médico: a) Inexistencia de una oferta de servicio diferenciadora dirigida a capturar al segmento de turismo médico; b) Un servicio homogéneo prestado al turista médico que no difiere de la atención prestada al turista convencional; c) Poca información y formación del talento humano para atender a un turista médico; d) Falencias en la demostración de competencias como el multilingüismo o en su defecto el dominio del idioma inglés, relaciones humanas, comunicación asertiva y capacidades técnicas para relacionarse con un turista-paciente.

En consecuencia, sería recomendable sugerir al sector hotelero iniciar una revisión de su modelo de negocios para poder iniciar un proceso de mejora que incorpore una oferta de valor diferenciadora, basada en el conocimiento específico de sus necesidades, requerimientos e incertidumbre, destinada a capturar la atención e interés del turista médico para seleccionarlo como alojamiento apropiado durante su recuperación, de igual manera, el sector hotelero fortalecería su competitividad en el mercado al visibilizarse en el espectro del turismo de salud y al vincular en su cadena de servicios a otros grupos de interés como agencias de viajes, enfermería privada, transporte, insumos médicos (farmacias, microempresas de equipos médicos, entre otros) lo cual a su vez lo haría parte del grupo de empresas que no solo tienen el propósito de lucrarse sino de contribuir a lograr algunos de los Objetivos del Desarrollo Sostenible, pues al vincular a otros grupos de interés minoritarios estaría abogando por un trabajo digno que minimice los índices de pobreza en la región.

Abstract

Local communities in many countries are working hard to improve the level of sustainable development. It is important to pursue an appropriate development policy at the local level, including security policy in order to eliminate social, economic, political and environmental threats. Considering the above, it can be concluded that the main objective of the article is to analyze the relationship between the effectiveness of the local security policy, reflected in the high sense of security of the inhabitants of rural areas in the Kuyavian-Pomeranian Province (territorial unit in Poland), and the level of achieving sustainable development goals by the districts inhabited by them. As a research method, we used a survey and conducted it in the Kuyavian-Pomeranian Province. From all the empirical material, only records concerning rural areas were selected. Then a synthetic measure was constructed from the total of the obtained results. It has shown that the analyzed districts represent an integrated measure of development significantly in the analysis. This means that within one administrative unit (province), the area of areas significantly varies with proving ground development. The analysis of the statistical correlation proves the lack of a statistically significant correlation between the effectiveness of the local security policy and the level of sustainable local development in the rural areas of the Kuyavian-Pomeranian Province. So far, no research has been carried out on the effectiveness of local security policy and the sustainable development of rural areas in the Kuyavian-Pomeranian Province. The conducted research is an analysis based on a wide range of towels influencing the sustainable development of the region.

Keywords: Sustainable Development, Rural Area, Local Security, Security Policy

Introduction

Many of the challenges facing the mankind, such as climate change, water scarcity, inequalities and hunger, can be solved not only at the global level (Walewicz, 2018, 2019; Gierszewski, Siemiątkowski and Urbanek, 2020), promoting sustainable development, but, above all, at the local level. Local communities in a number of countries are working hard to improve the level of sustainable development. They are the decision-makers and catalysts of change that unite global goals with their own local ones. In the above context, it is important to conduct an appropriate development policy at the local level, including security policy.

Local security policy should strategically ensure the sustainable development of the local community, while eliminating social, economic, political and environmental threats.

Local security policy has two dimensions:

a) actions of the state aimed at ensuring security, especially in the context of the subject - systemic (but also, as mentioned by some researchers: public security or social peace);

b) political concepts of security, based on traditional political doctrines - implemented or to be implemented in accordance with the declarations of the winners or local elections (Siemiątkowski and Tomaszewski, 2020, p. 29).

Cite this Article as: Piotr SIEMIATKOWSKI, Patryk TOMASZEWSKI, Joanna MARSZALEK-KAWA and Adrianna CZARNECKA " The Effectiveness of the Local Security Policy and Sustainable Development of Rural Areas in the Kuyavian-Pomeranian Province in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

We can distinguish other approaches to politics, not only in relation to local activities. so both politics and policy. Politics is sometimes reduced to pragmatic executive actions implemented by local government, mainly based on the guidelines of central authorities. Politics is then treated as a way of performing these tasks. It has been observed that “the concept of security policy covers, generally speaking, the activities of a given entity in some area in order to achieve previously adopted goals. This means that first, far-reaching goals had to be set by politics in a given, important area of operation" (Pokruszyński, 2011, p. 9). In the model approach, local policy is influenced by the concepts of state policy (strategies, programs), followed by financial resources for their implementation. In addition, politics in the region is important; it refers to cooperation programs between local governments in a given field, as well as development strategies of individual local governments, which are assumed to implement the electoral programme announced by election committees gaining power in a given local government (Siemiątkowski and Tomaszewski, 2020, p. 35). Local security policy should be carried out in coherence not only with central guidelines and indications, but in cooperation with residents (public consultations, cooperation with non-governmental organizations) and the economic environment.

Polish strategic documents, in line with international policy, specify that actions taken in the context of local security policy should be consistent with the principles of sustainable development. Sustainable socio-economic development is one of the most important challenges of the modern world. This concept was defined by the G. Brutland World Commission for Environment and Development established in 1983. It defined sustainable development as one in which the needs of the present generation can be met without depriving of the ability to meet the needs of future generations. This development relates to environmental, economic and social aspects (World Commission on Environment and Development, 1987). There are several other definitions of sustainable development in the literature. The definition proposed by Polish researcher Barbara Piontek is: "sustainable growth is such a growth, the essence of which is to ensure lasting improvement in the quality of life of contemporary and future generations by shaping the right proportions between three types of capital: economic, human and natural" (Piontek, 2002, p. 27).

In Poland, the document "Strategy for responsible development" from 2017 states: “Responsible development is development in which the needs of the present generation can be met without diminishing the chances of future generations. It is important to properly shape the relationship between the competitiveness of the economy, care for the environment and the quality of life. Thus, responsible development relates to economic, social, environmental, territorial and institutional issues. This means socio-economic development in which the process of integrating political, economic and social activities takes place, while maintaining the natural balance" (Ministerstwo Rozwoju, 2017, p. 35). As noted in the document, local government is an important link in this development. It is possible to analyze the activities for local security in rural areas, which are the foundation for the sustainable and balanced development of the country. In Poland, the development of small and medium-sized towns, especially rural areas, is particularly important in the local area. These often struggle with security issues, which are undoubtedly weak points in sustainable development. They include:

- unemployment rate affecting the sense of economic security;
- access to education and childcare;
- access to health care, especially specialist;
- environmental protection, especially accessibility to landfills, sewage treatment plants, household sewage treatment plants;
- green areas and afforestation;
- access to public transport;
- access to services;
- social participation.

The main goal of the article is to analyze the relationship between the effectiveness of the local security policy, expressed in the high level and sense of security of the inhabitants of rural areas of the Kuyavian-Pomeranian Province – located in the central and northern part of Poland. The total population of the province in 2016 was 2,083,000. 1,239,000 people lived in cities, while 844,000 people inhabited rural areas. The province is divided into 23 districts – including four cities with district rights. These are, in turn, divided into smaller territorial units – communes (there are 144 of them – municipal, municipal-rural and rural ones). The paper identifies the level of achieving sustainable development goals by the specific districts. In addition, the specific objective was implemented, i.e. the ranking of rural districts in the Kuyavian-Pomeranian Province in terms of the degree of implementation of the sustainable development goals was created. It was prepared with the application of linear ordering methods. In order to identify the sense of security among the inhabitants of the Kuyavian-Pomeranian Province, we applied questionnaire studies conducted between November 2017 and February 2018. The sample was selected in a targeted random way. The study was carried out using the PAPI (Paper and Pencil Interview) questionnaire. Targeted sampling consisted in interviewing the inhabitants of 19 districts of the Kuyavian-Pomeranian Province, while its randomness stemmed from the character of the research - the respondents had to be

willing to provide answers. There were 4,400 participants of the study. They answered questions concerning economic, political and health security and evaluated the efficiency of services (police, fire service).

In the study, the following research questions were asked:

Q1: Do the rural districts of the Kuyavian-Pomeranian Province strive to implement the assumptions of the sustainable development strategy to an equal extent?

Q2: Does the effectiveness of the local security policy in the surveyed territorial units affect the implementation of sustainable development goals?

The research process requires the following hypotheses:

H1: The examined districts show significant differences in taxonomic distances between synthetic indicators of sustainable development.

H2: The level of sustainable development is strongly correlated with the level of effectiveness of the local security policy. Hypothesis number two formulated in this way has its substantive justification. Theoretically, there is a cause-and-effect relationship between the level of sustainable development and the level of safety. Security is a basic human need. Having satisfied it, we feel an urge to fulfil higher needs, such as sustainable development.

Theoretical Background

From the national and local perspective, when pursuing a sustainable development policy, the following principles should be taken into account:

- sustainable development (balance of economic and social goals related to environmental protection; a holistic view of economic, social and environmental issues);
- non-discrimination in political, social and economic life;
- solidarity (including solidarity within and between generations);
- cohesion (territorial, regional, regulatory);
- public good and a democratic state (GUS, 2010, p. 10).

There are numerous publications on the safety of the local community, also in relation to the Kuyavian-Pomeranian Province in Poland (Gierszewski, Siemiątkowski and Urbanek, 2020; Siemiątkowski and Tomaszewski, 2020; Siemiątkowski *et al.*, 2020). A lot of research was conducted on the role of local government in the process of local development (Akukwe, 1996). In the context of local development, it is important to effectively manage shared resources, which also include local security. It is worth searching for effective tools to influence both central authorities and, above all, local governments, in order to direct the entire public administration system to stimulate local communities to effectively use common resources (Ostrom, 2009; Hurynak and Kordonska, 2018).

Since sustainable development was defined in 1983, it has been the subject of numerous studies. Papers have been published on the possibilities and anomalies of introducing sustainable development in general (Cooper and Vargas, 2004; Littig and Grießler, 2005; Du Pisani, 2006; Polski, 2009; Elliot, 2012) and in the context of Poland (Parysek, 1995; Brol, 1998; Noworól, 2007; Senczy, 2013). There are also more specific studies concerning sustainable development, especially in the fields of economy and ecology (Marsden and Smith, 2005; Polski, 2009).

Due to the changing role of cities, more and more attention is paid to the issue whether cities can develop in accordance with the principles of sustainable development (Basiago, 1996; Newman, 1996; Satterthwaite, 2009; Menegat, 2016). Research focuses on their influence on human security in areas such as sustainable local development, human rights and environmental protection, which are components of human security. It is shown that cities can significantly contribute to the safety of people, and thus to local development, including the rural areas that surround them (Szpak, 2015; Satterthwaite, 2016).

Rural areas play a special role in the research on sustainable development. The specific subjects include sustainable development in rural areas is analyzed in terms of both human capital as a factor of rural development, education, health care, as well as social problems of renewable energy development in rural areas (Kapur, 2019). A lot of attention has been paid to the state's tasks within rural activities, examining various contexts of these activities, from technological development through comprehensive rural planning and cooperation with cities (Knaap and Chakraborty, 2007), to the sustainable development of rural tourism (McAreavey and McDonagh, 2011; Lane and Kastenholz, 2015). What is an important element is innovative management that can meet the challenges of sustainable development (Biermann, Kanie and Kim, 2017).

Another significant determinant of both the level of local security and sustainable development is the quality of life of the inhabitants of local communities. The higher the level of the quality of life, the greater the attachment to the place of residence (Jankowska, 2014). Differences in the quality of life, on the other hand, result in the emergence of migratory movements and the movement of the population (Jankowska, 2013).

Methods

Two types of methods were used in this study. First, a fragment of a wide-ranging survey conducted by the authors in the territory of the Kuyavian-Pomeranian Province located in central Poland was presented. From all the empirical material, only records concerning rural areas were selected. The number of observations obtained was N = 1715. A synthetic measure was constructed from all the results obtained.

For this purpose, linear ordering methods were used to assess the level of object differentiation using a closed set of statistical features (Grabiński, Wydymus and Zielaś, 1989). The adopted method was described, inter alia, in other studies by the authors (Siemiątkowski, 2017; Siemiątkowski *et al.*, 2019, 2020; Gierszewski, Siemiątkowski and Urbanek, 2020; Siemiątkowski and Marszałek-Kawa, 2020), so there is no need to discuss it in detail. It is only worth noting that the standardization of features was carried out based on model methods, assuming the existence of a model object in relation to which taxonomic distances of the examined objects were determined.

The synthetic measure was calculated using Hellwig's method according to the formula:

$$d_i = 1 - \frac{d_{i0}}{d_0}$$

where:
d_{i0} − Euclidean distance of the object x_i from the reference object x_0,
d_0 − the critical distance of a given unit from the pattern (Ostasiewicz, 1998).

The individual elements of the local security system assessed in the aforementioned empirical study were adopted as the features of the examined facilities (districts), assessment of the sense of security and the prospects of its changes.

The same method was used to create a ranking of rural districts in the Kuyavian-Pomeranian Province in terms of achieving sustainable development goals. The assessment of the degree of achievement of the sustainable development goals according to the methodology of the Main Statistical Office (*Główny Urząd Statystyczny* - GUS), consistent with the international methodology, consists of twenty-two groups of indicators. They fall into four main areas: social order, economic order, environmental order and institutional and political order. Almost 180 different types of measures have been defined in them, which help to track the progress of a territorial unit (a state or its part) in implementing the idea of sustainable development. These measures have been adopted in this study as the features of the examined objects (districts) when creating their ranking in terms of achieving the goals of sustainable development.

It is extremely difficult to compare this progress in aggregate terms, given the significant number of indicators. On the other hand, comparing territorial units by means of one or several selected indicators does not give an unambiguous answer to the question which provinces are faster and which are slower in implementing the sustainable development goals. In this case, the so-called multivariate analyses come in handy.

In order to carry out a taxonomic study of the progress in the implementation of the assumptions of sustainable development of districts in the Kuyavian-Pomeranian Province, 178 features of objects (districts) were determined on the basis of the Main Statistical Office data. It should be emphasized that the list of indicators taken into account in building the synthetic measure is limited by the assumptions of the sustainable development strategy themselves. This means that other features than those indicated in the statistics of the Main Statistical Office, compliant with the international guidelines on the goals of sustainable development, are not included here.

Table 1: The list of district features included in the process of building a synthetic measure

Order	Field	Indicator	Dimension	No
social	Demographic changes	Natural increase per 1,000 population	in total	X_1
		Balance of migration for the permanent	in total	X_2

		residence of people of working age per 10,000 working age population		
		Demographic dependency indicators	post-working age population per 100 working age population	X_3
			the number of non-working age population per 100 persons of working age	X_4
			post-working age population per 100 pre-working age population	X_5
	Public health	Infant deaths per 1,000 live births	in total	X6
		Share of deaths by cause in the total deaths	cardiovascular disease	X_7
			cancer	X_8
			respiratory system diseases	X_9
		Deaths of people aged up to 65 per 1,000 people at that age	in total	X_{10}
	Poverty and living conditions	Share of people in households using environmental social assistance in the total population	in total	X_{11}
		Average monthly gross remuneration (business entities employing over nine people)	in total	X_{12}
		Average usable floor space per 1 person	in total	X_{13}
	Education	Share of children covered by pre-school education in the total number of children aged three-five	in total	X_{14}
			in the countryside	X_{15}
		Indicators of the quality of education and the level of knowledge of students	passing the final exams in vocational upper secondary schools	X_{16}
			passing the final exams in general secondary schools	X_{17}
	Access to the labor market	Share of the long-term unemployed (longer than one year) in the total number of registered unemployed	in total	X_{18}
		The number of the registered unemployed in relation to the number of people of working age (as of December 31)	unemployed - women	X_{19}
			unemployed people with higher education	X_{20}
		Job offers for disabled people per 1,000 disabled unemployed	in total	X_{21}
		Share of graduates (not working yet) in the total number of unemployed	in total	X_{22}
			graduates - women	X_{23}
		Registered unemployment rate	in total	X_{24}

	Consumption patterns	Number of passenger cars per 1,000 population	in total	X_{25}
		Utilities consumption in households per year per capita	electric energy	X_{26}
			gas	X_{27}
			water	X_{28}
	Income adequacy in old age	Share of long-term registered unemployed (longer than 1 year) aged 55-64 in total unemployed aged 55-64	in total	X_{29}
		Share of people in retirement age in households using environmental social assistance in the total number of people of that age	in total	X_{30}
	Determinants of health	Injured in accidents at work per 1,000 employees	in total	X_{31}
		Outpatient clinics for 10 thousand. residents	in total	X_{32}
	Criminality	The rate of detection of perpetrators of crimes identified by the Police	in total	X_{33}
		Crimes identified by the police in total per 1,000 inhabitants	in total	X_{34}
			criminal	X_{35}
			economic	X_{36}
			road	X_{37}
			against life and health	X_{38}
			against property	X_{39}
	Road accidents	Victims of road accidents per 100,000 registered vehicles	wounded	X_{40}
			fatal accidents	X_{41}
economic	Economic development	Investment outlays in enterprises (current prices; excluding economic entities employing up to nine people) per one inhabitant of working age	per 1 inhabitant of working age	X_{42}
		Entities of the national economy newly registered in REGON per 10,000 working age population	in total	X_{43}
		Value of foreign capital of companies per capita of working age	in total	X_{44}
		Share of investment outlays according to Polish Classification of Activity in total investment outlays of enterprises (excluding economic entities employing up to nine people)	agriculture, forestry, hunting and fishing	X_{45}
			industry and construction	X_{46}
			trade; repair of motor vehicles; transport and warehouse management; accommodation and catering; information and communication	X_{47}
			financial and insurance activities; real estate market services	X_{48}
			other services	X_{49}

	Employment	Natural persons running a business per 100 persons of working age	in total	X_{50}
		Entities of the national economy entered in the REGON register according to size classes per 10,000 inhabitants of working age	in total	X_{51}
			micro (up to 9 people)	X_{52}
			small (from 10 to 49 people)	X_{53}
			medium (from 50 to 249 people)	X_{54}
			large (over 250 people)	X_{55}
	Transport	Length of bicycle paths	per 10,000 km2	X_{56}
			per 10,000 residents	X_{57}
		Length of local public roads per 100 km2	hard surface	X_{58}
			soil surface	X_{59}
		Share of municipalities' expenditure on public roads in total expenditure	in total	X_{60}
		Share of districts' expenditure on public roads in total expenditure	in total	X_{61}
environmental	Climate change	Carbon emissions from plants especially noxious to air purity	in total	X_{62}
		Municipalities' expenditure on air and climate protection per capita	in total	X_{63}
	Energy	Electricity consumption per capita	in total	X_{64}
			in the city	X_{65}
			in the countryside	X_{66}
	Air protectioon	Air pollutants emission from plants especially noxious to air purity	gas	X_{67}
			dust	X_{68}
		Share of impurities retained or neutralized in pollution abatement equipment in plants especially noxious to air purity in general	gas (without CO2)	X_{69}
			dust	X_{70}
	Land use	Forest cover	in total	X_{71}
		Afforestation intensity	in total	X_{72}
	Biodiversity	Share of legally protected areas in the total area	in total	X_{73}
		Share of green areas in the total area	in total	X_{74}
	Waste management	Amount of mixed communal waste from households collected annually per person	in total	X_{75}
		Share of communal and industrial sewage	in total	X_{76}

		subjected to treatment as percent of total amount of sewage requiring treatment		
		Number of household treatment plants	in total	X_{77}
		Illegal dumping sites	number per 100 km2	X_{78}
			area per 100 km2	X_{79}
institutional and political	Openness and participation	Number of registered foundations, associations and social organizations per 10,000 residents	in total	X_{80}
		Voter turnout in local elections	1st round	X_{81}
			2nd round	X_{82}
		Participation of women councilors and councilors with higher education in the legislative bodies of communes and districts	women	X_{83}
			people with higher education	X_{84}
	Economic instruments	Proceeds to municipal budgets due to service charges per capita	in total	X_{85}
		Funds from the European Union for financing EU programs and projects obtained by communes and districts per capita	in total	X_{86}
		Expenditure from budgets of communes and districts for servicing public debt per PLN 1,000 in the total revenues of communes and districts budgets	in total (communes and districts together)	X_{87}
		Share of investment expenditure of communes and districts in total expenditure	in total (communes and districts together)	X_{88}
		Share of the area covered by the valid local spatial development plans in the total area	in total	X_{89}

Additionally, it should be emphasized that the requirements of the adopted method impose certain rigours on the statistical features of objects. First of all, the data must be complete and collected according to the same methodology. Of the features meeting the above requirements, 35 were considered stimulants (X1t, X12t, X13t, X14t, X16t, X17t, X25t, X32t, X42t, X43t, X44t, X45t, X46t, X47t, X48t, X49t, X50t, X51t, X52t, X53t, X54t, X55t, X56t, X57t, X58t, X59t, X60t, X71t, X73t, X77t, X80t, X83t, X84t, X88t, X89t) and 24 were identified as destimulants (X3t, X4t, X5t, X7t, X8t, X9t, X10t, X11t, X18t, X19t, X20t, X22t, X23t, X24t, X26t, X28t, X29t, X30t, X31t, X64t, X65t, X75t, X76t, X87t). The remaining features did not meet the rigorous methodological requirements of synthetic taxonomic measures. The features qualified for further procedure did not show an excessive degree of correlation with each other, and therefore they were all included in the synthetic index.

Finally, the degree of statistical correlation of the two integrated measures described above was checked. This procedure was to verify hypothesis number two.

Research Results

After carrying out appropriate procedures (including the selection of a pattern and the standardization of features), the values of a synthetic measure reflecting the effectiveness of the local security policy in rural areas in the province under study were calculated. This measure was calculated on the basis of the results of empirical research on the level of the sense of security of the inhabitants of districts in the Kuyavian-Pomeranian Province (see Figure 1).

Fig. 1: A synthetic measure of the effectiveness of the local security policy of residents in the rural districts of the Kuyavian-Pomeranian province

The ranking presented in Figure 1 shows significant taxonomic distances between the synthetic measures of security policy effectiveness across individual districts. The difference between the best and the weakest district in the value of the synthetic measure was as big as over 0.6, which means serious differences in the level of the perception of safety in the local environment and in the assessment of the elements of the local security system between individual districts. It also means that despite the fact that they belong to the same province, the inhabitants of its particular areas show significant differences in the assessment of the effectiveness of the local security policy.

The maximum value of the synthetic index reflecting the level of the sense of security and the assessment of individual elements of the local security system was over 0.6 (for the Mogilno district). This means that it was in the second quartile of the index distribution, which corresponds to a high level of local security. Two other districts were in a similar situation: Radziejowski and Brodnica. Nine districts obtained the value of the synthetic index between 0.25 and 0.5, which means the assessment of local safety at the level of poor. The remaining local government units (7) were in the last quartile of the distribution with the measure below 0.25 (= very poor level of local security).

It is worth emphasizing that the research on which the ranking was based was not fully representative. However, due to the collection of a significant amount of empirical material, it has a significant informative value.

Fig. 2: A taxonomic measure of sustainable development for rural districts of the Kuyavian-Pomeranian Province

The second conclusion concerns the level of sustainable development in the rural districts of the Kuyavian-Pomeranian Province. One can see a clear difference both in the ranking positions themselves and in the value of the synthetic measure. The maximum value of the synthetic index was approximately 0.3. This means that all the examined districts are below the second quartile of the distribution of the index values. This can be interpreted as a low or very low level of sustainability.

It is worth emphasizing that the ranking of the level of sustainable development was constructed on the basis of objective indicators (see Table 1). Therefore, it is not burdened with the subjective assessment of respondents, as was the case with the ranking of the effectiveness of local security policy. It can thus be concluded that from the objective point of view it is more credible. On the other hand, the presented comparison proves that the objective assessments of economic reality do not always coincide with subjective social perceptions.

The analysis of the correlation between the size of both synthetic measures brings interesting results. Pearson's correlation coefficient is only -0.27. In fact, this means that there is no statistically significant correlation between the effectiveness of the local security policy and sustainable local development in the rural areas of the Kuyavian-Pomeranian Province. A deeper analysis leads to the conclusion that some indicators taken into account in the process of constructing a synthetic measure of the local safety level are correlated to a slightly greater extent with the taxonomic measure of development. In all cases, the correlation is negative. It also does not mean a statistically significant relationship. In statistical terms, integrated local development in the districts of the Kuyavian-Pomeranian Province may be influenced by: strong attachment to the local community (correlation coefficient -0.35), assessment of the sense of security (-0.34) and attachment to the place of residence (-0.34). However, the level of the correlation coefficient does not allow us to formulate unambiguous hypotheses in the discussed scope.

Summary

The use of a multidimensional taxonomic analysis to study the relationship between the effectiveness of local security policy and sustainable local development has undeniable advantages. First of all, it allows us to objectively show the differences between districts in terms of extremely complex, multifaceted issues. It shows these differences on the basis of a whole set of diverse characteristics rather than single parameters (e.g. growth rate).Thus, the multidimensional approach reflects the differences between the studied objects much more precisely.

The examined districts showed significant differences in the level of the integrated development measure. This means that within one administrative unit (province), there are areas that differ significantly in the level of sustainable development. Thus, the hypothesis number 1 was confirmed.

The analysis of the statistical correlation reveals the lack of a statistically significant correlation between the effectiveness of the local security policy and the level of sustainable local development in the rural areas of the Kuyavian-Pomeranian Province. A deeper analysis leads to the conclusion that some indicators taken into account in the process of constructing a synthetic measure of the local safety level are correlated to a slightly greater extent with the taxonomic measure of development. However, the low level of the correlation coefficient does not allow us to formulate unambiguous hypotheses in the discussed scope. Thus, hypothesis number two was rejected.

Abstract

A comparative analysis of sustainable development in the category of economic order at the regional level has been carried out. A comparison of the level of implementation of the guidelines for economic order in Polish provinces has been made. The following research questions were formulated: Q1: What are the methods to apply in order to assess the level of sustainable development in the light of the plethora of the strategic goals of sustainable development and the implementation indicators of these goals; Q2: Do Polish provinces implement the assumptions of the sustainable development strategy with comparable efficiency. The following hypotheses were formulated: H1: The objects under research show significant differences in terms of the taxonomic distances between the synthetic measure of development which confirms the validity of applying the multidimensional analysis for measuring the levels of sustainable development; H2: Polish provinces differ significantly in terms of the level of sustainable development in the category of economic order. The aim of this article is to objectively measure the progress in the implementation of the goals of the sustainable development strategy in the category of economic order by Polish provinces. In order to meet the formulated goal, a synthetic measure was built with a view to defining the implementation level of the goals formulated in the sustainable development strategy in the category of economic order.

Keywords: sustainable development, economic order, provinces, Poland.

Introduction

Nowadays, sustainable development is one of the most popular concepts among researchers of multiple scientific disciplines, including economics, management, political science and administration, sociology, technical science and the science of security. The reason for this is the broad scope and interdisciplinarity of the concept. Several hundred indicators describing sustainable development are classified under the so called 'four orders', namely: social order, economic order, environmental order and political-institutional order.

The subject of analysis in this paper is economic order. A comparative analysis of sustainable development in the category of economic order at the regional level has been carried out. A comparison of the level of implementation of the guidelines for economic order in Polish provinces has been made.

The aim of this article is to objectively measure the progress in the implementation of the goals of the sustainable development strategy in the category of economic order by Polish provinces. In this case, the expression 'objectively' means embracing the advances in implementing all the goals within one single synthetic measure. This means that the assessment of the level of sustainable development in the category of economic order in particular provinces was carried out using a simultaneous analysis into the multiple aspects of this development. In order to meet the formulated goal, a synthetic measure (reflecting the plethora of sustainable development indicators) was built (using taxonomic analysis methods) with a view to defining the implementation level of the goals formulated in the sustainable development strategy in the category of economic order. The values adopted by the measure allowed creating a

ranking of all the provinces under investigation in terms of their advancement in the implementation of the goals of sustainable development in the category of economic order.

Theoretical Background

The issue of sustainable development has been the subject of research for years. The concept has been developed since the 1980s as "an attempt to examine relations between development and the environment" (Banerjee, 2003, p. 151).

A number of definitions concerning this area have been formulated in the literature and many of them also emphasize its local dimension. What should be stressed, there is no single, universally accepted, definition of this notion.

Ruth Kelly, Lorcan Sirr and John Ratcliffe go as far as to call it "an intuitively defined concept" (Kelly, Sirr and Ratcliffe, 2004, p. 80). As Hartmuth,, Huber and Rink, indicate, this lack of a precise definition of sustainable development has made this concept become even more attractive and fashionable. Differences in interpretations dominated the scientific discourse at a certain stage, initiating a sort of a battle for the definition (Hartmuth, Huber and Rink, 2008).

Robert, Parris and Leiserowitz argue that the adaptability of the notion makes it an open and constantly developing idea which can change to fit situations and concepts that are very different in terms of time and space." (Robert, Parris and Leiserowitz, 2005, p. 20). What should be emphasized the notions of "sustainability" and "'sustainable development" are used interchangeably (Banerjee, 2003).

According to Patel , "Sustainable development approaches typically seek to recognize and act on common interests and hence focus on consensus building" (Patel, 2000, p. 386). The author also indicates that what is the most important element of the concept of sustainable development is the thinking of the future (Patel, 2000, p. 387). Patel Z. adds that it is necessary to maintain a large margin when undertaking to define the notion of sustainable development as this term is, by nature, quite susceptible to contextual changes – in specific conditions it needs to be re-interpreted (Patel, 2000). As Redclift put it, "it means different things to different people" (Banerjee, 2003, p. 152).

One of the most frequently quoted definitions of sustainable development is the one formulated by the World Commission on Environment and Development (WCED) in the 1987 Report Our Common Future (Bruntland Commission), according to which "sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts: 1. the concept of 'needs', in particular the essential needs of the world's poor, to which overriding priority should be given; and 2. the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs" (World Commission on Environment and Development, 1987).

Another definition was proposed by Agyeman and Evans, who perceive "sustainability as both an all-embracing concept and a long-term policy objective" (Patterson and Theobald, 1995). Moreover, they indicate that "there must be international, national and regional frameworks and guidance, it is local policy and action which will ultimately deliver sustainability" (Patterson and Theobald, 1995, pp. 197–198).

Having conducted an analysis of 100 definitions of sustainable development, "Gladwin et al. (1995) identified several themes, including human development, inclusiveness (of ecological, economic, political, technological, and social systems), connectivity (of socio-political, economic, and environmental goals), equity (fair distribution of resources and property rights), prudence (avoiding irreversibilities and recognizing carrying capacities), and security (achieving a safe, healthy, and high quality of life)" (Banerjee, 2003).

Another important aspect of the studies of sustainable development is the issue of the evaluation of efficiency in goal achievement in this respect. Devuyst defines this assessment as a process of recognizing, anticipating and appraising the influence that a variety of initiatives (including lawmaking, regulations, measures, programmes, plans and projects) and their alternatives may have upon the sustainable development of a society. The process encompasses the formulation of a formal report on the sustainability evaluation in such a way that it enhances the publicly accountable decision-making process (Devuyst, 2000, p. 68).

Stevart and Davis note that "the aspiration for sustainable development can only be achieved through an integrated system of functions and institutions" (Patterson and Theobald, 1995, pp. 29–36). They also point out the consensus goals and targets (specified in ratified treaties, documents and declarations) which focus on the basic definition of sustainable development that encompasses meeting people's needs, the reduction of hunger and poverty, and, at the same time, the preservation of the life support systems of the planet (Parris and Kates, 2003, p. 381; Jankowska, 2014).

Many of the challenges facing the humankind, such as climate change, water shortage, inequality, famine, etc. can be overcome not only at the global level (Walewicz, 2018, 2019) by promoting sustainable development, but at the local level in the first place. In many countries, local communities are working hard to improve the level of sustainable development. They are the decision-makers and catalysts of change who combine global goals with their own, local, ones.

By attempting to define the concept of sustainable development at the local level, the authors of the Local Agenda Planning Guide, "An Introduction to Sustainable Planning", a document prepared by the International Council for Local Environmental Initiatives (ICLEI) in 1996, stressed that "sustainable development requires that local economic development supports community life and power, using the talents and resources of local residents. It further challenges us to distribute the benefits of development equitably, and to sustain these benefits for all social groups over the long term. This can only be achieved by preventing the waste of ecological wealth and the degradation of ecosystems by economic activities" (ICLEI, 1996).

It should be pointed out, as Patterson, A., & Theobald, K. S. have proven in their studies, "the move towards sustainable development is being hampered by the creation of a new and less participatory form of local and regional governance, which is reducing the capacity of local communities to respond to the environmental agenda, in terms of establishing and implementing policies for sustainable development" (Patterson and Theobald, 1995).

That is why considerations on sustainable development on the local level significantly differ from those concerning the possibility of implementing sustainable development in general (Cooper and Vargas, 2004; Du Pisani, 2006, Jarosz, 2019), because local development is vastly dependent on the conditions of a given state, region, and local communities (Littig and Grießler, 2005). It is important to comprehend the specificity of applied solutions aimed to realize the assumptions of sustainable development adjusted to particular areas across the whole world (Patterson and Theobald, 1995; Patel, 2000; Cuthill, 2002; Corbiére-Nicollier, Ferrari and Jolliet, 2003; Hurynak and Kordonska, 2018).

Therefore, operationalization tries become very useful, while properly elaborated measurements simultaneously associated with the process of methodic planning make possible to efficiently design sustainable development on the local level (Brugmann, 1997; Hartmuth, Huber and Rink, 2008). It seems that the set of the measurements is opened and constantly extended. Among often omitted elements that may have a meaning for local development there are cultural heritage (Murzyn-Kupisz, 2012; Hełpa-Liszowska, 2013) or external intervention (Gorzelak, 2000). Significantly more often attention is paid to the meaning of innovations for management (Tuziak, 2005; Kozuch and Kozuch, 2012; Silvestre and Ţîrcă, 2019), cultural tourism (Małek, 2003; Istoc, 2012; Durovic and Lovrentjev, 2014), financial matters, such as civil budget (Redo, 2016; Redo and Siemiątkowski, 2017; Sobol, 2017), and infrastructure, which may directly or indirectly influence on the realization of the majority of sustainable development's goals (Thacker *et al.*, 2019). The increasing meaning in the process of sustainable development is assigned also to renewable resources (Østergaard *et al.*, 2020) and activities related to climate change (Cramer *et al.*, 2018), as well as to the studies on artificial intelligence (Vinuesa *et al.*, 2020) or cities and human security (Szpak, 2015). It is connected with the dynamic technological progress. Currently there are showing up first reflections on the meaning of the coronavirus pandemic for sustainable development (Berchin and Guerra, 2020; Pirouz *et al.*, 2020).

Methods

The assessment of the level of achieving the goals of sustainable development in accordance with the methodology of the Main Statistical Office (*Główny Urząd Statystyczny* - GUS), compliant with international methodology, is made up of twenty-two groups of indicators. They come under the following four major categories: social order, economic order, environmental order and institutional-political order. Under the economic order, there are the following groups of indicators: economic growth, employment rates, innovativeness, transportation and the pattern of agricultural productions. They define 17 indicators, characterised by 32 different types of measures which help track the progress of territorial units (a country or a part of it) in implementing the concept of sustainable development in the category of economic order.

Considering the significant number of indicators, a comparison of the total progress is extremely difficult. On the other hand, a comparison of territorial units with only one or a few particular indicators fails to give a clear answer to the question of which provinces are quicker and which are slower in implementing the postulates of sustainable development. In such an event, the so called multidimensional analyses can be of great help.

In this paper, the subject of taxonomic assessment is local sustainable development of Polish provinces in the category of economic growth. To this end, the methods of linear ordering, used for the assessment of the level of objects differentiation by means of a closed set of statistical features (Grabiński, Wydymus and Zielaś, 1989), were applied. The applied method has been described thoroughly by other authors so there is no need to give a detailed overview of it (Siemiątkowski, 2017; Siemiątkowski *et al.*, 2019, 2020; Gierszewski, Siemiątkowski and Urbanek, 2020;

Siemiątkowski and Marszałek-Kawa, 2020). However, it is noteworthy to say that for the purposes of this assessment pattern methods were applied, implying the existence of the model object against which taxonomic distances of the objects under research were set.

The synthetic measure was calculated on the basis of the Hellwig method according to the following equation:

$$d_i = 1 - \frac{d_{i0}}{d_0}$$

where:

d_{i0} – the Euclidean distance of object x_i from pattern object x_0,
d_0 – the critical distance of the particular unit from the pattern (Ostasiewicz, 1998).

In order to carry out the taxonomic research into the advances in the implementation of the sustainable development of Polish provinces in the category of economic growth 32 features of objects (provinces) were selected on the basis of the data. It should be stressed that the number of the indicators taken into account in constructing the synthetic measure is limited by the sustainable development strategy postulates themselves. This means that only the features included in the statistical data by GUS were taken into account. They are the features compliant with international guidelines on the goals of sustainable development in the category of economic growth. The following features were taken into account:

$X1_t$ – gross domestic product per capita (current prices) – total,
$X2_t$ – gross domestic product per capita (current prices) – Poland = 100,
$X3_t$ – the share of gross added value according to the Polish Classification of Business Activities (*Polska Klasyfikacja Działalności* - PKD) 2007 in the total gross added value – agriculture, forestry, hunting and fishery,
$X4_t$ – the share of gross added value according to PKD 2007 in the total gross added value – heavy and light industry,
$X5_t$ – the share of gross added value according to PKD 2007 in the total gross added value – construction,
$X6_t$ – the share of gross added value according to PKD 2007 in the total gross added value – trade, car repair, transportation and warehousing management, accommodation and gastronomy, information and communication,
$X7_t$ – the share of gross added value according to PKD 2007 in the total gross added value – financial and insurance activities, the property market servicing,
$X8_t$ – the share of gross added value according to PKD 2007 in the total gross added value - other services and natural persons conducting business activity per 100 persons in the working-age population,
$X9_t$ – investment outlays by sectors per capita (current prices) – total,
$X10_t$ – investment outlays by sectors per capita (current prices) – in the public sector,
$X11_t$ – investment outlays by sectors per capita (current prices) – in the private sector,
$X12_t$ – employment indicator by age – total,
$X13_t$ – employment indicator by age – 15-24 years of age,
$X14_t$ – employment indicator by age – 50 and more years of age,
$X15_t$ – employment indicator by gender - women,
$X16_t$ – employment indicator by gender - men,
$X17_t$ – employment indicator by education – higher education,
$X18_t$ – employment indicator by education – secondary and primary education,
$X19_t$ – natural persons conducting business activity per 100 persons in the working-age population,
$X20_t$ – outlays on research and development against GDP,
X21t – share of innovative enterprises by sectors in the total number of enterprises – in the service sector,
X22t – share of innovative enterprises by sectors in the total number of enterprises – in the service sector – in the manufacturing sector,
X23t – share of sold output of new or significantly improved products launched on the market over the past three years against the value of the total sold output,
X24t – length of express roads and motorways network per 100 km2,
X25t – length of railroads network in operation per 100 km2,
X26t – length of bicycle path network per 100 km2,
X27t – length of bicycle path network per 10,000 inhabitants,
X28t – average price of regular single ticket for city bus fare,
X29t – share of acreage of ecological farms (with certificate) in total agricultural acreage,
X30t – consumption of mineral fertilisers per 1 ha ,
X31t – total number of big farm animals per 1 ha,
X32t – share of large-scale farms in total number of farms.

It should also be noted that the requirements of the applied method put particular rigours on the objects' statistical features. Most importantly, data must be complete and collected under the same methodology. From amongst the

features meeting these criteria 27 of them were recognised as stimulants, 4 as destimulants, and one was eliminated. The features qualified for further procedure did not show excessive correlation in relation to each other as all of them were included in the synthetic indicator.

Research Results

Following the implementation of relevant procedures (including the selection of the pattern, features standardization), the values of the synthetic measure of sustainable development were calculated.

Fig. 1: The synthetic measure of sustainable development of Polish provinces in the category of economic order in the years 2015 and 2018

The ranking in Figure 1 shows significant taxonomic distances between the synthetic measures of particular provinces. The difference between the best and the worst province in 2018 in the value of the synthetic measure was as much as 0.4557. In 2015, the value was 0.4166. This implies considerable differences between particular provinces in achieving the goals of the sustainable development strategy in the category of economic order and significant development delays of some of the country's regions. What is more, over the three years covered by Figure 1 those differences became even bigger. The Masovian province with the country's capital city of Warsaw stands out for the better. It is probable, as the local government authorities of that province have stressed many times, that the capital on its own would achieve a much higher value of the synthetic measure.

The second conclusion regards the level of sustainable development in the counties of the Kuyavian-Pomeranian province. The maximum value of the synthetic indicator was almost 0.5. This means that all of the provinces under investigation are below the second quartile of the indicator's value distribution. This can be interpreted as a low and very low level of sustainable development. Once more, it is worth paying attention to the status and high level of the

economic development of Poland's capital city which 'pulls up' the counties and municipalities of the Masovian province.

High indicator values were also achieved by the Lesser Poland province, Pomeranian province and Lower Silesian province. They are provinces with large metropolitan areas and numerous business enterprises.

At the bottom of the ranking are the peripheral provinces, namely Subcarpation, Warmian-Masurian and Świętokrzyskie, i.e. the so called "eastern wall". It is noteworthy to say that the ranking covered a considerable number of features making it fully credible. They are economically underdeveloped regions. Despite pumping considerable resources in them over the past years (special 'Eastern wall' dedicated programmes financed from EU funds) they still lag behind central or western provinces of Poland in terms of economic development.

Table 1: The percentage change in the synthetic indicator and ranking positions of provinces between 2015 and 2018

Province	Percentage change in the synthetic indicator	2018 ranking position	Change in ranking position against 2015
Lower Silesian (Dolnośląskie)	5.09%	4	0
Kuyavian-Pomeranian (Kujawsko-pomorskie)	-0.04%	8	0
Lublin (Lubelskie)	1.10%	13	-1
Lubusz (Lubuskie)	10.70%	10	0
Łódź (Łódzkie)	-4.29%	7	0
Lesser Poland (Małopolska)	-0.94%	5	0
Masovian (Mazowieckie)	3.07%	1	0
Opole (Opolskie)	24.80%	12	1
Subcarpatian (Podkarpackie)	16.96%	14	0
Podlaskie (Podlaskie)	-8.05%	11	-2
Pomeranian (Pomorskie)	9.12%	3	0
Silesian (Śląskie)	0.00%	6	0
Świętokrzyskie (Świętokrzyskie)	-58.65%	16	-1
Warmian-Masurian (Warmińsko-Mazurskie)	42.92%	15	1
Greater Poland (Wielkopolskie)	4.55%	2	0
West Pomeranian (Zachodniopomorskie)	29.12%	9	2

To conclude this analysis, it is also noteworthy to point to the changes which occurred during the period under investigation. The data presented in Table 1 show explicitly that the position of many provinces over the three years changed significantly. As many as six provinces changed their ranking position. The West-Pomeranian province moved two places up, while the Podlaskie province fell two places down.

The values of the integrated measure changed considerably, too. The greatest 'loss' in this respect was reported by the Świętokrzyskie province. The value of the synthetic indicator fell by as much as 60%. This resulted in the drop of the province in the ranking by one position. The highest increase in the indicator value was reported by the Warmian-Masurian province – by almost 43%. This resulted in the shift of the province of one position up.

Conclusions

The application of the multidimensional taxonomic analysis in measuring the progress of provinces in achieving the goals of sustainable development has undisputable advantages. Primarily, it allows showing the differences in the level of achieving the goals of the sustainable development strategy between particular provinces. Furthermore, it shows the differences not based on single parameters (e.g. growth rate) but on a whole set of various features. Thus,

the multidimensional approach is much more precise in reflecting the differences between the objects under investigation (Siemiątkowski and Jankowska, 2020).

The researched group of entities is characterised by significant differences in the level of the indicators analysed within the framework of the sustainable development strategy in the category of economic order. Consequently, the level of the synthetic indicator is highly varied. It is noteworthy that as many as nine out of 16 provinces are in the lower quartile of the synthetic distribution indicator, i.e. below 0.25. The remaining provinces are in the second quartile of the distribution, i.e. between 0.25 and 0.5 of the synthetic indicator range.

The relatively big taxonomic distances between the synthetic measures for particular provinces with a relatively large number of features are a proof of significant differentiation of particular regions of Poland in terms of achieving sustainable development. Particularly, the Masovian province with the capital city of Warsaw stands out for the better. The provinces of the so called 'Eastern wall' fare the worst. Despite the considerable outlays under UE programmes towards economic activation of these regions their level of development still leaves much to be desired.

Abstract

In the current situation associated with COVID-19, radical measures concerning social distance and mobility are increasingly being introduced. Borders are closing, but life in hospitals is experiencing trials for which no one has been sufficiently prepared. Infected people who need health care come to the hospitals. At the same time, to protect those who are in the hospital due to other problems and not to put them at risk. We also encounter a number of problems associated with the provision of medical supplies and equipment, the organization of newly established health departments, the adoption of adequate legislative standards, etc. We are witnessing the emergence of cohesion between peoples and countries and, at the same time, egoism at various levels. These events develop in conditions of relatively intensive migration of health workers. Its causes are mainly related to differences in working conditions and remuneration of health workers in individual countries and their shortage. The occurrence of the coronavirus epidemic has updated and multiplied the need for health professionals around the world. At the same time, from a common point of view, it is not clear what is happening with the migration of health professionals in the conditions of COVID-19. Several events and measures taken in individual countries should strengthen the migration of health professionals, while others should dampen and even suspend or re-emigrate (return home). What is actually happening with the migration flows of health workers, especially in European countries, is the subject of analyzes and findings of the study.

Keywords: Migration, COVID-19, Health Workers.

JEL Classification: I15, J61, J62.

Introduction

Only after a while do we begin to realize how this epidemic is changing and changing our daily lives. In the context of COVID-19, radical measures concerning social distance are being introduced more and more. People are encouraged but also forced to remain isolated both at home and in work teams. The activities of educational institutions, leisure facilities, cultural and sporting events are limited. The borders have closed, but life in hospitals is experiencing trials for which no one has been sufficiently prepared. The occurrence of the coronavirus epidemic has updated and multiplied the need for health professionals around the world. At the same time, from a common point of view, it is not clear what is happening with the migration of health professionals in the conditions of COVID-19. The topicality therefore lies precisely in the issue of migration. Is it or is it not necessary? Where appropriate, to what extent we focus on the health system and health professionals. Several events and measures taken in individual countries should strengthen the migration of health professionals, while others should dampen and even suspend or re-emigrate (return home). Of course, in such a short time, we cannot expect radical changes in the migration flows of health workers in the conditions of COVID-19, which could be detected using conventional research methods and statistical data. Therefore, our goal is to find out, on the basis of available information and logical considerations, at least changes in the speed and direction of migration flows of health workers in the conditions of COVID-19, but also to look for possible opportunities that migrants provide for the health system. What is actually happening with the migration flows of health workers, especially in European countries, is the subject of analyzes and findings of the study.

COVID-19 epidemic and migration of health workers

The introduction and exchange of pathogens between distant communities is as old as the human movement itself. The spread of epidemics of infectious diseases is not new in human history. (Greenaway & Gushulak, 2017). The

changing nature of crises and the increased expectations of pandemics, according to Karlsen (2016), are paving the way for many challenging crises in the future. Modernization and inequalities in a divided world also play a major role in this future, while organizational factors are often only responsible for inadequate crisis management. Karlsen's thinking in 2016 took on a formidable reality much earlier than we expected. COVID-19 is an infectious disease caused by a recently discovered coronavirus. It is a new virus and disease that was not known before the outbreak of the disease in Wuhan, China in December 2019 (Dong et al., 2020). A serious problem according to Zheng ate. (2020) is the fact that the increase in confirmed cases indicates an underestimation of preventive measures. Because health professionals are only human and are also exposed to this disease. Although they try to protect themselves to a high degree (if they have the equipment), it happens that the hospital staff also become infected. Of course, the hospitals of the countries are also counting on this possible scenario, and therefore they are creating personnel reserves, but in the event that the disease breaks out en masse at several epicenters, medical staff is not enough, nor is the equipment - for example Italy and the USA. According to the International Council Of Nurse (2020), Italian health workers have sacrificed and are sacrificing health in the fight against COVID-19, also due to a lack of protective equipment. Data from April 2020 showed an increase in cases of infected health workers, which accounted for up to 9%.

Jennifer Goforth Gregory (2020) also draws attention to a serious problem, who says that while America is currently facing a major health crisis, other factors also contribute to the very shortage of health workers. Most of the world is expected to face similar challenges in the next 10 years, and many countries are already in crisis. Its research direction includes the so-called The Baby Boomer generation, which includes 76 million Americans born after World War II from 1946 to 1964 (according to the United States Census Bureau). The oldest reached the age of 64 in 2010, and over the next 20 years, most of this population will be retired, many of whom are in the medical profession leaving many health care jobs. In addition, a large part of the aging population will require additional medical care from the health care system, which will be increasingly burdened by too many patients and a shortage of health professionals. According to Bidwell et al. (2014) estimate at about 4.3 million and these are the countries with the highest burden of various diseases. Wojczewski et al. (2015) argue that global health imbalances contribute to the malfunction of health services, especially in low-income countries. The loss of health workers, inadequately equipped health systems in poor countries makes this situation even worse. In many such countries, the vacancy rate for doctors and nurses is more than 50%. Thus, the brain drain has more far-reaching consequences. Following these findings, Stephen Khan (2020) also mentions the South African health system, which has a long-standing problem with a shortage of medical staff. The World Bank estimates that there are only 0.9 doctors for every 1,000 people in South Africa, compared to a global average of 1.6. The area has only 1.3 nurses and midwives for every 1,000 people, compared to a global average of 3.8. By mid-July 2020, COVID-19 would multiply this problem by 3% of the total number admitted to the infectious disease. The International Labor Organization (ILO, 2020) estimates that 244 million migrants live worldwide. A significant number of these migrants are low- or semi-skilled workers who live in conditions that raise concerns about social overcrowding and unsatisfactory hygiene. Although, according to the organization's findings to date, housing conditions have generally improved over the years, the conditions are not ideal for a pandemic situation. The current situation has highlighted the vulnerability of migrant workers as a working group. Following this, Ginsburg et al. (2018) states that the relationship between migration and health is multidimensional and two-way. Health can lead to migration, but such relocation can have an impact on health. Circular migration was also associated with the spread of health conditions or behavior between the target areas. Migration is a common manifestation of global trends in the labor market in all countries of the world, although from the perspective of European Union countries, this phenomenon develops in the conditions of the so-called free movement of labor within the Union (Krajnakova, Vojtovič, 2020). However, it is possible to talk about the emergence of large imbalances in the labor market, which are affected by the absence of balance sheets on the benefits and losses of labor migration for individual countries (Tupa, Vojtovic, 2018).

The reason for these migratory flows are, according to Shattuck et al. (2008) also motivate workers themselves in countries where low incomes cripple already fragile healthcare systems. Retaining health professionals is crucial to the performance of health systems, so it is how to best motivate and retain health professionals. . The International Organization for Migration (2020) adds that for more than a decade, the global shortage of health workers has been called a crisis, and programs to address human health resources need to be designed to overcome it. As early as 2006, the World Health Report drew attention to the unsatisfactory state of health care and the need for rapid progress towards improving the health care of the population, especially in view of the critical shortage of qualified health professionals in 57 countries. If we focus on the issue of migration of qualified health professionals. Thus, according to Schumann and Maaz (2019) in general and physicians in particular, it has become a global phenomenon of movement. This phenomenon has a significant impact on the quality of health care systems in the source countries, ie the countries of origin of the professionals who travel abroad for work, as well as in the destination countries that receive health workers. The Work Health Organization (2020) has the same opinion, confirming that even outside the epidemic, the migration of health workers is increasing. The number of migrant doctors and nurses working in OECD countries has increased by an incredible 60% in the last decade. Forecasts for the future point to a continuing acceleration of international migration of health professionals, with a growing

mismatch between supply and demand. It is necessary to understand the stimuli of the health worker to the migration itself. So what are the advantages and disadvantages or incentives for migration of health professionals? The summary in Table 1 will serve us for this.

Table 1: Select Advantages and Disadvantages of Circular Migration of Health Professionals

Source: Graziano Battistella (2020, ILO)

For The Migrands	For The Origin	For The Destination
Adventages	**Adventages**	**Adventages**
Preserve traditional and family associations.	Health workers return with greater skills and improved networks.	Savings in the training of health professionals.
Can still earn and professionally benefits of working with high incomes country.	Contribution to the health of the nation.	Part of a 'development friendly' national migration policy.
Able to contribute to the health of the homeland population.	Improved links with a destination country.	It can satisfy the shortage of health professionals in rural and remote areas.
Create opportunities for the family.	Brain drain human capital loss not as great.	Enhanced links with origin country.
Children can gain experience growing up in both countries.		Most health worker shortages handled in a flexible way.
Disadvantages	**Disadvantages**	**Disadvantages**
Disruption of moving.	Governance challenges.	Complications of organisation health system at destination.
Social costs of separation from family for part of the time.	Loss of skills for part of the time.	Governance challenges.
Complexity and costs of moving.	Difficulties with the organization of the health system with personnel only in the country for limited time.	Workers not available on a permanent basis.
Difficulties of adjusting to two work contexts.		Difficulties for immigration policy.

The issue of migration of health professionals can be viewed from different perspectives, as well as can be seen in the division according to Battistell (2020). Here are provided insights into the advantages and disadvantages in three basic areas (migrands, origin, destination). Of course, these can also differ from the preferences of the individual himself or the cultural society in which he works. Humphries et al. (2015) try to point out that the very stimuli for motivation change over time. Migration decisions are much more complex than the "binary scenario" often reported in the literature. The migration of health workers is affected by many factors, including those that are endogenous to the health system (such as the desire for better working conditions) and exogenous to the health system, such as the desire for better demands for citizenship and family reunification. Based on these studies, we note a great shortage of health workers in the future and thus their migration.

Objective and Methodology

All the above-mentioned events related to COVID-19 require the need for a larger number of health professionals and at the same time restrict their free movement and employment in specific health care facilities and in specific countries. Of course, in such a short time, we cannot expect radical changes in the migration flows of health workers, which could be detected using conventional research methods and statistics. Our goal is to find at least

changes in the speed and direction of migration flows of health workers in the conditions of COVID-19 on the basis of available information and logical considerations. This means that the intensity and extent of migration flows increased, remained at the previous level, or slowed down. In the article we use available statistical data on the migration of health workers from the OECD, thanks to which it was possible to point out the importance and nature of migrants working as health workers. At the same time, it is possible to assess how the individual affected countries approached this issue and from what sources they tried to obtain the necessary health workers. Because it was necessary to focus on the concepts that examined the phenomenon and the issue of the paper. In our case, it was a connection between the issue of viral disease (epidemic) and international migration of health workers. As a result, there were some opportunities for migration of health workers, but also threats associated with COVID-19 or the escape of health workers under better conditions. Subsequently, our findings allowed us to state the evaluations, but also to shape the very direction of the paper and its issues.

Problem Solution

Although the health care system has tried to gradually prepare for a larger number of patients with COVID-19 (coronavirus). It was necessary to transform some departments into so-called red pavilions, or in the worst crisis variant, transform the entire medical facility into a COVID hospital. During a pandemic, doctors have to deal with many problems, both they face enormous pressure and the fact that they deal with death more often than they are used to. Due to the restrictions that apply to a hospital visitor, they are often the last person to spend time with an terminally ill patient. This greatly affects their mental health, not to mention that these pressures weaken their immune system and are thus more susceptible to the disease itself. At the same time, it is necessary to point out that the medical staff where this disease appears among the employees, or is suspected of it, must go to quarantine (usually 2 weeks). So a paralyzed health system will receive another blow, not to mention if the burn is confirmed by doctors and they automatically drop out for an indefinite period. Many states have asked for help, or this help has been provided to them by other states as a show of solidarity, and so has the international migration of health workers. As the world faces pandemics, it is important that all authorities make every effort to confront xenophobia, including when migrants and others are exposed to discrimination or violence related to the origin and spread of the pandemic (United Nations Humans Rights, 2020). Migrants can be a driving force for hospitals that do not have enough staff. In response, a number of OECD countries (or states and provinces in the United States and Canada) have taken measures that have even enabled immigrant health workers to help cope with the sharp rise in demand for health care. These actions have facilitated the renewal of work permits, accelerated processing of the recognition of foreign qualifications, temporary and / or limited certification, or access to certain health jobs (OECD, 2020).

Examples of measures to facilitate the work permit of health professionals: In Chile, the National Health Service may employ foreign health professionals in the event of an emergency, even if their qualifications are not yet formally recognized. In contrast, the Spanish ministries had various urgent and coordinated measures to immediately employ foreign health workers willing to work in Spain. At the end of April 2020, about 400 people had been admitted. International nursing students can now work more than 40 hours every two weeks in Australia to ease the pressure on the workforce. In France, health professionals without a permit to study abroad can work as support staff in non-medical professions. Among other positive measures, we recommend free extension of visas in the case of a health worker (GOV-UK, 2020). Such measures have been introduced by the United Kingdom where health professionals are entitled to a free visa extension for one year. The condition is to have a visa, which expires between March 31 and October 1, 2020. Work for the NHS or an independent health care provider in an eligible profession. If the conditions are met, this benefit also applies to family members, who can also extend their visa for one year free of charge. According to Charlotter Oberti (Info Migrants, 2020), for example in France where health services were severely paralyzed during the coronary crisis, dozens of refugees and asylum seekers with medical knowledge in their home countries are ready to volunteer as a gesture of "gratitude". Because the inability to use their medical skills during this public health crisis has been very frustrating for them. As the pandemic continued to spread, on 25 March 2020, the French Ministry of Health called on active and retired people to help their colleagues voluntarily cope with the crisis. It was then a large-scale mobilization challenge in an industry known for its stringent authorization requirements. To facilitate the use of all volunteers, the French inter-ministerial delegation for the reception and integration of refugees stated that refugees with diplomas from outside the European Union who worked in their country of origin as doctors, dentists or pharmacists were entitled to work in French public institutions but "in contractual status ”and under the supervision of an accredited doctor. Even the government, in the urgency of the situation, extended these conditions during the crisis to "foreigners" who do not have refugee status in France.

It may be of interest, according to Dumpster and Smith (Center for Global Development, 2020), that the individual states affected rely on migrants, even though the policies of the states often restrict their movement. Studies show that in most high-income countries, migrants make up a large proportion of health workers. Today, one in six doctors in OECD countries has studied abroad, and the number of doctors and nurses born abroad has increased by an incredible 20% in the last decade. Migrants make up 12 percent of the UK's 1.9 million health workers and 17

percent of the US's 12.4 million healthcare workers. Thus, it can be stated that health systems rely heavily on migrant health workers. Confirmation of the following statements is also provided in the International Platform On Health Worker Mobility (2020). Who is tasked with maximizing the benefits and mitigating the adverse effects of labor mobility in the health sector through intensified dialogue, knowledge and cooperation. At the same time, they are trying to facilitate a strong political dialogue and measures in the field of health workforce mobility. In particular, through strong monitoring, country support, knowledge-sharing acquisition and sharing, and enhanced support for the implementation of the WHO Global Code and relevant ILO Conventions and Recommendations. The direction of their activities can be seen in the following diagram.

Scheme 1: International Platform On Health Worker Mobility

Source: Jim Campbell (Health Workforce Deparment, 2020)

At the same time, the idea of the availability of a sufficient number of qualified and, above all, motivated health professionals, who are essential for the performance of any health care system, comes to the fore, as pointed out by the current COVID-19 pandemic. The deep-rooted challenge of staff shortages was highlighted, as was the significant contribution of migrant doctors and nurses who contribute to the health workforce in many OECD countries. Numerically, we will follow up on these data in the statistical overview of migrants working in these countries.

Table 2: Number and share of migrant doctors and nurses working in OECD countries

	Migrant doctors				Migrant nurses

Source: OECD Health Statistics (2019)

In the previous table, OECD statistics show why migrants are so important to health systems. High percentages and figures speak of country dependencies. For example, in Australia, foreign-born migrants make up 53.9% of total doctors and nurses make up 35.3% of total nurses. Another example is Israel where foreign-born migrants make up 48.7% of total doctors and nurses 48% of total nurses. Of course, there are also countries with a low percentage, such as Italy, where foreign-born migrant doctors make up 4.3% of total doctors and nurses 10.7% of total nurses. As this country has become one of the epicenters of the pandemic, it is questionable whether this issue speaks of the difficulty of enforcing and implementing migrants, or the attractiveness of this country for their scope. Of course, it is important to note that it was not possible to prepare for this situation in advance, but it is possible to anticipate with greater interest in migrants and their easier adaptation to the labor market in countries around the world. However, the number of migrants themselves is limited, so it is necessary to think about how to address the shortage of health workers in the future.

Conclusion

There is no doubt that healthcare workers are the backbone of the healthcare system. Because of their profession, millions risk their health and lives at work every day, and in the case of the COVID-19 pandemic, it was no different. This disease has given us cards of imperfections and mistakes in the health system, and it is now up to us whether we want to win in this unequal struggle. It is also necessary to learn from small mistakes, which take on wide proportions in the accumulation. We know that the number of health professionals around the world is constantly declining, and if they decide to pursue this demanding and often unappreciated profession, they will certainly think about where they want to take root their help. Thus, there is an international migration of health workers examined by us. So what needs to be considered? First of all, to realize and at the same time show respect for the work of these people, to create them decent working conditions. These are extremely important in the current situation, because health professionals have encountered a great lack of protective equipment, but also insufficient equipment of medical facilities. The system that fell in the most important areas, such as healthcare, was disrupted. As a positive perception of the cohesion that has taken place in recent months, the world seems to have stopped and the long-running disputes between countries have cooled. The countries became in solidarity with each other as much as possible, regardless of nationality, they were willing to help where it was currently needed. This also supported the very migration of health workers who were willing to take their lives, leave their families and go literally into the unknown. Into situations they had never experienced before, unaware of whether they would ever return home. This is a huge thank you to them, they are the heroes of modern times. Although they do not have a sword or clear armor, they have a heart and a determination to protect lives at all costs, even knowing that they will lose theirs. On the other hand, we are very critical of the underestimation of the situation and the selfish attitude of the representatives of certain countries, because they were able to decide on the lives of millions of people on their own behalf without hearing them. The situation with access to migrants in individual countries, who often became hope and rescue for infected patients, was also resolved. An interesting finding was the fact that migrants were willing to take the risk associated with COVID-19, based on the specifics of this profession where they are "produced" non-monetary gains and human values (Ciarniene, 2017) under the influence of culture, education and training (Krajňáková, Vojtovič , 2011). The integration of migrants provided an important workforce, which was in short supply. This opened up a new sphere that needs to be addressed urgently, namely faster and more effective integration of migrants who are willing to work, but a lengthy and often discouraging bureaucratic system does not allow them to do so. It is in a situation of global threat, but also the number of statistics that have been published has shown that migrants are a normal part of society and need to be considered as an important and inevitable part of the labor market.

Abstract

Despite the growing prominence of e-commerce organizations and digital marketing as a branch of marketing management, there is paucity of research that attempted to describe the trends of scholarly outputs in this field of research. In addition, literature search reveal that African scholars pay little attention to the dynamics to this emerging field. It is upon this premise that the primary objective of this study was to systematically collect documents, scrutinize and critically analyze the relevant literature on the field of digital marketing. The specific objective was to identify key literature in the field of digital marketing as they relate with e-commerce organizations within the global market place, discover relevant emerging themes from digital marketing literature and to identify top e-commerce organizations around the world. In order to achieve this objectives, the researcher carried out a systematic review of digital marketing literature using the basic steps given by Yannascoli et al., (2013) in conducting a systematic review, the researcher (1). Made an initial plan (2). Conducted a search and (3). Extracted Data for the discussion of the emerging themes. By reviewing 60 articles, the author was able to discover eight key recurring themes which were covered in relevant literature of digital marketing namely; social media marketing, search engine marketing, digital display advertising, digital content marketing, mobile marketing, viral marketing, affiliate marketing and email marketing. Key findings show that there is an increase in the trend of more published article and that, more articles are published under social media marketing than the rest of the other themes, North American and European authors were found to be prominent in the literature. The author recommend that scholars and practitioners in the field of digital marketing from developing continents especially Africa and South America should focus on publishing more articles.

Keywords: Digital Marketing; E-commerce; Search Marketing; Social Media Marketing.

Introduction

Information technology has made trade among people, companies and countries easier through the creation of easier routes in which buyers can easily access sellers. Technology has changed the way business environment operates (Agboola, et al., 2019; Mayowa, et al., 2017). According to Totonch and Kakamanshadi (2011), a new global economy which is driven by technology and fired by information and knowledge has emerged due to technological changes.

Cite this Article as: OJO Kayode, OGUNNAIKE Olaleke, WORLU Rowland and SAMUEL Henry "E-Commerce Organizations in the Global Market Place: A Systematic Review of Digital Marketing Literature" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

According to Totonch and Kakamanshadi (2011), changes in technology and the use of technology has revolutionized the relationships within organizations and among organizations. Increased Productivity, customer participation, mass customization and reduction of cost are part of the advantages of changes in technology. The technology is used by different organizations to create and deliver product and services to different locations (Totonch and Kakamanshadi, 2011). The technology referred to here is the E-Commerce technology. E-commerce makes it possible for commercial transactions to cross cultural, regional and national borders in a way that is far more convenient and cost-effective than conventional trade permits (Laudon and Traver, 2018).

Globalization has created new opportunities which include access to new markets, access to capitals, greater income and employment opportunities (for individuals) and access to technology and information while challenges comes in form of threats from foreign competitors that come to the domestic market and reduce the cost of carrying out business (Totonch and Kakamanshadi, 2011). The market size for e-commerce is possibly the world population because the amount of people that can be reached through the internet is roughly the estimate of the world population (Laudon and Traver, 2018). According to Totonch and Kakamanshadi (2011), globalization and e-commerce is expected to change the economic structures of nations by increasing trades among nations. E-commerce reduces the cost involved in coordinating businesses among countries, eliminating the need for physical locations, manual processes and other expediting functions (Totonch and Kakamanshadi, 2011). The emergence of companies like Alibaba.com has helped with connecting many companies across the globe to companies in china (both small and medium scale) in sourcing for raw materials. Companies now find it easier to source for raw materials or outsource their production incapacities to manufacturing companies in china that produce goods and services at cheaper rates.

Objective of the Study

The primary objective of this study is to: systematically collect documents, scrutinize and critically analyze the current research literature on digital marketing. In order to achieve this primary objective, the specific objectives include to;

1. identify key literature in the field of digital marketing as they relate with e-commerce organizations within the global market place.
2. discover relevant emerging themes from digital marketing literature.

The History of Digital Marketing

It is very hard to identify the time when digital marketing began but it can be traced far back to the early 1980s (Tiwari, 2019). At this period, the first personal computer was launched by IBM. During this period, marketers were focused on creating relationships with their customers instead of pushing products. Companies were also able to gather information on their customers through the use of digital database. The emergence of digital database changed the buyer-seller relationship for the better. Kapost (2015), reported that by 1986, ACT, a customer management company introduced the first database marketing software to the business world. Several landmark database marketing solutions were provided by Robert Shaw and Robert Kestenbaum.

The use of customer relationship management software exploded in the early 1990s due to the popularity of personal computers. In the early 1990s, the first search engine (Archie) was launched. In 1993, the first clickable ad-banner was created. Google which is known as the most popular search engine was founded in 1998 (Tiwari, 2019). Lots of internet companies were created in this decade. Companies that provided several internet solutions were very popular in 1990 which created what was popularly known as the internet bubble. In the early 2000s the internet bubble busted which gave a lot of internet companies to rethink their business model. In the mid-2000s, digital behavior changed the dynamic between the buyer and the seller dramatically. In this period, consumers began to search online for products and services and started making buying decisions based on what information they got online (Tiwari, 2019). During this period, social media platforms began to emerge. People started networking online and companies started coming online to sell their products. LinkedIn in was launched 2002, Yelp and Facebook and google was launched 2004, YouTube was launched 2005 while Twitter was launched 2006 (Kapost, 2015). Marketers had to come up with new ways to sell to their consumers. During this period, new skills were needed to navigate the terrain of the online marketing world. Currently, more marketing automation companies have come up with the hope of simplifying the way things are been done.

A Profile of E-commerce Organizations in the Global Marketplace

E-commerce became possible around 1991 when the internet was opened for public use. Laudon, and Traver (2018) reported that the e-commerce business has grown to become an industry worth over several trillions of dollars. Most e-commerce companies has moved from just being an online retail store into something broader (Laudon, and Traver, 2018) especially amazon.com that started as an online book retailer, Alibaba.com which is a wholesaler marketplace also caters to retailer's needs, ebay.com not only provides a customer to customer (C2C) transaction, but also business to consumers (B2C) and many other e-commerce stores. Companies have also had to tap into the global marketplace in order to take advantage of various potentials in developing countries (Singh, Alhorr, and Bartikowski, 2010).

According to a report by E-commerce foundation (2018), over ¾ of the world population are between the ages of 25-54. Standardized marketing methods has helped the globalization of retail through the use of e-commerce platform. In the ranking of shopping websites according to the amount of visitors in the continent of South America, Mercadolibre.com had the most visitors in Argentina, Brazil, Columbia and Peru. E-commerce foundation (2018) reported that Brazil, Argentina and Columbia had the highest B2C turnover in South America respectively. See Appendix 1 for more details. In the ranking of shopping websites according to the amount of visitors in the continent of North America, Amazon, Mercadolibre and eBay are the leading ecommerce sites as reported by Ecommerce foundation (2018). United States, Mexico and Canada had the most Turnovers respectively. See Appendix 2 for more details.

Leading ecommerce sites in the continent of Europe are Amazon, eBay and Aliexpress while the top three countries ranked according to B2C turnover are United Kingdom, France and Germany respectively as reported by Ecommerce foundation (2018). See Appendix 3 for more details.

Ecommerce foundation (2018) reported that Amazon, Alexpress and eBay were the top three leading ecommerce sites in the Middle Eastern region while Iran, United Arab Emirates and Turkey were top three countries ranked by B2C turnover. See Appendix 4 for more details.

Souq, Avito and Gumtree were the top three ecommerce sites in the continent of Africa as reported by Ecommerce Foundation (2018), while Egypt, South Africa and Nigeria were the top three countries with highest B2C turnover in the continent of Africa. See Appendix 5 for more details.

Leading the ecommerce sites in the continent of Asia and Oceania are Amazon, eBay and Rakuten as reported by Ecommerce foundation (2018) while China, Japan and South Korea were reported as the countries ranked with the highest B2C turnover. See Appendix 6 for more details.

Gaps in Literature

The field of digital marketing is very vast. There are also numerous literature on this field. Several authors (Alalwan et al., 2016; Alalwan et al., 2017; Bala and Verma 2018) have written on specific aspect of digital marketing in a microscopic manner thereby looking at effects and impact of these so-called communication tools on consumer behavior, company's profitability and several other terms in which these tools can be measured against. Bala and Verma (2018) conceptually reviewed digital marketing as a whole but they didn't put in view the working and activities of E-commerce companies.

Despite the growing prominence of e-commerce organizations and digital marketing as a branch of marketing management, there is paucity of research that attempts to describe the trends of scholarly outputs in this field of research. Although series of literature review have been carried out on the field of digital marketing in a manner that shed light into the activities of marketers, none of these works has attempted to provide an outlook based on the recurring themes found in the literature.

Methodology

The researcher carried out a systematic review of digital marketing literature. A systematic review aims to compile, analyze and synthesize all available empirical data in a rigorous and reproducible way that satisfies pre-defined requirements to address a research question (Yannascoli, Schenker, Carey, Ahn, and Baldwin, 2013). Using the basic steps given by Yannascoli et al., (2013) in conducting a systematic review, the researcher (1). Made an initial plan (2). Conducted a search and (3). Extracted Data for the discussion of the emerging themes.

Step 1: Initial Plan

In this stage, the researcher used the PICO (population, intervention, comparison and outcome) mnemonic tool extracted from (Yannascoli et al., 2013) to identify and formulate relevant research questions which helped provide directions for the review.

Defining the Research Question

Who are the scholars and practitioners (ecommerce organization) in the field of digital marketing? What are the relevant literature in the field of digital marketing? What are the themes that emerged from the literature reviewed?

Study Justification

The researcher looked at previous literature on the field of digital marketing. Although series of literature review has been carried out on the field of digital marketing, none of these works systematically reviews the literature based on E-commerce organizations. The research aims to identify key literature in the field of digital marketing as they relate with e-commerce organizations within the global market place. The study also aims to discover relevant emerging themes from digital marketing literature.

Literature Search

The researcher analyzed several peer-reviewed journal articles since these are essential channels of communication for researchers, as noted earlier by (Creswell, 2009; Wilkie and Moore, 2003; Williams and Plouffe, 2007). Several selected marketing journals were also browsed by the author based on the advice given by Moussa and Touzani (2010 given the provision ofma well understandable quote-based marketing journal ranking. In addition, important search engines and databases were used, including the complete database of Google Search, Google Scholar, Scopus, JSTOR, ScienceDirect and Business Source (Ngai, 2003; Lamberton, and Stephen, 2016).

Selecting Search Terms

In selecting the search terms, some keywords were recognized in order to increase the quality of the searches and for the author to achieve a desirable outcome in terms of accomplishing the aim of the search which was to determine as much as possible all applicable identified in order to adequately address the research questions posed in the study. Such keywords included Digital marketing, E-commerce, and globalization. These keywords were matched with other recurring themes in order to get a large pool of literature in order not to repeat what has been done by other researchers. The first thing the researcher did was to investigate the article tittles. Many of these titles were highly suggestive of addressing digital marketing specifically. In order to ensure that applicable articles were not excluded in cases where they were not representative of a digital marketing emphasis in the article title, the author then reviewed their abstracts, keywords, and the complete length.

Inclusion and Exclusion Criteria

The author modified Petrosino (1995)'s inclusion criteria while selecting journal articles to review. The study reports were collected using the following criteria.

1. The article journal was published, printed or available between 1990 and 2019 were included.
2. Books were also included.
3. The title of the journals selected suggested that the content of the work discussed basically digital marketing subjects.
4. The articles selected also discussed or mentioned e-commerce in the abstract.
5. Articles less than 4 pages of content were excluded from the selection.
6. The researcher used themes discussed by Bala and Verma (2018) in navigating the prominent themes on the field of digital marketing.
7. The journal articles selected were all available in English language.

8. The researcher also selected articles that were indicative of e-commerce companies digital marketing practices.
9. Articles indicative of customer's behavior were excluded from the selection.

The researcher was concerned with articles that explained and described the prominent themes in digital marketing literature. The researcher noticed that emerging themes like search engine marketing, search engine optimization, social media marketing, and mobile marketing among other emerging themes. An article was considered qualitative when using qualitative methods for collecting, analyzing and presenting data was used while the use of quantitative methods such as survey, experiment and statistical package for social sciences was considered quantitative.

Data Base

In addition, important search engines and databases were used, including the complete database of Google Search, Google Scholar, Advanced Google Search, EBSCO, SAGE, Ebrary, Scopus, JSTOR, ScienceDirect and Business Source (Ngai, 2003; Lamberton, and Stephen, 2016).

Data Organization

In searching for digital marketing on different databases identified above, about 2,605,278 articles were identified. 2,570,000 were duplicates and removed while 35,228 articles were screened. Out of the 35,228 articles that was screened, the researcher excluded 35,000 articles because they were not related to the area of study and they did not fall into the date range that the researcher selected for study. Out of the 228 articles left, only 150 articles were related to e-commerce organizations. At the end of the screening process, the researcher systematically reviewed 60 articles.

Step 2: Conducting and Reviewing the Search

This stage is the implementation stage of the initial plan earlier discussed. A broad and thorough web search of important academic and business management related database was carried out to achieve the necessary requirements of a systematic review. Emphasis were laid on digital marketing and E-commerce. Google Scholar was the search engine employed. Peer-reviewed journals, periodicals, blogs and websites of industry players provided resource materials for this study.

Step 3: Data Extraction

In carrying out the data extraction, the researcher with the help of an independent reviewer carefully extracted the articles from the database in order to provide a thorough review of literature.

Findings: Evolving Themes from The Review

The study reviewed for this paper has been carried out in South America, North America, Europe, the Middle East, Africa, Asia and Oceania on various continents around the world. Most of the authors generated their data by themselves. These authors followed a qualitative approach when producing primary data, which offered rich insights to arrive at their conclusions and make useful recommendations. This analysis presents the topics and areas of study on digital marketing in the field of marketing and is discussed under various headings below.

A. Social Media Marketing (SMM)

One of the most prominent issue in the literature of digital marketing is social media marketing (SMM). Several authors' (Abed, et al., 2015; Alalwan, et al., 2016; Alalwan, et al., 2017; Hawkins, and Vel, 2013; Nwokah and Gladson-Nwokah, 2015; Zhu, and Chen, 2015) work were reviewed. Social media has been found to be one of the most progressive variables in the lives of people (Alalwan, et al., 2016; Hinz, et al., 2011; Zeng & Gerritsen, 2014). Social media marketing is an Internet marketing technique that uses websites for social networking as a marketing tool (Nwokah and Gladson-Nwokah, 2015). Hofer-Shall (2010) reported that the use of social media resulted in a significant increase in the number of listening platforms that regulate online discussions that demonstrated customer opinions through social media. Lea, et al., (2006) stated that social media plays an important role in commerce and the development of the economy. Social media marketing or SMM is an outgrowth of efforts from search engine marketing (Bala and Verma 2018). It includes moving traffic via

social media such as Facebook, Instagram, Twitter, Pinterest, Google+, LinkedIn, etc. to your media or company. Yadav and Rahman (2017)'s study provides e-commerce marketers with an important tool to evaluate the effectiveness of their Social Media Marketing Activities. The scale will help ecommerce firms understand and enhance the perception of whatever social media activities developed by their advertisers which will help marketers evaluate the existing perception and thereby create and enhance the positive perception of consumers Yadav and Rahman (2017). Ecommerce organizations' SMM efforts can be especially helpful for branding and driving sales (Bala and Verma 2018).

B. Search Engine

Yalçın and Köse (2010) describes search engine as a data collection software that gathers information on websites. The data the search engine collects include the web site URL, some keywords or groups of keywords that explains what the website contains or describes the content of the website, links provided on the website and the structure of the web page which is formed by the way the website is been coded (Yalçın and Köse, 2010). The search engine is a database in which all data and information gathered are been stored. The search engine software uses special programs which contains the crawler, spider and bot that goes through all the data collected in order to make meaning of the content of the website (Yalçın and Köse, 2010). Over 80% of internet users make use of the search engine in search for information (Yang, Shi, and Wang, 2015).

B. (I). Search Engine Marketing (SEM)

Search engine marketing was one of the influential topics explored in the literature of digital marketing. Search engine marketing is a type of internet marketing that includes particular actions taken by a marketer to increase the amount of searchers coming to the web by increasing the exposure of the web by paid organic means in search engine results (Moran and Hunt 2014). In search engines, SEM is all you do to improve the popularity of your site to draw more tourists. Brand equity is influenced by the order in which the search engine results are shown (Drèze & Zufryden, 2004; McCoy, et al., 2007; Rangaswamy, et al., 2009). A company's ranking on the search engine result page affects its revenue (Keane, O'Brien, & Smyth, 2008; Skiera, Eckert, & Hinz, 2010).Yang et al., (2015) reported that companies use SEM to increase sales of products and service by increasing specific keyword exposure. Search marketing is a vital way for your website to draw new users, regardless of the word you use (Moran and Hunt, 2014). The comprehensive strategy for driving traffic to your business, mainly through paid efforts, is Search Engine Marketing or SEM. Therefore, Paid Search Marketing is also named (Bala and Verma 2018). In their book titled "Search engine marketing, Inc.: Driving search traffic to your company's website" Moran and Hunt (2014) discussed the basic of web search, search and marketing mix and the challenges of search marketing. The basics of web search was categorized into kinds of search results and where searchers go. The kind of search result was divided into two parts namely organic results which is also known as natural results and paid results in which the marketer pays in order to be seen in the search results. Google is known to be the go to site of majority. According to Net Market Share (2019), Google holds 74.8% of the search engine market share. In their book, the authors Moran and Hunt (2014) explained the reasons why search engine marketing should be integrated into every companies' marketing mix. SEM 's world is diverse and confusing. Based on empirical studies of china's B2C e-commerce firms, Yang et al., (2015) concludes that a focus on SEM helps attract customers to the business thereby increasing financial performance (Bala and Verma 2018).

B (II). Search engine optimization

SEO stands for search engine optimization. Berman, and Katona's study (2013) focused on the roles of search engine optimization in search marketing. Search engine serves as an intermediary between the website and the customer (Berman, and Katona, 2013). Search engine optimization involves making changes to a website so your visitors can easily find it in a search engine. Web searchers prefer to click on organic links instead of the paid ones on the search engine and for this reason, advertisers try to game the algorithm (Berman, and Katona, 2013). Information about an unknown subject matter is usually searched on the first page of search engines (Yalçın and Köse, 2010). Users hardly get past the first five pages of the result page. Given this reason, advertisers try their best to move to the top list of search engines (Berman, and Katona, 2013; Yalçın and Köse, 2010). If the search engine optimization rules are followed, the advertiser and the web developer can move the page to rank on the first page (Yalçın and Köse, 2010). An attractive and a well-structured web page helps introduce the company's product or services better (Yalçın and Köse, 2010). SEO is the most cost-effective marketing strategy that will bring organic traffic to business (Bala and Verma 2018).

C. Digital Content Marketing

Another theme or area of interest for researchers under the field of digital marketing is digital content. Hollebeek and Macky (2019) worked on the role of digital marketing in fostering consumer engagement, trust and value. Based on the literature review, Hollebeek and Macky (2019) conceptualized digital content marketing as the creation and distribution of significant, value brand-related content to customers (both current and prospective) on various digital platforms in order to boost brand engagement, relationships and trust. Bala and Verma (2018) stated that digital content can be presented in a variety of formats, including blogs, white papers, e-books, case studies, guidebooks, questioning and answering articles, forums, news and updates, images, banners, info graphics, podcasts, webinars, videos or micro blogging and social media content (Bala and Verma 2018). Digital Content Marketing aims to increase the appreciation of the brand or company by adding value to the lives of the customers (Järvinen and Taiminen 2016). This can be done in form of educating the customers about the harm or usefulness of a certain product. DCM is based on the premise of a genuine and sincere desire to add value to the life of the consumer in a way that facilitates the acquisition or retention of customers (Taylor 2012). DCM helps the advertiser tell the brand story in a unique way that builds customer trust, encourage customer engagement and most importantly build customer relationship. (Gagnon 2014; Naidoo and Hollebeek 2016). Hollebeek and Macky (2019) also developed a conceptual framework that identifies significant consumer-based DCM backgrounds, including functional, hedonic, and authenticity-based motives for DCM interactions based on uses-and-gratifications (UandG).

D. Digital Display Advertising

Another recurring theme on literature is digital display advertising. Goldfarb and Tucker (2011) found out that matching an ad to the content of a website and increasing the obtrusiveness of an ad independently increases the intention to buy. Bala and Verma (2018) explains that digital display advertising is a part of search engine marketing efforts. Drèze and Hussherr (2003) found out that web browsers actively avoid looking at online banner ads. Lee, Fang, Kim, Li, and Palmatier (2018) explains how digital display advertising works. They made it clear that digital display advertising works in a pay per impression manner in a way that advertisers pay a predetermined or specified amount of money in order to expose their advert placement in form of banner, pop-up floating, or text advertisement. Bala and Verma (2018) reported that for e-commerce firs to get a good return on investment, they need a specialist or an expert advertiser which may be relatively expensive. In the study of 2,892 online display ad campaign Goldfarb and Tucker (2011) found out that customers dislike viewing highly visible or obtrusive ads.

E. Mobile Marketing

A study revealed that 50% of United States mobile consumers are mobile shoppers, 10% are heavy users while 40% are light users (Leo and Arc Worldwide, 2011). The Mobile Marketing Association (2011) define mobile marketing as the set of practices that allows organizations communicate and engage with their audience in a way that is interactive and relevant through any mobile device or network. Varnali and Toker (2010) reported that mobile marketing has transformed into an ultimate marketing vehicle which allows businesses establish their electronic presence with their customers anytime and anywhere because of the characteristics it possesses. Prominent issues that came up during the study were mobile marketing adoption (Aldás-Manzano, Ruiz-Mafé, and Sanz-Blas, 2009; Amin, 2008; Roach, 2009), mobile marketing use (Okazaki and Romero, 2010; Rau, Zhang, Shang, and Zhou, 2011), the value of mobile marketing to retailers (Okazaki, and Taylor, 2008), improved value of mobile marketing (Bellman, Potter, Treleaven-Hassard, Robinson, and Varan, 2011; Kim, and Jun, 2008).

F. Viral Marketing

The term viral marketing was introduced in 1997 by Steve Jurvetson and Tim Draper (Knight, 1999). Leskovec, Adamic, and Huberman (2007) related viral marketing to the diffusion of information about a product and the way the product is been adopted in a network. Viral marketing is also know as the electronic equal to what is known as the word of mouth (Bala and Verma, 2018). Lot of researchers focus on what motivates people to share a message online (Ho and Dempsey, 2010; Phelps, Lewis, Mobilio, Perry, and Raman, 2004). Empirical evidence shows that consumers depend on information from others when making buying decisions (Hill, Provost, and Volinsky 2006; Iyengar, Van den Bulte, and Valente 2011; Schmitt, Skiera, and Van den Bulte 2011). Viral Marketing is a strategy where a unique content spreads exponentially online, because the content is appreciated, shared and liked immensely. Pescher, Reichhart, and Spann (2014) reports that the focus of viral marketing campaigns is to capitalize on customers' referral behavior when it comes to disseminating information.

G. Email Marketing

E-mail marketing, as part of e-marketing, is used to increase site traffic and sales support (Kirš, and Harper, 2010). Hudák, Kianičková, and Madleňák, (2017) highlighted the importance and effectiveness of e-mail marketing as it relates to e-commerce. They concluded that it is necessary for companies to establish an explicit aim at the beginning of the campaign and also select the right metrics. When you send a commercial message through email to a list of potential customers, the strategy is called Email Marketing (Bala and Verma, 2018). Bala and Verma (2018) also explained that With effective email marketing software, you can maintain email lists that are segregated based on several factors, including customers‟ likes and dislikes, and spending habits.

H. Affiliate Marketing

Libai, Biyalogorsky, and Gerstner (2003) stated that affiliate marketing program is an important source of customer acquisition. Bala and Verma (2018) described Affiliate Marketing as a performance-based marketing program, where publishers that bring customers to an online platform are been paid by the platform. Duffy (2005) concluded that for affiliate marketing to be successful there has to be a construction of a win-win relationship the affiliate and the e-commerce company. The job of the affiliate marketers is to generate orders through his efforts (Duffy, 2005). A lot of e-commerce platforms use affiliate marketing (Dysart 2002; Fox 2000; Oberndorf 1999). Libai, et al., (2003) identified two payment plans used to pay affiliates which are pay-per-lead and pay-per-conversion. Bala and Verma (2018) stated that affiliate marketing is very useful for newly started online platforms.

Graphical representations of the emerging themes according to year and author's continent of origin.

In this section, three sets of bar chart were drawn (fig 1, fig 2 and fig 3) based on the emerging themes as well as the periods they were published. The continents of the authors were also represented in the bar chart.

Fig. 1: Graph showing the frequency of the recurring themes according to citations in the digital marketing literature.

Fig. 2: Graph showing the frequency of the citations according to years they were cited in the digital marketing literature reviewed.

Fig. 3: Graph showing the number of authors cited according to the continents the authors were from in the digital marketing literature.

Interpretations and Discussions of Findings

This paper takes a comprehensive look at digital marketing on a global level through a systematic review of literature that exist of the field. In the course of reviewing the literature on digital marketing, the researcher found out that social media marketing was the most discussed theme. Several authors (Abed, et al., 2015; Alalwan, et al., 2016; Alalwan, et al., 2017;

Hawkins, and Vel, 2013; Zhu, and Chen, 2015) discussed how social media marketing affects the lives of consumers. Mobile marketing was also a theme that was discussed by several authors across the field of digital marketing. Several authors (Aldás-Manzano, Ruiz-Mafé, and Sanz-Blas, 2009; Amin, 2008; Okazaki and Romero, 2010; Rau, Zhang, Shang, and Zhou, 2011; Roach, 2009) were found to be key authors on this field. Based on the search and the literature reviewed according to the inclusion and exclusion criteria, the researcher reviewed 9 articles on viral marketing, 8 on Search engine marketing, 6 on digital content marketing, 6 on affiliate marketing, 4 on digital display advertising, 3 on search engine optimization and 3 e-mail marketing. All these are well represented in fig 1 above.

The researcher also classified the study according to the frequency of works published every five years beginning from 1993 to 2018. The researcher found out that from 1993 to 1997 only four articles were published according to the inclusion and exclusion criteria the author used. 1998 to 2002, four published articles were selected, from 2003 to 2007 twelve published articles were selected, from 2008 to 2012, twenty-eight published articles were selected and from 2013 to the 2018 twenty-four published articles were selected by the researcher according to the inclusion and exclusion criteria. All these were shown on the graph in Fig 2.

The researcher also classified this work according to the continents the authors came from. In this study, the researcher found out that most of the authors that published given the inclusion and exclusion criteria came from the continent of North America, that is twenty six main authors came from North America while nineteen authors came from Europe, twelve authors came from Asia and Oceania, two from the Middle East while one is from Africa. All these are shown in the graph in Fig 3.

The researcher found out that there has been a rapid growth of the field of digital marketing in the global market place although there were scarce works done in developing countries like Nigeria and other African countries as regards the growth of the field. The field of digital marketing got off with a quick start when personal computers were introduced to the market and since then there has been ground breaking innovations that has allowed marketers to get across with their customers (prospective and current) in ways and manners that are cost effective and measurable.

The paper discussed the major recurring themes found on the literature systematically reviewed on the field of digital marketing. These themes were analyzed and explained in the paper in order to help broaden the view of subsequent researchers on the field of digital marketing.

Areas for Future Research

Several issues have emerged from this article that may serve as potential for future research.

First, a large number of studies are qualitative in nature. The researcher found out that quantitative and mixed methods are less popular. Therefore it is necessary for researchers working on this field to pay more attention to developing more studies that combine qualitative and quantitative research methods in digital marketing studies.

This article focused on several studies that showed the practices of e-commerce or online shopping platforms in the global market place, I recommend that future studies should be made into other industries that relates to digital marketing for example banking industry or the healthcare industry.

Future studies could also be made on bringing together several theories surrounding the topic of digital marketing practices and adoption of technologies surrounding it. This will help shed more light on how well the field of digital marketing has been developed so far.

Other aspects of marketing can also be focused on for example, researchers can try to understand the field of digital marketing by looking at the behavior of the consumers been marketed to. The financial performances of the companies under study could also be looked at just to give it a more profound context.

Future researchers can also carry out a comparative study trying to understand digital marketing practices among different industries. Their relationships, similarities, differences and impacts can also be reviewed in order to understand the practices in different industries.

Appendix

List of Top E-commerce Companies around the world segmented by continents according to Number of Visitors.

Appendix 1
South America: Top Shopping Websites.

Country			
	1st	2nd	3rd
"Argentina"	**"Mercadolibre.com.ar"**	"Mercadolibre.com"	"Olx.com.ar"
"Brazil"	**"Mercadolibre.com.br"**	"Olx.com.br"	"Americana.com.br"
"Chile"	**"Yapa.cl"**	"Mercadolibre.com.cl"	"Falabella.com"
"Columbia"	**"Mercadolibre.com.co"**	"Olx.com.co"	"Amazon.com"
"Peru"	**"Mercadolibre.com.pe"**	"Olx.com.pe"	"Falabella.com.pe"

Extracted from ecommercefoundation.org/reports
Leading commerce sites in the region

1. "MercadoLibre"
2. "Olx"
3. "Yapo"

Top Countries ranked by B2C Turnover

1. "Brazil".
2. "Argentina".
3. "Columbia".

Appendix 2
North America: Top Shopping Websites

Country			
	1st	2nd	3rd
"Canada"	**"Amazon.ca"**	"Kijiji.ca"	"Amazon.com"
"Mexico"	**"Mercadolibre.com.mx"**	"Amazon.com.mx"	"Amazon.com"
"United States"	**"Amazon.com"**	"Ebay.com"	"Craiglist.org"

Extracted from ecommercefoundation.org/reports
Leading commerce sites in the region

1. "Amazon"
2. "MercadoLibre"
3. "eBay"

Top Countries ranked by B2C Turnover

1. "United States".
2. "Mexico".
3. "Canada".

Appendix 3

Europe: Top Shopping Websites

Country			
	1st	2nd	3rd
"France"	**"Amazon.fr"**	"Leboncoin.fr"	"Cdiscount.com"
"Germany"	**"Amazon.de"**	"eBay.de"	"Otto.de"
"Italy"	**"Amazon.it"**	"Subito.it"	"eBay.it"
"Romania"	**"Olx.ro"**	"Emag.ro"	"Aliexpress.com"
"Russia"	**"Avito.ru"**	"Aliexpress.com"	"Market.yandex.ru"
"Spain"	**"Amazon.es"**	"Milanuncios.com"	"Aliexpress.com"
"Sweden"	**"Blocket.se"**	"Trader.com"	"Prisjakt.nu"
"United Kingdom"	**"Amazon.co.uk"**	"eBay.co.uk"	"Argos.co.uk"

Extracted from ecommercefoundation.org/reports
Leading commerce sites in the region

1. "Amazon"
2. "eBay"
3. "Aliexpress"

Top Countries ranked by B2C Turnover

1. "United Kingdom".
2. "France".
3. "Germany".

Appendix 4

Europe: Top Shopping Websites

Country			
	1st	2nd	3rd
"Armenia"	**"Amazon.com"**	"Aliexpress.com"	"eBay"
"Bahrain"	**"Amazon.com"**	"eBay"	"Aliexpress.com"

Abstract

All over the world, the satisfaction of employees in an organisation through work flexibility for career advancement is vital to organisational sustainability. This study recognizes an essential strategy of motivating the corporate workforce for improved performance by managers of public and private organisations in their desire to stay relevant and achieve the stated organisational goals and objectives. However, in the Nigerian public service, there have been unresolved issues of employees' dissatisfaction in the area of work flexibility for career advancement. Therefore, this study, through conceptual review, examined the influence of work flexibility for career advancement of employees' performance within the public service in Nigeria. The study concluded that were employees in the Nigerian public service failed to experience work flexibility for career advancement, they are not likely to put in their best into their assignments to achieve the organisation's desire for improved performance.

Keywords: Career advancement, Nigerian Public Service, Work Flexibility.

Introduction

The contributions of employees are a vital factor that indicates the level of growth, and survival of any organisation both in public and private sector of any nation, including Nigeria. In Nigeria, a high level of employment opportunities, engagement, and employment quality is a means to enhance the standard of living and satisfaction of its working populace and create opportunities for national development. In the quest to attain satisfaction, many individuals seek employment both in the international and their local environments to satisfy their desire to earn a living. The satisfaction of employees is one of the most significant issues in a diverse workplace (Chatterjee & Chatterjee, 2015).

SALAU, Olukemi ADE-ADENIJI and David ORENUGA "Employment Quality and Employees' Satisfaction in The Nigerian Public Service: A Conceptual Review" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Employers who rely on human resources competencies, skills, and experience are saddled with responsibilities to satisfy the needs of employees for performance. Employees' needs that are not satisfied by their organisations are likely to go a long way to negatively affect the performance, competitiveness, and existence of such organisations (Johnson, 2018). One of the ways employers in developed countries satisfy their employees' needs is the attempt to understand and provide adequate employment quality which affects the general well-being of the employees. Since the desires of individuals are generally different, then the value for certain employment aspects will be unique to them (Clark, 2015).

Aspects of good employment quality involve different dimensions (high job security, job content, pay, flexible work, interpersonal relationships and standard hours of work, quality training and development) in which participants in the labour market count as valuable to enable them achieve satisfaction. In previous studies, employee satisfaction has often been depicted as a function of the characteristics of the job itself among other things (Anh, Nguyen, Tuong Anh & Nguyen, 2018; Khalid, Salim & Loke, 2011). Furthermore, Ozguner and Ozguner (2014) state that employees' dissatisfaction is a common problem.

Studies backed by Fredrick Herzberg's hygiene theory have shown that low career advancement can lead to dissatisfaction. At the same time, perceived and consistent career advancement has revealed a reduction in the likelihood of an employee leaving an organisation which reflects their state of satisfaction (Stamolampros, Korfiatis, Chalvatzis & Buhalis, 2019; Dartey-Baah & Amoako, 2011). In the international environment, career advancement is explained to be improved by increases in the level of work flexibility which enhances employees' well-being in the workplace (Mansor, 2014; Shagvaliyeva & Yazdanifard, 2014). Yet, in Nigeria, few studies have been conducted on how career advancement can be enhanced by work flexibility, especially in the public service. Onah and Anikwe (2016) posit that work flexibility empowers individuals to facilitate healthier progressing careers, attracts and retain employees as well as appealing to all ages of the workforce. Hence, this study aims to examine the effect of work flexibility on career advancement.

In the developed countries, previous studies have revealed that job security is a determinant of employees' satisfaction and a part of Fredrick Herzberg's Motivators theory published on motivation to work in 1959 (Chatterjee & Chatterjee, 2015; Artz & Kaya, 2014; Dartey-Baah, & Amoako, 2011). Greater job security and employee performance was shown to be enhanced through training and development (Kum, Cowden & Karodia, 2014). However, in Nigeria, few studies have revealed that training and development can bring about job security leading to employees' satisfaction in the public service. Aborishade, (2016) posits that training and development can increase productivity, higher work flexibility, improved skills, and competences of workers that leads to the enhancement of employees' satisfaction. As a result, this present study aims to examine the influence of training and development on job security in an organisation with focus on employment quality, employees' satisfaction and work flexibility for career advancement in the Nigerian public service.

Concept of Employment Quality

The history of employment quality is dated back to the 1990s, where the concept was first seen as decent work (Sehnbruch, Burchell, Agloni & Piasna, 2015). The concept of decent work has been expanded by researchers and overlapped by other concepts like job quality, quality of employment, and employment quality (Kalleberg & Warhurst, 2013; Buchell, Sehnbruch, Piasna & Agloni, 2015). However, in this study, the concept is seen as employment quality. Clark, (2015) views employment quality as the weighted sum of the various job dimensions that matters to workers. He further explains that it is the job characteristics, job dimension, job aspect, and good quality/satisfying jobs offered by organisations to their employees. Employment quality enhances employees' happiness and well-being. It affects a worker's well-being, productivity, and organisation's performance (Oswald, Proto & Sgroi, 2015).

Concept of Work Flexibility

Work flexibility is a vital concept in today's world of works and it can be referred to as employment flexibility. The concept of work flexibility is yet to receive much attention from the public service within the work system of the Nigerian work environment (Akingbola, 2011). Furthermore, it has been rated as the most valuable option provided by employers (Oludayo, Gberevbie, Popoola & Omonijo, 2015). Mungania, Waiganjo and Kihoro (2016) stated that in a society filled with conflicting responsibilities and commitments, flexible work arrangement has become a predominant issue in the workplace. It has been noted that employees are increasingly clamoring for more flexible, autonomous, and creative functions. Consequently, there have been increasing interests on the part of employers on work flexibility and the majority of the employers have already started introducing a variety of flexible working

choices for their staff to encourage the creation of employee engagement within their organisations (Isiaka, Abdullah, Abogunrin, Aremu & Aliyu, 2015).

Work flexibility enables workers to fulfill their job duties while at the same time allowing them to act to a large degree in their non-working environment. Employees gain greater influence over time by advantageous flexible time policies or even seeking flexibility as to when and where they are employed (Oludayo, et al., 2015).

Concept of Employees' Satisfaction

The concept of employee satisfaction has been viewed in different ways by scholars. Employees' satisfaction is key to gaining the improved commitment of employees in the workplace. It represents a cogent factor that leads to a positive effect in the work environment, especially for organisations aiming to reach their planned goals and objectives (Saad, Muhammad & Rafi, 2012).

Also, employees' satisfaction is also a collection of positive feelings that an individual holds toward his or her job as well as part of his or her life's satisfaction (Singh & Mini, 2013). Employees' satisfaction has a significant effect on a person's life, as he/she spends a large portion of time and energy in the workplace (Abbas & Karage, 2015). It is also seen as a state that causes the workforce to feel hopeful and creates strong motivation that fosters a good work environment (Nayab, Shahid, Sadaf, Muhammad & Muhammad, 2015). And this is influenced by an employees' level of education, competence, ability, work experience, and identification with the job in question (Oyekunle & Onifade, Adigun, 2017). Employees' satisfaction represents a mental state that the workforce reach; it includes the knowledge and ideas gained about the reasons people work, how they are satisfied and the rate at which they derive satisfaction from their job in an organisation (Rahman, Gupta & Moudud-Ul-Huq, 2012; Saad *et al.,* 2012).

Concept of Career Advancement

Ugwu, Kekeocha and Chukwu (2018) argue that several organisations today have recognised the importance of career advancement and have designed programmes targeted to enhance the skills and expertise of their workers. Jauregui and Olivos (2017) see Career advancement as a promotion to higher levels in the organisational hierarchy or positions with greater responsibility. Fundamentally, career theorists and researchers explained that career advancement helps employees evaluate their skills so they can move to jobs that are more congruent with their personal goals and plans (Adewoye, Abioro & Hasimiyu, 2017). To establish the effectiveness of an organisation, captains of industry and business technocrats need to focus on aligning employees' career advancement to their organisational strategy of improved performance of their workforce. Pillay, Dawood and Karodia (2015) asserted that career advancement is the progression through the ranks of the organisational hierarchy. The lack of career advancement affects motivation and performance. In this regard, Adeniji and Osibanjo (2012) argue that career advancement can help reduce cost expended on recruiting and training new employees in organisations.

Theoretical Review: The theoretical review in this study is based on the Fredric Herzberg's Two-Factor theory.

Fredrick Herzberg's Two-Factor Theory

The Two-Factor theory, also known as the Motivators-Hygiene theory, was propounded by a behavioural scientist, Fredrick Herzberg, in 1959. According to Herzberg, some job factors result in satisfaction, which he calls motivational factors, while other job factors preventing dissatisfaction, which he calls Hygiene factors.

The Two-Factor Theory of Fredrick Herzberg believes that it is the motivators/satisfiers (non-financial aspects/indicators) that enables employees to get motivated in the workplace when present, and also the hygiene factors when available, will not necessarily motivate or satisfy employees but de-satisfy them when it is not present in the workplace. In essence, the theory is relevant to this study based on the fact that an organisation with a motivating/satisfying factor (s) like good job characteristics or aspects (employment quality) is likely to bring about enhanced employees' satisfaction for overall organisational performance. In this study, work flexibility is seen as a non-financial aspect/indicator that helps employers to bring about better satisfaction in different areas that concerns the employees in terms of career advancement, resulting in overall organisational performance.

Methodology

This study reviewed different concepts which are vital to the understanding of employment quality and employees' satisfaction in the Nigerian public service. These concepts include employment quality, work flexibility, employees' satisfaction and career advancement. It adopted Fredrick Herzbergs Two Factor theory to complement the knowledge of the key concepts reviewed in this paper. After that, the study developed a schematic model of employment quality and employees' satisfaction to support the proper understanding of the employees' work flexibility for career advancement in the Nigerian public service.

Nigerian Public Service

The Nigerian public service was established by the British in 1900, basically to implement the policies and programmes of the colonial government. However, at independence in October 1960, the role of the public service changed from that of maintenance of law and order to that of service delivery to the people (Gberevbie, 2010). Therefore, what was known at independence in 1960 as the Nigerian public service was a prototype of the British administrative system based on the weberian model "characterised by hierarchical patterns of authority, a division of labour and specialisation of a task and impersonal relationship" (Gberevbie, Ayo, Iyoha, Duruji & Abasilim, 2018:58).

The above characteristics played a significant role in the non-performance of the Nigerian public servants in the sense that the system did not allow for personal initiatives of the public servant to boost performance for career advancement. Furthermore, to reflect every segment of the Nigerian society in the public service, the federal character principle was introduced by the Federal Government of Nigeria at post-independence years (Gberevbie, 2010). The federal character principle, as contained in section 14(3) of the 1999 constitution of the Federal Republic of Nigeria as amended stated that:

The composition of the government of the federation or any of its agencies and the conduct of its affairs shall be carried out in such a manner as to reflect the federal character of Nigeria and the need to promote national unity and also to command national loyalty, thereby ensuring that there shall be no predominance of persons from a few states or from a few ethnic, sectional group in that government or any of its agencies (cited in Gberevbie, 2010:1449).

The above development of federal character principle introduced into the Nigerian work environment has brought about poor leadership, lack of work flexibility for career advancement and lack of the capacity to perform on the part of the Nigerian public servants (Gberevbie, Joshua, Excellence-Oluye & Oyeyemi, 2017).

Research Proposition

Work flexibility and Career Advancement

Career advancement is fundamental to employees who take part in the day to day activity of their organisation. It is the design of programmes targeted to enhance the skills and expertise of organisations' workforce. Career advancement is essential to increasing workforce satisfaction (Ugwu *et al.,* 2018). Scholars have found that career advancement opportunities lead to an increase in high employee satisfaction (Adewoye *et al.,* 2017). Ugwu, *et al* (2018) in their study on the impact of work-family conflict on career advancement, revealed that family obligation has a significant positive influence on career advancement of female professionals in the Nigerian banking industry. However, Oludayo *et al.* (2015) in their study on multiple work-life-balance initiatives in the Nigerian banking industry, revealed that flexible work arrangements made a unique influence on the employees' behavioural outcomes. This ranges from time-out for personal matters, compressed workweek, personal scheduling of work hours, teleworking and part-time working. The study further posits that most of the elements of work flexibility arrangements still run on the wheels of a co-worker and managerial support, which influences the level of an employee's satisfaction. Adewoye *et al.* (2017) in their study on functionality of career advancement and organisational effectiveness, showed that employees' career advancement in the workplace exerts a great influence on the operations of deposit money banks in Nigeria, and as such banks management should invest in employees development to stem employees' high rate of turnover and improve productivity.

Linge (2015) in a study, examined social-family factors and career advancement of Kenyan women employees and found out that social-family factors were not perceived as a barrier to the career advancement of Kenyan women employees. Also, Essien and Amah (2017) in their study, observed that the implementation of work flexible schedules in the banks positively impacts employee affective, continuance, and normative commitment to work.

Also, Ojo, *et al.* (2014) in their study on work-life-balance practices in Nigeria of three different sectors reported that when business organisations allow work flexibility in the workplace, employees accomplished their work and non-work needs better. Thus, based on the argument above, the study proposed that:

P1: work flexibility influence and enhances career advancement.

Fig. 1: Schematic model of Employment Quality and Employee Satisfaction

The diagram in figure 1 above, reveals how employees' satisfaction, such as career advancement, job security, and employee relationship management can be enhanced through employment quality provided by their organisations. These employment quality provided by an organisation is in terms of work flexibility. Where the diagram depicts that work flexibility influences and enhances career advancement in an organisation.

Conclusion

The importance of employment quality in the organisation cannot be underrated. Hence, the literature reviewed has been able to show the essentiality of work flexibility, the role it plays in improving employees' satisfaction in terms of career advancement that is noted as a motivator and hygiene factors in Fredrick Herzberg's Two Factor theory.

Implication and Recommendations

Career advancement is fundamental to employees' retention in an organisation, which tends to increase their satisfaction level in the workplace. Also, different things influence career advancement of which work flexibility plays a significant role. This study, therefore recommends that work flexibility under the aspect of employment quality should be implemented while making decisions to enhance employees' satisfaction in the Nigerian public service.

Contribution to Knowledge

This study contributes to knowledge by helping and enabling the Nigerian government to understand the concept of employment quality and the need to formulate employment quality policies that favour certain job aspects, which enhances the satisfaction of those in public service. In addition, the study stands out as a blueprint that would enable employees in the public sector to understand that their satisfaction is tied to the specific job characteristics offered to them at the point of employment and to seek those job characteristics such as work flexibility that would enhance their career advancement and well-being.

Suggestion for Further Study

To properly understand the role of work flexibility in the career advancement of employees for generalisation, further studies should be carried out comparatively in an empirical manner in the area of employment quality and employees' satisfaction in organisations both public and private sector. Furthermore, this is in addition to other job characteristics that form employment quality towards developing better employees' satisfaction for enhanced performance.

Abstract

A sense of security - or the lack of it - essentially determines the quality of life of every human being. Contemporary man, thanks to the digitized reality, has unlimited potential for creating his own existence. Cyberspace is now becoming an inevitable reality of everyday life. We are wrapped in technological advances that not only make our lives easier, but most of all provide us with a sense of security. This virtual space shapes our safety, actions and choices, influences our relationships and mutual connections in almost every sphere. The global COVID-19 pandemic has made our relations even more dependent on cyberspace, as most of us perform professional duties in the remote work system. This sudden dependence on remote working, however, opened up a whole new range of security and privacy risks. The purpose of this article is to present the impact and implications of civilization, technological and epidemic changes on the security level of remote work.

Keywords: Cyberspace, Pandemic, Remote Work, Digital Security

Introduction

In early March 2020, the World Health Organisation (WHO) announced the COVID-19 or SARS-Cov-2 pandemic[1] around the world. This decision had to be accepted also by the authorities of our country. Due to epidemiological threats, human life has almost completely shifted to virtual reality, i.e. the World Wide Web, which was described in his memoirs by Timothy Berners-Lee,(Berners-Lee 2000) British physicist and computer scientist, one of the creators of the WWW system, known today under the name of Internet. "The rise of the Internet gives us a foretaste of what is coming. Cyberspace is now a key element of our daily life, economy and security"(Harari 2017: 420). The COVID-19 pandemic has also made most people in the world switch to remote work. They usually work from home and so digital technology has become an important proverbial lifeline for them. This sudden dependence on remote work, however, opened a whole new range of threats to security and privacy.

Interdisciplinary security issues

Interdisciplinary security issues elude any systematisation because there is a multitude of divisions and patterns of such a widely understood matter. Security is typically perceived from the perspective of a human being as an individual, human collectivity, the whole society or international communities, hence it is usually analysed in the social, cultural, ecological, military, political or legal context. When analysing the problem of security, one should

[1] According to the Ministry of Health of the Republic of Poland, The SARS-Cov-2 coronavirus causes a disease called COVID-19, most often manifested by fever, coughing, shortness of breath, muscle aches and fatigue.

use research methods proven in social sciences that are characterised by methodological, epistemological, ontological and axiological pluralism.

It is difficult to unequivocally define security (if it is possible at all) because there are almost as many attempts to specify this concept scientifically due to the various area or thematic scope of the subject as there are subject experts. Despite this difficulty, the typologies of security most frequently cited in the literature on the subject are those distinguished on the basis of the following criteria: subjective, objective, time and source of threats. In the context of an individual's safety, one can refer to a dichotomous division which refers to structural and personal security. Structural security refers to social groups that are linked by common relationships. They can be formal and informal. This security was based on internal structures and ties and it is guarded by state institutions(Cf. Sztubrych 2006: 110). Structural security refers to the activities of individual structures of institutions and organisations in the local, regional, national and international context, the task of which is to shape social life in various aspects of human existence and thus ensure security in the personal dimension.

The subject of personal security is not only an individual, but also a social group or a community: national, regional, local, corporate, institutional, etc. Subjectivity is identified with conscious shaping of reality, transforming it in the direction consistent with one's own needs(Cf. Drabik 2013: 53). It is worth noting, however, that the awareness of individual entities is not very clear and difficult to grasp because in each collective entity there are usually differences in the awareness of specific groups and individuals. Personal security is usually associated with a sense of stability, durability, certainty and lack of threats, both in the physical and mental sphere.

Karen Horney pointed out that the need for security is the main motivation directing the way of life and human activity(See: Horney 2007: 28), which is related to the constant protection against the threat. Permanently experienced state of anxiety can be a source of personal threat. It can disorganise human activities, create unfavourable interpersonal contacts as well as lead to social isolation and limiting or avoiding contacts with other people. In certain situations it can also be a motive for aggressive behaviours. In the face of the growing awareness of threats, people feel the increasing need for security more and more often. The thought of a sense of security usually evokes associations relating to external aspects of broadly understood human existence and refers to an individual assessment of reality, the possibility of one's survival and growth. The quality of this security is determined by the state's ability to guarantee that people can fulfil their existential needs. In this context security can also be seen in an axiological context, as an aspect of human dignity(See: Chrzanowska-Gancarz and Gancarz 2019: 52–58). Thus, it can be concluded that security is not only the primary need but also a law of nature that determines survival and development not only of a human being but of all biological beings. As Wolfgang Sofsky notes, it was mainly for the sake of personal safety that people "laid down all weapon they produced over time and entrusted this weapon to several representatives, previously selected from among their own group"(Sofsky 1999: 20). An important, so far underestimated barrier to the proper development of civilisation, is the low level of awareness of personal security in cyberspace. The pandemic effectively impaired the sense of security, especially in the personal dimension.

Personal security and digital security of an organisation

Personal security faced with digital security of an organisation seems to be extremely important in the context of the currently developed digital economy and its challenges. The demand for new applications that support enterprises and organisations in digital transformation, automation of business processes and solving current problems is growing day by day. "Today, each and every organization operates on an information systems infrastructure that is internal as well as external(Kostopoulos 2013: 45)". This ensures the security of achieving the intended effect of the change. Therefore, modern management concepts focus on coordinating connections and relations between the links. Security of an organisation is the same as security in the personal sphere (employees, owners, suppliers, customers, etc.) because the main subject representing various categories of individual and collective stakeholders in a given organisation is a human being. In practice, it is almost impossible to analyse threats in the area of structural security without interfering with the personal aspect.

Structural security plays an ancillary role towards humans regardless of time and space, which makes it meaningful only when it is considered and implemented in the personal context. In order to reconcile all positions regarding the subjects of personal and structural security, three types of entities can be distinguished:

- individual personal entities,
- collective personal entities,
- structural entities, i.e. various types of organisations, including institutions that affect personal security. These entities fall under three basic categories of security: individual security, collective security and organisational security.

In digital reality, i.e. so-called fifth dimension, in which human beings stay more and more often, security has become an indispensable guarantor of normality and development in every possible area of modernity, i.e. politics, economy, health, education, culture, etc., hence it is the subject of multidimensional, interdisciplinary scientific research. This virtual space is also the subject of care and activities ensuring practical and proper functioning of both business and institutions of various levels(See: Berg, Freeman, and Schneider 2008: 34–37). For the economy 4.0 – so-called digital economy – it is the basis of its existence and a condition for innovation(Cf. Joint Task Force Transformation Initiative 2012). However, digital security is also a new type of "battlefield" in which entities that actually pose a threat (unfortunately, generated mainly by the human factor) must be constantly opposed even more actively – both through technology as well as creating appropriate, safe digital behaviours, especially from various stakeholders of the new digital reality: citizens, employees, customers. Despite having significant intellectual and technological resources as well as spending more and more money, digital security is an area where uncertainty and risk awareness is not decreasing but systematically growing.

At the level of functioning of an organisation there are more and more new faces of cyberthreats revealed. Their nature and effects have already exceeded the control of technical infrastructure, owned equipment and ICT devices. Currently, the greatest concerns connected with digital security relate to a wide range of technical and behavioural threats. Achieving a satisfactory level of digital security is a key challenge for decision-makers in various institutions as well as owners or managers of business entities. As various organisations develop and introduce innovative business models (e.g. e-business(Cf. Laracy and Leveson 2007)), the issue of cybersecurity is entering higher and higher organisational level. Providing cybersecurity within an organisation is a real challenge because as a rule organisations do not have their own ICT infrastructure and the condition for their operation is to distribute the services provided beyond the control of their own IT department. Digital security is thus becoming a problem at the interface between technology and the physical world in which humans play an immanent role. We are talking about information and communication technology (ICT), operational technology (OT) and the Internet of Things (IoT)(Cf, Grubicka 2018: 141–142).

The pace of e-business development is accelerating to algorithmic speeds as algorithms replace the human factor in making business decisions. Digital risks and digital opponents will continue to pose a challenge for organisations and we should expect an increasing number of threats and risks connected not only with data loss but also the assumed profits from operating activities. However, the complexity and range of systems, sectors and benchmarks where cybersecurity can and should be analysed means that looking for any effective approaches must necessarily be multifaceted and interdisciplinary. To this end, cooperation of specialists in many areas and specialities, both those representing the technical view of digital threats and the related security measures, as well as those from the field of social sciences, analysing the personal and subjective nature of digital risks in citizens' lives as well as an organisation's functioning and development opportunities, is necessary.

Cybersecurity is a dynamic process which actively involves entities that pose threats on the one hand and entities that oppose them on the other hand. The attacker–defender system, known from the military realities, cannot mean the defensive of the latter. Protecting digital security of an organisation is primarily prevention, improvement and innovation. It is equally important to search for effective business and operational strategies that can provide constant support for the creation of a threat-resistant organisational community that has the appropriate technology and competences and is capable of loyal cooperation in the name of a common goal. Technology, competences, ethics, cooperation – these are the key pillars of digital security of modern organisations. Recent technological advances in data processing, mass memory and Internet connectivity further emphasise the need to better understand general security systems which we rely on.

A current example of a situation in which the importance of cybersecurity has gained a new global dimension is the crisis caused by the COVID-19 threat. Therefore, studying digital security and its conditions in organisations of various types is necessary and extremely important, especially in the context of the new era of organisational behaviour in connection with the crisis caused by the epidemiological threat.

Threats to privacy and freedoms regarding remote work in the light of the COVID-19 pandemic

Coronavirus disease 2019 (COVID-19), which according to scientists first appeared in the city of Wuhan, Hubei Province, China, probably originated at the seafood and meat market called "Huanan." It belongs to the coronavirus family such as SARS and MERS. A pandemic caused by a virus whose genesis - so far - has proved to be quite difficult to determine, is not the only virus that has caused a pandemic to be declared. "The first of these epidemics (541–544) has been called the Plague of Justinian, since it occurred in the reign of the (eastern) Roman Emperor Justinian (527–565); the name has sometimes been extended to the entire 200-year period of the recurring epidemics

as well"(Hays 2005: 23). As we know from history, over the centuries there have been many pandemics that decimated humanity, such as:

- Smallpox Epidemic in Japan (735–737),
- disease called leprosy in medieval Europe, especially (but not only) between about 1000 and about 1350,
- The Black Death - the great epidemic of 1347–1353,
- The "French disease" at the end of the fifteenth century,
- smallpox (black pox) pandemic – in the 16th century it decimated South and North America,
- cholera in the 19th century – in Europe and America,
- Spanish influenza in 1918 and 1919 – the biggest flu pandemic in the history(See: Encyclopedia of Pestilence, Pandemics).

Certainly, the above-mentioned pandemics, like SARS-COV-2, made people change their previous habits, plans and dreams. A human being, as a social being and at the same time a part of a larger human community, usually strives for self-development but in a situation of insecurity – and a pandemic is undoubtedly such a situation – focuses mainly on satisfying the needs connected with survival. However, according to policy makers, the survival of citizens depends on introducing precautions suitable in the current situation. As it is commonly known, leaders of individual countries have decided to implement strict rules and regulations of conduct in the event of an epidemic emergency and state of epidemic, such as:

- obligation to wear face masks (when going outside and in all public spaces)
- wearing gloves in stores and supermarkets
- maintaining 2 metre distance between people
- remote learning
- no trips (as we probably remember, there was also a ban on entering forests and trips to the seaside)
- no business activity
- and many other rules and regulations which, if not complied with, meant (and still mean) imprisonment and high penalties.

These restrictions not only changed the current (and the only one we knew) lifestyle but also often cause fear and insecurity to constantly increase. People, fearing the rapid spread of the virus and out of concern for their own safety, are capable of attacking others who, in their opinion, do not strictly follow the pandemic-related guidelines. Moreover, the pandemic situation, forcing people to some form of isolation, causes stress which translates into a lack of motivation to continue living and to make plans for the future. Additionally, people who stay at home during the pandemic become lonely and fall into a state of discouragement, depression or even internal chaos. The existence of man is determined by certain actions, activities, leading a certain lifestyle, which Alvin Toffler equates with slavery(See: Toffler 1970: 312–313). Each activity has a specific purpose: we eat, drink and breathe to live; we want to be accepted by other people; we create and we learn to make our plans and dreams come true. We establish our own hierarchy and our own rules but to follow and apply them we need a sense of security.

Remote work system forced by the global pandemic. Cyber threats and ways to counteract online threats

Remote work, forced by the global pandemic, is exposed to a number of threats. This type of threats includes crimes involving the use of a stolen identity, which are usually committed online, although the process of identity theft does not always take place there. Identity theft offences are transaction-related frauds that harm so-called e-business. They consist in filling in the order form in the name of another person. The main difference that distinguishes this type of crime from traditional fraud is that in the virtual world it is possible to attack more stores in a very short time, often with impunity. Generally, identity is stolen in order to commit other crimes. It can be used to commit fraud, to resell it to other people or organisations that plan to commit fraud and to fabricate birth certificates, driving licenses or, for example, a passport. Stolen identity can also be used to access certain places online. Thanks to the Internet, the victim may not even know that someone is using their last name. Most often, the case is not discovered until this person receives a bank statement or when someone begins to demand payment for services and goods that the person did not order.

It very often happens that a criminal opens a new bank account using previously obtained information about a given person, such as name, date of birth, address or the mother's maiden name. This type of information can be obtained from the data available online, from companies that intercept it using "cookies" and, for example, from waste bins. It

happens that the criminal seizes the victim's bank account. To take over the account, the criminals need certain personal information which they can obtain in several ways:

- by using existing chat rooms; the criminal places a link to a website where a given topic can be discussed on the official list with the information on chat rooms; in fact this is the website where people are asked to fill in the form; this form includes questions and answers to these questions will give the fraud all the information needed to commit a crime; graphically the website looks like an original chat room and therefore it is easy to mislead other people
- by copying the seller's or service provider's website; it is a similar method to the one described above, however this time the criminal creates a page that is identical to the existing original page; the criminal collects orders, confirms them and receives the money without ever completing the orders
- by creating websites with pornographic content for which users do not have to pay but only provide their credit card details; such a website remains free but after obtaining the necessary information the criminal makes purchases on other sites.

Therefore, it is worth remembering to properly protect one's sensitive data against cyberattacks and, above all, invest in training to ensure safe work for yourself and your employees. Remote work presents a unique challenge for information security because its environments usually do not have the same security as in the office. In light of these changes, it is essential that the tools underlying sensitive and high-risk communication are carefully scrutinised. Digital security when working remotely comes down to many of the above-mentioned principles but we should also remember to:

- avoid using public Wi-Fi; if necessary, one should use personal hotspots or other means of encrypting the Internet connection
- use VPNs that allow you to connect to various services (websites, e-mail, SQL server, etc.) for remote access to many applications.

Cloud technology is another example of a concept that, on the one hand, brought great convenience (backup, data synchronisation, no need for large physical disks), and on the other, a great threat. By sending our files to an external server (i.e. the cloud), we do not get a total guarantee that they cannot be accessed (or that unauthorised person will not get the access to them by hacking or through leakage). Therefore, it is a reasonable solution to encrypt data before synchronisation. There are many applications available, including DiskCryptor, TrueCrypt or Gpg4win

Another threat from working online is spyware, which is becoming more common, but also dangerous. As a result of malicious use of spyware, all home and corporate users trying to take advantage of computer technology are at risk of serious losses. In addition to common malware, such as viruses, bugs, Trojans, backdoors, root user packages, telephone diallers, listening systems and spyware, a wide variety of different malicious programmes are infecting an increasing number of users and organisations. The set of problems that we call "spyware" is becoming more and more diverse. It is a particular expression of the complexity of the modern world.

The term "spyware"(See: Sun 2007: 555) covers a wide range of software that monitors computer usage without the user's knowledge or consent. Some versions of spyware appear in pop-up ads, while others track online activity, steal passwords or even hijack the user's computer(See: Crawford 2005: 1473–1474). Spyware is often classified into four types of software: (1) system monitors, (2) Trojans, (3) adware and (4) tracking cookies. System monitors pose a serious privacy risk as they can secretly intercept and transmit the user's personal information and passwords entered during online transactions. Trojans appear to be legitimate software, but they can be used to steal sensitive information, install malicious programmes, take control of a computer or compromise additional computers and networks. Adware tracks users' online activity to display targeted pop-up ads. Tracking cookies are small text files that are downloaded to the user's computer and retain preferences on certain websites. Once installed, spyware evades detection and is resistant to removal. Most spywares do not come with uninstallation software and even leave components behind when uninstalled. Such information may be used for legitimate data mining purposes or for identity theft and financial crimes committed by others.

One of the most modern spywares nowadays is Pegasus, which can be installed on iOS (Apple's operating system) and Android devices. In the second half of 2019 there were media reports saying that the Central Anticorruption Bureau could have purchased the Pegasus surveillance system. The software allows access to all phone content as well as the speaker and camera. The Pegasus system also enables downloading the content of instant messaging conversations, text messages and e-mails as well as access to photos and recordings stored on the phone. The spyware called Pegasus is an extremely sophisticated and dangerous cyberweapon that allows its operator to hijack the entire smartphone, including WhatsApp(Cf. Winstanley 2019: 1). The scope of activities on the Internet as well as the use of popular applications and the study of transparency and accountability mechanisms – important for relations

between corporations and state agencies in the field of personal data and other supervisory activities – have become the basis of research at Citizen Lab.

The report Citizen Lab published on April 3, 2020 (*Move Fast and Roll Your Own Crypto: A Quick Look at the Confidentiality of Zoom Meetings* 2020)highlighted the security issue with the Zoom's Waiting Room feature. In particular, it was found that the Zoom servers provided both the encryption keys and the Zoom meeting live video streams to all users in the Waiting Room, even if waiting users were not approved to join the meeting. This issue would allow any unauthorised Zoom user in the Waiting Room to intercept and decrypt "encrypted" video content(Cf. *Deibert:* 2020). Following the publication of the Citizen Lab report, Zoom took a number of security measures. The communication systems we rely on have seldom been designed with security in mind. Security has been routinely thought of as slowing the pace of innovation or as impossible to impose on basic systems that have chronic failures and that would require a complete overhaul of the communication infrastructure to become "secure". The consequence of such online contact solutions is that there is a wide variety of unpatched systems that leave constant security gaps behind. This risk covers the most basic layers of our shared infrastructure. For example, telecommunication and mobile networks still rely on a ten-year-old information exchange protocol called SS7, which has proved to be highly insecure and prone to abuse and illegal surveillance when sending credentials. The signs of cybercriminal attacks that are worth paying attention to when using a computer connected to the network include:

- the appearance of new programmes that have not been installed by us
- computer slowing down
- pop-up ads appearing on the screen
- loss of control over the mouse or keyboard.

A simple solution of updating modern anti-virus software may prove to be helpful in this situation. Ideally, employees should be able to use computers that are fast, well-maintained and dedicated to the tasks at hand(See: Grubicka 2019: 96–97). It is worth remembering that corporate and personal data should be stored separately. When it comes to cyberthreats in a company, employees are always the weakest link. About 90% of intrusions and problems connected with cybersecurity are caused by human error, which means that the best way to protect remote employees from cyberthreats is to invest in proper IT training. Taking care of one's privacy online, it is worth paying attention to every detail.

Conclusion

Functioning in virtual reality, in addition to the obvious, undeniable benefits – easy access to reliable information, the possibility of organising the process of remote education in a situation of having to limit direct contacts (see the SARS-COV-2 pandemic), the possibility of remote handling of civil and official matters, remote work, etc. – robs humanity of the sense of intimacy, sense of privacy, autonomy and freedom at the same time. What's more, the ever-changing formulas in the virtual sphere also force people living in modern times to accelerate the pace of life in the real sphere, which, paradoxically, results in a permanent lack of time for reliable performance of our daily duties, which our life and its quality depend on. Virtual reality has given the world a unique power, but also an unprecedented dependency and loss of privacy. It should be remembered that remote work is exposed to a number of risks. Digital espionage against civil society, documenting Internet filtering and other technologies and practices are more and more common examples of threats resulting from violating privacy on the Internet. The quoted examples of unlawful data analysis and information flow control have a huge impact on the sphere of both our freedom of speech and privacy. The solutions proposed in the article do not guarantee the protection of privacy on the Internet. Each software or technology has some weaknesses that can be exploited by a capable hacker or services with sophisticated equipment. It seems that the highest possible degree of anonymity in the cavernous abyss of human in the fifth dimension, if the simultaneous use of many of the options described, as well as using common sense, carefully disposing of information about yourself.

Abstract

Theoretical approaches to the definition of the essence of the concept of «financial support» of an enterprise are presented, the evolution of this concept is traced. The economic content of the financial support of an agricultural enterprise is disclosed. The relationship between the category «financial security» and such categories as «financial stability» and «financial stability» is considered. It has been substantiated that the financial support of an agricultural enterprise characterizes such a state of financial resources, in which the enterprise can maneuver cash to ensure a continuous process of financial and economic activities, as well as renewal and expansion of its funds. It has been established that at present agricultural enterprises, in addition to their own and borrowed financial resources, use attracted financial resources. The modern forms of financial support of the reproduction process in the agricultural sector are determined.

Keywords*:* Financial Security, Financial Resources, Own And Borrowed Financial Resources, Agricultural Enterprises, Financial Stability, Financial Stability

Introduction

Peculiarities of the development of financial relations within the state's economy, and in particular in the agricultural sector, are of great importance for understanding the essence of the concept of "financial security", the disclosure of the economic content that falls into this category.

Analysis of the views of domestic and foreign scholars, the wording given in the regulatory legal acts of Ukraine, economic dictionaries, indicates that there is a wide range of definitions that reveal the essence of the category of

"financial security". The views and opinions of economists on the essence and content of this category have been transformed and developed, but the issues still remain finally unresolved.

Analysis of recent research and publications

Important contribution to the development of the theory and methodology of formation and use of financial resources was made by Ukrainian scientists O. Hudz, M. Demianenko, V. Zinovchuk, V. Oparin, P. Stetsiuk, O. Tereshchenko, S. Yurii, Yu. Tsal-Tsalko and others. Scientific studies of V. Aleksiichuk, V. Andriichuk, P. Haidutskyi, P. Kaninskyi, P. Laiko, M. Malik, L. Maslovska, V. Mesel-Veseliak, H. Pidlisetskyi, P. Sabluk, A. Chupis and others are dedicated to issues of development of financial relations of resource-forming and resource-consuming nature in the globalized market environment.

Thus, V. I. Kravchenko notes that "… financial security – the amount of funds allocated for the maintenance of the objects of the social-and-cultural sphere, production and social infrastructure, social services, social protection, social security, financing of management staff and the programs of social-and-economic development… » [1, p.117].

According to A. P. Kovaliov, the main tasks of the finances of economic entities, regardless of their organizational-and-legal forms are:

- formation, maintenance of optimal structure and increase of production potential of the enterprise;
- support of current financial-and-economic activity;
- support of the participation of the business entity in the conducting of social policy.

Based on this, the author identifies three functions that perform the finances of enterprises: support, distribution and control.

The support function is directly related to the definition of the essence of the category "financial security". The essence of the support function of the finances of the business entity is to create monetary funds at the enterprise in the optimal amount. All production expenses must be covered by own income. Temporary additional need in funds is covered by credit or other loan sources. Herewith, the optimization of sources of monetary funds is one of the main tasks of enterprise financial management, because the excess of funds reduces the efficiency of their use, and financial difficulties appear in their absence that can lead to serious consequences [2].

A more complete interpretation of the category of financial support is made by V. M. Rodionov: "Financial support of expanded reproduction is covering the costs through the financial resources accumulated by business entities and the state". It takes three forms: self-financing, crediting and state financing. Financial support of the reproduction of production expenses is one of the important areas of financial influence on the processes of social development along with financial regulation and financial stimulation [3].

M. S. Maizus appreciates this point of view and believes that the financial activity of the enterprise are directly aimed at its financial support and aimed at creating financial resources for production and social development, increasing income by rising the labour productivity, reducing the prime cost, improving product quality, enhancing the use of production assets [4].

M. L. Lyshanskyi emphasizes that it is impossible to achieve high financial results, carrying out integration processes in the branch without stable and effective financial support of agrarian formations. In addition, the author notes that the mechanism of the financial security is not once an ingrained phenomenon, but must be constantly improved [5].

Charles Blancart, a well-known Western economist, concludes that individuals in financial relations make decisions and act orienting primarily on maximizing their own benefits. In this case, it is implied that a representative adult is always focused on maximizing his own benefits [6].

Objectives statement

Within the conditions of economic instability, the range of problems in financing, crediting and government support of agricultural enterprises has increased significantly. This necessitates their assessment, identification of the causes of underfunding and further research aimed at finding the best ways to solve the above problems.

Presentation of basic material of the research

There is a danger of limiting the growth of the financial potential of enterprises because of the fact that they cannot fully realize their opprtunities for expanded reproduction when using just own funds for economic activity.

Loan sources of financing play no less important role in the economic process except own sources of financial resources. Bank crediting is the most common source of loan financing in Ukraine, as every enterprise has a need to receive a credit in the process of economic activity. The current stage of development of the market economy in Ukraine necessitates the search for its own credit model to support agriculture.

Leasing could be another alternative source of financing for agricultural enterprises since most agricultural enterprises take credits to purchase machinery. This significantly accelerates and improves the technology of the process of production and cultivation of agricultural products, maintains the competitiveness of all parties to the leasing agreement.

Agricultural enterprises use borrowed financial resources in addition to their own and borrowed sources of financial resources. One of the sources of borrowed funds is assistance to agricultural enterprises by the state, which is expressed in the provision of subsidies, grants, budget allocations [7].

Some economists directly connect financial support and its efficiency with a category such as the "rural financial system". The authors include not only commercial banks to the group of possible creditors but also credit unions, cooperative banks, credit providers who borrow their private funds, pawnshops, and can provide financial services to small and medium enterprises and households in rural areas. This system includes both companies on the supply of material-and-technical resources and processing plants. All these institutions coexist in many countries and provide services according to different customer requirements [8].

O. S. Filimonenko, the economist, understands financial support in an interesting way. The author notes that enterprises operating in the conditions of the market relations are fully responsible for their obligations to the sections of the financial-and-credit system, suppliers, their employees, as well as the results of their production-and-financial activity [9].

Thus, we favour the idea of the author that the financial support of the enterprise is the ability of the enterprise to repay timely its debt obligations to the subjects of financial-and-credit relations.

Some authors connect financial support directly with the financial condition of the enterprise to self-develop at a certain point in time [10].

We do not share the point of view of these authors, as they do not reflect the financial sources to ensure the self-development of the enterprise. In our opinion, the concept of such a category as the financial stability of the enterprise is more successful in terms of content, which implies the ability of the enterprise to provide activity at the expense of its own and borrowed funds and timely settle its obligations.

A number of authors consider the category of "financial support" in a broader financial range, believing that the financial support can be provided in three forms: budget financing, crediting and self-financing. Budget financing is carried out on a non-repayable basis at the expense of budgets formed in the process of distribution and redistribution of the part of national income. The state redistributes financial resources with the help of budget financing between productive and non-productive spheres, in intersectoral and territorial divisions, between individual forms of ownership.

Crediting based on mobilization and redistribution of temporarily free funds of market participants. Loans, in contrast to budget financing, are provided in accordance with the principles of crediting: security, target character, urgency, repayment and payment.

Self-financing is based on the use of own resources to ensure economic and social development. Enterprises and organizations must either reduce some expenses or take loans in the absence of their own resources.

Different forms of financial support can be used in practice simultaneously. The development of the financial support system is not by displacing one form of another, but by establishing the optimal ratio between them for certain stage of the society development. Determining such proportions is one of the tasks of the financial policy of the state [11].

In addition, some economists directly connect financial support with the system of economic relations. They believe that the financial-and-credit mechanism should provide a continuous process of expanded agricultural production by monetary resources and at the same time influencing the improvement of the resuls of the economic activity. We share the point of view of those economists who define the content of the financial support not only as a form of distribution relations, but also from the standpoint of mediating the stage of production to consumption associated with the formation and use of the monetary funds. Finance with the help of distribution relations and exchange influences the stage of production and consumption, the strengthen of cost accounting.

Based on this, the authors conclude that the problem of raising the efficiency of agriculture of the entire agro-industrial complex is associated with the improvement of the financial-and-credit mechanism. The search for a more rational system of the financial support for production is determined by the improvement of distribution relations. Herewith, it is expected a rational combination of three methods of financing: commercial self-financing, credit and budget [12].

In our opinion, the category of "financial support" should be associated with such categories as "financial strength" and "financial stability", which directly complement each other in economic terms. According to M. Ya. Demianenko, the financial strength of the enterprise is characterized by the ability to keep the balance of its assets and liabilities, keep constantly paying capacity and investment attractiveness, within acceptable risk, use efficiently financial resources and implement profitable activity. The financial strength of the enterprise reflects the balanced state of cash and commodity taxes, income and expenses, instruments and sources of their formation, optimal proportions of own and borrowed capital. In the author's view, the financial stability is the achievement of different levels of the financial strength. The first level is characterized by the level of the financial strength when self-financing of the production-and-economic activity at the level of simple reproduction is provided. This is typical of a crisis state in the economy, when stability is provided as an opposition to the decline in production and the destruction of the resource potential. Financial stability is characterized by progressive economic growth and ensuring the development of enterprises through their own sources of funding [13].

The essence and sources of the financial support of the enterprises is reflected in a number of regulatory acts of the state. Thus, the Law of Ukraine "On Enterprises in Ukraine" (Article 24, paragraph 1) states: "The source of formation of the financial resources of the enterprise is the profit (income), depreciation deductions, funds received from the sale of securities, share contributions of the members of the labour collective, enterprises, organizations, citizens and other income."

In addition, this Law provides that the enterprise may use a bank credit (Article 24, paragraph 2) and state support (Article 28, paragraph 2). This is confirmed by the traditional channels of the financial support of the business entities. However, it would be appropriate to supplement the mentioned sources with a category such as commercial crediting, that is providing a loan from one entity to another and vice versa. The functioning of such mechanism of crediting is especially relevant in the market conditions and the financial instability of the agricultural sector. Commercial crediting will significantly alleviate the need to attract a bank credit, which is quite expensive and not always available to agricultural producers.

However, sometimes financial support was identified with the category of financing in the works of Soviet economists. Thus, A. M. Aleksandrov believes that funding is the provision of the monetary funds to the enterprises and organizations through budget allocations and the direction of their own resources for continuous cover the costs of expanded reproduction. The author also notes that these are:

a) Identification of fund needs and sources of satisfaction;
b) Provision of credits, organization of cash servicing of the budget and use of own funds of the enterprise;
c) Control over the targeted and efficient use of funds.

Sometimes the term financing was used in a broad sense, also covering short-term and long-term bank credits [14]. This interpretation is consistent with the definitions of modern economists, who have combined all sources of financing into one category.

For example, "financial resources are own and borrowed money capital by the firms used to finance their assets."

In recent years, financial science has undergone radical changes. Knowledge of finance has now become indispensable for people of practical business. For their part, scientists have revised their theories to reveal the real situation. Financial markets encouraged the development of various investment techniques and methods of capital mobilization. From this point of view, the view of Canadian scientists of Ehsan Nikbakht and A. A. Groppeli on the formation of internal and external sources of capital is interesting. The capital used by the firm comes from both

internal and external sources. The origin of funds from internal sources can be found in the balance sheets and income statements, which report on the funds received from retained earnings and amortization.

Funds from the internal sources reduce the need in external financing. They should be considered those which have the optimal possible cost of capital, without which the firm would have to issue new shares or bonds, which would mean the payment of dividends or annual interest because they are an alternative source of financing. In finance, it is common practice, when the cost of capital assumes to these internal sources of funds, that is, the firm seems to have borrowed or issued new shares. Note that each source counts on a different cost of capital, and plays an important role in determining the total cost of the firm's capital.

External sources of funds are presented in the right part of the balance sheet. The balance sheet shows the relative value of the long-term and short-term sources of the firm's financing. All you need to do is to compare the amounts that are formed due to current debt (short-term loans), long-term debts (mostly bonds) of preferred and ordinary shares [15].

Sometimes some authors equate the category of "financial support" with the category of "self-financing". However, the definition of the category of self-financing provides for the type of activity of economic entities in which the financial support of own funds. Although self-financing provides for the normal bank crediting (repayment of credits within a particular timeframe) and does not preclude budget financing of targeted purpose. In our opinion, the financial support provides a wider range of sources of the economic activity financing, and self-financing provides financial support of expanded reproduction, mainly at its own expense.

A number of domestic and foreign scientists believe that the general category of market economy and the appropriate form of organization of the economic activity of producers is a commercial accounting [16]. Commercial accounting provides coverage of current and capital expenses exclusively from own funds and bank credits, complete independence in decision-making, effective financial interest, financial responsibility for the results of all current economic and investment activity.

Commercial accounting is the basis of the organization of business finance. The economic mechanism of self-development under the market economy is based on the following basic principles: self-regulation, self-sufficiency and self-financing. Commercial accounting corresponds to these principles, that is the method of management, which consists in a constant comparison (in monetary terms) of expenses and results of activities. Its goal is to obtain the maximum income at the minimum expenses of the capital and the minimum possible risk. The question of what to produce, how to produce, for whom to produce, under market conditions for the enterprise is determined by the main guideline - profit.

Commercial accounting has a significant impact on the organization of business finance. It stipulates that the financial relations of enterprises are regulated by the state mainly by economic methods – with the help of the levers of the relevant tax, depreciation, currency, protectionist policy. Losses (including lost profits) incurred by the company as a result of following the instructions of government authorities and officials, which are contrary to the applicable legislation, must be reimbursed by the relevant authorities.

The entity has true financial independence, that is the right to decide by themselves what and how to produce, to whom to sell products, how to distribute revenue from sales, how to dispose of profits, what financial resources to generate and how to use them. Full independence of enterprises does not mean, however, the absence of any rules of their conduct. These rules are developed and enshrined in law in the relevant regulatory acts. It is clear that enterprises can make decisions independently only within the framework of the current laws. The subjects of the financial relations bear real economic responsibility for the results of activities and timely fulfillment of their obligations to suppliers, consumers, the state, banks. The enterprise is responsible for its obligations with its own property and income. The enterprise is subject to a system of financial sanctions for non-compliance of its obligations. In fact, the independent enterprise covers its outgoings and losses from financial reserves, insurance system and from its own profit. It is obliged to compensate the losses caused by irrational use of land and other natural resources, pollution of the environment, violation of production safety. The source of formation of the financial resources of the enterprises is the actually earned income from sales and financial investments. The economic responsibility of the enterprise is so great that it can be declared a bankrupt in case of excessive losses and inability to fulfill obligations before the creditors.

A wider range of categories "financial support" is provided in the State target program for sustainable development of the rural areas for the period up to 2020 and it is noted "Financial and investment support for the tasks fulfillment of the Program provides for the development of a mechanism of financing of the sustainable development of the rural areas, private funds, credit unions, mortgage loans, formation of bank and non-bank specialized structures.

Financing is carried out at the expense of the funds of state budget, local budgets, funds of enterprises, private investments, funds of international organizations and other sources not prohibited by law, through the introduction of a special tax regime… " [p. 14].

We support the opinion of the authors [Finance: Textbook / V.I. Ospishchev, L.I. Lachkova, O.P. Blyzniuk and others; Ed. by. V.I. Ospishchev. – 2nd ed., rev. and supp. – K.: Znannia, 2008. – p. 12-13], that the financial support is one of the areas of the financial influence on the process of the social development. Financial support of the needs of the financial reproduction process is at the expense of own or borrowed funds. According to these authors, the financial support of the reproduction process is carried out in the following forms:

- budget financing on a non-repayable basis;
- crediting – providing funds on the basis of return, payment, maturity, support;
- self-financing – financing the activities of the enterprise from its own financial resources;
- renting (leasing) – transfer of the right to use the property to a business entity on a paid basis and for a period specified in the agreement;
- investing – the process of investing money in entities with the aim of receiving additional income.

Conclusions

Thus, in our opinion, the financial support of the agricultural enterprise characterizes the state of financial resources in which the enterprise can maneuver by monetary funds to ensure a continuous process of the financial-and-economic activity, as well as renewal and expansion of its funds, that is meets the needs of the enterprise in accordance with the strategy of its development.

We do not specify the sources of the financial support in the defining of the mentioned category, the main filling of the needs of the enterprise by the financial resources – is its stability and ability to conduct expanded reproduction. The analysis of foreign experience proves that in addition to state financing, the forms and methods of the financial support of the agricultural producers are: crediting of the agricultural sector by private banks and cooperative credit institutions.

It was studied that the activity of the agricultural enterprises of the country to attract external (loan) financial resources necessary for the successful operation and development of agricultural production are characterized by:

- the predominance of short-term loans from the private suppliers and budget funds in the structure of external financing of the agricultural enterprises;
- annual reduction of budget support of agriculture, along with the use of mainly "compensation-and-expenditure approach" in planning the a budget program;
- insignificant role of credit and investment resources in the financial support of the agricultural enterprises.

Activity of Loan Funds and Guarantee Funds in The Aspect of Regional Development in Poland

Przemyslaw PLUSKOTA

University of Szczecin, Szczecin, Poland
przemyslaw.pluskota@usz.edu.pl

Abstract

The literature describes numerous research studies regarding the impact of financial institutions on the economy. Most of them pertain to the impact of national financial institutions on the national economy, proving their positive influence on economic development. However, there are studies that have shown a negative correlation. Generally, the correlation depends on the size of the financial sector and the kind of economy. However, there are few research studies and analyses that focus on regional financial institutions and their impact on development of the regions in which they operate. Even fewer address the activity of non-bank financial institutions and their impact on their environment. Global or national financial institutions serve local entrepreneurs without taking into account the specific nature of their businesses or benefits for the region. Therefore, it seems purposeful to have a look at the activity of regional financial institutions which many a time have taken root in the local community and support micro- and small enterprises in the regions. Even though the scale and effects of their operation are much smaller, their positive impact on the business and regional growth cannot be unappreciated. This article describes the functioning of non-bank financial institutions in Poland – loan funds and credit guarantee funds – and their impact on the regional economy. In most regions, a well-developed system of such institutions and their efficient operation in the area of granting loans and credit guarantees translate into improved economic indicators and benefits for enterprises. It is therefore possible to state that the financial institutions have a positive impact on both regional development and the operation of the the micro-, small and medium enterprises sector. Nevertheless, loan funds and credit guarantee funds will have to face some challenges. National authorities will need to recognise their contribution to business support, while regional authorities will have to meet the capital requirements so as to increase the effectiveness of their operation.

Keywords: Loan Funds, Guarantee Funds, Financial Instruments, Regional Development

Introduction

The regional market and the financial system creates numerous processes. In the theory of economics there are many concepts and views regarding the impact of the financial system on economic growth. Most of them indicate that development of the financial system stimulates economic growth. The mission of regional development should involve any and all local (regional) financial institutions, including those that are not banks, such as loan funds and credit guarantee funds. As research studies have shown, there is a positive correlation between development of the financial system and economic growth. Development of the financial system, also in the regional context, understood as increasing the availability of financial services, makes it possible to effectively fight the financial exclusion and to have a positive effect on the regional development [Beck. Demirguc-Kunt, Levine, 2010, pp. 1, 29; Beck. Demirguc-Kunt, Martinez Peria, 2008 p. 398]. In particular, this regards development of a business model which will significantly support the economic growth of the region, and will be favourably perceived by the local community in view of effective fulfilment of their needs and creating a potential for growth [Kulińska-Sadłocha E., Szambelańczyk J., 2014, p. 172].

The aim of this article to present the regional financial infrastructure in the in the aspect of regional development, as well as to specify the role and position of loan funds, credit guarantee funds, whose scope and area of activity are limited. Moreover, the article intends to indicate the relations between their activity and the condition of the regions.

Cite this Article as: Przemyslaw PLUSKOTA "Activity of Loan Funds and Guarantee Funds in The Aspect of Regional Development in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The article analyses the activity of loan and loan guarantee funds targeting their services at companies, as well as its regional diversification. These institutions operate all over Poland, however some are more active than the others. Although the scale of their activity in comparison with commercial banks is limited, a certain correlation may be observed between their number, the amount of a single support and the condition of regions reflected in GDP per capita, the level of investment, unemployment rate and enterprising behaviour. This is a topic that requires a deeper analysis of dependencies in a longer time horizon, which will be conducted by the author.

The Impact of Regional Financial Institutions on Business and Regional Development - Literature Review

All local (regional) financial institutions, including those that are not banks, such as loan funds and loan guarantee funds, should be involved in the implementation of the regional development mission. In particular, it should be aimed at creating a business model which significantly supports the economic development of the region and will be positively perceived by the local community due to the effective satisfaction of their needs and creation of development potential (Kulińska-Sadłocha, Szambelańczyk, 2014, p. 172). The regional market and financial system is the driver of many processes. In economic theory there are numerous different concepts and views on the impact of the financial system on economic development (A. Alińska, 2008a, p. 124). Many of these concepts confirm the beneficial effect (Luintel, Khan, Leon-Gonzalez, Li, 2016; Durusu-Cifci, Ispir, Yetkiner, 2017). Others indicate a non-linear relationship between financial market development and economic growth. Law and Singh (2014, pp. 36-44) analysed this relationship using data from 87 countries covering the period from 1980 to 2010. In their opinion, there is a certain threshold to which this relationship is positive and becomes negative when it is exceeded. This means that a larger financial sector is not always beneficial for the economy, as the financial crisis of 2008 demonstrated. The financial threshold varies and is lower for developing economies and higher for developed economies, while having a greater impact on the economy (Ruiz, 2018). The impact on developed and developing economies also varies, depending on the time horizon. In particular, a positive relationship exists in the medium term (Beck, Degryse, Kneer, 2004).

Other studies confirm that the development of financial intermediation in the economy determines the actual growth rate (Bencivenga, Smith, 1991), however this impact varies depending on the degree of development of the economy, the financial system (Beck, Demirguc-Kunt, Levine, 2010) and the target group (Bilau, St-Pierre, 2017). All of the above studies are focused on macro scale analysis. The solution, which provides valuable conclusions, involves the analysis of the impact of the development of the regional financial sector on the regional economy. Such an attempt was made by Gemzik-Salwach and Perz (2018) who analysed the relationship between the development of the financial sector and regional economic growth. By examining the impact of the five indicators[1] on the dynamics of GDP per capita in all voivodeships in Poland, she has proven the varied impact of the financial sector development level on the economic growth of individual regions. She observed a high positive correlation between the variables in two provinces, Zachodniopomorskie and Warmińsko-Mazurskie (Gemzik-Salwach, 2018).

Studies on refundable support in Central and Eastern European countries in the post-crisis period support the view that European Investment Bank (EIB) financing supported employment, income and profitability of SMEs (The impact ..., 2019). The reasonableness of refundable support for the enterprise sector, in which financial intermediaries participate, through loan funds, was confirmed by Amamou, Gereben, Wolski (2020). They recognised a positive impact of loans on employment, size of the company, level of investments and innovation capability. It is stronger in Central and Eastern and Southern Europe. In the western part of the continent it is also significant, however it is declining.

Moreover, the activity of loan guarantee funds has a positive impact on the activity of enterprises, in particular on the growth of assets, share of intangible assets, sales and employment. (Brault, Signore, 2019). Similar studies were carried out in Italy, Benelux and Nordic countries (Denmark, Finland, Norway, Sweden) between 2002 and 2016. The companies receiving the guarantee increased their assets, sales, employment and share of intangible assets compared to companies that did not receive such a guarantee (Bertoni et al., 2019). Petkovski and Kjosevski (2014), on the other hand, have not reached definitive conclusions on the impact of the financial sector on regional development. However, as they observed, it was influenced by the condition of financial institutions and the significant share of lost loans as a result of the financial crisis.

The funds set up by regional and local authorities are actively involved in many economic processes in the region, in particular by establishing cooperation with micro, small and medium-sized enterprises. In numerous cases, it is relational in nature, gaining a lasting advantage over global players. Financial intermediaries, both bank and non-bank, may eliminate the imperfections of the credit market, i.e. barriers to the inflow of capital to those most in need (Armendariz de Aghion, Morduch, 2009; Luintel, Khan, Leon-Gonzalez, Li, 2016; Pluskota, 2013). Those regional funds belong to microfinance institutions, which are very popular all over the world and increasing activities not only

in developing countries as well as in the developed countries.

Activity of the loan funds in Poland

Loan funds in Poland began to emerge with the advent of the market economy, when the emerging private property began to have problems with financing its activities. The first institutions of this type had a very simple structure and one purpose – to offer loans to businesses and business start-ups which did not meet banking criteria. They originate from the activities of microfinance institutions whose main purpose is to support people in need of external financing.

The term loan fund is understood as an institution which is not a bank, whose activity is focused on providing access to external sources of capital by granting loans to companies and persons starting their business activity, without a documented credit history, acceptable collateral and not meeting the banks' requirements in this respect (Bartkowiak, Flejterski, Pluskota, 2006). Since the beginning of the 1990s, loan funds have been supporting the development of Polish enterprises by creating a network of institutions providing external financing to micro, small and medium-sized enterprises (SMEs) available throughout the country. At the end of 2017, 80 loan funds operated in Poland, which had less than EUR 600 million in loan capital (last year its value dropped by 13.14%). In many cases, they are the only source of financing the entrepreneur's idea. In 2017, they granted 5,096 loans with a total value of over EUR 115 million. The average value of a single loan at that time was around EUR 26,000. Although these institutions are active throughout the country, in certain provinces their network is more extensive than in others (Table 1).

Table 1: Number and activity of loan funds by provinces at the end of 2017

The loan funds, fulfilling the role of institutions which bridge the financial gap, primarily finance the smallest enterprises, both in terms of quantity and value (*Fundusze pożyczkowe w Polsce...* 2018). This reveals the needs of micro-enterprises which coincide with those of other EU countries with respect to access to capital (Kraemer et al. 2019; Rupeika-Apoga, 2014). These institutions have gained a lasting position on local and regional financial markets and in the awareness of enterprises, which is confirmed by the purposes of loans, mainly pro-growth (Table 2).

The loan funds market will be posed with challenges, transformations resulting from the need to face banking competition, centralisation of activities and lending programmes by government institutions and consolidation due to capital shortages. Less active institutions face difficult times, which may lead to a decrease in their number and fewer opportunities to support the development of the SME sector. This problem may be solved, inter alia, by the conclusion of consortium agreements between funds and joint financing of enterprises' activities.

Activity of loan guarantee funds

Loan guarantee funds are institutions providing companies with the required collateral to enable them to obtain external financing in the form of bank loans or loans to companies. The economic and financial impact of their activities is based on two assumptions. Firstly, these funds may provide the companies with or increase their access to bank financing. Secondly, they enable more risky yet reliable companies to obtain better financing conditions, e.g. higher amount of financing, extended time limits, lower costs. The loan guarantees provided replace the collateral, which minimises moral hazard by reduced rationing of the loan due to information asymmetry. This is particularly relevant in periods of increased risk and/or risk aversion (Brault, Signore, 2019). Guarantee institutions are an integral part of local financial markets, not only in Poland but also in Europe. The example includes an organisation integrating such entities from the Old Continent – AECM (European Association of Guarantee Institutions), associating guarantee institutions from 28 EU Member States as well as from Bosnia and Herzegovina, Serbia, Russia or Turkey.

At the end of 2017, there were 41 loan guarantee funds operating in Poland, two less than in the previous year (Table 3). The institutions held a total capital of less than a quarter of 1 million euro and active guarantees of 370 million euro. The year 2017 was another year in which the number and value of guarantees increased by 10% and 5% respectively (Gajewski, Kubajek, Szczucki, 2018).

Guarantees of funds are supplementary to bank credit products, supporting entrepreneurs in their relations with the bank in terms of securing transactions. For many years the number of guarantees has been increasing year on year, however this is no longer the case. For the last two years, both the number and value of guarantees for banks has been decreasing (Table 4). This is due to competition from central programmes operated by the state-owned Bank Gospodarstwa Krajowego (BGK), such as the De Minimis Guarantee Line, or under the Intelligent Development Operational Programme (OP IR) and programmes distributed at European level, e.g. COSME (Programme for the Competitiveness of Enterprises and Small and Medium-Sized Enterprises), Horyzont 2020 or EaSI (EU Programme for Employment and Social Innovation).

Loan guarantee funds, forced to pursue new avenues of active business, began to guarantee for liabilities to entities other than banks and loan funds. This group includes bid bonds which constitute 50% of the transactions. Sureties for leasing transactions and performance bonds are much less common in transactions, however they demonstrate the diversification of activities and the intention to find new solutions. The clear prevalence of bid bonds in the guarantee portfolios of the funds on the one hand indicates the flexibility of these institutions, however, on the other hand raises doubts about their initial objectives. It reflects a reduced role of the funds as entities providing collateral for debt transactions, complementing credit products. The competition from government programmes and little interest of commercial banks to continue cooperation with many regional agents render it necessary to pursue new avenues, in particular through smaller, local and regional funds. One option is to diversify activities, mainly in terms of products and close cooperation with loan funds and cooperative banks.

Results

The activity of loan and guarantee funds directly affects the activity of enterprises, mainly the smallest ones. It additionally affects, directly and indirectly, the regions in which funds operate and their development. Studies on the impact of the financial sector, state aid, repayable support for business activities and local and regional development indicate a positive impact, although this is not always a linear relationship.

As a result of the analysis of the regional microfinance institutions' activity in Poland, mainly loan funds and loan guarantee funds, several conclusions may be drawn. In terms of loan funds, an above-average activity in several regions, both in terms of quantity and value, may be observed. The average value of both the loan and the guarantee varies considerably. Their value depends on the number and size of funds operating in a given region and the value of their capital. The data contained in Table 5 reveal that in certain regions (Lubelskie, Podkarpackie, Kujawsko-Pomorskie) the low average loan value corresponds to low GDP per capita. This is also correlated with a higher unemployment rate, low investment outlays and low economic activity. On the other hand, regions where the value of loans and guarantees is relatively high in comparison with other regions (Łódzkie, Zachodniopomorskie) are characterised by moderate wealth, but high level of entrepreneurship and above average level of investment outlays.

In Łódź province only loan funds are present, no guarantee fund is registered there.

As a result of the analysis, it may not be unequivocally concluded that the current loan and guarantee funds have a significant impact on the condition of the region. This is certainly due to the scale of their impact and their activity, which is much smaller than that of bank lending campaign (Bilau J., St-Pierre J., 2017). Other elements matter as well, such as the amount of capital and the condition, willingness of enterprises to invest. The functioning of the examined microfinance institutions is useful and reasonable, however, as a great number of these institutions faces capital shortages, the impact and role in the region will diminish. The concept of their operation should be reconsidered. The analysed data do not indicate a clear correlation between the number of funds, their size and activity and the level of economic development of the region. In certain regions, there are several loan and guarantee funds that are active, however the analysed indicators are below the average.

Today, loan and loan guarantee funds must seek new solutions to increase their importance and role. One such solution is the consolidation and creation of macro-regional funds, which would be able to respond to the demand from enterprises in the event of limited bank lending. The analysed institutions must also face competition from central (government) initiatives, which are generally undertaken on a larger (national) scale. This is particularly true for loan guarantee funds (Gonzales A., Rosenberg R., 2006). Capital enhancement and greater territorial coverage would enable increased cost-effectiveness, the use of modern technological solutions for evaluation and customer service. Through the economies of scale, the funds could increase the quality of their products. Larger entities would motivate the banks to extend the range of services. Loans and guarantees are an alternative to bank financing, however they are also supplemental products, especially for young and small companies, for whom cooperation with the analysed funds is the first contact with a financial institution. Loan and guarantee funds are not and never will be competitors for banks – they are their supplement. Their aim is to support companies excluded from the banking sector or to intervene in a situation where banks' activity is restricted or the market is failing.

However their activity provides evidence of their importance to economies, especially local ones. Moreover, to increase efficiency and effectiveness, certain assumptions need to be considered. Larger funds would have a greater impact on the market, yet there is a problem of ownership. Most of the funds belong to regional and local authorities. Another solution is to develop a comprehensive programme addressed to loan and guarantee near bank institutions, e.g. in the form of special, dedicated products.

Acknowledgment

The project is financed within the framework of the program of the Minister of Science and Higher Education under the name ”Regional Excellence Initiative” in the years 2019–2022; project numer 001/RID/2018/19; the amount of financing PLN 10,684,000.00.

Abstract

Being literate in the new era of technology is not only about being able to save, upload and download materials, share and chatting and responding to online activities in real time. University students nowadays are millennials and are more prone to technology usage in their daily life. In order to keep up with the current needs of millennials, it is crucial for educators to revise their teaching techniques coordinating it with not only with the knowledge on subject but also the current used of technology in education. This research looks into the usage of classroom game and identify the advantages and disadvantages of using online classroom game. This study was conducted qualitatively among 14 postgraduate students from the Department of International Business and Management Studies (Faculty of Business and Administration) particularly Human Resource Management. The students were selected among classes in which lecturers uses online classroom game in their teaching method. The findings of this study highlighted the Advantages and drawbacks of using online classroom game. This would make a significant contribution not only towards assessing the improvement of quality teaching and classroom engagement, but also involvement among students and lecturers that will help not only in terms of teaching improvement among lecturers but also in developing motivated, confident students, enhancing their learning abilities and to become lifelong learners towards this change.

Keywords: Online Classroom Game, Classroom Game, Classroom Engagement, Students Motivation.

Introduction

Classroom games, simulations and gamification are beginning to be assimilated in the traditional educational process. According to (Yang, Chen, & Jeng, 2010; Chiang, Lin, Cheng, & Liu, 2011) classroom games are deployed extensively in the field of education, with the intention to examine the relationship between games and education. Further, Mohd 2020, looks to examine the classroom engagement upon using classroom games as digital or web-based games have increasingly being used to support learning.

Classroom games used in higher education includes educational games (Çankaya & Karamete, 2009), digital game-based learning (DGBL) (Yang, 2012), and applied games (van Roessel & van Mastrigt-Ide, 2011). In addition, scholars, sometimes, include interactive exercises (Mueller, 2003), video games (Biddiss & Irwin, 2010), or even expand to next generation video games (Bausch, 2008), in the category of games. Gamification on the other hand, according to Deterding, Sicart, Nacke, O'Hara, & Dixon (2011) is defined as "the use of video game elements in non-gaming systems to improve user experience and user engagement" and has become a popular technique used across a variety of contexts to motivate people to engage in particular targeted behaviours. The popularity of gamification has been growing rapidly (Robertson, 2010). Classroom games, simulations and gamification show mixed effects across student performance, engagement, learning motivation and teachers' motivation. However, other studies focus only on certain disciplines which makes the gap in the literature concerning a clear framework of use across academic programmes still exist. The aim of this paper is to develop an understanding of the advantages and draw backs of online classroom games among postgraduate students

Literature Review

Students and technology are inseperable. Students are constantly on their phones, laptops, gaming systems, and even televisions. Technology is literally their world. It's no wonder, then, that today's students crave some technological interaction in education. Obviously, using technology all the time may not be a positive thing — we want to see students interact with each other, and we want to see them come out from behind a screen. But technology in moderation can be a great tool for students (and teachers). It often inspires students to work harder. It helps make learning more fun, fast-paced, and individualized. And most importantly, it helps engage all students.

Wang,2015 shows that integrating online classroom game into regular classroom lectures contributes to improvements in student engagement. In addition, Rosas et al. 2003, suggested that such tools excite students to actively engage in lectures and contribute to the learning environment.

Educational games are a great way to help encourage students to get involved in classroom although sometimes, traditional classroom games (that is, ones that don't rely on technology) don't allow every student to fully participate. By incorporating technology into the classroom, you can create a more interactive experience for all students. If answers are being entered on a cell phone, tablet, or Chromebook, every student has a voice and a chance to shine. Digital games also make it easier to accommodate students with disabilities or special needs so they don't feel left out of fun classroom activities. Therefore, this research looks forward to examine the influence of online classroom game on the classroom dynamics and students' engagement,

In addition to enriching learning, the effectiveness of online classroom game depends on whether students perceive the games as appealing, accessible, useful and of high quality. Papastergiou (2009) also found that students rated online classroom game as more appealing and more valuable as an educational tool compared to other performance-tracking educational websites that contained the same content. In spite of a small "wear off effect" of long-term online classroom game use on student communication and enjoyment (Wang, 2015), students who continued to use online classroom game throughout the semester reported positive impacts on learning and engagement similar to the excited new users. Students also commented that, even after a whole semester of using online classroom game, they were still motivated to do additional study to prepare for the weekly quizzes. This research paper examines the understanding of the advantages and draw backs of online classroom games among postgraduate students.

Methodology

A qualitative research approach for this study was chosen because qualitative methods are especially useful in discovering the meaning that people give to events that they experience (Merriam, 1998). Specifically, the phenomenological method was used to understand the effects of online classroom game on classroom dynamics, the influence of online classroom game on students' engagement, motivation towards learning and students' experience.

This study, which was based in the constructivist paradigm, used a phenomenological strategy to explain the effects of online classroom game on classroom dynamics, the influence of online classroom game on students' engagement, motivation towards learning and students' experience. Constructivist researchers focus on understanding and reconstructing the meanings that people (including the researcher) hold about the phenomenon being studied (Guba & Lincoln, 1994). Constructivists create knowledge through interaction between the researcher and participants (Guba & Lincoln, 1994), using dialogue and reasoning as the primary methods of investigation. Finally, constructivist researchers return frequently to the sources of data, asking what they meant to the participant and trying to integrate those with their meaning to the researcher (Rudestam & Newton, 1992). Phenomenology is effective in studying a small number of subjects – in this case, 25 participants – to identify the core of their experiences with the phenomenon (**Creswell, 2003)** and to produce patterns and identify relationships of meaning that build new knowledge (Moustakes, 1994). Thus, for this study, semi structured in-depth interviews were conducted through Padlet with 14 Postgraduate students.

The qualitative research methods used for this study includes purposive sampling, open-ended interviewing, and systematic and concurrent data collection and data analysis procedures. Specifically, the grounded theory or constant comparative method (Glaser & Strauss, 1967) was used to analyzed the data and discover influence of online classroom game on students' engagement, motivation towards learning and students' experience.

In this study, data analysis occurred in three phases. First, interview transcripts were reviewed several times, searching for "recurring regularities" (Merriam, 1998). Then researcher highlights the quotes and phrases from the interviews that were significant to the study. Researcher look through the transcripts to find relevant categories by using the constant comparative method (Glaser & Strauss, 1967). The researcher then named, coded and labelled the transcripts according to each category (Merriam, 1998). Next, the researcher looked into the coded interviews and looked for

relationships within and across the data sources. A table were developed to compare various coded interviews. Finally, the researcher will integrate and refine the categories until themes solidified (Strauss & Corbin, 1998).

Findings and Discussion

14 students participated in this study are the first year students of Master in Human Resource Management. In terms of demographic distribution, respondents consisted of 20 % male and 80 % female students. The findings of this study highlighted the understanding of the advantages and draw backs of online classroom games among postgraduate students.

Advantages

In terms of advantages of online classroom game, the findings of this study found three main themes and they are engagment, meaningfulness and excitement. The following paragraphs explains the findings according to theme.

Engagement

The first advantages of online classroom games is engagement. Students felt more engaged with the usage of online classroom game. This is supported by Wang (2015) and Rosas et al (2003) where online classroom game , when integrated with the regular classroom lectures, improves the classroom engagements. The following are the response of R1, R4 , R9, R11 and R13:

> *Increase the rate of student engagement in class activity* – R 1-
>
> *No more dull and boring session through out the online learning because students will pay attention to answer the questions at the end of each chapter.* –R4-
>
> *Enhance student-lecturer engagement.* –R9-
>
> *Attract student attention and the lesson become more engaging.* –R11-
>
> *It is an exciting tool for engaging students having short attention span* – R13-

Meaningfulness

> *Due to high students engagement, lecturers are able to measure understanding of lectures that were covered more accurately. It is also a good way to keep students engaged and encouraged them to have fun among the class.* – R2-
>
> *Student engagement and motivation with Kahoot! is very high. Students are enjoy playing Kahoot! and will increase better understanding of the material covered earlier and increase students' knowledge.* –R8-
>
> *Easy to understand the topic On the spot we will know which part we dont understand* – R12-
>
> *Can refresh the student brain after each topic so that the student are alert on each topic they learn. Also act as kind of revision for the student after the end of the class.* –R10-

The above are the responses on the advantages of using online classroom game in the classroom. Based on the above, online classroom game also creates meaningfulness in terms of understanding the subject being taught. The online game used in this study allows the students to build up the focus that leads to the understanding of the subject thus making any other preceeding discussions more effective as claimed by R9 and R 7

> *The advantage is student a well prepared, focusing to lecture and explaination, giving focus and full commitment during online class.* –R6-
>
> *The advantages of using this Kahoot! are we are more alert and focus to current chapter, we can observe our understanding towards that topic.*-R7-

Advantages i. Enhance student-lecturer engagement ii. Increases focus and interest on subject learnt iii. Enhances attention and healthy competition iv. Suitable side, additional learning aid aside normal lectures v. Increases motivation toward interactive learning -R9-

Excitement

The third advantage of using online classroom game is excitement. The respondents find that online classroom game brings the class to live with fun and excitement. As claimed by R1, R2, R13:

Bring laughter and joy, it also as a stress relief after long talk and brainstorming in online class – R1-

Encouraged them to have fun among the class. –R2-

It adds fun and excitement to a boring lesson and increase class participation –R13-

This is supported by Papastergiou (2009) and Wang (2015). According to Papastergiou (2009), online classroom game have a positive impact on student communication and enjoyment while Wang (2015) contended that , students who used online classroom game are even more motivated and excited to prepare for their weekly games.

Disadvantages

In terms of the disadvantages of online classroom game, the findings of this study found three main themes and they are Demotivating, Time constraint and Speed over substance. The following paragraphs explains the findings according to theme.

Demotivating

The disadvantage is, to student didn't pay attention during class will lose and make them demotivated.-R3-

it demotivated for some that cannot answer the question correctly. –R10-

Student feels frustrated as they di not get the correct answer plus getting the last place is not a good feeling. –R11_

The above is the responses from R3, R10 and R11 who claimed that the drawback of online classroom game is that it demotivates students especially when students pay less attention in class and could not answer correctly during the game.

Time Constraint

The disadvantage is the time limit are too fast and we cant even have enough time to think of the correct answer.-R5-

Limited of time will allow the student to not give the correct answer and will respond accordingly-R14-

Time constrain is the second disadvantage stated by the respondents. R5 and R14 explained that the timing of the game is too fast that it messed up with their responses. However, the time are set on the game applications.

Speed over substance

R8 and R13 emphasized that :

Hard to track the student's progress since lecturer do not know which student answer it correct or wrong. Since students receive more points for quicker answer, it can emphasize speed over substance. –R8-

Extra credit emphasizes on reaction time, since students receive more points for quicker answers, it can emphasize speed over substance. –R13-

Conclusion

Using online classroom game-based technology is proven to be effective in enhancing language skills as well as useful in initiating and fostering classroom engagement. From the results, it is found that the students have grasped the classroom objective of mastering synonyms based on their textbook. From the students' responses, it is found that the advantages of using online classroom game includes engagement, meaningfulness and excitement while the drawbacks includes demotivating, time constraint and speed over substance. Through these findings, it is evident that online classroom game should be implemented in the classroom from time to time to engage the students in classroom participation.

This research has made some significant contributions in terms of theory building towards assessing the improvement of quality teaching, classroom engagement and involvement among students and lecturers using online classroom learning. This will help not only in terms of improvements in teaching among lecturers but also in developing confident students, enhancing their learning abilities and to become lifelong learners towards this change.

Abstract

Energy security plays an extremely important role in the creation of geopolitical concepts and strategies of contemporary states. The constantly increasing demand for energy determines the foreign policy of many international entities, which aim atensuring the continuity of supply at both the lowest possible price and the best quality, to enable the productive use of energy while respecting the natural environment. This thesis is confirmed by the Polish strategy of energy security, which focuses on particular activities such as: ensuring a real diversification, development of the transmission and distribution system and conducting an appropriate storing policy. The Baltic Sea region plays a key role in the Polish energy supply system by creating the possibility for diversification of the supply of strategic resources. Additionally, geographical characteristic of this areais also used to create the superpower policy of the Russian Federation, which uses rich deposits of strategic resources as an instrument of political game.

Keywords: energy security, diversification, the Baltic Sea, LNG, Nord Stream.

JEL classification: A11, E20, E61, F52, G18, H42, O13, P48.

Introduction

Energy security is one of the primary areas of international security in the 21st century. The growing demand for energy on a global scale makes it a priority in the security strategies of modern countries. The crude oil and natural gas sector is a particularly important factor influencing contemporary energy relations. These resources can be an instrument of political pressure to maintain power or maximize income. An example of the existing resource dependencies and implications of energy policy is the Baltic Sea region.

This area, situated between the Scandinavian Peninsula and the central and eastern part of the European continent, is a mosaic of political and economic interests. Inhabited by 96.5 million people, it is of strategic importance for the countries of Central and Eastern Europe and the Russian Federation. Direct access to this body of water enables the creation of political and economic processes in order to increase the geopolitical advantage. This situation gives a privileged position to the Russian Federation, which, having the world's largest deposits of natural gas, can apply political pressure against the countries of Central and Eastern Europe. Thus, it is in the interest of the Polish security policy to become independent from the supply of hydrocarbons from the east. Achieving such a state will be possible when the gas balance is quickly supplemented with supplies from other directions. One of the methods of minimizing the risk associated with interruptions in the continuity of supplies of raw materials is the expansion of the energy infrastructure.

The aim of the article is to explore the most important factors and mechanisms determining the specificity of Poland's energy policy in the Baltic Sea region. In addition, the article focuses on diagnosing the relationship

Cite this Article as: Miłosz GAC, Ireneusz MICIUŁA and Henryk WOJTASZEK "Poland's Energy Security in The Baltic Sea Region" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

between Poland and Russia in the context of the existing interdependencies in energy relations, while attempting to define their current and future directions. With the above goals in mind, the article attempts to answer the following research questions:

a) what are the priorities of the Polish energy security policy in relation to the Baltic Sea?
b) to what extent do Russian energy projects in the Baltic Sea basin affect Poland's energy security?

Literature review - Poland's energy security strategy

The doctrinal basis for energy security in Poland is the Act of April 10, 1997 - Energy Law. In the document, the legislator specified that the goal of the state's energy policy is to ensure energy security, increase the competitiveness of the economy and its energy efficiency, and protect the environment (Journal of Laws of 1997, No. 54, as amended, Art. 3, p. 16). The definition of the Polish legislator refers to the state of the economy, which enables it to meet the demand for fuel and energy, taking into account environmental assumptions. This includes the diversification of imported fuel supplies, an increase in the share of energy from renewable sources, production capacity from domestic deposits - crude oil, natural gas, coal.

Another documents that attempted to define Poland's energy security were the Polish Energy Policy until 2030, of November 2009. The document defined the directions of development of the Polish energy policy, which include, among others: improving energy efficiency, increasing the security of fuel and energy supplies, diversifying the electricity generation structure by introducing nuclear energy, developing the use of renewable energy sources, including biofuels, developing competitive fuel and energy markets and reducing the environmental impact of energy. The need to reduce dependence on the supply of energy resources and the need to change the structure of the country's energy balance are also mentioned in the National Security Strategy of 2014, stating that: "access to energy resources, including abroad, diversification of sources and directions of fuel supplies and the construction of new capacities based on diversified production technologies, allows to balance the domestic demand for energy " (National Security Strategy of the Republic of Poland 2014, p. 15). More detailed data on the conditions for the development of the energy sector can be found in the document Energy Policy of Poland until 2050 of June 2015. According to the authors, the resources of hard coal and lignite are the stabilizer of energy security in Poland. The draft assumes that this raw material, which is the basis for the Polish energy sector, should be supplied at competitive prices from domestic deposits in order to maintain an adequate level of energy security (Draft Energy Policy of Poland until 2050).

The dominant role of coal results, above all, from the significant native deposits of this mineral from which over 80% of the energy generated in our country comes from. However, it should be emphasized that this raw material, ensuring Poland's energy independence, will have to be limited due to its combustion, which has a negative impact on the natural environment. Thus, the greatest challenge for Poland are and will be the climate packages due to the very difficult to achieve criteria of low gas emissions. Despite European trends assuming a gradual reduction in the role of coal, it is forecast that the demand for this raw material will remain at the level of 80-90 percent until 2030.
Hard coal production reaches 71.3 million tons, of which about 20 million tons is consumed by the heating and communal and living sectors (Rewizorski et al., 2013). On the other hand, the power sector exploits about 40 million tons of hard coal, 80 percent of which is consumed by electricity. It is expected that the share of electricity from hard coal will drop to 40 percent and lignite to 30% by 2025. It should be emphasized that these predictions will largely depend on the condition of Polish mines, the situation on the global market and the policy of reducing carbon dioxide emissions.

The gradual reduction of coal is mainly related to the introduction of nuclear energy and the use of renewable energy sources (RES). According to the Polish Nuclear Power Program of 2014, due to the expected long-term increase in fossil fuel prices and possible further burdens related to CO2 emissions and other atmospheric pollutants, it was found that nuclear power plants will be the most stable and economically effective source of energy (Polish monitor, 2014). The proposed scenario by the Ministry of Energy assumes that the share of nuclear energy in the energy balance will be 19 percent. It is worth mentioning, however, that the planned construction of a nuclear power plant, due to the lack of a long-term strategy, remains at the moment improvisation, \ the Ministry of Energy and the Parliamentary team for nuclear energy.

The time lag in the nuclear sector means that the Ministry of Energy began to attach great importance to the inclusion of renewable energy in the energy system. Such a policy is connected with new regulations imposed by the European Union (EU) on the member states. The latest regulations of December 18, 2017 obliged the EU to ensure that by 2030, at least 27 percent of total energy consumption should come from renewable sources (New Policy RES, 2017). The inclusion of renewable energy in the energy system is undoubtedly a challenge for the

Polish energy policy, which can be treated as an opportunity to overcome the barriers of habits, which is associated with the need to develop smart grids, not only in the power industry, but also in the heating sector.

Natural gas is also becoming an important fossil resource for the Polish economy. This fuel of organic origin, due to the possibility of storage in underground warehouses, is the most convenient energy carrier in economic and ecological terms. The growing demand for natural gas is primarily influenced by the development of technology, which prompts the development of new forms of transporting this raw material, in particular by sea.

In Poland, the production of natural gas amounts to over 4 billion m3, but it does not meet the total demand for this raw material. Consumption of this energy carrier is around 15 billion m3 per year. Thus, approximately 69 percent of this raw material is imported from abroad. Much of the country comes from Russia, which accounts for 3/4 of its total imports, based on a long-term contract with Gazprom. Small amounts of natural gas are also supplied from Germany (approx. 1.5 billion m³) and the Czech Republic (approx. 0.5 billion m³) (Czerniewicz, 2015). Additional opportunities for importing this energy carrier were created by the creation of the so-called reverse on the Yamal Gas Pipeline in the German Mallnow near Ko-strzyna on the Oder, thanks to which Polish companies can import 5.5 billion m³ of gas annually from Germany (Kublik, 2015).

The Polskie Górnictwo Naftowe i Gazownictwo SA (PGNiG) Capital Group is responsible for ensuring the security of supplies in the country and maintaining the necessary reserves of natural gas in Poland. The domination of the Polish gas sector by these two giants - with a poorly developed transmission and distribution infrastructure - gives a picture of the uncompetitive gas market in Poland. As a result, it should be stated that the market has a specific "pricing policy", including the necessity to tariff (Rewizorski et al., 2013).

The diversification of energy resources has a significant impact on increasing Polish security in the gas sector. LNG technology (liquefied natural gas) plays a key role in this respect. Liquefied gas is a fuel that is produced from conventional gas by a method of removing impurities and then changing the state of aggregation under the influence of pressure and very low temperature. After condensation, a clean, odorless fuel is obtained without corrosive and toxic properties (Kochanek, 2017). This raw material has many advantages in terms of use, which include:

• flexibility of supplies - due to the diversification of gas supplies for many countries

• efficiency - LNG has almost 600 times less volume;

• ecology - liquefied natural gas is additionally purified, which means that it has no toxic and corrosive properties;

• safety - liquefied gas, after contact with air, evaporates and is diluted in the air. Thus, it is a less harmful and safer fuel than crude oil or propane-butane.

In view of the shrinking fossil fuel resources in Europe and other parts of the world, in February 2016 the European Commission published a communication in which it emphasized the strategic importance of LNG in the diversification of energy sources (European Energy Security Strategy, 2014). This meant that Member States should have direct or indirect access to the gas market. In line with this intention, the expansion of energy infrastructure has become indispensable. In Poland, an investment in line with these assumptions was the construction of the LNG terminal in Świnoujście. The Świnoujście LNG terminal became the largest diversification project after 1989, which shows its enormous importance for increasing energy security not only of Poland, but the entire Baltic Sea region. LNG is delivered by sea, for which specially equipped tankers, called methane carriers, are used. After delivering liquefied gas to the port, the process of unloading, storage, regasification of the raw material and delivery to the natural gas transmission system takes place. The first LNG deliveries started at the end of 2015, pursuant to an agreement signed by PGNiG and LNG Qatargas. The agreement with Qatar provides for the supply of approximately 1.5 billion m3 of gas annually for 20 years, at a price of approximately USD 500 per 1,000 m3 of gas (Sawicki, 2017a). In addition to supplies from Qatar, the Świnoujście gas terminal is supplied with additional supplies based on short-term contracts, the so-called spot. The first load ordered on these terms from Statoil took place on June 25, 2016, when 140 thousand. m3 of LNG was delivered from the Norwegian port of Melkøya by "Arctic Princes".

Access to the international LNG market has resulted in the first mid-term contract for the import of American liquefied natural gas. Agreement signed on November 21, 2017 by PGNiG S.A. and Centrica LNG Company Limited, is a precedent on a European scale and the first contract for the supply of American LNG to Central and Northern Europe (Regular LNG deliveries, 2017). The contract provides for supplies of nine LNG loads, which is another step towards building Polish energy security and becoming independent from supplies from Russia.

The construction of the LNG terminal in Świnoujście, which is the first such a large stationary gas terminal in the Baltic Sea region, is of great strategic importance due to the concept of building the North-South Corridor. The idea is to create a network consisting of: LNG Terminal in Świnoujście, Croatian LNG Terminal Adria on the island of Krk in the Adriatic Sea (southern end) and interconnectors connecting the infrastructure in the Czech Republic, Slovakia and Hungary. The entire network is to be prepared to receive gas from the Norwegian direction, thanks to the construction of the Baltic Pipe gas pipeline at the bottom of the Baltic Sea. This investment would constitute a strategic infrastructure project aimed at creating gas transmission, directly from deposits located in Norway to the markets in Denmark and Poland. The Baltic Pipe offshore gas pipeline, as announced by the European Commission, would be built by 2022, which, from the point of view of Polish energy policy, would set the geopolitical context completely different, in particular in terms of negotiations with Gazprom. Poland's commitment to building a common energy market was confirmed by signing a declaration on energy cooperation with Denmark (Kubik, 2017). It should be emphasized, however, that the success of the investment will be largely determined by bilateral relations between Germany and Denmark and the political elections that will be held in the Nordic countries in 2019.

Results of the Research

Shaping energy interdependencies with the Russian Federation in the Baltic Sea region

Due to its specific location, the Baltic Sea region plays a strategic role in the energy policy of the Russian Federation. Having access to the Baltic Sea and, at the same time, enormous resource potential, Russia often uses the instrument of political pressure on the countries of the former Soviet sphere of influence. These activities are aimed at ensuring optimal conditions for economic cooperation and maintaining the position on the European energy market. The activation of the Russian energy policy in the Baltic Sea region has its origins in the doctrine of Valentin Fallin and Julij Kwiciński. This concept was aimed at developing new forms of cooperation with former satellites so that Moscow would retain its influence in them. Economic cooperation, and in particular their dependence on oil and gas supplies, was to be an incentive to maintain ties with Russia.

Russia's energy interests in the Baltic Sea region are pursued through companies owned in part or in full by the state. The most important of them is Gazprom, which is one of the largest gas producers in the world. The activities of Gazprom are of fundamental importance for the national economy of Russia, as evidenced by the company's revenues, which constitute 9.5 percent of Russian GDP (Młynarski, 2011). Moreover, the concern's activity generates 12 percent of industrial production in Russia and 16 percent of the value of Russian exports. Gazprom is also a tool for achieving political goals, consisting in maintaining control over the strategic transmission infrastructure in the Baltic Sea region and maintaining a monopoly on the distribution of raw materials in the Baltic basin. Such a strategy of the Russian company is unfavorable for Poland and is associated with a difficult policy of negation with the gas giant.

The beginnings of cooperation between the Polish gas sector and Gazprom date back to the nineties of the twentieth century. The most important event in this area was the inauguration of the construction of the first Polish section of the Yamal gas pipeline. The contract signed between PGNiG and Gazprom in September 1996 concerned approximately 10 billion cubic meters. gas transported via the Yamal-Europe gas pipeline. At that time, the pricing formula assumed that the only supplier of natural gas would be a Russian company. Moreover, the fact that the supplied gas provided for an overstated supply (250 billion m3 in 25 years) - the "take and pay" principle, had a negative impact. The adopted pricing formula for 1 thousand zlotys also turned out to be unfavorable. m3 of Russian gas, Poland paid 379 dollars, while Germany - 323 dollars (Pawlicki, 1996). This trend continues to this day, Gazprom supplies gas to Western countries at a rate related to spot prices, while for Poland the formula is related to the oil price (Czerniewicz, 2015). Thus, Poland pays the most for Russian gas in the European Union, in addition, in accordance with the agreement of the Polish and Russian governments in 2010, in the future the rates for the transit of Russian gas through Poland will be set by the Polish state-owned company Gaz-System. This means that with the current contract, where tariffs are set by EuRoPol Gaz, there will be no question of a simple extension of the current transit contract in the future.

Gazprom is also the main shareholder of Nord Stream. Nord Stream is a 1,224 km long gas pipeline designed to transport natural gas, the construction of which begins on the Russian coast near Vyborg and ends on the coast near Greiswald in Germany. The Russian-German project running on the bottom of the Baltic Sea has a capacity of 27.5 billion m3 of gas per year. In order to emphasize the importance of this undertaking, one should take into account its political nature, which focuses on strengthening the Russian position in the Baltic Sea region. The indication of political aspects is important due to the possibility of implementing the so-called "gas loop", which would facilitate bypassing Central and Eastern European countries in gas supplies. Thus, one of the main reasons for the construction of the Nord Stream gas pipeline was the desire to be marginalized

the transit importance of Belarus, Ukraine and Poland. The possibility of excluding both our country and the Baltic states, including Belarus and Ukraine, from the transit and supplies of Russian gas is an element of Moscow's strategic game, which consists in independence from the transit of oil or gas through Central European countries and preventing it countries to create an infrastructure that will allow them to overcome Russian domination in the field of supplies of energy resources.

A continuation of the Russian energy policy in the Baltic Sea region is the project to expand Nord Stream by two further lines with a total capacity of 55 billion m3 of natural gas annually (Ruszel, 2016). The venture in which Gazprom is the main shareholder has primarily a political dimension and concerns the suspension of the transmission of gas via pipelines that run through Ukraine. Eliminating the Ukrainian side from gas transit will result in even greater dependence on Russia, with which it has been in an armed conflict since 2014.

The project called Nord Stream II, based on German-Russian cooperation, hits not only the interests of other Eastern European countries, but also Poland for which Germany is the largest business partner and also a very influential member of the European Union. Therefore, it should be noted that the construction of another line of the Nord Stream gas pipeline will create certain instruments for playing the energy policy towards Poland in the context of a possible reduction in pressure in the Europe - Yamal pipeline. By accepting the hypothesis that the Yamal gas pipeline may no longer be needed, Russia may seek to sell gas without intermediaries. This would mean the need to re-orient the Polish transmission infrastructure towards obtaining raw material from Germany, as a result of which Poland would lose the status of a transit country, which would result in a lack of revenues from intermediation in transmission. To sum up, Polish energy policy finds itself in a difficult situation, where the sealing of the Russian-German economic partnership may sanction Gazprom's monopoly in Central Europe for decades. The implementation of the Nord Stream II project will cause the countries in the Baltic Sea region to increase their dependence on Russian natural gas, which in the context of Polish energy security may mean burying the plans to build a Norwegian gas pipeline, increasing imports of liquefied gas and creating a competitive gas market in Central Europe (Kublik, 2017b). Bearing in mind the above assumptions, Polish security policy should focus on preventing the situation in which Gazprom would be both the producer and seller of gas pumped through the planned Nord Stream II, and the owner of the pipe itself.

Recommendations for Poland's Energy Policy

The basic assumptions of Poland's energy policy include improving energy efficiency, increasing the country's energy security and reducing the environmental impact of the energy sector (Miciuła & Stępień, 2019). These goals result from the energy policy of the European Union, which assumes the creation of a competitive and efficient energy market, ensuring prosperity and increased competitiveness of Europe. The national legislation, similarly to the EU legislation, focused on introducing market mechanisms in electricity trading. The markets of the EU countries were liberalized, leading to the possibility of ordering electricity by end users from individual producers. However, while the sub-sector of generation and the supply of energy services can be considered the area of competition, the domain of natural monopoly is still the network structures in the field of transmission and distribution. This peculiar hybrid of competition and monopoly gives an important role to regulatory mechanisms that should prevent the tendency to collect monopoly rent. In recent decades, the development of renewable energy sources has become one of the main goals of the energy policy of the European Union countries. This was reflected in the establishment of mandatory national targets for the share of renewable energy sources in relation to total energy consumption. Undoubtedly, sustainable energy development based on the diversification of sources of energy raw materials, including renewable energy sources, brings with it many positive aspects and environmental, economic and social benefits.

Poland's membership in the IEA (International Energy Agency) preceded by many years of activities, including on changes and creation of new legal regulations in the field of maintaining an appropriate level of reserves or reducing demand, led to Poland becoming a member of the Agency in 2008. This significantly improves the safety of liquid fuels availability, but also allows Poland to participate in the work and shape issues related to the broadly understood issues of energy security (energy efficiency, use of renewable energy sources, counteracting the negative effects of disruptions in natural gas supplies, or clean coal combustion techniques) of the most important international organization in this area. However, we should not lose sight of the general assessment of the EU climate policy, which has been reduced to a role that is deaf to rational and, above all, financial arguments and doctrines (Miciuła et al., 2020). This maddening policy is driven by three engines: the interests, ideology and political need of the EU leaders, i.e. Germany and France, which are interested in selling renewable energy technologies and nuclear energy, respectively. Poland has to pay the highest gas prices in Europe, being the EU country best equipped with energy resources, one of the few European countries that could achieve energy independence, if only it did not allow colonial dependence on the West and energy dependence on the East. This is

also due to the ineptitude of the authorities and the lack of strategic investments in the country. For example, the condition of energy networks may pose a threat to the pursuit of an effective energy policy in the near future, and the possibilities of its expansion or modernization in the current legal state are limited. Despite the fact that the expansion of the grid is a public purpose investment, and the energy law obliges the operators of transmission and distribution systems to ensure an appropriate level and reliability of supplies, the Polish legal system does not provide adequate tools to meet these obligations (Stępień & Miciuła, 2016). In some matters, the lack of legal regulations, and in others, their multitude makes it a basic brake for Poland's energy development. Therefore, the recommendations for Poland's energy policy in the 2030 perspective include:

1. Improving energy efficiency
• consistent reduction of the energy consumption of the Polish economy to the EU - 15 level, incl. by modernizing the transmission system, regionalizing energy production and investing in infrastructure that favors innovative solutions,
2. Increased security of supply
• by diversifying the directions of supply, as part of strategic infrastructure investments (projects: LNG Świnoujście, the Baltic Pipe gas pipeline, the Odessa - Brody - Płock - Gdańsk oil pipeline, return to the project of connection with Norway, construction and expansion of interconnectors on four borders, with Germany and the Czech Republic, Slovakia and Lithuania,
• diversifying the share of energy sources in the energy mix means new jobs and more opportunities to obtain energy,
• maximum use of domestic energy resources, i.e. coal, as a step towards increasing Poland's energy independence,
• share in the EU internal energy market,
• increasing the storage capacity for inventories,
• new contracts for the import of liquefied gas from all over the world and an increase in domestic production, which currently amounts to 4 billion m3, which covers 25% of Poland's demand.
3. Investments in new production capacities
• implementation of ambitious government plans for the construction and expansion of coal-fired (15 blocks), gas (14 blocks), biomass (4 blocks), hydro and nuclear power plants.
4. Legislation favoring the development of competitive fuel and energy markets
• introducing market methods for shaping electricity and heat prices,
• lifting the barriers when switching electricity and gas suppliers,
• removing legal barriers, eg investment barriers or shale gas exploration.
5. Improving the management of the coal industry at the state level
• restructuring of unprofitable mines, the system of work and privileges, liquidation of intermediaries in trade in raw materials, reduction of taxation and increase in efficiency.
6. International politics
• instead of pursuing a policy of total dedication to the EU, skillfully negotiate in the interest of the country between EU countries and third countries, especially due to their geographical location,
• political negotiations along with maneuvering on the border of EU law in accordance with the examples (Germany - subsidies to hard coal mines until 2018, to the Rostock shipyard, and at the same time no consent to subsidies for other Member States, including Poland, lack of solidarity, the possibility of a loose interpretation of regulations, the possibility of renegotiating the goals to be achieved or failure to achieve them by some Member States).
7. Competitiveness
• an energy market should be created through infrastructure in order not to deal with a monopoly, and thus energy trading on market terms.
8. Investments in research and development of new technologies
• for example, the first in the world vertical wind turbine was built in Kodeń, the efficiency of which is higher by almost 50%, and its small size means that it can be installed on buildings, so the time for RES will come along with the new technology (Wojtaszek & Miciuła, 2019).
9. Promoting innovative and clean coal technologies
• the use and promotion of energy resources in line with energy efficiency and economic efficiency.

Poland needs a supra-political agreement on an energy strategy that would not change with the change of the ruling team. This would allow for the use of all favorable internal conditions and rational exploitation for the country's economic growth. In the near term, the most burdensome costs for coal-based countries will be the additional costs of CO_2 emission allowances, which will undoubtedly reduce the competitiveness of these economies. On the other hand, the situation of Poland in achieving the goals by 2020 is good, because the percentage of 15% of RES share will certainly be achieved, which amounts to 11.5% 5 years ahead of schedule. Also with regard to the reduction of greenhouse gas emissions, Poland is at the forefront of countries along with the rest of Central and Eastern Europe, and in terms of CO_2 emissions, it should be noted a significant improvement, in contrast to several EU countries that have achieved an intensive increase in its emissions. Due to the fact that many Member States have serious

problems in achieving the set goals, and some are not achieved by most EU members, e.g. a 10% share of biofuels, there will certainly be changes in the EU's climate and energy policy in the 2030 perspective. it is a shift towards economic growth and EU competitiveness in order to overcome the crisis to which climate policy contributed, which is currently observed on the international stage.

Summary

The energy sector is the basis of all economic activity, and thus the basis for the economic development of countries. It gained importance with the advent of the first industrial revolution, and the demand for energy has been growing ever since. Currently, it is impossible for societies to function normally without a constant energy supply. Energy is the driving force of economies around the world. Energy security plays an extremely important role in formulating the concept and geopolitical strategy of Poland. Its components include safety: oil, gas and electricity. The analysis showed that 30% of the energy consumed by Poland comes from raw materials, the production of which carries the risk of "political cut-off" or an increase in price for reasons impossible to eliminate. Oil and gas play a key role in the Polish energy sector. The high demand for these raw materials is still inadequate to the level of development of the manufacturing and transport infrastructure and the possibility of using political pressure by external entities. The strategic importance of energy security shows that the key role for Poland is to define the measures necessary to meet the current and future resource needs. The Baltic Sea region plays a special role in creating Polish energy policy and implementing its main goals. The stabilization of this area largely determines the possibility of diversifying sources of crude oil and natural gas. This applies above all to Russia, a state that is capable of resorting to political and military measures to increase European countries' dependence on supplies of energy resources from Moscow. In view of the above, the priority of the Polish energy security policy in relation to the Baltic Sea is the maximum reduction of Russian gas imports to Europe by supporting diversification projects and actions aimed at weakening Gazprom on the EU market. Moreover, a comparative analysis of Russian energy projects in the Baltic Sea basin showed that the construction of Nord Stream and the planned Nord Stream II is in line with the Kremlin's policy to date, which is a violation of the economic interests of Poland and other Baltic Sea countries.

Funding

The project was financed within the framework of the program of the Minister of Science and Higher Education in Poland under the name “Regional Excellence Initiative” in the years 2019–2022, project number 001/RID/2018/19.

Abstract

Climate change and air pollution problems require socially responsible behavior from all participants in economic and social relations. However, pressure on mining and manufacturing companies has led to the widespread practice of greenwashing, which misleads not only consumers, but also government organizations and financial institutions.
The authors raised questions about: the need for environmental disclosure to ensure the efficiency of the mining companies; ecological disclosure as order of the day.
The authors have developed and tested their own approach to quantitative and qualitative analysis of disclosure of information on corporate social responsibility of an oil company. This approach allowed to make conclusions about the dominance of companies' own interests in the implementation of the openness policy. Environmental information is only disclosed fully and qualitatively in the "Legally established obligations of the company". This indicates the positive results of the government environmental policy, but rejects the subordination of the company's financial, investment and staff policies to achieving sustainable development goals. As a result, it provides fragmented disclosure and contributes to misleading users.

Keywords: CSR, reporting, ecological activity, greenwashing, disclosure indicators and targets.

Introduction

The problem of information openness of mining companies, which have a negative impact on the environment through their activities, does not lose its relevance over a long period. The pursuit of sustainable development goals requires continuous dialogue between stakeholders. Meanwhile, information openness and the quality of disclosed information may be evidence of the extent of implementation of social responsibility, especially the environmental aspect.

Accordingly, the draft strategic plan of the IFAC states: "Our goal is not only to react, but also to anticipate. The many challenges caused by COVID-19 have highlighted the fragility of our global ecosystem and the importance of creating a more sustainable world. Our approach is based on the UN Sustainable Development Goals (SDGs). Achieving the SDGs requires high quality information, while accountants and auditors generate this information for the benefit of all stakeholders" [1].

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In addition, this document notes the need to demonstrate and evaluate environmental performance: “Billions of people affected by climate change and the effects of unfair development demand results, not words. For example, the indicator "significant reduction in carbon footprint" is not important, but whether we consider our efforts to be successful” [1].

The authors of the project highlight the increasing attention to sustainable development issues as a trend which leads to certain consequences for the profession and provides favorable opportunities. These possible consequences may include the call for holistic reporting by stakeholders to ensure long-term sustainability. Therefore, it is recognized that the provision of traditional historical financial information is not sufficient to assess the impact on society and the company's performance.

Consequently, “professional accountants can add value to reporting by providing a holistic and relevant opinion of a company’s performance and sustainability. This view recognizes the complexity of modern business and encompasses financial and non-financial performance as well as plays a role in protecting the public interest” [1].

As a result, the authors indicate two important debatable issues on the current agenda:

1. Environmental disclosure is a prerequisite for the efficient operation of mining companies developing in the paradigm of sustainable development.
2. Environmental disclosure characterize the current trend of information openness without a strategic nature.

The authors base their search for answers to these questions not only on the analysis of existing studies, but also on their own research performed according to the data of the largest Russian oil company.

Greenwashing as A Modern Ideology of Information Openness

As society has become aware of the challenges of climate change and air pollution, the demand for eco-friendly products and the value of low-waste businesses increased. Consequently, companies are forced to produce and sell products without negative impact on the environment. However, this pressure has led to the widespread practice of greenwashing in the form of misleading claim to persuade the public about the environmental benefits of a product or service. Greenwashing is an advertisement for dishonest companies in corporate social reporting that distorts disclosed information.

Ziyuan Sun and Weiwei Zhang (2019) admit the paramount importance of government regulation to prevent greenwashing through public power, green supply chain management and the corporate social responsibility. In their study, they used evolutionary game theory to examine the greenwashing behaviors of enterprises from the perspective of government regulation. There are two bounded rational players, Enterprise-A and Enterprise-B, in this game model. Companies can choose three types of combinations of green innovation and greenwashing strategies.

1. If one player chooses the green innovation strategy, and another - the greenwashing strategy, then the latter as a speculative behavior will appropriate part of the income of the enterprise that initially chose the green innovation strategy.
2. If both players choose the greenwashing strategy, then they will fail and lose market income.
3. If both players choose the green innovation strategy, then they will share the benefits, and their market income is determined by the proportional heterogeneity coefficient. In this case, the cost of green innovation is less than the cost of greenwashing. Therefore, the government punishment mechanism effectively prevents both dominant and inferior enterprises from greenwashing under certain circumstances and promotes the development of green innovation.

As the government punishment amount increases, the dominant enterprises abandon the greenwashing strategy and choose the green innovation one, and then the inferior enterprises change their strategic choice. The government also needs to encourage the public, industry institutions and third-party supervisors to participate in overseeing corporate greenwashing behavior.

The authors also proposed the hypothesis about the impact of the tax subsidy mechanism for green innovation to prevent greenwashing. However, the hypothesis was not confirmed because a mechanism can effectively regulate the greenwashing of inferior enterprises only under certain circumstances. Therefore, the propensity of enterprises to choose the green innovation strategy will depend on the number of government subsidies.

The authors recommend the government to strengthen corporate social responsibility construction, which will reduce the need for government intervention and the cost of governance.
It is interesting to note a study by Ali Uyar, Abdullah S. Karaman and Merve Kilic (2020), in which the authors suggest that companies may publish corporate social reporting for signaling or greenwashing purposes. Thus, for signaling purposes, companies with greater CSR performance are more likely to publish CSR reports to emphasize their good CSR efforts. On the other hand, for greenwashing purposes, companies with poor CSR performance are more likely to publish CSR reports to change stakeholder perceptions of their actual CSR performance.

As a result, they found a strong significant positive relationship between CSR performance and CSR reporting, which can eliminate the danger of greenwashing, but confirms the validity of signaling theory. This link is also important to mitigate public concerns about the legitimacy of firms.

Therefore, a proven link between CSR performance and CSR reporting sends very important signals to investors that the information is reliable in the reports, free from greenwashing or window-dressing, and reflects the actual situation in the companies.

Due to the growing relevance of corporate social responsibility, more attention is paid to the problem of its assessment. The vast majority of methods are indices that create a rating of companies in terms of CSR level. This method can assess the extent of CSR disclosure of a company, but it is impossible to measure the effectiveness of its corporate social activities. As noted above, if stakeholders identify CSR effectiveness, this can remove their doubts about the company's greenwashing goals. Borzakov D.V. (2015) mentioned that the indices most often do not contain a well-developed system of indicators and do not carry out primary screening of companies.

Proshkin A.V., Dukart S.A. (2015) state that it is impossible to compare enterprises by the quantitative index of social investment because the assessment methodology is based on interval indicators. In most cases, they cannot obtain an exact quantitative value. It complicates the data processing that converts interval values into an average indicator and adversely affects the accuracy of the estimate.

In addition, the index of specific social investment may increase if the company starts to lay off employees with a constant level of social investment. However, this will not reflect an increase in social responsibility. Meanwhile, the qualitative index of social investment does not reflect the scale of social responsibility because there is no general index that combines the quantitative and qualitative index.

Shikhverdiev A.P. and Seryakov A.V. (2008) indicate that comparison on a qualitative index will only be in favor of big business and monopolies because they can allocate huge budgets for social programs. However, it is extremely difficult for them to be socially responsible due to the large number of stakeholders with different interests. Consequently, a growth in the number of stakeholders reduces the overall social responsibility and the company then has to increase social investment.

Also, the methodology lacks detailed indicators of the quality of relationship with stakeholders because the presence or absence of a feature in the sample cannot adequately represent this.

Adriana Galant & Simon Cadez (2017) state that CSR reputation indices have been developed in international practice which allow assessing the social responsibility of different companies. The disadvantage of such indices is that rating agencies limit the coverage of companies by their size, industry affiliation and geographic location.

Amanpreet Kaur & Balwinder Singh (2018) claim that corporate reputation indices have been criticized for lack of comprehensiveness because they only take into account the views of only one stakeholder group and inappropriateness for scientific research. Also, these indices have limited applicability and bias due to the existence of a financial halo.

Maignan and Ferrell (2000) found that corporate reputation indices are not suitable for assessment all companies and that the elements of the KLD and Fortune index are inconsistent with theoretical arguments. The CSID as a well-known database measures the sum of a firm's average net strength and weakness for seven dimensions, including environment, diversity, corporate governance, products and business practices, community, employee relations and international operations (Mahoney and Thorne, 2005; Turker, 2009). The main limitation of these databases is their limited scope of assessment firms in some specific countries rather than the general business environment. However, they explain some key stakeholder relationships.

To conclude, relevant research issue is the problem of analyzing the relationship between information openness and the company's performance indicators for various groups of stakeholders.

Methodology of Research the Relationship of Information Openness and Company's Performance

The authors state the need for a comprehensive implementation, i.e. in the analysis of all aspects of social responsibility - economic, environmental and social.

As noted above, the index method is the main method for assessing information openness. Its main idea is to assess the ratio of the amount of data actually disclosed in the reporting to the maximum amount of data. The latter amount of data can be calculated: from actually achieved amount of disclosure by a group of subjects of the production and economic chain; amount according to the needs of stakeholders and requirements of standards. With this approach, the index value can vary from 0 to 1 as a percentage. However, the key disadvantage of the index method is measuring the amount, but not the quality of the information disclosed.

However, some modifications of the index method demonstrates the interest. Company reporting indicators are assigned scores by actual disclosure in reporting. Thus, 1 score is assigned, if information is disclosed; 0 score, if not. As a result of calculating the indices of disclosure of information in the reporting, the company which received the minimum score is assigned 1 score. The indices of other subjects are defined as the ratio of the actually scored points to the points of the subject with the minimum level of information disclosure. The higher the index than one, the higher the amount of actually disclosed information.

Content analysis of reporting is gaining popularity in modern research. As part of the content analysis of reporting, the disclosure index can be defined as the ratio of the actual number of key concepts in the reporting to the total number of such terms used in the analysis.

The authors propose their own approach to the analysis of information disclosure. The originality of the approach is shown in the selection of various focuses of the analysis. They are determined by the different extents of "maturity" of the subjects in terms of goal-setting, policy and disclosure tools:

- ensuring economic, social and environmental efficiency in the long term in the interests of economic subjects;
- demonstration of involvement in the sustainable development agenda in order to ensure investment attractiveness;
- a basis for dialogue with stakeholders in their interests;
- a systematic presentation of sustainable development policies and practices to ensure sustainability.

The authors propose to conduct a disclosure analysis at the intersection of areas that are defined by the disclosure parameters, sources and disclosure channels. This allowed for an assessment of the amount and quality of information of mining companies. As a result, researchers had the opportunity not only to qualify different levels of maturity in terms of information openness, but also to identify areas of information deficit that limit the achievement of sustainable development goals.

To analyze the reporting of a mining company, the authors applied an approach of Amanzholova B. A., Fribus N. V., Khomenko E. V (2016) that consists a qualitative analysis of the environmental disclosure in public reporting. This approach is based on conducting morphological analysis in relation to the audited published reporting of the company. The morphological analysis method could implement the study of various aspects of corporate environmental responsibility with the legal prerequisites for the formation of public reporting of mining companies. The purpose of the analysis is to assess the level of presentation and disclosure of environmental information of companies based on public reporting data.

Applying of the approach allowed to identify the most significant indicators of public reporting for the purposes of analysis. They contain the types of reporting (X), the legal prerequisites for its formation (Y) and the aspects of corporate social responsibility of enterprises (Z) (Fig 1).

Fig. 1: "Morphological cube" as a basis for analysis company reporting

The types of public reporting are presented along the X-axis: financial statements - X1; annual report - X2; Sustainability Report - X3.

The legal prerequisites for the formation of public reporting are presented on the Y-axis: legislatively enshrined obligations of the company - Y1; voluntarily assumed obligations under agreements with stakeholders - Y2; philanthropy - Y3.

Areas of corporate social responsibility are presented along the Z axis: economic - Z1; ecological - Z2; social - Z3.

The morphological analysis method assumes that the combination of these factors allows to comprehensively analyze the content of financial and non-financial information about the environmental activities of companies. Possible combinations are:

1. The combination (X1, Y1, Z1) implies the disclosure in the financial statement of the company's legislatively enshrined obligations for the formation of economic indicators on environmental activities. They contain explicit, estimated and contingent liabilities in accordance with accounting standards. In this case, the level of disclosure of environmental activities is not sufficient, which is necessary for users to meet their needs, but complies with legal requirements.
2. Combinations (X2, Y2, Z1), (X2, Y2, Z2), (X2, Y1, Z3), (X3, Y2, Z2) and others imply disclosure of financial and non-financial information in accordance with accounting standards, sustainable development standards and internal regulations. This combination of factors can satisfy the needs of most stakeholders.
3. Combinations (X3, Y3, Z1), (X3, Y3, Z3) and especially (X3, Y3, Z2) are ideal disclosure that can satisfy the needs of all users. With such combinations, information is disclosed in all areas of corporate social responsibility on voluntary obligations under agreements with stakeholders.

To apply the listed approaches the authors did the following:

- read the reporting;
- emphasized the quantitative indicators of aspects of the company's social responsibility;
- performed the dynamic analysis of the indicators of aspects of the company's social responsibility over the years;
- formed the composition of significant indicators of aspects of the company's social responsibility over the years;
- performed the calculation and analysis of integral indicators.

All of these actions related on the quantitative indicators of social responsibility disclosed in the reporting.

The authors applied a matrix approach for the qualitative analysis which allowed to systematize the information presented on the legal prerequisites for the formation of public reporting and aspects of social responsibility. The authors applied the following assessment scale:

If the disclosed information is equal in each year, 25% is assigned.

If the disclosed information is not fully disclosed in relation to the next year, 0-24% is assigned.

If the disclosed information is fully disclosed than in the next year, 26-100 is assigned.

Thus, the suggestions of the authors will allow to identify the relationship between the environmental disclosure and the performance of mining companies.

Discussion of The Results

The authors studied the sustainable development reports for the period from 2015 to 2018 and systematized indicators by groups of social responsibility: economic, social, environmental. A dynamic analysis was made of each indicator within each group for the specified period. For each indicator, the average value of the growth rate was calculated over three years, and the indicators were sorted in descending order. Further, indicators were identified for detailed analysis according to the following selection criteria:

- significant changes over the indicated periods (the highest average value of the growth (decrease) rate);
- materiality of absolute or relative values;
- direct influence on the conclusions and decisions of stakeholders.

As a result, 15 indicators out of 66 were selected. The assessment of the dynamics of information transparency of an oil company was performed according to these indicators (Fig 2).

Fig. 2: Results of the selection of indicators for assessing the dynamics of information transparency of an oil company

Table 1: dynamics of significant indicators of the social responsibility of an oil company across 2016-2018

Indicators	2016	2017	2018	Average growth rate, %	Weight, %
Economic					
Dividends	44%	20%	159%	74%	39%
Accruals to funds suppliers	16%	31%	55%	34%	18%
Insurance premiums	7%	33%	46%	28%	15%
Assets	15%	27%	37%	26%	14%
Accrued taxes and duties	-11%	16%	72%	26%	14%
Environmental					
Total volume of spilled oil and oil products	-83%	-83%	-86%	84%	35%
Training on industrial safety, labor protection and environmental protection	20%	62%	62%	48%	20%
Specific emissions of pollutants from oil refining and petrochemicals	18%	53%	43%	38%	16%

Financial and material reserves for the prevention and response situation	-41%	-36%	-32%	37%	15%
Fines accrued for violations of environmental legislation	29%	29%	44%	34%	14%
Social					
Wage fund (including preferential payments, one-time bonuses and annual remuneration)	11%	38%	50%	33%	29%
Social benefit fund	11%	31%	45%	29%	26%
Headcount at the end of the year	11%	23%	26%	20%	18%
Average headcount	2%	22%	24%	16%	15%
Average monthly salary	8%	13%	20%	14%	12%

It is important to note that each group includes indicators of various aspects of social responsibility and focus of influence. For example, there were indicators of relationships with staff and the local community in the social indicators group.

Graphs were built for each group of indicators and conclusions were made about the multidirectionality in their dynamics. An example of the analysis of environmental indicators is shown in Fig 3.

Fig. 3: Dynamics of environmental indicators disclosed in the reporting of a mining company for 2016-2018

Then, weights were calculated for the indicators from the average growth rate to form an integral indicator for each group. The value of the integral indicator was calculated for each year by the formula $y_i = \sum w_i * x_i$, where w_i is the weight of each indicator, x_i is the value of each indicator, $\sum w_i = 1$.

Table 2: dynamics of integral indicators of aspects of corporate social responsibility of an oil company for 2016-2018

Integral indicator	**2016**	**2017**	**2018**
Economic	22%	24%	94%
Environmental	-24%	-10%	-10%
Social	9%	28%	37%

Graphical interpretation of the behavior of integral indicators needs for a qualitative analysis of information disclosure in the reporting of an oil company (Fig 4).

Fig. 4: Dynamics of integral indicators of the aspects of corporate social responsibility of an oil company for 2016-2018

There is a trend of positive dynamics in all groups. At the same time, a significant increase in economic indicators implies an increase in the effectiveness of activities, including through dialogue with stakeholders about the environmental and social activities.

This hypothesis allowed the authors to make a qualitative assessment of information disclosure. It is subjective, but built on systematized prerequisites for the formation of reporting (Table 3).

Table 3: qualitative analysis of information disclosure in the reporting of an oil company on the legal prerequisites for formation of reporting, %

Legal prerequisites for formation of reporting	Indicators	Years			
		2015	2016	2017	2018
Legislatively enshrined obligations of the company	***Environmental***				
	Risks in industrial safety, labor protection and environment	15	25	25	35
	Stakeholders engagement on ISLPE issues	25	35	30	10

	Development of a labor protection and industrial safety management system	35	35	10	20
	Development of the environmental safety management system	40	25	20	15
	Key events in the ISLP	10	10	35	45
	Emergency warning and readiness to eliminate their consequences	5	25	35	35
	Conservation of biological diversity	10	5	35	50
	Waste management and remediation of contaminated land	15	15	10	60
	Economic				
	Payment of dividends	25	25	25	25
	Stakeholders engagement on the contribution to the development of the economy and infrastructure of the regions	15	20	30	35
	Corporate Pension and Veteran Care	30	20	25	25

	Import substitution and localization	50	15	25	10
	Compliance system development	30	30	20	20
	Social				
	Risks in staff management and social policy	25	25	25	25
	Stakeholders engagement on the social sphere, charity and education	20	15	35	30
	Employee Benefits	20	25	30	25
	Development of the staff training system	10	25	40	25
	Development of the staff health maintenance system	15	15	35	35
	Development of the staff management system	10	30	25	35
Voluntarily assumed obligations under agreements with stakeholders	***Environmental***				
	Implementation of the Gas Investment Program	25	25	25	25
	Measures to improve energy efficiency indicators	–	50	50	–
	Measures to improve the integrity of pipelines	–	50	50	–
	Greenhouse Gas Emissions Management	30	30	30	10
	Economic				
	Anti-fraud and corruption	25	20	20	35
Philanthropy	***Environmental***				
	Forest planting activities	20	20	30	30
	Environmental education of the population	30	30	20	20
	Economic				
	Allocation of funds to the budget for the development of regional territories	20	20	30	30
	Engaging with regions of presence	25	25	25	25
	Social				
	Organization of sports and entertainment events	30	35	15	20
	Implementation of charitable projects	5	30	40	25
	Support for the social sphere of the regions	25	25	25	25

Next, general assessments are summarized for reporting periods by groups of indicators and legal prerequisites for the formation of reporting (Table 4).

Table 4: assessment of the extent of disclosure of indicators according to the legal prerequisites for the formation of reporting, %

Basis for analysis		**Disclosure by years**		
Legal prerequisites for formation of reporting	Group of indicators	2016	2017	2018
Legislatively enshrined obligations of the company	Environmental	23	26	33
	Economic	22	25	23
	Social	23	32	29
Legislatively enshrined obligations of the company	Environmental	39	39	18
	Economic	20	20	35
Philanthropy	Environmental	25	25	25
	Economic	23	28	28
	Social	30	27	23

The score does not rise above 50%, which indicates the low quality of information disclosure about these indicators. The authors considered the dynamics of integral indicators in relationship with the assessment of the extent of disclosure.

Hypothesis for all groups of indicators. The better the integral indicator of the group, the higher the assessment of the extent of disclosure.

A correlation analysis was performed to assess the relationship in accordance with the legal prerequisites for the formation of reporting.

For the group "Legally enshrined obligations of the company", the authors believe that the hypothesis should be true for all groups of indicators because the level of government regulation is high in the oil industry. However, according to the results of calculations, the hypothesis is confirmed only in relation to the disclosure of environmental indicators (Fig 5).

Fig. 5: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Environmental indicators")

Thus, there is a direct relationship and confirmation of the hypothesis.

According to economic indicators, we can say that the relationship is not obvious (Fig 6).

Fig. 6: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Economic indicators")

The correlation coefficient between the integral economic indicator and assessment of disclosure equal to 0.28 that indicates a weak relationship. Thus, the hypothesis is not confirmed.

An inverse relationship was revealed in social indicators. (Fig 7).

Fig. 7: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Social indicators")

Thus, the relationship analysis for the group "Legally enshrined obligations of the company" revealed that such a relationship is only for environmental indicators of social responsibility.

Regarding the "Voluntary obligations under agreements with stakeholders" group, the authors believe that the hypothesis of a relationship should be true due to the existence of obligations.

However, this hypothesis was confirmed only for the group of economic indicators (Fig 9), and a negative correlation was revealed for the group of environmental indicators - 0.52 (Fig 8).

Fig. 8: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Environmental indicators")

Such results may be explained by inconsistent and incomparable disclosures of voluntary obligations under stakeholder agreements.

Fig. 9: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Economic indicators")

Regarding information on the “philanthropy” group, the authors suggest that the hypothesis of a relationship should also be true. Because such initiatives must be documented not only to improve the company's reputation, but also to improve investment attractiveness in a strategic context. However, according to the results of calculations, the hypothesis is not confirmed in relation to environmental (Fig 10), social (Fig 12), but is confirmed only in relation to the disclosure of economic indicators (Fig 11).

Fig. 10: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Environmental indicators")

The hypothesis is confirmed according to economic indicators because the relationship is positive and its strength is average - 0.52.

Fig. 11: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Economic indicators")

Lack of correlation on social indicators in relation to all legal prerequisites for reporting preparation raises questions.

Fig. 12: Dynamics of the integral indicator and assessment of disclosure for 2016-2018. (group "Social indicators")

An inverse relationship was revealed in the group of social indicators in the section "philanthropy". It can be explained by the incomparability of the indicators selected for calculating the integral indicator and the information disclosed in the reporting.

Conclusions

The approach allowed to the conclude that companies are primarily focused on the lowest level goal - demonstrating economic and environmental efficiency. This is evidenced by the analysis of the relationship between the value of integral indicators and the results of the assessment of disclosure. It is important to note that the analysis of the legal prerequisites for the preparation of reporting only revealed the existence of a relationship between economic indicators.

According to the authors, a full and high-quality environmental disclosure only in the "Legally enshrined obligations of the company" indicates the positive impact of the government environmental policy. However, the disclosure policy and tools will evolve due to the penetration of the sustainable development ideology into the company's financial, investment and staff policy. Otherwise, information disclosure becomes not only fragmentary, but can also mislead users.

As a result, the author's approach is constrained by the limitations. They consist of analyzing data from only one large company, which did not allow making a model with environmental, economic and social indicators. In the future, authors plan to process data from a large number of oil companies, which will allow to systematize industry-specific features according to legal prerequisites.

Abstract

The study assesses the use of forward sale for housing delivery in Lagos state. The research was conducted to explore forward sale as a veritable instrument for reducing housing deficit in the State. The study was a survey research that involved the use of structured questionnaires administered to property developers, prospective buyers and estate surveyors and valuers. Data analysis was achieved using descriptive statistics and relative importance index while Student's T-Test was used to test the hypothesis of the study. The result of the T-test clearly showed that forward sale is not popular among prospective home buyers in Lagos state, although it is a preferred funding option among by developers. The study further revealed that insecurity of prospective buyer's interest, developer's default, poor construction standard and poor workmanship are key factors influencing potential buyer's decision to commit to forward sale arrangement. The study therefore recommends government regulation of forward sale market for the purpose of boosting buyer's confidence.

Keywords: forward sale, finance, housing, property, strategies

Introduction

There exists in both rural and urban areas across the world a definite gap between supply and demand for diverse real estate products. In some rural areas, arable or fertile land may be in short supply coupled with lack of good farmstead and produce storage facilities. In many urban centres however, the different competing uses for the available urban land makes land a scarce commodity, thereby driving prices or rents of landed properties out of reach for many. Over the years post-independence, the demand for real estates in many urban centers in Nigeria has surpassed supply. For instance, in Lagos state alone, housing needs every twelve months have been conservatively projected to be of 224,000 and at least, 17 million units throughout the country (FMLHUD, 2012). Even with the humongous deficit, quite a lot of housing development projects being undertaken by developers remain largely unsubscribed and therefore either abandoned or remain uncompleted for a long time. Housing development has turned a nightmare for many developers due to cost escalation and unstable market dynamics. In Nigeria, the cost of finance is often high and could lead to cost overrun. In addition, reduction of purchasing power as a result of inflation, poor currency exchange rate and rising prices of building material often result in cost escalation. As a result, many housing development projects have experienced unnecessary delay, partial or total abandonment due to insufficient funding, stifled, diverted funding or outright withdrawal of fund.

Amongst the numerous sources of capital for real estate development projects in Nigeria is loan from financial institutions such as pension funds, insurance and commercial banks. Many a times, developers seek financial assistance in form of loan form these institutions and over the years, commercial banks have been patronized for providing such facilities albeit on short or medium term. Of recent however, the procurement of bank loan has become difficult and very risky because of the changing interest rate, difficult processing procedure, collateral requirements and unstable economy. Debt funding has always been combined with funds raised from private equity or public equity contributions such as forward sale. Forward sale is a popular strategy in Asian property market such as Hong Kong, Malaysia, Singapore, Taiwan, Japan and China. It is also used in America, Europe, United Kingdom and South Africa.

Forward sale involves the selling of upcoming project to end users, well before completion. Amongst the benefits is that the strategy boosts the flow of fund and facilitate timely completion of the project. Neug et. al. (2004) averred that forward sale provides access to smooth and sufficient fund, avoid payment of interest, make fund available in time, minimize cost overrun and anticipated profit in the long run. In spite of these inherent advantages, the construction field at various parts of the country is replete with uncompleted or totally neglected projects arising from paucity of development capital. It is also unclear whether this strategy is in use among developers and accepted among prospective buyers especially in Lagos. Arising from the foregoing, this study undertakes an assessment of the use of forward sale as a funding strategy for property development in Lagos State, Nigeria. This paper is structured into four sections namely; literature review, research methods, results and discussion and conclusion.

Literature Review

Development Finance

Ogedengbe and Adesopo (2003) describe property development as the process of carrying out a change in the use of land or the existing improvement or the extent of land use by means of tangible construction works. Variants of such developments include reconstruction, refurbishment, renovation, new development or the transformation of existing factory facilities into a multifunctional centre (Gehner, 2008). Sometimes such developments are finished on time, while others take longer period due to the quantum or size of the project as well as the accessibility and adequacy of development fund (Gehner, 2008). The accessibility, sufficiency and cost of finance procurement play significant roles in determining the profitability of a proposed project. Therefore developers look at different sources and means of raising capital. In processing the fund, investors consider sources that offer easy access to fund and are secured at minimal cost. Hence, understanding the various sources of finance available in the market is germane to investment decision making as this goes a long way to reducing the overall investment risk and maximize return in the long run. Availability and accessibility of finance is critical to rapid transformation and development of urban areas. Urbanization can be marred where capital is not available in sufficient quantity and easily accessed at minimal cost. Financing real estate projects becomes a problem as a result of the amount of funding required as well as the level of risks involved. Usually, the capital outlay exceeds financial capacity of the investor thereby necessitating arrangement for funds from other sources. Real estate financing according to Clauretie and Sirmans, (2006) means the procedure for acquiring funds specifically for the purpose of carrying out improvement on land. The authors further revealed that real estate finance entails observing relevant economic and markets indices, institutions and instruments engaged for the movement of credit facilities needed for developmental purposes. Since property development is always largely capital-intensive, funding is becomes critical, the nature of which is to provide capital to enable the enterprise operate commercially. According to Ogundipe (2020), the extreme volatile behavior of Africa's output and consumption is as a result of the level of exposure to external shocks in its trade earnings. This further indicates the rationale behind high cost of project in developing economies such as Nigeria.

Oloke, Ezema, Fayomi, E,metere, Omeje and Jesusegun (2020) in a study that compare the rental value of residential properties of border communities of Lagos and Ogun states observed that there is stark difference in values of properties due to the different level of development and infrastructure provision. The study further showed that majority of houses in the area was self-financed. Finance remains a vital input in all phases of project development. The timely completion of housing development project is a function of steady supply and unhindered access to fund. Availability and access to steady fund equip developers with the necessary state-of-the-art techniques and technologies to complete projects to time and specifications. Timely completion preserves project's value, anticipated profit and for this reason, developers have explored various financing strategies. These include debt capital from banks and mortgage institutions, credit unions, leaseback, reits, private equity, securitization and unitization, leases, pre-letting as well as presale (Hines 1995; Emoh and Nwanchukwu 2011). As much as these

funding strategies are available, the popularity and use of forward sale for property transaction in Nigeria, particularly in the study area have not being explored and is still not clear.

Real Estate Finance Strategies

According to Oloke, Iroham, Odetumbi and Oyedele (2020), real estate investment is capital intensive, time consuming and are often illiquid. Finance constitutes the lifeblood of real estate development. It is a critical pre-requisite for the conception, commencement, continuation and completion of any project development. Nkyi (2012) stated that developers most times encounter challenges in the process of raising finance for developmental purposes. In addition to this, optimizing developer's input and output constitute another aspect of development challenge. The judicious use of scarce means for alternative ends is a big task even in the construction industry. Consequently, financial strategies provide investors cum developers with the necessary ability to mobilize funds to execute a project. Bender and Ward (2002) described financial strategies as a way by which an organization source and maintain fund in a cost effective manner. By implication, this describes the process of ascertaining possible sources of funds, procurement requisites and approach to optimizing the resources. The authors further highlighted the characteristics of a good finance option as affordable, convenient and secured. According to Oloke, Olawale and Oni (2017), right prices of real estate products do not only facilitates transaction in property market but also encourages activities in the construction sector. As identified by Omuojine (1993), real estate funding methods include equity capital, loan, mortgage lending, and debenture and contractor finance. Hines (1995) further listed six methods. These are sale-leaseback, unsecured institutional lending, joint venture equity and debt financing, advance payment of key money, mortgage financing and sale of securities. Similar funding methods as pointed out in College of Estate Management, (1994); Emoh and Nwanchukwu, (2011) are convertible mortgages, pre-letting, sales and leaseback, securitization, lease and leaseback, partnership, forward contract, unitization, bank loan, mezzanine capital, finance lease, mortgage debenture, loan syndication. Therefore, aside debt capital or private fund, other funding arrangements have been explored in an attempt to meet the huge funding requirement of projects and one of such is presale. The understanding, benefits and regions where presale has been engaged are discussed in the following section. Not only this, the prospect of financing real estate development via liquid liabilities is still under investigation. As shown by Hassan, Osabuohien, Ayadi, Ejemeyowvi and Okafor (2020), controversies surrounding the effectiveness of growth finance in fostering liquid liabilities in Nigeria still abound.

Forward Sale

Also referred to as forward contract, presale, sell-then-build, forward sale according to Chau, Wong and Yiu, (2003) is a contractual agreement between two parties stating the details of sales price agreed of a property under construction, which will be transferred to the buyer upon completion. The author further opined that it is a risk sharing method of fund raising which involves the marketing and selling of units to end users or potential buyers prior to the starting or during the construction of the project. Leung and Hui (2005) posited that presale contract is an agreement between a buyer and a seller stating that the buyer undertakes to purchase a property under construction at a specified price and due for completion at a certain future date. Developers endeavour to advertise and dispose on-going developments by presale arrangement during planning or execution phase so as to boost the capital reserve especially for large-scale developments. This practice according to Leung and Hui (2005) is widespread among developers operating in urban centres with high population growth rates such as Kuala Lumpur, London, Toronto, Singapore, Beijing and Hong Kong. Chang and Ward, (1993) is also observed that presale is practiced in Asian countries such as Hong Kong, china, Taiwan and south America. Chau, Wong and Yiu (2003) opined that presale contract differ from the highly standardized commodity or financial futures traded in a centralized market. Nevertheless, It has been observed that majority of studies that exist on forward sales are found in Europe, Asia as well as North America (Wong, Yiu, Tse and Chau 2004). Furthermore, empirical studies on the use of forward sale as a strategy for consummating real estate transaction in emerging markets like Nigerian property market remains very scanty.

Institutional procedure for the forward sale transaction

Investors engage forward sale as a funding strategy primarily to raise capital at no cost. However, packaging the strategy differ significantly from one geographical property market to another. Chang and Ward, (1993) stated that in Asia, it is mandatory that developers who wish to raise fund through forward sale, complete a specific part of the development. In Brazil, the developers must submit schedule of quality and material quantity as well as the plan of execution and necessary designs to appropriate authority before the presale is allowed. In Hong Kong, government instituted a number of measures against speculation. These measures according to Chau, Wong and Yiu (2003) include;

- a period of nine months at most for the presale
- restriction of private sales quota from 50% to 10%. The rationale was that private sales encourage speculation since the vast majority of such buyers are not end-users"
- discouragement of short-term trading through increasing trading costs.
- Imposition of stamp duty (a kind of tax) imposed on the transactions of the Agreement of Sale and Purchase (ASP), rather than on the subsequent transactions of the Deed of Assignment

In the opinion of Renaud, Pretorius and Pasadilla (1997), these constraints created substantial impediment to purchasers and prevent them from engaging in aggressive short-term investment opportunities in the primary housing market. In addition, the government of Hong Kong further introduced consent scheme to monitor the sale of properties under construction.(Leung and Hui, 2005). Hence, the authority tried to protect the interest of prospective buyers in the presale housing market. Under the scheme, the major requirements that developers must meet include:

i. Legal documentations to show developer's financial ability to complete the project
ii. Developer's solicitor hold in trust, the stakeholder's payments.
iii. Payments only made for work certified by the architect as having executed
iv. sales brochures and price lists are made available to prospective buyers and the government prior to sales.
v. Purchasers are free to withdraw from the agreement or receive compensation if project could not be completed to date specified.
vi. Quality assurance is provided by the developer to ensure that the project is completed according to material and quality specification.

Leung and Hui (2005) averred that since the consent scheme was introduced, buyers of future projects have been protected against dishonest developers and associated risks significantly reduced. Unlike what obtains in Asia countries, Brazil, America and Europe, Oloke et. al. (2017) observed that the Nigeria housing market lacks necessary government laws that regulate forward sale transactions. This in turn has exposed prospective buyers to the danger of developer's defaults, speculation as well as the trap of advance fee fraud by those that take advantage of the loophole.

In view of the foregoing, it is established that forward sale is not only engaged as a method of raising development finance by developers, it also makes housing acquisition easy for prospective home-owners and facilitate the delivery of houses for different income groups. In addition, there exist institutional guidelines for engaging forward sale in countries that allow the use of forward sale in order to protect the interest of the parties involved in the transaction.

Research Methods

Primary and secondary data were involved in this study. Existing studies obtained from online published articles were reviewed. Structured questionnaires were also administered to developers, prospective buyers of housing projects and estate surveyors and valuers in the study area. The population considered in this study are the 343 estate surveying firms based in Lagos as obtained from the directory of the Nigerian Institution of Estate Surveyors and Valuers (NIESV, 2016) as well as the 372 registered Real Estate Development Companies obtained from the directory of Real Estate Developers Association of Nigeria (REDAN, 2015). However, the sample size was restricted to the population of each group in Ikeja area which has 84 development companies and 79 estate firms. Ikeja was selected because it has the highest concentration of development firms. Thus the total number of both firms sampled was 163. The population of prospective buyers who were sampled randomly was 158. This implied that the opinions of any two buyers of potential house buyers at each of the estate firm involved in the survey were obtained through the firm. Data were obtained from the respondents with respect to the sources of real estate finance, preference for financing strategy, popularity and acceptance of forward sale as well as the challenges of forward sale in the Nigerian property market. Hypothesis was also tested with Student's t-test in a bid to establish the popularity of forward sale among prospective house buyers while mean score and relative importance index was also used to determine the impact of the challenges. Results were presented in tables, percentages, and charts followed by discussion.

Findings and Discussion

Rate of response

The rate of response achieved in the administration of questionnaires is presented in Table 1.

Table 1: Response rate

Respondent class	Nr Distributed	Nr Retrieved	Rate of Response
Developers	84	62	74%
Estate valuers	79	69	87%
Potential buyers	158	133	84%
Total	321	264	82%

Key: Nr - Number

Table 1 showed the rate of response obtained from each category of respondents. The response rate from each category is above 50% and considered adequate for further analysis. Moreover, the response from prospective buyers and the overall response rate were encouraging and deemed fit for subsequent analysis.

Preference for funding source among developers

Respondents from development companies were asked to indicate the preferred source of finance for development projects by the company. Table 2 shows the analysis of the choices.

Table 2: Project financing used by developers

Finance strategy	Frequency	Percentage	Ranking
Mortgage	40	65%	4th
institutional lending	29	47%	5th
joint venture	46	74%	2nd
Debt	43	70%	3rd
sale-leaseback	11	18%	8th
forward sale	56	90%	1st
sale of securities	23	37%	7th
contractor finance	25	40%	6th
Syndicate loan	40	65%	4th

Table 2 showed amongst others that forward sale has the highest preference followed by joint venture equity and debt financing which ranked 2nd and 3rd respectively. This implies that the developers, under normal circumstances prefer to minimize their exposure to debt financing especially in a volatile and harsh economy like Nigeria's. This attests to the fact that forward sale is often used by developers especially for large development projects in Nigeria.

Prospective buyer's preference for forward sale

In this section, the preference of prospective buyers were obtained from the three categories of respondents, that is the potential buyers, developers and estate valuers who are the active and professional intermediary between developers and buyers of real estate products. Response were analysed and presented in Table 3.

Table 3: Preferred strategies for house acquisition

Respondents	Forward buy	Spot buy	Indifferent	Total
Potential buyers	17(13%)	104 (78%)	12(9%)	133(100%)
Estate Surveyors	9(13%)	53(77%)	7(10%)	69(100%)
Developers	10(16%)	50(81%)	2(3%)	62(100)
Total	36(14%)	207(78%)	21(8%)	264(100%)

From the Table, it is observed that spot buy has the highest preference of 78 percent of total responses obtained. This implies that majority of potential buyers prefer to procure houses that are already completed. This gives them the opportunity to inspect and explore or negotiate flexible payment plan once the house meet the standard. Nevertheless, about 14 percent also showed willingness to buy in advance in order to benefit from discount that comes with such arrangement while only 8 percent signifies indifference to either option. In addition, the high number of responses in favour of spot buy may not be unconnected to the opportunity to verify necessary documents and inspect the houses before commitment to purchase agreement with the developer. The low response recorded in favour of forward buy only revealed the general lack of confidence in presale arrangements among prospective house buyers in Nigeria as reflected in the responses of respondents in the study area.

Challenges facing forward sale

Presented in Table 4 are the challenges hindering the use of forward sale in the study area as indicated by respondents from each category of respondents.

Table 4: Challenges confronting the use of forward sale

Challenges	Developers			Estate Valuers			Potential Buyers		
	Freq	Perc	Rank	Freq	Perc	Rank	Freq	Perc	Rank
Poor quality	6	10%	13th	42	61%	5th	91	68%	4th
Substandard materials	10	16%	10th	41	59%	6th	98	74%	3rd
Furnishing problem	8	13%	11th	18	26%	15th	18	14%	15th
Insufficient information	7	11%	12th	44	64%	3rd	72	54%	8th
Payment default	51	82%	1st	51	74%	2nd	33	25%	14th
Developer's default	7	11%	12th	61	88%	1st	111	83%	2nd
Location	17	27%	7th	27	39%	13th	34	26%	13th
Design team acrimony	10	16%	10th	18	26%	15th	59	44%	12th
Poor management	10	16%	10th	20	29%	14th	65	49%	9th
planning permit problems	22	36%	5th	34	49%	11th	61	46%	11th
Title documents	14	23%	8th	38	55%	9th	89	67%	5th
Lack of regulatory policy	12	19%	9th	35	51%	10th	111	83%	2nd
Reputation of developers	23	37%	4th	40	58%	7th	91	68%	4th
Contractor's credibility	28	45%	3rd	32	46%	12th	62	47th	10th
Nature of development	14	23%	8th	39	57%	8th	77	58%	7th
Economic condition	31	50%	2nd	43	62%	4th	89	67%	5th
Activities of speculators	10	16%	10th	32	46%	12th	86	65%	6th
Vulnerability to fraudsters	18	29%	6th	39	57%	8th	126	95%	1st

Presented in Table 4 are the various challenges hindering the use of forward sale for property transaction as perceived by the developers, property brokers and prospective buyers. The table showed that payment default, economic condition and contractor's credibility are the top three factors hindering the use of presale among developers closely followed by developer's reputation, planning and regulatory challenges and activities of the fraudsters which ranked 4th, 5th and 6th respectively. On the other hand, developer's default, payment default and insufficient information constituted the top three challenges affecting forward sale arrangement from the perspective of the estate valuers. Next are economic condition, poor quality of construction and use of substandard building materials which ranked 4th, 5th and 6th respectively. Finally from the perspective of the buyers, vulnerability to fraudsters, developer's default, lack of regulatory policy and substandard materials are the top three hindrances to presale arrangement in Nigeria. These are closely followed by poor construction, problem of title

documents, economic condition and activities of speculators which ranked 4th, 5th and 6th respectively. It is also observed that majority of the challenges highlighted actually received above average of total responses from the perspectives of estate valuers and prospective buyers compared to the spread of response by the developers. The opposing stance indicates that the developers are still finding it pretty difficult to use forward sale in the property market in the study area.

Test of hypothesis

The hypothesis focus on these category of respondents because the mode of acquiring projects developed are suggested/designed by either the developer or the selling agent, that is the estate surveyors and valuers. The strategies are only introduced to potential buyers who decide whether to buy a completed project at the full market price (i.e. spot buy) or take advantage of the benefits offered with presale strategy. In order words, the developers market their products to prospective buyers with options to buy in advance or when completed. The estate valuers broker the transaction with the potential buyer. Therefore, in order to ascertain the popularity and acceptance of forward sale by potential buyers of real estate products in the study area, null and alternative hypotheses were set and independent sample t-test was carried out to test the hypothesis. The independent sample test was used to compare the means of two independent populations, the developers and estate surveyors and valuers.

Null Hypothesis:

Ho: There is no significant statistical difference in the response of developers and estate valuers on the popularity of forward sale among prospective home buyers in Lagos State, Nigeria

Alternative Hypothesis:

Ho_1: There is significant statistical difference in the response of developers and estate valuers on the popularity of forward sale among prospective home buyers in Lagos State, Nigeria

Table 5: Independent sample T-Test on the use of forward sale

Dependent (Test) Variable	Independent (Grouping) Variables	N	Sig.	T	Df	Sig. 2-tailed	Mean Diff.	Std Error Diff.
			Equal variances assumed					
Forward sale	Estate Valuers	133	.101	.178	193	.137	.3312	.2624
	Developers	62						

**Equal variances assumed **95% confidence interval of the difference*

With the Sig. value of .103, equality of variance is assumed. The t statistic under the assumption of equal variances has a value of .178 and degree of freedom (df) value of 193 with an associated sig. (2-tailed) value of .137. Since the sig. value of .137 is greater than .05, the null hypothesis which states that there is no significant statistical difference in the response of developers and estate valuers on the popularity of forward sale among prospective home buyers in Lagos State, Nigeria is accepted. The result of the hypothesis thus uphold and corroborates the conclusion in Table 3 that forward sale is still not popular among potential home buyers in the study area compared to spot buy.

Conclusion

This study examined the level of use of forward sales in Lagos property market transactions. The result have shown that all categories of respondents have a level of knowledge of forward sale as a method of carrying out property transaction in the Nigeria property market. Results have shown that while developers are predisposed to the use of forward sale, prospective buyers are careful or cautious about the strategy. Buyers are reluctant to pay in advance for housing units, the construction of which has not yet started or still under construction. Various factors affecting this decision were identified and ranked according to their significance from the perspective of each category of respondents. It was discovered that while buyers fears the prank of fraudster, poor construction, lack of policy protection, developer's default, developers are confronted with payment default, economic instability, contractor's

credibility and planning regulations challenges. These and others have seriously affected the use of presale in the Nigerian property market.

Arising from the foregoing, it is pertinent that government gets involved in the property market, especially in the use of forward sale. There is need for policy protection for the parties involved as it obtains in Asian market as well as Europe and America. Furthermore, developers need to involve users right from the planning and design stage in order to develop what the users want and completed with good workmanship, good construction, standard materials and adequate facilities. Government can also facilitate the delivery and completion if necessary planning and development permits are granted without undue delay and advance payments by prospective buyers are insured against default.

Importancia Del Aprovechamiento De Residuos Sólidos Orgánicos Bajo Un Esquema De Economía Circular: Caso Bogotá

Jenny Alexandra SEGURA OSUNA

docente de investigación Uniminuto Administración de Empresas, Bogotá, Colombia,
jseguraosun@uniminuto.edu.co

Resumen

En el presente documento de investigación de tipo descriptivo se expondrán los usos que tienen los residuos sólidos orgánicos (RSO) al ser reciclados provenientes de las frutas y los vegetales crudos, bajo un modelo económico de tipo circular donde su premisa más importante es la utilización eficiente de los recursos disponibles en la producción de los bienes y la reincorporación de elementos reciclables al sistema productivo, minimizando el desperdicio de material aprovechable. Así mismo, a través de una encuesta aplicada a recicladores de la ciudad de Bogotá en Colombia se mostrará que proporción de ellos se dedican a la actividad del reciclaje de dichos residuos, la postura y conocimientos que tienen ante dicha actividad, como estrategia para aportar al medio ambiente y sus ingresos provenientes de la recuperación, dentro del esquema de la economía circular.

Palabras clave: Economía circular; residuos sólidos orgánicos; reciclaje; medio ambiente.

Introducción

Los residuos sólidos orgánicos que provienen de frutas y vegetales son un arma de doble filo, ya que si son recicladas y utilizadas como materia prima para obtener otros bienes aportan a la economía circular, generando ingresos para quienes intervienen en el proceso y aportando a la descontaminación del medio ambiente, pero en caso contrario son fuente de contaminación, ya que son fácilmente putrefactibles con lo que se generan malos olores que pueden provocar enfermedades de tipo respiratorio y gastrointestinal para quienes habitan en zonas cercanas a los rellenos sanitarios o sitios de disposición final.

Teniendo en cuenta lo anterior en el presente documento se busca mostrar los usos e importancia que se le pueden dar a los residuos sólidos orgánicos que provienen de los vegetales y frutas crudos, por parte de los recicladores de la ciudad de Bogotá, especialmente la elaboración de abono orgánico, bajo el modelo circular de la economía y a través de la aplicación de encuestas a recicladores.

Metodología

El presente artículo es resultado de una investigación aplicada cuya población objetivo fueron los recicladores de la ciudad de Bogotá, la cual tiene un enfoque mixto donde se ha tenido en cuenta lo cualitativo y lo cuantitativo con una metodología de tipo descriptiva cuyo principal objetivo fue caracterizar a la población objetivo y analizar si ellos perciben la actividad del reciclaje de residuos sólidos como una fuente para generar ingresos, mejorar su calidad de vida y aportar a la descontaminación del medio ambiente.

Importancia del reciclaje de residuos sólidos de tipo orgánico

A nivel internacional se ha identificado que es muy importante la conservación del medio ambiente y el uso correcto de los recursos que existen, sin importar si se trate de los renovables o los no renovables en un enfoque de sostenibilidad, ejemplo de ello son los Objetivos de Desarrollo Sostenible (ODS) de los cuales tres hablan del uso eficiente de los recursos (Naciones Unidas, s. f.) tal como se puede observar en la figura 1:

Fig. 1: Objetivos de desarrollo sostenible relacionados con el reciclaje
Fuente: elaboración propia

El objetivo 8 tiene que ver con la importancia de que las personas tengan un medio de sustento que les permita tener una vida digna y a la vez aporte al crecimiento de la nación en conjunto, tratando de disminuir las brechas de desigualdad. El desempleo es un problema global que afecta a las personas con más bajos ingresos, lo cual afecta su estabilidad económica y en general su calidad de vida.

En relación con el reciclaje y las oportunidades laborales que brinda a los recicladores, se tiene que ellos son un grupo de personas que muchas veces no cuentan con altos niveles de educación, con bajos niveles de ingresos y viven en condiciones de pobreza. La mayoría se dedica a la recolección de residuos inorgánicos como vidrio, metales de todos los tipos, elementos de construcción, cartón y papel, pero se deja de lado la recolección de residuos orgánicos que pueden ser una fuente importante de ingresos.

En cuanto al objetivo 11, se desea que a la par que las ciudades crecen y se expanden, estas estén en la capacidad de llevar a cabo políticas para que ese crecimiento no afecte la sostenibilidad de largo plazo del medio ambiente, teniendo en cuenta el bienestar y el futuro de las generaciones que vienen en camino.

En el caso de la ciudad de Bogotá, el relleno Sanitario doña Juana, recibe toneladas diarias de residuos, que año a año aumentan con los procesos de crecimiento y urbanización de la ciudad y otros seis municipios aledaños a la capital, el problema es cuando el relleno comienza a copar su capacidad, que de acuerdo Estupiñán (2019) se proyecta tiene una vida útil hasta el año 2022, que se extendería 37 años, si se amplía la duración de la licencia actual, optimizando las áreas, con lo cual se siguen afectando los habitantes de localidades del sur de la ciudad como Ciudad Bolívar y Usme, en zonas urbanas y rurales de la ciudad.

Por su parte el objetivo 12 hace referencia a que el consumo y la producción de bienes y servicios se haga de forma responsable, que se minimice el impacto negativo sobre el medio ambiente. Así mismo que no haya desperdicios de alimentos tanto en los alimentos ya procesados, así como los que provienen de las cosechas.

Los alimentos provenientes de frutas y verduras generan residuos que no se consumen y que al ser utilizados se convierten en fuente de aprovechamiento para la producción de otros bienes y servicios, especialmente en abonos de tipo orgánicos, libres de químicos los cuales hacen que al usarlos en actividades como la agricultura o la jardinería se aprovechen sus propiedades, para hacer crecer de forma fuerte y frondosa todo tipo de vegetación y mejorando las características físicas y químicas de los suelos.

Economía Circular

La Economía circular se concibe como una forma de contribuir con el uso eficiente de los recursos, que aporta al medio ambiente a través de la reducción de emisiones de carbono, según Economía Circular (s. f.) uno de los objetivos de este sistema es generar empleos y crecimiento económico para los países de Europa que permite además aportar, a continuación, se presentan los beneficios que se tienen al adoptar un sistema económico de tipo circular en el cual:

Fig. 2: Beneficios de la economía circular

Fuente: elaboración propia, con base en Economía Circular (s. f.)

El reciclaje de los residuos sólidos orgánicos provenientes de los vegetales y frutos crudos se puede considerar una estrategia que hace parte de la economía circular, ya que en un inicio son cultivados en la naturaleza, utilizando para ellos recursos de la misma, con el objetivo de alimentar a las comunidades, las cuales no aprovechan todos sus componentes en un 100%, siendo esos residuos aprovechables en actividades como la elaboración de abono orgánico que a su vez permite que el suelo tenga propiedades que permitan que de nuevo comienzo el proceso productivo a través de los cultivos de otros frutos y vegetales o actividades como la jardinería, a partir de los cuales los suelos son acondicionados para que no pierdan sus nutrientes y se puede seguir aprovechando este recurso escaso. Pon (2019) lo ilustra de acuerdo a la figura 3:

Usos de los residuos sólidos orgánicos

El uso más conocido para los residuos sólidos orgánicos es la elaboración de compost, el cual devuelve la fertilidad a los suelos como lo ilustra Román, Martínez y Pantoja (2013) lo cual impacta el bienestar de las familias que se dedican a actividades como la agricultura con los cuales obtienen ingresos y generan puestos de trabajo y que para la humanidad es representa la seguridad alimentaria. Así mismo de los residuos sólidos orgánicos se pueden obtener además los siguientes bienes, ver figura 4:

Biocombustibles	•Alejos y Calvo (2015)
Alimentos para animales	•Vidales, Chávez, García, y Gómez (2004).
Elementos para naotecnología	•Mercado Castro (2016)
Hormigones para la contrucción	•Coloma (2015)
Papel reciclado	•González, Daza, Caballero y Martínez (2016)

Recolección de residuos sólidos orgánicos por los recicladores en la ciudad de Bogotá

Con el fin de conocer que tan difundidas entre los recicladores de la ciudad de Bogotá son los usos de los residuos sólidos orgánicos se realizaron encuestas en las diferentes localidades donde también se indagó si llevaban a cabo la recolección de estos materiales y si lo reconocen como una oportunidad para generar ingresos y mejorar sus condiciones de vida. Al indagar por la proporción de recicladores que recolectan residuos sólidos se encontró que solo el 32% del total de los encuestados recolecta residuos orgánicos frente a un 68% que dijo no dedicarse a ello, como se muestra en la figura 5.

Fig. 5: Recolección de residuos de origen orgánico

Fuente: Elaboración propia

Entre los materiales que ellos recolectan se encuentra principalmente residuos de madera con un 46%, un 23% dice recolectar residuos de alimentos tanto procesados como crudos y en una menor proporción con un 8% aserrín, pese que el 64% de ellos manifiesta conocer los usos que tienen dichos residuos, como se puede apreciar en la figura 6.

Fig. 6: Tipo de residuos sólidos recolectados
Fuente: Elaboración propia

Al preguntar si los recicladores encuestados conocen el uso de los residuos sólidos orgánicos se encontró que el 64% dice conocer los diferentes usos que se les puede dar a dicho material, mientras que un 36% manifiesta que no, lo cual indica que a pesar de que ellos tienen ese conocimiento no se dedican a la recolección de ese tipo de material, como se observa en la figura 7.

Fig.7: conocimiento sobre los usos de los RSO

Fuente: Elaboración propia

Respecto a los usos que se les puede dar a los residuos sólidos orgánicos se tiene que el más conocido para los recicladores es el papel reciclado con un 29%, luego el compostaje y colchones con 18.28% y 17.4% respectivamente y los menos difundidos son bloques de construcción y alimentos para animales con 10.1% y biocombustible y joyería artesanal con 7.2% cada uno, ver figura 8.

Fig. 8: Conocimiento de algunos de los usos de los RSO

Fuente: Elaboración propia

En cuanto a la apreciación que tienen los recicladores sobre una oportunidad para generar ingresos con el reciclaje de residuos sólidos orgánicos, la mayoría con un 76% percibe que si es una buena fuente de ingresos mientras que el 12% percibe que no y el otro 12% no sabe, ver figura 9.

Fig.9: percepción de los recicladores frente a la recolección de RSO como fuente de ingresos

Fuente: Elaboración propia

Conclusiones

A través de la revisión bibliográfica y el trabajo de campo se encontró que el reciclaje de residuos sólidos orgánicos es una forma de contribuir a la generación de ingresos para los recicladores, el aprovechamiento de material aprovechable dentro del esquema de la economía circular y una forma de aportar al medio ambiente. Por su parte de la Organización de Naciones Unidas ONU, a través de los Objetivos de Desarrollo Sostenible, se identifica que el reciclaje de los RSO es una forma de aportar a los objetivos número 8, 11 y 12.

Entre otros usos los RSO se pueden utilizar para obtener papel reciclado, piezas de nanotecnología, colchones, bloques de construcción, alimento para animales y sobre todo abono orgánico también llamado compost que es reconocido por sus propiedades para acondicionar física y químicamente los suelos, que también es un aporte a las actividades de la agricultura y la jardinería.

Sin embargo, se encontró que esta actividad no se realiza con frecuencia por los recicladores pese a que tienen el conocimiento de sus usos y que ellos mismos los perciben como fuente de ingresos, debido a que en los mercados son más comerciados los residuos provenientes de elementos como el vidrio, el plástico, metales, entre otros.

Educación Financiera Como Estrategia De Supervivencia Y Protección Ante Crisis Económicas Para Los Recicladores De Bogotá

Jenny Alexandra SEGURA OSUNA

docente de investigación Uniminuto Administración de Empresas, Bogotá, Colombia,
jseguraosun@uniminuto.edu.co

Resumen

La educación financiera es una herramienta que puede mejorar el bienestar de personas vulnerables dedicadas a la actividad económica del reciclaje en la ciudad de Bogotá, especialmente en la coyuntura sanitaria y económica actual, donde se han visto expuestos a mayores riesgos. Con una mayor estabilidad en materia económica y financiera vía sus ingresos, ellos tendrían la posibilidad de acatar medidas como el confinamiento obligatorio, pero dado que ellos perciben que sus ingresos son insuficientes y necesarios para su supervivencia y cubrimiento de sus necesidades no es posible llevarla a cabo. Con el estudio realizado en el cual se aplicaron encuestas a recicladores de la ciudad de Bogotá, se encontró que los ingresos para este grupo poblacional han disminuido, que no han tenido la posibilidad de tomar todas las medidas preventivas ante COVID-19 y que todo en conjunto hace que su situación empeore.

Palabras clave: Educación Financiera; Reciclaje; Crisis Económica; Informalidad.

Introducción

La actual crisis económica derivada de la pandemia del COVID-19 ha traído consigo lecciones para personas de todas las edades y los diferentes niveles socioeconómicos, siendo los de menores recursos y menores niveles de educación los más afectados, ya que dependen de trabajos informales y del día a día. En ese grupo de población se encuentran los recicladores quienes a nivel ambiental juegan un papel muy importante al recolectar, transportar y transformar el material que para algunos es "basura" pero que para ellos representa su sustento día a día.

La ciudad de Bogotá es la capital de Colombia y es el centro económico de mayor tamaño en todo el país, por lo que a diario hogares y empresas generan grandes cantidades de residuos los cuales muchas veces no son aprovechados y van a parar al relleno sanitario de doña Juana, el cual se ubica al sur de la ciudad y que de acuerdo al Departamento Nacional de planeación (DNP, 2018) para el año 2017 en promedio a diario se producen 6.265,46 toneladas de residuos. Sin embargo, hay personas que se dedican a la recuperación de elementos reciclables con lo cual no solo se le aporta al medio ambiente sino también a la salud de los miles de personas que viven en cercanías del relleno, las cuales frecuentemente sufren de afecciones respiratorias dado los vectores a los que a diario se encuentran expuestos, donde los más afectados son los niños y las personas de la tercera edad.

No sólo los recicladores se encuentran entre los trabajadores informales que están expuestos a los riesgos generados por la pandemia del COVID-19, Silva Mariños (2020) identifica que el personal doméstico, cargueros, recolectores de basura, domiciliarios, albañiles, personal de seguridad, vendedores ambulantes e informales, entre otros, sin embargo. La característica común de dichos oficios es que no son calificados y mal remunerados teniendo en cuenta el riesgo al que a diario se enfrentan y la labora social y comunitaria que cumplen.

Dada dicha importancia de la labor de los recuperadores de oficio, es importante generar políticas y acciones que les permita tener una mayor calidad de vida y un mejor aprovechamiento de los recursos que son generados a través de esta actividad. La educación financiera como la concibe la Organización para la Cooperación y el Desarrollo Económico (OCDE, 2005) es un conjunto de conocimientos y habilidades en temas como la inversión, el ahorro, los servicios del sistema financiero formal, los derechos del consumidor financiero, entre otros que le permite a la persona mejorar sus condiciones y calidad de vida.

Metodología

En el presente artículo se utilizo una metodología de tipo descriptiva en la cual se caracterizo de acuerdo a su información sociodemográfica a recicladores de la ciudad de Bogotá, teniendo en cuenta lo anterior en el presente

Cite this Article as: Jenny Alexandra SEGURA OSUNA "Educación Financiera Como Estrategia De Supervivencia Y Protección Ante Crisis Económicas Para Los Recicladores De Bogotá" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

documento se desea establecer la importancia que tiene la educación financiera como estrategia para que las personas dedicadas a la actividad económica del reciclaje en la ciudad de Bogotá tengan la posibilidad de enfrentar una crisis económica y de salud pública sin tener que exponer sus vidas y bienestar, a través de un estudio de tipo descriptivo con enfoque mixto donde se tiene en cuenta lo cualitativo y cuantitativo. Lo cualitativo en relación con las teorías que destacan la importancia de la educación financiera y los elementos de los que depende y lo cuantitativo a través de encuestas aplicadas a los recicladores de diferentes localidades de la ciudad.

Importancia de la educación financiera y la inclusión para las personas dedicadas al reciclaje

Lusardi y Mitchell (2011) señalan que el nivel educativo y la edad son factores determinantes en el grado de educación financiero y las buenas decisiones que propenden al bienestar de la persona. Por su parte Parra y Orjuela (2018) en un estudio aplicado a recicladores de la localidad de Suba, identificaron que el principal factor que afecta los bajos niveles de educación financiera en dicha población son los bajos niveles de escolaridad lo cual los excluye del conocimiento y uso de los servicios financieros del sistema formal. Respecto a este tema se encontró que el 58.3% de los encuestados alcanzaron un nivel educativo de bachillerato y el restante 41.7% solo la primaria.

Grifoni, et. al. (2020) señalan que una política en materia de educación financiera debe incluir principalmente a aquellas personas más vulnerables con bajos niveles de educación y bajos niveles de ingresos, especialmente a sectores como los trabajadores informales (donde se pueden incluir los recicladores) la Mipymes, mujeres, jóvenes, personas dedicadas a actividades relacionadas con la agricultura y áreas rurales. Para dichos grupos poblacionales es necesario identificar los servicios del sector financiero formal que se ajusten a sus necesidades, así como la implementación de sistemas tecnológicos que aporten a la inclusión financiera.

Anaya, Buelvas y Romero (2020) identifican que la inclusión y educación financiera en poblaciones vulnerables con altos niveles de pobreza es una herramienta que permite mejorar en el mediano y largo plazo las condiciones socioeconómicas de este tipo de poblaciones, a través de un estudio realizado a familias de la ciudad de Montería. Así mismo encontraron que si el jefe del hogar tiene educación financiera y la familia se ubica en el área rural, hace que en conjunto un hogar tenga mayor probabilidad de tener educación financiera.

Uno de los principales impedimentos que los recicladores perciben para ahorrar o invertir a partir de los recursos que son generados con su actividad es que son insuficientes, que muchas veces solo alcanza a cubrir sus necesidades básicas, por lo que siempre parecieran estar en una trampa de pobreza que no les permite avanzar a una mayor calidad de vida. Lo anterior se refleja en el hecho que de los encuestados el 75% afirma que son insuficientes y solo un 25% piensa que son suficientes. Dicho ciclo de pobreza de acuerdo como lo describe Samuelson y Northaus (2010) se visualiza de la siguiente forma:

Fig. 1: Ciclo de la pobreza

Fuente: Samuelson y Northaus 2010

Como se puede observar en la figura dicha insuficiencia no les permite acumular el capital suficiente, propio del sistema capitalista moderno, por lo que muchas veces dependen de lo que les venden a los grandes centros de acopio, en los cuales el pago del material recuperado se hace a precios muy bajos, teniendo como resultado un ciclo de pobreza del que no pueden escapar. Una estrategia para escapar a esa trampa de pobreza es la educación en general, que sea integral y contenga conceptos del adecuado manejo de las finanzas personales y empresariales.

Fig. 2: Percepción de sus ingresos en la actividad del reciclaje

Fuente: elaboración propia

Como se puede observar en la figura 2, la mayoría de los recicladores encuestados percibe que la actividad del reciclaje no le genera los ingresos suficientes (75%), por lo que una estrategia de ahorro no es posible ya que hay necesidades básicas que ellos deben satisfacer con sus ingresos. Ninguno manifiesta que son más que suficientes y solo el 25% manifiesta que son suficientes en los que la posibilidad de ahorro también sería baja.

Hallazgos

A partir de las encuestas realizadas a los recicladores se encontró que ante la actual pandemia del COVID-19 las condiciones socioeconómicas de dicha población han empeorado, no sólo por lo que se refiere a los ingresos sino en general lo que tiene que ver con la percepción que ellos tienen respecto a su vulnerabilidad antes esa situación, dado que el 83.3% dice sentirse expuesto a mayores riesgos, el 16.7% no percibe cambios en su vulnerabilidad ante esta situación, ver figura 3.

Fig. 3: Vulnerabilidad de los recicladores en tiempos de pandemia

Fuente: elaboración propia

Como se observa en la figura 4, la mayoría manifiesta de los encuestados que no ha podido tomar las medidas necesarias como el acatamiento de las cuarentenas obligatorias que se recomendaron desde el gobierno nacional y distrital, ya que solo el 16.7% del total de la muestra encuestada acato esta medida mientras que el 83.3% no lo pudo hacer, teniendo en cuenta que no tenían los recursos suficientes cubrir sus necesidades.

Fig. 4: Posibilidad de acatamiento de la cuarentena obligatoria por el Covid-19

Fuente: elaboración propia

Respecto a los ingresos desde el inicio de la emergencia sanitaria el 75% de los encuestados percibe una disminución en sus ingresos, mientras que el restante 25% dice que se han mantenido como se ve en la figura 5, pero a cambio de salir a las calles a realizar su labor diaria, donde el 87.3% se siente discriminado por el tipo de actividad que realiza, ver figura 6:

Fig. 5: Ingresos de los recicladores en cuarentena

Fuente: elaboración propia

Fuente: elaboración propia

Conclusiones

Pese a que la actividad del reciclaje es muy importante a nivel ambiental, social y económico, aún no se le reconoce ni es bien visto por la mayoría de personas a tal punto que ellos sienten que son discriminados. En tiempos de pandemia aún más han sido golpeados por la situación económica mundial a tal punto que se sienten más vulnerables y sus ingresos han disminuido pese a que no han podido cumplir las cuarentenas que buscaban disminuir la velocidad de contagio.

Ante el panorama anterior una salida es la formación en educación financiera que les permita hacer frente a este tipo de crisis, sin que se expongan a contagios y otros factores negativos que atentan contra su integridad. Una cultura del ahorro, así sea en pequeñas proporciones puede hacer que ellos estén en la capacidad de expandir su consumo futuro, hacer frente a crisis que afecten sus ingresos e incluso a futuro proveer los medios para incrementar su capital de trabajo.

Résumé

Le dessein de cette recherche est de s'interroger sur la manière dont les collectivités territoriales, et plus particulièrement les communes, devraient se centrer sur l'habitant pour déployer leurs stratégies territoriales.
L'étude de la gouvernance s'inscrit dans le champ de recherches sur la transformation de l'action publique locale et sur les nouvelles formes de coordinations multi-niveaux et multi-acteurs : quels rôles jouent les dispositifs et les outils en l'occurrence marketing dans la fabrique de la gouvernance locale pour une attractivité réussie, et comment favoriser une gouvernance basée sur une stratégie endogène ?
Ce document a pour principale vocation de constituer un outil de réflexivité pour renforcer la gouvernance territoriale, il en expose les enjeux et propose de contribuer à l'ingénierie de la gouvernance territoriale définie comme « l'ensemble des méthodes et outils permettant la coordination, la participation et l'apprentissage des acteurs ainsi que le pilotage des projets de territoires ».

Mots Clés : Gouvernance Territoriale, Stratégie Endogène, Attractivité Territoriale, Habitant.

Introduction

La gouvernance territoriale n'est ni un mythe ni une figure rhétorique mais bien un outil d'intelligence territoriale en faveur du développement partagé et harmonieux des territoires, c'est là la thèse défendue dans le projet « PSDR Gouv.Innov » mené au total par vingt-deux personnes, chercheurs et acteurs locaux engagés dans l'élaboration d'un guide, fruit d'une co-construction rassemblant des chercheurs de disciplines diverses et d'un panel d'agents de développement local de différentes collectivités ainsi que des conseillers spécialisés.

Le concept de la gouvernance territorial est font en signification et il est chargé de deux mutations la première concerne la gouvernance elle-même ainsi que ses modes, la deuxième se focalise sur le territoire lui-même.

Ces deux mutations sont essentielles pour la survie d'un citoyen dans un territoire et pour le développement d'un territoire dans un monde de plus en plus marqué par la complexité et une volonté féroce de s'inscrire dans la responsabilité sociale et sociétale durable.

Ce document a pour vocation de constituer un outil de réflexivité pour renforcer la gouvernance, il en expose les enjeux et propose de contribuer à l'ingénierie de la gouvernance territoriale définie comme l'ensemble des méthodes et outils permettant la coordination, la participation et l'apprentissage des acteurs ainsi que le pilotage des projets de territoires .

La Gouvernance Territoriale Est Un Processus Dynamique

Dans cette synthèse, la gouvernance territoriale peut être définie comme « un processus dynamique de coordination (hiérarchie, conflits, concertation) entre des acteurs publics et privés aux identités multiples et aux ressources (au sens très large : pouvoirs, relations, savoirs, statuts, capitaux financiers) asymétriques » ; l'accent est mis sur la nécessité de prendre en compte « les enjeux de coordination dans des situations asymétriques et sur la nature du processus, dynamique et collectif, qui nécessite des apprentissages et privilégie des démarches adaptatives tenant compte du long terme. Elle ne peut être réduite à de la participation, mais elle concerne aussi des formules de pilotage innovantes permettant : d'élargir les partenariats à des combinaisons public/privé, de privilégier le caractère intégré et transversal

Cite this Article as : YASMINE ALAOUI" L'habitant Au Cœur De La Gouvernance Territoriale " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN : 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

et de mettre en correspondance les moyens et les besoins entre échelles, tout en renforçant les solidarités des territoires autour des pratiques de mutualisation. »

Est alors proposée la grille d'analyse opérationnelle reportée ci-dessous :

Hiérarchie, conflits, concertation,		participation citoyenne…
Agencement de : Procédures, mesures, connaissances, savoir faire et informations diversifiées	Processus dynamique de coordination entre des acteurs publics et privés aux identités multiples et aux ressources asymétriques autour d'enjeux territorialisés (i) visant la construction collective d'objectifs et d'actions, (ii) en mettant en œuvre des <u>dispositifs multiples</u> qui reposent sur des apprentissages collectifs et participent des innovations institutionnelles et organisationnelles au sein des territoires.	Au sens large, en termes de : Pouvoirs, relations, savoirs, statuts, capitaux

Une autre analyse comparative conduite par Beuret et Cadoret, portant sur plus de 300 initiatives relatives à la conduite d'une gouvernance territoriale endogène de l'environnement fait émerger des proximités organisées à des échelles ajustées, contribuant à doter les territoires d'un capital social territorial spécifique et exposent les contours de ce que pourraient être des politiques d'appui à ces formes de gouvernance.

L'intérêt d'une telle étude pour notre objet de recherche réside dans le fait de pouvoir transposer la démarche proposée dans d'autres champs que celui de l'environnement.

En effet, des notions éclairantes sont alors explicitées dans cette analyse : les initiatives locales portées par des élus, des agents de collectivités locales, des associations ou de simples citoyens font partie de la gouvernance définie comme l'ensemble des formes de régulation qui ne sont ni marchandes, ni étatiques (Benko et Lipietz, 1992), une gouvernance qui émergerait au cœur des territoires, contrairement à d'autres formes de gouvernance qui elles, seraient impulsées par l'extérieur.

Envisagée ici comme un mode d'organisation des acteurs (institutions, entreprises, associations), cette régulation repose davantage sur l'accommodement que sur la hiérarchie ou la domination, destiné à concevoir et à mettre en œuvre un projet (Laganier, Villalba, Zuindeau, 2002), dans le cadre de la création d'un ordre qui résulte de l'interaction d'un grand nombre de gouvernants qui s'influencent réciproquement (Kooiman et Van Vliet, 1993).

La gouvernance mise en œuvre dans les territoires résulterait alors de deux types de dynamiques : une gouvernance territoriale exogène, mise en place par des autorités publiques externes au territoire, de manière coercitive et sur la base de procédures imposées ; et une gouvernance territoriale endogène, issue d'initiatives locales. La première serait issue d'une régulation de contrôle alors que la seconde s'inscrirait davantage dans une régulation autonome (Reynaud, 1989), même si les deux peuvent être combinées dans une régulation conjointe.

Il est aussi rappelé que de nombreux auteurs comme Leloup (2005), Hüfty (2008) ou Létourneau (2009) ont souligné le caractère polysémique du concept de gouvernance territoriale. Distinguons le recours à la « bonne gouvernance », c'est à dire à la transparence et à l'imputabilité des la gestion publique, de la gouvernance comme théorie qui vise plutôt les processus de décision sur des questions d'intérêt public, en faisant référence à une pluralité d'acteurs ou de groupes (Létourneau, 2009) ; c'est précisément cette deuxième acception qui sera ici retenue, en nous intéressant à des formes de gouvernance qui peuvent être indépendantes de politiques de décision publique mais qui les rejoignent par le fait de correspondre à de « nouvelles modalités de production de l'intérêt général » (Petrella et Richez-Battesti, 2010).

Citant Gilly, Leroux et Wallet (2004), qui énoncent que « la gouvernance locale est le processus de structuration d'une mise en compatibilité de différentes modalités de coordination entre des acteurs géographiquement proches », les auteurs de cette étude rapprochent cette notion-là de celle de développement local aussi qualifié d'endogène, compte tenu de l'implication croissante des acteurs privés dans ces démarches : « processus non seulement de

coordination des acteurs mais aussi d'appropriation des ressources et de construction de la territorialité (…) Y sont mises en valeur les vertus d'imagination, d'organisation et de coordination de ces acteurs locaux » (Leloup *et al.*, 2005).

La place qu'occupent l'Etat, le marché ou les coordinations multi-partenariales ont permis à Petrella et Richez-Battesti (2010) de distinguer une gouvernance multilatérale ou partenariale qui implique une diversité d'acteurs publics et privés où les pouvoirs publics joueraient un rôle de facilitateur, d'une gouvernance citoyenne de laquelle se rapprocherait davantage la gouvernance territoriale endogène dans sa fonction de révélation de demandes sociales émergeantes.

Riches de tous ces éclairages, les auteurs nous proposent la définition suivante de la gouvernance territoriale endogène comme étant « l'ensemble des initiatives de gouvernance qui émergent dans des espaces publics locaux et associent des acteurs aux statuts et prérogatives diverses qui se mobilisent autour d'un bien commun envisagé comme un construit territorial. »

De La Concertation A La Coopération

Avec Beuret et Cadoret, retenons que la concertation désigne des processus de construction collective de visions, d'objectifs, de projets communs, en vue d'agir ou de décider ensemble (Beuret, 2006), où l'orientation coopérative prédomine, l'intention partagée étant de construire ensemble (Touzard, 2006). La gouvernance territoriale endogène se développe dans des espaces publics, au sens où Habermas l'entendait en 1978 dans son ouvrage « Raison et légitimité », comme étant un lieu qui « repose sur la liberté et l'autonomie des citoyens pour la formation par la raison d'une opinion et d'une volonté collective qui viendraient influer la production de lois ».

La gouvernance territoriale endogène recouvre une large diversité d'interventions, selon que l'on se situe en amont, en aval ou au cœur de la concertation entre les acteurs.

L'étude de Beuret et Cadoret vient encore éclairer une dynamique portant sur la notion d'itinéraire de concertation qui comprend plusieurs étapes : celui ci débute bien par la mise en place d'instances de concertation, visant le plus souvent à mobiliser ou à rapprocher les participants, alors que d'autres peuvent favoriser la mise en œuvre d'idées issues de concertations ou peuvent se situer en fin d'itinéraire.

« Finalement, l'objectif des initiatives relevant de la gouvernance territoriale endogène peut être de rendre une catégorie d'acteurs prête au dialogue, de faciliter l'émergence du dialogue (en offrant des supports de dialogue, de rapprochement), de le conduire, de mettre en place une médiation dans un conflit, de traduire les idées issues du dialogue en actes, de consolider le dialogue en l'élargissant vers de nouveaux acteurs, ou de faciliter la reproduction du dialogue dans des situations similaires (essaimage). »

Dépassant la dichotomie entre démocratie représentative (les élus sont légitimes pour décider au nom de ceux qui les ont désignés) et démocratie participative (les citoyens et représentants associatifs sont invités à participer à la gestion publique), une voie permettrait l'émergence d'espaces de développement co-construits par et pour les acteurs, qui viserait moins à faire naitre un consensus autour d'avis ou de propositions (objectif principal des dispositifs de participation), que de construire de l'action collective par la coopération.

Dès lors, nous pourrions retenir avec Beuret et Cadoret (2010) la définition suivante pour la démocratie collaborative : « c'est une démocratie polycentrée (terme mis en avant par Létourneau, 2009) qui reconnaît comme un fait la distribution du pouvoir, des ressources et des informations entre de nombreuses mains et envisage la coopération comme l'un des moyens d'une coordination efficace. La démocratie coopérative vise à construire de l'action collective plus que du consensus (…) La place de l'Etat de droit est repensée avec un rôle d'animateur, de catalyseur, et de capacitateur (ce que Giddens appelle the enabiling state) (…) Enfin, c'est une démocratie appelée à reconnaître des initiatives prises en faveur d'un intérêt qui dépasse celui de leurs promoteurs, fondées sur un attachement au territoire et à certains biens communs localisés ».

Enfin dans cette même étude, le point de vue de Rusconi (1994), cité par Gaudin, (1999) met en lumière un point intéressant sur le fait que la mobilisation de chacun ne relève ni totalement de la recherche de l'avantage individuel et direct, ni uniquement de la quête d'un sens global et solidaire, mais d'un dosage variable de ces deux perspectives. Cette approche nous pousse alors à dépasser une vision des relations entre acteurs publics et privés centrés sur la contractualisation ou la négociation, pour tendre vers une prolifération de centres d'initiatives et de négociations multipolaires, parfois instables, il faut le reconnaître.

Se pose aussi la question de la place qu'occuperait la gouvernance territoriale endogène vis à vis des politiques publiques ; il semblerait opportun de leur trouver une place dans un espace global où elles seraient intégrées, là où se rencontreraient politiques publiques et initiatives locales, un espace régi par des règles édictées par l'Etat et d'autres construites par les acteurs locaux, l'exercice du gouvernement et les expérimentations pratiques de gouvernance.

Comment alors exploiter les complémentarités existantes ? Et quels en seraient les limites et les atouts ?

Du Réseau Au Partenariat

Progressivement dans la littérature péri-professionnelle, nous avons pu assister à un glissement sémantique du concept de réseau à celui de partenariat, mettant en exergue des problématiques relatives aux conditions de coopération. De toutes les définitions, proposons de retenir celle de Claude Neuschwander qui dans un article de la revue « Pour » en 1991, sur la proximité et la connivence des acteurs entre eux, définissait le réseau comme « un assemblage variable d'acteurs libres qui entretiennent entre eux une communication forte. » Celle ci compterait trois caractéristiques :

- premièrement, elle s'établirait autour d'un intérêt commun, un domaine de connaissances, de compétences, ou d'activités par rapport auquel le réseau permettrait d'établir des relations d'échange ;
- deuxièmement, cette communication ne se maintiendrait que s'il y a compréhension (concepts familiers, forme de culture commune et même des valeurs partagées) ;
- enfin, cette communication ne se réalise que s'il y a une crédibilité mutuelle quasi immédiate ; elle ne connaît ni délais, ni procédure ; elle ne tolère ni formalisme, ni hiérarchie ; elle ne concerne que les individus, jamais les institutions.

Considérer La Complexité Des Dynamiques Instituantes Impliquées (Règles, Sens Et Identité)

La centralisation et l'administration pyramidale ont laissé place à la décentralisation et à la territorialisation d'actions déclinées sous forme de programmes qui sont eux même au confluent de plusieurs politiques publiques. Les défis de l'action publique territoriale qui se présentent désormais sont intrinsèquement liés au pilotage de dispositifs portés par des organes composés de plusieurs institutions présentes sur le territoire conduisant des agents de culture et de métiers différents, à travailler ensemble, dans un objectif de transversalité des interventions. Il s'agit de développer des projets qui correspondent au problématiques locales et aux attentes des usagers pour faire émerger ce que Philippe Lyet a notamment présenté comme étant une « gouvernance partenariale ».

Citant lui même Jacques Ion, il précise encore que l'enjeu est alors « de faire parler un même langage à des intervenants (personnes ou institutions) usant de langages différents, ayant des intérêts qui ne sont pas convergents ». Il en ressort bien souvent que l'énergie dépensée à vouloir faire collaborer ensemble collectivités territoriales, services de l'Etat, associations, etc., est largement autant orientée à organiser et à réguler la collaboration (et par conséquent les conflits induits) qu'à réellement mettre en œuvre l'action.

Il ne suffit pas donc de vouloir articuler différentes politiques dans une dynamique territoriale, inciter à monter un dispositif d'élaboration collective de la décision autour de normes partagées et commune, pour arriver à travailler ensemble. Il faut aussi faire face à des tensions intra-institutionnelles et inter-institutionnelles et à une réelle capacité de résistance au changement ; dans l'esprit de ce qu'avait mis en lumière Michel Crozier, cette résistance tient à des conflits d'intérêts, à des identités parfois malmenées ou aux difficultés des personnes à trouver du sens à des compromis ou à des projets ayant pu être élaborés sans eux, les laissant comme en marge des décisions finales.

Comme le souligne Lyet, il est à regretter que la dimension extra-institutionnelle de quelques actions initiées de manière isolée et créative, doive faire face à un déficit d'appropriation de ces mêmes actions par les institutions. En effet, force est de constater que l' « on observe de manière générale un décalage entre ce développement d'initiatives (par création ascendante ou par appropriation descendante) et la faible capacité des organisations à, d'une part, accompagner leurs professionnels dans leurs tentatives pour créer un projet ex nihilo (…) et, d'autre part, permettre que les « inventions » locales soient diffusées aux autres agents et services de l'organisation pour éclairer et enrichir par capitalisation d'expériences d'autres initiatives du même genre. »

Il nous met également en garde contre le risque d'une stratégie de réorientation de l'action publique qui pourrait être rendue inopérante par déficit d'institution : en effet, on pourrait penser que le renouvellement d'une action confiée en mode projet partagé à plusieurs acteurs en capacité d'agir, et s'appuyant sur des particularités transversales et connues

d'eux, suffirait à échapper à des modes d'intervention trop rigides et uniformes ; mais tel n'est pas le cas : en effet, plusieurs objections pourraient être émises.

Premièrement, cette stratégie de développement de l'action publique s'apparenterait à un mode de management qui mettrait l'accent sur la capacité d'initiative de petits collectifs porteurs de projets et sur la responsabilisation de quelques acteurs, ceux-ci étant eux-mêmes réduits à une dimension individuelle (Boltanski et Chiapello, 1999), or il apparaît périlleux de séparer, d'une part, la question de l'action et de son développement et, d'autre part, la question du pouvoir ; pourtant c'est bien de cela dont il s'agit le plus souvent, dans la stratégie récente de l'action publique : le pilotage et le portage des actions restant déconnectés.

Deuxièmement, il est à craindre que le prix à payer pour cette stratégie ne soit que trop élevé : en effet, c'est parfois beaucoup d'effort dépensé pour un résultat incertain, pas toujours capitalisé et qui pourrait s'évaporer une fois le collectif dissout.

Troisièmement, une action n'est pas qu'une adaptation à un besoin ; son processus de construction est une création institutionnelle qui s'ancre dans une certaine conception des problématiques et des voies de solutions ; aussi ce qui s'invente dans un partenariat – s'il ne peut être transposé tel quel – reste toujours porteur de leçons pour d'autres parce qu'il permet de construire un cadre normatif ou symbolique, susceptible de produire de nouveaux développements, dans des articulations entre local et global, sur des tiers lieux par exemple.

« En résumé, pour la question qui nous intéresse, ces collaborations territoriales et transversales mobilisent, face à l'évolution des problématiques, des professionnels sur la recherche de nouvelles modalités d'action, en collaboration avec des intervenants avec lesquels il ne leur était pas habituel de travailler. Il s'agit de réaliser ce que Pierre Tesseirenc (1994) a nommé « création institutionnelle » à propos d'initiatives de développement local. Mais ce processus est rarement abouti pour des raisons qui conduisent à se demander si ces nouvelles formes d'action publique ne pècheraient pas par déficit d'institution. »

Tout semble montrer que la gouvernance partenariale est vécue de manière paradoxale. Si les différentes parties prenantes d'un territoire, mobilisées sur une action de co-construction, en reconnaissent l'intérêt et la valorisent ouvertement, leur engagement et implication « réels » dans ce partenariat aurait aussi tendance à être anxiogène parfois, les inscrivant dans une situation où ils seraient conduits à abdiquer une part de leur « pouvoir » dans un jeu collectif aux contours incertains.

Force est de constater que de nouvelles perspectives se profilent sur l'engagement même des parties prenantes ; l'article de Berthoin Antal et Sobczak en expose différentes approches
:
en effet, l'évolution des enjeux sociétaux conduit les acteurs locaux à porter une attente différente à l'égard des entreprises notamment : il ne s'agit plus seulement d'évaluer les performances réalisées, mais l'intérêt est porté sur de plus larges enjeux sociétaux nécessitant souvent des solutions complexes, comme la lutte contre le réchauffement climatique, la promotion de l'égalité des chances…

« En passant du terme de « relations entre l'entreprise et la société » vers celui de « responsabilité sociale des entreprises », on modifie cependant la perspective de l'analyse, mettant cette fois-ci l'entreprise, ses activités et ses modes de décision au cœur du débat. Cela s'est également traduit au niveau des cadres théoriques mobilisés par les chercheurs en sciences de gestion (Gond et Mullenbach-Servayre, 2003) – la théorie des parties prenantes, la théorie contractualiste et la théorie institutionnaliste – s'articulent toutes autour de différentes manières de concevoir le rôle de l'entreprise et ses relations avec les autres acteurs. »

Cela était déjà particulièrement d'actualité lorsque R. Edward Freeman en 1984 développait la théorie des parties prenantes en focalisant son analyse sur les relations entre l'entreprise et la société et encore plus sur la responsabilité sociale des entreprises ; cette théorie avait alors été reprise par les chercheurs comme Post, Preston et Sachs en 2002, pour définir les principes permettant aux entreprises de « manager » leur parties prenantes, dans une perspectives instrumentale.

Or dans un contexte mondial qui se complexifie, la question des enjeux économiques, sociaux et environnementaux implique de plus en plus souvent une co-construction de solutions collectives avec tous les acteurs, quel que soit leur statut. Bento, 2009, suggérait alors de tendre vers la notion plus élargie de responsabilité sociale des organisations (non pas seulement des entreprises). Dans cette même lignée, Berthoin Antal et Sobczak, 2004, proposent d'aller encore plus loin pour retenir la notion de responsabilité globale qui met aussi mieux en évidence que les intérêts à

prendre en compte ne sont pas uniquement sociaux, mais au moins aussi environnementaux et économiques et qu'ils doivent être abordés de manière transversales et dans un contexte international.

Gouvernance endogène et nouveau marketing territorial

La démarche du marketing territorial et donc le projet d'attractivité territoriale doit être communiqué au premier lieu aux habitants, et pourquoi pas coproduit et fait pour et par les résidents, partagé mais aussi compris et porté par les parties prenantes d'où l'importance de l'application d'une stratégie de gouvernance qui commence par le résident et qui émerge du cœur du territoire et ne peut aucunement etre impulsée par l'extérieur.

Il est dans ce sens important de se focaliser sur l'implication du citoyen constituant l'élément essentiel de la démarche d'hospitalité définie comme la capacité d'un territoire à garder sur place les ressources (résidents, touristes et investisseurs) déjà acquis.

L'implication de l'habitant n'est plus un choix mais une nécessité primordiale pour la réussite de la démarche d'attractivité territoriale, et ce pour deux raisons essentielles : la première étant d'impliquer d'une façon directe le citoyen dans la gestion de l'affaire public du fait le projet du territoire devrait traduire sa personne en général. et la deuxième conforte le nombre de voix qui se sont élevés dernièrement afin de plaider en faveur de la recherche des atouts immatériels des territoires consistant à toucher en premier la sensibilité, l'affection et le sentiment d'appartenance du résident. C'est sans doute ce résident qui construit et constitue le territoire au quotidien et qui, de fait, coopèrent à véhiculer ce que fait que le territoire est ce qu'il est d'après leurs perception propre et façonnent donc directement ou indirectement son image de marque.

Dans cette même veine il est important de rappeler que le résident peut jouer quatre rôles par rapport à son territoire : il est de prime à bord une cible directe, il peut être un argument valorisant du territoire, un partenaire dans construction du processus d'attractivité et finalement un ambassadeur et un avocat passionné pouvant facilement influencer la décision d'autres cibles.

Conclusion

La notion de gouvernance et/ou de « management » des parties prenantes a évolué vers celle d' « engagement » traduisant le fait que quelques entreprises innovantes soient passées d'un management réactif des enjeux sociétaux qui se limitait à respecter les normes, à la mise en œuvre d'initiatives plus proactives et interactives permettant de traiter ces enjeux de manière plus efficace par des stratégies d'engagement de leurs réseaux de parties prenantes (Andriof et Waddock, 2002).

La notion même d'engagement est alors à expliciter : dans la culture anglo-saxonne, ce terme évoque un mariage ou un accord mais aussi une lutte ; dans le dictionnaire français, on retrouve assez bien cette idée dans « un combat de courte durée et localisée », comme dans le fait de « prendre parti sur les problèmes politiques et sociaux par son action et ses discours ».

Il est rappelé que Greenwood (2007) proposait de définir l'engagement des parties prenantes comme un ou des processus de consultation, de communication, de dialogue et d'échange. Aussi, proposons avec Berthoin Antal et Sobczak de définir l'engagement des parties prenantes « comme la création active de relations d'apprentissage avec les différentes parties prenantes afin de trouver des solutions aux enjeux économiques, sociaux et environnementaux », sans perdre de vue que le conflit puisse y paraître quasi inévitable.

Cela illustre la diversité et la complexité des formes de gouvernance marquées par l'engagement des parties prenantes, différentes approches citées dans cet article révélant une dimension humaine inhérente à tout engagement, donnant un visage à chaque partie prenante considérée, l'énergie du conflit devant être transcendée pour entrer dans une relation plus constructive reposant sur des compromis fondés sur des solutions innovantes. D'autres approches ici reprises insistent sur la dimension affective la gouvernance endogène et de l'engagement des parties prenantes dans la responsabilité globale qui repose souvent sur la passion des individus, leur empathie et leur capacité d'influence ou d'entrainement des autres acteurs. Cette part de subjectivité ne doit pas être sous-estimée.

The Importance of Key Performance Indicators When Eliminating Bottlenecks, Using Modern Research Methods in Process Management

Joanna LISOK

Silesian University of Technology, Gliwice, Poland
Joanna.Lisok@polsl.pl

Abstract

Implementation of the organization's basic strategic assumptions for measurable goals is a complicated and often tedious process. Most often it takes place behind closed doors, among the top management, whose determination and involvement in the implementation of the assumed tasks within the assumed period of time allow to realize actions aimed at achieving the assumed goal. Such an action is very important, because the guarantee of success is the assumption that the whole organization is going in one direction. It is a great challenge to build a clear and unambiguous way of communicating goals and the degree of their realization. The KPIs (Key Performance Indicators) and Result Indicators (RI) are the main tools to help. Tools supporting the Lean process approach in addition to indicators are the SMED method and the Spaghetti Chart method. The concept of SMED methodology was developed between 1950 and 1960, when Shigeo Shingo, a Japanese industrial engineer, in consultation with the Japanese company, considered its problems of inability to eliminate bottlenecks when creating TOYOTA car bodies using presses. The "bottlenecks" in the Japanese company were caused by long machine changeover times, which significantly affected production efficiency. Because Shigeo Shingo, considered to be the world's leading expert in production practices, was looking for the optimal solution for the factors that had a significant impact and control over the production processes that took place at the TOYOTA factory. The only effective solution was to reduce the company's expenses by minimizing the number of production batches, which shortened the machine changeover time. SMED system turned out to be a comprehensive tool. SMED (Single Minute Exchange of Die) is a one-digit minute changeover method. The machine change-over time for production is very important and significantly affects the flexibility and profitability of the production process. If we shorten the set-up time, it will be possible to produce more products in a shorter time, which will have a significant impact on the production flow. The change-over time will also allow to increase the range of manufactured components, which increases the company's attractiveness on the subcontractor market. Spaghetti chart is one of the tools of lean manufacturing. It is used to eliminate or reduce significantly losses in the production process. These include losses caused by overproduction, corrections, over processing, overstock, transport, and losses caused by waiting and movement. These losses occur in every production process and should be systematically reduced and eliminated. The spaghetti diagram is a visualization of movements and flows in the production process. With this method we can analyze both product, document and employee flows. With this tool you can find out which way an employee goes on the job, how much time it takes, what operations he performs and at what time. It also shows the distances and waiting times. When creating a diagram, it is necessary to pay special attention to the actual process, as it occurs in everyday work, with all its errors, flaws, problems. When creating a diagram, we focus on the real process even if it differs from standards and procedures. The Lean Management concept is based on delivering value to the customer. The current trend is to personalize services and products for its customers, optimize costs and processes. Managing a company is a big challenge, so it is worth trying to improve it with methods that are easy to implement. By using practical Lean Management solutions, production or sales results can be significantly improved.

In the article the author will analyze modern Lean methods in order to develop guidelines for Lean Management.

Keywords: Lean, SMED methodology, Kaizen, 5W.

SMED Methodology

SMED (Single Minute Exchange of Die) is a one-digit minute changeover method. The machine change-over time for production is very important and significantly affects the flexibility and profitability of the production process. If we shorten the set-up time, it will be possible to produce more products in a shorter time, which will have a significant impact on the production flow. The change-over time will also allow to increase the range of

manufactured components, which increases the company's attractiveness on the subcontractor market. SMED methodology allows to reduce this type of costs in a very significant way and is described by means of 4 stages, namely: Stage 0 - changeover process analysis - filming, motion analysis and operation analysis; Stage 1 - internal and external changeover - control card, operation control, transport of parts and tools; Stage 2 - changeover transformation - advanced work preparation, standardization, intermediate clamping devices; Stage 3 - improvements - tool storage and management, parallel operations, clamping tools, elimination of regulation, mechanization.

Stage 0 - Activities of employees or machines on raw materials, components, finished products and machine parts are called operations. The changeover is the preparation or appropriate setting of the machine before and after the processing of each subsequent batch. The most important stage of SMED implementation is separation of internal and external changeover operations. Transportation and preparation of parts for work while the machine is in motion (other batches of goods are produced) allows to reduce the changeover time from about 30% to about 50%. The changeover operation consists of two types of operations;

- internal operations, that is, operations that can only be performed when the machine is switched off. An example of such an operation can be a matrix change. A new matrix can only be installed when the machine is turned off.
- and external operations, i.e., operations that are performed while the machine is in motion and running. An example of such an operation is the transport of the matrix from the storage location.

The idea of the whole SMED methodology is to bring the minimum number of internal operations to the point where the minimum number of external operations is performed while the machine is running.

Stage 1 - SMED implementation consists in separating the operations that should be performed when the machine is in motion from the operations performed during its shutdown. Some tasks can certainly be performed before the machine is switched off in order to change-over. For example, you can prepare people as well as all necessary tools and parts, or make necessary repairs and corrections, according to Sz. Kubik. Unfortunately, very often it turns out that such operations are performed only after the machine is switched off. However, these actions should be performed while the machine was producing the previous batch. Separation of these elements and making them within the framework of external change-over may bring us fundamental benefits in the form of shorter time from about 30% to about 50%. Practical solutions helping to separate internal and external operations include; Use of checklists, Checking the efficiency of tools, Improving the transport of dies and other parts. Checklists contain the elements needed to perform the changeover and setup the next operation. These elements are: Tools, Technical Specifications, Personnel performing the appropriate operations, Determining the correct operating conditions for the operation. It is very important to develop a separate list for each machine and operation, [1]. The use of generic checklists that are undifferentiated throughout the enterprise can be disappointing, as such lists are very often ignored by employees. A fitness check should be carried out in advance before the changeover begins, so that the necessary repairs can be made, which will result in fewer breakdowns, during start-up and later on. If, after starting the machine, we notice that the matrix is cracked, there are visible scratches on the mould and the transport handle is damaged, it should be stated that it will certainly extend the changeover time and increase production costs. A very important element during the changeover operation is the transport of parts and tools. Matrices, indicators, moulds and other parts needed during the operation should be transported between the storage place and the machine on which they are used.

Transportation of these elements must be carried out during the external changeover operation, in other words they must be delivered to the machine before stopping for the changeover. Tools and parts must be returned to their storage location after the machine has been properly started up and the detail is free from defects and complies with expectations and standards.

Stage 2. In stage 1 of the SMED implementation, we have separated the operations that require turning off the machine from those that can be performed during its operation. However, this is not enough to reduce the internal changeover operations to less than 10 minutes according to Sz. Kubik. During the implementation of SMED methodology the following steps can be distinguished:

- Analysis of the actual functions and goals of all current internal change-over operations.
- Finding ways to replace internal change-over operations with external ones.

Conversion of internal operations into external ones will be facilitated by three practical solutions. These are: prior preparation of operational conditions, standardization of the most important functions and use of intermediate handles according to Sz. Kubik.

The earlier preparation of operations determines the preparation of parts, tools and conditions before starting the internal changeover operations. While the above mentioned elements will be prepared on site, unproductive downtime will be avoided. SMED uses a method called function standardization according to Sz. Kubik. When creating dies, tools and parts, you can avoid waste by standardizing important elements for the set-up time, e.g. screw size. The function standardization is implemented in two stages:

- Analysis of the function during the changeover and determination of which functions should and can be standardized,
- Re-analysing and determining at which points in time you can increase productivity by replacing a small number of parts.

In processes, the conversion of internal to external conversion operations can be done using intermediate handles. Examples of such holders are plates or frames with standard dimensions, which can easily be replaced according to the Sz. Kubik. The grips enable the conversion of the operation as they allow to prepare dies and other elements while the machine is in motion. When one die is used in a running machine, another one is fixed in a special intermediate holder, it is centred and ready to use. When the machine finishes working with the first die, it can be quickly and easily replaced with the No. 2. The machine with the intermediate holders is restarted in just a few minutes.

Stage 3 - In the previous stages the steps of separating the internal and external operations were discussed, and the internal operations were transformed into the operations during operation. The final step of the SMED methodology is to improve all the circumstances during the changeover operation. In this phase all internal and external elements of the changeover will be improved. By implementing the third stage, we will in almost every case lead to the moment when the changeover time is below 10 minutes. Constructive solutions introduced in this stage can be divided into two:

- Improvements in external operations,
- Improvements in internal operations.

The improvement of external operations is connected with further improvement of parts and tools transport and their storage. In the case of smaller tools, blades, dies, chucks and gauges, the issues related to their management according to Sz. Kubik must first be resolved. These items should be properly arranged, kept in the best possible condition so that they are always ready for the next operation. Storage of dies very often causes many problems, especially when there are more of them. An improvement that can be made is the proper marking of their colors and shelf numbers to which they will be assigned. Such marking can also be applied to the above mentioned shelves, thanks to which it will be easier to identify or find them, and the employees will always put them in the right places. At this point it should also be noted that the best improvement is to store the matrices closest to the place where they are used, thanks to which it will be easier to access them. Improving internal operations includes:

- Introducing parallel operations,
- Use of functional terminals,
- Elimination of setting adjustments,
- Mechanization,

Parallel operations allow to divide the changeover between two people, working on both ends of the machine. Involving two people eliminates the need to walk back and forth, and thus reduces the time of the operation, which previously took about 12 minutes, to about 4 minutes, according to Sz. Kubik. When 2 operators work in parallel, activities are carried out much faster and more efficiently, and the key element is mutual communication, thus limiting the same activities and interrupting each other. It is important that before starting to work each of them is trained and knows exactly what activities they have to perform at the moment. In the traditional changeover method, screws are often used to attach the dies to the machine, which significantly slows down work. Very often also during the changeover, the screws are lost falling into the corners of the hall, which forces them to find or fit new ones, taking the valuable time of the employee. In the SMED system, such waste can be eliminated by using a solution called a functional clamp. This term defines the connecting elements, which allow to keep the object in the right position, using the minimum amount of time and effort. The role of such a "functional clamp" can be played by a screw after appropriate modification or a completely different connecting element, which can be easily clamped and released. Functional clamps are very often permanently attached to the machine, so in addition to saving time and energy, it is impossible to lose them or to connect them wrongly. The trial series in a traditional system and the associated adjustments can take up to half the time of the entire changeover. If you manage to eliminate the setting adjustments, the idle time of the machines will be significantly reduced and the size of the trial runs will be significantly reduced, thus the amount of raw material used for production will be saved. The size of the trial runs and the corrections related to the machine start-up will depend on the accuracy of the centring, dimensioning and conditions that will be prepared in the earlier stages of the changeover. Therefore, in order for the elimination of the corrections to be successful and to achieve the desired result, previous operations must be improved and standardized.

Solutions supporting the elimination of setting adjustments:

- Numerical scale and standardization of settings

Operators should rely on fixed numerical values rather than their own intuition when setting up the machine. For this purpose it is helpful to create a step-by-step scale that represents different settings. Using a measuring scale allows you to set the machine with an accuracy of 0.5 mm. Another method of numerical setting is to use gauge blocks or shims to determine the distance between two elements. The used gauge blocks and shims precisely determine a very large range of distances.
- Mark the center lines and reference planes
Clear determination of centerlines and reference planes is an effective method of eliminating later corrections according to Sz. Kubik. Center lines and reference planes in traditional conversion are often not clearly marked. Unfortunately, in practice this means that the operator's intuition and the trial and error method are invariably used to determine the correct tool or workpiece position. Determining the center lines and planes to which reference can be made will cause the size of the test series to be minimized and operators with more or less experience will be able to do the same work with the same efficiency.

The mechanization should be used for fine-tuning and not for making drastic changes according to Sz. Kubik. Mechanization should be the last step that will be considered only after all previous solutions are implemented. This principle should be strictly observed because:

- Using the earlier changes allows to reduce the changeover time from 1.5 h to 7 min. and mechanization can save us about 1 min.
- Mechanization of the operation, which is inefficient, may lead to shortening the set-up time, but it will certainly not bring benefits in the form of improving the process.

To sum up, mechanization should be an element used to tune the production process and not to introduce drastic changes during the process. Mechanization is necessary in case of handling large elements such as: dies, casting and injection moulds. Practical solutions allowing to mechanize operations are:

- Forklift trucks, cranes used for inserting parts into machines.
- Movable supports on which heavy dies are moved.
- Electric motors for distance control.
- Press energy used to move the dies.

Techniques and Methods to Support SMED

The SMED method is a way to reduce machine set-up time by reducing to a minimum the activities necessary for the proper execution of this process and completely eliminating unnecessary movements, steps, activities. Operations are supported by lean manufacturing techniques and methods. These techniques allow the analysis of the current state of affairs to be carried out correctly to show the information about the time of the current changeover method, the activities performed by the operators and the route they have to travel. SMED methods and techniques also allow to discover and see the bottlenecks in the process, develop optimal solutions to improve both the changeover time and new methods, activities and tools according to Sz. Kubik.

PDCA method - this method has different names such as: the Deming circle, the Deming cycle, the Shewhart cycle, the Shewhart cycle. Its beginning is attributed by some to Francis Bacon (1561 - 1626), an English philosopher considered to be a precursor of modern scientific methodology with a major emphasis on experimentation and induction. Bacon was also inscribed in history as one of the founders of the philosophical doctrine of empiricism. One of the main works of Francis Bacon is "Novum Organon" published in 1620, in which he included examples of his reflections, which he called true induction, which he included in the form of tables of presence, absence and degrees. It was a matter of capturing a form of warmth through comparative analysis. The author carries out experiments, analyses and draws conclusions. In the early 20th century, Walter Andrew Shewhart (1891-1967), an American statistician, physicist and engineer, also known as the father of statistical quality control, joined the Western Electric Company's quality engineering group at Hawthorne Works. At that time, industrial quality was underdeveloped, resulting in quality control only of finished products and removal of defective ones. The change took place in May 1924, when Walter Shewhart, PhD in physics, prepared a short memorandum that included a diagram and description of the schematic control card. He distinguished between two types of variations, the first "attributable variable" and the second "accidental cause. The diagram he created was a tool to distinguish between the two variables. Shewhart argued that reducing the production process to a state of statistical control, where only the variation of the case and its control appear, was necessary to improve quality and reduce production waste. Shewhart's second important achievement was to bring production down to statistical control, monitored in three steps: Specification, production, control. He also believed that this three-step process should be repeated after each

full cycle. This is the only way to gain scientific knowledge. The analyst should make a hypothesis, conduct an experiment and test the hypothesis, and repeat the steps after the cycle. A group of engineers working at Hawthorne have conducted experiments to improve quality and production processes. In the 1930s, a major crisis occurred, resulting in group layoffs at Hawthorne and ending the group of engineers at that plant. Shewhart's work has caught the attention of global manufacturers, but has not changed the global approach to production and control. Some thought Shewhart was a talented statistician and theorist, but was unable to pass on his qualitative ideas to production workers. Hawthorne engineers also included William Edwards Deming (1900-1993), an American statistician, who worked with Shewhart for several years, becoming a master of his techniques and methods. Deming himself admitted that his mentor was Shewhart. During the Second World War, Deming supported war production and taught employees the techniques of statistical control of production processes. At that time, war production was extensive and its production management and quality control methods were often used. After the war, he left for Japan, where he took care of the census. Over time, his knowledge and experience helped to rebuild the Japanese economy, which was in regression after World War II. In 1950, Deming gave the first symposium on statistical quality control. This speech was addressed to Japanese managers and top management. Deming's greatest work was the 14 points that concerned management and the PDCA model, which was developed by Shewhart, but refined and distributed by Deming. He called it the Shewharata circle in honor of his mentor, but many people use the name of the Deming circle because it was he who distributed it according to S. Lachowski. As you can see, the PDCA cycle has a long history that has evolved over the years. Backon, Shewhart and Deming have come to the conclusion that the hypothesis needs to be proved by experiments or observations in order to draw appropriate conclusions. The final cause-and-effect cycle of PDCA contains 4 steps that follow each other. Once the cycle is completed, it must be restarted. This means that the fourth part of the cycle does not end the cycle but starts step number one. This is the only way to continue to develop and move on to the next level of continuous improvement in order to eliminate quality defects and eliminate costs and losses, etc. The PDCA cycle starts with the first step P (PLAN/PPLACE). At this initial stage it is necessary to determine what we want to improve, improve or achieve. Do it by identifying and concretizing problems, opportunities or needs. At this stage, we also make analyses of the current state. We study, research and look at the actual production process and make evaluations by verifying available data, process maps, plans and production times, process operations etc. We plan the future state, i.e. what we want to achieve in the future. In order to pass through this stage correctly you will need appropriate techniques and auxiliary tools. These methods include: process mapping, cause and effect analysis, Pareto analysis, or brainstorming. At this point you should also designate a person or group responsible for the implementation of the project and assign appropriate completion dates for each stage. The second stage is D (DO/PRODUCT) At this stage, proposals for changes, improvement plan, processes, operations are implemented in the actual state. All changes, goals and assumptions from the first phase of the PDCA cycle are reflected in reality. In this phase you may encounter problems related to the implementation of the initial plan. Problems may result from unforeseen factors or situations. You can only use a smaller PDCA as a remedy for a specific problem. In this way the shortcomings of the first phase are eliminated. This is also where we start to check whether the attempt to change the plan is working. The important thing when making changes is to be able to solve problems. The employees responsible for the project should be trained and have knowledge of the experiment. The project manager should have leadership skills and supervise subordinates in an appropriate way. His duties include training and conflict resolution. Stage 3 C/S (CHECK/CONTROLL/STUDIES) This is the stage where the results of the conducted changes are compared with the planned assumptions and results of the first stage. It is at this point that we analyze new solutions, processes and changes. It is very important to make reliable and real measurements of the results of the changes. For the measurements you can use the change sheets and control cards. We compare the data and results with the intended objectives, results that were planned. We collect as much data as possible, which will be needed for the next stage. The fourth stage A (ACT/USTAW) Level four ends a single cycle. In this stage we implement changes if the results from the previous stage are satisfactory. We standardize the new process and prepare documentation. If the results are not satisfactory, we draw information from this trial what has not been improved and, if necessary, make corrections to solve the problem. At this stage we have the knowledge that will be used for the new PDCA cycle. Here, with the knowledge, information and experience we start planning from stage one. Please note that the Deming cycle is a loop that has no end. The processes, the effects of the changes made from now on begin to be the real state, the starting point, which should be improved. By finishing the fourth stage you should start PDCA from the beginning, so we plan future results to which changes will be made. In this way we move to the next level of improvement. The PDCA cycle was initially closely linked to the production processes. Later on, it was used in various activities that need to be changed or improved in efficiency. This model is effective because it breaks down the change process into smaller parts so that we are able to go through it step by step by step, gathering information, improving our experience and performing the experience. These changes are implemented gradually, so you can avoid untested changes in processes on a large scale. This can result in increased costs and risk of failure. A simple but effective Deming cycle also has some limitations that need to be taken into account before implementing this model. One of the limitations is the time to implement changes and achieve the intended effects. Urgent or emergency situations may not be dealt with. When introducing PDCA a lot of

knowledge about processes and control system is required. Creative initiative and innovative approach are also very important aspects. The model does not affect human resistance and lack of motivation according to S. Lachowski.
Kaizen method. Kaizen was initiated after World War II in Japan. It was then that Toyota introduced quality wheels into its production process. The group consisted of employees who did the same or approximate work. The meetings of the group were cyclical in nature, during which work related problems were analysed. Once a problem was identified, it was followed by a process of elimination. The introduction of such a method was greatly influenced by American engineers who came to Japan after World War II. Masaaki Imai is considered the father of Kaizen philosophy and in 1986 he published a book entitled "Kaizen. In it he contained all the principles and rules of philosophy. The expression Kaizen comes from two Japanese words "change". (kai) and "for the better" (zen). These words fully convey the message that this philosophy conveys. Kaizen is a way of continuous self-improvement which, although created for business and production processes, can be applied to any area of life. It is a way of engaging employees at all levels of the company's organizational structure, from the ordinary employees to the members of the management board, to improve processes, workstations, information flows, savings, elimination of losses. The improvement takes place gradually eliminating the problems and incompatibilities encountered. It is a continuous and endless process. Kaizen is based on PDCA principles, i.e., planning, execution, checking, operation. However, Kaizen is focused on making small changes at a fast pace. The philosophy is based on two fundamental principles. The first principle is about improvement and change for the better, while the second principle is about an ongoing process. The philosophy gives us 10 tips on how to strive for improvement and perfection according to J. Bicheno;

1) Improve everything and everywhere
2) Do not give in to traditional assumptions and concepts
3 Excuses are not acceptable and cannot be made
4 If something doesn't work properly, correct it
5. improving in small steps is better than looking for the ideal
6. search for information and knowledge from many people
7. apply principle 5 WHY
8 Try, check, approve, implement
9. there is a hidden opportunity in the problems
10. do not stop improving, it is an infinite process

The Major Kaizen method is a branch of Kaizen philosophy. The principle of use is the same. The difference is in the scope of application. Kaizen is oriented towards simple, quick changes. Major Kaizen deals with things that are more complicated to improve and require more time. It is used when the solution to the problem is not known at the start of the project. The basic support tools are: 5W+1H, 4M, 5WHY. The project involves larger teams than in standard kaizenie. The area manager is the project leader and controls the progress of work and verifies the use of appropriate tools and methods. Documentation is prepared in the form of a presentation, a visualization board is placed in the place where the problem occurs, divided into sections. The sections include descriptions and photographs of the work undertaken at each stage and the tools for their implementation. In the column "problem" we deal with defining the problem. Pareto analysis and data stratification should be performed. In individual cases you can use a historical loss monitoring chart. Then it is necessary to show what the loss is and to divide the losses into levels. In the "team" column we place the composition of the team and radar of the employees. To the team it is necessary to appoint persons adequate to the problem specification. It is necessary to know why specific people have been included in this team. The "plan" column is devoted to the team work schedule and deadlines. The action plan is based on the PDCA method, which focuses on determining the beginning and end of the next phase. The next step is to "describe the phenomenon" in which we characterize the problem, describing how the problem occurred, where and when the problem occurred and how it was noticed. The description of the phenomena is supported by the 5W 1H method. In case when the technical problem does not have a description of the phenomenon we use sketches and photographs. Section "system" is based on the description of machines and equipment. Moreover, we place in it a process map and links between processes. In the section "goal setting" we describe measurable goals. When losses are not completely eliminated, we need to know why and to what extent they should be eliminated. It should be based on an indicator, which will be the basis for calculating financial and material losses. We place terms on the timeline. In the "cause analysis" we make an Ishikawa diagram and/or the 5 WHY method for the causes marked on the arms of the Ishikawa diagram. The results of measurements, tests, expert opinions must be based on facts. We clearly state the root cause.

Metda Spaghetti Chart is one of the tools of lean manufacturing. It is used to eliminate or reduce significantly losses in the production process. These include losses caused by overproduction, corrections, overprocessing, overstock, transport, and losses caused by waiting and movement. These losses occur in every production process and should be systematically reduced and eliminated. The spaghetti diagram is a visualisation of movements and flows in the production process. With this method we can analyze both product, document and employee flows. With this tool

you can find out which way an employee goes on the job, how much time it takes, what operations he performs and at what time. It also shows the distances and waiting times. When creating a diagram, it is necessary to pay special attention to the actual process, as it occurs in everyday work, with all its errors, flaws, problems. When creating a diagram, we focus on the real process even if it differs from standards and procedures. We start creating a diagram by drawing or printing the workstation or process. This is a general view of the area that has been selected for analysis. There should be approximate distances between operations, paths, shelves, desktops, tables. On the template prepared in this way we place the first action - the beginning of the process. From this point on, we mark with different colors the direction arrows for next operations, route, stop or wait, transport. Lines should be drawn for each activity and each movement. Attention should be paid to each even the smallest movement, operation, route. The next step is to measure the time for each observed activity, and present the tool needed to perform the operation. After a thorough input of the data on the sheet, we proceed to the process analysis. We draw various variants of changes, improvements. We try to arrange the process in such a way that the operations follow each other as quickly as possible and do not contain unnecessary route and activities. We place the tools necessary to perform the activities as close to the operation as possible, which saves the route the operator has to travel. After the analysis and choosing the best option we test it in the real process. When our new methods have improved the process, we consider them a standard. Spaghetti greyhound at first sight looks like a mess or chaos, it is complicated and twisted, like a spaghetti dish, that is why its name comes from. But in practice it is a help and a very effective method to visualize problems and losses. Thanks to this diagram we can minimize or eliminate them. Among the strengths of Spaghetti Chart can be the identification of inefficiencies in the production process, help in identifying losses. It also helps to improve productivity and reduce overloads. It also reduces employee fatigue by reducing unnecessary movements. Improves safety at the workplace.

The 5 WHY- method, developed by Toyota Motor Corporation, was distributed in the 1970s. Its task is to reveal the original source of the problem and to find a solution to this shortcoming. The problem, which is repeated, generates a waste of time, resources and materials. Such a situation occurs when the cause of the problem has not been properly defined. In such a case, remedies do not eliminate the problem but act prophylactically on its symptoms. Such an action will lead to the problem becoming apparent in the future. The method is often used during the planning stage at PDCA. The method itself involves asking 5 questions about why, starting with the occurrence of the problem. To proceed to 5 WHY, we create a group of employees who know the process or system. However, employees should be from different departments such as production, quality, engineering. Each of the employees will bring their own autonomous point of view on the problem. The next stage of the group's work is to identify the problem, the revealed anomalies should be described in a clear and concise way. Wrong identification of the problem may result in prolongation of the problem solving process. After the problem is identified, a question should be asked why the problem occurred. The answers cannot be based on conjecture or conjecture. Facts and data are the elements that should appear in the answer. After that, we ask the next questions why and get an honest answer. We repeat the process until we discover the essence of the problem. In some cases it is not necessary to ask why 5 times, because the root cause can be found in question 3 or 4. In other cases, you will find the answer in question five or six. Thus, the number of questions depends on the structure of the problem and its symptoms. In case you manage to determine the main cause of the problem, we go to the next step. At this stage you should develop measures and methods of counteracting the essence of the problem. This is done with the question "how? We also repeat this question several times until we get the main solution. The 5 WHY method is a simple method in determining the source problems in each process. The employees who are part of the group do not need special preparation. It forces the group through analytical thinking and deduction to look for the real cause of the problem on their own. When using 5 WHY, attention should be paid to the logic of questions and answers. Failure to comply with this condition can result in mistakes that lead to wrong and inappropriate conclusions being drawn.

The Pareto Method - The Pareto Principle was created by the Italian economist Vilfredo Pareto from his name. During his research, Pareto noted that 80% of the wealth and gratuities in Italy went to 20% of the population living in Italy. Thanks to this observation, which also applies to other aspects of activity, Pareto has created a principle that illustrates the fact that 80% of problems are caused by 20%. In the 1950s, the American management theorist Joseph Juran, who was inspired by the research of Vilfredo Pareto, published a book in which he included the principle and the Pareto Diagram. The principles in question are also called the 80-20 rule, the Pareto or Pareto-Lorenzo Diagram. The diagram in question is a bar chart and a line diagram. The bars show the frequency of problems, costs, defects and where they occur. The bars are arranged in a decreasing way from left to right. The tall bars on the left are much more important than the bars on the right. In this way a visualization is created that helps to define the hierarchy and priorities according to M.Ben-Day and P.M.Charantimath. The bar chart is complemented by a linear chart, which contains the cumulative sums of each category, i.e. percentage shares in relation to the whole problem or phenomenon. Thanks to this visualization you can choose important problems, sources, defects from many or several other trivial ones. This allows you to completely reject or deal with factors having a marginal impact on the examined phenomenon at a later time. In order to make a Pareto diagram you need to perform a number of actions, starting from listing the action, cause or source and their frequency and placing

them in a table. Categories should be presented from the largest, left side, to the smallest, right side. Then you need to calculate the sum of all the categories that are in the table.

The next step is to calculate the total percentage presented by each cause, source or action and add this value to the table. The next step in creating the Pareto diagram is to put the causes on the x-axis and the cumulative percentage on the y-axis. The cumulative percentages from different sources and categories, marked with respect to the y-axis, should be combined by drawing a cumulative curve. On the same graph, place the causes on the x-axis and the percentage frequency on the y-axis using a bar graph. When the diagram is created, it is time for its analysis. Search for the breakpoint on the cumulative percentages chart that separates the more significant problems, costs, defects or places of their occurrence from the trivial ones. A significant change in the slope of the chart will help to determine this point. This point indicates where the analysis should be done in order to eliminate it as a priority [25]. The Pareto diagram is a tool used for total quality control and Six Sigma. It allows you to highlight the main critical factors. It determines which 20% of the sources caused 80% of the defects, errors or costs incurred in the production process. It indicates which categories or factors should be corrected, corrected or improved. Moreover, it provides information which categories are necessary to solve first. This method can also be used when checking changes already made to find out whether the improvement has had the intended effect.

Conclusions

1 Benefits of the SMED principle for the enterprise:

- Increased flexibility - companies can adapt to changing customer needs without spending on additional inventory;
- Faster deliveries - reducing the size of production batches reduces the duration of the production cycle and thus the lead time and delivery;
- higher quality - reducing the size of stocks means reducing the number of shortages resulting from the storage of the product or semi-finished product; at the same time, proper preparation and organization of equipment settings allows for the reduction of shortages resulting from setting errors and eliminates the need for test series for a new product;
- increased productivity - shorter set-up times reduce machine downtime, which means a higher equipment productivity factor.

Benefits of the SMED principle for the employee:

- Increased changeover safety - by simplifying tool changeover rules, with less physical effort or risk of injury;
- Facilitates production and increases safety - Reducing material inventory means less clutter at the workplace, making production easier and safer;
- workstation arrangement - rearming is standardized and simplified, which means fewer tool changes and therefore fewer things at the workstation.

The changeover time for internal operations has been reduced from 120 minutes to 9 minutes, i.e. by 89.2%. For the above results, it is worth mentioning the fact of gaining 56 minutes or 46%. This is related to the introduction of 5S rules and changeover standard for individual operations at the workstation, which has contributed to eliminating the need for unnecessary search for tools as well as unnecessary movement of operators. The introduction of 5S rules was only connected with cleaning up workstations with unnecessary materials and tools and assigning the necessary equipment to a fixed place.

The presented research analysis shows the validity of the method by achieving the goal of 15 minutes. It should be remembered that after introducing all the improvements in the production process, the level of 9 minutes will be reached. After the first stage of the project implementation, the machine time was reduced by 46%, with the amount spent on investments equal to 0 PLN. The introduced changes were associated with the transfer of a significant amount of internal works to external ones.

Modern Tools and Techniques of Employee Training in The Era of Remote Work and Education

Joanna LISOK
Silesian University of Technology, Gliwice, Poland
Joanna.Lisok@polsl.pl

Abstract

In the twenty-first century a manager should be characterized by excellent performance, experience, supported by knowledge and knowledge of modern information technologies. Virtual reality (VR) is a three-dimensional image that was created by computer. VR can represent different objects, objects and even whole events. Depending on the concept, virtual reality is based both on elements of the real world and completely fictional. The easiest way to say it is to say that this term simply means a virtual imitation of reality. VR is the ideal solution in cases where the implementation could actually be extremely expensive or particularly dangerous. So now it can be used, for example, for various types of training of future pilots, or conducting surgery classes in medical studies. In such situations, virtual reality allows you to gain a real and valuable experience in a virtual and maximum safe world. In most cases it is also the most economical solution. More and more often in the field of logistics or management engineering effective methods of training management and employees are sought.
The young generation born in the era of modern IT solutions is more willing to undertake training based on modern solutions. One of them is the application of so-called augmented reality (AR), which combines the real world with the virtual world. The AR usually uses the image from a camera and then overlays the computer generated 3D elements on it. Nowadays, AR is used, similarly to VR, in aviation, medicine or automotive, as well as for marketing purposes, e.g. in applications for smartphones, which allow users to virtually change the color of the walls, or to place furniture from a given store in the room. There is no doubt that virtual reality is a technology that will be further developed - both in terms of entertainment and applications in various industries.
The ability to combine modern technologies and proven Lean management methods is undoubtedly a desirable feature among managers. In the article, the author will characterize the methodology of effective training of employees, with an indication of the group of society that shows particular predispositions for effective education.

Keywords: Lean, Virtual reality (VR), augmented reality (AR), IT.

VR Technology

In the XXI century there has been a development of information technologies and devices for visualization and tracking of user activities by observing their movements and location in a virtual environment. With the increasing use of modern visualization software dedicated not only to personal computers but also to smartphones, and due to the rapid development of computer technology to generate real-time images, universities are also looking for innovative solutions to reach students through the senses: sight, hearing and touch. The diversity of student learning strategies must be taken into account, so the use of Virtual reality (VR) in education is a response to the specifics of modern times and the expectations of future employers. As a creative creator, the student consciously seeks modern techniques of obtaining information, thanks to which he or she can educate many valuable skills, such as: independence in planning and performing tasks and cooperation in a team. In this context it is necessary to acquaint students with soft competences, but also with modern technologies supporting elements of teamwork.

Digitization has become a source of communication, information and knowledge acquisition, and in view of this reality, the traditional methods of educating students require significant improvement in terms of the form of communication, which is quite a challenge for university managers. To follow new trends in education, new technical solutions, such as virtual reality, are willingly introduced. The SAMR model developed by Dr. Ruben Puentedur can help in understanding the place and importance of new technologies in education. At this point it should be noted that the role of a lecturer should remain very important and boil down primarily to the position of a mentor or professional expert in knowledge and effective learning. The key to the optimal use of the available technology dedicated to educational purposes is a much greater knowledge of the lecturer as well as his experience in the tools he uses when working with students. The SAMR model describes four levels of introducing new

Cite this Article as: Joanna LISOK " Modern Tools and Techniques of Employee Training in The Era of Remote Work and Education" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

educational technologies in didactics and allows to better understand how we use modern tools. SAMR stands for the first letters of the four words in English:

- Substitution,
- Augmentation (enlargement, extension),
- Modification (modification),
- Redefinition.

On the one hand, this model describes different ways of using technology in teaching, but on the other hand, it also shows how the most constructive change in the teaching process occurs. In the 1930s, thanks to Pygmalion - Stanley G. Weinbaum's glasses, the user could experience a fictional world through holography, smell, taste and touch. In hindsight, the experience Weinbaum described as a visionary of the development of technology, for those who wore glasses, allows to reproduce the experience of virtual reality. In the post-war period new possibilities were created, which focused mainly on experiences with the image of illusion. In the mid-fifties, another creator, Morton Heilig, developed Sensorama, the so-called analog virtual reality. The invention, patented in 1962, was a theater cabinet that would stimulate all the senses, not just sight and sound. The Sensorama included stereo speakers, a stereoscopic 3D display, fans, odor generators, and a chair that could be put into vibrations. Heilig, whose next invention was a telescopic mask (patented in 1960), was also the first example of a head-mounted display (HMD), with no tracking capability. The headset allowed to provide stereoscopic 3D vision and wide vision with stereo sound. In 1961, engineers at Philco Corporation (Comeau & Bryan) developed the first HMD, which is known today as Headsight. This device gave the ability to combine a video screen for each eye with a magnetic motion tracking system that was connected to a closed camera.

The system produced by Comeau and Bryan engineers was not a virtual reality due to the lack of computer simulation, but was definitely the first step in the evolution of VR HMD. The head movements, on the other hand, allowed the remote camera to be moved, thus allowing the user to look at the surrounding environment naturally. In the following years Ivan Sutherland, introduced an impression device as a 3D image. Three-dimensional images are created using stereoscopic and non-stereoscopic techniques, among them the most advanced is the hologram technique, currently used in cinemas and on mobile video devices. In 1969, Myron Kruegere, creator of computers with virtual reality, developed a series of experiences that he called "artificial reality". Projects such as: glowflow, metaplay and psychic space) is a phenomenon of immersion, which has found its fullest artistic expression in the field of video installation and interactive cinema. This technology enabled communication with each other in a friendly environment generated by the computer, regardless of the distance between the listeners. The term Virtual Reality (VR) was introduced in 1986 by an intellectual, Jaron Lanier, who defines VR as a technology that provides stimulation to the senses, causing the illusion of presence in digitally created spaces. Over the next few years, software companies have been working onThe games have been outdoing each other all the time in the inventiveness of their products. And so one of those that conquered the market were games on the Nintendo Virtual Boy console (initially known as VR-32). The 3D gaming console, VR-32, was announced the first portable console that can display real 3D graphics. In 1999. Witchowski's film - Matrix gave direction to the development of virtual reality, as the film showed characters who live in a simulated world. It should also be noted that although some earlier films, such as Throne in 1982 and Man in Space in 1992, began to present themselves in virtual reality, the company's "Matrix" had a major impact on culture and promoted the topic of simulation to the mainstream. In the era of globalization, access to smartphones has given new opportunities to individual customers, who can now use games and other mobile applications with virtually no major limitations. It is worth noting that a company such as Google has released temporary virtual real products (Google Cardboard), or an equal type of devices supporting basic human activities, as exemplified by a DIY headset, for calling and giving first aid using smartphones. A real specialist in novelties is Samsung, which has taken up this concept and is developing further with new products. Currently we are observing the development of VR, which has taken place since 2012, thanks to the goglomeration of virtual reality, e.g. the "VR": Oculus Rift, invented by Palmer Luckey, a teenager who used the existing solutions, adding some of his own ideas.

For many years in the field of cooperation between psychologists and engineers, the research work included, among others, video games, as a model of internally motivated science. Within an effective learning environment based on educational games, the student works in such a way as to achieve a certain goal, taking various challenges along the way, making key decisions with their consequences. Techniques such as control mechanisms, challenges, curiosity, cooperation or rivalry are a basic element of motivation theory. The basis for understanding the application of the VR technique in education is to become acquainted with the systems thanks to which a person can see at least on the display of virtual glasses so-called goggles (headset) the simulated environment, while at the same time being tracked by a device that imitates its movements and reflects them in virtual reality, which is something like moving in a created world. Because in order to immerse yourself in the virtual world from a technical point of view, you need the so-called game engine, which deals with the interaction of game elements. The engine can have built-in

modules for graphics, inputs, networks, or artificial intelligence (AI). It is most often performed using an object-oriented paradigm, in which programs are defined by means of objects - elements connecting the state described by means of data, most often called fields and behaviour, so called procedures and methods. New market. The technology is very resilient and dynamic, while following new trends. As a result, game engine manufacturers outdo each other in the ingenuity of new software applications. At present, on the global market of new technologies, two engines, which are products of leading brands, deserve attention. An example of such an engine is Unreal Engine created by Epic Games, whose main features are simulation of physics, possibility of animation, artificial intelligence, and the ability to add various algorithms. The second engine, in turn, which is used on a large scale, is Unity 3D, a product of the global Unity Technology platform, which is very popular in the world as an integrated environment for creating 3D and 2D computer games or other interactive materials such as visualizations or animations. This system is very often used by individual users as it allows to create applications also for web browsers, as well as personal computers, video game consoles or mobile devices. Such an action indicates that it can be said that new technologies are now available for every average user. On the basis of the latest statistics provided by the Virtual Reality Brief portal, it appears that almost 85% of educators have access to virtual reality devices, but they are used by only about 8% of the audience. Despite the fact that virtual reality technologies are entering the world of science very dynamically, there is still a concern about involving more experienced lecturers in the use of new teaching techniques. Perhaps the reason for such a belaying approach should be found in the ignorance of the advantages of VR or in the lack of an idea for implementing such scientific aids. However, the experts note the need to introduce virtual reality into education, as it allows to provide experiences that are directly compatible with the material given during lectures, using VR, which in their opinion is even advisable. Researchers involved in VR education should consider the benefits of developing experiences that reflect and support the existing curriculum, especially in cases where it is not possible to implement many experiences in the actual conditions of the university.

Technologies extending the current reality or allowing to create new realities, or combining them, are already ready, and the main potential of education based on the augmented reality technique lies in the VR method - i.e. the superimposition of information generated by the computer on real objects, as well as work on virtual objects, in the real environment. Education in combination with VR makes it possible to create artificial laboratories where research can be carried out - both amateur and professional for learning purposes.

The most obvious application of VR, for example: for the aviation industry, is the training of cabin crew. One aviation organization uses VR to support the training not only of pilots, but also of flight attendants and ground crews. Publicly available popular flight simulators have been used for years and can also be used at home. In professional space, companies such as Boeing have created simulators, based on the construction of a real airplane cockpit, replacing windows with film screens. It should be remembered, however, that this is only a training tool, because this type of simulators are expensive and unwieldy. Today, companies using VR technology aim to modernize the simulators. Various types of interactive simulations deserve attention, which have been operating for years on both the home and professional market. The combination of e.g., Oculus Rift DK2 type head displays, precise gesture sensor and Leap Motion controllers with D-BOX seats and their own landscape rendering engine make the new BIS simulator possible to experience virtually stunning sensations that exactly mimic every aspect of the flight, from control to switching on and off the engines with sound effects, as well as vibrations during turbulence. Future Visual from VR at the symposium of the International Air Transport Association (IATA), presented a concept for training airline personnel in external aircraft inspection. Using the Oculus Rift head display, participants could go through the whole process of walking on the aircraft before the flight, checking it for malfunctions or problems, and then locating the security equipment inside the aircraft. During the E3 fair in 2019.

Microsoft has announced that the new Flight Simulator is already advanced in production. Microsoft Flight Simulator is the next instalment of the valued flight simulator, which was launched on the market in 2020, as the team operating under the wings of the American giant completed the latest instalment of the Microsoft Flight Simulator series. It will give the opportunity to sit behind the wheel of a variety of aircraft, both larger and smaller, both during the day and night and in favourable or unfavourable weather conditions. The latest instalment of the popular simulation series will allow you to visit various corners of the planet, which have been mapped with great attention to detail, which was achieved, among others, thanks to satellite images. Microsoft producer informs that Microsoft Flight Simulator will allow to create and upload modifications, which in turn will satisfy both old and completely new fans of this series. To sum up, virtual reality is more and more appreciated in the scientific community, because every area of science, raises issues that are worth exploring, even tangibly. Thanks to the new technology, students can experience, among other things: remote places that would be too expensive, e.g.: in standard field trips. For example, thanks to VR, students can take part in a virtual trip to the airport to visit the airport infrastructure and learn about the organization of work at the airport. VR gives endless opportunities to move to places that are usually inaccessible such as space. There is also evidence that the experience of VR is very different from other learning techniques because it causes an emotional connection between the student and the

subject discussed during classes. Experts also suggest that information provided by VR is more easily absorbed and stored by the human brain. So far, virtual reality techniques have been known to be used in the military and medicine on a large scale. Nowadays their value has been appreciated both in safety, ergonomics and even mining. New technologies are used for various types of simulations and training of personnel in case of emergency situations. VR training is especially useful when training in natural conditions can endanger health or life. One of the proposals of the cabin manufacturer in the UK EDM are virtual reality headphones (VR) used in cabin crew training to meet the growing demand from airlines for modern technology. The headsets can be used in conjunction with existing EDM aircraft fuselage models, and the entire EDM range also includes replicas of aircraft doors to instruct stewardesses on how to open them in an emergency as well as in normal use. Crew training using the VR simulator has proven to improve memory and concentration, while simplifying complex training scenarios. VR training offers a pleasant way to learn, which allows for greater involvement and understanding during the training, taking into account different learning styles and skills.

3D Scanning

The author of the article will talk about 3D scanning on the example of a project carried out for the Police in the field of documenting the place of the event. The main part of the forensic event site inventory is its visual inspection. By following the forensic techniques, they allow to extract evidence, secure traces and identify the perpetrators of the event. These visual inspections are sometimes crucial for the whole procedure, as they allow for an accurate reconstruction of events using appropriate tools. A breakthrough in forensic technology is the possibility of using laser scanning technology during the inspection of the site of the event. Previously, this technology was used mainly in the geodesic, construction or reverse engineering industries. The main advantage of ground-based laser scanning of the event site is its accuracy. Depending on the complexity of the surveyed area, the number of sites to be scanned increases. The selection of this number of stations results from the necessity to eliminate the so-called dead areas, i.e. those places which cannot be covered by the laser. As a result of establishing the reference system and connecting the scan-scanning stations with each other, we usually obtain a point cloud of several million. This cloud, which is a combination of the components of the laser scanning files, reflects the area under analysis and is also an input image for further processing. Measurements, spatial analyses and various transformations can be performed directly in the native software attached to our scanner as well as in dedicated software available on the market. Dedicated software gives forensic scientist more possibilities for detailed analysis, because it has built-in functions and algorithms used in the reconstruction of events. Completing the selection of evidence based on the point cloud is the ability to create diagrams and site plans and simulations, which are a form of documentation of the performed activities. The laser scans used in the work were made during the inspection of the forensic event sites using the following scanners. The following software was used during the research and a number of operations on the laser scanners:

- Z+F LaserControl,
- VXElements,
- Maptek I-Site Forensic,
- SolidWorks,
- IronCAD,
- DXF online file browser,
- Adobe Acrobat Reader DC.

The digitalization process consists in converting a physical object into a digital object (reverse engineering), ready for further processing. The initial effect of this process is a point cloud, on the basis of which we can build first a surface model of the area under study and then a solid model. Laser scanning is one of the most modern and dynamically developing technologies used in practice today. The 3D scanners used in the process of laser scanning allow to quickly obtain detailed information on the topology of the environment and the characteristics of objects thanks to remote sensing technology. On the basis of this information, it is possible to map the real object in the form of its digital equivalent. It should be mentioned here that the digital model is created while maintaining the actual dimensions of the examined element. Laser scanning in relation to forensic examination is particularly important due to its accuracy and versatility. A very important aspect is the fact that the scanning is carried out using a contactless method, which is of great importance in forensic science due to securing evidence of crime. By taking measurements from several positions we are able to obtain an almost ideal reflection of the place of the incident. On the basis of a precisely performed scan we are able to easily determine, among other things, the braking distance of the vehicle, the degree of surface deformation, shoe imprint and other key aspects relevant to the evidence. An inseparable element of the scanning system right next to the 3D scanner itself is the control unit in the form of a computer. The scanner is connected to this unit with USB and VGA cables. The scanner is controlled by the software installed on the control computer. This software usually requires considerable computing power from the central unit. For research purposes, a computer with the following high parameters in terms of graphics

card, memory, and high-speed suction disk was used. A "strong" central unit is an essential element in the process of processing digital images resulting from digitalization. Laser scanning gives us almost unlimited possibilities for 3D visualization of the forensic inspection site. Computer programs adapted to work with scans process obtained digital images from single point registrations. The number of processed scans depends on the examined place of event. Depending on the area to be visualized and the range of the scanner, it is necessary to select an appropriate number of scan positions. In practice, usually this number oscillates around a dozen or so scan sites. After combining the scans from individual stations we get a 3D model of the entire room where the crime took place. The three-dimensional model is fully mobile, which means that it can be freely rotated, scaled, browsed, divided into batches and highlighted.

An important role in processing the resulting scan files is played by the method of combining them into one whole. Measurements taken from several scan locations should be recorded in one whole in order to create reliable documentation from forensic inspection sites. It is essential to have a model of scanner orientation in space. The Maptek environment allows the user to view the scanner orientation parameters recorded during the process of terrestrial laser scanning. By using the available settings, the user is able to accurately record the position of the scanner in relation to the individual steps of the scanned area. When registering the position of the scanner, the user is forced to provide the spatial coordinates of its location. Using the preview settings offered by the Maptek environment, the user only needs to enter a few numbers representing the scanner's location in space and its angular range. The software automatically downloads information about the 3D scanner model used. Depending on the number of scan locations of the inspection area, the user is forced to register the same number of component scans. Using the available configuration of the scanner settings, this process is not very cumbersome but only time-consuming. If all the component scans are registered correctly, the user should create a complete scan of the entire area. In order to do so, he has to register the global component scans. Figure below shows the global registration configuration window for the scans. The user specifies which component scans are to be merged into one whole. He also specifies the method of their rotation and displacement. It is possible to indicate which of the component scans will be the reference point for the rest of the component scans. The user can use a built-in algorithm to optimize the recording of scans. In case of choosing the intelligent filtering option, the algorithm omits points that may hinder more accurate registration. On the other hand, if the intelligent sampling option is selected, the algorithm selects fewer, more strategic points for faster recording of scans. However, the use of this procedure worsens the degree of accuracy of matching the component scans into one whole. Maptek environment has a built-in library of markers used to describe traces found at the crime scene (victim models, reference points, descriptive plaques, text fields, etc.). The illustration below shows a group of holes in the wall resulting from a gunshot with marked flight trajectories.

A number of operations performed in the Maptek environment and conversions to data obtained in the process of ground laser scanning, such as:

- geometric calculations and CAD capabilities,
- creating animations, reports, plans and diagrams,
- Intelligent linking and filtration of measurement data,
- analysis of blood splash trajectory,
- analysis of the bullet's trajectory,
- detection of surface changes,
- analysis of the bombing,

show that users using Maptek software can process measurement data in many ways.
A series of actions taken and research in the scope of possibilities and functionalities offered by the Maptek software allow to clearly state that the research hypothesis is correct. All actions taken in the work prove that Maptek environment allows the user to process the measurement data from the places where the event was inspected in such a way as to adjust it for the needs of the report from the place respected by authorities and court experts.

Automation of Information Flow

Knowing what is happening on the production floor and where is happening is essential to maintain continuity of production - especially when it comes to failures and malfunctions. The person in charge of maintenance in a given area must have current access to such information so that he or she can react quickly and plan to counteract the threats. Let's take a look at what this looks like in the Profesal Maintenance system, where it has been solved on the basis of the so-called "resource manager". The person assigned in the system with this role, as responsible for the machine or other object, gets an automatic notification in case of a failure or malfunction, by e-mail or SMS. The content includes information defined in the notification scenario, such as the cause of the failure, its priority,

description, and attached files. All persons with access to the system have access to information about the person who accepted the order, with whom they cooperated during repairs and how long it took. An interesting use of the system is one of the clients from the real estate industry. FM Solutions provides comprehensive technical services for large-area properties throughout Poland. Its aim is to constantly improve and respond to the needs of its clients and continuously optimize processes in order to provide even better services to its clients. Facility managers and a team of specialized technicians see clients from the complexes to which they are assigned as a supervisor. This solution significantly affects the timeliness and quality of services, raising them to an even higher level. In addition, they receive notifications with the necessary information, which minimizes the response time to new faults. If the system is integrated with SCADA or MES software, the application created in them is automatically sent to the system. Here, data exchange takes place much faster than in the case of traditional request creation, but it lacks a description of the situation created according to employee analysis. Such automation of information flow is close to the idea of Industry 4.0. and on its basis we can predict how in the near future service robots, having information from other systems, will be able to send each other information on servicing via Internet Things. For example, there may be an option to automatically send tools necessary for repair, via mobile robots, to a designated employee.

Conclusions

The use of newer and newer solutions to visualize processes, places and events is a real challenge in the 21st century, due to the many different applications and tools introduced to the market practically every day. A future-oriented engineer is one for whom operating modern tools is not a problem.

Abstract

The article deals with the planning and evaluation of the functioning of the maritime search and rescue system. Based on emergency flight reports collected over the 25-year period of the system's operation and numerical simulations, an analysis of the system's effectiveness was carried out. The analysis of experiences indicates the need to modernize the system due to the long flight times of rescue units and the large uneven distribution of arrival times in the area. With the use of mathematical modelling and programming tools, a number of simulations were carried out to reflect the actual rescue operations. The following criteria were adopted for the evaluation: time to the rescue point, flight speed taking into account wind, available operational time, length of the search path and fuel supply. The results indicate that virtual system simulations can be very useful in the processes of planning, risk assessment, cost analysis and planning logistic activities.

Keywords: Search And Rescue (SAR), planning.

Introduction

Provision of activities aimed at searching and saving life at sea and combating threats and pollution of the marine environment results from international conventions to which the Republic of Poland is a party: the International Convention on Sea Search and Rescue (SAR Convention - search and rescue) and the Convention on the Protection of the Marine Environment the Baltic Sea area (Helsinki Convention). The Polish Maritime Search and Rescue Service SAR was established on January 1, 2002. The Republic of Poland has accepted the obligation to ensure the operation of 24-hour air and sea service and SAR coordination in its territory, territorial waters and in the open sea. A search and rescue region is an area of the sea adjacent to the coast of a state, in a body of water to which it has committed itself to fully coordinate its search and rescue operations. Assistance in this area should be provided to any person in distress at sea, regardless of their nationality, status or the circumstances in which they were found. Each region of responsibility for search and rescue is created by an agreement concluded between states. The region of responsibility for search and rescue at sea in the Republic of Poland is limited by a line passing through the following points (Fig. 1):

a) a point with coordinates: φ = 53° 55′ 45.45″ N λ = 014° 13′ 40.78″ E,
b) point with coordinates: φ = 54° 55′ 00″ N λ = 014° 22′ 00″ E,
c) part of a circle with a radius of 16 NM deletion from Ronne airport on Bornholm,
d) point with coordinates: φ = 54° 55′ 00″ N λ = 015° 08′ 11″ E,
e) a point with coordinates: φ = 54° 55′ 00″ N λ = 015° 52′ 00″ E,
f) point with coordinates: φ = 55° 50′ 45″ N λ = 017° 33′ 15″ E,
g) point with coordinates: φ = 54° 27′ 28.63″ N λ = 019° 38′ 30.96″ E.

Fig. 1: The Polish zone of maritime search and rescue responsibility in the Baltic Sea (DZ. U. 1991)

The basic tool that secures the functioning of the SAR system in the Polish area of responsibility is a helicopter. Until recently, the following helicopters were used in Polish aviation for sea rescue: Mi14PŁ/PS, Mi-8MTW-1/Mi-17, PZL W-3RM Anakonda and Mi-2. Currently, only the Mi14PŁ / PSiW-3RM Anakonda helicopters are available to rescue services. M-28 Skytruck planes are also used, however, it is the helicopters that determine the effectiveness of rescue operations. There are plans to purchase modern equipment that will enable the effective functioning of the sea rescue system.

Taking into account the conditions of the functioning of the Polish responsibility zone in the Baltic Sea and the technical equipment of units participating in rescue operations, an important issue is the planning process of individual rescue operations as well as the aspect of the location of base stations where helicopters are stationed.The aim of the article is to present the issues of the location of base stations in the Polish SAR zone of responsibility and the issues of planning rescue operations.

Literature Analysis

In the article (Barbarosoğlu et al., 2002) the authors present a mathematical model of mission planning for a helicopter fleet during humanitarian aid operations during various types of disasters. The decisions inherent in the problem are hierarchically broken down into two sub-problems where tactical decisions are made at the highest level and routing and loading decisions are made at the basic level. Consistency between distributed problems is achieved through an iterative coordination procedure that brings the expected information from the baseline to improve decisions at the highest level. The existence of conflicting multiple goals in this hierarchical structure requires the development of a multi-criteria analysis, and an interactive procedure for assessing the preferences of alternative undominant solutions has been developed with the top decision maker.

The similarities of the presented model to the Search and Rescue System are as follows:

- the problem concerns the deployed base stations (warehouses),
- the location of the destination is non-deterministic and unknown beforehand,
- getting medicines from the warehouse to the first aid point is a similar transport issue,
- there is also the transport of injured persons to health care facilities, where the time of operation is the most important.

The mobilization of logistics resources within a mission includes both tactical and operational decisions, which can be briefly defined as follows:

1. determining the fleet composition, taking into account the operational parameters of the helicopters,
2. assignment of pilots according to training for a given helicopter type and day and night flight loads,
3. determination for one helicopter, the number of flights to the destination,

4. determining optimal flight plans, with partial satisfaction of the demand (many helicopters supply a single point),
5. plans for loading / unloading, delivery, handling and rescue of each helicopter during each route,
6. refuelling and airworthiness renewal planning.

The mathematical decision model at the tactical level concerns decisions 1, 2 and 3, it is in fact a model of integer mathematical programming whose criterion function is in the form (Barbarosoğlu et al., 2002):

$$\text{Min} \qquad Z_1 = \sum_i \sum_j \sum_k w_{ik} R_{ijk} + \sum_i \sum_j \sum_k \sum_m \sum_{q \in P_k} v_q^{ikm} Z_q^{ijkm} \qquad (1)$$

where:
w_{ik} is the cost of the assignment of a *k*-type helicopter from home base and base of operations, R_{ijk} is the cost of the assignment of a *k*-type helicopter from home base and base of operations, v_q^{ikm} is the cost of assigning pilot *q* on duty at base *m* to a helicopter type *k* from home base , Z_q^{ijkm} binary decision variable indicating that pilot *q* on service at base *m* is assigned to helicopter *j* of type *k* located at home base.

The Z_1 function is a function that minimizes the cost of selecting different helicopters and assigning crews to them to complete the mission.

The article (Azofra et al., 2007) presents a tool for determining the objective location of rescue resources in the study area. At the stage of building the tool, the authors took into account such factors as: incident characteristics (e.g. type of vessel, scale of damage to the vessel), type of incident, location of helicopters, tugs, patrol boats together with parameters describing their operation potential (e.g. range of operation) and Cost-effectiveness. An attempt was made to build two variants of models, i.e. an individual model in which the criterion function depends on individual rescue operations and a zone model in which each call is aggregated to the position of a super incident, and the criterion function is a function of the distance between the starting base and the incident site. The authors indicate that the developed tool makes it possible to identify an object-oriented solution that is independent of the interregional policy in a given country. Furthermore, they emphasize that further research should be directed towards predicting the occurrence of incidents requiring the intervention of search and rescue services.

In turn, in the work (Afshartous et al., 2009) the authors referred to the problem of the location of US Coast Guard air bases, from which rescue units set off for individual calls. A solution was determined that would be resistant to the uncertainty of the location of rescue operations. The approach of integer linear optimization was applied together with simulation of discrete phenomena based on statistics based on real data. A model of spatial statistics was developed, which on the basis of the available real data from rescue operations creates a measure of the statistical intensity of rescue operations.

In the article (Wagner and Radovilsky, 2012), the authors presented an integer programming model that optimally assigns rescue resources to databases. On the basis of the obtained results, it is possible to recommend changes that will contribute to the reduction of unnecessary supplies of rescue units in some bases and supplementing them in other bases. In addition, in crisis situations, the model takes into account the possibility of servicing the demand in the base by the rescue unit from the neighbouring base.

Razi and Karatas (2016) presented a multi-criteria optimization model for the location of search and rescue resources, in which the input data are rescue operations recorded by the Turkish SAR service. The authors point out that the activities of search and rescue services should be well planned, coordinated and optimized due to the aspect that time efficiency determines life and death. They postulate that a well-developed SAR service plan is one in which the number of rescue units has been appropriately and sufficiently assigned to incidents, there are optimal response times, low operating costs, a balanced distribution of loads between individual rescue units, and reasonable implementation of business and technical rules.

In the article (Wagner and Radovilsky, 2012), the authors presented an integer programming model that optimally assigns rescue resources to databases. On the basis of the obtained results, it is possible to recommend changes that will contribute to the reduction of unnecessary supplies of rescue units in some bases and supplementing them in other bases. In addition, in crisis situations, the model takes into account the possibility of servicing the demand in the base by the rescue unit from the neighbouring base.

Razi and Karatas (2016) presented a multi-criteria optimization model for the location of search and rescue resources, in which the input data are rescue operations recorded by the Turkish SAR service. The authors point out that the activities of search and rescue services should be well planned, coordinated and optimized due to the aspect that time efficiency determines life and death. They postulate that a well-developed SAR service plan is one in

which the number of rescue units has been appropriately and sufficiently assigned to incidents, there are optimal response times, low operating costs, a balanced distribution of loads between individual rescue units, and reasonable implementation of business and technical rules. This model is based on official maritime preparedness guidelines and can be used to evaluate various contingency system designs with regard to the number, capacity and location of search and rescue helicopters by modelling the extent of the area under consideration (for future research it may be interesting to took design thinking tools into consideration, Kostrzewski, 2018). The model uses environmental data. It contains a number of stochastic parameters that show a complex system of dependencies and interdependencies between the locations of base stations and incidents. As a result, a contour map is generated to visualize the rescue capability. The case study presented in the paper concerns the Barents Sea, which is characterized by long distances and difficult environmental conditions. It shows possible solutions of the crisis response system in this area. The model is based on the determination of the capacity matrix *C*, which is the number of people that can be taken from the sea by a rescue helicopter in time t^{max}, each C_{txy} element of this matrix is determined from the relationship (Razi and Karatas, 2016):

$$C_{txy} = \sum_{r=1}^{|R|} \frac{(t^{max} - t^{mob} - A_{rtxy})E_r}{P_{txy}} \tag{2}$$

where:
$r \in R$ is the *r*-th helicopter belonging to the set of all rescue helicopters assigned to the bases from which it is possible to reach the point *(x, y)*,t^{max} is the critical time of a man in a protective suit at sea, t^{mob} is the time to put the helicopter on standby, A_{rtxy} is the flight time matrix of the *r*-th helicopter in the *t*-th time period to points *(x, y)*,E_r is a modelled coefficient of cooperation effectiveness of many rescue units in one place of the operation (the more helicopters, the smaller their share in increasing the rescue capacity), P_{txy} is the calculated time needed to pick up one person from the sea in the *t*-th time period at the point *(x, y)*.

In the paper (Karatas et al., 2017), the authors presented a hybrid model of resource allocation of the SAR service, which includes an integer programming model, a simulation model and a rule-based algorithm. For example, the following input data were used in the simulation model, i.e. the distribution of the probability density of rescue actions (based on historical data), weather conditions, helicopter failures, the distribution of base stations and the helicopters stationed in them.

Akbari, Eiselt and Pelot (2018) conducted a multi-criteria analysis of the location of SAR resources in Canada. The activities were based on the service-customer structure, which is the same as the location of fire stations, the location of medical facilities or the location of ambulance stations. The following assumptions were made in the research process:

- the average speed used to calculate the SAR units journey time is equal to its cruising speed taken from the technical specifications,
- the access time is the same as the travel time, where the time of the survivor's taking operation is omitted in the model,
- environmental influences, e.g. wind force, sea state, visibility are not taken into account,
- time losses on coordination and planning of the action are not taken into account,
- the maximum admissible access time in primary and secondary coverage is six hours,
- the available units capable of responding to the call belong to the set of units assigned to the fleet.

Model of the SAR system in the Polish zone of responsibility

Identification of elements of the ***AR*** rescue action model:
- organization of a rescue flight with specification of the purpose of the flight, the level of readiness of the rescue operation, weather conditions (hydro meteorological),
- determination and indication of helicopter type used for the action, taking into account its operational capabilities (number of places on board, flight duration),
- helicopter crew with special regard to the level of training (daily, night, IFR, VFR flights), crew composition (presence of a doctor, lifeguard),
- implementation of the task, taking into account the readiness of the helicopter, the crew, the starting place for the action, the course of the action (searching for a person or persons, object), the costs of the action,
- logistics protection of the rescue operation.

The individual elements of the model are marked with individual symbols and the model of the ***AR*** rescue action is presented in the form of an ordered five, i.e.:

$$\boldsymbol{AR} = \langle \boldsymbol{OL}, \boldsymbol{ST}, \boldsymbol{ZS}, \boldsymbol{RZ}, \boldsymbol{ZLA} \rangle \quad (3)$$

where:
$\boldsymbol{OL}$ – organization of the rescue flight,
$\boldsymbol{ST}$ – means of transport (helicopters),
$\boldsymbol{ZS}$ – helicopter crew,
$\boldsymbol{RZ}$ – task fulfillment,
$\boldsymbol{ZLA}$ – logistic supply.

To build the SAR system model it is necessary to know the organization of the rescue flight, means of transport used for the action, information about the crew of the means of transport (helicopter), knowledge of the components necessary to perform the task.
For modelling purposes, we assume that the organization of an $\boldsymbol{OL}$ flight can be saved in the form of an ordered triplet:

$$\boldsymbol{OL} = \langle \boldsymbol{CL}, \boldsymbol{PG}, \boldsymbol{WP} \rangle \quad (4)$$

where:
$\boldsymbol{CL}$ – flight destination,
$\boldsymbol{PG}$ – readiness level,
$\boldsymbol{WP}$ – hydrometeorogical conditions.

The mapping of the flight order model, the level of readiness of a given rescue operation, weather conditions prevailing during the rescue operation are parameters of the system structure that may decide about the functioning of the system or its non-functioning. In accordance with the adopted assumption, the purpose of the $\boldsymbol{CL}$ rescue flight is the mapping of the structure of the SAR system in the Baltic area and in the designated area of land. For modeling purposes, we assume that the structure of the rescue flight is presented in the form of the SAR system model, i.e.:

$$\boldsymbol{CL} = \langle \boldsymbol{G}, \boldsymbol{F} \rangle \quad (5)$$

where:
$\boldsymbol{G}$ – graph of SAR system structure based on actions carried out in the past,
$\boldsymbol{F}$ – a set of functions defined on elements of the graph $\boldsymbol{G}$.

Further considerations using graph theory (Izdebski and Jacyna, 2018; Janecki et al., 2019; Soczowka et al., 2020; Izdebski et al., 2018; Wasiak et al., 2019; Zak, 2013; Zochowska et al., 2010; Kozlowski et al., 2020) will be the subject of subsequent publications. In this article, it is enough to mention that the SAR rescue system is a complex system in which characteristic subsystems can be extracted. In turn, each subsystem is characterized by a structure described by the transport network (Woźniak et al., 2016) of the system (all possible places located in the area of the rescue operation carried out).
For the purpose of modelling rescue operations, we assume that $\boldsymbol{ST}$ transport resources can be saved in the form of an ordered two:

$$\boldsymbol{ST} = \langle \boldsymbol{TS}, \boldsymbol{MO} \rangle \quad (6)$$

where:
$\boldsymbol{TS}$ – helicopter type,
$\boldsymbol{MO}$ – operationalcapabilities.

Means of transport are characterized by various technical, operational and economic parameters. Depending on the type of helicopter, its operational capabilities are different. Currently, two types of helicopters participate in rescue operations: Mi-14PS and W-3RM.
For a full description of the model (3) it would also be necessary to distinguish such model mappings as:

- representation of the crew of the $\boldsymbol{ZS}$ helicopter,
- mapping the implementation of the $\boldsymbol{RZ}$ task,
- mapping of logistic security for $\boldsymbol{ZLA}$ shares.

Simulation studies of the SAR system in the Polish zone of responsibility

A series of stochastic numerical simulations of the flight of the rescue unit to a point within the Polish SAR zone of responsibility, in the Baltic Sea and in the land part were carried out.
The simulation tests were carried out due to the fact that in the Polish zone there are two bases from which rescue operations are carried out. The simulations are intended to check whether increasing the number of bases will

improve the availability of rescue units operating in the SAR system. The following elements were taken into account in the simulation:

- meteorological conditions (wind direction and speed),
- operational and operational parameters of rescue units (fuel supply, flight speed, etc.),
- geographic location of base stations and geographic coordinates of the boundary points of the area of responsibility.

In the simulation, criteria indicators were calculated at randomly generated points within the area under consideration, especially that randomization is of high importance in simulation research Kostrzewski (2020), Kostrzewski et al. (2020), Gontarczyk et al. (2016). The simulation is based on the concept of assigning a base and a rescue unit to each point in the area. After assignment, the journey between the base and the point was calculated taking into account all simulation parameters, including variable wind conditions. Criterion parameter maps created in this way are used to evaluate the functioning and capabilities of the system.

Figure 2 shows the operational fuel supply for helicopters taking off from specific bases. There is a division into two areas assigned to both databases. Other types of helicopters with smaller fuel tanks take off from the EPOK base. Due to the fact that the fuel consumption of this type is lower than the helicopter starting from EPDA, it can achieve similar length of search path with less fuel reserve.

Fig. 2: Operational fuel reserve in search and rescue operation

Figure 3 shows the length of the search path that directly determines the search capabilities of the rescue unit at a given point. This length, depending on the size of the searched object and the hydro meteorological conditions (wind, sea state, visibility), translates into the surface area of the area that can be effectively searched; the longer the length the better. Despite the differences in the type of helicopter, these lengths are similar.

Fig. 3: Search Path Length

Figure 4 shows the available operating time, which is calculated assuming average fuel consumption under hovering conditions (maximum fuel consumption). This value takes into account the amount of fuel needed to return to base and all necessary supplies.

Fig. 4: Operating time available

Figure 5 shows the ground speed to the destination point, taking into account the effects of the wind. In the presented, exemplary scenario, the differentiation of the forward speed depending on the direction of flight has been shown. This translates directly into the time of reaching the point, as shown in Figure 6. This indicator is the main criterion in planning the allocation of rescue resources in the SAR system, because the shorter the time to reach the disaster point, the greater the chances of success and saving lives or property.

Fig. 5: Average speed of reaching the point

Fig. 6: Average time to get to the point

Conclusions

Both the analysis of the literature dealing with the SAR issue and the simulations carried out lead to the hypothesis that increasing the number of rescue bases and the use of helicopters with a high level of technical advancement, and thus reduced fuel consumption, increases the availability of rescue units and thus increases the level of safety of people and maritime units. Modern simulation tools make it possible to predict key performance and efficiency indicators of the system and the impact of nondeterministic parameters on the result. The presented simulation shows how the area of the Polish SAR zone is covered with indicators such as: rescue service availability time, search and rescue potential expressed in the length of the search path. Numerical simulations are characterized by a relatively short computational time, in addition, it is not required that the system function in reality. Nevertheless, it is possible to predict the key figures at the stage of planning the deployment of rescue resources and infrastructure. Performing virtual rescue operations using mathematical models and programming tools allows you to test a large number of system configurations and make a qualitative comparison. It is very useful in the processes of planning, risk assessment, cost analysis and planning of logistics activities.

Abstract

This article presents the health systems of selected European countries. Different models of health systems and their implementation are presented. The solutions used in different European countries provide an opportunity for comparison and proposals that can improve the efficiency of the health systems.

Keywords: Health Policy, Public Health, Health Protection, Health System.

Introduction

According to the WHO (2000) definition, a health system is defined as a cohesive whole whose multiple, interrelated parts, collectively, have a positive effect on the health of the population. The health system is, in turn, an organised and co-ordinated set of activities, the aim of which is to implement preventive, therapeutic and rehabilitation services and services, aimed at securing and improving the health of the individual and the collective (Marcinów 2011). It is a conceptually isolated whole, the parts of which, together, contribute to the success of the whole and this success is understood as the fulfilment of the mission of health policy.

Models of Health Systems

A characteristic of the organisation of modern healthcare systems is the presence of an intermediary between the patient and the physician. Most frequently, this *rôle* is assigned to private and state insurance companies, central budgetary units and local budgets. This means that the health sector can be funded simultaneously, albeit to varying degrees:

- from universal insurance contributions paid by the employee and employer,
- from general taxes and
- from voluntary contributions

The classification of traditional health systems takes into account the three basic sub-systems and the related three models (Suchecka 2010):

- Bismarck's Universal Health Insurance model,
- Beveridge's National Health Service model,
- the private, free market insurance model,

The Universal Health Insurance Model.

This model assumes the existence of mandatory health insurance (*public-contract model*, *social security contribution*). It was first created by the German Chancellor Otto von Bismarck in 1883. Its aim was to protect the population from the unintended consequences of unforeseeable random events that could contribute to loss of income and threaten the material existence of parts of society (Białynicki-Birula 2010); it displays the following characteristics (Depta 2011):

- the patient is free to choose the healthcare provider from among those who have entered into the relevant contracts.
- the expenses for benefits for the insured are covered by income from premiums collected by insurance institutions.
- local authorities who have no control over statutory funding are legally responsible.
- the global budget is a mechanism for funding hospitals,
- the remuneration of family doctors is linked to the agreed terms of the contract or they receive a fee for the benefits provided,
- treatment-related costs, such as medication, may be covered in full or in part,
- the state sets a precise legal framework for its operation and supervises the system.

The model of Universal Health Insurance is based on the assumption that diseases are treated in terms of social risk. In accordance with the principle of solidarity, its effects are reduced by spreading the risk to wider social groups, that is, to the co-insured. It assumes, to a wide extent, the use of the mechanism of the public contracting of benefits – the institution of the public funder (such institutions being both state agencies and insurance companies). The financial means collected from the insured are used in order to create funds for contracting health services with healthcare providers from different sectors. Hospital care is dominated by the public sector, while outpatient care is dominated by the private sector. In Bismarck's model, there are many healthcare insurers who compete for the insured and their premiums. Politicians do not have much influence over the allocation of health funds (Bundsministerium 2019).

The National Health Service Model

The National Health Service Model assumes funding for health services by allocating funds through a *publicly-integrated, tax-funded model*. This implies a dominant state position, as is evidenced by the fact that the majority of healthcare providers are in the public sector. It combines elements of Universal Health Insurance with a public guarantee of access to healthcare. It was introduced in 1948, in Britain, by Lord William Beveridge. The basis for this system was the much earlier Social Security Act of 1911. Beveridge excluded medical care from the social security system, creating a special fund financed by general taxes. The health service also became distinct, in terms of management and organisation, with universal health benefits receiving funding from the state budget. Characteristic of this model is the provision of services to all, regardless of social status. The state has a responsibility for universal access to health services and performs this duty through the National Health Service. Healthcare is funded through general, as well as through local, taxes.

The functioning of this system is governed by the following principles:

- all citizens are guaranteed health safety, or are excluded on the basis of a negative list
- health services for citizens are free and offered widely;
- health funding comes from the state budget, is mainly sourced from taxes and depends on state revenues; the amount is allocated annually by Parliament
- family doctors enter contracts as independent health sector players;
- decisions on the funding of health benefits are taken centrally;
- National Health Service employees, on employment contracts, are officially dependent on the state, which acts as a monopoly, creating strong subordination within the service;
- the healthcare system is governed by legislation.

The system, based on Beveridge's model, is dominated by the belief that the health of citizens is a public good and its protection is the duty of the state. The system is based on a bureaucratic model and has most of its flaws. The lack of competition and private operators reduces its effectiveness.

Also, in the countries of central and eastern Europe, the model of a centralised healthcare system was in place after World War II; it was, however, based on a model created in the 1930's in the Soviet Union by the People's Commissar for Health, one Nikolai Siemashko (Rutkowska-Podołowska et al 2011). The system built on this model had state

funding and, like Beveridge's model, was centrally managed. It was founded on the basis of full, equal and free access to health services for the whole of society. Co-funding only occurred when buying drugs.
The general principles of this model are:

- financing from taxes through the central budget;
- government control and organisational uniformity of the whole system under central management;
- the hiring, by the state, of the medical staff;
- a full range of completely free benefits, except for certain medicines available in outpatient care;
- nationwide attitudes towards prevention;
- public participation in activities promoting health and the protection, thereof;
- the health sector is considered a non-productive part of the national economy;
- no private service sector.

The Free Market Model

The Free Market Model is based on voluntary health insurance; it is a residual model with *a private insurance/provider; most of the systems are mixed and there is private financing*. The private health insurance model assumes the dominance of the private sector in healthcare, mostly operating on a profit basis. The benefits are funded by insurance companies and the absence of insurance means that the full cost of treatment is covered directly by the patient. Only strictly defined categories of people, such as pensioners and the disabled are covered by public health programmes (Prędkiewicz 2011).

The main principles of this system are that:

- the health of the individual is independent of public health because the state participates in a very limited range of healthcare organization;
- individuals themselves bear health risks by devoting a portion of their income to current or future entitlement to health benefits;
- healthcare is funded by private citizens and is treated equally with other sectors of the national economy;
- medical services are financed through private insurance;
- public health benefits are only available for certain groups of people, that is the seriously financially disadvantaged, the elderly and mothers and children in particularly difficult material situations.

The free-market model, which is not present in Europe, shifts responsibility for health from the state to the citizen. Healthcare is treated as a fully-fledged branch of the economy.

Legal basis and public sector expenditure on health in EU countries

The financing of medical care is not uniformly legally regulated in the European Union. Legal bases are diverse and reflect different social choices. Regulations have been limited in scope and have related mainly to public health since the 1990's. This is linked to the rapid development of this medical field. This situation was influenced by emerging epidemiological threats such as BSM, Avian Influenza and the rise of AIDS in Europe. On the other hand, financial crises in the European countries indicated that attention should focus on preventing disease and promoting health which, in the longer term, saves the national budgets' money. Health protection was first mentioned in the original law of the European Union in the Treaty of Rome, then in the Uniform European Act. It was only in the Treaty of Maastricht that clear regulations were made, which were later transferred to the Treaty of Amsterdam. These concerned the following issues:

- activities in the realm of health and safety at work (*the Treaty of Paris of 1951*)
- improving working and living conditions as one of the primary objectives of the community *(the Treaty of Rome of 1957*)
- striving for a high level of health protection (*provisions of Article 129 of the Maastricht Treaty of 1992, which is now the content of Article 152 of the Treaty of Amsterdam, 1997*)

Article 152 of the Treaty of Amsterdam, in force since 1 May 1999, imposes a high level of human health protection within EU countries, together with the removal of sources of health risks and the prevention of disease. The activities of the European Union in the field of healthcare organisations, generally cover the following areas:

1) establishing high standards of quality and safety in human organs, in substances of human origin, in blood and in its derivatives,
2) taking measures to protect public health in veterinary and plant protection areas,

3) protection and improvement of human health without interfering with the laws of the member states; it is the responsibility of the Member States, not the European Union, to provide and finance healthcare. It is the Member States who organise the health service and the health insurance system in their own right (Paszkowska 2006).

Despite differences in organisation and funding, health systems in EU countries are based on common values, as recognised by the Council (2006) of Health Ministers in 2006: universality, access to quality care, fairness and solidarity (European Commission 2017) .

The communication of the European Commission (Report 2016) on effective, accessible and resilient healthcare systems sets out a strategic agenda for healthcare systems in the EU. The public sector plays a crucial *rôle* in funding health benefits. It funds more than 70% of healthcare spending in 18 of the 27 EU Member States.

Member States with the highest share of expenditure on public health sector are the Czech Republic (83%), Denmark (84%), Germany (85%), Luxembourg (83%), The Netherlands (81%) and Sweden (84%).

In 2015 public spending on healthcare amounted to 7.8% of GDP across the EU. The ratio of healthcare expenditure to GDP, which is equal to *or higher than* the EU weighted average, was recorded in eight Member States: Belgium, Denmark, Germany, France, the Netherlands, Austria, Sweden and the United Kingdom. Member States with the lowest share of public health expenditure were Cyprus and Latvia (3.5%), while rates below 5% were recorded in Bulgaria, Estonia, Lithuania, Hungary, Poland and Romania.

Healthcare funding in OECD Countries

Depending on the healthcare model assumed, there are different methods of financing healthcare. For OECD countries, this is shown in Table 1. The following healthcare models dominate here: Universal Health Insurance and a National Health Service; these are used in a similar number of states. In the OECD group of countries, only the USA operates private health insurance, despite a reform introduced by President Obama, in 2010, that introduced mandatory insurance and from which President Trump's administration intends to withdraw, albeit partially.

Table 1: Healthcare financing in OECD countries in relation to the healthcare model implemented

Universal Health Insurance	National Health Service	Private Insurance
Austria, Belgium, the Czech Republic, France, Netherlands, Japan, Korea, Germany, Luxembourg, Mexico, Poland, Slovakia, Switzerland, Turkey, Hungary, Lithuania, Latvia, Estonia, Bulgaria, Romania	Australia, Denmark, Finland, Greece Spain, Ireland, Iceland, Canada, Norway, New Zealand, Portugal, Sweden, United Kingdom, Italy	the USA

Source: self-published by A. Wagstaff, (2009), Evansa and Etienne (2010),

Table 2 shows the evolutionary changes of healthcare models in OECD countries (1960-2006). Denmark, Greece, Iceland, Norway, Portugal, Spain and Sweden moved away from universal insurance in favour of the direct financing of healthcare from taxes; conversely, the countries of the former eastern bloc, *namely, the Czech Republic, Poland, Slovakia and Hungary* moved away from

Table 2: Healthcare Models in OECD countries

Source: self-published by Saltman and Dubois (2004), Carrin and James (2005), Rothgang et al (2010)

universal insurance, in favour of the direct financing of healthcare from taxes, *after* their regimes changed. In Poland, Universal Health Insurance was introduced in 2003 after the liquidation of the Healthcare Funds and the establishment of the centralised National Health Fund. After the changes that took place in 2016 *and thereafter,* the Health Fund has increasingly been a system based on budget funding.

Due to rising spending on healthcare, especially in relation to overall public spending, reforms are being implemented in almost all developed countries, to curb its growth. Therefore, typical model solutions are not used in their pure form (Białynicki-Biryla 2012).

On the one hand, societies want their health needs to be fully met, which is increasingly costly. On the other hand, however, there is a need to maintain solvency within a state's financial system. Therefore, two types of action are being taken:

- an increase in the efficiency and rationalisation of expenditure in the health sector, related to better healthcare management, and
- an improvement in access to healthcare by increasing the health protection coverage of the population.

Table 3 shows the mechanisms for consolidating healthcare funding in OECD countries, as well as their advantages and disadvantages. The main direction of the evolution of healthcare systems leads to the formation of intermediate systems.

Table 3: Mechanisms for consolidating healthcare funding in OECD countries

Mechanisms for the consolidation of financial means	Advantages	Disadvantages	Countries where the mechanism is dominant
Budgetary funds	- Broad access to benefits, – Differentiation source of funds	Dependence on the budgetary situation, - Necessity to compete with other sectors for budget resources	Australia, Canada, Denmark, Finland, Greece, Spain Iceland, Ireland, Norway Portugal, Sweden, United Kingdom, Italy,
Universal Health Insurance	– Stable amount of income, – Transparency of funding	- Effectiveness depends on social, - economic and political factors, - Generally higher costs of administering the system	Austria, Belgium, Czech Republic, Estonia, France, Netherlands, Luxembourg, Germany, Switzerland, Israel, Japan, South Korea, Poland, Slovakia, Slovenia, Hungary, Turkey
Private health insurance	– Less pressure on public funds	- Access to benefits limited to people with insurance policies - Vulnerability to market failure typical of insurance	the United States

Source: self-published by Gottret and Schieber (2012)

In most countries, public funds for health protection are collected at a national level, which means that there is a single risk pooling entity; this is the case for example, in Belgium, Canada, Japan, France, Hungary, Ireland, the Netherlands, Portugal and Poland.

The exception are countries where healthcare is co-financed by local taxes; these include Denmark, Finland, Italy, Sweden and countries where Universal Health Insurance funds are responsible for collecting contributions from their own members, such as in the Czech Republic, Germany, Slovakia, Greece and Austria. In the case of countries with local, tax-based funding, there is usually a compensatory mechanism aimed at redistributing funds to increase income and resources in regions with lower tax revenues. These mechanisms are characteristic of most countries and are designed to increase financial means in funds whose members have lower incomes or represent higher health risks. In countries where the organisation of healthcare is based on the model of Universal Health Insurance, systems, *proven in countries with similar national systems and vice versa,* are introduced. In most countries, the healthcare system is decentralised, resulting in regional health policies.

Payment, either partial or total, for certain medicines and patient health benefits and expenditure control mechanisms are introduced on a wider scale. The *rôle* of the state increasingly comes down to policing the effectiveness of health funding and making healthcare providers more efficient. The importance of the general practitioner (GP) acting as the guardian of the system is growing, especially in countries with Universal Health Insurance, which has hitherto been a hallmark of the National Health Service System. Market mechanisms in health allocation processes have been adopted and accepted. The internal market (*'quasi markets', so-called*) was created by separating the function of the funder, that is the fundholder, from the function of the service provider. In these systems, the implementation of health benefits is based on contracts concluded between public bodies acting as funders and service providers. In some countries, such as Switzerland, there is full freedom to contract benefits, while in others, like the Netherlands and the Czech Republic, there is a limited possibility of signing a contract, known as *'selective contracting'*. Similarly, in National Health Service Systems, the direct management of health units (*directly-financed facilities*) has shifted away from the predominant direct management of health units to self-reliance in the broad meaning of this term, enabling the introduction of *selective contracting rules.* For example, in the UK, the NHS, i.e., *the National Health Service***,** *which was hitherto a symbol of hierarchically integrated healthcare and where the production and funding of services took place under a single, organisational system*, internal market solutions have been successfully introduced, since the early 1990's.

Conclusions from the comparison of public health funding systems

When comparing public health funding systems, one can see that each has its own advantages and disadvantages.

Virtually none of them exists in pure form. Systems built primarily by developed countries exploit the advantages and try to minimise the disadvantages of individual models. Most European countries built their systems using the experience of their predecessors, such as the German Chancellor Otto von Bismarck and Lord William Beveridge in the United Kingdom and the People's Commissioner for Health in the USSR, Nikolai Siemashko.

In the free-market model that is not present in Europe, responsibility for health has been transferred from the state to the citizen and health protection is treated as a fully-fledged branch of the economy.

Regardless of the shape of the healthcare system and the value of the budget and the funding model adopted, the flow of funds between the funder and the providers of benefits is ultimately important. Changing the funder alone does not guarantee the proper quality of the funds.

The issue of the flow of funds between the funder and the provider actually consists of two questions: the quality of securing access to benefits and the quality of the management of public funds. That is, the *de facto* question of how effectively the state apparatus operates in this regard. It should be noted at the outset that this question should not be understood in terms of the sense of the Minister of Health and, above all, *sensu largo*, in terms of the foundations of the state.

The main determinant of the effectiveness of a health system is its ability to improve the health of the population. However, this condition is determined by a number of different factors.

According to M. Lalonde (1974) , Canada's Minister of Health and Welfare, the biggest impact on every person's health, up to 50 per cent, is lifestyle. This is followed by physical environment (20%) and genetic factors (20%). Healthcare has the least impact (10%). Meanwhile, healthcare systems provide some 100,000 jobs, equal to around 90% of all healthcare spending. Expenditure on health education and lifestyle development is only 1.5%, while its impact on mortality reduction is 43%. All of this must be taken into account when assessing the effectiveness of spending on the healthcare system. It follows from these considerations that it is necessary to invest in the health of citizens through education and prevention. It is better to teach society how to eat healthily and live actively than to treat the costly effects of being overweight or obese.

1 – factors related to life style
2 - genetic factors
3 - factors related to the model of healthcare system
4 - environmental factors

Fig. 1: Effects of various factors on health

Source: self-published by M. Lalonde (1974)

The promotion of healthy lifestyles, including physical activity and proper nutrition, should be the result of co-ordinated action by public authorities, medical bodies and patients' organisations. It is also necessary to define a coherent, comprehensive and multi-annual prevention strategy aimed at maintaining a healthy lifestyle and preventing disease.

Abstract

The aim of this paper is to analyse, describe and discuss the processes contributing to the development of product eco-innovations in companies-suppliers of environmentally sound technologies (ETSs) in Poland based on Technology Readiness Levels (TRL) model. The key research question in this paper is: How do companies-suppliers of ESTs develop product eco-innovations? The paper is based on empirical data gathered through qualitative research techniques: in-depth, semi-standardized and semi-structured interviews. The research results allowed to identify and describe two main scenarios of developing eco-innovations in Polish EST companies. First, to use the idea of an innovator, and then develop it personally or with the help of specialists from previously existing company or research institution (this path was usually followed). Second, to set up a company specifically to create a new product. Common to both scenarios of creating eco-innovations are: the variety of knowledge areas necessary to create new technologies, the importance of knowledge, experience and competences of actors involved in the process of creating innovations, and the need to conduct research and development activities, cooperation between the entrepreneurs and users aimed at improving offered technologies and adjusting them to market needs. The detailed process of developing product eco-innovations was described based on TRL model. In case of Polish companies some phases TRL3 and TRL4, as well as TRL5 and TRL6 overlap, whereas TRL7 was not performed at all.

Keywords: Eco-Innovation, Environmental Innovation, Technology Development, TRL

Introduction

The paper covers an important and up-to-date topic related to eco-innovations. It is focused on new product solutions created in the environmental technologies (further: ETs) sector (eco-innovations). In the era of increasingly strong pressure from public policy to implement environment-friendly solutions, learning how to build them is crucial for further development of ETs management. This issue has not yet been fully developed in literature, especially with regard to Polish ETs suppliers (Piotrowska 2012; Urbaniec 2015; Ryszko 2016; Marczewska 2016). According to Ostraszewska and Tylec (2019), interest in the idea of sustainable development increased together with reorientation of companies towards eco-innovative strategies. Both terms are associated with the perception of the eco-innovations, which on the one hand are caused by necessity and on the other hand by a chance for promotion and development of a particular company. Although there is an increasing interest in this research topic, most of the existing research covered mainly developed countries and focused on process eco-innovations regardless of industry or within a specific industry, e.g.: Triguero et al. (2013), Noci and Verganti (1999), Brunnermeier and Cohen (2003), Frondel et al. (2008), Horbach et al. (2013), Nawrocki et al. (2018), Krolikowski et al. (2020), Jacyna et al. (2017), Kowal et al. (2018). Among the specific industry usually chemical, manufacturing industry and service sector were mentioned, as well as recently printing industry: Lipiak and Salwin (2019), steel production (manufacturing): Korol et al. (2016), Ryszko (2016),

agriculture: Dudek and Wrzaszcz (2020), logistics planning for food grain industry (environmental conscious logistics): Maiyar and Thakkara (2019) and many others. The research of Ostraszewska and Tylec (2019) showed that less than one third of the EU countries can be treated as innovative and eco-innovative, nevertheless Poland was not mentioned among these countries.

The aim of this paper is to analyse, describe and discuss the processes contributing to the development of product eco-innovations in companies-suppliers of environmentally sound technologies (further: ESTs) in Poland Technology Readiness Levels (TRL) model ((Sanchez, 2011). The key research question in this paper is: How do companies-suppliers of ESTs develop product eco-innovations?

The next section of the paper focus on indispensable definitions' analysis in order to present the research area and settle it in overall methodology. It is followed by theoretical framework and a presentation of a research method. Subsequent section provides results of empirical research and describes the development of eco-innovations. The paper ends with conclusions.

Focus of Analysis

The paper aims to explain how companies-suppliers of ESTs develop eco-innovative products. The focus of this analysis is graphically presented in Figure 1.

In order to follow the logic of the paper, it is necessary to build a common understanding of the following terms and concepts, that were used as a basis of presented research:

- ESTs: "technologies that have the potential for significantly improved environmental performance relative to other technologies." (International Environmental Technology Centre, 2003: 16; European Commission, 2002: 5);
- Innovations: "implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations." (OECD, 2005: 46);
- Eco-innovations: "the production, assimilation or exploitation of a product, production process, service or management or business method that is novel to the organisation (developing or adopting it) and which results, throughout its life cycle, in a reduction of environmental risk, pollution and other negative impacts of resources use (including energy use) compared to relevant alternatives." (Kemp and Pearson, 2007: 7); since production and logistics processes are similar to and accompanying each other, then this definition might include logistics processes, logistics products and services as well, Kostrzewski (2018: 41);
- Product innovations: "the introduction of a good or service that is new or significantly improved with respect to its characteristics or intended uses. This includes significant improvements in technical specifications, components and materials, incorporated software, user friendliness or other functional characteristics." (OECD, 2005: 48).

Fig. 1: Focus of analysis. Source: own elaboration based on International Environmental Technology Centre (2003: 16), European Commission (2002: 5), OECD (2005: 48-51), Kemp and Pearson (2007: 7).

The analysis of the above presented concepts and their graphical presentation (Figure 1) leads to the conclusion that not every ETS is innovative. Many of these technologies lack the novelty element therefore are hardly innovative. Such technologies are certainly important for the environment, nevertheless the most desirable are those technologies, which incorporate novelty since they lead to general development. Thus, the research presented in this paper is focused on innovative ESTs (eco-innovations). The study focuses exclusively on product eco-innovations developed in the ESTs industry, which in this paper are interchangeably termed eco-innovations, innovations or environmentally sound technologies.

Theoretical Framework

The emergence of ETs depends on many factors such as knowledge, experience, available products, services, equipment, procedures as well as organizational and managerial systems. A thorough, universal description of the ETs that would reflect their nature and the development process, and could be related to any geographical, technological and economic conditions seems to be a challenge. Environmentally friendly technologies in a given time and geographic context will certainly be replaced in the future by other, greener solutions. Similarly, what is considered eco-friendly in one country or region does not necessarily has to be seen this way in other regions (International Environmental Technology Centre, 2003: 16). That is why, companies while developing or transferring environmentally friendly technologies should consider specific socio-economic, cultural and environmental factors of the region they operate or wish to focus on (Tébar et al. 2005: 7).

The development of eco-innovations relies on existence of appropriate market mechanisms and regulatory instruments. Well-developed environmental standards can be one of the factors supporting their development, use and transfer (Chaudhuri and Mukhopadhyay, 2013: 206). The factors influencing the development of such solutions may vary depending on, inter alia, the type of technology, its individual characteristics and the sector in which it is created (Berkhout, 2005: 77-79). Fundamental differences regarding development process can be distinguished between innovative product and process solutions (Cleff and Rennings, 1999; Rehfeld et al., 2007). Findings on the impact of environmental regulation on product and process innovation development, given in Cleff and Rennings (1999), document their greater impact on the emergence of process innovation. Regulations and environmental policies are particularly important for the development of ESTs in the mature, heavily polluting sectors of the economy (Fukasaku, 2005: 251-267). On the other hand, other market forces (Cleff and Rennings, 1999) and investments in R&D (Rehfeld et al., 2007) are crucial for product innovation development. These in case of process innovations, have a negligible effect.

Fig. 2: Technology readiness levels in TRL model. Source: own elaboration based on Sanchez (2011: 22), Dz.U. MON 2007 nr 18, poz. 191: 964 and Dz.U. 2011 nr 18 poz. 91: 1315.

Rational resource management (along with resource logistics) and environmental management, including relevant use of natural resources in order to meet the basic needs of societies, with the least amount of raw materials involved, requires extensive knowledge in various fields. Making environmentally friendly investments is possible, inter alia, by increased R&D activities undertaken both by public institutions and companies, and by striving towards a knowledge-based organization. Introduction of such changes can facilitate the development of new production and consumption systems, consistent with the principles of sustainable development (European Commission, 2002: 4). Consequently, along with sustainable production and consumption, a need to create a strategy for the development of environmentally friendly technologies is observed (International Environmental Technology Centre, 2003: 18). To prepare such a strategy, extensive analysis of the ways in which individual technologies are developed is necessary. This can be done using the Technology Readiness Levels (TRL) model (presented in Figure 2), which consists of nine successive levels that describe the possible stages of technology development, from its creation to commercialization and deployment (Sanchez, 2011: 20-22).

Well-designed ESTs can be described using the following attributes:

- sustainability;
- “cradle-to-cradle” design (regenerative design);
- waste and pollution reduction by changing production and consumption patterns;
- alternatives to technologies that negatively affect health and the environment;
- contribute to the establishment of a center of economic activity around technologies and products that bring environmental benefits, accelerate their implementation and diffusion, and contribute to the creation of new jobs (Chakrabarti, 2014: 3-4).

Research Methods

The paper is based on empirical data gathered through qualitative research techniques: in-depth, semi-standardized and semi-structured interviews. The purposefully selected research sample included forty companies-suppliers of ESTs based in Poland, which were the winners of the GreenEvo - Green Technology Accelerator project (editions 1, 2 and 3), run by the Polish Ministry of the Environment. The researched companies were located countrywide, represented six broad technological areas, and developed product eco-innovations that are original, ecologically significant and have a great potential for development. The characteristics of these companies are presented in Figure 3.

Fig. 3: Characteristics of the companies from the sample. Source: own elaboration based on interviews.

The study was based on a fifteen-page script. Interviews were recorded (average duration: 157 minutes), transcribed, anonymised, coded in a codebook of 77 codes and analysed according to the grounded theory approach (Glaser and Strauss, 2006). The research results presented in this article include information classified in 10 codes presented in Figure 4.

Fig. 4: Codes used to conduct this research. Source: own elaboration based on interviews.

Development of Eco-Innovations: Results of Empirical Research

Innovations are rarely developed by one person. It is usually a sum of efforts of many specialists. Therefore, it is difficult to determine quantitative contribution to innovation's success. As indicated in Figure 5, in the majority of interviewed companies, the development of technologies from the very beginning was influenced mainly by people working in the company. Interestingly, help from external partners, or representatives of scientific institutions have not contributed to this process at all or contributed only to a negligible extent.

Fig. 5: Innovators / technologies' sources (explanations: percentages do not sum up to 100, because some of the interviewees gave several answers). Source: own elaboration based on interviews.

According to interviewees, in 77.5% of cases technology was created by the owners of the company, its shareholders or founders. These people often created ideas, and a technical refinement was done by specialists from a company who sometimes used advices or help from scientific institutions' experts. Such a model for developing new solutions was indicated most often in companies were already present on the market. The established business position of a company, own machine park, facilities, as well as employed specialists and constructors were undoubtedly a facilitation in the further development process.

"The idea came from the owners of the company and was passed on to employees for development and implementation. (…) A lot of people worked on the technology. (…) We spent over 5 years of work developing this solution. We are constantly developing this technology and also are implementing new solutions. We have a whole department of R&D, which is working all the time to develop this technology, implement new solutions, new instruments for even better management. It will be a permanent process."

[Enterprise 9] (further: *[E<No.>]*)

When companies with a stable market position develop a new solution, they may achieve more than competitors who have just entered a market. Companies expanding their offer with new technologies can fully use their employees and constructors to develop it without anxiety on a position among competitors. As the interviewees declared, resources and engineers who are constantly working on new solutions are an engine of a company's development. Despite the benefits from cooperation with specialized engineers, in a few companies from the analysed sample owners in person, without additional help, developed the technology from the scratch.

"I am the creator of this technology. And not just this one, because I have many patents. This one is patented around the world and is actually a novum."

[E25]

Almost a quarter of the companies from the sample were set up for the purpose and with the view to develop innovative

technology. These companies were created simultaneously with the development of an idea for a new solution. Some of them were detached from the mother company, others from the beginning were completely separate, new entities.

„It was a group ... it is still a group of people working in the company. Including the owners and employees ... I cannot say the department, but let's say the research group in our company (…) who dealt exclusively with this project and this group expanded overtime and still operates today."

[E40]

Some technologies were created thanks to companies' owners experience gained while working in competitive enterprises. It happened that the inspiration was very strong and led to the development of very similar technologies, however with higher usability potential (not a copy of already existing solutions).

"[The inventor] worked in minefields since graduation. He was managing mechanical devices. He knew these giant machines, how they operate, wear out, what are their problems. Eventually he took the risk of creating and developing the new device himself."

[E11]

A large group of companies developed their technologies through the joint work of originators: owners, research institutes and employees. These companies decided to implement and test their ideas in cooperation with clients, what led to efficient identification and improvement of technologies' deficiencies.

„We built and tested. We have also set up our solutions on stations owned by our friends to see how these works, what is happening. We were giving in return free service. (…) Some of them allowed us to [experiment] because of sympathy, simply with pure curiosity. These were former engineers, former directors. They did not even want this free service. Normally they paid, they looked at our work, they were looking for solutions themselves (...).

[E20]

Few companies used the global patent as the basis for their solution. Only two interviewees declared that this was the way of their technology development. Nevertheless, they claimed that created solutions are not copies of patents. They used longstanding patents only as part of general knowledge and inspiration for completely new, functional technologies.

"The technology is based on a particular patent, which is associated with production of electricity with hydrogen. And this is a global solution, most probably developed by many famous research institutes (...). [Our solution] is what the team has been working on for several years. At some point we got the EU grant for the development of this technology (...). This technology was created in cooperation with the Warsaw University of Technology (WUT). We did part of the work ourselves, part jointly with the WUT."

[E1]

The development of new technologies depends on experience and knowledge of innovators, and it is facilitated thanks to engagement of technical workers, constructors, and designers with different backgrounds. However, it is impossible to indicate a single scientific area that was the basis for the development of a given technology. Although the interviewees represented companies dealing with ETs, the variety of knowledge areas necessary to operate in this industry is surprisingly wide. Figure 6 presents the main areas of knowledge necessary to develop environmentally friendly technologies in Poland.

Fig. 6: Main areas of knowledge necessary to develop environmentally friendly technologies in Poland (*i* - number of indications for a given area of knowledge by the interviewed enterprises). Source: own elaboration based on interviews.

According to the interviewees, the knowledge of chemical science and electronics is the most useful for the development of ETs. These areas were indicated 13 times as the basis for creating a good solution, alongside other narrower branches of science given in Figure 7.

"Mainly topics related to biotechnology, chemistry and all technical issues, because here you have to know about the installation of technology, construction, electrics, automation. This is a broad ... broad concept. I would say, a wide range of knowledge is needed to build this type of product."

[E26]

Fig. 7: Additional areas of knowledge necessary to develop ETs. Source: own elaboration based on the interviews.

Most of knowledge areas that were considered as necessary for new technologies creation by companies of the studied sample can be qualified as technical knowledge. A distinguishing area that was considered essential by many interviewees is business knowledge (with economics and management), including knowledge of the industry, market, and marketing and sales tools. A significant number of these entrepreneurs believed that developing a good technological solution is not the biggest issue. The ability to present and sell it on the market is more important.

"*Optics. Electronics, mechanics, mechatronics, programming, engineering. In the meantime, patent applications have arisen. Broad technical knowledge. But later at the sales stage, other tools - marketing and sales - were required."*

[E18]

The interviewees mentioned 39 knowledge areas in total that were necessary to create and implement their technologies. It is conceivable that this is not a comprehensive list knowing how broad of ETs field.

Based on the interviewees' answers concerning the science field, knowledge of which was essential to create the technology, it can be concluded that the solutions proposed by the companies from the studied sample required its appropriate use combined with the experience of innovators, constructors and designers. According to 27 interviewees (67.5% of respondents), the technologies were created on the basis of scientific research.

"[Research was conducted] on a model created in a laboratory scale (...) to determine optimal parameters of this technology (...). It was developed using external facilities, in a company where our technologist worked. (…) He did it as an extra work. He just wanted to create something, to build (...)."

[E26]

In order to succeed, companies developing ETs in Poland, carried out various kinds of research. Relatively few enterprises used the help of external units, cooperating with them or commissioning some research tasks. More interviewees declared that research on the technology was conducted in R&D departments or in company workshops, based on the knowledge and experience of employees working in the company.

"We have conducted scientific research, in our own way. It was not research for research institutions. We worked on projects, and that's why we had to do a lot of research. We had products that were not very successful. Fortunately, (…) we drew conclusions from these mistakes. We also investigated which technical solutions are optimal for our current flagship project (...). We have also investigated the electromagnetic compatibility of our equipment and various components, because this is very important, and it is a requirement to meet all EU standards and directives."

[E14]

Among the companies conducting scientific research, the largest group was made up of entrepreneurs associated in various ways with universities, both as research workers and members of project teams.

"Developer of the technology is a scientist, a doctor of chemistry. His field of expertise is really complex (...), which gives us a big step ahead of our competition."

[E37]

„The developer of the technology is very well known both in business and science. He holds a doctorate. "Thousands" of scientific papers he wrote, were written with doctors, professors of such universities as University of Gdansk, AGH, WUT, Wroclaw University of Technology (WrUT)."

[E4]

In a few cases, the technology was created as a result of research initiated during the studies of its creator and continued after graduation with the view to develop a new solution.

"[The creator of the technology] since his studies participated in a research association, where he was awarded. (…). We feel engineering, we are strongly connected with our universities."

[E18]

Twelve companies declare that their first environmental technology was not based on research. Most of them developed new solutions step by step, thanks to relatively quick introduction of its prototypes to the market, observation, constant

updates, verification of its original assumptions as well as continuous modifications and improvements.

"We are the company that implements. Therefore, we learn every day, while we implement and develop."

[E16]

Developing a technology based on research activities by the companies in the sample is largely the result of previous experiences of workers and business owners. Almost half of these innovators previously worked in the environmental protection or advanced technology industries, many of which had previous experience in international companies. More than one third of them were employed both in business and university.

"[Technology developer] worked abroad where he was involved in the installation of sewage treatment plants, but very complicated, very difficult to operate, where he needed a very large professional knowledge and training. And he came up with an idea for a solution, something so that the Pole would not break it. And it worked."

[E36]

Interviewees state that any experience, scientific or business-like, absolutely contributed to the technology. 38 people representing companies from the sample (95% of enterprises) confirmed that the experience from research, teaching or work in other companies had a positive impact on the parameters and pace of technology development.

"Any business experience was useful. Each year we have gained experience in the company. And earlier, experience from previous companies. (…) I cannot imagine a situation where the experience, understanding or new skills interfere with development. It helps the development rather than disturb."

[E14]

However, the development of even the best technology does not guarantee business success. Commercialization is the key and can be performed in various forms (sales, licensing, etc.). 23 companies (57.5%) existed before a particular technology was created, so new technology could be implemented with the use of existing institutional structures, while eight companies (20%) were established to refine and commercialize the technology (Figure 8).

"First, the company was founded and then the product was developed. However, the idea existed earlier in my head. (…) It is important to distinguish here that the ability to design a turbine was the knowledge gained at the university (…), during expert and laboratory work (I tested over 70 water turbines in a laboratory at WrUT). This knowledge was shaping up and, in my head, I developed the product."

[E38]

Over 30% of the previously existing companies modified their offer and industry over time. Six companies (15%) declared that since their founding, their scope of activity expanded significantly. It can be concluded that the entities from the studied sample develop dynamically over time.

"The company was founded much earlier. The new solution was added to the business, the company was rebranded, and we have built the sewage treatment plant. Before that the company was operating in a completely different industry, another sector."

[E36]

Fig. 8: The moment of developing the analyzed technologies in the context of establishing an enterprise. Source: own elaboration based on the interviews.

"We started as an installation company, later became an implementation and installation company, later implementation-commercial, later production-implementation-commercial and so far, we have remained such a company."

[E23]

Every fifth company was founded to finalize and deploy technology to the market. This approach was usually repeated when new solutions were developed with the use of human and machine resources of the parent company, which then established a new entity focused on the development and implementation of technology.

"Yes [the company was founded after the creation of the technology]. It is dedicated to this technology and to the development of all new technologies in our company that are currently being considered."

[E37]

According to some interviewees, it is a necessity, because conducting research is very expensive, and public funds for this purpose are relatively difficult to obtain for individuals who have an idea to develop a new technology.

"In general, it is very difficult for private companies in Poland to acquire funds for new technology, for new investments. As far as technological research is concerned, the research institutes are the main beneficiaries. (…) This is a great pain. That is why we really need to finance these initial studies somehow. That is why we started a company, to help finance our research."

[E37]

Some companies (8) were established much later than the technologies were developed. Some of the originators at the time of developing the technology had a different job, while others, at the stage of designing a new solution, had no intention of selling it, they only conducted research.

"First was an idea that there is a need for such technology. I mean… one day I told my partner that we have a very good idea to use ozone technology. I suggested that we just need to… to start a business, start selling it. Back then, we did not have money, resources, references, technology, nothing…"

[E24]

An idea or even a developed solution can be the base of a new enterprise only with relevant capital and funding. Enterprises from the sample are mostly private, often family enterprises, therefore it is not surprising that 75% of the initial capital of these companies came from private resources. Only 10% of the interviewees (4 companies) declared

that the entities they represented used bank loans.

"There was an investor who wanted to buy the latest type of system and invested his money in this. And so, the technology has grown. Another investor decided to buy another implementation, so we made another technological development and hence we had money to build it."

[E11]

Conclusion

The research results allowed to identify and describe two main scenarios of developing eco-innovations in Polish enterprises-suppliers of ETs. The first scenario for creating an eco-innovative solution was to use the idea of an innovator, and then develop it based on one of the following paths:

- refine it and further develop with the help of specialists from the company or research institutions (this path was usually followed);
- refine it and further develop personally (this path was rarely followed).

Such a model of developing new solutions most often took place in companies that previously existed on the market, i.e. in the case of 23 companies.

The second scenario for creating an eco-innovative solution was to set up a company specifically to create a new product. This was the case in 40% of the interviewed companies (16 companies). Some of them were separated from the mother company, others were completely separate, new entities from the very beginning. In most such cases, new solutions were created thanks to the joint work of the company's owners and employees.

Common to both scenarios of creating eco-innovations are: the variety of knowledge areas necessary to create new technologies, the importance of knowledge, experience and competences of people involved in the process of creating innovations, and the need to conduct research and development activities, cooperation between the entrepreneurs and users aimed at improving offered technologies and adjusting them to market needs.

The research results presented above describe the efforts that have to be undertaken in order to develop and commercialize ETs. The analysis of the cases of the companies from the analyzed sample shows that it is possible to successfully develop and implement eco-innovations on the Polish market of ESTs. The process of developing such solutions can be described based on TRL model (Sanchez, 2011) consisting of successive levels of technology development, from its inception to commercialization and implementation and supplemented with detailed information obtained during empirical research (Figure 9). At least it is worth mentioning that eco-innovations are challenge for production, logistics and other economy representatives, however worth elaborating.

Fig. 9: The process of developing product eco-innovations by companies-suppliers of ETs based on TRL model. Source: own elaboration based on the interviews and Sanchez (2011), Dz.U. MON 2007 nr 18, poz. 191 and Dz.U. 2011 nr 18 poz. 91.

Abstract

Are managers sentenced to carry out logistical planning processes using a spreadsheet? Is Industry 4.0 a distant vision of the future or maybe a reality? The article presents the implemented and proven in practice method of Logistics Planning 9A (PL9A), a process-integrated and computer-aided methodology with dedicated PL9A software. The presentation of the method used by STERLOG Poland allows planning in a complete, system-oriented manner, proven even in COVID-19 lockdown conditions. The solution brings managers closer to low-cost dynamic modelling of logistic resources covering all important areas of its functioning in the supply chain, such as delivery, storage, distribution in engineering as well as economic terms. The presented example of applying the PL9A method allows investigating the problem of optimization in the supply chain from a different perspective. The search for efficiency is transferred to the level of system optimization, limiting the impact of sub-optimization on results. The application of the PL9A method allows to carry out the process of modelling any number of objects integrated in the supply chain according to the same criteria and tools, for the comparability of the modelling results. The modelling process in the IT system allows developing instantaneous simulations and scenarios, with a low workload, shortening the whole planning process and increasing the efficiency of managers and teams responsible for planning. The authors present in the article a concept of building a structure for dynamic modelling of a logistic system based on logistic resources, flowing streams of goods and mathematical modelling.

In the article, the authors also discuss the issue of company evaluation in terms of the requirements of the Industry 4.0 UNITY Consulting & Innovation Roadmap concept: Logistics.

Keywords: Industry 4.0, logistics planning, management, supply chain.

Introduction

Management, command and leadership involves pursuing a goal, using necessary resources, as well as planning and defining how to achieve the intended goal. According to H. Fayol (Lachiewicz and Matejun, 2012) definition, management should be decomposed into planning, organizing, commanding, coordinating, and controlling. In commanding, which is used primarily in the military (Karaszewski, 2010) management is the process of planning, organizing, motivating and controlling operations. Leadership (Świerczek, 2006) can be understood as the ability to influence individuals or a group, oriented towards achieving specific effects and involving setting directions, providing inspiration, building teams, setting an example, and finally, being accepted.

Logistics management , on the other hand (Chamier-Gliszczyński and Staniuk, 2018) can be defined as a sequence of activities that comprise the process of creating a concept for logistics activities, the development of logistics planning in its entirety as well as the process of executing plans control and control systems.

The planning process is common to all the above mentioned methods (Cole and Kelly, 2011; Chamier-Gliszczyński and Staniuk, 2018) of structured action aimed at achieving the planned objective and outcome. Considering the progressive process of computerization in management as well as the consolidation and standardization of management methods aimed at achieving synergy (Mańkowski, 2010), a redefinition of the logistic management method can be proposed. Such a new definition of Logistic Management as a process initiated by the development of a logistic plan aimed at achieving the set out goal, based on the appropriate material resources and capital in order to ensure the implementation of the logistic task in accordance with 7R canon.

The importance of planning in logistics

Planning in logistics is understood in many ways, from coordination and integration of key business activities from the procurement of raw materials to the distribution of the final products to the customer (Gupta and Maranas, 2003), minimalisation of transport and inventory costs (Berman and Wang, 2006) to coordination of production (Kowal et al., 2018; Bukowski and Karkula, 2004) and distribution planning (Chandra and Fisher, 1994) and designing of storage facilities (Jacyna et al., 2017; Jacyna et al., 2017a; Jacyna et al., 2016).

Authors define logistical planning as a structured process involving all company activities, which is related to planning future activities, making economic, business and operational decisions.

In business practice, logistical planning covers production, supply, storage and transport processes (Kozłowski et al., 2020), the aim of which is to adapt the production and logistical processes to:

1. Changes in the specifications of product manufacturing processes,
2. Technical and organizational changes to major production processes,
3. Technical and organizational changes to auxiliary production processes,
4. Changes on the supply side,
5. Changes on the demand side,
6. Changes in the legal and macroeconomic environment of the enterprise, determining market conditions on the demand and supply side,
7. Changes in the production technology (Krolikowski et al., 2019),
8. The occurrence of random events significantly affecting supply and demand and the safety and continuity of operations,
9. The existence of a state of emergency,
10. Changes in the distribution and supply system linked to changes in the distribution network or supply chain (Jacyna-Gołda, 2015; Jacyna-Gołda et al., 2017; Jacyna-Gołda and Lewczuk. K, 2017; Jacyna-Gołda et al., 2018; Wasiak et al., 2019; Jacyna-Gołda et al., 2016; Lenort et al., 2014; Bukowski and Feliks, 2014; Bukowski and Feliks, 2012; Wicher et al., 2012; Kiciński et al., 2019, Witkowski et al., 2012).

Acknowledging the impact of market changes on demand and supply is essential towards developing new strategic and operational plans for a company. The next industrial revolution - Industry 4.0 presented by UNITY Consulting & Innovation determines (Unity, 2020) new management methods and tools, which through the integration of outcomes towards synergy, allow the achievement of the economic goal.

Prior to the implantation of the method it is worth discussing the current guidelines of the Industry 4.0 (current solutions developed in the logistics context of Industry 4.0 were presented in Kostrzewski et al., 2020). The concept presented by UNITY Consulting & Innovation Roadmap Logistics does not provide clear directives which can be applied towards identifying the evolutionary stage of the company towards the new standard. The general concept reveals the limited possibilities of using Unity Roadmaps to assess the state of development of a company's logistics system due to the apparent references to the automotive industry and large companies. Instead STERLOG presents Stages of logistics evolution towards Industry 4.0 (Fig.1) concept distinguished by a versatile applicability and capability to evaluate both production and distribution enterprises of all sizes.

Fig. 1: Stages of the logistic system evolution. Source: STERLOG Polska 2020

The process of adapting the organization to the on-going changes provides a challenge for managers. The computerization of processes and transferring them to cloud platforms is not sufficient. The risk lurking in the process of implementing new information technologies is connected with the existing paradox of information technology productivity. This paradox has been widely described by Jelonek (2016). From the perspective of managers, high productivity of information technologies is not so obvious and certain. The problem of "unobvious high productivity of information technology" examined by Jelonek (2016) revealed the fact that benefits arise only "when IT enables tasks to be performed in a new, innovative way".

The aim of the study is to present a new method of logistical planning considers the paradigm of change and continuous adaptation of the technical and organizational system of enterprises to the new economic, social and legal reality.

Currently, multiple logistical planning methods are applied:

1. Planning methods according to the TOC limit theory, e.g. Drum Buffer Rope,
2. APS planning methods - Advanced Planning and Scheduling,
3. MRPII planning methods - Manufacturing Resource Planning,
4. APICS logistics planning,
5. Material Resource Planning MRP,
6. MRP II Generation Resource Planning,
7. Planning with demand forecasting DEM - Demand Management,
8. Production process planning according to REFA,
9. Methods and tools for planning order execution,
10. Planning of production resources.

An analysis of logistical planning found the above mentioned methods of high labor intensity and relatively low accuracy of results. These results are further supported by studies on the effectiveness of the implementing changes in production (PWC, 2017) and the published report "The effectiveness of the implementation of changes in production". This is also confirmed by research on the effectiveness of implementing of changes in production, described in the study conducted by PWC (Fig. 2) and the published in report "Industry 4.0 or the challenges of modern production". The effectiveness of the implementing changes is certainly important; and one of potential way of its examining are simulation models of logistics and production facilities, as Kostrzewski (2020), Kostrzewski (2017).

Fig. 2: Research on barriers to the implementation of projects modernizing production according to the Industry 4.0 concept. Source: Own study based on PWC report (PWC, 2017)

The high investment expenditures and a lack of clear vision and support from management are the main barriers for the development of companies. Of particular interest is the fact that the respondents indicated unclear economic benefits from computerization, thus confirming the information technology productivity paradox of Jelonek 2016.

The most recent STERLOG studies on planning indicate that logistics took over the main competence in planning processes (Fig. 3). The main reason for this aspect lies in broad access to information about resources and processes.

As means of overcoming the above mentioned challenges, the developed methodology of the Logistics Planning 9A is presented, together with the results of its application as an alternative to the currently existing and challenged methods.

Characteristics of the Logistic Planning 9A method

The Logistic Planning 9A method was developed by STERLOG Polska team as an alternative to spreadsheets and very sophisticated modeling and simulation applications such as FlexSim and Anylogic, which allow very precise modeling of processes but do not answer all logistics and planning questions. The aim of the project was to create an application allowing for very precise modeling and simulation of logistics depending on changes in important parameters of the supply chain, allowing planners to react faster to the internal and external environment changes.

Fig. 3 : Research on planning process – Participants of planning process Source: Own study based on results from 2020 survey on planning process

Planning in logistics is a long-term process involving teams of managers, specialists and consultants. The labor intensity of the planning processes, together with the expected precision of results, time pressure and the necessity of multi-variant modeling of a logistics plan are the core of every logistical enterprise. An example of challenges embedded in the development of the logistics plan are provide by the 7R canon guidelines:

1. Identification and assessment of logistical resources,
2. Market analysis on the demand and supply side,
3. Assessment and planning of the material and cash flows,
4. Assessment of the risks affecting the implementation of the plan and its progress,
5. An assessment of the economic feasibility of implementing the operational efficiency plan.

These steps are further affected by changing legal and macroeconomic environments, as well as the accompanying social and political changes, which determine the intensity of implementing corrective measures.

The Logistic Audit 9A method (Chamier-Gliszczyński and Staniuk, 2018) as been applied since 2010, specifically towards integrating process examination together with the identification of areas, where system mismatch – so-called "bottlenecks" – occur, both in management and economic terms. The procedures and IT tools used in Logistic Audit 9A provide the auditors with the possibility of carrying out process testing and their subsequent mathematical modelling aimed at eliminating the impact of sub-optimization on the economic and operational efficiency of the company.

The research-based development of the methodology and IT tools was aimed at supporting logistic planning processes in order to satisfy the needs and expectations of managers. Such a multi-faceted solution was based on the report from the Logistic Audit 9A, which is a complementary source of information for the developed methodology. The development of the supporting computer application was experience- and literature-based thus providing a coherent structure for the dynamic modelling of the logistics system (Fig. 4).

Fig. 4: Dynamic modelling of the logistics system - own elaboration

The dynamic modelling of the logistics system is associated with an integrated, multi-level and holistic approach to the process of adapting the logistics system to changes on the demand and supply side. The PL9A method is based on a process-approach towards its implementation and comprises of:

1. Testing of flowing streams of goods,
2. Inventorying and testing the suitability of logistical resources,
3. Establishment of reference quantities for the designed logistics system,
4. Development of a conceptual design for the logistics system,
5. Establishing a catalogue of logistical processes,
6. Carrying out the process of mathematical modelling,
7. Evaluation of the logistic system concept,
8. Approval and referral for further work.

The comparison of the PL9A method with those used in practice is shown in Figure 5.
An important innovation is the transfer of the logistical planning process from spreadsheets to a computer program.

Establishing reference quantities of the logistical system involves investigation of the logistical processes in relation to the results of analyzing good flows, including physical, logistical and economic parameters. In order to addresses these challenges, the classic ABC and XYZ analyses methods have been extended to better reflect the specificity of the market and logistical conditions.

Example of PL9A method implementation in supply chain management

In the year 2020, the PL9A method was used in the project to optimize the logistic system of a dairy products production company. In order to accomplish this task, the following objectives were defined in the beginning of the optimization process:

1. Improving the operational efficiency of the logistics system,
2. Reduction of external storage facilities,
3. Improving quality in logistical processes,
4. Ensuring the operational flexibility of the company's logistics system, ensuring its ability to adapt to market changes on the demand and supply side,
5. Preparation of the budget for investment outlays,
6. Development of mathematical models for the simulation of logistics cost accounting.

Fig. 5: Comparison of PL9A Logistic Planning method with the practical ones

The implementation of the work required the definition of the structure and scope of data necessary to conduct quantitative and statistical research. This required establishing the reference values characterizing the company's logistic system.

The following scope of work was conducted in order to develop a multi-variant concept for the reconstruction of the company's logistics system:

1. Process mapping,

2. Inventory and assessment of the suitability of technical infrastructure components,
3. Study and evaluation of the implementation of IT systems supporting logistics management,
4. Study of organizational structure and employment levels in logistical processes,
5. Calculation of logistics costs for the storage and distribution phase,
6. Identification of barriers and areas of systemic mismatch,
7. Development of multivariate concepts for adapting the logistics system.

The company's logistics system was characterized by the following sizes and values in Table 1.

Table 1: Characteristics of the enterprise logistics system

Pos.	Parameter	Unit	Audit phase
1	Capacity of the system	pallet unit	100%
2	Stock holding size	pallet unit	Minimum- 22% Maximum – 110 %
3	Optimal storage system capacity	pallet unit	161%
4	Balance of capacity	pallet unit	-61%
5	Number of storage facilities	unit	100%
6	Employment in warehousing processes	FTE	100%
7	Warehouse system area	m^2	100%

Eight concepts were developed in order to develop an optimal solution for the organization of the storage and distribution system. These concepts included equipment selection, cost estimates, simulating changes in logistics costs accounting for the specific nature of the technological solutions used. This included taking account of:

1. Storage equipment,
2. Internal transport equipment,
3. Systems supporting the management of logistics,
4. Construction of warehouse facilities,
5. Execution of construction works related to the adaptation of existing facilities to changes resulting from the planned changes.

Finally, the process of assessing economic efficiency included a comparison of the amount of capital expenditure related to the implementation of the planned changes and the amount of logistics costs, including costs of the storage and distribution phase.

For the purpose of this article, the two most effective concepts addressed by the project team consisting of design consultants and managers are presented. The team responsible for the development of these two concepts was responsible for production and logistical management, and was successfully evaluated by the company's Management Board.

The results of the research, conceptual and design work, as well as the costing of capital expenditure and modelling of operating costs are presented in Table 2.

The selection of the appropriate solution was preceded by an internal assessment of evaluating the effectiveness of its implementation, including:

1. Logistics cost account,
2. NPV cash flow analysis,
3. Malfunction costs,
4. Transport costs,
5. Costs of production program changes,
6. Complaint and quality maintenance costs,
7. Production and sales plans,
8. Timely delivery,
9. Costs of delays and management of changes,
10. Long-term forecasts of changes on the demand side,
11. Forecasts of long-term changes on the supply side.

The analysis and evaluation of the presented concepts, taking into account the above mentioned extended project evaluation, carried out by the management board and owners, showed the potential success of both presented variants. The final decision on which of the two variants would be chosen was postponed in order to assess the additional internal investment risk and to verify the impact of the proposed changes on the functioning of the supply chain.

Table 2: Selected results of the company's logistics system optimization using the PL9A method

Pos.	System parameter	Unit	Audit phase	Concept 1	Concept 3
1	Capacity of the system	pallet unit	100%	200%	172%
2	Optimal storage system capacity	pallet unit	161%	80%	93%
3	Balance of capacity	pallet unit	-61%	24%	7%
4	Number of storage facilities	unit	100%	33%	33%
5	Employment in warehousing processes	FTE	100%	200%	180%
6	Warehouse system area	m^2	100%	108%	108%
7	Total investment expenditures	EUR/unit	-	100%	125%
8	Investment expenditures on buildings and structures	EUR/unit	-	100%	100%
9	Investment expenditures on technological equipment	EUR/unit	-	100%	154%

The proposed logistics planning method PL9A allows quick generation of possible logistical solutions, with limited involvement and development of additional responsibilities for the operational level managers. The determination of the quantities characterizing the company's logistic system was conducted on the basis of the study of aggregated logistic data records, as well as the inventorying of resources and process mapping (similarly as published by Woźniak and Wojnarowski, 2015; Woźniak et al., 2015).

Embedding the logistic planning process in a computer application allows to shorten the process of modelling and developing a logistic plan with a limited amount of time, thus limiting the impact of risks affecting the quality of the planning process, in particular:

1. Risks of data scalability,
2. Data consistency risk,
3. Risk of elapsed time for the application process and accuracy of decisions,
4. Risk of managing dispersed, repeatedly processed data in a diverse IT environment.

In combination with the Logistic Audit 9A, the Logistic Planning 9A method allows analysis, modelling and development a project of changes in the company's logistic system within a period of up to 3 months, providing the operational level managers, management and owners a sufficient period of time to verify the project, select an appropriate option, and to convert it into an investment project with a specified payback period.

The project of optimization of the logistic system according to the PL9A method includes data verification processes and presentation of the results of analyses. The documentation, analyses and conceptual drawings prepared in electronic form make it possible to carry out the process of logistics design in conditions of limited accessibility to cost generating locations and recording logistic and economic events.

The availability of logistic data, ordered in time series, provides the consultants and designers with the opportunity to determine the size and values characterizing a company with a high level of confidence and accuracy.

Conclusions

The Logistics Planning PL9A method was applied and verified in streamlining and optimizing logistics in manufacturing and distribution companies operating in global supply chains, which are characterized by the following features:

1. From FMCG, DIY and AUTOMOTIVE industry
2. Working within international and open supply chains
3. Operating on market with independent demand

4. With both push and pull distribution system
5. With separated logistics function
6. Operating under commercial law or the capital market listed on stock exchanges
7. Size of medium and large companies
8. With implemented IT systems supporting ERP class enterprise management
9. With planning process based on S&OP method

The implementation of the PL9A method requires from organizations to meet the minimal conditions and standards:

1. Implemented ERP, WMS and TMS system
2. Separate organisational structures for logistics management
3. Recognise the function of logistics costs in management
4. Specified and quantified logistics system
5. Possessing structured logistic data from the period of min. 36 months

Logistic Planning PL9A initiates the process of implementation of integrated logistics management of enterprises operating in integrated supply chains based on resource efficiency.

For companies that do not meet the above mentioned requirements, the process of implementation of the PL9A method should be followed by identification and examination of the suitability of logistics resources combined with the assessment and determination of logistics flows according to the Logistics Audit 9A method.

In the implemented projects, the submitted changes in the supply chain management allowed companies to improve their operational efficiency ensuring a return on investment in a period of 2 to 5 years.

The application of the PL9A method is based on the study of logistics processes in combination with business processes inherent in supply chain management and the satisfaction of consumer needs. The research and the inference process, in a holistic way, reduces the risk of sub optimisation resulting from a mismatch between the logistical resources and the flows of goods described in the logistical task.

The application of the Logistics Audit 9A and Logistics Planning 9A method allows companies to identify areas of imbalance and focus on improving them in areas with a short payback period. It is worth noting that the findings of the Benefit Catalogue refer to a set of logistical resources and processes in the area of the supply chain of the surveyed company and as such improve the quality and efficiency of the supply chain performance.

Common strategic planning methods with an annual or long-term planning horizon, based on indicator and economic analyses and evaluations, do not ensure that companies are able to react quickly to demand and adapt to new trends or changes on the demand and supply side and changes in costs relevant to the economic calculation.

The close link between the consumer and the producer of goods resulting from the application of e-commerce technology, postulated in the fourth industrial revolution, shortens the distance and time to make managerial decisions, with simultaneous pressure on costs and efficiency measured by the level of consumer satisfaction with a wider range than just price. Is the decision made in the planning process carried out in the 4th quarter of the previous year still valid, effective and efficient after two quarters of the following year?

Practitioners already know how 2020 has verified the plans, methods and conclusions.

The PL9A method was successfully tested under COVID-19 lockdown conditions with 90% of work done remotely.

Measures of Mutual in Deafferenting of Technical Condition Using Computer Software

Mariusz ZOLTOWSKI

Warsaw University of Life Sciences – SGGW, Warsaw, Poland
mariusz_zoltowski@sggw.edu.pl

Abstract

In the article author identifies a possible bone of mutual vibration energy measuring application used in the study of standard rail, as part of a dedicated research methodology and detailed methodologies developed in many previous author studies. Theoretical analysis and practical verification of susceptibility testing measurement information complex vibration processes indicates a possibilities for their use.
Recognizing the need to improve methods of machines and structures testing in order to assess their degradation state - this work presents important results of the research in the verification field of the proposed measures effectiveness of mutual research bench.

Keywords: construction loads, degradation state, vibration, statistical study.

Introduction

Ensure the safe and trouble-free operation of machines and structures requires a search or improvement of tools, methods and techniques for non-invasive assessment of the emergency state. A common trend in recent years is the scheme and to organize various business areas targeted for specific purposes. Ensuring repeatable perform actions leading to the intended purpose it is possible, using a variety of situations dedicated research developed methodological procedures allowing for action in various areas.

Developed in a number of author's publications [2,7,11] vibration research methodology dedicated to solving technical problems of discipline "building" gives useful procedures endearing research issues:

- acquisition processes in the vibration tests,
- processing processes by vibration, optimization algorithms,
- evaluate the vibration processes relationship in models of decision-making,
- sensitivity vibration parameters,
- statistical inference,
- visualization analysis.

The problem description and study of changes in the components destruction, materials, design and construction are carried out using the measurement of simple and complex vibration diagnostics methods based on modal analysis [1,3]. An important issue here is the description and propagation study of useful vibration energy is already widely used in diagnostic vibration and a little less used in modal analysis methods [10,12].

In this paper the suitability test measures in the monitoring complex process of the rail connections state with the base concrete, which is associated with many problems specific railway construction. The use of composite measurements mapping the interactions measured vibration process is simpler and less subject to error than the complicated procedures simulation based on numerical methods [8,9].

Mutual measures of vibration process

Research mutual similarities processes vibration through mutual estimators allows to specify:

- interdependencies between processes;

Cite this Article as: Mariusz ZOLTOWSKI "Measures of Mutual in Deafferenting of Technical Condition Using Computer Software" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain

- correlation between sources;
- compliance within one process;
- changes in the road propagation processes in the machine and structure.

Measurement processes mutual indicate a change of source or variation in the transfer passage ways signal extortion and answers. For these measures may include [4,5]:

- cross-correlation function;
- coherence function;
- transfer function;
- FRF function *(Frequency Response Function).*

The process of measurement of the vibration are determined from the measured numerical procedures base signal, which is the value of the measured process or the two measured signals: force and the system response to put force. The concept of using vibration energy propagation of measurement uses the value of the mean square amplitude of dynamic directly proportional to the energy of the signal and written in the form [1,6]:

$$U = \int_0^T x(t)^2 dt \tag{1}$$

A measure of the propagation efficiency of vibration energy ***H*** binding force signal ***x (t)*** of forcing ***F (t)*** takes the form:

$$H = \frac{\int_0^T x(t)^2 dt}{\int_0^T F(t)^2 dt} \tag{2}$$

Due to the large range of amplitudes of vibration signals is a deliberate to use logarithmic scale for comparing the numerical values of these measures:

$$H_{[\log\ ]} = \log(H) \tag{3}$$

Large potential research opportunities creates the analysis results described in the form of a matrix using measures built at different intervals integration or preprocessed waveforms.

The concept measures the propagation of vibration energy refers to the Parseval's theory [7], which indicates the identity of the signal energy presented in the time and frequency domains:

$$\int_{-\infty}^{\infty} x^2(t)dt = \int_{-\infty}^{\infty} \left|X(f)^2\right| df \tag{4}$$

It is thus possible to define the measure of vibration energy propagation also in the frequency domain, and then the equation (2) becomes:
