The European Commission's "Green Paper: Promoting a European Framework for Corporate Social Responsibility" as of 2001 describes CSR "as a concept whereby companies integrate social and environmental concerns in their business operations and their interaction with their stakeholders on voluntary basis." (European Commission Green Paper, 2001) The definition stresses the main points, that CSR involves social and environmental issues of business strategies, and it is based on the principle of voluntarism. Besides that, the definition points out the importance of engagement of internal and external stakeholders, the internal stakeholders being primarily employees and shareholders (this involves such issues as investing in human capital, health and safety, and managing change), while the external stakeholders are business partners and suppliers, customers, public authorities and NGOs representing local communities, as well as the environment. (Ibid.) The Green paper strives to answer four main questions regarding CSR. (1) What is the role of CSR in corporate business strategies? (2) What are the best ways to establish and develop a process of structured dialogue between companies and their various stakeholders? (3) What should be the respective roles of the main actors? (4) What are the best means to develop, evaluate and ensure the effectiveness and reliability of CSR instruments? Another approach is related to the problem of corporate social performance, i.e., the ways companies act in the society and how responsive they are to the societal demands. Donna J. Wood (1991) admits that the basic idea of corporate social responsibility is that business and society are interwoven rather than distinct entities; therefore, society has certain expectations for appropriate business behavior and outcomes. However, a review of the literature shows that attempts to specify principles of CSR have not distinguished among three conceptually distinct though related phenomena: expectations placed on all businesses because of their roles as economic institutions, expectations placed on firms because of what they are and what they do, and expectations placed on managers (and others) as moral actors within the firm. When these three phenomena (institutional, organizational, and individual) are being distinguished, it is possible to stress the performance aspect of the corporate social responsibility. The author proposes the following scheme: principles of corporate social responsibility comprise legitimacy (the institutional principle; public responsibility (the organizational principle); managerial discretion (the individual principle). This helps to define processes of corporate social responsiveness (environmental assessment, stakeholder management and issues management), and outcomes of corporate behavior, such as social impacts, social programs, and social policies. (Ibid.) The identification of specific responsive processes shows the channels through which companies act out their involvements with the external environment, whereas incorporating social impacts, policies, and programs as the collective outputs of a company's environmental interactions accounts for more pragmatic approach on the strategic management level.

Impact of corporate social responsibility on companies' competitiveness has been discussed among others by M. Porter and M. Kramer (2006) in their article "The Competitive Advantage of Corporate Philanthropy." In their opinion, corporations can use their charitable efforts to improve their *competitive context* – the quality of the business environment in the location or locations where they operate. Using philanthropy to enhance context brings social goals into alignment and improves a company's long-term business prospects. (Ibid.) According to them, the company's competitive context consists of four interrelated elements: factor conditions, or the available inputs of production; demand conditions; the context for strategy and rivalry; and related and supporting industries. Analysis of these factors can identify areas where economic and social values overlap and possibilities for increasing business competitiveness in a more context-focused way. The similar problem is being brought about also by R. Dobrea and A. Gaman in their article "Aspects of the correlation between corporate social responsibility and competitiveness of organization." (2011) Summarizing vast amount of literature on the subject the authors have pinpointed three main approaches to the corporate social responsibility. First, addressing CSR as an obligation to the shareholders, activities designed to increase its profits so long as it stays within the rules of the game. This entails that maximizing profits for shareholders is the central concern of any organization, while socially responsible activities and initiatives are not the companies' concerns. Second, addressing CSR as an obligation to all stakeholders. According to this point of view, the organizations are not only responsible to their shareholders / owners, but they also should take into account the divergent interests of those social groups affected by the company activities, or those who can also influence the fulfillment of corporate goals. Third, addressing CSR as an obligation to society. This perspective emphasizes that organizations are responsible to society, by the fact that they are open systems and constantly interact with the social environment. (Ibid.) The authors find positive correlation between corporate social responsibility and microeconomic competitiveness that leads to better economic performance. These common issues are: guidance on the values of ethics; common interests of the stakeholders,

employees and shareholders; dependence on the production process or service quality; dependence on the quality of human resources; dependence on organizational culture and performance orientation, as well as medium and long-term orientation. Although the main goal of business organizations is to produce profit, under the pressure of they must redefine their strategic goals to achieve business success that complies with obligations to shareholders, social welfare and environmental protection. De Sousa Filho and others address the question of the strategic corporate social responsibility management. They state that there are three types of social investment (altruistic, selfish and strategic) and that the strategic investment creates better results for companies that try to simultaneously achieve the maximization of both profit and positive advantages to society and local community. It also consists of additional benefits to the company – enhanced reputation and qualifies staff, the differentiation of products and extraction of premium price. Thus, companies can add value and obtain competitive advantage through socially responsible activities. It is important that they should relate to the corporate strategies. (De Sousa Filho *et.al*. 2010) All these approaches, however different, seek create and exploit win – win situations for enterprises and for society at large. CSR is increasingly recognized as being about having good business practices and its impacts are contributing to an organization's reputation and performance. The latter is becoming more and more important as the value of business becomes more and more reliant on intangible elements. (Vasilescu et.al*.,* 2010)

Still our interest of the current study lies specifically with the corporate social responsibility in retailing, therefore in what follows we present a brief overview of the literature in the field. Although, in general, all the categories and characteristics of the CSR are applicable to the sphere of retailing, there are some idiosyncratic features to be mentioned here. Thus J. Anselmasson and U. Johansson (2007) distinguish three main attitude-based dimensions – human responsibility, product responsibility, and environmental responsibility. The human responsibility is related to the principles of fair-trade, the product responsibility refers to full and user-friendly information about the content of goods, whereas the environmental one regards the eco-friendly, free of chemicals shopping opportunities for customers, as well as eco-disposable packaging. There are studies devoted to the supply chains in the retail sector that conclude that in the case of mega-retailers there exist a myriad of social risks, such as, threat of child labor, local farmer and natural environment abuse. (Jones et al., 2007) In other words, the longer the retailing supply chain, the greater possibility of irresponsibility. All in all, the CSR issues in the retail sector can be divided along the following lines (Martinuzzi et al., 2011):

- Fair-trade, support of local producers; organic produce
- Protection of natural environment, energy use and waste reduction, recycling;
- Product safety, distribution of eco-goods and local produce;
- Ethical trading
- Employment policies and working conditions, health and safety at work, discrimination, corruption, foreign labor;
- Sustainability, corporate reputation;
- Charity, philanthropy, support for local communities, social, educational and environmental programs;
- Consumer loyalty and purchasing behavior.

The specific role of e retailer is the one of the gatekeeper between the producer and the consumer in the supply chain, therefore, it is important to study the impact of corporate social responsibility from the viewpoint of consumers. One of the most recent investigations in the field is the one conducted by H. Schramm-Klein and others, entitled "Retailer corporate social responsibility is relevant to consumer behavior" (2016). The authors have developed the according conceptual model that consists of six interrelated elements: perceived CSR activities+perceived retailer attributes lead to consumer loyalty and eventually to purchasing behavior; the process is influenced by CSR credibility and CSR orientation. The authors conclude that in retail consumer perception of the combined CSR activities and retailer's attributes has a greater impact on loyalty rather than purchasing behavior. Generally, the study also reveals that most consumers are not fully aware of the CSR activities, thus the ongoing communication at the point of sale is very important for keeping consumers informed about company activities. (Ibid.) E. Herpen and others (2003) distinguish two main aspects in perception of the retailers' social initiatives - the beneficiary of the activity and the intrinsic contribution of the retailer. In other words, consumers want to know profit of the beneficiary and how much the retailer invests in the activity. This entails that the best way to convey a high level of CSR, and thereby increase consumer trust and store evaluation, is to focus on activities that both benefit society and require a high level of contribution. T. Wagner and others (2008) in their research have tried to identify the critical spheres of corporate social responsibility in retailing, that is, the spheres that could be perceived as irresponsible by the consumers. They have put forward 14 different aspects (in the ranking order): societal rules, employee discrimination, local working conditions, dishonesty, pricing policies, natural environment, employee benefits, foreign labor, employee wages, local businesses, local employment, offensive material, foreign economies and sales practices.

Customer satisfaction and loyalty in retailing

Customer satisfaction is a significant indicator of any company performance. It can be defined as S. M. S. Rana and others define it as felling or attitude of a consumer towards a product/service after it has been used. It can be measured by the fact if consumer's expectations have been met fully, partly or not met at all. (2014) Still, by and large, the main determinants of the customer satisfaction, according to the previous research, are: customer service, brand variety, store environment, location, shopping convenience, product quality, service, price, promotional campaigns, personnel interaction, etc. (Ibid) Though all these factors are of a real importance from the customers' viewpoint, it should be mentioned that this list has some serious omissions, namely, we can't see here customers evaluation of the retailers' social, environmental and communal activism. In our opinion, the social dimension of the retailing that includes, for example, such aspects as responsible attitude to environment and recycling, employment policies and participation in social projects can strengthen company's competitive power. The satisfied customer also will recommend and patronize to other customers for choosing the according retailer, this is a basis of good reputation and a dimension of sustainability. (Irshad et al. 2017; Luo & Bhattacharya, 2006)

It is possible to classify the description of the customer satisfaction in relation different marketing tasks (see Fig 1).

Fig. 1: Characteristics of consumer satisfaction approaches

Thus, for example, I. Howard and I. Sheth state that the customer satisfaction is a cognitive situation of the customer, that comes about because of the adequate or inadequate award (the result of shopping). (Howard & Shets, 1969) Emotional reaction has been stressed by R. Oliver (2010) who concludes that the customer satisfaction is a complex psychological state grounded in combination of expectations and after buying experiences. I. Engel and R. Blackwel (1993), in their turn, pinpoint the aspect of alternative choices, namely, evaluation if the chosen alternative meets the expectations. The situation with customer satisfaction in the retail trade is rather different since the retailer is a mediator in the distribution channel between the producer, the supplier and the end user. Therefore, to ensure the customer satisfaction the retailer must influence producers and/or distributers (wholesalers) by the means of orders, contracts, etc., as well as they must foster collaboration with them. Besides that, the retail trade adds an additional value to the goods through the sorting, prepacking, packing and other actions. The retailers provide the customer service in the traditional shops, outside the shops and through the internet sites. From these specific features of the retailing there follows that the customer satisfaction rests upon provision of both material products (goods) non-material products (services). This influences the (all stages of the customer satisfaction formation in the realm. The level and intensity of the impact depends on service level (large outlet, small store, etc.), sales mode (traditional shop or selling outside the shop) and other factors. These factors are well described in the article "Consumer satisfaction in retail stores: theory and implications" (Paul et al., 2016) The authors conclude that the consumer attitudes which are the significant predictors of shopping satisfaction are being classified in the following way: those favorable to large formats, those favorable to small formats and those who hold neutral attitudes (no specific preferences). Their research suggests that there are two factors (deal proneness and shopping economy) that have a reasonable predictive power regarding shopping satisfaction, while there are differences in other attitudinal dimensions among regarding the large outlets and small stores. Namely, the small store customer satisfaction depends on the social desirability, the shop location, the staff friendliness, but the outlet customer satisfaction is closely tied with overall shopping experience (including the entertainment and dining facilities), the shopping ambience (atmosphere, announcement, music, navigation, etc.) and family shopping opportunities (including, for example, the kids' corner with adult supervision). (Ibid.) The customer satisfaction is a step toward the customer loyalty.

Building customer loyalty in retailing

The phenomenon of customer satisfaction is one of the preconditions to long-term and profitable relationship with customers formation that, in its turn, leads to the customer loyalty. Attraction of new customers to businesses is significantly more expensive than retaining the existing ones, since the regular consumers spend more, but cost less to the company itself. (Karjaluoto et. al., 2012). The research in the field has demonstrated that the acquisition of new consumers costs 5-7 times more than serving the existing consumers. Essential also are the studies about the importance of developing consumer attitudes towards the offers before the purchase process (attitudinal loyalty). (Backman & Compton, 1991; Day, 1969) The one the most influential research of loyalty has been accomplished by R. Oliver (2010). He does not object to the statement that the process of loyalty formation is rooted in the customer attitude, nevertheless he offers his four consecutive dimensions model (see Fig 2).

Fig. 2: Loyalty model of four consecutive dimensions (Oliver, 2010)

This model presupposes the knowledge/information about the produce and the store, the emotional attitude (I buy because this offer appeals to me), the aspect of reliance (I buy because I trust this offer), everything comes together in the behavioral loyalty. So, the loyal customer exhibits such characteristics: they are buying more and buying more often, they maintain their loyalty in the case of price increase, they recommend brand/store/service to other potential customers.

Summing up the previous research in the field, the authors of the current article have come up with the specific features of the customer loyalty in the realm of retailing:

1) Customer can be loyal to the outlet/store due to the following factors: availability of the product/brand he is satisfied with, satisfaction with the product/price ratio, satisfaction with the service quality, social factors;
2) Perception of the afore mentioned factors depend on the geographic, demographic, economic, social and psychological characteristics of the target audience, though the importance of the factors can differ (e.g., despite the satisfactory price level, service quality the customer can still be not loyal in case of unavailability of the necessary product/brand);
3) Unlike other industries, the retail trade can have a fairly large number of the false loyal customers (making purchase only due to the advantageous location of the store) and the ones who although satisfied, are not re-purchasing, since they focus on sales and price discounts;
4) The attitudinal loyalty relates mainly to the product/brand values and the relation "product / brand value - consumer expenses", but the behavioral loyalty - to service quality. Therefore, it is imperative to pay attention to both dimensions of loyalty;
5) The consequences of consumer loyalty are different, but the main thing about it is to make repeated purchases. Other signs of loyalty - low price sensitivity and positive "mouth-to-mouth" communication are less typical because they concern specific products/brands rather than retailers.

A few researchers have paid attention issues regarding the impact of the corporate social responsibility to the customer loyalty. (Berens et al. 2005; Golob et al., 2008; Stanaland et al., 2011; Sindhu & Arfi, 2017) The studies disclose both theoretically and empirically that the ethical standards as determinants of commitment to the corporate social responsibility activities have a significant impact on the customer loyalty. They show also that it is a matter of high relevance to inform customers about the CSR activities of the retailer (via Facebook page, Instagram, newsletter, printed statement, etc.).

To the current investigation the authors have worked out the conceptual model of the CSR impact on the customer satisfaction and eventually on their loyalty (see Fig 3).

Figure 3: Conceptual model of CSR impact on customer satisfaction and loyalty

The current model puts forward three aspects of the corporate social responsibility that are decisive in the realm of retailing – (1) employment policies and attitude to employees; (2) responsible attitude to environment (including retailers' orientation toward the local and eco produce, recycling, etc.); (3) organization of and participation in the social projects decisive (different charity projects, social marketing activities, etc.).

Results and Discussion

Retail enterprises as a member of the product distribution chain fulfill such functions: eliminates the disproportion of demand and supply, conducts the inventory management, facilitates the efficiency of product transportation, assembles goods in accordance with the consumer needs, establishes contacts and organizes discussions with product suppliers, serves consumers, sells goods and services to them, carries out marketing activities and takes on the risk that the process of goods distribution works smoothly. Because of these functions, the value of products and the value of consumption increase. (Kotler & Keller, 2006; Best, 2005)

The role of the retail trade in the development of the country's economy is evidenced by such indicators as turnover and its fluctuation (see Fig 4).

Fig. 4: Retail trade turnover in the Baltic countries (csb.gov.lv., 2018)

To evaluate the factors of consumer satisfaction and loyalty formation and their relation to the corporate social responsibility in Baltic countries the authors employed the survey method (the questionnaire). (Rust et al., 2004) The survey was carried out in all three Baltic countries – Latvia, Lithuania and Estonia. Considering the aim of the research and characteristics of the respondents the standardized questionnaire was used. All respondents were offered the similar statements in the identical order, the evaluation was according to 5-point Likert scale. The non-probability snowball sampling method was used to gather information, namely, the first set of respondents were contacted by the means of e-mail, they, in their turn, identified the next set of respondents, and so on. As the result 1446 questionnaires were admitted as valid: 673 from Latvia, 388 from Lithuania, and 385 from Estonia (the population – residents of all countries). According to 95% data accuracy, the research sample size was calculated as 385 respondents (min.). (Doane & Seward, 2011) The respondents (consumers) answered questions about factors that influence their choice of supermarket – assortment of goods (including the local and eco produce), price level, product placement and shopping convenience, marketing activities, service quality, attitude to employees and

employment policy, responsible attitude to environment, as well as participation in the social projects and organizing them. The results are depicted in the Table 1.

Table 1: Factors influencing consumers' choice of supermarket

Customer service quality	Mean	Median	Mode	Standard deviation	Dispersion	Variation	Min	Max	Sum
Product assortment, incl. local and eco produce	3.97	4.00	4.00	0.75	0.57	0.04	1	5	1753
Price level	3.54	3.00	3.00	0.82	0.67	0.05	1	5	1565
Product placement and shopping convenience	3.05	3.00	3.00	1.04	1.09	0.08	1	5	1346
Marketing activities	3.94	4.00	5.00	1.09	1.19	0.06	1	5	1742
Service quality	3.99	4.00	4.00	0.96	0.92	0.05	1	5	1762
Attitude to employees and employment policy	3.33	3.00	3.00	0.87	0.76	0.06	1	5	1472
Responsible attitude to environment	3.68	4.00	4.00	0.77	0.59	0.05	1	5	1627
Participation in social projects	2.68	3.00	3.00	1.08	1.16	0.09	1	5	1185

The answers to all the questions were processed and analyzed by the SPSS program. As it follows from the table 1, the respondents regard quality of service as the most important factor ($\bar{X}$ = 3,99; Me = 4,00; Mo = 5,00). Then there follows assortment of goods, including also availability of the local and eco products (3,97; 4,00; 4,00), marketing activities (3,94; 4,00; 5,00), responsible attitude to the environment (3,68; 4,00; 4,00), price level (3,54; 3,00; 3,00), attitude to employees and employment policies (3,33; 3,00; 3,00), as well as placement of goods and shopping convenience (3,05; 3,00; 3,00). Of all criteria the lowest value was assigned to the one of participation in social projects and organizing them (2,68; 3,00; 3,00). It should be noted, that variation level in all criteria was slight (0.04-0.08), it means that the differences in customer opinion are quite insignificant.

After evaluation of the supermarket choice factors, the respondents were asked to evaluate the impact of these factors while really shopping. To do that the blocks of questions were formed, the answers allowed us to see the reasons behind the answers and to verify their credibility. Results are depicted in the Table 2.

Table 2: Consumers' evaluation of supermarkets

Customer service quality	Mean	Median	Mode	Standard deviation	Dispersion	Variation	Min	Max	Sum
Product assortment, incl. local and eco produce	3.64	4.00	4.00	0.84	0.71	0.05	1	5	1608
Price level	3.78	4.00	4.00	0.99	0.97	0.06	1	5	1670
Product placement and shopping convenience	3.38	3.00	3.00	0.96	0.92	0.06	1	5	1496
Marketing activities	3.42	3.00	3.00	0.81	0.66	0.05	1	5	1510
Service quality	3.15	3.00	3.00	0.93	0.86	0.07	1	5	1393

Attitude to employees and employment policy	2.88	3.00	3.00	0.94	0.89	0.07	1	5	1271
Responsible attitude to environment	3.15	3.00	3.00	0.93	0.86	0.07	1	5	1393
Participation in social projects	3.99	4.00	4.00	0.96	0.92	0.05	1	5	1762

As we can see from the table 2, the customers assigned the highest value to company's participation in and organizing the social projects ($\bar{X}$ = 3,99; Me = 4,00; Mo = 4,00), then follows price level (3,78; 4,00; 4,00), assortment of goods and shopping convenience, including availability of the local and eco products (3,64; 4,00; 4,00), marketing activities (3,42; 3,00; 3,00), product placement and shopping convenience (3,38; 3,00; 3,00), the similar value are assigned to service quality and responsible attitude to environment (3,15; 3,00; 3,00). Of all criteria the lowest value was assigned to the attitude to employees and employment policies (2,88; 3,00; 3,00). There is insignificant variation level regarding all criteria.

It is useful to compare the factors of customers' supermarket choice and evaluation of the real situation. The graphical depiction of these indicators (see Fig. 5) and their comparison allows us to conclude that the mean indicators of the assortment of goods (including the local and eco produce), the marketing activities, the attitude to employees and the employment policy, as well as the responsible attitude to environment in the view of supermarket evaluation are lower than the ones of the supermarket choice. These differences entail that the consumers' expectations were not fully met, and supermarkets must work to improve the situation. On the other hand, the mean indicators of the price level, the product placement and the shopping convenience, as well as the participation in the social projects are in the view of supermarket evaluation are higher than the ones related to the consumers' choice of supermarkets. Still, we believe that here is the place for improvement. The situation in the market can change rather quickly due to changes in the internal and external environment of the retail trade enterprises. At the same time, the certain steps taken in the direction of the ethical business practices can facilitate changes in the consumption patterns (for example, the corporate social responsibility of the enterprise can become a significant factor of the supermarket choice).

Fig. 5: Comparison of the factors influencing consumers' supermarket choice and indicators of supermarket evaluation (arithmetic means)

Conclusions

The results of the research make it possible to come to the following conclusions:

1. The consumers in the Baltic states exhibit comparatively low level of the loyalty coefficient to the enterprise. The retailers do not use all possibilities to attract and retain customers yet. The increase of the consumer loyalty would entail the increase of the company value, on one hand, and, on the other hand, it would bring profit to the economy in general.

2. Comparison of the factors influencing the supermarket choice with the supermarket evaluation by the consumers show that five criteria of supermarket choice (the assortment of goods, including the local and eco produce, the marketing activities, the service quality, the attitude to employees and the employment policy, the responsible attitude to environment) received higher scores than the same criteria in the actual evaluation.
3. The fact that in supermarket actual evaluation the highest score was assigned to the social activities of the enterprise attests to the changes in the consumers' perception, namely, activities related to the corporate social responsibility can significantly increase the customers' loyalty to the enterprise level.

Abstract

The sustainable development of society is based on the synergy of many sub-areas and approaches relating to the development of society and conservation of natural resources. The social development is, in many cases, achieved regardless of sustaining the stable environment. The contemporary society has been evaluating these conflicting requirements for decades by means of intersectional solutions of multicriteria mathematical models.
Having evaluated scientific publication sources, this paper aims to identify sets of criteria that can be used for multicriteria assessment of the use, protection, and maintenance of water resources. The results of multicriteria models are used as an evaluation factor within the framework of ensuring the sustainable development of the society and as a factor of competitiveness and adaptability of accounting units.
The outcome of this work is to design a structure of criteria for the use of multicriteria assessment of management processes of organisational units, based on which it is possible to evaluate approaches to the protection and maintenance of water resources in terms of sustainable development in production and non-profit organisations.

Keywords: Water resources, sustainable development, multicriteria evaluation, competitiveness.

Introduction

Water resources are an indispensable element to life on the entire planet. Their protection and rational use pose a significant problem of the present social consciousness. Water resources are classified as free goods, which historically led to the underestimation of their importance and uneconomical use. In recent decades, the limitation of their usability due to changing climatic conditions has been added, which leads to the deterioration in the availability and quality of drinking and service water resources.

The sustainability of water resources as an essential part of human life is faced with the insurmountable boundary of synergy of society´s main requirements - increasing production to meet human needs. As surface water is becoming scarcer and precipitation is more and more variable, the reliance on groundwater reserves for agricultural use is expected to increase. In this respect, nature conservation measures and economic incentives for agricultural production to maintain the vitality of agricultural communities come into play. Tools for conservation planning and management of groundwater, the use of suitable land resources and the protection and maintenance of biological diversity are being put into practice. (Bourque et.al., 2019)

The issues of the use of water resources are becoming evident on a global scale. In connection with the increasing population and improving living standards, the demand for water is also increasing. Reducing the availability of fresh water across the Earth can cause harm to human health and reduce or eliminate crop yields. Monitoring the status and level of water resources is included among the security risks of states.

Problem Formulation

Based on the need to determine the current state, there are models of water resources availability that have been used for several decades and which should monitor the development of this issue and support the sustainable development (Kaewmai et al. 2019 or Li, Chen, Singh et al. 2020).

Current research in individual countries focuses on a comprehensive overview of groundwater use and evaluation of its renewability. Groundwater (GW) resources provide a large share of the world´s water demand for various sections such as agriculture, industry, and drinking water (Naghibi, Hashemi, Berndtsson et al. 2020). A special attention is paid to the interaction between groundwater consumption, its replenishment, and the quantity of surface water, which is crucial in the assessment of sustainable groundwater consumption. The authors (Mukherjee and Singh 2020) show that the overexploitation of groundwater impairs its properties and increasingly leads to situations when arid/semi-arid rural areas are more and more vulnerable to the risks of groundwater scarcity. Many studies use the groundwater analysis to identify the impact of climate fluctuation - for example, Margues et al. (2020) specifically in the Alto Grande basin in north-eastern Brazil.

To reuse water shows to be one of the ways of how to use water resources sparingly. Water reclamation and ecological reuse are gradually becoming a popular solution to address the high pollutant load and insufficient ecological flow of many urban rivers. However, emerging contaminants in the water reuse system and related risks to human health as well as environmental risks need to be assessed (Lin, Xu, Keller et al. 2020). Reclaimed water can be used in different applications that affect performance in economic, environmental, and social dimensions. However, the inadequacy of technologies and the economic burden in the case of new technological processes do not allow this issue to be assessed appropriately in full and estimates of the future availability of water resources are therefore very uncertain. It is necessary to overcome significant problems in data acquisition and research (Bierkens and Wada 2019). A separate group of studies focused on the removal of undesirable elements from water for the purpose of its further use can be traced. These include the removal of manganese, ferrum and antibiotics from water simultaneously by oxidation (Du, Yang, Liu et al. 2020) or the removal of arsenic in groundwater using Slag based calcined layered double hydroxides (Zhou, H., Ai, J., Gao, H. et al. 2020) and, last but not least, the removal of fluorides (Yan, Chen, Zhang, et al. 2020).

Continuous and local monitoring of the use, protection and sustainability of water resources is one of the fundamental issues to evaluate the society´s sustainable development within the selected state. This situation must be evaluated by the multicriteria mathematical models using specific criteria and by determining their significance by the criterion weight. An interesting approach to selecting weights is the one of Sun, Li and Deng (2020), who combine the negation of probability distribution with the theory of evidence to reduce the uncertainty caused by the subjective determination of weight coefficients of various criteria using a questionnaire survey, and who propose a method to determine weights for multicriteria decision based on the negation of probability distribution. According to them, the quantitative evaluation of the criterion fuzzy degree reduces the uncertainty caused by human subjective factors and the subjective error is corrected to a certain extent.

Results

Water resources have two basic functions in the sustainable development of society:
1) the natural function - the basis of all life and
2) the utility function – the production potential.

Water consumption must be assessed not only in terms of the internal impact (economic costs), but also from the external impact on the environment (sustainable development). This issue therefore applies not only to production units, but must also be addressed in non-profit organisations, state administration and even in individual households. Problems in the protection and sustainability of water resources can be grouped into the following problem areas:

- falling groundwater levels due to climate change,
- pollution of water resources due to intensive production activities in agriculture and industry,
- excessive economic burden of development and use of new technologies to reduce water consumption,
- improper use of foreign chemical substances in large-scale farming,
- accumulation of antibiotics and hormones from wastewater due to imperfect technologies of sewage treatment plants,
- reducing water seepage into the lower layers due to soil solidification and compaction as a consequence of the use of heavy mechanisms,
- groundwater contamination due to floods,
- low level of literacy of the population concerning the issue of using water sparingly.

The observed criteria in the field of protection and maintenance of water resources can be divided into three areas (economic, environmental and social), which are interconnected, and in terms of sustainable development it is necessary to seek solutions in the intersection sets of their impact by means of multicriteria models.

Economic area:

- Economic results of accounting entities
- Costs of availability of water resources in the monitored area
- Competitiveness of accounting entities
- Setting and regulating the government´s subsidy policy
- Penalisation of interventions in the landscape due to production activities
- Financial risks - diversification of water resources
- Investment intensity of new technologies when using water resources
- Financial costs of operation of new technologies

Environmental area:

- An amount of annual precipitation in the monitored area
- Deviations of precipitation from the average during the year
- Capacity and availability of water resources
- Quality and availability of water resources
- Biodiversity of crops in sowing procedures
- Landscape biodiversity in the monitored area

Social area:

- The employment rate in the monitored area
- The cost of living in society
- The educational policy in relation to the issues
- The population´s access to information
- The moral approach and responsibility of entities in relation to the conservation of water resources
- Crisis situation management (droughts, floods)

Decision-making situations are based on the above-mentioned interconnected criteria, where the output solution consists of a compromise set of variants, which contains the optimal impact of decision-making criteria. All monitored parameters must complement and interconnect one another in order to achieve sustainable availability of the essential resources. For this purpose, multicriteria evaluation models are used where values of subjective or generally beneficial preferences of decision-makers also enter into the analysis of decision-making situations. These are based on the values of proposed variants V = (v1, v2,…, vn) and on the list of evaluation criteria K = (k1, k2,…, kk). Each variant Vi (i = 1, 2,…, n) is described by a vector of criterion values (y11,…, ynk) for which a mathematical model of the criterion matrix containing vectors of criterion values is constructed.

$$Y = \begin{bmatrix} y_{11}, y_{12}, \ldots, y_{1k} \\ y_{21}, y_{22}, \ldots, y_{2k} \\ \ldots \\ \ldots \\ y_{n1}, \ldots\ldots\ldots, y_{nk} \end{bmatrix}$$

Fig. 1 : Multicriteria matrix for assessing the selected indicators. Source: own processing, 2020.

The monitored criteria are variable in terms of evaluation and their quantities are:
a) objectively identifiable - quantities of absolute values,
b) ratio - the probability of occurrence,
c) scale - subjective, technical scoring.

To calculate the multicriteria model, real values must be entered for the individual criteria. This is exceedingly difficult when addressing the environmental impacts, as most of the criteria in this area are based on subjective assessment. Grading and rating scales are used for this purpose. Various methods (classification, scoring, binary scale, ratio, interval, etc.) can be used to set the values. To express the preference of certain criteria, it is possible to use

either the order of importance or to determine the weight of individual criteria, which can again be based on numerous methods of determination (the scoring method, the weighted sum, etc.) (Triantaphyllou 2000).

The criteria are significantly influenced by the weighting value of individual factors that are variable in time series, which requires setting the coefficient of determination. Model situations must be assessed in longer time series with respect to the variability of natural conditions in a given locality (Kraatz et al., 2019). The decision-making space is not only determined by the structure of the process, but also by the structure of their mutual relations and objectively existing constraints. The individual criteria are set as minimizing or maximizing. The basic problem in solving decision-making situations by quantitative methods is their system quantification and approaches to limit the set of permissible variants of this decision-making space.

A set of the so-called non-dominant variants, containing the best evaluation of the mentioned criteria set in varied proportion, is created by solving the mathematical model. It is possible to identify the theoretically best (ideal) variant and the worst (basal) variant from the output solutions.

Research Limitations

The use of multicriteria models for assessing the use and protection of water resources in production and other organisational entities enables us to better understand the structure of the observed issues and to better focus on selected criteria.

When evaluating the observed issues, it is necessary to consider the two main risks, namely the risk of incorrect selection of evaluation criteria and the risk of incorrectly set weights of criteria. Both risks can be eliminated by using experienced and highly competent evaluators from various areas of the issues under consideration. To use multidisciplinary teams of researchers is a complete must in order to solve these situations.

Conclusion

This paper proposes the structure of multicriteria assessment of the use, protection and conservation of water resources. A similar multicriteria modelling approach was used in the study by Karunanidhi, Aravinthasama, Deepali et al., 2020, namely to understand the chemical evolution of groundwater, the entropic water quality index to assess the suitability of groundwater for human consumption and the overall hazard index to determine possible non-carcinogenic risks to children, women and men in the industrial area (South India). The multicriteria analysis using the Fuzzy UTASTAR method was also used by Haider, Singh, Ali et al. (2015) to assess the sustainability of surface water quality management in developing countries. Five main sustainability criteria (SSC) are considered in this model - including cost (capital, land and operational), land requirements, operation and maintenance issues, environmental impacts, and socio-economic impacts. In addition, several sub-criteria (impacts) have also been included to rationally justify the assessment of SSC by the decision makers.

The multicriteria approach to the evaluation of the mentioned water issues also found justification in the field of water erosion (authors: Guidoum, A., Nemouchi, A. and Hamlat, A., 2014), or more precisely in the sustainability of water management (authors: Chung, E-S. & Lee, K. S., 2009) - in this study, the authors also dealt with the appropriate way to determine the criteria weights and decided on the process of analytical hierarchy.

The research by Latinopoulos (2008), which aimed to develop a methodology that would be suitable for estimating possible environmental, economic and social impacts of irrigation water prices, is the closest one to the proposed model in this article, composed of sets of economic, environmental and social aspects. The authors of this article have thus verified the applicability of the model and will apply it in their further research, namely on water resources of the Czech Republic.

Non-uniform Application of International Uniform Law – Reasons, Consequences, Remedies

Daniel DABROWSKI

ORCID 0000-0003-3072-5267
University of Szczecin, Szczecin, Poland, daniel.dabrowski@usz.edu.pl

Abstract

Conventions that include private law norms play a special role among international agreements. Their objective is to streamline rules concerning a specific legal measure. Convention on Contracts for the International Sale of Goods (CISG) and conventions on contracts of carriage of goods in individual branches of transport have such a character. Provisions of these conventions regulate legal relationships between entities under private law. They are applied directly by national courts if a given convention is applicable to a given legal relationship.

Adopting a convention and bringing it into force does not end the process of unifying the law. Law is truly uniform if it is uniformly applied by national courts in individual countries which are parties to conventions. However, it is difficult to achieve.

The aim of this paper is to demonstrate obstacles in courts' uniform application of conventions that comprise private law norms and negative effects of non-uniform application of such conventions. Methods that can serve to strengthen the unity of application of conventions are also specified. Appointment of advisory bodies which issue non-binding opinions on the interpretation of provisions of a given convention is a plausibly effective solution when certain conditions are met.

The analysis of legal acts and of judicial decisions of national courts from various countries and the European Union are the research methods applied by the author. Literature studies have also been carried out in order to obtain the broadest possible picture of the discussed issue.

Keywords: uniform law, unification of law, transport law, CISG, CMR.

Introduction

Unification of private law, which started in the 19th century, greatly facilitates international trading. Significant success in this area was achieved mainly in the field of transport. Contracts for carriage of goods in all most important branches of transport were uniformly regulated under a convention. Carriage by sea and by air was uniformed on a global scale, while carriage by rail, by road and by inland waterways on a regional scale. Contracts for carriage of passengers by air and by rail and (though to a small degree) by sea were also uniformed. Many world countries signed the Convention on Contracts for the International Sale of Goods (CISG). Other conventions on various types of contracts did not get such popularity, though they also play a certain role in international trading.

Reaching an agreement while working on a convention is not an easy task. It is because various, often conflicting interests of countries that are to become parties to the convention need to be taken into account. Searching for solutions that can be accepted by states with different traditions and legal systems (especially the common law and the civil law system) also causes difficulties. Likewise, it is difficult to ensure uniform application of the convention by national courts of countries that are its signatories. Failure to apply the convention uniformly ruins the effects of unification of the law. Such trends, called renationalisation of unified law in the literature, can be observed especially in relation to some conventions and are a serious obstacle to unification of private law (Munday, 1978, pp. 451-452; Gebauer, 2000, p. 684; Rajski, 1999, pp. 415-416).

Two elements make up uniform application of a convention. First of them is uniform interpretation of its provisions. It is essential that provisions of a convention be interpreted autonomously, that is without reference to terms and concepts characteristic to a national legal system (Gebauer, 2000, p. 686; Felemegas, 2002;

Cite this Article as: Daniel DABROWSKI "Non-uniform Application of International Uniform Law – Reasons, Consequences, Remedies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Ribeiro-Bidaoui, 2020, pp. 146-147). Such a rule of interpretation results i.a from the provision of Article 31 of the Vienna Convention on the Law of Treaties (VCLT) which are applied also to conventions unifying private law (Gebauer, 2000, 692; Czapski, 2006, p. 553-554; Hoeks, 2010, p. 137-141; Verheyen, 2016, p. 442). Due to the fact that the Convention codified earlier norms of customary law, these rules may be applied as well in the interpretation of international agreements which entered into force before VCLT. Pursuant to the said Article 31 VCLT, "a treaty shall be interpreted in good faith in accordance with the ordinary meaning to be given to the terms of the treaty in their context and in the light of its object and purpose". Conventions unifying private law (their preamble or the content itself) usually name their purpose, which involves unification of rules on a specific legal measure. This purpose needs to be taken into account when interpreting the convention's provisions. Similar interpretative guidelines also include some conventions unifying private law: CISG (Article 7(1)) "In the interpretation of this Convention, regard is to be had to its international character and to the need to promote uniformity in its application and the observance of good faith in international trade") and Convention concerning International Carriage by Rail (COTIF) (Article 8(1): "When interpreting and applying the Convention, its character of international law and the necessity to promote uniformity shall be taken into account").

The second element of uniform application of the convention is related to the method of removing the so-called internal gaps in the convention, that is issues which were not regulated therein despite the fact that they do, as a rule, fall under the matter regulated by the convention. Such gaps should not be removed by reference to national law but by application of other methods allowing similar results in different countries irrespective of the content of the national law. CISG includes clear guidelines on removing the gaps. Pursuant to Article 7(2) CISG "Questions concerning matters governed by this Convention which are not expressly settled in it are to be settled in conformity with the general principles on which it is based or, in the absence of such principles, in conformity with the law applicable by virtue of the rules of private international law". There is no precise equivalent of this provision in carriage conventions, but the views developed on its ground may be helpful to a significant degree in solving problems arising against the background of the carriage conventions (Dąbrowski, 2018, p. 94-99).

"Renationalisation" of unified law - causes and effects

Ensuring uniform application of law is a difficulty not only in reference to conventions unifying private law. National law also often features discrepancies in judicial decisions or views of legal scholars and commentators on interpreting specific provisions. The main reasons for such discrepancies is language deficiency, where the language is a tool of communication, and a lack of precision in non-linguistic methods of interpretation. However, other reasons hamper a uniform interpretation of provisions of international conventions.

First of all, conventions are made in one or two authentic languages. Texts of conventions in these languages should be the basis of interpretation of these conventions (Article 33(2) VCLT). Discrepancies in individual language versions may cause a certain difficulty, but Articles 33(3) and (4) VCLT give guidelines on removing them. However, what is more important is the fact that authentic languages of a convention are usually not official languages of countries-parties to this convention. Then a natural trend among entities applying the law (usually courts) is to reach for a translation of the convention into an official language of a given country. Meanwhile, the translation is already in itself a certain "interpretation" of the authentic text; interpretation that is not always perfect and often defective (Ambrożuk, 2018, pp. 166-171). Basing on a translated text may, then, lead to erroneous outcomes of interpretation and result in non-uniformity of application of the convention.

Secondly, rules of interpretation feature great differentiation in legal systems of individual countries. As a principle, these rules should not be applied in interpreting provisions of international agreements. As pointed out above, in such a case the court should use interpretation according to the guidelines provided in Articles 31-33 VCLT, or analogical rules resulting from established international customs. However, in practise it is difficult to get detached from the adopted behaviour patterns. Also, the methodology of the profession of a lawyer is differentiated in different countries. Common law lawyers first refer to case-law, look for precedence. Civil law lawyers are first likely to look for answers in commentaries and literature. Results of interpretation may also be significantly affected by differences in legal culture and tradition.

Thirdly, in the national law there are usually mechanisms that encourage unification of interpretation of provisions. The discrepancies that occur in the case law are usually removed in a longer run thanks to judicial decisions of higher instance courts, especially national supreme courts. Their decisions, even if not binding on lower instance courts in a given legal system, outline directions of interpretation of the law. Therefore, they help maintain uniformity of its application. This also refers to provisions of conventions that unify the law, which thanks to judicial decisions may be uniformly applied in the territory of a given country. However, positive effects of judicial activity do not usually cross country borders. Judicial decisions issued in reference to a specific convention by national courts are not usually known in other countries and adjudicating courts do not take them into account. There are, in fact, exceptions from this rule, though not frequent. At the same time, there is no international court which could uniform interpretation of conventions on a global scale, that is in reference to all countries that are its

contracting parties. Only the Convention on the Contract for the International Carriage of Goods by Road (CMR) stipulates the possibility of appeal at the International Court of Justice (ICJ). Pursuant to its Article 47, "Any dispute between two or more Contracting Parties relating to the interpretation or application of this Convention, which the parties are unable to settle by negotiation or other means may, at the request of any one of the Contracting Parties concerned, be referred for settlement to the International Court of Justice". This provision, however, is a dead letter and during close to sixty years of validity of the convention, no dispute concerning its interpretation or application was filed at the ICJ. The clause included in Article 47 CMR is typical to international agreements that govern relationships between countries (entities under international law). However, it cannot fulfil its function in the case of conventions that unify private law (Wesołowski, 2013, p. 77). Discrepancies in the application and interpretation of conventions affect individuals, not countries. Individuals cannot be parties to proceedings before the ICJ and courts cannot refer questions to the ICJ for a preliminary ruling in individual cases.

Fourthly, results of the process of interpretation of uniform law may also be affected by political factors. Countries which are parties to conventions - even those which unify private law - often have divergent interests. It is clearly noticeable on the example of sea conventions. A marked dispute between "biggest flag states" and countries without their own fleet has been noticeable for years, which in fact makes it impossible to adopt a new convention governing carriage of goods by sea which would replace the old-fashioned Hague–Visby Rules. This conflict of interests may also play a role in the process of interpretation of the law. The courts of "biggest flag states" may tend to interpret it in favour of carriers, while courts of countries that do not have their own fleer may tend to favour shippers. Another example is a conflict about application of the so-called unimodal conventions (that is concerning a specific branch of carriage) to multimodal carriage. This dispute is especially significant on the ground of CMR. The problem boils down to answering the question whether CMR applies to the road leg of the journey where one agreement for multimodal carriage was signed (e.g. involving carriage by air and by road). In the well-known ruling of the English Court of Appeal of 27 March 2002 in *Quantum Corporation Inc. and others v. Plane Trucking Ltd.* the English court ruled for application of CMR in such a case assuming that the term used in Article 1(1) CMR "contract for the carriage of goods" applies also to an agreement on the basis of which the carrier committed to carry by a vehicle or by other means of transport (in separate legs of the carriage). It needs to be emphasized that the ruling in the discussed case was given excellent reasoning. The court examined both language versions of the Convention, reviewed case-law of foreign countries, etc. However, it is not ruled out that the final result of the process of interpretation could have been influenced by the English courts' inclination to "appropriate jurisdiction", that is to favour an expanding interpretation of provisions on jurisdiction so that the English legal system achieves a leading role in examining international disputes. It is interesting that the same problem was resolved differently by the Dutch Hoge Raad in a ruling of 1 June 2012 in *Goðafoss*, where the court abstracted from the previous, seemingly regulated, line of judicial decisions. The judgement could also have been politically motivated here. Interpretation which excludes application of CMR to a road leg of multimodal carriage eliminates the conflict between CMR and the Rotterdam Rules - a new convention regulating carriage performed at least partially by sea (including multimodal carriage). Therefore, it is possible that adopting such an interpretation of Article 1 CMR was influenced by a desire to promote the Rotterdam Rules and to "fit" CMR to them.

Fifthly, uniform application of the convention may also weaken the manner of filling internal gaps in the Convention. Filling gaps should occur either by means of the so-called analogy within a convention or by reference to general rules on which the convention is based (Felemegas, 2002; Brander, 1999; Dąbrowski, 2018, pp. 94-99). Only when these rules prove inefficient should one refer to the relevant national law. Meanwhile, thoughtless recourse primarily to solutions that result from national law is relatively frequent. Such a measure is to some extent understandable since usually it is the easiest way to fill the gap, though it does not encourage unity of application of the law.

It may also be added on the side that non-uniformity of application of the convention may be also a result of a reference to the national law included in the convention (Calme, 2016, p. 61). There are relatively many references like this in carriage conventions, especially in CMR and Uniform Rules concerning the Contract of International Carriage of Passengers by Rail (CIV – Appendix A to COTIF). An example here may be a reference in Article 29(1) CMR, which stipulated that "the carrier shall not be entitled to avail himself of the provisions of this chapter (...) if the damage was caused by his wilful misconduct or by such default on his part as, in accordance with the law of the court or tribunal seised of the case, is considered as equivalent to wilful misconduct". As a result of this reference, the degree of due care which is required from carriers by e.g. German courts is significantly higher than the one required by the courts in the Netherlands (Hoeks, 2010, p. 115).

Non-uniform application of conventions unifying private law results basically in a lack of legal security. Parties to an agreement are not certain as to the regime under which the agreement will be performed, especially which regime will apply in the event of failure to perform or the improper performance of the obligation. Resolution of this dispute may be different depending on the country in which the dispute will be examined. One needs to add at that that usually more than one country has jurisdiction for adjudicating the dispute. Lack of legal security increases the so-called friction costs thus hindering the operation of small and medium-sized enterprises (Hoeks, 2010, p. 16).

The phenomenon of forum shopping is also a consequence of non-uniform application of conventions. It involves the contracting parties looking for jurisdiction which in a given situation may be "more favourable" to that party. This phenomenon, naturally, has plenty more reasons than non-uniform application of international conventions (Fuchs, 2005, pp. 407-423). In cases examined under CMR which usually concern damage to the cargo it often adopts the form of a "race" to court. Each party of the dispute tries to initiate proceedings earlier in a jurisdiction that is favourable to it. The claimant, therefore, initiates proceedings for damages before a court of a country in which the line of judicial decisions is less favourable to carriers. Whereas a carrier tries to initiate proceedings to establish that they are not liable for the damage in a country known to have a more lenient approach to carriers. Initiating proceedings before one court excludes - in line with the Court of Justice's case-law - conducting proceedings before another (Ambrożuk, 2015, pp. 197-209). This is why each party tries to be quicker than the other in filing a claim. A side effect of such rivalry may involve higher litigation costs (Fuchs, 2005, pp. 410-411).

Methods of Counteracting The "Renationalisation" of Unified Law

Counteracting non-uniform application of conventions is not an easy task. There are profound reasons for this. Exchange of information about rulings passed in national courts, manner of interpretation of provisions of conventions, manner of filling internal gaps, etc. are especially important. Such activity is taken up by i.a. international organizations, research centres and also organizations of stakeholders of specific conventions. One of the aspects of information activity involves creating databases (Ribeiro-Bidaoui, 2020, pp. 155-157). A huge database concerning CISG kept for more than 20 years by the Institute of International Commercial Law operating at the Elisabeth School of Law at Pace University is especially noteworthy. This database includes convention-based decisions issued by courts of many countries that are parties to the convention, as well as scholarly materials and abundant references. A similar database, though significantly smaller, concerning CMR is kept by Institut du Droit International des Transports. United Nations Commission on International Trade Law (UNCITRAL) keeps the CLOUT database which includes decisions of national courts of various countries of the world that address legal instruments developed under the auspices of UNCITRAL. The significance of the discussed databases cannot be appreciated enough. They allow comparative studies, a search for solutions that are common to various systems and a search for established lines of judicial decisions. Undoubtedly then, they counteract "renationalisation" of unified law

A more direct method would be to appoint an international court which could issue preliminary rulings for questions referred by national courts, or possibly examine complaints for national courts' decisions based on the provisions of conventions. Establishing such a court (regardless of whether it would be to deal with one convention only, or a selected few or all conventions unifying private law), it does not seem possible (Ribeiro-Bidaoui, 2020, p. 152). It would require cooperation of many countries and a political will which is missing. However, it is worth noting the significant efficiency of this manner of ensuring uniformity of law application, which is confirmed by the activity of the Court of Justice of the European Union. Admittedly the activity of the Court of Justice is sometimes criticised, but there are no doubts that it is a guarantee of uniform application of European Union law. One needs to add at that that the Court's case-law may also influence the unity of interpretation of the discussed conventions. This stems from two reasons. First of all, in the light of Article 267 of the Treaty on the Functioning of the European Union, the Court of Justice may adjudicate in preliminary rulings i.a. on the interpretation of international agreements that the European Union is a party to. Therefore, the Court may interpret provisions of COTIF (and under its framework – the appendices to COTIF concerning transportation of passengers by rail (CIV) and carriage of goods by rail (CIM)), of the Convention for the Unification of Certain Rules for International Carriage by Air (MC) and of the Athens Convention relating to the Carriage of Passengers and their Luggage by Sea (PAL). These are the conventions that the European Union acceded to. Irrespective of this, CIV and PAL were implemented into the Union's law thus becoming annexes to regulations issued by the European Parliament and the Council. The Court of Justice can also interpret these regulations. Of course interpretation done by the Court of Justice will not be binding on countries that are not members of the European Union. However, one may assume that due to the prestige of the Court of Justice they will be taken into account also by courts of countries that are not part of the Union. Secondly, the Court of Justice has already issued decisions which formally interpreted provisions of acts of Union's law, but in practice the Court interprets convention provisions in them. The judgement of 4 May 2010 in *TNT Express Nederland BV v. AXA Versicherung AG* (C-533/08) and of 19 December 2013 in *Nipponkoa Insurance Co. (Europe) Ltd v. Inter-Zuid Transport BV* (C-452/12) may provide examples here. In both of these judgements the Court indirectly interpreted provisions of Article 31(2) and (3) CMR. Legal commentators point out that the Court exceeded its competence in these judgements and violated autonomy of international law (Wesołowski, 2011, pp. 133-142). Not questioning this allegation, one needs to note a positive aspect of the Court's decisions, that is unification of application of Article 31(2) and (3) CMR, at least in countries that are EU members.

Unification of law may also be supported by the activity of committees that issue opinions on certain problems associated with the interpretation of a convention. Such a committee which deals with CISG ((CISG Advisory Council (CISG-AC)) has been operating since 2001 at the aforementioned Institute of International Commercial

Law. At the moment it is composed of 17 members, mainly scholars, specialists in international trade law. So far CISG-AC has issued 20 opinions concerning interpretation of the convention. These opinions were cited in 29 national courts' decisions in cases examined on the basis of CISG. The activity of CISG-AC is assessed positively enough to formulate a postulate on appointing a similar body which would interpret CMR provisions (Legros, 2017, pp. 27-30). This postulate is justified in all respects. CMR has great significance to carriage by vehicles. The scope of its application is still growing and covers practically the entire Europe, part of northern Africa and a significant part of Asia. It translates into the number of cases examined on the basis of provisions of this convention. Expanding the scope of application of the convention increases the risk of non-uniform interpretation of its provisions. Hence the greater need to take actions intended to maintain this uniformity. Efficiency of such an advisory council would depend on a few factors. Firstly, it would have to be composed of persons with great prestige, renown specialists of transport law. Secondly, it would have to be an independent body not influenced by CMR stakeholders. In particular, such a council could not act under the auspices of any organization of carriers, since there would be a risk of failure to maintain the necessary balance between interests of carriers and claimants. Thirdly, the activity of the council would have to be adequately publicised, promoted, so that national courts that apply CMR are familiar with them.

Summary

Unification of private law is a long process. It does not stop at adopting a convention that standardizes a specific measure. What is necessary is to ensure uniform application of its provisions. In a majority of cases there is no such institution that could safeguard this. European Union's accession to certain conventions relating to the contract of carriage creates an opportunity for the Court of Justice to issue rulings concerning provisions of these conventions, which may significantly affect national courts, also in countries that do not belong to the European Union. Irrespective of this, it is necessary to use other methods that encourage uniform application of unified law - information, education or promotion of certain solutions. Responsibility for uniform application of law rests with national courts. Failure to understand the weight of this responsibility may lead to disintegration of unified law and its renationalisation.

The Subject Matter of Mandate Contract as Defined by The Polish Civil Code – Polish Codification and Foreign Influence

Krzysztof KUBASIK

ORCID 0000-0002-3122-4539
University of Szczecin, Szczecin, Poland, krzysztof.kubasik@usz.edu.pl

Abstract

Contracts of mandate have a long history and date back to the law of ancient Rome. Over the centuries, mandate contract has been substantially modified, in particular with regard to its subject matter and admissibility of remuneration. Another important aspect is the historical connection between mandate contract and the power of attorney. Mandate contract has also undergone major changes in the Polish law. Under the current Civil Code, its subject matter is the performance of acts in law, which is a significant limitation compared to the previous model. The aim of the paper is to analyze its legal status and modifications made, including comparison of with the Swiss model which served as a benchmark for the Polish codification, in particular the mandate contract governing provisions set out in the 1933 Code of Obligations. However, adoption of solutions similar to the Swiss model caused a lot of interpretative confusion. In consequence, its legal status had to be amended and its subject matter narrowed down to the performance of legal acts. Ultimately, after long years, the Polish model took a different shape. The main goal of changes implemented in the Polish legal system was to prevent interpretative doubts created by the too wide contract's subject matter. However, the objective has not been achieved. In view of the above, the opinion that mandate contracts with broad subject matter, encompassing legal and factual acts, would be a better response to current social and economic needs is justified.

Keywords: mandate contract, service contract, Polish legal system, Swiss legal system, proper application of law

Introduction

Foreign influences on the shaping of legal institutions in other legal systems are often fairly strong. Such practice is justified as it allows to adopt proven solutions and eliminate ones that do not meet the needs of social relationships. Analysis of legal solutions applied in other states is not an easy task, as it has to take into account the political, economic and cultural specifics of legal systems, without discounting national differences and the conditions they will operate in.

From the historical perspective, the way the mandate contract, being a key agreement regulating the provision of services, evolved over time in the Polish law is interesting. Analysis of these changes allows not only to follow the path of its evolution that culminates in the present day model, but also appreciate the significance of legal and comparative research.

Mandate contract was already known in ancient law, and over the centuries, its role and conceptualization underwent significant, and sometimes even dramatic, changes with regard to the contract's subject matter as encompassing performance of legal and factual acts, remuneration for the acts performed and the connection with the power of attorney. Each of these key aspects was regulated differently, often in the extreme, over the centuries, from mandate contract covering only legal acts for which remuneration was not payable and bound to the power of attorney, to the other extreme, that is a contract whose subject matter is also the performance of factual acts, both paid and unpaid, clearly distinct from the power of attorney.

The complexity of the subject matter inspired the author to analyze the Polish legal system in this respect, and to make an overview of historical evolution and foreign influences on the Polish mandate contract model.

Mandate contract in Polish civil law; reference to proper application of mandate contract governing provisions to other service contracts

Mandate contract is regulated in the Polish law by art. 734 et seq. of the Act of 23 April 1964 – the Civil Code (CC)(Journal of Laws 2020, item 1740). A number of factors, including political and economic, influenced this regulation since the process of codification of the Polish civil law was initiated in the interwar period and continued after world war II in the socialist system which focused on production geared towards satisfying economic and human needs, and marginalized the "un-productive" service sector.

However, an analysis of the solutions adopted in the Polish Civil Code reveals that these regulations draw from other legal systems and, interestingly, Western European systems despite Poland being in the Soviet sphere of influence.

The observation that the mandate contract model that took decades to shape drew, to a high degree, from other legal systems, will be followed by a historical and legal and comparative analysis. What is more, in recent decades the regulation was not amended, therefore the author dares to ascertain that the final model is not only stands the test of time, but also performed well in completely different socio-economic conditions.

As already mentioned, the regulation of the subject matter started with the provisions of art. 734 Civil Code, with § 1 stipulating that the mandatary entering into a mandate contract is obliged to perform a definite act in law for the mandator. The Polish Civil Code does not mention the historical connection of the mandate contract with the power of attorney, and while this connection is not that strong in the Polish system as in other legal systems, still art. 734(2) CC provides that in the absence of other agreement, the mandate contract gives authority to perform acts or transactions on behalf of the mandator. This provision does not preclude the provisions on the power of attorney. Adoption of the principle that a mandate contract includes also authority to perform legal acts is justified inasmuch as the subject matter of the mandate contract is limited only to the execution of legal acts. Essentially, conclusion of a mandate contract has a binding effect, i.e. imposing an obligation on the mandatary to perform a definite legal act, but also an authorizing effect by conferring the power to perform a definite legal act for and on behalf of the mandator. However, the parties may agree that the mandatary will act for the mandator, but on his own behalf, and will be obliged to return to the mandatory whatever they gained from the contract. The Polish legislator adopted a principle that for the performance of mandate contract remuneration must be paid save as otherwise provided in the contract (art. 735(1) CC).

The narrow subject matter of a mandate contract certainly affects its practical significance, thus questioning the above thesis that it is fundamental to contracts for the provision of services, in particular with regard to the important role of services consisting in the performance of factual acts or a combination of factual and legal acts. It should be pointed out that the regulation of mandate contract has an additional, and broad scope of reference arising from art. 750 CC. The provision stipulates that: "Mandate contract governing provisions shall apply to service contracts which are otherwise not regulated by other provisions of law". Thus, the subject matter of a mandate contract is the performance of a legal act, yet through reference to proper application of the mandate contract provisions, these provisions are also applicable to other legal relationships which may consist in performance of factual acts or a combination of factual and legal acts. The formula used ensures some flexibility since proper application of the provisions means that some of them will be expressly applicable (without any modifications), whereas others will need to be modified, and yet other will not be applied as not relevant to the nature of a legal relationship (e.g. provisions about the power of attorney cannot be applied to services consisting in the performance of factual acts) (Nowacki, 1964, p.372).

Such regulation gave rise to significant interpretative doubts. Essentially, the scope of reference is analyzed each time, depending on the kind of unregulated service provision agreement doubts pertain to. It was also noted that the reference contained in art. 750 CC may in fact asserts the fundamental role of mandate contract among various service contracts, making it a benchmark model and, moreover, complementary to the legal regime for regulations of "other service provision contracts". However, the dominant view is that in fact, this reference is applicable to other service contracts which are not, or only in part, statutorily regulated. Thus, the reference would encompass a variety of unnamed contracts, but would not apply to other, named service contracts, i.e. regulated by law. Some also claim that by virtue of art. 750 CC, the mandate contract provisions can be properly applied to other named service contracts with regard to aspects which have not been regulated by the legislator (however, in case law such practice tends to be explained as interpretation *per analogiam*).

The subject matter is even more complicated by the confusion about the set of service contracts regulated by law and contracts included therein (Ogieglo, 1985, p. 56. According to this author "the codified service contracts include: mandate contract, agency agreement, commissioned sales agreement, transport agreement, forwarding agreement, storage agreement, warehousing agreement, bank account agreement and the so-called hotel agreement. Contract for specific work and construction work contract are treated as a separate group of contracts based on their material scope

and construction distinction"). Significant differences in this regard can be seen in the legal doctrine, focusing mainly on the nature of specific work contract and construction work contract.

The issue presented above still raises doubts, definitely compelling from the theoretical perspective, but also having important practical implications. It seems that a legal and comparative analysis of the said regulation, including an overview of its historical evolution, may have some significance for the proper interpretation of the said provisions of law.

The influence of the Code of Obligations on regulation of the contract of mandate by the Civil Code

The act which has the biggest impact on the currently applicable regulation of the contemporary law of obligations was the Ordinance of the President of the Republic of Poland of 27 October 1933 – Code of Obligations (Journal of Laws 1933, No 82, item 598). It also set out legal provisions regarding the provision of services which, to a large extent, were re-enacted in the present Civil Code. Sosniak (1981, p.61) points out that, quote, "Regulation of service contracts by the CC was in fact, as most of the regulations detailed in book III, a modified replica of the interwar legislation". Grzybowski (1967, p.1278) argues that, quote, "The new code approached the contract of mandate traditionally, re-enacting most of the content and structure of provisions from the Code of Obligation.". Therefore, it is essential to look into the legal environment that became the foundation for the future legal system.

Pursuant to art.498(1) Code of Obligations (CO), the contract of mandate is an agreement under which the mandatary undertakes to perform a definite act in law for the mandator. Compared to the presently applicable regulation, the difference is that in the CO the material scope of the mandate contract encompassed both legal and factual acts. Thus, there is another essential difference in the defining scope of the contract application which today is limited to legal acts only, and had a much larger scope in the previous code. This is why the mandate contract's leading role among service contracts was only logical, both with regard to service contracts regulated by the CO, and referred to the Ordinance of the President of the Republic of Poland of 27 June 1934 – the Commercial Code (Journal of Laws 1934, No 57, item 502). The broad material scope lay grounds for the mandate contract as one of the basic service contracts, justified even more by the absence of subjective limitations and the contract's flexibility (Ogieglo, 1985, p.51, including references cited therein).

However, the material scope of mandate contract was extended beyond that by the provisions set out in art. 498(2) of the Ordinance, which provided that, quote, "Service contracts, unregulated as a special kind of contracts, are subject to provisions regarding the contract of mandate.". In consequence, the mandate contract became a legal framework for regulation of a broad variety of commercial relationships consisting in the performance of both factual and legal acts. The role of art.498(2) CO was to extend the scope of application of the mandate contract provisions to encompass also "all kinds of factual acts provided that there are no features of other service contracts" (Szpunar, 1976, p.389, including references cited therein). It is worth adding that even in the early stages, that is when the drafts of the obligation law were being developed, in the works by Longchamps de Berier and Till the mandate contract had a narrower scope, limited only to legal acts.

Since the mandate contract could encompass the execution of legal acts, art. 499 CO adopted a principle that in such situation, in absence of another contract, the contract of mandate should embrace the authority to perform acts on behalf of the mandator. The historical connection between the mandate contract and the power of attorney was reflected also in this regulation as justified by the subject matter of the obligatory relationship. Another principle was that remuneration was due for the performance of the mandate contract.

However, the very broad material scope of the mandate contract regulation and its flexibility gave rise to interpretative confusion. At the time of defining the subject matter of the mandate contract as a "definite act", almost all relationships in which one party assumes the obligation to perform some acts for the other party qualified under the regulation (Sosniak, 1981, p.64, including references cited therein). In attempts to resolve the issue, prior to subjecting a given legal relationship to the mandate contract regulation, a "negative qualification" was made, i.e, mandate contract governing provisions were applied to a contract only if it did not fall within the regulation of other service contracts. Moreover, the Ordinance contained a separate chapter (chapter XI) titled "Service contracts" with seven sections regulating various commercial relationships, including work, specific work contract and mandate contract. However, there were also other kinds of service contracts operating in the legal system, such as e.g. the ones regulated by the Commercial Code.

Now, therefore, the applicatory scope of the mandate contract in the CO was much broader than the model in force today. Interpretative issues that occurred with regard to the understanding of the "acts" triggered a change in the defining elements of the mandate contract. The model applicable today, despite the fact that a vast majority of the

provisions of the Code of Obligations was reenacted in the Civil Code, is significantly different from the old model, a change inspired by the experience of using a too-broad a definition of mandate contract (Ogieglo, 1985, p.53).

The other elements that affected the shape of the subject matter of the mandate contract, i.e. the foreign models, are also worth analyzing.

Swiss law and its influence on Polish codification

It is commonly claimed that the way mandate contract and in general, service contracts, were regulated in the CO was affected by the solutions adopted in the Swiss law (Ogieglo, 2011, p.559; Szpunar, 1976, p. 389).

First, it should be noted that the detailed part of the Code of Obligations, often referred to separately, provided a grouping of contracts according to their similarities or economic purpose (Longchamps de Berier, 1938, p. 443). The structure of the act, i.e. the pooling of different types of contracts into systemic categories was modeled on the solutions adopted in, i.a. the Swiss and German law (Longchamps de Berier, 1938, p. 443).

The Polish legislation on mandate contract was significantly influenced by the Code of Obligations adopted in Switzerland on 30 March 1911, becoming the fifth book of the Swiss Civil Code (Bundesgesetz betreffend die Ergänzung des Schweizerischen Zivilgesetzbuches. Fünfter Teil: Obligationenrecht). In turn, this regulation was hugely modeled on the earliest version of the Code of Obligations, adopted in 1881, which was influenced by French and German legislation (Macierzynska-Franaszczyk, 2014, p. 103; Schwenzer, 2012 p. 2; Bucher, 2004, p. 107).

The mandate contract was regulated by Title XIII of the act, with section 1 regulating what was called a "simple agency contract". Pursuant to art. 394 (1), quote, "By concluding an agency contract, the agent undertakes to perform certain legal or factual acts, remuneration for which is payable or not, in the interest and according to the will of the principal." (translated by: Macierzynska-Franaszczyk, 2014, p. 106; cf. Zabinski, 1972, pp. 114-115). The scope of application of the agency contract regulation is extended by the next provision – art. 394(2) which provides that „Contracts for the provision of work or services not covered by any other specific type of contract are subject to the provisions governing agency" (Zabinski, 1972, p. 115). Pursuant to art. 394 (3), remuneration is payable where agreed or customary. The scope of agency is defined in art. 396 (2), which provides that an agency contract includes, in particular, the authority to carry out transactions as are required for the performance of the contract. It can be thus concluded that one of the key elements of a mandate contract is the concern for the best interest of the principle and readiness to act as required for the performance of the contract.

The mandate contract has major practical significance in the Swiss law, in particular the simple agency contract (Macierzynska-Franaszczyk, 2014, p. 106), which is due to, i.a., the option to ensure the right to remuneration (Zabinski, 1963, p.12). The mandate contract covers a very broad scope of legal relationships regarding the performance of both legal and factual acts. In this way, the regulation comes close to the original conceptualization of this contract as expressed in the Roman law, and additionally, a definite separation of mandate contract from contract of lease was made. However, it should be noted that such a broad scope of the said contract may raise doubts when classifying specific relationships according to statutory types of contracts. To solve this issue, Swiss lawyers refer to the division of contracts into contracts of due diligence and contracts of result (Macierzynska-Franaszczyk, 2014, p. 106; Honsell, 2012, p. 7).

It is thus evident what inspired the authors of art. 498 Polish Code of Obligations. The material scope of mandate contract in the Swiss law is rather broad, as it encompasses legal and factual acts, and the obligation to perform legal acts is connected with the authority to undertake such acts on behalf of the principle. The provision of such services may be for a fee or free of charge (though this principle looks different in the two legal systems). In essence, the main solutions of the Polish codification are remarkably similar to the Swiss legislation, thereby confirming that the Swiss model was the source of inspiration for the authors of the Polish CO.

Despite the fact that the currently applicable CC re-enacted the provisions regarding the contract for specific work contained in the Code of Obligations and that the two regulations are tellingly similar, they differ significantly with regard to the material scope of the contract. However, the practice of application of provisions demonstrates that the limitation of mandate contract to the performance of specific legal acts did not, in fact, eliminate interpretative doubts. And yet, this is not due to the imprecision in defining the subject matter of the contract, since the subject matter of the obligation consisting in performance of certain legal act may constitute sufficient grounds to distinguish this contract from other types of service contracts. In fact, the interpretative confusion is created by the second scope of reference of the mandate governing provisions set out in art. 750 CC which instructs that these provisions should be applied to otherwise unregulated service contracts. It seems thus that the mere narrowing of the subject of the mandate

while retaining the principle of proper application of its provisions to other types of service contracts, the subject matter of which may be the performance of factual acts, could not have brought about a desired result.

In fact, the model adopted in Poland perpetuates the classification problems regarding the distinction between specific work contract and mandate contract, in the case of which – and it is same under the Swiss law – the division into contracts of result and of due diligence is applied. Furthermore, a narrow subject matter of the mandate contract also creates another problem regarding the separation of a traditional mandate contract, i.e. performance of legal acts, from contracts which are a combination of legal and factual acts. Such situation is unwished for, therefore today there are proponents of the old regulations, modeled on Swiss law, calling for their reenactment.

Summary

Polish codifiers of the interwar period carried out a lot of legal and comparative studies, the findings of which often influenced the regulations adopted. This was also the case with the mandate contract modeled, to a large extent, on the Swiss law, which in turn reflected the influence of the great 19th century codifications, including the French and German civil codes.

The main goal of the Polish mandate contract governing provisions was to eliminate interpretative doubts and the confusion regarding the qualification of legal relationships. However, these problems have not been solved and the role of mandate contract, with a narrow subject matter application, was limited.

Based on the experience gained from application of mandate contract's governing provisions in the Swiss and Polish legal system, the Polish legislator adopted different solutions with regard to the subject matter of the contract. As a matter of fact, the narrow model adopted in the Civil Code while maintaining the reference to proper application of the mandate contract's governing provisions to unregulated service contracts is a factitious measure, and – as it seems today – not suitable to the needs of present day market which is overly dominated by the service sector.

Abstract

There is a maxim repeated by goods and services providers in Poland which says that „advertising is the leverage of trade". In market economy, new goods and services proliferate causing market expansion and increased competition. In such a challenging environment businesses have to strive to reach the target audient with their products and services. Therefore, advertising is ubiquitous in modern day society, and its volume is increasing dramatically worldwide. Whatever advertising media are used, it is undeniable that endorsement - which uses images or names of public figures or celebrities who command a high degree of trust or recognition to promote a product or service - increases the chance that a potential consumer will purchase the product advertised. Unsurprisingly, increasingly more businesses opt for celebrity endorsement as there is an undeniable appeal in a famous actress lending her image to a face cream or a famous footballer to a sneakers' brand. However, from the perspective of consumer protection law, using celebrity endorsement in advertising is not so indisputable and arbitrary. Consumers are the weaker party of the legal relationship, and they are protected by the law not only the moment they enter into an agreement and after its conclusion, but also prior to that, which is why the use of celebrity endorsement is to some degree restricted.
This paper explores the issue of celebrity endorsement in the context of consumer rights and consumer protection law on the basis of case studies exemplifying the presentation of medicinal products by celebrities or health professionals. The author applied a number of research methods, and focused mostly on the analysis of Polish regulations in the context of the legal doctrine and case law. The research methodology also includes references to consumer protection laws of other countries, an approach that enabled a comprehensive analysis of the subject.

Keywords: Consumer, Advertising, Consumer Protection, Image Advertising.

Introduction

Television, Internet, public space – advertising surrounds us from all sides. For some, it is a way to generate funding for their ventures, whereas for others it is a way to present their products and brand. Interestingly, according to the data collected by the National Broadcasting Council of Poland for 2015, a staggering 24% of all commercials broadcasted in popular tv channels were commercials of drugs and pharmaceuticals (KRRiT report). Moreover, as per the data collected by Starcom, an international media network, the value of the pharmaceutical industry advertising sector in Poland in 2019 was just second to the entire goods and services advertising sector (Starcom report prepared by nowymarketing.pl).

These data vividly demonstrate the huge spending on pharmaceutical advertising and its significance for the entire advertising sector. Multinational pharmaceutical corporations go to great length, just as other businesses, to reach their target groups and increase sales through advertising. In fact, advertising is an important driver of the whole economy. The attractiveness of advertising messages and credibility of celebrity endorsers are the factors that sell or do not sell a product. i.e. determine whether people succumb to advertising or not. It has been proven that the appeal or attractiveness of an advertisement is enhanced if celebrity endorsement is used, in particular if the celebrity or public figure is recognized as a credible person, lending his/her credibility to the brand or product (Mylek, 2015, p. 84).

The aforementioned issue has significant consequences in the legal context in view of the fact that one of the primary tasks of the legislator is to protect the weaker parties of a legal relationship. In the entrepreneur – consumer relationship, the consumer is, undoubtedly, the weaker and more vulnerable party (Judgment of the Supreme Court, III SK 24/14, LEX). Therefore, it is so important for the consumer law to encompass not only the moment of entering into a legal relationship, but also the things that happen prior to that, such as the way goods and services are presented

in advertisements. And although in Poland there are no major restrictions on using celebrity endorsement for the promotion of general goods and services, such restrictions exist with regard to the marketing and advertising of pharmaceuticals.

Pharmaceutical products, that is prescription drugs and over-the-counter drugs, are a special kind of products, as their consumption directly affects people's health and life. A complete, unregulated freedom in creation of drug commercials would infringe on safety of potential consumers. Definitely, a recipient of commercials has little information about the promoted drug than its producer, and very often is not able to interpret the advertiser's intentions if they are not conveyed clearly enough. Therefore, both the Polish and European legislator have enforced a number of restrictions on endorsement of drugs, i.e. the use of images of some persons, in order to protect consumers against unfair market practices.

The using celebrity images in advertising from the perspective of consumer protection law is very complex, which is why in this paper this issue was explored in the context of pharmaceutical products' advertisements. The paper's purpose was to analyze Polish regulations in this regard in correlation with the doctrine and case law. This research was supplemented by a comparative analysis of equivalent regulations applicable in other countries.

Misleading Advertising

Since this paper intends to explore the relationship between product endorsement advertising and consumer protection law on the example of pharmaceutical ads, the aspect of misleading advertising will also be analyzed in relation to the advertising of drugs. In Poland advertising of medicinal products is primarily regulated by the Act of 6 September 2001 Pharmaceutical Law (Journal of Laws 2020, item 944, as amended (PhL)). The Polish legislator divided medicinal product advertising into two categories – advertising of medicinal products addressed to the general public (advertising of over-the-counter drugs) and advertising of medicinal products addressed to professionals, that is persons qualified to prescribe them or to persons trading in them (mostly prescription drugs). Such division stems from the EU regulations and is the result of implementing the Directive 2001/83/EC of 16 November 2001 on the Community Code relating to medicinal products for human use (OJ L 311, 28.11.2001, p. 67–128, to date). The advertising of drugs has been similarly regulated in Australia, where it is also prohibited to advertise prescription drugs to the general public (Doran, 2013, p. 24). In contrast, in the United States, advertising of prescription drugs can also be targeted at the general public (information retrieved from the U.S. Food and Drug Administration official website, Parekh, Shrank, 2018, Makowska, 2016, p. 156).

In the context of consumer law, advertising of drugs addressed to the general public are more important as they affect consumers directly and impact their purchase decisions.

Misleading advertising may also be involved in celebrity endorsement advertising. This is why first the author shall explain how "misleading advertising" is understood in the general context.

Advertising of medicinal products, just as all other types of advertising, may not be misleading as one of the basic consumers' rights is right to (truthful) information, which was also emphasized by J.F. Kennedy's speech on 15 March 1962. Advertising may not convey false, misleading or deceptive information about the product and its features or effects (Nowinska, 2012, LEX). According to the Polish case law and legal doctrine, an instance of misleading advertising (alternately, false advertising) occurs even if the purchase agreement is not concluded. A consumer may not buy the drug advertised, but it is sufficient that the advertising generates false beliefs about the product in an individual (Judgment of the Supreme Administrative Court, NSA II GSK 962/08, Kondrat, 2016, LEX, commentary to art. 52 PhL).

The misleading of consumers by drug advertising was regulated, e.g. in Great Britain (Human Medicines Regulations 2012 "the Regulations" – SI 2012/1916) and Germany (Gesetz über die Werbung auf dem Gebiete des Heilwesens (Heilmittelwerbegesetz - HWG). It is worth adding that according to the Polish law, misleading or deceiving of a consumer also constitutes an act of unfair competition, and is thus subject to the general clause laid down in the Act of 16 April 1993 on combating unfair competition (Journal of Laws 2019, item 1010, as amended), (Judgment of the Administrative Court, SA I ACa 149/05).

It is rather obvious that "misleading" should be understood as conveying false information to consumers. However, conveying insufficient or incomplete information may also create false beliefs in the ads' recipients, and thus be misleading or deceptive. This means that information does not necessarily has to be (objectively) false to judge advertising as misleading (Judgment of the Supreme Administrative Court, NSA II GSK 20148/17, Judgment of the Supreme Administrative Court, NSA II GSK 2466/15). For example, a research conducted in the United States research on pharmaceutical ads showed that many of them not contain false information, but rather provide incomplete information on the side-effects or risks involved in their use (Faerber, Kreling, 2014). Certainly, the goal of

advertising of medicinal products is to entice consumers to buy a given product, and thus increasing its sales, yet one of the court judgments rightly emphasized that advertising must comply with the law and, most importantly, may not mislead consumers (Judgment of the Provincial Administrative Court Judgment, WSA VII SA/Wa 556/08).

Celebrity Endorsement and Consumer Protection

Endorsing products by famous people has become a very popular form of advertising and statistical data show that approximately in every 4th advert a celebrity is involved (Knoll, Matthes, 2016, p. 55). Research was conducted in Japan on response to drug advertisements endorsed by famous persons. The findings show that there is a correlation between who endorses the product and how the brand and the product are received by consumers (Morimoto, 2020). It should not come across as a surprise that consumers identify the brand/ product advertised with the endorser (Kozlowska, 2005, p.1).

Nonetheless, as it comes to the advertising of medicinal products which are not an ordinary type of goods, the issue of who endorses them requires special regulation. Under Polish legislation, medicinal products cannot be advertised by any public persona, scientists, medical or pharmaceutical professionals, or any persons that suggest they might have such qualifications (art. 55 s.1(1) PhL). Certainly, doctors' endorsement of medicinal products would be beneficial for pharmaceutical businesses as doctors are perceived by consumers as experts, lending credibility to the medicinal products endorsed (Grzegorczyk, 2012, p. 150). However, one must bear in mind that a recipient of drug adverts is a special kind of consumer, one that needs special protection ensured by, i.a., endorsement restrictions (Ganczar, Szewczak, 2017).

The said prohibition to endorse medicinal products is very often breached in Poland, which is reflected in the decisions taken by the Chief Pharmaceutical Inspectorate (CPI), which in Poland is the supervisory authority responsible for the monitoring of medicinal product advertising and their compliance with the law (art. 62 s.1 PhL).

The Polish legislator highlights that a medical professional is forbidden to appear in commercials or ads. Thus, definitely, a doctor may not endorse any pharmaceutical product. The responsibility for a doctor's appearance in advertising pharmaceuticals rests on the advertiser and the doctor himself. In Poland, any medical professional who endorse pharmaceuticals breach, first of all, the Code of Medical Ethics which states, i.a., that a doctor should not consent to his name and image to be used for commercial purposes. Medical Courts in Poland (which adjudicate issues of medical liability) tend to use, in the first instance, a letter of reprimand (Skrzypczak, 2017, p.227). However, from the perspective of consumer protection, reprimanding the entity responsible for advertising is not sufficient as they should, first of all, put an end to the broadcasting of such commercials. This is what the Chief Pharmaceutical Inspectorate is trying to do whenever a commercial violates applicable provisions of law.

Apart from prohibiting medical professionals to endorse drugs, the law also prohibits endorsing of drugs by persons whose looks or behavior could make the audience think that they have medical qualifications. Very often advert recipients are not able to verify whether a real medical expert or just an actor with a façade of a doctor appears in the commercial. To illustrate that, a commercial was aired that was staged in a pharmacy. One of the actors was looking for some meds, and the other actress, dressed in a white lab jacket was trying to find out what ailment that the guy was suffering from. The Chief Pharmaceutical Inspectorate stated that the visual representation breached the aforementioned prohibition, as the behavior and dress code of the actress plainly suggested pharmaceutical qualifications. However, the advertising entity denied that by emphasizing that not a single word or statement was uttered in the commercial to unanimously imply that the actress is a pharmacist, and that the white lab coat is no more than a piece of outerwear, and not a uniform of a person employed in a pharmacy. Yet, the CPI did not accept this argumentation and highlighted that associations of a pharmacist giving advice on best medication were evoked in the audience, which is in breach with the law. Moreover, the CPI also debunked the advertiser's argument that the lab coat did not suggest that the actress is a pharmacist by stating that her behavior conveyed self-confidence and knowledge of the medication stock as if she was working in the pharmacy. In conclusion, such visual deception makes the consumer mistake the actress for a pharmacy employee, whereas pursuant to the Polish law only pharmacists and pharmacy technicians are allowed to work in pharmacies (CPI Decision PR.600.28.2017.JD). The logic used by the CPI is sound, as the audience had practically no chance to verify whether the actress starring in the commercial had – or did not have – qualifications required by law to work in a pharmacy, and that the typical white lab coat she was wearing must have been misleading for consumers.

Another commercial showed scenes from a lab, with people dressed in white lab coats in the background. The voice-over said "in our lab we have found a solution to (…)". In the opinion of the CPI, such portrayal violates the statutory prohibition of employing images suggesting the actor is a medical professional. The CPI argued that portraying people dressed in white lab coats typical of scientists conveys to consumers a clear message that the persons shown have medical or similar qualifications as only such qualifications would have made it possible to discover "a drug". The opposing party argued that the commercial was not in breach of the law since the actors dressed in white coats did

not present a drug per se, and that there was no overt mention of their education in the commercial. The latter arguments could not be rebuked, but the CPI responded that it was the combination of the visual layer with the voice-over that suggested to the audience that the persons presented were the inventors of the advertised drug (CPI Decision GIF-P-R-450/9-4/ZW/11).

Yet another commercial showed a man dressed in white lab coat with a stethoscope hanging around his neck. There can be no doubts that such a commercial violates the said prohibition. The CPI issued an order to immediately stop the broadcasting of this commercial (CPI Decision GIF-P-R-450/72-5/JD/11)/

The above examples refer to tv commercials, i.e. audiovisual advertising, which does not imply that the prohibition may be breached in other forms of advertising, such as radio spots or print ads (Szafranska, Szyszka, 2012, p. 81-93).

It should be emphasized that the cases analyzed above do not only breach statutory regulations on the prohibition of drug endorsement in advertising, but they also affect the audience in the way discussed before – they mislead consumers (Ignatowicz, 2016, LEX). If in a commercial an actor is made to look/ behave in a way that suggests him to be a medical professional, although this is not true, then definitely it is a case of misleading consumers. In the case of drug advertising, the misleading does not have to be in the form of false information about the medicinal product's features, but also refers to the visual deception which makes consumers mistake actors for medical professionals.

Aside from the ban on drug endorsement by medical professionals or persons suggested to be healthcare professionals, the legislator also imposed a ban on drug advertising by persons known to the general public. In the Polish legislation a word for "a person known to the wide public" is lacking, therefore frequently the English term "celebrity" is used, which denotes highly-visible entertainment and media figures. Appearance of a celebrity in a drug commercial affects the consumer almost in the same way as the appearance of a medical professional – the advertised content becomes more attractive and more credible to the consumer.

So far, the author has discussed the ban on presentation of medicinal products by scientists, medical professionals and celebrities, and persons standing in for them in terms of directly using the "image", but such an image can also be used indirectly, as stated in art. 55 s.1(2) PhL. The provision lays down that the drug advertising should not involve any reference to recommendations by celebrities, scientists, healthcare professionals or persons suggested to be healthcare professionals. It is worth illustrating what is meant by "referring to" expert recommendation with a real life example. There was a case of a poster advert which, besides a graphic presentation of the medicinal product, included also a caption saying that the drug is recommended in certain ailments while patients wait for a consultation with a physician. This utterance was signed by a name of a well-known medical expert, citing his degrees and position. Upon analyzing the said content, the CPI pointed out that citing a healthcare professional on a drug advertising poster makes people respond to the utterance quoted as if it were a recommendation to use the said drug. The advertising party argued that the graphic layout which visually separated the citation from the rest of the poster does not provide sufficient grounds to believe that the citation is a recommendation within the meaning of the statutory prohibition. Moreover, the advertiser highlighted that the utterance quoted was not made by the person whose name was contained in it, which should be treated as an argument that the said advert did not violate the prohibition to refer to recommendations of medical professionals. Notwithstanding this, the CPI rebuffed these arguments as well, insisting that the visual "separation" did not really disconnect the citation from the content of the poster. Furthermore, the fact that the quotation was not made by the undersigned person in fact means just the opposite, i.e. is a proof of violation, as an average consumer has no way of verifying whether the undersigned person authored the words quoted or not. The average consumer, as a recipient of advertising, has the right to assume that the quotation posted is a recommendation to use the product advertised, and also, that the recommendation comes from a renown medical expert (CPI Decision GIF-P-R-450/25-6/JD/15). Lastly, it should be underlined that signing the statement quoted with a name of a person who has not authored it is definitely a case of consumer misleading.

Summary

It has been emphasized in this paper that medicinal products constitute a special type of products and therefore, for the sake of consumer safety, special restrictions are needed to regulate how they are presented in advertising. Undoubtedly, advertising also has positive effects for consumers such as allowing them to get to know new products and services, and enabling them to choose what is best for them. However, it is very important for the consumer to be able to make informed decisions, dictated by their actual needs, in particular when purchasing a medicinal product. To ensure that, advertising of medicinal products must be devoid of endorsement by celebrities and public figures since such endorsement, i.e. the use of their image, name and likeness or recommendations distort the reception of information conveyed in commercials and advertisements.

Polish Investment Zone - Legal Assessment of The Two Years of Operation of The Mechanism of Public Aid Given to Entrepreneurs

Dominika WROBLEWSKA

ORCID 0000-0001-6805-0547
University of Szczecin, Szczecin, Poland, dominika.wroblewska@usz.edu.pl

Abstract

The Polish Investment Zone (PIZ), which in 2018 replaced Special Economic Zones (SEZ) operating from 1994, is a new mechanism of providing support to entrepreneurs in taking up new investment. The support is given in the form of income tax exemption and falls under regional aid consistent with the European Union's community law. Public aid under PIZ is not limited to a specific location, as is the case with SEZs, but covers the entire Poland with its scope. The study compares PIZ and SEZs in terms of the aid's reach, criteria for obtaining support and also goals that both support instruments were supposed to serve. The main aim of this paper is to verify whether principles of public aid granted under PIZ are simpler and quicker, and whether tax advantages are greater than in the case of SEZs. Moreover, the study aims to assess the effects of PIZ's functioning from the perspective of two years of operation and to verify whether PIZ is a tool supporting Poland's uniform and sustainable development.

Various different research methods are employed in the study: examination of applicable laws, analysis, and legal comparison. It will be reasonable to base the methodology of the conducted research not only on the analysis of the Polish and EU legal order, but also on the views of legal scholars and commentators and data published by the Ministry of Development, Labor and Technology.

Keywords: support system for new investments, decision on support, Polish Investment Zone, Special Economic Zones

Introduction

An entrepreneur is a natural person, a legal person or an organisational unit not being a legal person that is granted legal capacity by a separate act of law, conducting economic activity**.** The new mechanism of providing support to entrepreneurs in taking up new investments on the territory of Poland which involves granting an income tax exemption was introduced on the basis of the Act of 10 May 2018 on supporting new investment (Dz. U. (Journal of Laws) item 1162 as amended (hereinafter: SNI)). In practice, exercising this support was only possible from 5 September 2018 after entry into force of implementing rules for the SNI Act, that is Regulation of the Council of Ministers of 28 August 2018 on public aid granted to certain entrepreneurs for implementing new investments (Dz. U. (Journal of Laws) item 1713 (hereinafter: Regulation)).

The support is granted on the basis of a Decision on Support (DoS) in the form of exemption from income tax, under the terms and conditions specified accordingly in the provisions of the act of 26 July 1991 on personal income tax (consolidated text: Dz. U. (Journal of Laws) of 2020 item 1426 as amended) or in provisions of the Act of 15 February 1992 on corporate income tax (consolidated text: Dz. U. (Journal of Laws) of 2020 item 1406 as amended). Exemption form income tax is a regional aid, which is why the aid given to entrepreneurs must be compliant with Commission Regulation (EU) No 651/2014 (GBER Regulation), which is one of legal acts that regulate public aid at the Union level.

Thanks to the SNI Act, entrepreneurs who meet quantitative criteria (relating to the sum of investment outlays) and qualitative criteria (relating to the manner of taking up activities for sustainable social and economic development) may enjoy a tax exemption regardless of where the investment is located. PIZ replaced the system of tax exemptions functioning in Poland for more than 20 years under the Act of 20 October 1994 on special economic zones (consolidated text: Dz. U. (Journal of Laws) of 2020 item 1670 as amended) (SEZ Act).

Due to the fact that the new mechanism of public aid has been functioning for two years now, it is possible to assess whether it has met the adopted goals and whether this has translated into entrepreneurs' interest and investments under PIZ.

Reasons for introducing the Polish Investment Zone

In the legal approach, a special economic zone is an enclave in the territory of a state where regulations governing domestic economic activity do not apply. Is a specific legal and political construct created point-by-point on the basis of adopted regulations, establishing more favourable conditions for development of companies than those applicable outside the zone (Bazydło, Smętkowski 2000, p. 17). According to the position of another representative of legal scholarship, Waligórski (1997, p. 15), norms applicable within special economic zones are to secure, that is enable and facilitate, implementation of the country's economic tasks and goals.

The promotion of special economic zones is an attempt to deal with infrastructural deficiencies, procedural complexities, bureaucratic hassles and barriers raised by monetary, trade, fiscal, taxation, tariff and labour policies. Since country-wide development of infrastructure is expensive and implementation of structural reforms would require time, due to given socio-economic and political institutions, the establishment of industrial enclaves (SEZs) is seen as an important strategic tool for expediting the process of industrialisation in these countries. (Aggarwal 2006, p. 4533)

SEZs cover 14 administratively dedicated zones with the surface area as of 230 km^2, that is 0.07% of Poland's area, as at 31 December 2019 (Sejm Paper no. 397). Until PIZ was introduced, entrepreneurs could obtain preferential conditions for conducting economic entity including, i.a. a tax exemption, only for economic activity carried out in the territory of SEZs. Availability of a tax exemption under SEZs was territorially limited, which is why the most essential change introduced by the SNI Act was to remove this restriction. Carrying out a new investment on the territory of the entire Poland, both on private and public grounds, allows the use of public aid. The requirements for obtaining support depend on the size of the company, the sector in which the investment is carried out and also unemployment rates in a given district. The company size is established pursuant to the GBER Regulation taking into account the average annual employment and annual turnover or annual balance sheet total.

It needs to be remembered that the SEZ Act was introduced in a different social and economic reality. The choice of the model of a special economic zone would depend on the degree of the country's economic development and also on the goals that this instrument of economic policy is to serve. After 1989 at the beginning of the period of political transformation, the greatest barrier to the development of Polish economy was lack of investment outlays sufficient for necessary structural transformations in the economy. Strong competition in this period from companies with foreign capital caused the collapse of many Polish companies and in effect numerous job losses (Lichota 2016, p.101). SEZs and their appropriate location were to be the tool for increasing investment outlays in the economy (Miłaszewicz 2011, pp. 7-8). One of the fundamental reasons for introducing preferential conditions for carrying out economic activity under SEZs was a wish to bind the investor with the region and to incorporate new economic undertakings into this region's economy (Typa 2003, p. 83).

The main aim of creating SEZs was to create jobs in regions marked with high structural unemployment (and thus reducing budget expenditure for unemployment benefits) by directing new investments there thanks to the application of a portfolio of investment incentives. The establishment of SEZs was to result in breaking industry monoculture and diversification of production structure in individual regions, in generating GDP growth in them and in supporting local technical infrastructure (Ministry of Economy and Labour, 2005).

As pointed out by Warżała (2013, p. 3), from the macroeconomic point of view, SEZs did not reduce disproportions in regional development of the country, but reinforced them. Regions with a strong position in the country attracted most investments which were willingly located in SEZs operating there.

This is why reasons for establishing preferential conditions for conducting economic activity in the territory of the entire Poland (the so-called establishment of a special economic zone throughout Poland) were mainly economic and resulted from the need to adjust the principles and mode of supporting new investments to the changing social and economic realities. The legislator pointed to the need for lasting economic development and territorially sustainable development. Due to this fact, the SNI Act emphasized the development of all territories by reinforcing smart specializations of each region, removing barriers and including in the developmental processes regions which face restructuring- and adaptation-related difficulties, mid-size towns which are losing social and economic functions and other towns and villages which are located in the territories of districts where unemployment exceeds 160% of the national average (Sejm Paper no. 2307). Expansion of the scope of support for implementation of new investments

by means of the SNI Act deserves credit, since SEZs deepened economic and social disproportions among Poland's regions.

Rules for obtaining public aid under the Polish Investment Zone

According to the SNI Act, DoS may be issued in relation to the implementation of a new investment. A new investment means investment in tangible and/or intangible assets relating to i.a.:

- the setting-up of a new establishment,
- the extension of the capacity of an existing establishment
- the diversification of the output of an establishment into products not previously produced in the establishment, or
- a fundamental change in the overall production process of an existing establishment, excluding establishments for which insolvency proceedings have been initiated or a request to the court has been made to declare the establishment insolvent.

The Polish legislator, pursuant to the Act of 19 June 2020 on subsidising interest of bank credit granted to entrepreneurs affected by COVID-19 and on summary proceedings on approving the composition due to the occurrence of COVID-19 (Dz. U. (Journal of Laws) item 1086), expanded the above catalogue with another type of new investment - acquisition of assets of an insolvent company. Such a type of initial investment was taken into account in the SEZ Act and in the GBER Regulation as investment which may be covered with support. Therefore, the SNI Act was more restrictive than national regulations applicable in SEZs and Union's regulations alike. As a result of the changes, from 24 June 2020 onwards a new investment is considered to include also an acquisition of assets belonging to an establishment that has closed or would have closed had it not been purchased (where the assets are bought by an investor unrelated to the seller and sole acquisition of the shares of an undertaking is excluded).

Unification of the definition of a "new investment" with the definition of an "initial investment" of the GBER Regulation deserves credit since it enables managing the property of companies which are in a difficult situation. This is a particularly important aspect due to difficult economic conditions caused by the COVID-19 pandemic. This is, however, the only change in the SNI Act aimed at counteracting negative economic impact of COVID-19 pandemic.

Public aid in the form of exemption from taxation may be granted solely to those entrepreneurs who conduct their economic activity on the basis of market rules, that is those who perform economically substantiated acts in their activity. This means that the Polish legislator excludes granting aid to entrepreneurs who avoid or evade taxes. It is a specific way to combat abuses and aggressive tax optimisation and to improve the efficiency of combating tax fraud and taxation evasion that fall under activity undertaken on the European Union forum (Communication from the Commission to the European parliament and the Council, COM (2012) 722).

A Decision on Support, on the basis of which public aid is granted, may be issued for new investments from the sector of modern business services (e.g. call center, accounting and book-keeping services, data processing, IT, financial auditing, research, development works, architectural and engineering services, environmental consulting, head offices and management consulting), research and development (R&D) and the industry sector. Under PIZ, similar to the case of public aid granted under SEZs, there are strictly defined areas of economic activity that do not qualify for support. According to the Regulation, DoS is not granted for economic activity involving e.g. the manufacture of explosives, the manufacture of tobacco products, production, bottling and processing of alcoholic beverages, operation of a gambling establishment, sewage disposal and treatment, construction, trade and hospitality. Moreover, pursuant to the GBER Regulation aid cannot be granted for a new investment in i.e. the steel and iron sector, the coal sector, the shipbuilding sector or the synthetic fibres sector, the transport sector, energy generation, distribution and infrastructure, and financial and insurance activities.

A Decision on Support is given for the period of 10 years when the new investment is located in a region of maximum aid intensity of 10%, 20% or 25%, 12 years if the maximum intensity is 35% or 15 years when the intensity is 50%. What is essential, as in the case of SEZs, an entrepreneur seeking public aid under PIZ cannot launch an investment project before receiving a DoS. A basis for exercising public aid granted under the SEZ Act was a permit to conduct economic activity on the territory of a given zone. Entrepreneurs who obtained public aid under the Special Economic Zones (SEZs) may enjoy it till the end of 2026. This means that the period of exemption from income tax for entrepreneurs who obtained the permit in 2018 is 8.5 years.

In order for the income to be exempt from taxation on the basis of a DoS the following requirements must be met jointly: (i) the economic activity is carried out on the territory indicated in the DoS, and (ii) the income was obtained from the economic activity indicated in the DoS by means of the Polish Classification of Goods and Services

(PKWiU) - up to the available limit resulting from this DoS. Because this aid is granted in the form of an exemption from income tax, an entrepreneur will truly enjoy it if the activity conducted on the basis of the DoS brings profit and income tax is due.

The way of calculating the tax relief under PIZ was the same as in the case of SEZs. This is why entrepreneurs may enjoy the existing abundant judicial decisions from the almost twenty-year long period of operation of SEZs. The limit for the tax exemption is calculated as a product of eligible costs and aid intensity for a given area established on the basis of a regional aid map for 2014-2020 (Regulation of the Council of Ministers of 30 June 2014). The intensity means the percentage of costs eligible for aid. Additionally, maximum intensity of regional investment aid is increased by 20 percentage points in the case of micro- and small enterprises, and in the case of medium-sized enterprises by 10 percentage points.

Eligible costs of a new investment include, for example, (i) two-year employment costs, or (ii) costs of acquisition of land, leasing land or buildings, acquisition, production, extension or modernisation of fixed assets (e.g. machines and devices) and also costs of acquisition of intangible assets (e.g. know-how, licences). Most often entrepreneurs who carry out investment from the modern business services sector exercise the calculation of the exemption limit on the basis of two-year costs of employment of newly taken-on staff. Projects from the services sector do not need significant investment outlays in the form e.g. purchase of land, machinery or devices.

The table below refers to the quantitative criterion, i.e. it indicates a minimum value of eligible costs that need to be borne by an entrepreneur who applies for public aid in the form of a DoS. The sum of investment expenditure depends on the company size or object of investment, but also the unemployment rate in the district relevant for the place of implementation of a new investment.

Table 1: Minimum eligible costs [in PLN] PLN 1 = EUR 0.22

Unemployment rate in the investment's district		**Minimum eligible costs**			
as % of national average*	(in %)	Large enterprise	Medium-sized enterprise	Small enterprise investment in the scope of: modern businesses services, R&D	Micro enterprise
≤60% national average	0/-3.66	100 million	20 million	5 million	2 million
from 60% up to average	3.67/-6.1	80 million	16 million	4 million	1.6 million
above average up to 130%	6.11/-7.93	60 million	12 million	3 million	1.2 million
130%-160%	7.94/-9.76	40 million	8 million	2 million	800 thousand
160%-200%	9.77/-12.2	20 million	4 million	1 million	400 thousand
200%-250%	12.21/-15.25	15 million	3 million	750 thousand	300 thousand
>250%	from 15.26.	10 million	2 million	500 thousand	200 thousand

** The average unemployment rate nationwide and in the territory of districts is established on the basis of the annual Notice of the President of Statistics Poland and as at 30 June 2020 it was 6.1% (GUS, 2020b).*

As demonstrated in the table, the smaller the enterprise and the higher the unemployment rate in a given district, the higher the value of required investment outlays. The lowest investment thresholds, typical to districts with an unemployment rate higher than 250% of the national average, apply also in medium-sized towns which are losing social and economic functions (the Regulation enumerated them) and in municipalities that neighbour such towns.

Making the amount of investment outlays dependent on the company size has significantly facilitated carrying out investments and may be key from the perspective of obtaining a DoS especially by micro, small and medium-sized enterprises (MSE).

The quantitative criterion for obtaining public aid for investment implemented in the area covered with the SEZ status was minimum EUR 100,000 (equivalent to PLN 417,010 at the exchange rate for 2 January 2018) regardless of the company size. When a location outside a SEZ was chosen, entrepreneurs could request that the area be included in the SEZ. This required between PLN 17 to 350 million worth of investment outlays or the creation of 50-500 new jobs, and the procedure itself of expanding the SEZ territory was time-consuming and complicated. In turn, a DoS is issued within 30 days from submitting an application.

When comparing outlays-wise an investment of a large enterprise from the industry sector on the territory of a SEZ with an investment under a new support instrument in a district with the unemployment rate equal to or lower than the national average, large enterprises must bear eligible costs of PLN 100 million, that is more than 220 times more than under SEZs. From this perspective it seems that the criteria for the size of investment outlays with regard to large enterprises were tightened under PIZ. However, these changes should not limit investment of large enterprises significantly, because when planning a new investment, they can choose an adequate location suitable for the value of the planned investment.

In the case of investment in the modern business services sector carried out in a district where the unemployment rate is more than 250% of the national average, PIZ obliges the entrepreneur to outlay PLN 500 thousand for the investment. In turn, where it is necessary to conduct the procedure of expanding the PIZ area he would have to invest PLN 20 million or create 150 jobs and maintain them for 5 years. This example shows that new rules for support are less restrictive than in the case of investment carried out outside the SEZs.

As has been pointed out, entrepreneurs interested in obtaining a DoS are also obliged to meet qualitative criteria along with quantitative ones. When implementing a new investment in areas with intensity of 10%, 20% or 25%, entrepreneurs are obliged to meet at least 6 criteria presented in the table below. The minimum of investment in the region with public aid intensity of 35% is 5 criteria, and for a 50% intensity - 4 criteria.

Meeting one criterion presented in the table below awards 1 point to the entrepreneur. As a rule, qualitative criteria are similar for investment carried out in the services sector and the industry sector.

Table 2: Comparison of qualitative criteria for a new investment carried out in the services sector and the industry sector

SERVICES SECTOR	INDUSTRY SECTOR
CRITERIA OF ECONOMIC SUSTAINABLE DEVELOPMENT	
Investment in projects supporting industries compliant with the current state development policy (strategic sectors)	
Achieving adequate level of sales outside the territory of Poland (in 2019 - 23.2%)*	
Carrying out research and development activity	
Creating a modern business services centre with a scope reaching outside the territory of Poland	Belonging to a Key National Cluster
Having a SME status	
CRITERIA OF SOCIAL SUSTAINABLE DEVELOPMENT	
Creating highly-paid jobs and offering stable employment	Creating specialised jobs to conduct economic activity falling under the new investment and offering stable employment
Conducting economic activity with a low negative environmental impact	
Locating the investment in medium-sized towns which are losing their social and economic functions or in municipalities that border these towns, or in districts where the unemployment rate is at least 160% of the average unemployment rate	
Supporting education and obtaining professional qualifications and cooperation with vocational schools	
Undertaking activity with regard to caring for employees (e.g. providing additional employee benefits in terms of culture and education, sports and recreation, insurance, health care plans; minimum cost of the benefit is PLN 800 gross per employee per year;	

* Intensity of sales outside the territory of Poland, understood as a share of revenue from these sales in net revenues on the sales of company products, goods and materials is equal to at least an average intensity of such sales of non-financial companies in the national economy for a calendar year, established on the basis of a report of Statistics Poland "Financial results of economic actors" (GUS, 2020c).

Qualitative criteria formulated in this way show that the aim of introducing PIZ is to create new stable highly-paid jobs for qualified employees, to develop inter-community delivery to Member States as well as export to non-EU countries, to mitigate the growth of differences in the development of regions, to develop innovative technologies and also to enhance competitiveness of goods produced in Poland and Polish services, which translates directly into Poland's economic development.

It seems that compared to investment carried out under SEZs entrepreneurs planning to obtain a DoS have more obligations, because they must additionally meet the qualitative criterion. Whereas a detailed analysis of the manner of verification of meeting this criterion leads to conclusions that entrepreneurs will not have trouble obtaining 4 to 6 points from the above table.

As much as in the case of existing SEZs it was essential primarily to create a great number of new jobs, with PIZ the quality of the created jobs was key in obtaining support. This change results most probably from the difference in the rate of registered unemployment noted in Poland. In 1994 the average annual level of unemployment was 16.49%, in 1999 - 11.99%, in 2004 - 19.51%, in 2009 - 10.97%, in 2014 - 12.33%, whereas in 2016 this value dropped to 8.94% and in 2018 to 6.08% (GUS, 2020a).

Impact of introduction of a new system of supporting entrepreneurs on the level of investment

As results from the data made available by the Ministry of Development, Labour and Technology (2020), in the two years of PIZ's functioning 580 DoSs have been issued for 556 entrepreneurs, and the joint declared sum of investment was PLN 25.2 billion (as at July 2020).

The first DoS was issued in September 2018, that is as early as 2 weeks after entry into force of implementing rules to the SNI Act (Pomorska Specjalna Strefa Ekonomiczna, 2018). In the period from September 2018 to the end of that year, a total of DoSs issued was 83 and the total number of issued permits, that is declared investment under SEZ, was 264.

The number of investments in 2017 (last full year of SEZs' functioning before the changes) and in 2019 (the first full year of PIZ's functioning) was similar, where 348 permits were issued in 2017 and 358 DoSs were issued in 2019. However, their total declared value was significantly higher for SEZs in 2017 (PLN 19,1 billion) than for PIZ in 2019 (PLN 15 billion). In my opinion, uncertainty as to what the conditions for obtaining support under new rules will be like has encouraged entrepreneurs recently to invest in SEZs and to obtain public aid on old, familiar terms. The reason for a decline in the value of investment may be also sought in unclear regulations on accounting for the granted tax exemption for a new investment involving extension of the capacity of an existing establishment (Sienkiewicz, Zwolenik, 2020, pp. 19-25). Certainly, explanation of doubts about using the exemption would make PIZ more attractive to entrepreneurs.

In 2019 as much as 74% of the total number of declared investments in PIZ were from entrepreneurs with Polish capital. Whereas from the perspective of the value of declared investments, Polish entrepreneurs carry out smaller investments compared to investors with foreign capital and in 2019 they declared 44% of the total value of new investments. In 2019, 54% investments were located outside the territory of existing SEZs, and this rate grew to 71% by the end of July in an annual average approach. This demonstrates that introducing the SNI Act and extending the scope of the support was necessary and PIZ is a tool which supports Poland's even and sustainable territorial development.

From January to July 2020 139 DoSs were issued for new investments with the value of PLN 4 billion. The situation associated with the COVID-19 pandemic, which brought critical outcomes for the entire world, has certainly contributed to the absence of an increase in the number of investments and a significant drop in their value compared to 2019. Restrictions on economic activity resulting from the epidemic threat are observed in a majority of countries throughout the world. Due to the dynamic situation, it is difficult to specify at the moment the precise scale of the phenomenon. Nevertheless, the data available for the date of preparation of this study points to a significant deterioration of the economic situation (GUS, 2020d).

PIZ enables the development of SMEs, which seems particularly essential for the fact that their contribution to providing new jobs which are created in the PIZ is important and amounts to 79% of new jobs created in the PIZ.

Conclusions

The support system under the PIZ is an important and effective tool encouraging entrepreneurs to invest all over the country. The expansion of territories on which enterprises may apply for public aid leads to an interest in new locations that are outside the existing SEZ territories. Detachment of the possibility of supporting entrepreneurs by income tax exemptions from a specific area as well as unification and acceleration of the procedure for obtaining public aid are unquestionable values which encourage entrepreneurs to make further investments in Poland and also attract new foreign investors. New rules of support have greatly increased attractiveness of districts with the greatest unemployment and towns which are losing their social and economic functions, thus giving them an opportunity for development. In future it will be possible to even out significant economic and social disproportions between Polish regions thanks to the granting of public aid (which so far has only been available under SEZs) on terms that favour less developed regions. Introduction of minimum thresholds of investment outlays dependent of the size of the enterprise and unemployment in the district where the investment is to be located, and also increasing the maximum regional aid intensity for SMEs is a change that mitigates the advantage of foreign companies, which have a much greater capital at their disposal than smaller Polish companies. The changes have resulted in the increase of the investment rate among SMEs.

The change in the social and economic realities required adaptation of a portfolio of tax incentives and the rules introduced by the SNI Act fulfilled their task in this respect.

Abstract

e-Government system leverages Information and Communication Technology (ICT) to transform the relationship between government bodies and citizens, businesses and other government ministries, department, and agencies. The primary aim is to make government services more seamless, efficient and timely for every citizen and organisation. However, e-Government systems are now faced with security threats and cyberattacks, and these challenges have raised concerns about users' privacy as well as the confidentiality and integrity of user data. Therefore, this paper assesses the degree of risk and vulnerability associated with websites used for e-Government function. We consider one such website, the Saudi's e-government website, Yesser by using three penetration test tools namely Zap, Rapid7, and Nessus. The results show that Yesser website does not have critical vulnerabilities but, has severe and medium-level vulnerabilities. The paper proposes a new framework which can integrate blockchain based scheme into Saudi e-Government system. The framework represents a hierarchical model and involves use of blockchain between De Militarized Zone (DMZ) and Secured Intranet zone.

Keywords: Blockchain, e-Government, Cyber threats, Penetration Test Tools.

Introduction

Technology has shaped the world and turned the universe into a global village. The developments in information technology cut across both public and private sectors. Basically, the integration of IT into business to provide public services online as well as increase government's efficiency is called e-Government. However, as promising and great as e-Government is, it faces the challenge of cyber threats. According to Rehman *et al.* (2016), concerns about cyberthreats have affected user acceptability of e-government systems. Users perceive that hackers or third parties may have access to confidential information like credit card details.

Meanwhile, it is government's responsibility to protect user data and strengthen the e-Government system against any form of security threat. Blockchain technology is a good option to secure e-Government. Blockchain technology, the concept behind cryptocurrencies such as Bitcoin, Ethereum etc., can be used for the benefit of the public sector. It can make government operations and services more secured, more efficient and guarantee improved public service delivery. Ultimately, there will be an increase in public trust. Blockchain is a distributed ledger shared among parties participating in a network. The majority of the participants must agree before a transaction can be approved.

Ølnes and Jansen (2017) noted that blockchain technology can be easily mastered, adopted and adapted by a large number of people. The study revealed that the blockchain technology is now an emerging technology for new innovations and development not only in the financial systems but also in the government agencies and organizations.

In this study, we take a closer look at identifying the vulnerabilities and risks associated with present e-Government systems around the world. As a matter of example case study, we conduct our study on the e-Government system created and implemented by the government of Saudi Arabia. In Saudi Arabia, the government has embraced a new

Cite this Article as: Haitham ASSIRI, Priyadarsi NANDA and Manoranjan MOHANTY "Risk and Vulnerability Assessment of e-Government Framework using Blockchain Technology" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

technological era in which technology is utilised as an instrument to make communication, government services, and connectivity more seamless. Saudi's e-Government system, Yesser, is pivotal to the realization of the Saudi Vision 2030. As a result, it is important that Yesser website has adequate security. This paper aims to determine the level of security of Yesser website by utilizing three penetration test tools to scan the website. The tools include Zap, Rapid7 and Nessus. Based on the analysis, this paper proposes a new framework with the use of blockchain into **Yesser.** The framework represents a hierarchical model and involves use of blockchain between De Militarized Zone (DMZ) and Secured Intranet zone.

The specific objectives of this paper include the following:

a. To determine the degree of vulnerability of e-government services to breach of privacy, trust, confidentiality and security.
b. To determine the degree of vulnerability of Saudi e-government system (Yesser) to cyberattacks.
c. To propose a new framework that leverages blockchain to secure Saudi e-Government system.

The structure of the paper is as follows: Section II presents a review of the existing literature. In Section III, the methods used in the study are discussed. Section IV presents the results and discussion. Finally, Section V concludes the paper while setting the stage for further research works.

Literature Review

Vulnerability of e-Government Services

According to AlGarni (2015), hacking, terrorism and software error constitute the major types of vulnerabilities of Saudi e-government systems. On the part of the government and employees dealing with e-government services, there are issues like lack of professionalism and accountability, poor IT infrastructure, lack of awareness of security perspectives at customer level, and inadequate laws and policies guiding e-Government services.

Choejey *et al.,* (2015) noted that the lack of or limited use of a standard web security policy and risk management practices have led to cybersecurity threats like malware, phishing scams and hacking in Bhutan. Alsmadi and Abu-Shanab (2016) used Rapid7 security and penetration testing tools to explore the vulnerabilities of major e-government websites in Jordan. The outcomes of the tests carried out indicated that most of the websites are prone to attacks.

Also, having realised that only little efforts were made towards evaluating the security level of Saudi Arabia's e-government websites, Al-Sanea and Al-Daraiseh (2015) assessed 150 websites owned by financial, governmental, academic and commercial organisations. The paper noted that vulnerabilities in e-government websites are caused by wrong configuration, weaknesses in programming, or lack of updates. The result of the assessment revealed that the websites are faced with low, medium and high impact vulnerabilities. For instance, 61% are vulnerable to Clickjacking, 17.5% are vulnerable to SQL injection and 13.5% are vulnerable to Shell injection. Based on the number of vulnerabilities found, a comparison was made between government and commercial websites. The result of this comparison showed that commercial websites are more secure than government websites.

Using tools like Google Speed Insight, Pingdom, Acunetix, and w3c Checker, Elisa (2017) assessed the accessibility, usability, and web security vulnerabilities of seventy-nine (79) selected e-government websites in Tanzania. The outcomes on web security vulnerabilities showed that forty (50.6%) out of the 79 websites assessed have one or more high-severity vulnerability (cross site scripting-XSS or SQL injection) while fifty-one (64.5%) have one or more medium severity vulnerabilities (Denial of Service or Cross site request forgery).

Bissyandé *et al.* (2015) carried out an empirical assessment of e-government websites' security in Burkina Faso. A systematic scanning of the websites for simple and well-known vulnerabilities showed that there are serious security issues calling for urgent attention. For example, it was possible to crawl all information (including hostname and password) from temporary backup files in a government website to read and write directly in the database thereby impersonating the website's administrator.

Murah and Ali (2018) evaluated 16 Libyan e-government websites using a penetration testing framework. Content analysis was also carried out to determine how far the privacy and security policies on the websites have been implemented. The results of the test revealed that nine out of the sixty websites have high to medium vulnerabilities. Most of these vulnerabilities were due to miss-configuration of the systems and outdated software. Only two of the websites have privacy and security policies published on their websites.

Pandya and Patel (2017) explored the relationship between technology in relation to the vulnerability severity and vulnerability type in 26 e-government applications and websites of Gujarat, India. Most of the websites made use of Microsoft technology while some used Apache technology. It was observed that there are more medium to low vulnerabilities in websites using Apache technology compared to those using Microsoft technology. Meanwhile, informational vulnerabilities and validation-type vulnerabilities are higher in Microsoft technology than Apache technology.

Use of Blockchain for e-Government Systems

As noted by Choejey et al., (2015), the existing e-government services are highly centralised making them vulnerable to outside attacks. Due to its reliance on human controls, the likelihood of errors is high. Inside rogue users can compromise the data for selfish purposes. Since blockchain is completely descentralised, it becomes a strong option. Yang *et al.* (2018) proposed a framework of descentralised, privacy preserving and secure e-government system using artificial intelligence and blockchain technology. The paper noted that intrusion detection and blockchain technology can complement each other. Blockchain will ensure security, trust and privacy while intrusion detection will help in detecting anomalies during blockchain transactions.

In their own research, Diallo *et al.* (2018) proposed the use of decentralised autonomous organisation (DAO) and blockchain technology to improve the e-government system. A high-level architectural description of the model was made after which a detailed design was carried out. The design involves user registration, preparation of contract, monitoring contract execution, and auditing. Through this, the researchers were able to demonstrate that a blockchain-based government DAO can allow monitoring and analysis of e-Gov services as well as provide accountability, transparency, better national resource management and immutability.

In another research, Elisa *et al.* (2018) noted that information security and privacy can be further improved by data encryption and distribution over the entire network. A blockchain-based peer to peer exchange and transactions of an e-government system was proposed by the authors as given in Figure 1. In the figure, G2C means Government to Citizens, G2G means Government to Government, while G2B means Government to Business. The figure typically shows how citizens and businesses interact with government services in a blockchain-based e-government system.

Figure 1: A blockchain-based e-government system (Elisa et al., 2018).

According to Swan (2015), blockchain technology can be used for information exchange and any transaction that occurs in government. The study noted that blockchain can be implemented in asset registry, information exchange, inventory, intangible assets (like votes, patents, health data, reputation, information etc.) and hard assets like physical property. With blockchain, government agencies can keep track of a ledger and the immutable history of transactions. Swan (2015) noted that blockchain applications in government include keeping record of judicial decisions, marital status, digital identity, e-voting, criminal records, tracing money, tax records, passports, business licenses, etc.

Challenges and Difficulties of applying Blockchain to e-Government Systems

Carter and Ubacht (2018) noted that the challenges facing the adoption of blockchain in e-Government include scalability, flexibility and security. From organisational perspective, the challenges relate to acceptability and the necessity of a new governance model. Meanwhile, from environmental perspective, lack of regulations is the main challenge. Carter and Ubacht (2018) also opined that the lack of an overall application platform where the scalability, flexibility, security, reliability, and interoperability of blockchain technology for e-Government system are dealt with

calls for the need to make a proper design solution. In addition, the adoption of blockchain technology will lead to organisational transformation leading to significant changes in process, structure, culture and strategy.

Hou (2017) noted that the application of blockchain in Chinese e-government system offers some benefits like greater accessibility and transparency of government information; improvements in the quality and quantity of government services; and development of information-sharing across different organizations. However, the system still faces the problems of reliability and information security (Hou, 2017). Therefore, it is important to create a general application platform of blockchain technology while also developing management standards to ensure an effective integration of blockchain into e-government.

Analysis Methods

Research Objective 1: PRISMA format for a Systematic Literature Review (SLR)

To determine the degree of vulnerability of e-Government services to breach of privacy, trust, confidentiality and security, this research leverages the outcomes of existing related literature by carrying out a Systematic Literature Review. The SLR follows the PRISMA format (Mohrer, 2009). The steps adopted include Database Search, Exclusion and Inclusion Criteria, Quality Evaluation and Data Analysis. The search sources used are EBSCO Information Sciences (www.ebsco.com/), IEEE Xplore (www.ieexplore.ieee.org/Xplore/), Elsevier ScienceDirect (www.sciencedirect.com/) and Google Scholar (www.scholar.google.com.au/). The search terms entered into the databases include “e-government frameworks”, “effectiveness of e-Government”, “cyber security of e-Government systems”, “blockchain technology” and “blockchain in e-Government”.

Research Objective 2: Use of Penetration Testing tools on Yesser’s website

This research leverages three penetration testing tools to determine the degree of vulnerability of Yesser’s website (www.yesser.gov.sa) to cyber threats and attacks. The three tools used include the following:

1. Rapid7
2. Nessus
3. Zap

These penetration testing tools are used because they make it easy to bypass local network restrictions in order to scan from external IP addresses. They also make it possible to create reliable proof-of-concepts to prove the risk of vulnerabilities. After scanning the Yesser website using each of the three tools the results have been collected and analysed.

Research Objective 3: New e-Government Framework

e-Government systems are vulnerable to external and internal threats and attacks due to various reasons as discussed before in this review. Watching for such attacks and taking appropriate remedial steps is necessary. Based on this, we propose a new framework which integrates blockchain technology into e-Government for security and privacy protection of the system and users. This directly addresses research objective 3. The framework is shown in Figure 2 below.

Figure 2: A Proposed Framework with Integrtion of Blockchain for e-Governemment

In Figure 2, "R" represents Blocks, "F" represents router firewall, and "→" represents switches in an enterprise government network. IPS is a standard intrusion prevention system.

Looking at the schematic presented, the left side is termed as untrusted as this is public internet where the end users' system security policy is open and cannot be regulated as per government organisations' mandates. The right-hand side involves connection to different businesses which are required to make e-government system meet users' service request. The zone in-between is DMZ (de militarized zone) acting as a connection termination point for both untrusted and semi-trusted zones. DMZ is secured with three firewalls acting as a perimeter security system and two individual IPS for any malicious traffic. The Blockchain technology is put between DMZ zone and Secured Intranet zone. Adding blockchain between the two secure zones will create a high level of confidentiality, trust, data integrity, privacy, and access control. Blockchain technology protects security and privacy through separate personal keys and public keys for access, distributed blocks of the database, consensus rules for authentication, peer-to-peer endorsements, and decentralisation.

Results and Discussion

In this section we discuss our research findings addressing directly the three research questions mentioned in previous section of this paper. The first research question relates to our finding analysing various works on e-fovernment adopted by different countries. This gives us scopes to move to the next research question in which, we demonstrate how different penetration tools are being used to assess the risks and vulnerabilities in one specific e-government website, Yesser. Based on our findings, we then propose a new e-government framework to address our third research question.

PRISMA format for a Systematic Literature Review

After the search terms were entered into the search sources, 138 papers were identified. Out of these papers, 36 duplicates were found thereby reducing the number of papers to 102. The remaining papers were then screened to determine their relevance based on titles, abstracts and full texts. At the end of this screening, 66 studies were eliminated resulting in 36 articles. These 36 papers are then evaluated for quality and the results give 10 papers that are ultimately included in this SLR as provided in Table 1 below.

Table 1. Summary of Papers on Privacy and Security of e-Governance

Paper	Description	Method	Weakness & Limitations	eGov Security Requirements		
				Confidentiality	Trust/ Privacy	Integrity
Zhao, J. and Zhao, S. (2010)	Carried out an assessment of e-government sites owned by United States to look for the opportunities and the threats the sites offer to the users. Less than half of the sites clearly stated their security measures. 98% of the sites used SSL encryption to secure user accounts.	Information Security Auditing, Computer network security mapping and Web content analysis	Paper identified a lot of security lapses but failed to provide solutions for all.	No	Yes	No
Alshehri, M., and Drew, S. (2010)	The paper identified the challenges and barriers affecting the adoption of e-government by Saudi citizens.	Online Survey and Data Analysis	Paper did not explore the security requirements of eGovt. in detail.	Yes	Yes	No
Bertot, J., *et al.* (2014)	The paper examined the ways current information policy framework failed to address different policy challenges in e-government. The paper then offered recommendations as starting point to revise the policy.	Survey	The paper is limited to the US only	No	Yes	No
Rehman, M., Esichaikul, V., and Kamal, M. (2012)	The study explored the factors that promote end-user adoption of e-government services in Pakistan. The factors revealed revealed by the findings include user data privacy, performance expectancy, awareness, and social influence.	Unified Theory of Acceptance and Use of Technology (UTAUT) model. Online survey. Statistical descriptive analysis	Data sample used is small as the survey had 115 respondents	No	Yes	No
Rodrigues, G., Sarabdeen, J., &Balasubramania	The research identified the factors that influence adoption of e-government services in UAE. Factors identified	UTAUT model, Exploratory factor analysis, Regression analysis,	The study failed to provide the ways the factors	Yes	Yes	Yes

n, S. (2016)	include confidentiality, users' attitude, and trust.	Correlation analysis	identified can be addressed.			
Osman, I. H., Anouze, A. L., Irani, Z., Al-Ayoubi, B., Lee, H., Balcı, A., . . . Weerakkody, V. (2014)	The study proposed a COBRAS (Cost; Opportunity; Benefit; Risk; Analysis for Satisfaction) framework which balances user's risk and cost of engaging with an e-government service with the associated opportunity and benefit.	Proposed COBRAS framework. 79 questionnaires filled by 2785 users of Turkey e-govt portal. Utilized structural equation modeling & confirmatory factor analysis.	The security requirements of e-government were not thoroughly explored.	No	Yes	No
AlKalbani, A., Deng, H., and Kam, B. (2015)	This examined how organisational security culture affects information security compliance in public agencies and organisations e-government development. The study showed that information security awareness, accountability, social pressure and management commitments positively influence information security compliance in public organisations.	Developed an information security model and hierarchical regression analysis	No insight was provided on how to improve accountability, information security awareness and management commitments, which were the factors identified to have positive influence on information security compliance.	Yes	No	Yes
Botchwey, G. (2018)	This paper assessed the level of public trust and confidence in the integrity of data and systems exchanged on Ghana's e-Government platform, with a specific focus on data protection and integrity. The study showed that there is a huge weakness concerning the issues of confidentiality, services' continuous availability and data integrity on e-Government platforms.	Cross sectional survey with respondents drawn from four regions with a high concentration of e-government services.	While the study identified major challenges that need to be addressed like lack of national database to verify information, service exclusion, poor internet etc., it did not provide any solutions.	Yes	Yes	Yes
Riswan, M.M. and	The study examined the cause of low participation in e-	120 respondents selected on	Sample is small; the study noted	No	Yes	No

Rajandran, K.V.R., (2017)	Government in Thanjavur district and found out the causes include level of awareness, acceptance, attitude towards sustainable development and security of e-Government.	the basis of random sampling, regression and correlation analysis	that e-Government web security needs to be improved but did not state the specific improvements to be made and how.			
Haran, M. (2016)	The study identified the relevant stakeholders who are insiders as far as e-Government IT infrastructure is concerned and listed the threats that may be caused by these insiders. The paper then provided ways to mitigate such threats.	Proposed a robust framework mechanism for early detection and mitigation of insider threats.	The paper is limited to insider threats alone	No	Yes	No
Choejey, P., Fung, C. C., Wong, K. W., Murray, D., and Xie, H. (2015)	An assessment of factors affecting the implementation of cybersecurity program in government agencies in Bhutan. The research showed that several organisations are affected by cybersecurity threats like hacking, phishing scams and malware. The recommendations provided include technological and managerial practices to improve people's level of confidence and trust in e-government services.	Survey with 157 respondents	Sample for the survey is small	Yes	Yes	No

Use of three Penetration Testing tools on Yesser's website

We use three different penetration tools; Rapid7, Zap and Nessus to analyse the risks and vulnerabilities associated with e-government websites.

1) Rapid7

The Yesser website was scanned using InsightVM from Rapid7 LLC on February 24, 2020. The website was found to be active and its vulnerabilities by severity are represented by Figure 3. The vulnerabilities by severity are divided into three parts; critical, severe and moderate.

Figure 3: Yesser Vulnerabilities by Severity

As shown in Figure 3, there were no critical vulnerabilities found during the scan of Yesser website. Also, there was no moderate vulnerabilities discovered. However, there was one severe vulnerability. The severe vulnerability detected was that the subject common name (CN) field in the X.509 certificate is different from the name of the entity providing the certificate.

By vulnerability categories, the Rapid7 scan found 1 vulnerability instance each in the HTTP and Web categories, thereby making them the most common vulnerability categories as shown in Figure 4.

Figure 4: Yesser's Most Common Vulnerabilities

The HTTP and HTTPS services were found on the Yesser website, making them the most common services (Figure 5).

Figure 5: Yesser's Most Vulnerable Services

1) Zap

The Zap scan of the Yesser website was carried out on June 13th, 2020. The summary of the scan is provided in Table 2 below:

Table 2: Summary of Zap Scan of Yesser Websites

Risk Level	Number of Alerts
High	0
Medium	1
Low	10
Informational	2

The medium alert received showed that the X-frame options header is not set. The simple solution to this is to ensure that X-frame options HTTP header is set on all pages on the Yesser website. The low impact vulnerabilities detected by the scan include Absence of Anti-CSRF Tokens, Cookie Without SameSite Attribute, Cross-Domain JavaScript Source File Inclusion, Cookie Without Secure Flag, Cookie No HttpOnly Flag, Web Browser XSS Protection Not Enabled, Incomplete or No Cache-control and, Secure Pages Include Mixed Content, Private IP Disclosure.

The following are the two informational vulnerabilities detected by the scan:

(a) Information Disclosure - Suspicious Comments. The solution to this is to remove all comments that return information capable of helping the and solve any underlying problems.

(b) Timestamp Disclosure – Unix. Here, the solution is to manually confirm that the timestamp data is not sensitive, and that the data cannot be aggregated to disclose exploitable patterns.

2) Nessus

The Nessus penetration test tool was used to scan www.yesser.gov.sa on February 24th, 2020. The results (Figure 6) showed that there were no critical or high vulnerabilities in Yesser. However, two medium-level vulnerabilities were found. Also, 22 informational vulnerabilities were detected.

Figure 6: Result of Nessus Scan of Yesser Website

The first medium vulnerability is F5 Big-IP Cookie Remote Information Disclosure. The remote load balancer suffers from an information disclosure vulnerability. The second medium vulnerability is that web application is potentially vulnerable to Clickjacking.

Proposed e-Government Framework

The current e-government framework in Saudi Arabia (Yesser) uses a centralised database thereby having low level of confidentiality and trust (Al-Mushayt *et al.,* 2012). The proposed model (shown in figure 2) offers a better security as it is completely based on a descentralised database.

In the proposed framework, there are three different access scenarios. These include Consumer to Government (C2G), Government to Business (G2B), and Government to Government (G2G). For C2G and G2B, the customer node and business node made lightweight nodes. However, for G2G, the node becomes a full node. In C2G, the government service bus connects directly with internet, mobile apps, kiosk etc. (consumers); in G2B, it connects with business providers; and in G2G, it connects with a government website (which can be owned by a government agency or ministry). As shown in Figure 2, these three relationships are secured by putting the blockchain technology between DMZ zone and Secured Intranet zone. By adding the blockchain technology to the new framework is to make the GSB more secure by distributing GSB across multiple sites and running blockchain in making any one site's security

compromise not affecting the information integrity as a whole. The benefit of using blockchain is decentralized which does not rely on a central point of control, blockchain is resistant to modification of data, blockchain brings Trust in a trustless world and blockchain is beyond securing Financial Transactions.

Conclusion and Future Work

The study presented in this paper explores most existing literature on securing e-Government systems in different countries. Our study reveals that there are several security and privacy issues (particularly as regards confidentiality, trust and integrity) which the existing e-government frameworks have not been able to address thoroughly. While many researchers have made efforts to address security challenges in e-Government system, our study shows that, there are still some loopholes that need to be blocked. For example, most of the existing frameworks and models do not capture the necessary e-government security requirements; have a lack of trust in internet-mediated transactions, and unauthorized access to systems with the help of insiders. In particular, this paper showed that the Yesser website has a few security issues which are majorly categorised as severe, medium-level and low-impact vulnerabilities. Also, this paper proposes a new framework that leverages blockchain to secure Saudi e-Government system. This proposed model brings decentralisation, access control, confidentiality, and privacy and trust into e-Government service. It is believed that future researchers will explore the extent to which blockchain integration has helped in solving the current issues of Yesser and improve the Saudi e-government services in general.

Instruments to Support Short Food Supply Chains And Local Food Systems in France

Anna KAPALA
Wrocław University of Environmental and Life Sciences; Wroclaw, Poland
anna.kapala@upwr.edu.pl,

Abstract

The purpose of the study is to identify what legal instruments supporting short food supply chains and, more generally, local food systems are implemented in France. These rules have been drawn from a variety of domains and levels, including national laws, government policies, and local government initiatives and analysed in relation to various forms of short circuits present in French territory, which are the key components of local food systems, such as direct marketing, producers' stores, basket systems, urban agriculture, and deliveries to public catering. Overall, the French instruments are multiple, diverse, mostly innovative, taking into account social, environmental, and solidarity values, and can be a good example to follow. Most of them are established on the local level, being thus an expression of new models of local food governance, corresponding to the values of participative economy and food democracy.

Keywords: local food systems, short supply chains, direct sales, French law.

Introduction

Short food supply chains (SFSCs), "*les circuit courts*" in French, are part of local or also referred to in the literature as "alternative" or "territorial" food systems. In France, SFSCs is not a new phenomenon. From the very beginning of agriculture, farmers sold their produce to consumers on the farm or at a nearby market and often supplied stores in large cities. Direct sales at marketplaces remained important until the 1950s for some products. Self-sourcing farming has been practised for a long time in rural areas and has not completely disappeared in developed countries, contributing to the protection of rural and suburban areas, as observed by Philipon, Chiffoleau, Wallet (2017).

The authors pointed out that SFSC began to disappear after World War II when the American model of agriculture was promoted, aiming at mechanization, intensification of production based on chemicals, enlarging the area of farms and their specialization, the concentration of the agri-food industry and supply chains in the country in the hands of several large entities. In the '50s and '60s first self-service stores were opened which started hypermarkets. Since then, food has been packaged, labelled, standardized, often processed and sold cheaper than local shopkeepers, who are more likely to buy from local farmers than wholesalers. The methods of producing and selling the products of the land have changed dramatically. However, since the beginning of the 21st century, direct selling, or more broadly the SFSCs, have been making a comeback, along with grassroots movements initiated by consumers concerned about the quality and origin of food and dissatisfied with the "dehumanized" way in which it is being sold (Philipon, Chiffoleau, Wallet, 2017).

New forms of SFSCs have emerged, such as French associations for the support of peasant agriculture (AMAPs) or collective sale points. Short circuits have also appeared in legal texts and national food policy. For some, according to Philipon, Chiffoleau, Wallet (2017) the choice of short supply chains is an expression of a global approach, opposing the concentration of distribution in the hands of giants and an economic model in which the producer does not receive fair remuneration for his work and often runs a type of agriculture that is harmful to the environment.

The concept of local food systems (LFS) is not defined in French law. In the literature, the term "territorial food systems" is used more often, however it is also not a legal concept. Bodiguel and Bréger (2018) noticed that it has been gradually developed in response to changing farming and food practices. The concept of "Territorialised Food Systems" was defined by Rastoin (2017) as "a set of agri-food chains that meet the criteria of sustainable development, located in a geographic area with a regional dimension and coordinated by territorial governance. These systems develop according to several principles: the sustainability of agricultural systems and the ability to renew the natural resources of the territories; food democracy and building the local economy; participatory management; and finally

corporate social responsibility. The concept of territorial food systems, according to Bodiguel, Bréger (2018) can therefore be analysed as a "third way" between a globalized production-oriented model and a subsistence (family) farming model.
The purpose of the study is to identify what legal instruments supporting short food supply chains and, more generally, local food systems are implemented in France. It is not an easy task, as the regulations concerning the SFSCs and LFS cannot be found in one single act devoted to this issue. Instead, they need to be drawn from a variety of domains and levels, including national laws, government policies, and local governance initiatives. These rules will be analysed in relation to various forms of SFSCc which are the key components of local food systems, such as direct marketing, producers' stores, basket systems, urban agriculture, and supplies to public catering.

National policy supporting SFSCs and the definition of "*circuit court*"

SFSCs appear in legal texts, in the 2010 law on the national commitment for the environment, and in the 2010 law on modernization of agriculture and fishing. The latter act included "the development of short circuits and the promotion of geographical proximity between producers and processors", likewise, "the supply of local agricultural products in public and private collective catering" in the objectives of the agri-food policy set forth in the Rural and Maritime Fisheries Code (RMFC). Furthermore, the 2014 Law of the Future for Agriculture, Food and Forestry encourages the "territorial anchoring of the production, processing and marketing of agricultural products". Thus, the territorial anchorage of food and the development of the SFSC are the priorities of the national food policy. The law on modernization of agriculture and fishing brought also some novelties in the institutional area. Besides the classic forms of producers grouping, it is possible to create economic and environmental interest group which can bring together all the actors of the SFSCs at the territorial level and promote the emergence of new food governance and new forms of contractual regulation adjusted to SFSCs as pointed out by Friant-Perrot (2016).

An important tool for the territorial food systems development are the "territorial food projects" (TFPs), defined in RMFC, as they should bring together all the actors concerned; and the sector should be locally organized around production, processing and local consumption (Bodiguel, Bréger, 2018). Essentially in the form of contracts, these projects are carried out "in concert with all the players in a territory and meet the objective of structuring the agricultural economy and implementing a territorial food system. They participate in the consolidation of localized sectors and the development of the consumption of products from short circuits, in particular relating to organic production".

The TFPs often form public-private partnerships involving local authorities, local communities and farmers with the aim of developing urban agriculture, supplying public catering with local food or creating brands of local products. The instruments used by TFPs, as listed for example by Bodiguel, Bréger (2018), include public land policies to reclaim peri-urban agricultural space and regulate the land market (town planning and land use planning), the use of protected geographical indications, or even the creation of local brands to promote local productions and better inform the consumer.

Regarding the concept of "short food supply chains" in France, although the term "short circuits" appears in the legal provisions (Articles L. 1 and L. 111-2-2 (RMFC), it is not legally defined and there is no consensus on its concept. In the Action Plan for the development of short circuits of June 2009, prepared by the Minister of Agriculture, "short circuit" means "a method of marketing agricultural products that is exercised either by direct sale from the producer to the consumer, or by indirect sale on condition that there is only one intermediary between the farmer and the consumer". This definition refers to a method of commercialization and the number of intermediaries and no to the production method. There is no criterion of geographical proximity between the producer and the consumer. While it is generally accepted that short chains contain this condition, the kilometre limit is not defined by any norm. In a research study by Grimonprez (2016) it was emphasised that the proximity of the places of production and purchase and a relationship as direct as possible between the producer and the consumer should be included in the definition. The buyers, as well as the producers, care about direct social relations, far from the anonymity of large-format stores. Thus, these two criteria, geographical and social, distinguish SFSCs from long chains.

Certainly, geographical proximity is not a guarantee of all expected non-market values, such as the quality of a product and more solidary commercial relations as was aptly observed by Friant-Perrot (2016). According to some views, presented by Philipon, Chiffoleau, Wallet (2017) the definition lacks the requirement of environmentally friendly production methods as well as a reference to the farmer's fair revenues. Likewise, important in these distribution methods are higher margins where there are no more (or fewer) middlemen. Producers not only want to take over a greater share of the added value of their products but also to be independent in their work and overcome the limitations of long supply chains (Philipon, Chiffoleau, Wallet 2017).

The EU definition, laid down in Article 2 of Regulation (EU) No 1305/2013, is more complete. It includes the criterion of geographical proximity and also takes into account values such as close relations between SSC participants, which are the basic element that distinguishes these chains from long ones. However, the distance that determines geographic proximity is also not defined.
While the national authorities in France wish to promote the SFSC, they have not imposed a specific model of the legal framework for these alternative forms of distribution. At the local level, the conditions for achieving food policy goals have not been defined. It is left mainly to the initiative of the regions and local stakeholders to take legal or organizational action on this matter. Hence, this is done through a bottom-up approach where consumers, various social organizations, professional farming organizations such as the CIVAM Farmers Network and rural actors are involved in creating the regulatory model for the SFSC. The chambers of agriculture and agricultural trade unions (*la Federation nationale des syndicats d'exploitants agricoles*) also play an important role in promoting them (Philipon, Chiffoleau, Wallet 2017). In 2015, for example, the chain "*Chaines alimentaires courtes de proximite pour ue alimentation durable*" was established - bringing together entities to exchange their experiences and create an expert platform on SFSCs.

SFSCs facilitate food governance by mobilizing all the players, such as local authorities, farmers, artisans, traders, consumers, restaurants, being an expression of food democracy at the local level. In this model of the food system, power is exercised by the community, rather than by the state or the market, therefore activities are decentralized, involving local institutions and entities in elaborating of rules (Friant-Perrot, 2016). Thus, on the one hand, government policy is of great importance for the development of the SFSCs, but on the other hand, local authorities are generally designated by law as the most relevant primary initiators to support projects concerning local food systems (eg, local food projects, short circuits, urban agriculture) and implement them (Bodiguel, 2018).

Forms of short food supply chains in France

There are various forms of SFSC, both traditional and innovative. The traditional ones include sales on farms, e.g. on a wine farm or in agritourism, and sale at marketplaces. More innovative forms are producers' markets, reserved only for producers, to which wholesalers, traders, intermediaries have no access. Other innovative forms, listed by Philipon, Chiffoleau, Wallet (2017) are online ordering system, itinerant shops, local products supply for public catering (school canteens, hospitals, prisons, retirement houses, etc.), collective public gardens in cities, crops on terraces and balconies, baskets systems, where the producer sells a set of products corresponding to the average weekly consumption, adapting to the type of consumer. Well established practice in France, inspired by the "Community-supported agriculture" developed in the USA and the Japanese *teikei* system, are the AMAPs (consumer and producer associations in which the consumer undertakes to purchase the farmer's products as baskets and to participate in his work or sale).

Producers sell their products individually or collectively. Some of the collective groups are formally organized, eg in the form of cooperatives or in the association of "1901 law" type. Sale practices are most often purely contractual, although in some cases self-regulatory statutes are used, as in the case of AMAP. There are also local brands ("*Iles des France*", "*Aubagne*"), which have been established on the basis of dialogue between local economic actors (producers, restaurant owners), consumers and local authorities (Friant-Perrot, 2016).

Direct sales

Direct sale is the primary form of commercialization in short food supply chains. It may take place directly to the consumer, to large stores, local stores or mass caterers. In the legal terms, the sale of agricultural products (as well as their processing) directly by the farmer is considered as part of an "auxiliary" agricultural activity which is the "extension of the act of production" (as defined in Article L.311-1 (RMFC). In order not to qualify as a commercial activity, direct sales must be carried out by the farmer and concern only products from his farm (Bodiguel, Cardwell, 2005). The Internet is used as a direct sales support tool, such as popular in France websites „*drives fermier*".

Under the social security regulations, processing, preservation and commercialization of agricultural products is an activity qualified as an extension of the act of agricultural production. Thus, a farmer carrying out these activities benefits from the social security scheme established for "self-employed in agricultural professions". Likewise, under tax law, the sale and processing of agricultural products are assimilated to agricultural activity (Rochdi, 2016). These agricultural, tax and social legislation qualifying direct sales as an agricultural activity is an important instrument to facilitate direct sales of agricultural products, both basic and processed.

However, within the legal framework, there are some issues and ambiguities regarding this activity. Firstly, as observed by Rochdi, (2016), although direct sales, under the RMFC, is a "civil" activity, not subject to commercial regulations, its legal regulations are derived from commercial law. Thus, even though a farmer retains his status he

cannot be exempt from the rules which apply to any sale operation, concerning safety, hygiene, labelling, etc. Formally, the commercial regime remains complementary to the agricultural regime. Secondly, while the sale of products produced on the farm remains an agricultural activity, a farmer who sells products purchased from another farmer is not only a farmer but also becomes a trader, because such activity under the Commercial Code is a commercial activity. In practice, often a farmer, to expand his offer and retain customers, buys products and adds them to his own to produce a new product. Such an action meets the definition of a commercial act. If he is then considered a farmer, his actions may result in unfair competition against sellers, and under tax regulations may conflict with equality in terms of public charges (Rochdi, 2016). Furthermore, in the case of innovative forms of sale, the issue of qualifying direct sales as an agricultural activity arises. As a rule, only sales by the farmer himself at fairs, markets, on the farm, in baskets, shops or public catering establishments can be considered as "agricultural". So, when it passes through an intermediary such as a collective structure, there is a risk that the sale will turn into a "commercial act" (Grimonprez, 2016).

Therefore, in the research study by Rochdi (2016) a postulate has been put forward to redefine the boundaries of agricultural status, which is necessary for the development of short supply chains. In the absence of clear legal boundaries for the activity that remains agricultural, the delimitation of which has in practice been left to a court decision, the producer-seller remains exposed to re-qualifying his sales activity and subordinating it to various statuses of farmer, merchant or artisan. This is often the case with AMAPs that are taxed on commercial profits due to the lucrative nature of their business, as will be discussed later in the study In terms of social insurance, the disqualification of sales as an agricultural activity will also result in the farmer being subject to various social insurance regimes (Rochdi, 2016).

Collective Sale Points

Producers' stores are defined in art. L 611-8 RMFC, under which groups of local agricultural producers market their products in their stores within the framework of a short circuit. They can offer only their products whether raw or processed which must represent in value at least 70% of the total turnover of this point of sale. A maximum of 30% of the products sold can come from agricultural cooperatives, food artisans and, or producers who are not members of the store. Thus, this kind of collective sale by agricultural producers is officially recognized by French law. By excluding situations where producers sell products that have not been proven to be of local origin or that are wholesale, the law aims to ensure that products sold and presented as "local" is indeed such. Other products would not correspond to the authenticity of the short circuit model. The purpose of this provision is also to ensure that, under the Law of Consumption of 17 March 2014 collective selling is not a deceptive commercial practice. The formula nevertheless leaves uncertainties about the notions of "local" agricultural producers and "organized short circuits".

Producers' stores are particularly popular in the Rhône-Alpes region, where the association "*Terre d´envies*" has even registered a trademark with the French National Institute for Industrial Property for products sold in these points. Word and figurative mark "Products from our farms sold by us" (*Produits de nos fermes, vendus par nous- mêmes*) may be used by farmers with the consent of the association.

From a legal and organizational point of view, as there is no legal category for collective outlets, such points can be run in the form of a limited liability company, economic interest groups, agricultural cooperative or association of the "1901 law" type. An important event took place in 1997 when the AVEC Rhone-Alpes association convinced the Minister of Agriculture to recognize the producer stores as a form of direct delivery to consumers, the same as selling on the market or the farm. Such recognition makes it possible to qualify the collective sales to the so-called "extension of the agricultural activity of the farm", which translates into benefits in many areas (sanitary requirements, fiscal law, social security system).

Baskets Systems and AMAP

The basket system is quite diverse and purchasing groups are very common in France. Many of them operate informally, being set up by producers or consumers. In general, baskets are organized in form and structure at the initiative of producers or consumers themselves. The basic principles of their functioning are relatively simple. A group of producers or consumers organizes to jointly sell or buy products, mostly agri-food products. Consumer-initiated baskets are often organized in the legal form of an association of the "1901 law" type. However, there is no ready-made scheme for creating a basket system. An example of a basket system is *Les Paniers de Saint-Gilles*, established on the initiative of the municipal association of environmentalists in 2006. Only consumers and producers from closely adjacent municipalities participate in the basket. The system is based on the principles of supporting local agriculture that creates jobs and promotes economic dynamism by focusing on environmentally respectful production and supply systems (Maréchal, 2008).

Another example is the original form of a basket with a strong social vocation, organized in the form of the collective ecological garden *Les Jardins de Cocagne*. Founded in 1991 as associations under the law of 1901, aimed at social and professional integration. Through the production and distribution of organic vegetables in the form of weekly baskets but also on the markets, to members-consumers, these gardens allow adults in difficulty to find a job and rebuild a professional project. Thus, they are a part of the social economy and solidarity *sensu stricto* (Maréchal, 2008).

The AMAP *(*Association for the Preservation of Peasant Agriculture) is the formal and networked result of the "baskets system". It first appeared in France in the early 2000s and is now an important phenomenon in French territorial food systems. This model is based on a partnership agreement between consumers and producers, referred to by Rochdi (2016) as a solidarity contract. Consumers contractually commit to purchase the farmers' production in advance and make a prepayment of the costs of products that will be delivered to them, thus allowing these farmers to have working capital or sufficient cash to meet their expenses and investments. Through their activity, AMAPs allow producers not only to obtain outlets but also to provide them with an income. The box prices are fixed in the "fair manner" so that the farmer receives a fair revenue and the price for the consumer is affordable (Friant-Perrot, 2016).. Their legal form of organization is the associations of the "1901 law" type, the purpose of which is to create a direct link between consumers and a farmer.

The activity of AMAPs is considered from the point of view of tax principles as lucrative and they are subject to commercial taxes regardless of their size and the amount of their income. However, as these associations receive in principle only modest revenues, the consequences of the taxation of these structures are in practice limited. Producers and consumers contractually undertake to comply with the AMAP Charter created in 2003 by Alliance PEC. It combines several goals: economic, social and solidarity aspects; environmental protection; a healthy and varied diet and in sufficient quantity, as well as the civic and political dimensions. AMAPs and more generally basket systems were characterised by Lamine and Perrot (2008) as phenomenon promoting the logic of "peasant, socially just and ecologically healthy" agriculture and the defence of "local farms" in the form of an alternative agri-food system as opposed to the dominant agri-food system characterized by a coupling of intensive farming and mass distribution.

Supplies to Public Catering

In general, it is difficult to adopt criteria such as "local origin" of products or "proximity" in public procurement law as this may be contrary to the EU principle of free movement of goods and free competition. However, an important amendment to Art. 53 of the Public market's code was established, which consequently allows for the selection of tenders for deliveries to mass caterers "the development performance of direct supplies of agricultural products". The direct delivery criterion opens up the possibility for short circuits of supplying school canteens, hospitals, retirement houses, and other collective catering points. At the same time, it does not prohibit deliveries in long chains, provided that the criterion of direct delivery is met as observed by Rochdi (2016).

In 2014 the French government in the Practical Guide issued by the Minister of Agriculture fixed the objective that till 2017 in the collective restaurants 40% of products should be local. To achieve this goal local authorities create and carry local food projects. To supply school canteens, municipalities decide to develop their local agriculture while controlling the distribution channels. These strategies take many forms, from simple contracts with suburban farmers (after calls for tender), to the placement of one or more farmers on the municipality's own land ("agricultural pole of proximity") to the creation of "agricultural boards" which are municipal structures in charge of production" as defined by Grimonprez (2016). Thus, in France, in order to secure the supply of fresh produce for the benefit of local collective catering, a whole range of partnerships and public-private agreements are established. Many producer groups in the form of associations, economic interest groups and cooperatives of interest have also been established to offer a more complete range of products.

Another important legal initiative to develop local (territorial) food systems was launched in 2018 through the law of 30 October 2018 for the balance of trade relations in the agricultural and food sector and healthy, sustainable and accessible food for all, which set the goal to "Promote healthy, safe and sustainable food". As part of this target, public catering is required to source at least 50% of local products or with indications of origin and quality, including 20% from organic farming by 2022. This obligation would allow local farmers to have a stable market for fresh, seasonal products, and state institutions to have nutritious food. Although the law is not in force, it proves the nation's commitment to supporting local growers and thus supporting the regional food system.

Urban Agriculture

Since 2017, the Biodiversity Law requires the production of renewable energy or greening systems on the roofs of retail stores in commercial zones. In cases where edible plants are planted on rooftops, this law can play a role in

promoting local food security and strengthening community resilience. It can also contribute to increasing connections between green zones for local nature. Apart from this act undertaken at the national level, as a general rule, the legal instruments in favour of urban and suburban agriculture are based on the will and resources of local authorities. This is the case, as observed Bodiguel (2018), with the protection of agricultural land, in particular, land in urban and peri-urban areas, which involves town planning documents blocking the artificialization of agricultural land. An interesting example of local land use policy beneficial for local farming in the urban and peri-urban area is the Rennes Métropole "local plan for agriculture". This document aims to support the concept of an "urban archipelago", which is supposed to hinder the city's expansion beyond the ring road and to maintain "green" areas between the city and the "satellite municipalities" while preserving land for the cultivation and development of the SFSC. Thriving agriculture is considered under this policy to be the best and most economical way to maintain the "green belt". Another example is Mouans-Sartoux town, where the municipal agricultural office manages four hectares of the municipality land to produce vegetables for the school catering (Bodiguel, 2018).

Conclusions

The considerations have shown that instruments supporting short food chains and local food systems in France can be identified at the national and local level. The decisive role to play in the development of short circuits and LFS has been left to municipalities and regions. Thus, the effectiveness of SFSC development activities depends on local governance. As the agricultural policy is traditionally decided and conducted at European and national level, for a long time local authorities have not dealt with a topic that was not clearly within their remit. Consequently, local agriculture is suffering from a lack of governance.

However, for ten years, municipalities have started to participate in local agricultural policy, including the protection of arable land in suburban areas, the creation of local agricultural centres, assistance in the creation of short circuits, etc.(Grimonprez, 2016). The inclusion of local authorities in agricultural governance is called in the literature by Bodiguel and Bréger (2018) as a process of "reterritorialization" of agricultural and food policies. Nevertheless, there is still uncertainty over the distribution of administrative powers.

Also important are the initiatives taken by local actors to embody the food democracy, which are numerous in France and of which only a few examples are presented in this study. AMAPs are the best example of formalisation of solidarity relations on the local level. They represent the will to ensure a better revenue for farmers and bigger independence from other links in the chain, as well as to respond to the consumers' needs and preserve the local economy. SFSCs thrive on these new forms of partnership between consumers and producers. Their further expansion depends on the involvement of players in support, in particular organizations and communities involved in the development of agriculture.

Unfortunately, there is no legal system tending to contractual justice (willingness to provide a fair income for farmers) and food democracy (citizen participation), which has been identified by Friant-Perrot (2016) as a real obstacle for the SFSC to develop and to be more than a marginal but a meaningful distribution chain. Consequently, as a fruit of the new food governance, the short circuit legal framework is derived from private and public regulations, often taking into account environmental and social standards (AMAP charter, paralegals standards of various organizations, ministerial Practical Guide), the normative force of which varies (Friant-Perrot, 2016). Therefore, as it was aptly noted in the literature by Friant-Perrot (2016), the normative structure of the SFSC is characterized by legal pluralism: a plurality of legal orders (European, national, regional, local), a plurality of entities (farmers, consumers, social and agricultural organizations, local authorities) and a plurality of regulations (legal provisions, legal judgments, private norms, technical standards).

Overall, it can be said that the French SFSC and LFS development instruments are multiple, diverse, mostly innovative, and well-established, and can be a good example to follow. However, the law in force does not yet provide an ideal framework for the development of a global project of local agriculture (Grimonprez, 2016). Therefore, state and local authorities should continue to become more involved in the development of LFS, using the existing support instruments, expanding them and creating new ones. Short circuits do not have to be a marginal model of agriculture, they can be an alternative model that should be considered by the political and legislative authorities, both national and local.

Abstract

In the first part of a paper were detailed study of the discriminant analysis, based on the concept of distance between elements, and on the criterion of proximity constructed on calculating a cosine of the angle between two vectors was conducted. Also, all constructions relying on the example of texts classification are provided. In the second part of the article the method of support vector machines (SVM - Support Vector Machines), included in the set of algorithms called as "supervised learning" was examined. They are also effectively used in problems of classification as a method of discriminant analysis too. Thus, the article analyzes in detail the problem of data classification. In particular, it is proposed to modify the particle swarm optimization algorithm and use it in conjunction with the SVM algorithm.

Keywords: data classification, genetic algorithms, support vectors, data preprocessing, discriminant functions.

Introduction

The overload of information generated by everyday life today has led to the concept of automating the extraction of knowledge from text and beyond. This direction is related to a wide range of tasks - from recognizing blurred images to event detection and opinion classification. Sometimes it is hard to believe that more than 80 percent of business data are in text form. Examples of the analyses under consideration include call center transcriptions, online reviews, product surveys and customer opinions as well as other text documents such as legal contracts. Most of this data is unused and is a mine of interesting conclusions waiting to be discovered. One of the methods of studying these texts is text exploration and analysis supported by innovative technologies. The proposed method is a contribution to the big issue of text mining.

One of the most effective classification algorithms is support vector machine (SVM). It is easy to use for linearly separable sets. For non-separable sets, it requires a kernel transformation in special cases. One of the most difficult choices is to adapt the kernel type to the problem under investigation in such a way as to achieve high accuracy of data classification. This paper shows an example of using swarm intelligence as a way to optimize classification accuracy.

Literature Review

Text information processing tasks are very often based on classification and grouping concepts, see e.g. Domingos & Pazzani (1997), Ghazanfar & Prugel-Benet (2010), Gordon (1999), Reiten (2017), Sebastiani (2002), Shah & Patel (2016). The classification refers to the determination in advance of the belonging of certain elements to one of the classes created. Clusterization consists in breaking down a set of elements into clusters, the number of which is defined, and locating the elements of the cluster in such a way that they are close to the natural centers of these clusters. The realization of the classification problem must initially be based on a set of demands, the basic ones being a priori information about the original set of objects and ameasure of closeness, similarity of elements and classes.

The Bayesian classifier is based on the assumption that the previous probabilities of the P(c_i) hypothesis are known, i.e. in particular the probability of losing the c_i classes (i = 1.2,..., k). Unfortunately, the answer to the question how to determine them, the Bayesian classifier does not give (see e.g. Domingos & Pazzani 1997, Zheng & Webb 2005, 2008). The naive Bayesian classifier, however, allows for a poor estimate of these probabilities, but sometimes it is better than nothing. The most commonly used area of the naive Bayesian classifier belongs precisely to the problem of text classification, where this method gives relatively good results as it has been shown by Reiten (2017) or Sebastiani (2002). The naive Bayesian classifier assumes conditional independence of attributes, and especially when processing texts, these assumptions are absolutely discouraging. After all, the probability of a word appearing does not depend on other words in the document, and moreover, it does not depend on the size of the document. Surprisingly, naive Bayesian text processing classifier is relatively effective and has been widely used, especially to filter spam The example has been shown by Ghazanfar & Prügel-Bennet (2010).

One of the most frequently used procedures to find models with mixed empirical distributions is the EM (Expectation Maximization) algorithm proposed by A.Dempster, M.Laird and D.Rubin (1977). The basic example are tasks in which the algorithm should include a linear combination, for example normal distributions. On the basis of selected mixed normal distributions, the discrimination or classification of objects is determined.

Many text classification methods such as supervised text classification algorithms, (decision trees, carrier vector machine, Naive Bayesian, k-nearest neighbors) can be found in the literature (Pitigala et. al. 2011, Reiten 2017, Sebastiani 2002, Shah & Patel 2016, Soucy & Mineau 2001, Zheng & Webb 2005, 2008)

Other approaches were also proposed for this purpose. One of them is evolutionary algorithms that apply to solving grouping and classification problems due to their ability to avoid local optimal solutions and come close to a global solution. Examples of such applications can be found in the literature. Basic content analysis procedures with single term indexing models were introduced as early as 1988 by Salton and Buckley (1988). Several examples of the use of genetic algorithms for text classification are described in the literature. Shumeyko & Sotnik (2009, 2010), Wang & Li (2013) have been applied such examples. Text classification is the process of dividing documents based on their contents into a predefined set of categories. The choice of features here is essential to improve the effectiveness of classification. The use of genetic algorithms to select attributes using classifiers Naive Bayes (NB), Nearest Neighbours (KNN) and Support Vector Machines (SVM) were presented by Noria Bidi and Elberrichi Zakaria (2016). Latent semantic indexing (LSI) together with the genetic algorithm was used in the work Uosal and Gunal (2014).

One of the most effective classification algorithms treated as unattended learning is the support vector machine (SVM) (Bidi & Zakaria 2016, Cortes & Vapnik 1995, Vapnik & Lerner 1963, Vapnik & Chervonenkis 1974, Cristianini & Shawe-Taylor 2000, Rossi & Villa 2006, Hamel 2009, Kim & Choi 2014). It is simple to use for linearly separated sets, but for linearly unseparable sets, it may require kernel transformation like proposed by Cristianini & Shawe-Taylor (2000) or Bordes et. al. (2005). One of the most difficult choices is to adapt the kernel type to the problem under investigation in such a way as to achieve high accuracy of data classification. This paper shows an example of using swarm intelligence as a way to optimize classification accuracy.

In the further part of the article, after defining the criterion of similarity constructed on the basis of calculation of cosine angle between two vectors (Chapter 2.1), the control vector was used, which allowed to determine appropriate classes. Then the approach using Voronoi diagrams is described (Chapter 2.2). In both cases the genetic algorithm was used to determine the optimal division. Chapter 3.1 is an introduction to the SVM, which together with the swarm intelligence (Chapter 3.2) allowed to perform a trial classification. Finally, the conclusions are briefly presented.

Using of genetic algorithms for creation of the vector classifiers

Reduction of class dimensions in text classification

In the discriminatory analysis under consideration, the basis is a measure of similarity of objects usually based on the concept of distance between elements. The similarity measures used here are very different as it has been shown by Gordon (1999), Reiten (2017), Sebastiani (2002). The introduced criterion of closeness constructed on the basis of the calculation of the cosine angle between two vectors seems to be relatively promising especially when applied to the classification of texts The examples have been applied by Shumeyko & Sotnik (2009, 2011), Yesin et. al. (2019).

The first stage of the analysis consists of preliminary data processing, i.e. creating sets of statistics for available classes. For the creation of the set of statistics all sets of word forms $b^{\nu},\ \nu = 0,\ldots,M-1$ are consistently processed, for text belonging to one class $B = \{b^{\nu}\}_{\nu=0}^{M-1}$. On the set of word forms of each processed text b^{ν} the set of the unique (not repeating) word forms and their counters is under construction : (w_i^{ν}, n_i^{ν}) $(i = 0,\ldots,N^{\nu}-1)$. Here N^{ν} is a quantity of unique word forms for the text b^{ν}. After that data for each document separately are normalized in the form presented in equation (1).

$$\underline{n}_i^\nu = \frac{n_i^\nu}{\sqrt{\sum_{j=0}^{N^\nu-1}(n_j^\nu)^2}} (i = 0, \dots, N^\nu - 1) \qquad (1)$$

Then, we arrange all words for each document in the same order (the word order is not essential, the main thing that words in each of structures $(w_i^\nu, \underline{n}_i^\nu)(i = 0, \dots, N^\nu - 1)$ went in the same order) and we find the sum of all vectors $n_i(B) = \sum_{j=0}^{M-1} n_i^\nu \ (i = 0, \dots, N(B))$ (where $N(B)$ is a quantity of unique word forms for the class B in general) also we normalize it by its unit as it is shown in equation (2).

$$\underline{n}_i(B) = \frac{n_i(B)}{\sqrt{\sum_{j=0}^{N(B)}(n_j(B))^2}} \qquad (2)$$

For the received central point of the class we create the set of statistics, writing down in it values $\left(w_i(B), \underline{n}_i(B)\right) \ (i = 0, \dots, N(B))$.

For creating the central vector of classes $\{B^\mu\}_{\mu=0}^{K-1}$ where each class B^μ is described by the central vector $(w_i(B^\mu), \underline{n}_i(B^\mu))(i = 0, \dots, N(B^\mu))$, it is necessary to find their sum, having summed up all coordinates from all vectors for each value of the word form, that is for the word form ω we receive the coordinate is described by equation (3).

$$n(\omega) = \sum_{\mu=0}^{K-1}\{\underline{n}_i(B^\mu) | \omega_i(B^\mu) = \omega, \quad i = 0, \dots N(B^\mu)\} \qquad (3)$$

Therefore, it is necessary to make the list of unique word forms on all central vectors of classes $\{B^\mu\}_{\mu=0}^{K-1}$ and to sum up their coordinates. The set consisting their unique (not repeating) word forms and their coordinates can be written as (4),

$$\left(w_i\left(\{B^\mu\}_{\mu=0}^{K-1}\right), n_i\left(\{B^\mu\}_{\mu=0}^{K-1}\right)\right) \ (i = 0, \dots, N(\{B^\mu\}_{\mu=0}^{K-1})) \qquad (4)$$

where $N(\{B^\mu\}_{\mu=0}^{K-1})$ is a quantity of unique word forms of the set of classes $\{B^\mu\}_{\mu=0}^{K-1}$. It is necessary to normalize the received coordinates (see eq. (5)).

$$\underline{n}_i(\{B^\mu\}_{\mu=0}^{K-1}) = \frac{n_i(\{B^\mu\}_{\mu=0}^{K-1})}{\sqrt{\sum_{j=0}^{N(\{B^\mu\}_{\mu=0}^{K-1})}(n_j(\{B^\mu\}_{\mu=0}^{K-1}))^2}} \qquad (5)$$

From here the received vector $\left(w_i\left(\{B^\mu\}_{\mu=0}^{K-1}\right), \hat{n}_i\left(\{B^\mu\}_{\mu=0}^{K-1}\right)\right) (i = 0, \dots, N(\{B^\mu\}_{\mu=0}^{K-1}))$ can be the central vector of the set $\{B^\mu\}_{\mu=0}^{K-1}$.

Ideally created classification of the vector method is such set of classes $\{B^\mu\}_{\mu=0}^{K-1}$, for which the following condition (6) is satisfied: $\forall b \in B^\mu, \mu = 0, \dots, K-1$ the inequality takes place.

$$\langle \underline{n}(b), \underline{n}(B^\mu)\rangle < \langle \underline{n}(b), \underline{n}(B^\nu)\rangle, \ \ \nu \neq \mu \qquad (6)$$

Let's consider the vector Λ (control vector) of dimension $N(B^\mu)$, which coordinates accept only the one or the other admissible values (zero) $\lambda_i = \{0\ 1\}$.

Through Λ*b* let's designate the direct product of vectors Λ and *b*, that is

$$\Lambda b = (\lambda_0 \underline{n}_0(b), \lambda_1 \underline{n}_1(b), \dots, \lambda_{N(B^\mu)} \underline{n}_{N(B^\mu)}(b)).$$

The control Λ let's call admissible on the class $B^\mu = \{b^k\}_{k=0}^{M-1}$, if the condition (7) is satisfied.

$$\langle \underline{\Lambda n}(b^k), \underline{\Lambda n}(B^\mu)\rangle < \langle \underline{\Lambda n}(b^k), \underline{n}(B^\nu)\rangle, \ \nu \neq \mu, \ k = 0,1, \dots, M-1 \qquad (7)$$

Admissible control vector Λ for which this inequality (2) and at the same time which is fulfilling the condition $\sum_{k=0}^{M-1}(\Lambda b^k)^2 \to \max$, is called the optimum.

If for $\nu \neq \mu$ the set of admissible controls is degenerated, the class $B^{\mu} = \{b^k\}_{k=0}^{M-1}$ is defined incorrectly, i.e. it is inseparable from the class B^{ν} .

The problem of finding the optimum control by classical methods is rather difficult therefore we will apply genetic algorithms to its decision (Rana 1999).

For that matter, the single-point crossing over (single-point crossover) is used. It is modeled as follows: Let there are two parent individuals with chromosomes $X = \{x_i, i \in \{0, \ldots, L\}\}$ and $Y = \{y_i, i \in \{0, \ldots, L\}\}$. In a random way the point in the chromosome is defined (discontinuity point) in which both chromosomes are divided into two parts and exchange them. After processing reproduction we can get mutation. It is reached because accidentally chosen gene in the chromosome changes.

Fig. 1: The chart of reduction of dimension of categories when using genetic algorithms.

For creating new population we used the elite selection. Intermediate population which includes both parents, and their descendants are created. Members of this population are evaluated, and behind that N of the best get out of them (suitable) which will enter the next generation.

The result of applicating the genetic algorithm to the problem of reducing class dimension, is given in the figure 1.

Reduction of class dimensions in the text classification using Voronoi polyhedron

Let's notice that the vector method as a criterion of quality uses the size of the scalar product of basis vectors, thus, the class of unit vectors (documents) is limited on the sphere by the circle with the center at the end of the central vector of the class. As sphere cuts on the circle cannot densely pack all surface of the single sphere, there is the point set (basis vectors) which cannot essentially get to one class. Thus, there is the need to break the point set on the single sphere so that elements of this splitting densely packed all surface of the single sphere, that is allowed to classify any document unambiguously.

For any center of system $\{A\}$ it is possible to specify area of space which all points are closer to this center, than to any other center of system. Such area is called the Voronoi polyhedron or Voronoi diagram. The Voronoi diagram usually carry to the polyhedron also its outer surface. In three-dimensional space the Voronoi diagram for any *i* center of systems $\{A\}$ is the convex polyhedron, in two-dimensional space it is the convex polygon. Formally Voronoi polygons T_i in R^2 are defined as follows:

$$T_i = \{x \in R^2 : d(x, x_i) < d(x, x_j)\ \forall j \neq i\}.$$

where *d* is a distance function.

Creating an approximation relies on fundamental property for randomly selected *n* set points on the plane *S*. For any node from *n* on the plane, there is the great number of natural neighbors *N*. The concept of natural neighbors is closely connected with splitting the Voronoi diagram cells. For the nonempty Voronoi cell *V*(*R*), where $R \subset S$ the natural neighbors for a vertex of Delon's triangles $r \in R$, are points incidental to *V*(*R*).

The two-dimensional Voronoi polyhedron (polygon on the plane) is shown on the Fig. 2. The lines Voronoi which generated edges at the polygon are called the forming lines and the relevant centers of system are the geometrical

neighbors of this center A. Among geometrical neighbors (natural) we can distinguish two kinds of them. For the first kind is the bisecting point of a segment connecting it to the central node lies on the verge of the Voronoi polyhedron. For the second kind the bisection point is out of the edge and, therefore, out of the polyhedron.

Fig. 2: The Voronoi polyhedron (polygon) for the center A in two-dimensional system.

Polyhedrons Voronoi, the systems constructed for each center $\{A\}$, give the mosaic of polyhedrons - splitting Voronoi points (see Fig.3). Polyhedrons Voronoi systems $\{A\}$ do not enter each other and fill the space, being adjacent on the whole edges. Splitting space into Voronoi polyhedrons unambiguously is defined by system $\{A\}$ and converse uniquely defines it.

Fig. 3: The Voronoi chart on the plane.

Using the design of Voronoi diagrams in relation to points on the multidimensional single sphere, we receive splitting all basis vectors of documents into natural classes. Borders of classes will be the hyper planes dividing spherical Voronoi polyhedrons. Points on the single sphere, which in relation to all hyperplanes limiting this class lie on the same side of sphere, as the central vector of this class, will belong to one class.

Let classes of documents be checked for the splitting correctness C_ν and C_μ. For corresponding basis vector (the central vectors) $\hat{C}_\nu$, $\hat{C}_\mu$, we build the difference vector

$$\vec{\Delta}_{\nu,\mu} = \hat{C}_\nu - \hat{C}_\mu = \{\hat{n}^\nu(w_i) - \hat{n}^\mu(w_i)\}$$

and sum vector

$$\vec{\Xi}_{\nu,\mu} = \frac{1}{2}(\hat{C}_\nu + \hat{C}_\mu) = \frac{1}{2}\{\hat{n}^\nu(w_i) + \hat{n}^\mu(w_i)\}.$$

The half-sum of vectors begin coordinates of this vector in number. Let's designate it through $\Xi_{\nu,\mu}$. Let's carry out through the point $\Sigma_{\nu,\mu}$ the plane with the normal vector $\vec{\Delta}_{\nu,\mu}$

$$\Omega_{\nu,\mu} = \langle \vec{\Delta}_{\nu,\mu} \cdot (P - \Xi_{\nu,\mu}) \rangle = 0\ . \qquad (8)$$

This plane splits classes. In order to the method correctly splits classes, it is necessary that all points (documents) of one class are on the one side of the planes, that is if $b \in C_\nu$, then

$$\langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{C}_\nu - \Xi_{\nu,\mu}) \rangle \langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{b} - \Xi_{\nu,\mu}) \rangle \geq 0.$$

Points in which this condition is not satisfied need to be considered relating to belonging to category C_μ.

For the solving this problem the following method can be taken into account. Let's consider categories C_ν and C_μ. Let's split them by the plane (3), and all points lying on the one side, we will collect in new two categories C_ν^* and C_μ^*.

Let

$$d(B, \Omega_{\nu,\mu}) = \frac{|\langle \vec{\Delta}_{\nu,\mu} \cdot (B - \Xi_{\nu,\mu})\rangle|}{|\vec{\Delta}_{\nu,\mu}|}$$

be a distance from the point $B = \{b_i\}$ to the plane $\Omega_{\nu,\mu}$.

If the condition is satisfied (that is, after cutting off of data both categories are removed from each other)

$$\{d(C_\nu^*, \Omega_{\nu,\mu}) - d(C_\nu, \Omega_{\nu,\mu}) > 0, d(C_\mu^*, \Omega_{\nu,\mu}) - d(C_\mu, \Omega_{\nu,\mu}) > 0\},$$

that categories C_ν and C_μ have nonempty crossing $\tilde{C}$, which can be defined as follows, $b \in \tilde{C}$ if $b \in C_\nu$ and at the same time

$$\langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{C}_\nu - \Xi_{\nu,\mu})\rangle \langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{b} - \Xi_{\nu,\mu})\rangle < 0,$$

or, if $b \in C_\mu$,

$$\langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{C}_\mu - \Xi_{\nu,\mu})\rangle \langle \vec{\Delta}_{\nu,\mu} \cdot (\hat{b} - \Xi_{\nu,\mu})\rangle < 0.$$

It is natural that the problem of classes dimension reduction is also urgent for the method constructed on Voronoi diagrams.

Fig. 4: The result of applicating the algorithm of Bayes.

Comparative analysis of application of different discriminatory analyses to test base of documents (from Reuters-21578 text categorization test collection) is given in the following figures (see fig. 4; fig. 5; fig. 6).

Fig. 5: The result of applicating the vector algorithm.

Fig. 6: The result of applicating the algorithm based on Voronoi diagrams.

Thus, for given test base on condition of hit in the class not less than 90% of documents, dimension of classes from 10% was succeeded to reduce to 50%.

Application of swarm intelligence in matching the SVM classifier

Introduction to Support Vector Machine (SVM)

The method of support vectors (SVM) is included in the set of algorithms called as "supervised learning". They are effectively used in problems of classification. In 1963 Vapnik and Lerner (1963) proposed an algorithm which if the data are linearly separable then finds the maximal margin between the fixed boundary and the nearest points of each class. The next work by Vapnik & Chervonenkis (1974) is the cornerstone of SVM. Work on the SVM has been developed and its application can be found in many areas. The support vector network is a learning machine for two-group classification problems developed by Cortes and Vapnik (1995).

Classification models using active collection techniques were described and made available by T. Joachims (2008). In his publication you can also find the use of SVM in text classification (Joachims 2009).

One of the first comprehensive introductions to the Carrier Vector Machines (SVM), a new generation learning system based on the latest advances in statistical learning theory, was described by Cristianini and Shawe-Taylor (2000). They show that SVMs provide state-of-the-art performance in real-world applications such as text categorization, manual character recognition, image classification, biosecurity analysis, etc., SVMs are now recognized as one of the standard tools for machine learning and data mining. SVM method belongs to family of linear qualifiers.

The simplest discriminating functions of the linear classifier can be illustrated as lines separating data belonging to different classes (see Fig. 7). It can be written down in the form $g(x) = w^t x + w_0$, where $g(x) > 0 \Rightarrow x \in Class[1]$ and $g(x) < 0 \Rightarrow x \in Class[2]$.

Fig. 7: The simplest discriminating functions

Thus the discriminant function is described by the equation $g(x) = 0$. Distance between the point x and the point of dividing function $g(x) = 0$ is equal to $\frac{|w^t x + w_0|}{\|w\|}$.

Fig. 8: The maximum dividing corridor.

Let x_i lie on short circuit of border, that is $|w^t x_i + w_0| = 1$. Border width of the dividing margin, is chosen as wide as possible (see Fig. 8). Considering that short strip of border meets the condition $|w^t x_i + w_0| = 1$, then distance from x_i to $g(x) = 0$ is

$$\frac{|w^t x + w_0|}{\|w\|} = \frac{1}{\|w\|}, \tag{8}$$

thus, width of the dividing strip is equal $\frac{2}{\|w\|}$ (see Fig. 9).

Fig. 9: Illustration of creating support vectors.

To exclude points from the dividing margin, we will write out the condition (9) of belonging to classes.

$$\begin{cases} w^t x_i + w_0 \geq 1 & \text{if } x_i \text{ belongs to class } 1 \\ w^t x_i + w_0 \leq -1 & \text{if } x_i \text{ belongs to class } 2 \end{cases} \quad (9)$$

Let's enter the index function (10).

$$\begin{cases} u_i = 1 & \text{if } x_i \text{ belongs to class } 1 \\ u_i = -1 & \text{if } x_i \text{ belongs to class } 2 \end{cases} \quad (10)$$

Thus, the problem of estimating the dividing function generating the corridor of the greatest width is possible to write down as a problem of minimizing in the following form given as (11).

$$J(w) = \frac{1}{2}\|w\|^2 \to min \quad (11)$$

under the condition $u_i(w^t x_i + w_0) \geq 1$ for all i.

As the objective function is a square function, so this task has the only one resolve.

According to Kuhn-Tucker's theorem the condition (11) is equivalent to the following task

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j u_i u_j x_i^T x_j \to \max \quad (12)$$

provided that $\alpha \geq 0$ for all i and $\sum_{i=1}^{n} \alpha_i u_i = 0$, where $\alpha = \{\alpha_1, \ldots, \alpha_n\}$ are new variables. Let's rewrite $L(\alpha)$ in the matrix form

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix}^T H \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix}$$

Where coefficients of the matrix H are calculated as follows

$$H_{i,j} = u_i u_j x_i^T x_j \ .$$

The task $L(\alpha) \to max$ is solved by methods of quadratic programming.

After finding the optimum $\alpha = \{\alpha_1, \ldots, \alpha_n\}$ for each i there is verified the conditions

- $\alpha_i = 0$ (it corresponds i is not a support vector);
- $\alpha_i \neq 0$ and $u_i(w^t x_i + w_0 - 1) = 0$ (it corresponds i is a support vector);

Then w from the ratio (4) can be found $w = \sum_{i=1}^{n} \alpha_i u_i x_i$ and the value w_0 is calculated considering that for any $\alpha_i > 0$ and $\alpha_i[u_i(w^t x_i + w_0) - 1] = 0$

$$w_0 = \frac{1}{u_i} - w^t x_i.$$

Then, at last, the discriminant function is received

$$g(x) = (\sum\{\alpha_i u_i x_i \mid x_i \in S\})^T x + w_0.$$

Notice that summing is carried out not on all vectors but only on the set S which represents the set of support vectors i.e. $S = \{x_i | \alpha_i \neq 0\}$.

Unfortunately, the described above algorithm is implementable only for linearly separable sets. In practice this sets are not met frequently. In 1995 there was proposed modified algorithm for solving the problem for nonlinear separable sets. More examples reader can find in works by Cortes & Vapnik (1995), Cristianini & Shawe-Taylor (2000) and Hamel (2009) Let's give the modernization of the algorithm for the case of nonlinearly separable sets.

In order to allow for misclassification in the model, it is entered additional variables ξ_i, which characterize the mistake size on each object of x_i. In the objective function, the penalty for the aggregate error is introduced in the equation (13).

$$\begin{cases} \frac{1}{2}\|w\|^2 + \lambda \sum_{i=1}^{n} \xi_i \quad \rightarrow \quad \min, \\ u_i(w^t x_i + w_0) \geq 1 - \xi_i, \quad i = 1,\ldots,n, \\ \xi_i \geq 0, \quad i = 1,\ldots,n, \end{cases} \qquad (13)$$

Here λ is the parameter specifying the cost of misclassifications. It allows to govern the relation between maximizing width of the dividing strip and minimization of the aggregate error (Bordes et. al. 2005, Hamel 2009).

Penalty size ξ_i for the corresponding object x_i depends on the arrangement of the object in dividing strip. So, if x_i lies on the opposite side of discriminant function, then the penalty size is $\xi_i > 1$. If x_i lies in the dividing strip, but on the same side of discriminant function as the class, then the corresponding weight can take a value $0 < \xi_i < 1$. For the ideal separable case the penalty size is taken as $\xi_i < 0$ (see Fig. 10).

Fig. 10: Points to which penalties are applied.

Then the task (13) can be rewritten in the form below (14)(see Borser et.al. 1992)

$$J(w, \xi_1,\ldots,\xi_n) = \frac{1}{2}\|w\|^2 + \beta \sum_{i=1}^{n} I(\xi_i > 0) \ \rightarrow \ \min, \qquad (14)$$

that is in the way of minimization elements which do not represent the ideal case participate. Here

$$I(\xi_i > 0) = \begin{cases} 1, & \xi_i > 0, \\ 0, & \xi_i \leq 0, \end{cases}$$

when fulfilling conditions $u_i(w^t x_i + w_0) \geq 1 - \xi_i$ and $\xi_i \geq 0$. In the formula (14) the constant β is the weight considering the bandwidth. If β is not enough, then we allow to arrange relatively many elements in the imperfect position, that is, in the dividing strip. If β is big, then we demand existence of small quantity of elements in the imperfect position, that is, in the dividing strip.

Unfortunately, in (14), the problem of minimization is rather difficult, in view of discontinuity $I(\xi_i)$. Instead we will consider a value minimization

$$J(w, \xi_1, \ldots, \xi_n) = \frac{1}{2}\|w\|^2 + \beta \sum_{i=1}^{n} \xi_i$$

with restrictions for all i in the following form

$$\begin{cases} u_i(w^t x_i + w_0) \geq 1 - \xi_i \\ \xi_i \geq 0 \end{cases}.$$

Using Kuhn-Tucker's theorem, from here we receive

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j u_i u_j x_i^T x_j \ \rightarrow \ \max \qquad (15)$$

Provided that $0 \leq \alpha_i \leq \beta, \ \forall i$ and $\sum_{i=1}^{n} \alpha_i u_i = 0$.

From the ratio (13) we can find $w = \sum_{i=1}^{n} \alpha_i u_i x_i$. The value w_0 is also possible to find, considering that for all i $0 \leq \alpha_i \leq \beta$ and $\alpha_i[u_i(w^t x_i + w_0) - 1] = 0$.

The other idea of the SVM method (in the case when a linear division of classes is impossible), is transition to space of bigger dimension in which such division is possible. Some exaples can be find in works by Bordes et.al (2005), Christiani & Shawe-Taylor (2000), Hamel (2009), Rossi & Villa (2006) and Swidan et.al. (2013).

For solving the nonlinear classification problem by the linear qualifier it is necessary:

- to design data x in space of higher dimension by means of transformation $\Pi(x)$.
- to find a symmetric discriminant function for data $\Pi(x)$.
- the received nonlinear discriminant function can be written down in the following form

$$g(x) = w^t \varphi(x) + w_0.$$

The received symmetric discriminant function for two-dimensional X data can take a form:

$$g\left(x^{(1)}\ x^{(2)}\right) = [w_1\ w_1\ ]\left[x^{(1)}\ x^{(2)}\ \right] + w_0.$$

The one-dimensional discriminant function for nonlinear separable data using the function $\Pi(x)$ = (x, x^2) is written as follows:

$$g(x) = w_1 x + w_2 x^2 + w_0.$$

The example is shown on Fig. 11. For transferring data in space of higher dimension it is used so-called kernel functions.

$$\downarrow \ \varphi(x) = (x, x^2)$$

Fig. 11. An example of linear division of sets upon transition to space of higher dimension.

Let's go back to written above (15) the extremum problem of the method of support vectors in the following form

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j u_i u_j x_i^T x_j \to \max.$$

Let's notice that the optimization depends on the formula $x_i^T x_j$. If we transfer x_i to space of higher dimension using the display function $\Pi(x)$, then it is necessary to calculate the similar formula in space of higher dimension $\Pi(x)^T \Pi(x)$.

The idea of the method consists that it is necessary to find kernel function $K(x_i, x_j) = \Pi(x_i)^T \Pi(x_j)$ and to maximize the following objective function

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j u_i u_j K(x_i, x_j) \to \max.$$

Let's review the new example and take kernel function in the form$K(x, y) = (x^T y)^2$. It is simple to find out the display $\Pi(x)$ corresponding to the kernel function.

$$K(x, y) = (x^T y)^2 = ([x^{(1)}\ x^{(2)}][y^{(1)}\ y^{(2)}])^2 = (x^{(1)}y^{(1)} + x^{(2)}y^{(2)})^2 =$$

$$= (x^{(1)}y^{(1)})^2 + 2(x^{(1)}y^{(1)})(x^{(2)}y^{(2)}) + (x^{(2)}y^{(2)})^2 =$$

$$= [(x^{(1)})^2, \sqrt{2}x^{(1)}x^{(2)}, (x^{(2)})^2][(y^{(1)})^2, \sqrt{2}y^{(1)}y^{(2)}, (y^{(2)})^2]^T.$$

Thus, the display function can be written in the following form $\Pi(x) = [(x^{(1)})^2, \sqrt{2}x^{(1)}x^{(2)}, (x^{(2)})^2]$.

It is important to noticed that the choice of kernel function is rather difficult.

Let's review the example but more examples in paper by Joachims (2008,2009).

Class [1]: x_1=[1,-1], x_2=[-1,1].

Class [2]: x_3=[1,1], x_4=[-1,-1].

It is illustrated on Fig. 12.

Fig. 12: An example of linearly inseparable sets.

For creation of nonlinear discriminant function we use kernel function in the following form

$$K(x_i, x_j) = (x_i^T x_j + 1)^2.$$

The display function Π corresponding to the kernel function can be written as follows

$$\Pi(x) = [1, \sqrt{2}x^{(1)}, \sqrt{2}x^{(2)}, \sqrt{2}x^{(1)}x^{(2)}, (x^{(1)})^2, (x^{(2)})^2\ ].$$

Further it is necessary to maximize the objective function

$$L(\alpha) = \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} \alpha_i \alpha_j u_i u_j (x_i^T x_j + 1)^2 \to \max$$

with restrictions

$$\alpha_i \geq 0,\ \alpha_1 + \alpha_2 - \alpha_3 - \alpha_4 = 0.$$

Let's rewrite the task in the following form

$$L(\alpha) = \sum_{i=1}^{4} \alpha_i - \frac{1}{4}\alpha^T H \alpha\ ,$$

where $\alpha = [\alpha_1 \quad \alpha_2 \quad \alpha_3 \quad \alpha_4]^T$ and $H = \begin{pmatrix} 9 & 1 & -1 & -1 \\ 1 & 9 & -1 & -1 \\ -1 & -1 & 9 & 1 \\ -1 & -1 & 1 & 9 \end{pmatrix}$.

For finding the maximum, we can calculate the partial derivatives with regards to unknown parameters α_i and equate zero these derivatives to zero. Then, we will find values of unknown on which the maximum of the objective function is reached.

$$\frac{d}{d\alpha} L(\alpha) = \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} - \begin{pmatrix} 9 & 1 & -1 & -1 \\ 1 & 9 & -1 & -1 \\ -1 & -1 & 9 & 1 \\ -1 & -1 & 1 & 9 \end{pmatrix} \alpha = 0.$$

Solving the system equations, we receive $\alpha_1 = \alpha_2 = \alpha_3 = \alpha_4 = \frac{1}{4}$, and

$$w = \sum_{i=1}^{4} \alpha_i u_i \Pi(x_i) = \frac{1}{4}(\Pi(x_i) + \Pi(x_2) - \Pi(x_3) - \Pi(x_4)) = [0 \quad 0 \quad 0 \quad -\sqrt{2} \quad 0 \quad 0]$$

and, at last, the nonlinear discriminant function can take the following form

$$g(x) = w\Pi(x) = \sum_{i=1}^{6} w_i \Pi_i(x) = -\sqrt{2}(\sqrt{2}x^{(1)}x^{(2)}) = -2x^{(1)}x^{(2)} .$$

The result is shown on Fig. 13.

Fig.13: An example of linearly inseparable sets after using the kernel function

In conclusion we give a few of the most widespread kernel functions used for division of classes:

- The polynomial homogeneous kernel $K(x_i, x_j) = (x_i^T x_j)^d$.
- The polynomial heterogeneous kernel $K(x_i, x_j) = (x_i^T x_j + 1)^d$.
- The radial basis function (RBF kernel) $K(x_i, x_j) = exp(-\frac{\|x_i - x_j\|^2}{2\sigma^2})$.
- The sigmoid kernel $K(x_i, x_j) = \tanh\big((x_i^T x_j + 1)\big)$

As a result of training the SVM classifier, support vectors are determined that are closest to the hyperplane separating the classes and carry all the information about the separation of classes. The main problem that arises when training an SVM classifier is the lack of selection recommendations values of the regularization parameter C, kernel function $K(x_i, x_j)$, and as well as the values of the parameters of the kernel function itself, at which high accuracy of data classification will be ensured. This problem can be solved by replacing optimization algorithms with an algorithm using swarm intelligence (PSO).

Quality assessment of the SVM classifier can be performed using various classification quality indicators as it has been shown by Demidova et. al. (2017). This can be for example an indicator that consider cross-validation data, indicators of classification accuracy and completeness, an indicator based on the analysis of the ROC curve, etc.

Using Particle Swarm Optimization (PSO) in ensemble with SVM

When implementing the traditional PSO algorithm, the *n*-dimensional search space (where *n* is the number of parameters to be optimized) is inhabited by a swarm of *m* particle agents (elementary solutions). The position (position) of the *i*-th particle is determined by a vector that defines a certain set of optimization parameter values. Moreover, in the analytical record of the objective function of the optimization algorithm (the optimum is, for example, the minimum of which must be found), such parameters may occur in either explicit or implicit form coding as $x_i = (x_i^1, x_i^2, \dots, x_i^n)$, $u(x) = u(x^1, x^2, \dots, x^n)$. During the swarm initialization process, particles are randomly located throughout the search area. Moreover, each *i*-th particle has its own velocity vector, which at each particular moment of time corresponding to a certain iteration of the PSO algorithm and in a certain way affects the coordinates of the position of the *i*-th particle These coordinates in the *n*-dimensional search space uniquely determine the value of the target function, which is some solution to the optimization problem $(i = 1,\ 2, \dots, m)$ $v_i \in R^n$.
For each position of the n-dimensional search space visited by the *i*-th particle, the value of the objective function *u* is calculated. In this case, each *i*-th particle remembers what the best value of the objective function it personally found, as well as the coordinates of the position in *n*-dimensional space corresponding to this value of the objective function. In addition, each *i*- th particle "knows" where the position is located, which position is the best (from the point of view of achieving the optimum objective function) among all the positions that the particles "explored" (tested). Thanks to this, an instant exchange of information between all swarm particles is simulated. At each iteration, the particles adjust their speed so that, on the one hand, they are closer to the best position that the particle found itself, and at the same time closer to the position, which is currently globally the best (among the totality of positions found by all particles). After a certain number of iterations, the particles should gather near the best position

(globally best according to the results of all iterations). However, it is possible that part of the particles of the swarm will remain somewhere in a relatively good local optimum or several such optima.

The convergence of the PSO algorithm depends on how the particle velocity vectors are corrected.

In this case it is possible to "degenerate" a particle, i.e. to change its coordinate by the type number of the kernel function whose particles show the highest possible classification quality. With "rebirth", it is possible to change the values of the parameters x_{i1}, x_{i1}, and C_i so that they correspond to a new type of kernel function (consider, the ranges of changes in their values). Particles that have not undergone "degeneration" carry out movement in their own search space (of a certain dimension).

The proportion of particles participating in the "degeneration" is determined before the algorithm is launched, it is recommended to choose from 15 to 25% so that the particles can explore their search space, but do not stay there for long if their indicators turn out to be the worst.

In the course of experiments conducted for various experimental data, for a specific set, several SVM classifiers were trained with different types of kernel functions, different values of the parameters of the kernel function and the regularization parameter; at the same time, training and test samples were randomly generated from the initial data. After that, the principle of maximum decorrelation (for selecting private classifiers into an ensemble) and various strategies for the formation of an aggregated classifier were applied to trained classifiers. In determining the aggregated decision, the majority voting method was also used.

The proposed modification of the PSO algorithm will be described in more detail in the next publication.

Conclusions

In summary, the article considers the classification problem. It is a task in which there are many objects that need to be divided in some way into classes. The algorithms that are able to classify any object from the original set are analyzed.

In the first part of the paper a text classification is proposed. Two measures were considered as a measure of similarity of documents: one based on the cosine angle between vectors, while the other used Voronoi polyhedrons. Since the problem of finding an optimal solution by classical methods is quite difficult, a genetic algorithm was used. Proposed methods were tested on the Reuters document collection and proved to be relatively more effective.

In the second part of the work on selection of kernel functions in non-linear SVM methods the use of swarm intelligence (PSO) was proposed. Modified PSO algorithm allows to determine the best type of kernel functions, the values of kernel function parameters and the value of the regulation parameter, which ensures high quality object classification at reasonable time costs, which are much lower than in case of using traditional PSO algorithm. Good results were obtained thanks to "degeneration" of particles in modified PSO algorithm. Particles participating in the "rebirth" process change their type of kernel function to the type corresponding to the particle with the highest classification accuracy. In addition, these particles change the parameter values according to their ranges of change, if necessary. Further research will be related to the development of recommendations for the application of detailed description of PSO algorithm modifications.

Application of the TOPSIS Method for Assessing Sustainable Development in the Context of Education and Health Determinants in ASEAN Countries in 2019

Adam STECYK

Professor of the Univeristy of Szczecin, PhD
Institute of Spatial Management and Socio-Economic Geography, University of Szczecin, 70-453 Szczecin, Poland, adam.stecyk@usz.edu.pl

Abstract

The aim of the paper is to present the practical use of a multi-criteria TOPSIS method for linear ordering of multi-feature facilities, in order to expertly assess the level of sustainable, education and health development of South East Asia countries (ASEAN) in 2019. The article has been divided into two main parts. The theoretical (methodological) part contains the characteristics of TOPSIS method and in the empirical part, the results of the analysis were presented. The main source of statistical data is the annual report published by The Association of Southeast Asian Nations: ASEAN Statistical Yearbook 2019, which contains information on most important development areas (e.g. population, education and health, employment, macroeconomics, transport, tourism, agriculture, etc.). The proposed research concept can be used to build the computational models and indicators in order to look for more complex dependencies among factors which determine sustainable development of studied phenomena and objects.

Keywords: sustainable development, education, health, social governance, mcdm, topsis, asean

Introduction

In the era of progressing globalization and the information society, the wealth of knowledge and flow of information is essential for sustainable development and economic growth. The big problem with which modern decision makers meet is, above all, a very large amount of information and difficulties in the interpretation of statistical data. It is true that many institutions and government agencies conduct research on the development of individual continents, countries, areas and social groups, resulting in integrated indicators describing changes in the social and economic development (Hummels and Argyrou 2020), (Glavic and Lukman 2007), (Steffen, et al. 2015), (T. Borys 2011), (Gasparatos, El-Haram and Horner 2008), (Ness, et al. 2007), (Stagl 2007). Nevertheless, the presented results have the character of an aggregate that synthetically describes the studied phenomena or objects. An example of this can be SDG index (sustainable development goals), published for years by the UN and pointing to the main areas of development such as: poverty and hunger, health and education, economic growth, reduction of inequalities, quality of life, climate change, etc. This view is very useful in making comparisons at the global level in very general terms. An investigator who wants to make a more detailed analysis must be equipped with tools and skills to build his own computational models and indicators in order to look for more complex dependencies. In other words, it is time to prepare for the searching of such data analysis methods, which on the one hand, will give the best description on the studied objects, but also will be easy to use in analyzing significant problems. The contemporary analytical issues are of interdisciplinary nature, therefore research on sustainable development must take into account a wide range of economic, social, demographic, ecological and legal factors which can be compared with each other and lead to meaningful conclusions. One of the proposals that meets such expectations is the application of the multi-criteria decision making methods (MCDM) in the study of dynamically changing reality (Saaty & Ergu, 2015), (Ruano, 2018), (Nermend, 2017), (Bedir, Özder, & Eren, 2016), (Trzaskalik, Wielokryterialne wspomaganie decyzji. Przegląd metod i zastosowań, 2014), (Behzadiana, Kazemzadeh, Albadvi, & Aghdasi, 2010), (Saaty R. , 2002), (Diech, Korbicz, Rutkowski, & Tadeusiewicz, 2000), (Bana e Costa & Vansnick, 1999), (Edwards & Barron, 1994), (Saaty T. , 1988) (Brans & Vincke, 1985).

Multi-criteria decision-making approaches allow selection of the variant best suited to specific targets and preferences (selection problem) and positioning of the considered decision-making alternatives from the best to the worst (ranking

problem). In other words, the MCDM methods spotlight the decision issues in which the set of all satisfactory decisions is a discrete, containing a finite, predetermined number of possible variants of the solution (Bewszko, 2004).

The main methods include such tools as ELECTRE (Elimination et Choice Translating Reality) I, II, III, IV (Banayoun, Roy, & Sussman, 1966); SMART and SMARTER (Simple Multi-Attribute Ranking Technique and Simple Multi-Attribute Ranking Technique Exploiting Ranks) (Edwards & Barron, SMARTS and SMARTER: improved Simple methods for mulitiattribute measurement, 1994); MACBETH (Measuring Attractiveness by a Categorical Based Evaluation TecHnique) (Bana e Costa & Vansnick, Sur la quantification des jugements de valeur: L 'approche Macbeth, Cahiers du LAMSADE, 1999); PROMETHEE I, II, MAPPACC, PRAGMA (Diech, Korbicz, Rutkowski, & Tadeusiewicz, 2000); DEA (data envelopment analysis) (Charnes, Cooper, & Rhodes, 1978); TOPIS (The Technique for Order of Preference by Similarity to Ideal Solution) (Boutkhoum, Hanine, Agouti, & Tikniouine, 2017), (Jahanshahloo, Hosseinzadeh Lotfi i Izadikhah, 1999); AHP/FAHP (Fuzzy/Analytic Hierarchy Process) and ANP (Analytic Network Process) (Saaty R. , 2002).

The aim of the paper is to present the practical use of a multi-criteria TOPSIS method, in order to expertly assess the level of sustainable, education and health development of South East Asia countries (ASEAN) in 2019.

Methodical assumptions and analysis

The research procedure proposed in the article has the following stages:

1. Discussing the methodical issues of the TOPSIS method.
2. Presenting the source data and analytical model.
3. Conducting research.

The multi-criteria method used in the discussed example is the TOPSIS method, which consists of determining the distance of the analyzed phenomenon or object (set with a finite number of elements) from the so-called, ideal and anti-ideal solution, resulting in a final, synthetic indicator that allows to create a ranking of the tested objectives (alternatives). The best element in the study is the one whose distance from the ideal solution is the smallest and at the same time has the largest distance from the anti-ideal solution. The use of the TOPSIS method includes the following steps:

1. Determination of weights for selected criteria; in the analyzed example the weight of the ech criteria is the same: 12,5%.

2. Creating a normalized data matrix according to the formula.

$$z_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}} \quad (1)$$

where i=1 ,2,…, m and j=1,2,…,n

3. Weight application according to the formula $v_{ij} = w_j \otimes z_{ij}$

4. Determination of the vector value of the ideal solution A^+ and anti-ideal A^- (positive ideal solution, negative ideal solution)

$$a^+ = (a_1^+, a_2^+, \dots, a_n^+) := \left\{ \left(\begin{matrix} max v_{ij} \\ i = 1,.,m \end{matrix} | j \in J_Q \right), \left(\begin{matrix} min v_{ij} \\ i = 1,.,m \end{matrix} | j \in J_c \right) \right\} \quad (2)$$

$$a^- = (a_1^-, a_2^-, \dots, a_n^-) := \left\{ \left(\begin{matrix} min v_{ij} \\ i = 1,.,m \end{matrix} | j \in J_Q \right), \left(\begin{matrix} max v_{ij} \\ i = 1,.,m \end{matrix} | j \in J_c \right) \right\} \quad (3)$$

where J_q is a beneficial criteria, and J_c is a non-beneficial (cost) criteria.

5. Calculation of the Euclidean distance of the tested objects from the ideal and anti-ideal solution:

$$S_i^+ = \sqrt{\sum_{j=1}^{n} \left(v_{ij} - a_j^+\right)^2} \quad (4) \qquad S_i^- = \sqrt{\sum_{j=1}^{n} \left(v_{ij} - a_j^i\right)^2} \quad (5)$$

where i = 1,2, ..., m and j = 1,2, ..., n

6. Calculation of the performance score R_i for the examined objects, according to the formula:

$$R_i = \frac{s_i^-}{s_i^+ + s_i^-} \quad (6)$$

The performance score R_i of the highest value are the best solution (the best alternative) in the considered problem of linear ordering (ranking).

The presented TOPSIS method can be used to build an original indicator on selected aspects (such as health and education) regarding sustainable development in the countries of south-east Asia (ASEAN). The main source of statistical data is the annual report published by The Association of Southeast Asian Nations: ASEAN Statistical Yearbook 2019[1], which contains information on such development areas as: population, education and health, employment, macroeconomics, trade in goods and services, investments, transport, tourism, agriculture, manufacturing etc. The main assumption in the study was the construction of an original indicator in the area of education and health, containing the following 7 variables (the statistics refer to 2019, and in the absence of information for individual countries, data from previous years were used):

- C1 – Crude Death Rate;
- C2 – Prevalence of Malaria per 1000 population;
- C3 – HIV Prevalence Rate Among 15-49 Year Old People;
- C4 – Adult Literacy Rate;
- C5 – Life Expectancy at Birth;
- C6 – Access to safe drinking water;
- C7 – Access to improved sanitation.

Table 1: Statistical data for selected variables.

Country	C1	C2	C3	C4	C5	C6	C7
Brunei Darussalam	0,039	1,700	0,000	0,966	80,700	1,000	0,920
Cambodia	0,061	8,900	0,050	0,844	69,900	0,650	0,760
Indonesia	0,071	0,800	0,004	0,954	71,100	0,720	0,680
Laos	0,067	7,800	0,003	0,847	67,000	0,780	0,750
Malaysia	0,049	7,600	0,004	0,942	75,500	0,970	0,960
Myanmar	0,081	2,300	0,007	0,897	66,700	0,800	0,810
Philippines	0,065	0,500	0,001	0,965	69,200	0,920	0,740
Singapore	0,048	0,000	0,002	0,970	83,100	1,000	1,000
Thailand	0,079	1,600	0,003	0,929	75,500	0,980	0,930
Vietnam	0,058	35,000	0,011	0,950	76,500	0,980	0,820

Source: Own elaboration.

An important element in the TOPSIS analysis is to understand the nature of the assessment, which can take on the characteristics of benefcial or non-beneficial (cost) criteria. In the analyzed example, criterion C1 – Crude Death Rate, C2 – Prevalence of Malaria per 1000 population and C3 – HIV Prevalence Rate Among 15-49 Year Old People, are cost criteria (the desired value should be kept to a minimum); the remaining C4-C7 criteria are beneficial criteria for which the desired values are going to the maximum.

According to the TOPSIS methodology, a normalized weighted matrix was created (equivalence of criteria was adopted, which means the same weights for each criterion), and then vectors for ideal and anti-ideal solutions were calculated (table 2 and table 3).

Table 3: Euclidean distance from the ideal and anti-ideal solution and a performance score for the ASEAN countries.

Country	S^+	S^-	R_i
Brunei Darussalam	0,78618	18,99088	0,96025
Cambodia	14,3959	9,96924	0,40916
Indonesia	3,47372	18,07015	0,83876
Laos	4,21371	16,51733	0,79674
Malaysia	3,20203	16,62809	0,83853
Myanmar	4,08555	17,09747	0,80713
Philippines	2,53283	18,80242	0,88128
Singapore	0,84595	18,99004	0,95735
Thailand	3,10734	18,16315	0,85391
Vietnam	13,6631	10,99384	0,44587

Source: Own elaboration.

On the basis of the obtained results, a performance score R_i was calculated, enabling the ranking of ASEAN countries according to specific education and health criteria C1-C7. Table 4 contains a list of ASEAN countries, ordered by the score (descending sorting). Detailed analysis of the results obtained, exceeds the scope of this study (for this purpose a specific expert sensitivity analysis of individual criteria should be carried out), nevertheless, it is possible to group countries according to the education and health factor and a subjective reference point based on expert knowledge in the area of development. The group achieving a satisfactory level of development may include countries that achieved the $R_i > 0.9$, which is Brunei Darussalam and Singapore. The group of countries for which the ranking belongs to the range from 0.5 to 0.8 may be defined as a set with a sufficient level of development. The remaining countries can be included in the group with insufficient level of development and requiring special attention in the future.

Table 4: Ranking for the ASEAN countries in education and health area in 2019.

No.	Country	Ranking
1	**Brunei Darussalam**	0,96025
2	**Singapore**	0,95735
3	**Philippines**	0,88128
4	**Thailand**	0,85391
5	**Indonesia**	0,83876
6	**Malaysia**	0,83853
7	**Myanmar**	0,80713
8	**Laos**	0,79674
9	**Vietnam**	0,44587
10	**Cambodia**	0,40916

Summary and conclusions

An important element of conducting scientific research is a critical approach to the obtained results and the selected research model. From this point of view, it is assumed that the proposed concept is universal, but it can also be a starting point for further, in-depth analyzes and scientific discussions, indicating potential modifications of specific elements, both in terms of content and methodology. However, it is already possible to make a preliminary summary of both the methodological and substantive areas in the context of sustainable development of ASEAN countries in 2019. The most important applications include:

1. The key stage of the analysis is the proper selection of criteria determining the level of assessment of education and health development of the ASEAN countries. From this point of view, the proposed C1-C7 factors are a subjectively selected set that can be subjected to any modifications, depending on the purpose of the analysis. What's more, the concept proposed is of a general nature. It seems reasonable to specify the purpose of the analysis within a more limited or completely different area, such as ecology, demography, macroeconomics, etc. and the selection of the new appropriate characteristics.
2. In terms of methods, the proposed methodology, based on a TOPSIS method, deserves attention. The question arises about the possibility of modifying the computational model both in the area of choice (eg parallel analysis based on other models and comparison of results), and in the method itself (eg, using fuzzy numbers in TOPSIS analysis, etc.)

Summing up, it should be noted that regardless of the substantive (eg choice of criteria) and methodical problems (method selection), the use of multi-criteria methods will be increasingly applicable to decision-makers responsible for both local and central politics, as well as managers in commercial enterprises. Any such study, allows a new look at an analised problem; the comparisons between results and carrying out a sensitivity analysis enables a deep understanding of the socio-economic processes taking place in the researched areas. What's more, experimenting with new computational models allows to strive for the best description of the world around us and understanding the complex relationships within it.

Abstract

Rapid changes of technology have forced economies and societies to shift their activity to the digital environment. The article highlights the use of new business opportunities in the context of convergent services that lead to the development of digital information ecosystems. Objectives of the article are as follows:

- defining the concept of convergence,
- defining the concept of a digital information ecosystem,
- determining the level of convergent services in the business environment, and
- developing a model of action for those who create the digital information ecosystem.

In order to achieve these objectives, the article refers to the essence of the ecosystem, which is a basis for the research problem. Additionally, literature analysis is presented which has enabled to develop a model action to enhance convergence in the digital information ecosystem.

The article uses research methods, such as critical analysis of scientific literature, synthesis and generalization, questionnaire survey and graphical visualization.

Keywords: Information Ecosystem, Convergence, Digital Economy

Introduction

Advancement in information technology contributes to the development of the digital economy. Technology is the ultimate driving force of the evolution toward the information society and a basis of the process. The development of technology has translated into the development of telecommunication and information technology, and thus into the development of a broad information technique. The process of building a digital information ecosystem is based on the creation of an appropriate ICT infrastructure, where technology (Internet) forms the basis of the information society and e-economy. Access to and range of the Internet are particularly important. The development in this area has created better communication opportunities, while at the same time led to the amalgamation of previously separate technologies and services, in other words their convergence[1]. It should be noted that the growing convergence has caused the expansion of communication technologies in all spheres of social and economic life. This is a subject of a number of studies (Jabłoński, 2008, Quah, 1996, Delgado, Porter, Stern, 2014, Borsi, Metiu, 2015). The expansion is reflected in digital information ecosystems.

The concept of convergence

It should be noted that convergence trends have been observed for many years and they result from the development of telecommunications, globalization of networks, and the introduction of innovative technologies. In Europe, the convergence began in 1987. The first step in the process of defining the convergence was the publication by the

[1] The word "convergence" comes from the Latin *convergere* which means to converge.

European Commission of a Green Paper on the convergence of telecommunications, media and information technology sectors and the implications for Regulation - towards the information society approach (*1997)*. This document was developed as a response to the growing impact of modern technologies on narrowing down differences between telecommunications and audiovisual sectors and the growth of services which no longer could be attributed to one sector, in particular due to new information media.
As defined in this document, convergence is:

- capability of different networks to convey similar services,
- process of combining computers, TV sets and telephones into a single device.

D. C. Moschella (1997) in the book: *Waves of power: The dynamics of global technology leadership* defined convergence as 4C: Computers, Communications, Consumer Electronics and Content. He noted that in the future we can expect dynamic amalgamation of communications, content, information technology and consumer electronics, as we observe it today.

Therefore, the description of convergence should relate to the following key areas:

- service convergence (Babis, 2011), i.e. the possibility of providing identical or similar electronic communications services via different networks and terminals. Service convergence my involve the following (1) migration of services, which previously have been typical of a given sector, to another sector, most often through other technologies, (2) provision of common services, both known and offered in traditional networks, as well as entirely new ones developed because new opportunities have been created in converged networks, (3) creation of services to support network substitution, i.e. Services that make one network similar to another, and (4) substitutability. The convergence changes communication patterns and determines communication roles of
- technological convergence (Noll, 2002), which involves transmission of all types of electronic communication signals, regardless of their source, in a single digital form within a common transmission medium:

- convergence of networks by the integration of multiple multimedia applications (data, voice, video, photos) on a common IP-based platform with the global Internet. The convergence of telecommunications and information networks has led to the creation of so-called smart networks.
- convergence of devices (Gilder, 1994, Carey, 2015) involves the combination of different functions within a single device. According to some authors (Jenkins, 2001, Vukanovic, 2018), we live surrounded by media and we will use all types of media that are interconnected.

- economic convergence:

- convergence of markets, which means the merger of telecommunications, information technology and media markets,
- corporate convergence which involves merger of businesses to concentrate capital (joint venture), form consortia, strategic alliances, and equity mergers to promote synergies. They write about such synergy Budziewicz-Guźlecka, Czaplewski, Drab-Kurowska (2018),
- regulatory convergence, or harmonization of regulations due to the convergence of services and markets. It is very difficult to determine the role of the regulator in industry convergence. The challenge for regulators is to develop coherent and suitable regulations that do not hamper the development of a given sector, but instead encourage technological innovation.

The authors claim that all these areas are components of convergence.

On the one hand, a rapid technological convergence results in the creation of new services, new distribution platforms and new devices. On the other hand, it extends the convergence market to include new actors, which have so far been active only in one sector (e.g. telecom operators) (Budziewicz-Guźlecka, 2009).

For example, next generation networks (NGN) have eliminated the separation of voice and data, and provided a transmission of single IP pocket network which is common to all multimedia (voice, data, video). The convergence of telecommunications and information networks has led to the creation of so-called smart networks. However, we also need to emphasize the social aspect. C. Mercer (2003) has payed particular attention to the social aspect. He sees convergence as "a new, powerful force based on the interaction between producers and consumers, in which consumers, by virtue of their interactivity, can become creators. Furthermore, "progressing integration of production and consumption through various media, culture and creative industries marks the emergence of a global convergence culture based on increasingly participatory and interactive involvement of different media and industries, between people and their media, as well as professionals and amateur media creators" (Deuze, 2009, Hardy, 2017). As Budziewicz-Guźlecka (2019) claims that convergence is not, however, self-existent, it fulfills as a result of human

actions, decisions, goals, and impact assessment. Convergence is therefore a social phenomenon resulting from what is happening in and with the society.

According to L. Zachera (2007), convergent services offered by networks not only generate or enable new types and forms of activity but also create a new space for people to live and create. It needs to be emphasized that the development of technologies includes both telecommunication networks and devices used by individuals to communicate, as well as functionalities of these devices and software that supports complex communication processes. Key technologies that have significantly influenced communication over the past decades include personal computer, accessible public computer network – the Internet, electronic mail, mobile phone, mobile devices, e.g. smartphone, tablet, instant messengers, and social networks.

The proliferation of these solutions has led to a major change in communication behavior and in the economy as such. These changes are global and virtually affect almost entire societies and their ecosystems.

The Essence of the Business Ecosystem

The classic approach of the business ecosystem is the analogy to biological ecosystems. It means that activities undertaken by enterprises have some sort of impact on the quality of the network, which in turn has a positive or negative impact on the efficiency. It should be stressed that the business ecosystem is a purposeful structure of multilateral arrangement between actors who focus their activities on a key value and aim to create a product or service that is in line with consumer demands (Adner, 2017). Definitions found in the specialist literature indicate that this is an arrangement involving many organizations from different sectors which comprise a strategic community of interests and values (Kiyotaki, Moore, 1997). The structure of a classical business ecosystem consists of suppliers (indirect and direct), producers of leading and complementary products or services (including ecosystem leaders), competitors (direct and potential), stakeholders (investors, owners, business associations, trade unions) and the government and quasi-governmental regulatory agencies (Kiyotaki, Moore, 1997). Interactions between parties involved are based on the flow of resources and information, from highly specialized to highly generalized (Kandiah, Gossain, 1998).

The main features of ecosystems include:

– diversity, or the number of real-time participants of a given system, and
– resilience to system disturbances related to the diversity of participants/species.
It should be stressed that a more versatile system is more stable and adaptable to change.

Convergence and The Digital Information Ecosystem

The phenomenon of convergence has undeniably affected the contemporary digital information ecosystem. The influencing of economic processes that take into account information resources in ecosystems is one of the pillars of the knowledge-based economy, which is a precondition of sustainable development. It needs to be stressed that the analysis of information should be seen as a method supporting economic processes streamlined to promote sustainable growth. In this context, the analysis of the information ecosystem allows to explore the structure of phenomena, processes and information flows within ecosystems and in the cybernetic context of the ecosystem, as shown in Figure 1.

Fig. 1: Cyber-ecosystem

Source: the authors

It should be stressed that ecosystems are increasingly often digital. This leads to the convergence of digital platform standard and benefits participants of the process. The current digitization promotes integration of the inter-organizational actors of the digital information ecosystem. Moreover, it is also an important factor inducing changes to competition and the organization of information sectors. Today, businesses, consumers, products and services are connected via digital networks. This leads to increased network effects and value-creation in information ecosystems (Paulus-Rohmer, Schatton, Bauernhandel, 2016). The phenomenon is shown in Figure 2.

Fig. 2: Creation of value in information ecosystems

Source: the authors

A digital information ecosystem in the context of convergence

The literature indicates that due to the rapidly changing conditions in ecosystems, businesses need to undergo agile digital transformation (Markus, Loebbecke, 2013). This is linked to platforms that enable ecosystem participants to use services, tools or technologies with the aim to increase benefits for individual companies and improve their performance (Iansiti, Levien, 2004). This applies to a specific ecosystem – a digital ecosystem based on platform technologies. The ecosystem, which uses the platform as an integrating component, consists of a stable platform provider, businesses and people – platform-based products and services providers and end customers. In many instances, end customers also include companies, not just individuals (Corallo, Passiante, Prencipe, 2007).

Platforms are described as places that create virtual environments. Such environments offer new opportunities to create value based on the involvement of participants and highly accessible web-based technologies (Bertot, Jaeger, Grimes, 2010). These technologies include the following: Internet, software, multimedia, virtual reality tools, intelligent agents (Nambian, Baron, 2007). These platforms can take different forms.

The ecosystem research focuses primarily on constituent elements, the role of the ecosystem and its strategy. It shows that key players form a platform while niche players add value to it (Stanczyk-Hugit, 2015). This is linked to the digital policy of linking business processes through platforms (Budziewicz-Guźlecka, Drab-Kurowska, 2017 and 2012) (mainly digital ones). It is worth adding that, in line with the digital business policy, the processing of designing products or services itself is geared toward convergence. The adoption of the digital policy by businesses should be preceded by a detailed examination of interactions between organizations that comprise the business ecosystem, its structure and roles. The impact of digitization on interactions between digital policy and the business ecosystem is shown in Figure 3.

Fig. 3: Impact of digitization on interactions between digital policy and business ecosystem
Source: the authors

The digital business policy emphasizes the resource-based approach to business, while stressing the importance of cooperation and business-to-business relations. This implies ecosystem-specific properties, while maintaining principles and assumptions of the resource theory. As Drab-Kurowska (2019) claims that the digital policy focuses mainly on intangible, digital assets. In this context, the literature stresses that material resources are no longer considered as the main source of competitive advantage (Kunasz, 2006). This condition is met by resources that are not susceptible to imitation and substitution, e.g. relationships and knowledge (Grabowska, 2014). Sources of the relational competitive advantage include convergent resources: intangible resources, long-term relationships, knowledge exchange between companies, and effective coordination of activities.

Research Methodology

In order to verify the main goal of the paper, the analysis focused on results of a survey involving a group of 84 respondents – enterprises located in the Western Pomerania Province, Poland. The questionnaire survey was developed by the Authors, members of the Information Ecosystem and Society 5.0 Team.

The choice of the method was based on the low cost of such studies, speed of collecting information and the need to acquire general information.

Sampling scheme:

1. Non-random choice.
2. Convenience sample.
3. Determination of sample size.

The significance factor was set at α=0.1 and the permissible error at d=0.09. The sample includes 84 companies.

Survey Findings

The survey covered 84 companies from the Western Pomerania Province, Poland. Service and commercial companies prevailed in the sample, respectively (56%) and (37%). More than half of the companies (71%) had up to 9 employees, while every fourth company (25%) had between 10 and 50 employees. In the sample, 4% of companies employed more than 50 people.

Almost half of the companies (46%) have concentrated their activities on local and regional markets. On the other hand, almost every fourth company offers its services or products not only on the domestic market but also on foreign markets.

The survey used a questionnaire. Empirical studies have been designed to:

- determine the extent to which converged services are used in business activity,
- identify where converged services are used, and
- determine the degree of converged services offered to businesses.

The survey has shown that the highest level of converged services can be found in medium-sized enterprises. However, the lowest use of the services examined is small companies, which is the result of lower investment in modern technologies and innovation, as shown in Figure 4.

Fig. 4: The level of use of convergent services in business operation

Source: the authors

The survey has also examined areas where converged services are used. This may apply to both the operational area (voice communication + IMP services + Internet services) and the commercial area, as shown in Figure 5.

Fig. 5: Areas of convergent services

Source: the authors

The survey has shown that companies use the operational area more often. These services are essential to support processes within the organization. Medium-sized companies also had the highest score in this area (57% and 65%). This can be interpreted as major openness to modern technologies and innovation used within company's internal processes.

The survey also covered willingness to offer convergent services. It seems that companies had the lowest score in this area.
The level of converged services offered is less than 50%. The highest score was in the group of medium-sized companies (45%). In the case of small businesses, only every fourth company expressed their willingness to offer convergent services.

Fig. 6: The level of convergent services offered to businesses

Source: the authors

Summarizing, it should be noted trends among companies to use and offer convergent services are very clear. Although the scale of the phenomenon is still limited, the outlook is optimistic. Activity in this area is going to increase in the coming years. It should be stressed that the digital ecosystem forces companies to develop services by permanent use of modern technologies and implementation of innovation.

A model of the effective digital information ecosystem in the context of convergence

The survey has shown that it is important to make entrepreneurs aware of the need to enter a digital information ecosystem. However, particular attention should be paid to the quality of the ecosystem. The most common criteria for ecosystem quality are efficiency, strength and the creation of new niches (Iansiti, Levien, Levin, Regine, 1999), as shown in Figure 7.

Fig. 7: The way to high-quality information ecosystem

Source: the authors

The efficiency of the information ecosystem is expressed by its capacity to transform technologies and other sources of innovation on a sustainable basis to promote cost reduction and development of new products. A number of indicators can be used to measure ecosystem efficiency. The most common are the return on capital investment in a given ecosystem. When ecosystems show higher return on investment, both competitors involved in the system and external organizations are more inclined to work together long-term and develop cooperation. This trend will evolve depending on the return on capital invested.

While determining the effectiveness of the ecosystem, we need to examine the access to innovation. The analysis primarily covers the speed and cost of innovation transfer, ease of assimilation and implementation, and benefits for members of the business ecosystem who leverage these innovations in their strategic actions. The strength of the business ecosystem is reflected in possibilities to overcome threats to the ecosystem environment, in particular unforeseen technological changes.

Ecosystem strength is also demonstrated by the sustainability of the ecosystem structure and its aging rate. Ecosystems where links between members are durable and the structure of links clear can be considered strong. Ecosystems with increased strength compared to other systems are more inclined to create and develop cooperative relationships. Competitors prefer to cooperate with systems that protect parties from external attacks and create conditions that help to predict innovation.

The criterion for creating new niches demonstrates the ability to create new functionalities or market opportunities as a result of the implementation of technological innovations created by the business ecosystem. This does not mean that once new opportunities appear we should abandon our previous activity. The ecosystem shapes new business opportunities with rational use of its own standards and technological innovation. While developing the portfolio of business opportunities, ecosystems seek to avoid risks of excessive growth, inefficient use of their resources and excessively narrow identification of niches that may result in missed opportunities. The model efficiency of the system is shown in Figure 8.

Fig. 8: The model efficiency of digital information ecosystems in the context of convergence

Conclusion

Convergent services should be seen as a key vehicle and environment for the transfer of knowledge, information and the development of ideas as well as information society services. The economic and social potential of these services is enormous, primarily due to their unique versatility. Convergence is a driving force for the development of digital information ecosystems whose effectiveness is crucial for the resilience of the ecosystem. It should be pointed out that cooperative relationships are growing when the business ecosystem is able to generate new growth prospects for business opportunities (niches). This is particularly evident when ecosystems spread to include new sectors or geographic markets with a high strategic potential and at the same time a high risk of activity. Leaders of digital information ecosystems seek to maintain and/or improve system resilience. By initiating technological innovation, they engage new actors in the ecosystem and individual projects, thus stimulating the transfer of knowledge within the digital ecosystem. Convergence is taking place in the pursuit of new applications for existing technologies and skills and the implementation of new solutions. Convergence provides ecosystem members with access to new knowledge and information. Consequently, the resilience of the ecosystem improves both within the system and between competing ecosystems together with the tendency to cooperate.

Resumen

El comercio internacional del producto aguardiente de uva (pisco) por parte de Chile y Perú está sujeto a una controversia debido a su denominación de origen desde hace varias décadas. El objetivo de este trabajo es analizar el desempeño del comercio internacional de este producto por parte de ambos países mediante indicadores de competitividad, eficiencia y redes comerciales. Los resultados muestran un claro predominio de Perú, a pesar de que su estrategia comercial es más reciente y que ambos países establecieron estrategias distintas para validar, proteger y posicionar su denominación de origen (DO) en los mercados internacionales. La evolución del precio en los mercados analizados ha presentado un comportamiento al alza. El reconocimiento de la DO no ha ofrecido una ventaja especial a ninguno de los dos países. En tal sentido, una estrategia binacional para la promoción del producto, así como la creación de un organismo regulador que vele por la calidad en los procesos de producción y evaluación de la calidad del pisco les puede ayudar a alcanzar mayor visualización en los mercados internacionales.

Palabras Claves: Denominación de Origen, Exportaciones, Pisco, Competitividad.

Abstract

The international trade of the product grape brandy (pisco) by Chile and Peru is subject to a controversy for its designation of origin for several decades. The objective of this work is to analyze the performance of international trade of this product by both countries through indicators of competitiveness, efficiency, and commercial networks. The results show a clear predominance of Peru, despite the fact that its trade strategy is more recent and that both countries established different strategies to validate, protect and position their denomination of origin (DO) in international markets. The evolution of prices in the analyzed markets has shown an upward trend. The recognition of the DO has not offered a special advantage to either country. In this sense, a binational strategy for the promotion of the product, as well as the creation of a regulatory body to ensure quality in the production and quality assessment processes of pisco can help them achieve greater visibility in the international markets.

Keywords: Designation of Origin, Exports, Pisco, Competitiveness.

Introducción

El pisco o el agua ardiente de uva es un licor que se obtiene al destilar el producto final de la vid. Se produce en el norte de Chile y el Sur de Perú en Sudamérica, regiones semiáridas que presentan un clima y suelo similar, lo que permite la producción de las uvas pisqueras de origen europeo, desde la época de la colonia española (Mitchell & Terry, 2011). Ambos países mantienen una controversia respecto al origen de la bebida alcohólica.

La norma técnica peruana (NTP 211.001 del 2002), indica que el pisco es el aguardiente obtenido exclusivamente por destilación de mostos frescos de "Uvas Pisqueras" recientemente fermentados, utilizando métodos que mantengan el principio tradicional de calidad establecido en las zonas de producción reconocidas (Quebranta, Negra Criolla, Mollar, Italia, Moscatel, Albilla, Torontel y Uvina). Por otra parte, en Chile la Ley 18455 (1985) fija las condiciones de la Denominación Origen (DO) del pisco. Éste indica que es el aguardiente producido y envasado, en unidades de consumo en las Regiones de Atacama y Coquimbo, elaborado por destilación de vino genuino potable, proveniente de las variedades de vides plantadas en dichas regiones y que se determinan en el reglamento 521 del Ministerio de la Agricultura.

El pisco peruano difiere del chileno, y de destilados similares de otros países, porque no implica la rectificación (la adición de agua) ni el envejecimiento. Lo anterior, con el objetivo de retener los compuestos aromáticos derivados de las uvas y su fermentación y la destilación en alambiques de cobre (Cacho et al., 2013).

Para el siglo XVI y XVII Perú lideraba la producción de pisco al ser el mayor exportador, y Chile constituía un actor secundario. Sin embargo, debido a las relaciones políticas y sociales de Chile, y su condición de país minero especializado en cobre (materia prima para la elaboración de artefactos usados en la fabricación de este producto), las lamentables catástrofes naturales que afectaron a Perú en el siglo XVIII junto a la revolución industrial inglesa que lo obligó a cambiar el pisco por la caña de azúcar, pusieron a Chile como principal exportador, entrando incluso al mercado de Perú. En el siglo XX se retoma la industria del destilado de uvas en Perú, mejorando su calidad, ganando una mayor promoción y un importante desarrollo en la industria. De esta manera, volvieron a poner al país en competencia, obteniendo una cuota de mercado y de producción similar a la de Chile (Lacoste el at., 2013).

La disputa entre países vecinos sobre el origen del pisco está aún vigente. En 1931, Chile logra la DO (más antigua de América), logrando delimitarlo y protegerlo mediante el decreto n°181 del 15 de mayo de 1931, lo cual logra asegurar una calidad reforzada para este producto. Perú logró esta denominación en 1991, creando una disputa para obtener el reconocimiento exterior sobre esta DO. A través del tiempo la confrontación entre ambas naciones continúa, y cada una ha obtenido ganancias o distinciones en el comercio internacional. En el caso de Chile, la Organización Mundial del Comercio y la Organización Mundial de la viña y el vino establecieron los derechos de este sobre la DO del pisco (Pszczólkowski & Lacoste, 2016).

Las investigaciones históricas sobre el origen del pisco son muy importantes debido a que sirven como base a los países para defender sus posturas ante la comunidad internacional. Sin embargo, analizar la efectividad de las estrategias comerciales en el comercio internacional puede ayudar a comprender si los esfuerzos en materia de reconocimiento de la DO son efectivos, o se debe apostar a nuevas estrategias, ya sea en conjunto o cada país por separado, con el fin de maximizar los resultados de este producto.

En este contexto, esta investigación tiene como objetivo determinar de manera empírica cómo los flujos del comercio internacional del pisco avalan la posición comercial de Chile y Perú, determinando si el reconocimiento de la DO ha significado algún tipo de ventajas para ellos. Para su desarrollo se analizaron los flujos de comerciales mediante análisis de redes. Además, se evaluó el desempeño de Chile y Perú en el comercio internacional del pisco mediante matrices de competitividad aplicadas sobre los principales importadores de pisco en el periodo 2010-2019. Se analizó, además, la evolución del crecimiento utilizando las variables volumen y precio de las exportaciones.

Antecedentes Teóricos

La importancia de la DO está regida por el vínculo del producto y su lugar de origen. Esta otorga un nivel de exclusividad y originalidad, ligado también a los lazos históricos y culturales que caracterizan al producto, así como a los factores naturales y humanos que lo hacen único, aumentando su calidad (Harrel, 2009).

Uno de los ejemplos más emblemáticos a nivel internacional es el caso del champagne originario de Champagne en Francia. Este vino, fabricado masivamente alrededor del mundo, llevó a Francia a una gran disputa con Estados Unidos por el nombre del licor. Éste último aseguraba que el consumo mayoritario de la bebida fue principalmente en su país y en Inglaterra durante los últimos dos siglos, por lo que los franceses no se podían apropiar de la palabra. Posteriormente Suiza entró en la disputa por la DO del champagne, debido a que poseen un pueblo con el nombre Champagne donde se produce el licor. Francia ganó el debate de la DO del Champagne alegando que es originario del pueblo Champagne y es fabricado a través de procesos ancestrales y con uvas originarias de la región, por lo que el producto resultante es de una calidad superior al resto de los vinos espumantes, por lo tanto, de mayor exclusividad (Jay & Taylor, 2018).

Otra controversia por la DO fue el caso del queso feta originario de Grecia. Olushola (2017) indica que el proceso por la denominación del queso entre Grecia, Alemania y Dinamarca estuvo en juicio por quince años. Si bien el queso feta se originó en Grecia, este ha sido fabricado y vendido alrededor del mundo durante el último siglo con el mismo nombre. Grecia obtuvo la DO a mediados de 1980, y se otorgó un periodo de cinco años a los demás países para que cambiaran el nombre a "queso tipo griego". Se ha planteado que la DO debe establecerse en el plazo más breve posible, debido a que el producto puede perder sus características únicas que le agregan valor y exclusividad (Olushola, 2017). Estos beneficios que la DO consigue son de gran apoyo al desarrollo económico del país, mediante el aumento de las ventajas competitivas, oportunidades de exportación, atracción turística de la región y el desarrollo de áreas rurales.

La disputa entre Perú y Chile se basa principalmente en obtener la DO del pisco. El argumento de Perú son los lazos históricos que tiene con el pisco, por otro lado, el de Chile es el aporte al desarrollo industrial del licor a nivel nacional e internacional. Harrell (2009) menciona que, con una indicación geográfica homónima, los países podrían compartir la DO del pisco, y así poner un fin al conflicto, pero eso significaría que el licor pierda exclusividad al ser considerado un producto con distintos orígenes y de similares características, lo que conlleva a una menor competitividad en el comercio internacional.

Pero ¿por qué es tan importante el comercio internacional para el pisco? Krugman (1980) destaca que el intercambio de productos entre un país y otro se produce por la diferencia de costos de producción y porque aumenta el bienestar económico de cada uno al permitirle obtener productos que no produce y a menores costos. Las industrias locales se benefician al ampliar su mercado y aprovechar las economías de escala al aumentar la producción. La DO será esencial para la promoción de este producto y asegurar alianzas o redes internacionales con los países con los que se distribuye (Aranda, Gómez & Molina, 2015).

En los últimos años, ha aumentado el consumo de pisco en el mercado interno chileno, así como su exportación a países desarrollados, al considerarse un producto de alta calidad y de menor precio en comparación a otros destilados.

Según Mitchell & Terry (2011), Perú exporta mayormente a los Estados Unidos y curiosamente a Chile, sin embargo, la producción chilena es considerablemente mayor. Desde 1990 ambos países comenzaron a establecer nuevos acuerdos y relaciones comerciales, con el fin de ampliar el mercado potencial de sus sectores de exportación. Por ejemplo, el FTA (Free Trade Agreement) entre Estados unidos y Chile establece que ningún otro país puede vender el producto como "pisco chileno". Sin embargo, otros países pueden vender su propia versión de pisco sin que esté etiquetado como producto de ese otro país.

Perú ha perseguido agresivamente la aprobación internacional del producto exclusivamente peruano, ganando su reconocimiento en la India (2010) donde actualmente ninguno de los países en disputa exporta este producto, lo que puede ser estratégico a la hora de proyectar el mercado asiático (Mitchell & Terry, 2011). Perú en búsqueda de su reconocimiento se ha adherido al pacto de Lisboa lo cual le dio reconocimiento de la DO en un número importante de mercados (Nudman, 2007). Por su parte, Chile ha intentado compartir la denominación para gestionar y promocionar el producto conjuntamente, pero Perú se ha mantenido firme en rechazarlo con el argumento de que ambos productos son diferentes.

A través de la DO, los países buscan mejorar su competitividad en el mercado internacional. Para evaluar el desempeño del comercio internacional es usual utilizar indicadores como el índice de las ventajas comparativas reveladas VCR (Laursen, 2015; Stellian & Danna-Buitrago, 2019; Valencia, & Zetina, 2017). Este indicador permite diferenciar países con una ventaja competitiva en ciertos productos con los que no la tienen, y la comparación competitiva con otros países que se encuentran en el mismo mercado (Guevara & Morales, 2018a y 2018b). Otro método muy usado para el análisis de competitividad es la cuota de mercado constante (CMS), que sirve para estudiar el crecimiento de flujos comerciales de exportación de un grupo de países en un determinado periodo de tiempo (Guevara & Morales, 2018a; Liu, Shi, & Laurenceson, 2020).

Los métodos analizados anteriormente son muy útiles para analizar mercados muy competitivos o de alta concurrencia en cuanto a exportadores. En el caso del pisco, es útil utilizar las matrices de competitividad, las cuales buscan analizar la relación entre el comportamiento de las exportaciones con el dinamismo de la cuota de participación y el dinamismo del mercado importador (Guevara & Morales, 2018a; Fernández & Curado, 2019). Hasta el momento, no se evidencian estudios que evalúen la competitividad de Chile o Perú mediante el uso de estas metodologías, u otras similares.

Metodología

Fuente

Las bases de datos utilizadas provienen del Servicio Nacional de Aduana de Perú y Chile, los que abarcan el periodo 2008 al 2019.

Se utilizaron dos códigos arancelarios diferentes para cada país debido al problema existente de DO. Para Chile el código es 22082010 y para Perú el código 2208202100. Con el fin de obtener una matriz única se sumó ambos códigos por cada destino. Además, se utilizó el código 22082090 para el producto sin la DO para Chile (Brandy) y la suma de los códigos 2208202200, 2208202900 y 2208203000 para Perú. Esto, para un mejor estudio del efecto del precio del agua ardiente sin DO "Brandy" contra el agua ardiente con DO "Pisco".

Los países importadores se escogieron siguiendo los siguientes criterios: que la suma de sus exportaciones de pisco supere los 2 millones de dólares en el periodo analizado y que reciban exportaciones desde ambos orígenes con valores superiores a los 30 mil dólares en el año 2019. Estos países son Alemania, Argentina, España, USA, Francia y Reino Unido.

Método

Se realizó un análisis del flujo de comercio entre los países estudiados y sus principales importadores de pisco, representándolo de forma simplificada mediante un gráfico de malla elaborado en el software UCINET. Esta herramienta representa redes que analizan la interacción entre individuos u organizaciones (Botella, Stuart & Gadea, 2015).

Además, se evaluó la competitividad con el índice de participación de mercado o competitividad, y el índice de participación sectorial o dinamismo. Mediante ambos índices se realizó el análisis de matrices de competitividad.

Índice de participación de mercado o competitividad (MS)

Este índice refleja la capacidad de un país de incrementar su participación en un determinado mercado en relación con el resto de los países que exportan al mismo (Guevara & Morales, 2018a y 2018b) y estima la competitividad (Obschatko & Von Bernard, 2003). Puede interpretarse analizando el comportamiento de la participación, debido a que si esta aumenta significa que el sector o producto gana competitividad y viceversa. De esta manera, este índice vincula la competitividad con el desempeño exportador. Se puede calcular con la siguiente expresión algebraica:

$$\mathrm{MS} = \frac{X_{ij}}{\mathrm{M}_i} \quad \textbf{(1)}$$

Donde Xij son las exportaciones del producto i en el país j hacia el país considerado, Mi es el total de las importaciones del producto i del país considerado.

Índice de participación sectorial o dinamismo (PS)

Este índice permite observar para un momento en específico, la relación de las importaciones de un producto dado en un mercado determinado (independiente del origen del producto), y el total de importaciones de aquel mercado (Picardi, González & Valls, 2015). Este puede ser dinámico cuando aumenta, constante cuando se mantiene o en retroceso cuando disminuye, y su cálculo se realiza a partir de la siguiente fórmula:

$$\mathrm{PS} = \frac{\mathrm{M}_i}{M_t} \quad \textbf{(2)}$$

Donde M_i es el total de las importaciones del producto i del país considerado y M_t es el total de importaciones del producto i por el mundo.

Matriz de competitividad

Esta herramienta se utiliza para representar los datos de un estudio y analizar el estado de competitividad de la cuota de mercado, o la participación del mercado y el dinamismo, o la participación de las exportaciones del bien.

Para su representación usaremos la matriz modificada usada por Guevara & Morales (2018 a), la cual se divide en nueve cuadrantes como se muestra en la figura 1. Estos muestran el estado del mercado en tres fases (No dinámico, estancado o en transacción y dinámico) y la cuota de mercado o la participación que muestra cada país (pierde cuota, se mantiene o gana cuota).

Participación del mercado (competitividad)				
	Creciente (Sectores competitivos)	Ganador en mercado deprimido	Ganador en mercado estable	Ganador en mercado en auge
	Constante (Sectores en transición)	Persistente en mercado deprimido	Persistente en mercado estable	Persistente en mercado en auge
	Decreciente (Sectores no competitivos)	Perdedor en mercado deprimido	Perdedor en mercado estable	Perdedor en mercado en auge
		Decreciente (Sectores estancados)	Constante (Sectores en transición)	Creciente (Sectores dinámicos)
		Participación Sectorial (Dinamismo)		

Fig. 1: Matriz de Competitividad.

Fuente: Guevara & Morales (2018 a)

La matriz que resulta de combinar estos dos indicadores da a conocer que no es suficiente solo aumentar la competitividad sino también desarrollarla en sectores dinámicos, con el fin de lograr una exitosa inserción en el comercio internacional y lograr la categoría de "estrella naciente" o ganador en mercados en auge para este caso (Obschatko & Von Bernard, 2003; Guevara & Morales, 2018a).

Otra variable relevante desarrollada en este estudio es el precio de exportación a cada mercado analizado. Este se obtuvo mediante la división de los valores exportados en dólares ($) por la cantidad expresada en kg, como resultante el precio unitario se expresa en $/kg.

Eficiencia exportadora

Para analizar el desempeño exportador global de Chile y Perú en los mercados escogidos, se aplicó una descomposición del crecimiento anual que se compone del valor exportado. Este método consiste en explicar la tasa de crecimiento del valor exportado mediante la descomposición de la tasa de crecimiento del valor exportado y la tasa de crecimiento del precio exportado. Para su mejor compresión se plantea la siguiente ecuación:

$$GR_{vj} = \left[(X_{(k+n)j}/X_{kj})^{(\frac{1}{n})} - 1\right] + \left[(P_{(k+n)j}/P_{kj})^{(\frac{1}{n})} - 1\right] \qquad (3)$$

Donde

GR_{vj}: Tasa de crecimiento anual compuesto del valor exportado por el país j.

n: Cantidad de periodos analizados.

X_{kj}: Volumen de exportaciones del producto en el periodo k (inicial) por el país j.

$X_{(k+nj)}$: Volumen de exportaciones de del producto en el periodo k+n (presente) por el país j.

P_{kj}: Precio del producto en el periodo k (inicial) del país j.

$P_{(k+nj)}$: Precio del producto en el periodo k+n (presente) del país j.

Análisis De Resultados

La red de comercio mostrada en la figura 2, visualiza las relaciones del comercio del pisco para el año 2019. En su conjunto se logró una exportación total de 9.1 millones de USD con una participación de 68% para Perú y el 32%

para Chile. Los principales flujos de comercio son hacia USA, España y los Países Bajos. USA concentró un 42% de las compras totalizando 3,9 millones de dólares, de los cuales el 80% son importaciones de Perú. El segundo mercado de mayor flujo es España con 10% seguido de Países Bajos con un 6%. En ambos casos Perú es el principal proveedor con 84% y 98% en cada mercado, respectivamente.

Fig. 2: Flujo de comercio de Perú y Chile para el producto pisco en el año 2019.

En la mayoría de los mercados coinciden las exportaciones de ambos países, aunque se observa que Perú ha abierto nuevos mercados como es el caso de Italia y Ecuador. Resulta interesante que pese a la existencia de un litigio entorno a la DO de este producto existe un comercio bilateral entre Chile y Perú, siendo las exportaciones de este último las más significativas.

Análisis de competitividad en los principales destinos.

Luego del análisis de la competitividad global, se analiza la competitividad hacia los principales destinos. En el caso del mercado de USA (Fig. 3), el mayor importador muestra una función ($y = 0.0012x + 0.3644$) con un valor de $P = 0.8$, lo que indica que el país no tiene una tendencia. Perú muestra ventaja debido a que se ubica como ganador en el mercado estable, con una cuota del 75% para el periodo analizado, ganando una mayor competitividad. Debe destacarse que USA firmó un tratado de libre comercio con ambos países donde reconoce el pisco tanto de origen chileno como peruano. Esto hace suponer que para el caso del mercado estadounidense no es determinante la DO, entre estos dos países.

Por otro lado, la Unión Europea estableció el reconocimiento de la DO del pisco para productos originarios de Chile y la protección geográfica del pisco para productos originarios de Perú. Dentro de los países pertenecientes a la Unión Europea analizados en esta investigación se encuentra España, con una función ($y = 0.0057x + 0.0273$) y un valor de $P = 0.03$, lo que lo ubica en un mercado en crecimiento, siendo tanto Chile como Perú constantes en un mercado en auge, este último con una mayor cuota con un 74% (Fig. 3).

Fig. 3: Matrices de competitividad de los mercados del pisco en USA y España, 2008 a 2019.

El mercado de Argentina (Fig. 4), el más cercano geográficamente de estos dos países exportadores, tiene una función (y = -0,0055x + 0,087) con un valor de P = 0.001. Se encuentra en un mercado en decrecimiento, en el cual Chile se encuentra como el ganador de competitividad con una cuota del 80%, a pesar de que este país no ha reconocido la DO del pisco a favor de ningún país.

Por otro lado, el mercado de Alemania (Fig. 4) obtuvo una función (y= -0.0006x + 0.049) con un valor de P = 0.5, lo que lo ubica en un mercado estancado, ubicando a Chile como el ganador de competitividad con una cuota del 56%.

Fig. 4: Matrices de competitividad de los mercados del pisco en Argentina y Alemania,

periodo de 2008 a 2019.

Al analizar el mercado de Francia (Fig. 5), se obtuvo una función (y= 0,0007x + 0,0312) y un valor de P = 0.7, demostrando que no tiene una tendencia aparente. A pesar de que Chile cuenta con una cuota de mercado del 52%, superior a la de Perú, este último ha ganado competitividad en el mercado estable francés.

En cuanto al mercado de Reino Unido (Fig. 5), se obtuvo una función (y = 0,0027x + 0,011) y P = 0.02, encontrándose en un mercado creciente. Perú tiene una cuota de mercado de un 62% en este mercado encontrándose como un ganador de competitividad.

Fig. 5: Matrices de competitividad de los mercados del pisco en Francia y Reino Unido, periodo de 2008 a 2019.

En la tabla 1 se puede observar que para los 6 países importadores de pisco estudiados no existe una ventaja especial para Chile o Perú mediante el reconocimiento de la DO. Es decir, en todos los destinos se le ha reconocido la DO, específicamente al producto de cada país como pisco chileno o como pisco peruano, excepto Argentina que no ha reconocido a ningún de las dos naciones.

Tabla 1: Reconocimiento de la D.O. según los mercados analizados.

País Importador	Principal Exportador	Cuota de mercado	Reconocimiento de la D.O.
USA	Peru	75%	Chile- Peru
Spain	Peru	74%	Chile - Peru
Germany	Chile	57%	Chile - Peru
Argentina	Chile	80%	—
France	Chile	52%	Chile - Peru
United Kingdom	Peru	62%	Chile - Peru

Análisis de precio y eficiencia exportadora.

En el análisis de los precios de la figura 6, se puede observar que la evolución del precio en los mercados analizados ha presentado un comportamiento al alza en la mayoría de los mercados para ambos productores.

Fig. 6: Precios del pisco para Chile y Perú en los distintos mercados, para el periodo del 2008 al 2019.

Perú presentó un mayor precio promedio que Chile, diferencia que se presenta en todos los mercados analizados con excepción de Francia. El precio del producto chileno ha crecido de manera importante en Francia y España. Para el caso del pisco peruano, el único mercado en el cual el precio disminuye fue en Reino Unido. Para el producto sin DO "Brandy", los precios son muy similares y estables en el tiempo para ambos países, sin embargo, en los último 3 años Perú muestra mayor valor que Chile.

En términos absolutos en el periodo analizado, la variación del precio en los mercados analizados es importante. Chile presentó un incremento del precio de 74% (de US $ 2,4 a US $ 4,2) y Perú de un 17% de (US $ 3,9 a US $ 4,6).

Las tasas más altas de crecimiento del volumen y valor se presentan para el caso del producto sin DO para Perú, aunque es el único que en promedio disminuyó sus precios (Fig. 7). Para el caso del pisco el mejor desempeño en términos de valor y volumen lo presenta Perú, aunque Chile lidera el crecimiento en precios, marcado por su desempeño en Francia. En términos generales se observa que la denominación de origen no está agregando valor para ninguno de los dos países respecto al aguardiente sin DO en cuanto a demanda, pero si en cuanto al crecimiento del precio.

Fig. 7: Tasa de crecimiento anual compuesto por precio, volumen y valor del pisco vs el aguardiente.

Conclusiones

El predominio de Perú en los mercados internacionales del pisco es innegable. Sus resultados en términos de crecimiento de valor y volumen exportado, participación de mercado y precios es superior para la mayoría de los mercados analizados en comparación con Chile.

Ambos países establecieron estrategias distintas para validar, proteger y posicionar su DO en los mercados internacionales. Chile realizó una estratega activa de reconocimiento de la DO en base a las suscripciones de tratados de libre comercio (TLC) desde el año 1997 (19 en particular, que le dan presencia en América del Norte, la Unión Europea, Asia y Oceanía) y contados registros de DO extranjeros (Costa Rica, El Salvador y Chile). Por su parte, la estrategia peruana se basó en el arreglo de Lisboa del 2006 que le concede registro de DO en 19 países y una agresiva estrategia registral desde 1998 (con 22 inscripciones), y recientemente la suscripción de TLC.

En términos comerciales la estrategia peruana ha sido mucho más exitosa, siendo la estrategia chilena más bien reactiva ahora con juicios pendientes con Perú en los mercados de India, Tailandia y el Salvador. La participación del estado en tales estrategias es fundamental, siendo el estado peruano un actor clave en la consolidación de su producto. Por otra parte, el éxito peruano también se le atribuye a una mayor integración a canales como hoteles, restaurantes y cafeterías basado en su gran prestigio culinario.

Dado que no se puede concluir que el reconocimiento de la DO haya ofrecido una ventaja especial a ninguno de los dos países, se recomienda una estrategia binacional para la promoción del producto, así como la creación de un organismo regulador que vele por la calidad en los procesos de producción y evaluación de la calidad del pisco. Esto, teniendo en cuenta que otros países con cuestiones similares de indicaciones geográficas transfronterizas, han trabajado activamente juntos para resolver el problema de cómo proteger conjuntamente sus productos y alcanzar mayor visualización en los mercados internacionales (Mitchell & Terry, 2011)

The Impact of the COVID-19 Pandemic on a Selected Automotive Industry - a Case Study of Poland

Wojciech LEWICKI

Faculty of Economics, West Pomeranian University of Technology Szczecin, Poland.
e-mail:Wojciech.Lewicki@zut.edu.pl

Abstract

The coronavirus pandemic has greatly affected the European economy. No one doubts in today's commercial reality. One of the key industries that has obviously suffered from the effects of the economic crisis is the automotive industry. The COVID-19 situation is changing dynamically and, because that industry is increasingly internationalized, possible effects will certainly continue to result from the supply shock and be observed as a global demand shock. The aim of the research is to present current challenges which are being taken on to tackle the economic and social crisis, based on the example of the European automotive industry – a Poland case study. Therefore, the article presents only selected research results relating to the impact of the COVID-19 pandemic on the particular segments of the industry. Specifically, an attempt was made to identify changes taking place in the sales and distribution systems for new cars and spare parts, as well as maintenance and repair services. The research study may contribute to the faster development of universal solutions in the field of addressing the crisis by means of identifying the areas which require adaptation to the new market rules. In addition, our presentation and interpretation of the results may be a basis and incentive to conduct further research on the topic related to the impact of the pandemic on the industry in terms of identifying further consequences for both the supply and the demand part of the industry.

Keywords: automotive, market, crisis, COVID-19.

Introduction

The most frequent statement in the literature on the subject is that the automotive industry is one of the most complex industries in terms of multiplicity and various relationships with the environment(Wells,2013;Mohammad Nazir, and Shavarebi,2019).Companies producing passenger cars create extensive networks of connections with numerous market entities, i.e. sub-suppliers, influential and opinion-forming organizations, as well as financial institutions (Bailey et.al 2010;Kallstrom,2015). It is estimated that an average final vehicle manufacturer produces only 15% of their vehicle parts. (Ha et al. 2009). The rest are manufactured by numerous sub-suppliers located in various national markets. In many countries, distribution and / or retail sales are also carried out by third parties. Despite such a complexity of the process, researchers find the automotive industry to be one of the most innovative. (Vaz et al.2017;Blankesteijn, 2019; Wang et al.2018). At the same time, its important role in the global development of entrepreneurship is emphasized. (Kallstrom, 2015; Vošta& Kocourek, 2017). Reports and studies show that, until recently, the automotive sector provided jobs for 13.8 million Europeans, which accounted for 6.1% of the total employment figure in the European Union. The automotive industry is particularly important for the Polish economy, not only because it generates hundreds of thousands of jobs both directly and indirectly, but also has a direct impact on other sectors of the economy. Moreover, according to the available data, like in other countries, the industry is highly dependent on exports, the value of which totaled over PLN 130 billion in 2019, which accounted for almost 13% of the total exports of goods from Poland (Statista, 2020).

As emphasized in the literature on the subject, the current crisis in the automotive industry has been caused by both the demand and supply factors. This means that the scale of negative effects will significantly exceed the previous crises (OECD, 2020a; OECD 2020b; Mahalingam, 2020). The high sensitivity of the automotive sector to disruptions in the supply chains and susceptibility to changes in the economic situation will only intensify that effect, which will result in reduced production, lower levels of exports and declining employment. (Ludvigson et al. 2020; Baker et al. 2020). Consequently, both the position and the role of the automotive sector in the EU and Polish

Cite this Article as: Wojciech LEWICKI "The Impact of the COVID-19 Pandemic on a Selected Automotive Industry - a Case Study of Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

economy will change in the near future, which certainly requires in-depth analysis and research conducted with academic and practical considerations taken into account (Piparsania, 2020; Kaitwade, 2020; Queiroz, et al. 2020). Analysis of the literature on the subject showed that it is limited in terms of taking considerations for the automotive industry into account. In particular, there are no publications describing changes caused by the crisis in the automotive industry in relation to the European market, based on the example of the Central European countries, including Poland, and focusing on issues related to the distribution of new passenger cars and spare parts, or identification of problems arising in the automotive services sector - both service and repair. The study is therefore an attempt to fill the gap in the literature on the subject by not only identifying changes taking place in this market, but also pointing out to likely scenarios. At the same time, it provides an incentive for further reflection on developing methods and ways for the automotive sector to deal with the COVID-19 pandemic.

Therefore, this article has numerous important practical implications, both political and economic. The aim of the research was to obtain extensive knowledge regarding the impact of the COVID-19 pandemic on goods and services provided in the modern automotive market. Chapter 2 of the article contains a detailed description of the purpose, scope and research method used in response to the research questions. Chapter 3 describes the results of experimental research and their interpretation. Chapter 4, however, discusses the results achieved by the author and presents the conclusions. It shows their limitations in the context of research that has been conducted to date and points out to future research directions in relation to the problems of the crisis that the European automotive market is currently undergoing.

Materials and Methods

Conceptual Assumptions

The aim of the entire research project was to obtain extensive knowledge on the impact of the global COVID-19 pandemic on selected sectors of the automotive industry in Poland. The description of the selected issue concerning the subject of the impact of the coronavirus on particular industries has therefore been presented in a multi-sectoral perspective (both in relation to the demand and the supply part of the industry). The research area focused on identifying changes caused by the coronavirus and how it affected the sales and distribution systems for new passenger cars and spare parts, as well as service and repair services. As a result, an attempt was made to answer the following research questions:

- What changes have occurred in the sales and distribution of new passenger cars?
- How have the distribution channels for new spare parts changed?
- What changes have been made in the field of maintenance and repair services?
- In which areas of their operation do entities from the automotive sector forecast the most significant changes?

Method of sample selection

Affirmative actions were taken with regard to the correct selection of research participants by sending questionnaires to these entities which conduct their activity only in the automotive industry. Therefore, the awareness criterion was the main factor determining participation of a particular person in the study. The potential respondents were first asked if they were related to the automotive industry. During the survey, all the respondents confirmed that and answered positively to the first question asked in this regard.

The selection of respondents for the survey was made amongst vehicle manufacturers, sub-suppliers of automotive parts and components, car dealers, as well as repair and service workshops. The selection was not classified according to the size of the entity, form of ownership or type of business. The respondents were quality engineers, directors, traders, managers, and service managers. Because the respondents diversed in terms of age, gender, and type of business they were involved in, part of research was conducted using one communication channel, i.e. the Internet. 450 interviews were collected during the research phase. The adopted strategy recognized the sample as sufficient for the adopted analysis scheme and, therefore, enabled to answer the research questions.

Description of the tool

The CAWI method (computer-assisted web interviewing) was used as part of the study. The questionnaire form to be filled in electronically was sent to the relevant entities related to the automotive industry. The survey was anonymous, which enabled the respondents to express their opinions freely. The completed questionnaires are reflected in the layout of the results.

Analysis Scheme

During the research 450 completed answer sheets were obtained in electronic form by means of an online questionnaire. The research was conducted in Poland, an EU country, from March 2020 to June 2020, during lockdown, i.e. the first phase of the pandemic. The survey contained 8 questions (answers to 4 of them are presented in the article) related to the impact of the pandemic on the automotive industry in Poland. In the scheme adopted the questions pertained to changes in the channels and distribution of new cars and spare parts, service and repair services, and forecast changes in particular operational areas of the entities in that market sector. The study contains substantive comments and charts including answers to the questions contained in the forms. After entering the answers into a spreadsheet, the obtained research data was subjected to statistical and substantive analysis. In order to increase readability of the obtained answers, the results are presented in percentages (simplest form possible) using figures 1 to 4.

Unless otherwise stated, the percentages were added up to 100% of the surveyed group of respondents. The answers, which were less than 10% of the total, were considered irrelevant and were left out at a later stage of the analysis. However, in the case of multiple-choice questions and more than one answer provided, the percentage distribution did not add up to 100%, but was calculated as a percentage by comparing the number of people providing an answer with the total number of respondents.

The technical notes on the data presentation method are placed in the titles and footnotes to the figures. Since the respondents were not required to answer all the questions in the survey, the number of valid answers varied for different questions , which did not affect the final result as the number and percentage losses were not significant. The layout of all analyzes corresponded to the objectives of the study.

Results

At the first stage of the research, the respondents were asked to reveal changes in the sales and distribution of new passenger cars. (fig. 1).

Fig.1: Changes in the distribution and sales systems of new passenger cars

Source: own study

The analysis of the obtained response results showed that the most important change revealed by over 90% of the respondents was a noticeable fall in demand for new vehicles. In addition, in terms of distribution and sales systems for new passenger cars, the most significant change was observed in the transition from direct sales to online sales. This fact was revealed by 80% of the respondents. 37% of the respondents pointed out that the waiting period for new vehicles (particularly for models with customized equipment) was extended. It is worth noting that 22% of the respondents indicated consolidation of the sales systems operated by particular dealers carrying several makes of vehicles from the same business group. However, only 11% emphasized the fact that new forms of financing purchase of a vehicle were introduced.

At the next stage, the respondents were asked to indicate changes in the distribution systems for new passenger car spare parts (fig.2).

Fig.2: Changes the systems for distribution and sale of spare parts systems sector in connection with the COVID-19 pandemic

Source: own study

The research shows that 82% of the respondents revealed a decrease in demand for new spare parts. Over 40% of the respondents emphasized that the logistics processes related to the delivery of new original spare parts were extended, and 24% of the respondents indicated limitations in their market availability (particularly in the case of spare parts and components whose inventory levels were kept at a low level before the pandemic). Moreover, 35% of the respondents revealed changes in the distribution systems, consisting in an increase in the market share of independent distributors of spare parts. It is worth noting that only 22% of the respondents indicated that changes occurred in the systems for selling spare parts, i.e. a decrease in direct sales and an increase in online sales. At the next stage of the research the respondents were asked to reveal changes in the scope of maintenance and repair services. (fig.3).

Fig. 3: Changes in repair and maintenance services sector as a result of the pandemic COVID-19

Source: own study

The results from the obtained responses show that in as many as 61% of service and repair workshops a decrease in demand for their services was observed. 28% of the respondents pointed out to the fact that customers depart from services offered by authorized garages and choose unauthorized ones. 21% of the respondents revealed a noticeable increase in the prices of repair and maintenance services offered. Over 18% of the respondents pointed out to the

fact that the waiting time for the service was shortened. It is worth noting that 16% of the respondents showed an increase in demand for complex and specialized repairs, including repairs of the gearbox or power units.

The last stage of the research included answers to the question in which areas of their operation the entities from the automotive sector forecast the most significant changes. (fig.4)

Fig. 4: The areas of changes in the functioning of an entity from the automotive sector in connection with the COVID-19 pandemic

Source: own study

The results from the obtained responses show that the largest number of respondents, i.e. over 70%, indicate possible changes in the field of employment - redundancy or reduction of salaries and wages. Over 50% of the respondents confirmed changes in the sales systems, i.e. limited direct contact with the customer. In addition, 42% of the respondents confirmed changes in the working systems, i.e. introduction of the so-called work from home, if possible. About 30% of the respondents emphasize that there will be limitations in terms of investment in the company's development. On the other hand, 22% of the respondents confirmed changes in the pricing policies (an increase in prices).

Discussion and Conclusions

Although the car industry was subject to various trends related both to the changes occurring within it and to the development of the entire world economy, it was, until recently, one of the fastest growing sectors of the economy of the European Union (Dooley, 2020). Experts from the automotive industry agree that the industry has not faced a crisis of such scale to date, and that it will have global economic effects (Ivanov, 2020; Bloomberg, 2020; Melin & Kim, 2020). Many researchers point out that one of the key elements in the analysis of the environment of enterprises operating in a particular market should be identification of changes and trends they are affected by. (Baldwin &Tomiura, 2020; Kotler et al.2020). Because, as one of the researchers emphasizes, the correct analysis of their impact on the functioning of entities in a particular market enables to take appropriate measures, e.g. addressing threats and emerging crises (Anwar & El-Bassiouny,2020;Baldwin & Weder di Mauro,2020). Therefore, the main objective of the research was to present the current challenges faced by the European automotive industry in order to tackle the COVID-19 crisis.

The author shares the opinion of other researchers, who analyzed previous crises, that the impact of the COVID-19 pandemic is much wider and will, to a greater extent, affect many European markets related to the automotive sector. (Foldy, 2020;Word Bank, 2020). It is due to three main factors. Domestic demand was very quickly reduced by the pandemic. Therefore, all the European markets, which are closely related to the domestic markets (for example the Polish automotive industry analyzed in this article), are also affected by the pandemic. In addition, in the last dozen or so years, China's role in the global automotive industry has increased significantly. It has become the world's largest car manufacturer and one of the largest suppliers of components for the automotive sector

(Bloomberg,2020). As one researcher emphasizes, a significant delay in the delivery of one component from China may result in the suspension of the operation of numerous plants in Europe, which rely on just-in-time supply management.(Gereffi, 2020; Kano et.al,2020; Demirel, 2019).

The research results relating to the Polish automotive industry seem to confirm that. Over 90% of the respondents revealed a noticeable decline in demand for new vehicles, which was confirmed by other authors' studies relating to the analyzes of automotive industries in other countries. The author claims that it is the result of forced social isolation and restrictions on movement. This also translates into supply opportunities. The overcapacity that emerged in connection with the pandemic had a negative effect on financial liquidity. In addition, research results show that vehicle sales have moved from direct to online sales. This change in the method of distribution and sales of vehicles results from the need for maintaining an even greater social distance in direct contacts. In this regard, the author agrees with other researchers (Anwar & El-Bassiouny. 2020; Kraus et al. 2020) that presenting a car and conducting tests online may be an effective solution to increasing sales in the COVID-19 era. It is worth noting that 37% of the respondents revealed that the waiting period for new vehicles was extended (particularly for models with customized equipment). According to the author, this resulted from the closure of some factories and reduced production, as well as from the need to get rid of excess inventory in the range of the most sold vehicle models with standard equipment.

In terms of changes in the distribution of spare parts, the majority of respondents revealed three important trends: a decrease in demand for new spare parts, extension of logistics processes for the supply of new, original spare parts, and an increase in the market share of parts from independent distributors. The author argues that this resulted from two processes: a fall in production of new original parts by sub-suppliers, and a sudden, rapid decrease in mobility and number of vehicles on the roads. Only 22% of the respondents pointed out to a change in the systems for distribution and sales of spare parts. The author claims that B2C sales on-line on the spare parts market have been operating for several years. Therefore, the situation related to COVID-19 has only led to an increased role of e-commerce in this market. From being an auxiliary or additional means of selling spare parts, this channel has turned into the main tool for accessing customers. In terms of changes in the field of maintenance and repair services, the majority of respondents revealed two key trends, i.e. a decrease in demand for their services as well as departure of customers from the services provided by authorized garages and migration to those offered by unauthorized garages. Like in the case of the previously analyzed cases, according to the author and other researchers (Zhang et. al. 2020), this state of affairs is influenced by the lower mobility of the society, i.e. reduction in vehicle operation processes. On the other hand, according to the author of the research, the departure of customers from authorized garages in favor of unauthorized ones, is related to the attempts of users to reduce repair costs. In the current economic crisis, this trend is absolutely natural.

As regards the anticipated changes in the functioning of entities in the automotive sector, research shows changes in three key areas. Over 70% confirm possible employment changes, i.e. redundancies or reduced wages and salaries. This may result from the fact that the downtime in car production caused by the coronavirus resulted in a reduced volume of manufactured goods, as well as further reduction in demand for automotive products. In addition, 50% of the respondents declare further changes in the sales systems, i.e. limiting direct contact with the customer. About 42% of the respondents revealed changes in the working systems, i.e. introduction of the so-called work from home, if possible. On the other hand, what is worrying is probable limitations with regard to investments, which was shown by 30% of the respondents.

On the other hand, the prices anticipated within the pricing policy are a matter of dispute with other authors (Verma & Gustafsson, 2020;Ashraf,2020). The author claims that first of all COVID-19 has led to a drastic reduction in demand and consequently reduction in profits. Restarting production is associated with an increase in costs (securing personnel, searching for new business strategies, etc.). Therefore, the supply part of the industry will want to recover as soon as possible. The upward trend in prices might be one of the ways to do so.

The analysis of research results shows that the COVID-19 pandemic has an obvious impact on both the supply and the demand part of the industry. At the same time, it paves way for changes taking place in the automotive industry, which is certainly an answer to the research questions posed. The research confirmed the thesis promoted in the literature by other researchers (Buruzs & Torma, 2017;Cioca et.al. 2019, Zhang et. al, 2020) that in the automotive industry we often deal with long chains of connections and cooperation, which means that the situation faced by the market of one country not only affects other domestic markets but also all related entities in this industry. It all leads to the so-called "domino effect" described in the economic literature.

Although the research focused on the analysis of changes in relation to the Polish automotive industry, the author argues that the conclusions of the research may be implemented in the automotive industries operating in particular countries of the European Union.

The paper uses data from a survey performed on a specific research sample: 450 entities from the Polish automotive sector. Certainly, in the near future, much wider analyzes will be necessary, particularly with the use of time series variability. For example, it will be necessary in the case of comparing the effects of the first and second phases of the pandemic on the industry. In addition, further research on this topic should focus on aspects related to analysis of the impact of the COVID-19 pandemic on sectors related to the automotive industry, including the banking or motor insurance sector.

Summing up the research results on the impact of the COVID-19 pandemic on the automotive industry for the case study 'Poland', one might say that they do not fully cover the whole issue, but are an attempt to signal the complexity of the presented research problem. Certainly, the subject requires further analysis and research to understand how that industry functions and what impact a global pandemic has on a micro, macro and global scale. Therefore, such analysis will be the subject of future work to identify key factors for tackling the crisis in that sector of the industry.

Financial Liquidity Strategies of Mining Enterprises in Poland And in The World

Aneta MICHALAK

Silesian University of Technology, Gliwice, Poland
aneta.michalak@polsl.pl

Abstract

Financial liquidity strategies are one of the most important decision-making problems in an enterprise. The article attempts to discuss and examine the liquidity strategies used in the hard coal mining industry in Poland and in the world. The paper puts forward a thesis that due to the high degree of immobilization of assets, mining enterprises use conservative liquidity strategies. The nature of the liquidity strategy was defined on the basis of the financial liquidity ratios: current ratio, quick ratio and cash ratio. The analysis was complemented with the establishment of the working capital. This allowed to characterise the liquidity strategies used in the hard coal mining industry. The research was based on literature studies and data from the financial statements of the surveyed enterprises. The conducted analysis is of preliminary study nature and will be extended in further works by extending the methodology of liquidity measurement.

Keywords: Financial Liquidity, Working Capital, Mining Enterprises.

Introduction

Managing the financial liquidity of enterprises in the current turbulent economic conditions is a difficult task. This is even more of a challenge in industries, such as hard coal mining. The activity of mining enterprises is extremely difficult, due to the occurrence of natural hazards related to the geological and mining conditions of the extracted deposits. This is additionally overlapped by international, EU and national political and legal conditions, the frequent lack of support from trade unions, as well as local and regional communities or environmental organisations. The financial dimension of the efficient and effective management of such enterprises is the maintenance of sufficient financial liquidity. Managing financial liquidity in mining enterprises involves making decisions related to acquiring short-term and long-term sources of financing the mining enterprise, which affects the final shape of the capital structure and working capital. Such decisions, due to the high level of risk associated with this activity, pose a serious challenge for the extractive industry.

The main **goal** of this article is to systematise the issues of financial liquidity management of enterprises, taking into account the specificity of mining enterprises, and to identify the strategies adopted in this regard by the largest Polish and global mining enterprises. The implementation of such a defined goal takes place in two stages. In the first one, the author reviews the literature in the field of financial liquidity management of enterprises, trying to highlight the industry conditions. In the second stage, the liquidity strategies implemented in selected mining enterprises are analysed. The paper puts forward a thesis that due to the high degree of immobilization of assets, mining enterprises use conservative liquidity strategies.

Literature Review

Financial liquidity is the enterprise's ability to pay its liabilities on time. It is a complex category, that requires a comprehensive and multi-faceted approach, especially in the case of mining enterprises. At the same time, it is an extremely topical issue, and of great importance from the point of view of ensuring the enterprise's survival on the market (Meijer et al., 2019, pp. 114-126). The magnitude of this issue is so high, that we can talk about financial liquidity management in enterprises. It is understood as keeping assets easily convertible into cash and reserves of cash and securities at the level optimal for the enterprise (Ding et al. 2013, pp. 1490-1507; Enqvist et al. 2014, pp.36-49; Lind et al., 2012, pp. 92-100; Vahid et al. 2012, pp. 1313-1318). If the enterprise has insufficient financial liquidity, it may become insolvent, which is one of the most important causes of bankruptcy. In turn, too high financial liquidity, defined as excess liquidity, reduces the profitability of the enterprise, as part of the capital is frozen (Wędzki, 2003, p. 34).

Cite this Article as: Aneta MICHALAK "Financial Liquidity Strategies of Mining Enterprises in Poland And in The World" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The term working capital management is used interchangeably with the term financial liquidity management (Bei and Wijewardana, 2012, pp. 695-700; Opler et al., 1999, pp. 3-46; Aktas et al., 2015, 98-113). It is defined as shaping the level and structure of the part of the current assets financed with equity and long-term liabilities. Equity increased by long-term liabilities is the so-called fixed capital of the enterprise. This capital should be high enough to finance all the enterprise's fixed assets and part of its current assets. That part of the current assets that is financed with fixed capital is called net working capital or working capital.

Maintaining sufficient financial liquidity largely depends on the availability of cash, which – in turn – is determined by the possession of assets that are easily convertible into these funds (Zimon, 2019, p. 366). In the case of mining enterprises, there is a high degree of immobilisation of assets, which are generally difficult to sell. Underground buildings, technical equipment and machinery play an important role in the fixed assets of these enterprises, which, due to them being underground, practically cannot be liquefied. Their sale and conversion to cash would entail high costs of dismantling and transport, which could exceed the revenues gained from their sale. Having easily marketable fixed assets is an important determinant of financial liquidity, though not the only one.

The technology used and the organisation of the production process are also important. They determine the length of the production cycle and the level of inventories and, therefore, affect the degree of immobilisation of current assets. The more time passes from the production of the product to its sale, the greater the risk of a lack of cash for the current payment of liabilities. In the case of mining enterprises, there is a significant level of immobilisation of assets in inventories of finished products. Coal with the best quality parameters is sold relatively quickly, while the remaining coal can be stored for a long time. This overlaps with the problem of seasonal demand, which is an additional factor affecting the length of the inventory turnover cycle and the freezing of cash (Czekaj, Dresler, 2006, p. 187).

In addition to internal factors, financial liquidity is influenced by a large group of factors independent of the enterprise, coming from its environment. One of them is the economic situation. Its influence on liquidity is especially visible in periods of economic downturn. Then the risk associated with running a business increases, which creates the need to have a larger reserve of funds to pay off current liabilities, in the event of difficulties in collecting receivables or liquidation of inventories (Okręglicka, 2015, p. 387). During an economic downturn, managers find it difficult to predict the enterprise's cash flow in the context of increasing macroeconomic uncertainty, so they may decide to maintain higher cash reserves to maintain liquidity (Baum et al., 2006, pp. 289-304).

Another determinant of financial liquidity is monetary policy. It consists in the influence of the state on the demand for money and the supply of money in the economy, mainly through interest rates. They translate into interest rates at commercial banks, at the same time influencing the preferences of enterprises regarding investing capital in banking products and taking out credits and other interest-bearing liabilities.

The level of taxes is also of great importance in the area of financial liquidity of enterprises. A higher rate of income tax reduces the net profit that can be credited to your working capital. The list of factors determining financial liquidity is long (cf. Grabowska, 2012, p. 20). Those listed above are only examples of them. The influence of each of these factors may be of different intensity, depending on the specific situation, industry in which the enterprise operates, the period taken into consideration etc. (Sierpińska, Rzeszowski 2012, p. 199).

Materials and Methods

The research problem undertaken in the article is the identification of the financial liquidity strategy used in hard coal mining in Poland and in the world. In order to examine the financial liquidity strategy, data from financial statements of the surveyed enterprises was used, taking into account the book values of selected items. On their basis, a set of financial ratios was calculated and the level of working capital was examined. The years 2016-2019 were adopted as the research period.

The subject of the research is an analysis based on the three classical ratios of liquidity and net working capital. The examined ratios include:

- current ratio,
- quick ratio,
- cash ratio.

The **current ratio**, also known as the current liability coverage ratio, gives an overview of the financial liquidity. It is calculated according to the following formula:

$$W_{pb} = \frac{A_b}{Z_b}$$

where: W_{pb} – current ratio,
A_b – current assets,
Z_b – current liabilities.

The structure of this ratio is based on the assumption that the enterprise's liquidity, i.e. its ability to pay its liabilities on time, depends on the value of its current assets, i.e. assets that can be easily converted into cash. These assets, according to the balance sheet approach, include inventories, receivables with maturities of up to 12 months and short-term investments. The enterprise's financial liquidity will be positively assessed if the value of current assets is higher than the value of current liabilities. Due to possible issues related to the liquidation of these assets, the assumed standard is a prudent assumption, in which current assets exceed the value of current liabilities by 20-100%. The optimal value of this ratio in enterprises should, therefore, range from 1.2 to 2.0 (Czekaj, Dresler, 2006, p. 211). Taking into account the specificity of mining enterprises, and in particular large immobilization of assets in the form of underground fixed assets and hardly tradable coal stocks on dumps, this value may be even closer to the upper limit of this norm. Below this level, there is a risk of liquidity or lack of liquidity, and above this level, there is excess liquidity. Financial excess liquidity is a condition which, on the one hand, may indicate that current assets are too large or insufficiently rotated and, on the other hand, insufficient use of current liabilities in the structure of financing current assets. The liquidity is then maintained, but the enterprise incurs high costs for its excessive maintenance, related to the entrapment of capital in current assets (costs of maintaining stocks, financing recipients). The current ratio is the most commonly used measure for assessing the enterprise's liquidity, but it does not take into account the various possibilities of converting individual current assets into cash. Some of them, such as inventories, are converted into cash over a relatively long period. In order to overcome these shortcomings, the second measure is proposed, which is the quick ratio.

The **quick ratio**, also known as the ratio of increased liquidity, determines the degree of coverage of current liabilities with assets of high liquidity. To calculate it, the current assets shown in the numerator of the current ratio are reduced by the least liquid components, i.e. inventories and deferred charges. The ratio formula takes the form:

$$W_{psz} = \frac{A_b - Z - RM_{cz}}{Z_b}$$

where: W_{psz} – quick ratio,
RM_{cz} – deferred charges,
Z – inventories.

The optimal value of the ratio is in the range from 1 to 1.2. This means that current liabilities should be fully covered in the most liquid assets of the enterprise, i.e. receivables and short-term investments. The value of the ratio below 1 means lack of quick liquidity, i.e. problems with timely payment of current liabilities. On the other hand, a level above 1.2 suggests excess liquidity, which may result from an excessive level of receivables and short-term investments.

Another ratio is the **cash ratio**, which only takes into account the most liquid assets of an enterprise, in the form of short-term investments. These are those components of current assets that, in a given period of time, are not related to the operational process, i.e. short-term financial assets, as well as cash and other cash assets. The value of this ratio informs about the degree of coverage of current liabilities from these assets and can be calculated according to the formula:

$$W_{śp} = \frac{I_k}{Z_b}$$

where: $W_{śp}$ – cash ratio,
I_k – short-term investments.

The literature does not provide standards for this ratio, so the enterprise should monitor its value over time and adapt it to the environmental conditions and economic conditions (Sierpińska, Jachna, 2007, pp. 80-88). This means the necessity to continuously monitor the most mature current liabilities, so that they can be settled with the use of cash and short-term financial assets (Brigham, Houston, 2005, p. 108).

Another variable that has been considered to be an important ratio of the financial liquidity strategy is the **level of net working capital**, also known as **working capital** (Wysłocka, 2008, pp. 127-137). Net working capital is calculated as the difference between the fixed capital and fixed assets or as the difference between current assets and short-term sources of their financing (Lamberg and Vålming, 2009, p. 17). Working capital is a guarantee of financial liquidity for the enterprise in situations of delays in payments or difficulties with selling products. This capital may have the following value:

- positive – it is an indicator of a conservative liquidity strategy, which is characterised by the fact that part of the current assets is financed with fixed capital. This reduces the risk of losing financial liquidity, but – at the same time – makes it impossible to invest the employed fixed capital in more profitable fixed assets,
- zero – means that current assets are fully financed with short-term capital. Such a situation in enterprises usually occurs temporarily. The level oscillating around zero is equated with the moderate strategy,
- negative – it means that the fixed capital is not sufficient to cover the fixed assets and, therefore, the assets are – to some extent – also financed with short-term capital. In such a case, the enterprise has a high probability of losing financial liquidity, because it may not be possible to change the fixed assets to cash when short-term liabilities mature, due to their low conversion rate. This applies in particular to mining enterprises, which are often characterized by fixed assets that are difficult to sell stationary underground, e.g. coal shearer. The occurrence of negative working capital is only considered acceptable in situations, where the enterprise is able to renew its short-term liabilities on a permanent basis. This type of liquidity strategy is known as an aggressive strategy.

While the first and second situations should be considered correct, the fact that fixed assets are financed by liabilities with maturities shorter than one year may involve the risk of losing financial liquidity. This will happen when it is not possible to pay due liabilities with liquid assets. This is a particularly risky situation in the case of capital-intensive industries, such as mining, where we are dealing with high immobilisation of high-value assets, which, for the most part, are very difficult to monetise (buildings and underground engineering structures, pits, specialised mining equipment etc.).

The **subject of research** in this article are selected enterprises from the hard coal mining industry in Poland and in the world. The two largest enterprises listed on the Warsaw Stock Exchange were selected as representatives of the Polish hard coal mining industry:

- Jastrzębska Spółka Węglowa SA (JSW),
- Lubelski Węgiel “Bogdanka” SA (LWB).

An enterprise not listed on the capital market was not included in the research sample of Polish mining enterprises, due to the unavailability of financial data. Nor did the study include an enterprise that is part of a large energy concern, which could only misrepresent the analysis relating to the hard coal mining industry. Moreover, the smallest mining enterprises operating on the Polish market in the form of limited liability companies were excluded from the analysis.

For the needs of the research, for comparative purposes, the largest global mining enterprises in terms of hard coal mining were included in the research sample, with the exception of those that do not provide their basic financial data. Selected entities are listed on the world's largest stock exchanges, such as:

- New York Stock Exchange (NYSE) in New York, USA,
- Shanghai Stock Exchange (SSE) in Shanghai, China,
- Hong Kong Stock Exchange (HKSE) in Hong Kong, China,
- Australian Securities Exchange (ASX) in Sydney, Australia,
- London Stock Exchange (LSE) in London, UK,
- National Stock Exchange of India (NSE) in Mumbai, India

The selection of enterprises for this sample was governed by the principle of business homogeneity, i.e. all selected enterprises make a significant part of their revenues (over 50%) from hard coal mining. Among the selected mining enterprises, there are American, Chinese, Australian, English and Indian companies listed on the global stock exchanges. Polish and foreign enterprises being the subject of the research are listed in Table 1, in the order corresponding to the stock exchanges, on which their shares are listed. Their short characteristics are presented below, based on the websites of individual companies, www.statista.com and stock exchange reports.

Table 1: List of Polish and foreign mining enterprises surveyed

No	Name	Headquarters	Listed since	Exchange	Business area
1	Jastrzębska Spółka Węglowa SA (JSW SA)	Poland	2011	WSE Poland, Warsaw	Poland
2	Lubelski Węgiel Bogdanka SA (LWB SA)	Poland	2009	WSE Poland, Warsaw	Poland
3	CONSOL Energy	USA	1999	NYSE, USA, New York	USA
4	Peabody Energy Corp.	USA	2001	NYSE, USA, New York	China

Source: own study based on data from the financial website of yahoo.com and the market service on the Financial Times website – available on the World Wide Web: http://finance.yahoo.com/, http://www.ft.com/intl/markets.

Jastrzębska Spółka Węglowa SA was established on 1 April 1993. It is the largest producer of ortho-coke coal in the European Union, characterised by high quality parameters, which is primarily used in the production of the highest quality blast furnace coke. The company employs about 28,000 people.

Lubelski Węgiel Bogdanka S.A. is a mine extracting hard coal in the Lublin Coal Basin. The beginnings of this enterprise date back to 1975. Currently, the enterprise operates as an independent mine – joint stock company. The energy hard coal sold by the enterprise is primarily used for the production of electricity, heat and cement production. The company employs about 5,000 people.

CONSOL Energy – The company was founded in the USA in 1864. It has been operating in its present form since 1991. It extracts hard coal for the energy and metallurgical markets. It also processes steam coal for the energy industry and metallurgical coal for steel and coke producers. It employs over 9,000 people. It is regarded as one of the most modern (technologically) and safest companies in the world. In the USA, it satisfies 6.5% of the energy demand for hard coal.

Peabody Energy Corp. was founded in 1883 in St. Louis, Missouri, USA. It deals with mining, processing and sale of steam coal for power plants and metallurgical coal for industrial customers. Peabody has stakes in 30 coal mines located in the USA and Australia. It employs approximately 8,000 people.

Rio Tinto was founded in 1873 in London. The company is engaged in exploration, extraction and processing of mineral resources on a global scale. It has open-pit and underground mines, as well as refineries and processing plants. Rio Tinto extracts steam and coking coal, as well as other mineral resources, such as copper, gold, molybdenum and others. It conducts business in Australia, North and South America, Asia, Europe and South Africa. It employs over 66,000 people.

Inner Mongolia Yitai Coal was founded in 1997, with its headquarters in China, manufactures, transports and sells hard coal and fuel products. The coal extracted by the company is marketed under the Yitai brand name. Its annual production is about 35 million tonnes of coal. The company mainly operates on the domestic market. It employs over 6,000 people.

Yanzhou Coal Mining, with its headquarters in China, extracts, processes and sells steam and coking coal in China, Japan, South Korea and Australia. Coal is extracted in 6 mines. The company employs nearly 40,000 people. **China Coal Energy** was founded in 1999. It is an enterprise extracting hard coal in China. The enterprise has 17 active hard coal mines and 29 mines under construction. The company employs over 40,000 people.

Shenhua is the second largest coal mining company in the world. It was founded in 1995 and mining is carried out in China. It employs around 150,000 people and has 30 active hard.

New Hope Corporation was founded in 1904. Its main activity is hard coal mining, but its activities also include the extraction of oil and natural gas. Its hard coal mining operations are mainly located in Australia, but it also mines in Chile, Taiwan, China and Korea. It employs over 42,000 people

Whitehaven Coal Ltd – founded in 1999, with its headquarters in Australia. It has both open-pit and underground hard coal mines. Its extraction activities are mainly conducted in Australia. It employs around 5,000 people

Anglo American Coal was founded in 1917 in Johannesburg and reorganised in 1999 as Anglo American plc., with its headquarters in London. The enterprise extracts mineral resources, including hard coal, conducting operations all over the world. Hard coal is mainly extracted in Australia and South Africa. The enterprise employs around 100,000 people.

Coal India, founded in 1975, is the largest coal mining company in the world. It employs over 357,000 people, owns 470 mines, of which 164 are open-pit, 275 underground and 31 mixed. The company for – the most part – mines in India, but has a subsidiary in Mozambique.

Results

The first step to identify the financial liquidity strategies of the surveyed mining enterprises was the calculation of three liquidity ratios. Table 2 presents the level of the first one, i.e. the current ratio.

Table 2: Current ratio of Polish and foreign mining enterprises in the period 2016-2019

No.	Name	2016	2017	2018	2019
1	Jastrzębska Spółka Węglowa SA (JSW SA)	1.02	1.57	0.95	0.96

The current ratio gives a general view of financial liquidity. The optimal value of this ration should range from 1.2 to 2.0. Above this range, we are dealing with excess liquidity, which is manifested in maintaining too high levels of current assets. In the case of mining enterprises, these may be excessive amounts of hard coal inventories or high receivables. As shown in Table 1, the mining industry has no problems with excess liquidity. Only one of the surveyed enterprises, in two years of the analysed period, significantly exceeded the recommended standard for the current ratio. This being the New Hope Corporation. Most of the surveyed enterprises maintain the standards. However, in order to fully evaluate their liquidity strategies, further ratios should be taken into account. Table 3 presents the level of the quick ratio.

Table 3: Quick ratio of Polish and foreign mining enterprises in the period 2016-2019

No.	Name	2016	2017	2018	2019
1	Jastrzębska Spółka Węglowa SA (JSW SA)	0.88	1.37	0.77	0.64

13	Coal India	1.40	1.23	1.39	1.59

Source: own work.

The quick ratio shows whether enterprises are able to cover their current liabilities with assets of high liquidity, i.e. assets not including inventories. 6 out of the 13 surveyed mining enterprises have problems with maintaining liquidity. This group includes Polish enterprises, CONSOL Energy operating in the USA and Chinese enterprises: Yanzhou Coal Mining and China Coal Energy, as well as Australian Whitehaven Coal.

In the surveyed group, one can also observe a situation, in which there is excess liquidity, which may result from the excessive level of receivables and short-term investments. New Hope Corporation has a significant excess liquidity throughout most of the period. The following entities also maintain quick ratio levels above the recommended limit of 1.2: Coal India, Anglo American Coal, Shenhua (in the last two years), Peabody Energy. Periodically, there are also single cases of exceeding or not achieving the recommended levels of the standard.

The financial liquidity ratio analysis is complemented with the cash ratio. Its level in the surveyed enterprises is presented in Table 4.

Table 4: Cash ratio of Polish and foreign mining enterprises in the period 2016-2019

No.	Name	2016	2017	2018	2019
1	Jastrzębska Spółka Węglowa SA (JSW SA)	0.05	0.40	0.41	0.31
2	Lubelski Węgiel Bogdanka SA (LWB SA)	0.72	0.58	0.38	1.02
3	CONSOL Energy	0.04	0.36	0.48	0.20
4	Peabody Energy Corp.	0.86	0.81	0.93	0.75

The literature does not provide standards for this ratio. In the studied group, a large differentiation in this respect can be noticed, both in relation to the individual markets, on which the surveyed enterprises operate, and in the individual years of the studied period.

Another examined item is **net working capital,** also known as working capital. Its positive level proves that some of the so-called fixed capital (equity and long-term liabilities), after covering fixed assets, finances current assets. This is a feature of enterprises that follow a conservative funding strategy that limit their funding risk. The negative level of working capital means that part of the fixed assets is financed with short-term liabilities. It is a very risky situation from the point of view of losing financial liquidity and characterises enterprises in a financial crisis or applying an aggressive strategy aimed at minimising the cost of capital. The nature of working capital is presented in Table 5, marked with "+" for positive and with "-" for negative net working capital.

Table 5: The nature of working capital of Polish and foreign mining enterprises in the period 2016-2019

No.	Name	2016	2017	2018	2019
1	Jastrzębska Spółka Węglowa SA (JSW SA)	+	+	-	-
2	Lubelski Węgiel Bogdanka SA (LWB SA)	+	-	+	+

Source: own work.

Negative working capital predominates in the analysed period only in two mining enterprises. These are: China Coal Energy and CONSOL Energy. The ratio analysis already shows that these enterprises do not have sufficient current or quick liquidity. The liquidity strategy used in these enterprises has the characteristics of an aggressive strategy. The financial risk of these enterprises is high and carries the risk of insolvency.

The lack of a stable liquidity strategy can be observed in both Polish mining enterprises (JSW SA and LWB SA) and in Yanzhou Coal Mining. The financial liquidity ratios and the level of working capital of these enterprises are constantly fluctuating. In each year of the analysed period, the surveyed enterprises alternately have sufficient liquidity or are losing liquidity. Amid such changes, the relatively high level of cash and other liquid cash assets is noteworthy. In these enterprises (except for one year), it does not fall below 31% of the value of current liabilities.

Positive working capital can be observed in most enterprises from the hard coal mining industry. It indicates that fixed assets and part of the current assets are financed with fixed capital, i.e. equity and long-term liabilities. These enterprises try to avoid financial risks. It should be borne in mind, that mining enterprises mainly have firmly immobilised fixed assets, that are hard to turn into cash. Therefore, they cannot afford to finance it with short-term liabilities. In most cases, a conservative financial liquidity strategy is used. On the one hand, it provides current financial liquidity at an acceptable level, but on the other hand, there are higher financing costs and there may be a smaller positive financial leverage effect. As a result, the efficiency of capital use and profitability in these enterprises is lower than in entities leaning towards an aggressive strategy.

Fuhid.alanazi@student.uts.edu.au

Valerie GAY
University of Technology Sydney, Australia
Valerie.Gay@uts.edu.au

Abstract

The need to give support to patients with diabetes through the use of e-health has become increasingly necessary in recent times. This study aims to determine how e-health applications can benefit the self-management of diabetes in patients in Saudi Arabia through a systematic literature review. Barriers and solutions e-health for the self-management of diabetes are the core focus of this study. Google Scholar, JSTOR, PubMed and Research Gate were used to access articles published. Mobile-enabled and e-health applications were consistently found promising in most of the papers. The search yielded 20 usable papers, described then categorised according to the topic and direction of findings. Some barriers found in the study are; integration of patient records at the national level, training of people operating and maintaining the system, etc. The study found that cultural, religious and social practices of the societies significantly affect the effective use of e-health in the study area and everyone including parents need to be educated.

Keywords: Diabetes management, e-health, telemedicine.

Introduction

The United States National Centre for Health Statistics defines a chronic disease as any disease which lasts long, typically over three months or more (Shiel Jr, 2018). The long-term care of chronic diseases consists of multiple approaches. This makes many chronic diseases amenable to self-management. One such chronic disease is diabetes. Musaiger (2011) conducted a study in Saudi Arabia (SA) where he found that food intake and the lifestyle of people in SA has contributed greatly to one's propensity of getting the disease and exacerbating it thereafter. He noted that fast food which includes large amounts of sugar and fat, is produced in large quantities and is widely available in the country.

These findings were also supported by Naeem (2012) in the study "Increasing trend of Junk food use in Saudi Arabia and health implications". The study found that diet is a key determinant that can dictate whether an individual will suffer from diabetes or not. Naeem (2012) added that the culture specific diets determine food intake and can aid a chronic disease such as diabetes. It was however mentioned that the increase in the consumption of junk food in Saudi Arabia might be attributed to lifestyle changes owing to work, career, profession etc. Assessing the impact that e-health via self-management can have on diabetes patients is the focus of this study; the barriers, as well as the solutions of effective use of e-health, are also discussed. This study also illustrates how cultural factors play a significant role in disease management and treatment.

Diabetes

Shrivastava, Shrivastava, and Ramasamy (2013) saw diabetes or more precisely, Diabetes Mellitus (DM) as "a chronic progressive metabolic disorder characterised by hyper-glycemia mainly due to absolute (Type 1 DM) or relative (Type 2 DM) deficiency of insulin hormone. The seven essential components of self-management of diabetes include healthy eating, being physically active, monitoring of blood sugar, compliance with medications, good problem-solving skills, healthy coping skills and risk-reduction behaviours.. These were further identified by Shrivastava, Shrivastava, and Ramasamy (2013) in their study. Clearly, all these practices may not be essential for all patients at all times. Some of them may be more critical than others. These include closer monitoring of blood

sugar levels when the person already has a high level of blood sugar. To what extent the diabetes patients follow these practices and in what contexts are an important aspect.

Similarly, observations have further shown that diabetes, when not well managed, can lead to other health complications in the patients. Hence, the prevention and self-management of diabetes especially through diet change and fitness is key. Aside from diabetes, hypertension, obesity, mellitus and other coronary heart diseases could be the aftermath of poor dietary intake and a sedentary lifestyle.

e-Health

e-health may be defined in many ways. Eysenbach (2001) defined the term as, "emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies" (Eysenbach 2001:20). E-health is therefore, an online platform that provides healthcare services for people with or without offline activities. E-health remains functional regardless of the location of the patients. Boslaugh (2013) noted that secondary care centres via an online platform should be created for patients so that they can have access to some level of treatment through awareness, knowledge and self-management.

In a broader sense, e-health represents not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology. This is one of the reasons why e-health should be promoted irrespective of culture, religion, tribe and social norms. Stiffler, Cullen and Luna (2014) contend that some patients have difficulty to access e-health services because of the bias that exists in their culture and religion against e-health services and processes. Mayberry (2014) enhanced Stiffler, Cullen and Luna's (2014) argument by stating that for patients who may miss their scheduled clinical appointments, e-health via self-management,would bring about ease for both the patient and their family members catering for them. A vital concern, however, pertains to the level of access that patients may have. This would be access to technology as well as access to the ability to make use of e-health facilities.

e-Health and Self-Management of Diabetes

The relevance of self-management of diabetes in Saudi Arabia arises from the fact that it is a serious demographic threat to the country. In a recent review by Abdulaziz Al Dawish, et al. (2016), it was noted that the WHO established that Saudi Arabia tops the Middle East and is seventh in the world regarding the population affected by diabetes. Therefore, out of a population of 7 million, 3 million have been affected by diabetes. Shara (2010) further noted that the high rate of diabetes in Saudi Arabia may bear a correlation with it being one of the largest producers of red meat, carbohydrates, and sugar. This combination makes the citizens of the country have easy access to food that is detrimental to health and can increase the propensity of an individual to be diagnosed with diabetes. These studies point to the context specific reasons for the high prevalence of diabetes in the country. Understanding this context is vital as it will pave the way for culturally sensitive and suitable policies and interventions that can address this health concern.

An article by Jennifer Bell in Arab News (2019) cited Colliers International, which estimates that 17.9% of the Saudi population is currently affected by diabetes. In addition, about 35.4% of the Saudi population is obese, which is a predisposing factor for diabetes. Translated into numbers, the Saudi population in 2019 is 34.1 million and 17.9% of this will be about 6 million diabetics and 12 million obese. Thus, Saudi Arabia needs to focus on approximately 20 million of its population. The Saudi Vision 2030 has targets to increase fitness and sports participation of youth by 25%. This strategy will play a vital role in addressing and in reducing diabetes in the country as well.

In order to effectively manage their diabetes, the patients must learn to manage their diabetes on their own and without the constant need for hospital visits. The seven elements of diabetes self-management prescribed by Srivastava et al. (2013) listed above are relevant here. The usefulness of self-management in producing positive outcomes for diabetic patients in Saudi Arabia was demonstrated by AlShareef, (2017) through a survey. However, in another survey by Saad, et al. (2018) it was found that only foot care and medication self-management were practised by the majority of diabetic patients.

In line with the aforementioned, diet control, exercise and blood glucose monitoring were not being practised as a part of self-management by most of them. Since these were the factors which enhanced self-efficacy, it was low in the surveyed population. Low level of self-management practices except medication was also reported by Al Johani,

Kendall, and Snider (2015) from their survey. Jackson et al. (2014) added that for e-health and self-management to be effective and successful, there is a need for healthcare providers to create awareness among people regarding its value. In a review of research on self-management of diabetes in the Gulf Cooperation Council or GCC countries, Al Slamah, Nicholl, Alslail, and Melville (2017) mentioned three papers that argue for culturally relevant self-management practices. This may be an important factor in the case of strongly Islamic states like Saudi Arabia. As was discussed earlier, the country has specific reasons that point to a rate of diabetes among its population and so culturally specific interventions may prove to be useful.

The discussions thus far reveal that self-management practices in treating diabetes can produce positive outcomes for patients. However, compliance levels were found to below. Alsomali (2018) listed culture and religion, gender, stigma, social support, and healthcare environment and support from spouse, friends and healthcare professionals as affecting self-management of diabetes. Similar and more detailed factors at micro, meso and macro levels were identified by Alharbi (2018). Different opinions from family, friends, and colleagues have been reported as some of the factors that confuse diabetes patients regarding the use of e-health and self-management.

Considering e-health applications in self-management of diabetes, Aldahmash, Ahmed, Qadri, Thapa, and AlMuammar (2019) pointed out the ability of e-health applications to reach inaccessible and remote localities. It improves access and affordability of diabetes care through self-management. The availability of internet facilities determines accessibility in rural and remote areas. Hospital visits are kept to a minimum, as patients can seek medical advice through remote access when in need. This makes e-health for diabetes affordable and accessible. The use of cloud medical records, online patient records, computer-based health records, and electronic patient records have been noted as some of the advantages of e-health by Al Otaibi et al. (2016). The internet penetration was noted as being high in Saudi Arabia in the year 2018. However, as earlier mentioned in the study, there are limitations to access due to regional, social and religious cultural barriers and other factors. For comparison, the global access figure is 58% for 2019 (Clement, 2019). Except for Africa, Asia and Lain America/Caribbean, all other regions have over 80% internet penetration as per Internet World Stats (2019). The average for the Middle East, however, is 67%. More than 90% penetration has been reported for Bahrain, Qatar, Kuwait, Lebanon, Saudi Arabia and UAE. Thus, Saudi Arabia is well-placed when compared to many other countries in the region as well as the world. Therefore, internet access cannot be a limiting factor for e-health application for self-management of diabetes in the country.

Healthcare is treated as a "right" in Saudi Arabia. So, all the costs to the patients at the point of care are free for Saudi citizens and expatriates. However, increasing costs have forced a review of this issue. Privatisation and insurance schemes are considered to cover the costs to the government. A survey study by Al-Hanawi, Alsharqi, Almazrou, and Vaidya (2018) showed that some dissatisfaction over the quality of care, the availability of appointments, waiting times at the hospitals and the availability of medicines and other materials existed among the patients.

From the discussion so far, it is clear that diabetes and obesity are two major demographic health problems for Saudi Arabia. Self-management of diabetes by patients is a partial solution to the cost burden of both patients and the country. E-health offers scope to reduce this cost further with increased accessibility and affordability within the high internet penetration scenario of Saudi Arabia. However, there are problems and barriers at various levels for the successful implementation of e-health. These problems need to be identified and solutions found. Such solutions would benefit from being context specific and taking into consideration the cultural sensitivities of the country. This systematic review aims to identify and solve the problems of implementing e-health for self-management of diabetes in Saudi Arabia.

Methodology

The study sought to review how e-health applications can benefit the self-management of diabetes in Saudi Arabia using a systematic review. This review made use of key words such as diabetes management, e-health, telemedicine. These keywords were used to narrow down on the pool of useful and relevant articles. A total of 60 articles were obtained by searching the first five pages of Google Scholar, JSTOR, PubMed and Research Gate using articles published from the year 2005 and beyond as time frame. An additional 10 articles were obtained by cross-references. Thus 70 articles were identified. In the next step of screening 30 papers were excluded because they did not have direct relevance to the topic of the review. This step yielded 20 papers for further screening.

Inclusion Criteria

This study was carried out after the following inclusion criteria were met; i. the study identified the essential components of self-management of diabetes in Saudi Arabia, ii. The study ascertained the relevance of self-management of diabetes in Saudi Arabia, iii. The study determined the rate of increase in diabetes in Saudi Arabia, iv. the study examined the usefulness of self-management in producing positive outcomes for diabetic patients, v. the study determined the foot care and medication self-management and vi. the study further examined the healthcare problems for Saudi Arabia. Abstracts that contained useful information were also included.

Exclusion Criteria

Out of the 30 papers yielded for use in the study, 10 papers were excluded because they were not specific to Saudi Arabia or discussed e-health in more theoretical than practical manner. This filtering resulted in the final selection of 20 usable papers for this review.

Search Methods

A systematic literature search was conducted to identify articles, journals and literature about the benefit of self-management of diabetes. The search was comprehensively done through Google search engine, Google Scholar, JSTOR, PubMed, Research Gate, and several other viable tools. The topic was used as the search term to collect literature from five web pages each for three different time frames. Works in the English language were collected. These papers used are listed and briefly described below categorised in various ways to derive findings and conclusions.

Fig. 1: PRISMA diagram

Results

Mobile/smartphone

An intelligent mobile application for diabetes management and educational system for patients in Saudi Arabia with type 2 diabetes, SAED, was developed by Alotaibi, Istepanian, Sungoor, and Philip (2014). It has a patient/healthcare component and an intelligent diabetes management component. The first of these has two units, one for the patient and the other for the diabetes specialist unit. In the intelligent management system, there is a database module, intelligent decision support based on fuzzy logic, an SMS reminder module and a diabetes education module. Stored clinical data like test results, medication and other interventions, along with the decision support system, facilitates monitoring and recommending suitable interventions by clinicians as and when required. Trials to validate the system were to be undertaken. The SAED system was validated for its effectiveness in reducing HbA1C levels in a pilot trial by Alotaibi, Istepanian, and Philip (2016),. Similarly, a six-month study on the feasibility of mobile messages to control type 1 diabetes in children was conducted by Bin-Abbas, Jabbari, Al-Fares, El-Dali, and Al-Orifi (2014). This study showed a small reduction in the blood sugar glucose level. In the trial, parents of 200 children were sent daily information and weekly interaction messages were sent to the parents. The knowledge of parents about diabetes and its management improved due to this effort. Such mobile messaging serves as a useful intervention between clinical visits.

It was revealed that a high percentage of youngsters favoured the application of mobile technologies and social networking for diabetes self-management in the studies of Alanzi, Istepanian, Philip, and Sungoor (2014). Although there was no significant impact of screen size of mobile phones on the comprehension of content of diabetes related information, small screens reduced the speed of reading the contents. This finding was reported by Alghamdi, Yunus, and Househ (2013). Based on surveys and interviews, Alotaibi M. M. (2015) concluded that there is a high level of support from youngsters for the use of mobile technology for effective management and health awareness of fasting diabetes in Saudi Arabia. The study was done during Ramadan time. Thus, cultural congruence was ensured in this study. A mobile information and education system for gestational diabetes was proposed by Alotaibi and Albalawi (2018). It integrates the patient information and ongoing interventions and their outcomes with the already available information on the topic, so that continuous contextual updating happens. The framework is to be tested through randomised controlled trials on a wide scale in Saudi Arabia.

Problems and predictors of e-health or smartphone applications

The barriers associated with implementation of e-health initiatives were discussed by Almuayqil, Atkins, and Sharp (2015). Absence of systems to connect health information systems available at various levels to integrate at national level was one such barrier. Additionally, the lack of technical and computer skills to use design and use health information systems was also found. The absence of guidelines on using health information records and poor maintenance of networks and computers, slow connections and old terminals were included here. Human barriers such as negative perceptions of healthcare professionals about new technologies, a lack of trust towards computer-based solutions constituted the third barrier. Cultural barriers were also found to stand in the way of virtual contact in favour of physical contact. The possibility of medication safety due to lack of communication or miscommunication is another barrier. Communication gaps among healthcare institutions and limited use of technology to compensate for illegible prescriptions are also included in this barrier. The high cost of transferring paper records into digital records is another barrier. Security and privacy problems of the internet is a major barrier. To solve this problem, the authors proposed knowledge management and knowledge discovery. Alanzi (2018) identified the lack of mHealth expertise and human shortage, inadequacies of funding and infrastructure investments, legal, privacy standardisation and regulatory obstacles, health care organizations and bureaucracy problems, as barriers for implementing m-health for self-management of diabetes. In the same vein, inadequate functional health literacy, overall effective self-care affected by depressed mood were noted from the survey results by Almigbal, et al. (2019). However, functional health literacy was not associated with self-management. Functional health literacy was significantly influenced by age, gender, educational level, employment status and level of the depressive symptoms were significantly.

Alwin Robert, et al. (2016) noted that over the last two decades, there was a 500% increase in the expenses in healthcare and treatment of diabetes in Saudi Arabia. In 2014, out of the total health care budget of SR180 billion, about 25 billion (13.9%) was spent on diabetic care alone. To mitigate the situation, a comprehensive epidemic control program using a multidisciplinary approach needs to be stringently enforced. The authors identified the rising prevalence rate of diabetes and its pre-conditions, increasing prevalence among children and younger population, lifestyle risks, obesity and delayed diagnosis as the major challenges of implementing effective diabetes

control programmes. The same obstacles are relevant in self-management and e-health applications for self-management.

Combining the Theory of Planned Behaviour and Technology Acceptance Model, AlBar and Hoque (2018) examined the factors influencing patient acceptance of e-health services in Saudi Arabia. Perceived usefulness and perceived ease of use strongly influenced attitude towards e-health. Attitude and subjective norm highly influenced patient behavioural intention to use e-health services. On the other hand, perceived behavioural control did not affect patient behavioural intention to use e-health services. These findings may be applicable in the case of e-health applications for self-management of diabetes also. Also, Musaiger (2011) conducted a study in Saudi Arabia where he found that food intake and the lifestyle of people in SA has contributed greatly to having the disease. He noted that fast foods which include large amounts of sugar and fat products are greatly produced in the country.

Naeem (2012) on the study of "Increasing trend of Junk food use in Saudi Arabia and health implications" where it was found that diet is a key factor that can dictate if diabetes will come to stay or not. Almalki et al. (2011) noted that the reason for Saudi Arabia has a high rate of diabetes is because the country is the world's biggest extractor and transporter of oil. Shara (2010) further noted that Saudi Arabia is a large producer of red meat, carbohydrates, and sugar- making citizens have access to enough fat and oil.

E-Health Literacy Measuring

An e-health literacy scale (SeHL) was developed by Zakaria, et al. (2018) to facilitate self-management of chronic diseases like diabetes. Four key aspects of e-health literacy were identified for measurement of e-health literacy and implementation of strategies to enhance e-health literacy of chronic patients. These four were – the use of technology/media, information-seeking, usefulness and confidence. Mashi, et al. (2019) found from a survey that health literacy level was high among Saudi diabetes patients, but it was not used for effective glycaemic control. Abdullah (2018) tried to identify predictors of Saudi female diabetic patients' intention to use smartphones for self-management of diabetes. Performance expectancy, effort expectancy, social influence and patient-centred factors were tested as likely predictors. The results showed that Saudi female diabetic patients were using and intended to use smartphones in the future also for self-management of the disease. The current use of such technology by them influenced their intention for future use. Only effort expectancy was a significant predictor of intention to use smartphones in future. The use of cloud medical records, online patient records, computer-based health records, and electronic patient records have been noted as some of the advantages of e-health by Al Otaibi et al. (2016).

Education through RNs in PHCs

Asiri (2015) recognised the importance of diabetic education programmes for diabetic patients to manage their problems better to reduce complications and thereby reduce costs. PHCs can play an active role in this respect through their registered nurses. The author proposed an educational plan for PHC centres in the southern region to meet this objective of Saudi Arabia. AlShareef et al. (2017) found that self-management is a tool for producing positive outcomes for diabetic patients when well monitored via viable knowledge and content. Jackson et al. (2014) found that for e-health and self-management to be effective, healthcare providers should create awareness among people for the need to use e-health.

Social Robotics for Children

An innovative social robotics system for diabetes management and educational system for diabetic children in the Kingdom of Saudi Arabia was proposed by Alotaibi and Choudhury (2015). The system made use of Aisoy1 v5 robot applicable in mobile health technologies. The system was aimed to improve type 1 diabetes management by empowering them with relevant knowledge about diabetes and its management to create awareness among them. Similar to the social robotics system for children for diabetes management and education (Alotaibi & Choudhury, 2015), a social robotics system for obesity management for children was also proposed by Alotaibi M. (2018). A systematic review by Alotaibi M. (2017) revealed the usefulness of social robots to improve the diabetic management and awareness among Saudi children.

Knowledge Creation and Management

The knowledge creation model, Socialization, Externalisation, Combination and Internalisation (SECI) facilitates interaction of tacit and explicit knowledge by applying the four conversion modes implied in the model. Almuayqil, Atkins, and Sharp (2017) proposed a framework to support diabetic patients and healthcare professionals to enable

self-manage by patients. It has two components: data mining and the SECI model integrated suitable for this purpose.

Findings from International Studies

In their study, Öberg, Orre, Isaksson, Schimmer, Larsson, and Hörnsten (2018) explored the perceptions of Swedish nurses of using digital e-Health systems to support patient self-management. As per the authors, if nurses are to adapt to the new policies and practices that go with the digitalised development in Swedish primary healthcare, the concept of a nurse's traditional work role needs to be amended. The study highlighted the need for greater research to enable eHealth systems/services to be designed to fulfil multiple requirements. The authors recommend that digitised systems should be a tool for achieving good quality self-management support as well as for giving the primary healthcare nurses adequate resources to support patients' self-management while still maintaining the values associated with person-centred care.

Wake, He, Czesak, Mughal, and Cunningham (2016) explored the evidence for online interventions in diabetes in the context of current and ongoing developments for MyDiabetesMyWay (MDMW), a national electronic personal health record and self-management platform for diabetes patients in Scotland.

The 2017 study by Gao, Zhou, Liu, Wang and Bowers explored the features and contents of Chinese diabetes mobile applications in terms of their suitability for use by older adults with diabetes. Out of a set of 552 diabetes apps, 71 diabetes apps were randomly selected. The results of the study showed that though the usability of all tested apps was rated moderate to good, the features of most apps failed to include content areas of known importance for managing diabetes in older adults.

According to Saha, Riemenschneider, Müller, Levin-Zamir, Van den Broucke, and Schwarz, in their 2017 study, Diabetes Self-Management Education (DSME) is considered as an integral part of diabetes care. Due to this, the study aimed to carry out a comparative analysis of existing DSME programs (DSMEP) implemented in the European Union member states. Comparative analysis of the data indicated that a majority of programs are aimed at adults and only a minority at children and elderly. Only a small percentage of the programs utilise information technology for teaching and learning, and only one out of five programs pay attention to depression. The identified DSMEP aimed primarily to empower patients through increasing knowledge and changing attitudes and beliefs towards diabetes.

Some Trends

Topics of the selected papers

Some interesting trends were observable in the selected papers. A large majority of the papers dealt with mobile/smart phones applications as e-health tools. The trend of papers virtually meant that e-health means m-health. More trends on the topics of the papers are given in Table 1.

In the table below, the numbers given in the references are the item numbers in the brief description of the papers. EH-e-health, SM-smartphone/mobile. FHL-Functional Health Literacy.

Table 1: Topics dealt by the selected papers

Topic	Number	References
Mobile/smartphone	6	1,2, 3, 4, 8, 11
Problems/challenges/barriers/obstacles/factors/predictors of e-health or smartphone applications	11	5 EH, 6EH, 12SM, 13FHL, 14EH, 18SM, 19EH, 23, 24, 24, 26,
e-health literacy measuring	4	7, 16, 18, 27
Education through RNs in PHCs	3	9, 21, 22
Social robotics for children	3	10, 17, 20
Knowledge creation and management	1	15

As Table 1 shows, 6 papers dealt directly with mobile phone or smartphone as e-health tool, often termed as m-health. An additional two papers dealt with problems and challenges related to m-health. Together, out of 20 papers, 8 (40%) were m-health related. The papers are dealing with e-health mostly dealt with problems and challenges.

There were 4 such papers. Three papers dealt with functional health literacy, FHL. Out of these, two were related to its measurement and one was related to factors affecting FHL. Thus, only seven papers dealt with e-health topics. Social robotics for diabetes education of children was the subject of three papers, all led by a single author. One of these was a review. Only one paper dealt with knowledge creation and management, although as said above, three papers measured FHL, which is a product of knowledge creation and management.

Direction of Findings

Some problems affect generalisability and identifying common trends via meta-analysis of quantitative data across the papers, as discussed below. Instead, a simple method of categorising the direction of the overall findings was done in Table 2. It answers the question: Does this paper support or reject e-health applications for self-management of diabetes as an effective method to control diabetes in Saudi population.

Table 2: Direction of findings for e-health applications in Self-Management

Direction of findings	References	Number of papers
Positive	2, 3, 4, 7, 8, 9, 10, 17, 18, 19, 20	11
Negative	5, 6, 12, 13, 14, 16	6
No trend	1, 11, 15	3

From the table above, it is evident that 11 out of 20 papers are positive towards e-health as a self-management tool for diabetes and more so, with mobile/smartphone applications. Those papers that discussed the predictors came to be classified as 'positive'. Negative findings related to the challenges and barriers for e-health were also found but were outweighed by the positives. These papers focused on the problems, challenges and barriers. It may be inferred, therefore, that once these problems are sufficiently addressed, e-health has the potential to become a positive tool for self-management of diabetes. Only three papers were found to describe some aspects without fully assessing all the components of e-health and hence could not be categorised either way. These were grouped as 'No Trend' papers.

Discussion

The main finding of this review is that e-health for self-management can be implemented successfully using mobile/smart phones in Saudi Arabia. This is evident from the large number of positive findings in the study conducted. Since this paper has already discussed the high internet penetration rate in the country, it follows that problems of connectivity, especially in remote areas, and slow connections can be effectively addressed. This would mean that the majority of the diabetic population can be covered with e-health for diabetes self-management in the country. This can reduce the cost both at the patient side and the government side, ultimately leading to desisting from privatisation of health insurance for reducing cost.

Many challenges, problems and barriers of various types and at various levels (Almuayqil, Atkins, & Sharp, 2016) were identified by many papers. These challenges and problems lead to negative results of e-health applications for diabetes self-management. As long as these barriers are not addressed, the implementation of e-health for diabetes self-management will not be successful. The government and health experts need to consider how these problems and challenges can be tackled and implement the solutions while implementing e-health for diabetes self-management. This review sees the scope for future studies to be conducted on solutions rather than identifying and measuring the challenges and problems are. This is especially the case since the current papers only provide some broad recommendations about addressing the problems rather than specific ones.

The role of cultural factors, especially relevant to countries like Saudi Arabia, cannot be underestimated. Some papers advocated for culturally compatible e-health steps. This would entail matching the e-health strategies with Islamic religious rules. The paper by Alotaibi M. M. (2015) on diabetes self-management during the Ramadan fasting period touched upon this but provided no clear answer on what to do when sugar levels are beyond control during Ramadan fasting, as people tend to overeat after fasting time of the day is over. Not only Ramadan, but other religious observations also need to be researched similarly, but with the aim of finding solutions. Hence, as has been discussed in this paper already, there is a scope for context specific studies and solutions to be found. This too would provide a valuable avenue for future research.

Another crucial aspect for the successful use of e-health for diabetes self-management, is patient awareness so that the patient may be adequately equipped with all the relevant information. Knowledge creation and management of

that knowledge for applications in e-health for diabetes self-management should aim at gaining functional health literacy. Thus, the two types of papers are inter-connected. There are two ways of achieving this. One way is using the registered nurses of PHCs as was suggested by Asiri (2015) or training community workers and using them as diabetes educators. In both these cases, e-health is applied when nurses or educators provide round-the clock services through mobile applications, in addition to personal discussions.

The incidence of diabetes and obesity are increasing among the younger population including children in Saudi Arabia. This trend leads to a potential for continued high incidence of diabetes for a long time, resisting any serious attempts to control diabetes at the population level. It may be worthwhile to educate children also about diabetes and obesity and how to control them. Two papers of Alotaibi M. (2017) and Alotaibi M. (2018) deal with these aspects. However, children are often forced by their parents to overeat leading to obesity and diabetes. Therefore, simultaneous education of parents is also required. Although the author did mention this, it was not given sufficient importance in the papers, probably because the papers were about the system architecture and actual validation awaited further research.

Diabetes management of women during pregnancy and self-management of type 1 diabetes among children are two aspects on which only one paper each was seen. The need for more research on these two aspects is evident.

Limitations of this Review

The time frame sitting for the selection of papers may restrict selections. An attempt was made to address this by searching with three overlapping time frames. Using only the first five web pages of databases used may miss out papers after the fifth page. To address this, a cross-check was done beyond the 5th page to assess the number of papers not accessed. No significant problem was noted.

Many systematic reviews include meta-analyses across the quantitative data to find common trends and generalise the findings. Being a review related to a single country, meta-analysis of data across the papers might seem to be useful. However, the variety of topics within a small range of only 20 papers lead to too many variations to be accounted for and this means, when applying normal statistical procedures, many basic assumptions need to be diluted and many new assumptions to be made. Hence, meta-analysis was not attempted.

Conclusion and Future Work

The reviewed papers clearly point to mobile-enabled e-health systems for diabetes self-management as the most effective and efficient route. However, there is a need for patients to be educated through a direct approach, mobile applications and social networking through mobile phones. Internet connectivity and speed need to be improved to reach even remote locations. Other infrastructures need to be provided. Patient information scattered in different provider units at different places needs to be integrated at the national level. People involved in operating and maintaining the system need to be trained, including the nursing staff. Nurses need to learn to adapt around the change in their job descriptions due to the increasing use of e-health solutions for diabetes self-management. All the problems, challenges and barriers need to be addressed.

Future research on the problems and challenges must focus on the solutions rather than just identification of the issues and barriers. There is also a need for further research on the education of children through social robotics along with education of their parents is highlighted. Apart from Ramadan, the impact of other religious practices on adaptation of diabetes self-management needs to be researched. Two other aspects needing attention of researchers are: type 1 diabetes self-management among children and self-management of diabetes by women during pregnancy. The question to be answered may be: How smartphone enabled e-health can serve these two purposes. The study therefore, concludes that several barriers and challenges become the effective use of e-health via self-management for diabetes patients- therefore drafting functional and context specific solutions to make self-management via e-health work is key.

Post-Cloud Solutions for Power Industry Digitization

Ireneusz TOMECKI

Abstract

This article presents a revolutionary approach to the construction of IT infrastructure for such a critical sector as power industry, based on the ideas of fog computing.
Fog computing enables the power industry to store measurement data reliably and safely on a large scale. No theoretical algorithm, even the most sophisticated one, can withstand the challenge of rapid real-time analysis of large measurement data quantities. This is what fog computing used in critical infrastructure areas, such as power grids, provides, and it is currently the most promising tool. Undoubtedly, apart from a strategic discussion on the scale and depth of changes, it will be vital to carry out a number of pilot solution tests that will allow for the development of the ICT layer used in the energy sector, and to support the reached position with the analysis of current solutions. Pilot tests are currently being carried out in the Polish energy sector for applications of IT systems based on fog computing technologies. If scaling up to the entire power industry is possible, it will mean a leap forward in improving the stability and efficiency of power networks.

Keywords: cloud computing; smart grid; fog computing; resource management;

Introduction

In the power industry, both in the field of energy production and distribution, there is a growing problem with opening up to modern solutions and innovations in the ICT area. At the same time, the threat of cyber-attacks is steadily growing, becoming a major barrier to their spread. So, is this opening up even possible in the near future? Will power industry, as a particularly sensitive area, benefit from the opportunities offered by the fourth industrial revolution? This is a broader issue and concerns many sensitive areas, but it is especially magnified in energy generation and distribution fields. It affects almost all of them indirectly, as electricity is becoming the primary energy carrier in large agglomerations.

The introduction of safe solutions to the power industry will be crucial and will determine the scale and pace of change in this industry. The accelerating fourth industrial revolution is primarily about an exponential increase in the amount of processed and analysed data so that we are able to make faster and more rational business decisions. This data are the main element of modern smart grid class systems, and the procedures related to their processing, storage, transfer and security should be the primary determinant in support of the decision-making process about the use of specific technologies or an architectural model in the power industry.

Deciding on the core technology for digitization of this sector is of huge importance. Its outcome will make changing the adopted solution and introducing another one impossible for many years. This will have a major impact on the pace of change, local market simulations and, above all, the efficiency and security of critical IT infrastructure, as well as being the starting point for creating a new paradigm of building IT systems for critical infrastructure.

Current state

The energy infrastructure is characterized by a large geographical spread and a high level of heterogeneity. Its elements take years to develop and have been modernized for decades. Many of them have been monitored and even remotely controlled for a long time. The knowledge gained during this long-term process is an excellent basis for defining the objectives of future smart grid system. However, this happens at the highest, high and only partially medium voltage network levels with a low-density measurement system. Going to the next lower level, i.e. medium and low voltage, exponentially increases the number of measuring points, which already struggle with the amount of

transmitted and processed data even in the current low-density measuring system. The use of instantaneous measurements of voltage, current and power obtained from sensors at all or most of the network outlets, and collected by the system operating in real time will result in an exponential increase in the demand for IT systems and will not be possible without the use of completely new technologies. Currently existing control & measurement, and automation solutions are local and closed. They carry out a specific task in a strictly defined area. In most cases, they consist of a control & measurement or sensory layer, and a local SCADA class data aggregation system. This solution is very natural and stems from the current paradigm of IT systems building. Each element of the system is designed for one specific task and there is no sharing of resources between them. In practice, unnecessary duplication of infrastructure elements is a very common occurrence. With the current state of the infrastructure and the security system, using measurement data by two or more organizational units of an operator is very difficult. Consequently, nowadays we are dealing with a decentralized IT infrastructure with many decision-making centres which are in no way connected or correlated. This is sufficient until there is an analysis or business decision to be made based on datasets from several locations.

The reason for adopting such an infrastructure model was quite simple. Considering that these systems act as controllers, low response time to events and full local autonomy were required. These are the basic features of critical infrastructure system operation. Operational security was a determining factor in favour of local autonomy. This means that systems must operate independently and concurrently. In other words, if one stops working, the other systems will not be affected. In turn, low response times have become crucial as they allow for quick business or operational decision making. In this situation, the existing model of IT architecture has been preserved and no good solution has been found with the current state of information technology.

Post-Cloud Solutions for Power Industry.

Historically, the development of information systems has undergone cyclical changes of centralization/decentralization. It was no different in the power industry.

The first phase of energy systems development - centralization - was closely related to the level of information technology development. During this phase computers occupied entire large rooms and centralization was the only possible solution.

Phase two – decentralization - a phase of PC systems and portable computing units development, and the creation of Ethernet networks. A completely distributed model of IT systems in the power industry is created and it remains in place until now.
Phase three - centralization - is the phase of cloud computing of huge data centres and centralized IT systems. For the reasons shown above, this is the phase currently being used in the power industry in a limited way.

Phase four - decentralization - for improvement of calculation speeds and reducing the strain on communication links based on post-cloud solutions. Phase four is also a fundamental element of the fourth industrial revolution and a response to cyber-security demands.

Having the already available solutions in mind, if we know that there will be a change of trends in architecture, we should answer the following question: what should the target IT system look like and what kind of challenges does it face? Universal Internet access, widespread technology and growing automation are trends that exert a significant impact on the development of the young generation. Due to this, the operation of IT systems becomes the basis of education while simultaneously the number of specialists in other fields, such as power engineering, is decreasing. This trend will inevitably force the digitization of industrial sectors on a scale that we have not witnessed so far. Not because of the desire to progress, but through the need to improve the quality of the services provided while the expert resources dwindle. This means that aforementioned IT systems will become the basic working tool for the next generation. The time to make directional decisions as to how to prepare for this has come. The fourth industrial revolution and the introduction of 5G technology translates into millions of connected devices, computers and smartphones and, above all, machines and sensory devices that emit the data sets based on which decisions are made. The problem of IT systems will be not so much the collection of information, as its transmission and processing. The role of the next generation of employees will be reduced to that of the system operator and decision maker approving the scenarios developed by the IT systems. This will allow us to maintain an increase in service levels, for example in the energy sector. Artificial Intelligence (AI) support will also play an increasing part in the development of optimal scenarios. For this purpose, it is already necessary to consider the collection of historical data, which will serve as the basis for the development of optimal decision-making models.

Observing market trends and cycles, we can expect a rapid growth and an increase in the sensory layer, followed by the amount of stored data and the need for computing power capable of processing these resources. The current decentralized architecture is highly inadequate in the face of the upcoming scale of the problem and going further in this direction will cause an exponential increase in problems concerning the maintenance of data integrity and, above all, security. Having multiple disconnected systems forces a separate security policy for each system, which increases the risk of undesired events. Introducing master units in the form of central operators of both information and the maintenance will be sufficient, at least temporarily, however, in the long run it will carry a significant risk of hindering market development. The introduction of a central operator and a consistent data warehouse solves the previously mentioned problem of interoperability and work on data sets coming from different regions. However, it does not solve the problem of disparate security policies related to the maintenance of the entire system. Such a solution also carries performance risks. Currently, there is no computing centre in our country that would be able to collect measurement information of the entire energy sector for the predicted number of sensors and measurement systems even for low-frequency processes. Under the consideration are also scenarios introducing a centralized system based on building and self-maintaining the infrastructure in the form of large server rooms or on implementing calculation clouds located in the country and under local control. There is a strong temptation to introduce centralized solutions, however, it may enable the establishment of a vendor lock in the newly emerging smart grid market. Therefore, it has to be asked, whether these systems meet the fundamental objectives and goals that the energy industry sets for itself for the coming years, and how will they fit into the nation's public security policy if we consider the energy sector as a sector under special supervision? We can assume that large computing centres may prove sufficient for performance in the context of a digital wave, at least up to a point. However, with the current performance level of the communication infrastructure, they will not be able to perform an efficient and quick analysis due to the inability to deliver data from a large number of sensors in the time required for analysis. Therefore, they will not meet the aforementioned requirement that a modern smart grid system should support the operating process, and not only the analytical process performed afterwards. Another important aspect is the data security, which raises considerable doubts in the case of storing it on servers outside the country. In turn, the decision to create local data centres in the country will also force the construction of redundant systems, while the possibility to incur such costs in the foreseeable period is doubtful. The introduction of the central system will result in the local autonomy condition not being met. It will be necessary to introduce special operational procedures in case of destruction or failure of the central node, which raises a number of additional problems that a modern IT system supporting the work of the entire sector should not be burdened with. Thus, centralized architecture does not meet the fundamental objectives of security, scalability and interoperability that modern smart grid class infrastructure should have in the age of the fourth industrial revolution. For this very reason, the business and technical circles are debating the future of distributed systems. We bear witness to the turbulent process of adopting distributed systems based on blockchain technology, which are rapidly conquering the trading market and are a real threat to the long-standing status quo. 2017 saw the birth of the blockchain based distributed data storage market, which aims to completely abolish the monopoly of large data centres in favour of small local infrastructure providers. Currently, large financial institutions, including the largest Polish banks, are introducing this technology into their transaction systems, which additionally confirms their usefulness and guarantees further development. Such decentralization, thanks to post-cloud technologies, also opens up the market for local services, enabling local suppliers to compete openly for local customers while at the same time being part of a global system. Their major advantages will be flexibility and quick access to data for local users. Exactly the same trend is followed by a concept called fog computing, which is supposed to erase the need to build wide-area networks and large computing centres for local infrastructure providers.

Fog Computing as an Alternative to Cloud Solutions.

The conceptual model of the fog computing was already described in March 2018 by the American Institute of Standards and Technology (NIST). It defines a new architectural model, an important part of which is the distributed infrastructure layer working on local data centres and edge computers. Its task is to aggregate and process data swiftly using available, dynamically allocated resources.

The concept of fog computing perfectly meets the requirements and directions of smart grid systems development. It introduces a unified infrastructure management mechanism and eliminates maintenance problems defined at the centralized system level. It does not have a central unit, thus measuring up to the objectives of local autonomy. The concept of fog computing described by NIST precisely defines the direction in which the market will go and what expectations should be met by IT systems in the era of total digitization. Smart grid is a technological challenge which goal is to combine coherently operating IT systems and the entire energy infrastructure of both the modern automated, as well as the older ones in order to optimize energy production and distribution in a given area. That is why distributed systems are a breakthrough for Industry 4.0. The most important features are location awareness and low latency. Computing nodes belong to an extensive p2p-class network that can locate the nearest computing resources

and data warehouses. By fog computing we mean solutions characterized by minimal communication delays, with simultaneous dynamic resources allocation and lossless calculations performed on demand. The fog computing systems will process data much faster, more efficiently and ultimately cheaper than current cloud systems.
The local allocation of resources results in a drastic reduction of costs related to data storage and an equally drastic reduction of the strain on telecommunication links. Fog computing uses distributed networks (p2p), which is primarily a different model of communication based on connections, where nodes can connect with many other nodes in the network and establish communication with each other even using other nodes as intermediaries. If they are not able to establish a direct connection, the cloud computing software has a number of functionalities that enable the teaming up of distributed networks operating even without Internet access.

Another crucial feature is the dynamic allocation of resources. The main challenge of fog computing is quick adaptation to current calculation requirements and resource release when they are no longer needed. The distributed processing system contains a mechanism that allocates resources in the nearest server room and at the exact time when they are needed. Thanks to a specific data addressing system, fog computing gives the data set a unique identifier with which we query the whole network and the knowledge of the network node to which the set belongs is not required.

If we have generated the redundancy mechanism by allocating selected collections not in one, but in several nodes, then we will be able to receive them automatically from several sources at the time of reading. This approach allows us to introduce the previously described local autonomy in which the system works properly, even without access to the Internet, and provides the data continuously.

Managing extensive infrastructure of up to thousands of nodes in different locations can be difficult without the right tools to support the process. Priority is given to the implementation of the private blockchain concept serving as a distributed fog computing control & management mechanism. It is thanks to this that all resources can be controlled in complete safety without introducing the central unit.

The listed functionalities are only some of those that a well-designed fog computing solution should have. Introducing this kind of consistent environment into the power industry will make it possible to build a scalable IT system and a structure independent of external suppliers. Solutions already available on the market should be used as additional data warehouses and computing units that are not critical to the capacity and security of the whole system.

Emil MUSAT

The Bucharest University of Economic Studies, Bucharest, Romania, emilmusat@yahoo.com

Abstract:

For a better understanding on how projects implemented by Local action Groups can contribute to the development of Romanian rural areas, one should start from analyzing the interest shown in submitting projects on sustainable development of rural areas.
The present paper analyzes how those local communities from Calarasi, which through the territorial administrative unit are members of a LAG, have responded effectively to local development strategies and measures proposed by them for rural development by modernizing localities, investments in agricultural and non-agriculture activities, supporting entrepreneurship and farmers young generation, as well as through social and cultural investments.
By examining the Local Development Strategies and their evaluation, the proposed measures and the submitted projects, it can be seen that, the most interested in accessing the available funds are the public beneficiaries, who submit projects aimed at ensuring public comfort and public safety, ensuring the conditions for recreational activities or improving local social services. If we are to talk about private beneficiaries, it can be highlighted that they have submitted projects late, especially in the agricultural field, and the number of projects is significantly smaller than that of public beneficiaries is at least reluctant.
The most accessed areas have been stimulating the development and modernization of localities, followed by the promotion and young farmers support, and also investments in agricultural activities.
Main causes for the smaller number of projects submitted by potential private beneficiaries are represented by the lack of knowledge for drafting projects and obtaining the necessary approvals, but also fear of consuming resources without completing the process with the conclusion of a contract.

Keywords: Local Action Groups, Impact, Local Development Strategies.

Introduction

Local action groups are practically set up as an interface between the community and the public financier, and through their activity they have the mission to ensure the transposition of the community's needs in projects of the widest possible interest. Although the whole process of establishing the need for intervention is, according to the characteristics of the LEADER program, from the bottom up, theoretically assuming local population active participation in planning and making decisions for implementing the local development strategy, the funded projects practically do not solve the economic problems of the area, these projects being more a tool to increase citizens' confidence in the idea of European Union.

Through LAG practically is being realized the perception that the local public administration has the possibility to decide on the distribution of money from the European Union, approaching in this way, at least at the level of perception, two essential components: the local community and the European Union. This does not mean that the money allocated to the projects carried out through the LAG has the aim of ensuring the perception of the population and increasing confidence in European structures, this is a subsidiary effect, the main effect being the project implementation`s result, achievement of proposed result indicators but to some measure also growth of rural areas quality life.

Cite this Article as: Rares-Alexandru IONESCU and Emil MUSAT " The Addressability and Impact of Projects Submitted and Financed Through Local Action Groups Between 2014 And 2020 - Case Study Calarasi County" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

However, in order to understand how the implementation of the Local Development Strategy, developed at the level of Local Action Groups, can influence the development of the Romanian village, it is important that, before analyzing the results, to proceed to an analysis of interest shown by potential beneficiaries to actively participate in the process of rural community development, with projects that meet both their needs and the community`s.

In order to observe the behavior of the actors in the activity of generating local development, the specific activity of the three LAGs operating in Calarasi County (Baraganul de Sud-Est, Colinele Argeșului and Valea Mostiștei) was analyzed. The evaluation process of the implementation of the local development strategy found that in the middle of the strategic period for implementing the measures proposed for the development of areas covered by LAGs the project submission process is unsatisfactory, which led to an intensification of contacts of LAG partners with various categories of target audience in order to increase the number of submitted projects. This effort has largely borne fruit, ensuring that the measures proposed for the development of the rural area are covered by projects. Despite all the efforts made by LAG`s representatives, the number of private beneficiaries who submitted projects remained under expectations. The public beneficiaries, having either specialized staff or greater opportunities to access consulting services, have mobilized much better and managed to submit projects to cover not only the measures proposed by local development strategies but even to cover a very wide range of community needs. Establishing the context in which this activity completed with the submission of projects took place will be a useful tool to better understand the effects of the implementation of each local rural development strategy.

Literature Review

The literature review provides many materials that develop the subject of ensuring the sustainable development of rural areas through the LEADER program. The history, characteristics and advantages of the LEADER program as well as the establishment and operation of LAGs as its beneficiaries are widely discussed.

One approach that needs to be considered is that according to which this program is based on a model of economic development of rural areas called Community-*led Theory of Rural Development* which, however, in oder to generate sustainable economic development in rural areas requires the existence of community capacity to function efficiently on the basis of self-help (Albu and Chițu, 2014). We consider that in this context, in which Romanian villages are aging due to the migration of young people to urban areas and many of the Territorial Administrative Units have serious budgetary problems, the concept of self-help can only refer to identifying rural areas most pressing problems , as well as identifying those issues that underlie the emergence of new community issues. It could also refer to the wise selection of projects that are to be funded.

In a critical approach on how communities act in order to generate their own development, starting from the "Community-led Theory of Rural Development", I.J. Terluin (2001) concludes that, from this point of view, many regions and rural communities face genuine difficulties in generating economic development, largely due to insufficient capacity to solve economic problems, an inadequate institutional environment and a lack of political responsibilities (Albu and Chitu, 2014). It is unanimously acknowledged that there is a strong link between the way institutions work and the development of the community / society. Behind any economic success story, there are always efficient institutions. The same goes for regional development, which, in addition to efficient institutions, needs a solid administrative background and a decentralized decision-making procedure. Romania is characterized by institutional weakening and limited administrative capacity, despite the implementation of concrete steps towards decentralization (Mosora and Mosora M.H., 2012).

In theory, there are also approaches that challenge the LAG's ability to play its role of involvement in the decision to generate local community development, thus "in a scenario where it should promote direct contact and cooperation between subjects not only with commercial interests, LAGs, on the other hand, seem to be able to offer only a very limited participation. Moreover, ordinary citizens could not exert any real influence on LAGs " (Belligiano and Salento, 2017). However, despite all the critics, it is undeniable that this bottom-up approach, even imperfectly put into practice, proved its worth and aroused in many local actors the feeling of belonging to the rural area, determining their involvement in implementing Local Development Strategies.

At some point, LAGs were seen as the new intermediary institutions that would ensure the territory governence and support the economic development of specific areas. Due to their structure, both with public and private subjects, they were expected to promote the cohesion and strengthening of local communities (Belligiano and Salento, 2017). Although, through their activity, the LAGs have determined a change in the attitude of the administrative and business segment of the community, the idea that it could become an intermediary institution with a role in governing the territory is not current, this being impossible to achieve, at least in Romania, especially due to the legislation on territorial organization.

The LAG remains what was initially established: partnerships consisting of various representatives of the socio-economic sector from territory, representing the interests of residents and the rural community, being the engine of the LEADER Program, responsible for developing an integrated local rural development strategy and ensuring its implementation. Due to its specificity, the LEADER Program can remain relevant for a long time, but one must consider that in order to maintain the innovative feature of the Leader approach, it is important to fund actions to enhance local resources and promote local specificity (Albu and Chițu, 2014).

General overview of Local Action Groups in Calarasi county

The research was carried out on the activity of the three LAGs operating in Calarași County: Baraganul de Sud-Est, Colinele Argeșului and Valea Mostistei.
A documentation of the way in which the local development strategies were carried out was made. Official statistics and public information on the activities of the mentioned entities were used, such as the evaluation reports of the local development strategies as well as information obtained by interviewing the presidents of the 3 LAGs.

Baraganul de Sud-Est LAG - (21 public partners, 17 private partners, 9 civil society partners) comprises 21 rural localities and, according to the 2011 census, covers a population of 86,281 inhabitants. The area of the LAG is 248,835 hectares, of which the agricultural area is 210,395 hectares. LAGs territory is poorly industrialized.
Objectives proposed by the local development strategy are the followings: 1. Promoting the competitiveness of agriculture; 2. Achieving a balanced territorial development of rural economies and communities, including job creation and maintenance, and fostering the competitiveness of agriculture.
The amount allotted to finance the submitted projects is 3.873.883 euro (Baraganul of South-East LAG, 2019, SDL).

Colinele Argeșului LAG– (11 public partners, 32 private partners, 3 partners from the civil society) embraces 11 rural localities and according to the census of 2011 the population covered by the LAG is of 44,795 inhabitans. It is noticed a descending trend of the population at the census of 2002 this being of 46,716 inhabitants. Causes: the ageing of the population, the low natural growth rate, the migration of young people from the rural areas and their establishment, for economical reasons, in towns. The average population density is 64,25 inhabitants/km2. The LAG's area is of 69,719 hectares from which the agricultural area is 56,333 hectares. The LAG has also 368 hectares of non-productive areas.

Objectives proposed by the Local development strategy: 1. prompting the competitiveness of agriculture; 2. achieving a balanced territorial development of rural economies and communities including the creation and maintenance of employment.

The amount alloted to finance the submitted projects is of 1,804.218 euro.

Valea Mostiștei LAG - (16 public partners, 26 private partners, 14 partners from the civil society) embraces 16 localities, from which 15 rural localities and small town. The population covered by the LAG, according to the census of 2011 is of 57,042 inhabitants. The average population density is 45,3 inhabitants/km^2. The population dynamics highlights a decreasing starting with 2002, when almost 9% of the population was lost. Objectives proposed by the Local Development Strategy: 1. Promoting the competitiveness of agriculture; 2. Ensuring sustainable management of natural resources and combating climate change; 3. Achieving balanced local development of rural economies and communities, including the creation and employment maintenance.
The amount assigned to finance the submitted projects is of 2,441.476 euro.

It can be observed that all the three LAGs have proposed as an objective to promote competitiveness of agriculture. We consider that the investment of small amounts in agriculture it is not enough to ensure an important contribution to the development of the rural area, because, unfortunately, the impact won't even be a local one. Moreover, it can not be mentioned an impact on the development of the region of the financed projects in the agricultural domain. The modernization of agricultural holdings, either by acquisition of machinery or by building new spaces, can't assure and give the desired value for the development of the local rural area, the results limiting themselves to increasing of efficiency and profitability of the concerned holdings.

A bigger impact could have, nonetheless, the projects concerning the establishment and the sustainability of young farmers, if they were to be continued with projects aimed to ensure, in certain conditions, the development of their farms. Perhaps this way it will grow the number of small agricultural holdings with high efficiency and raised profitability, the development of the rural areas can be significantly influenced through projects financed by the LAG. We can't state that the measure comes without an impact, there is a positive one, but until now, and still further extremely limited, to a very limited number of people, namely the beneficiaries of the projects, the people in

their proximity and their contract partners. We make this statement knowing the results of other projects implemented for the development and the modernization of some agricultural holdings, which made of the implemented agriculture in Calarasi county, a performant, efficient and profitable agriculture carried out on big surfaces. However, the reality proves that the development of the agriculture does not automatically involve the development of the rural area. One possible explanation is that a small number of people own large-scale agricultural holdings, and the modernization involved the production of high-performance machinery served by qualified personnel and in smaller numbers. Another possible explanation of the low impact of small-scale investment in agriculture is that agricultural products are not subject to a process by adding value through processing in the community or in the region but are put to direct use by the holding, it has nothing to do with the community.

However, the impact of SDL deployment is ensured by the contact of as many inhabitants as possible with the final outcome of the projects.

So far, the projects with the local public authorities and various structures with public attention (cultural, religious and social welfare entities) have proved to have a great impact as beneficiaries. This is because a project, regardless the value ,it serves a wider category of inhabitants (Baragan South-East LAG, 2019, SDL Evaluation report).

Even projects carried out under the measures to support entrepreneurship, non-agricultural income-generating activities, have proved to have a greater effective impact by ensuring access to various categories of products or services for the community residents.

The status of submitted and selected projects

Baragan South-East LAG

58 projects were submitted, of which 44 were selected and 14 were not selected

Measure	Number of projects submitted	The amount value of the grant claimed-euro	The amount allotted through SDL-euro
M1/6B-Stimulating territorial development of LAG Bărăganul	20	2.006.984	2.014.677
M2/6A - Establishment and development of non-agricultural businesses in the LAG territory	6	629.674	630.242
M3/6B-Establishment, modernization or rehabilitation of worship monuments of local importance	6	297.174	300.000
M4/2B-Flat-rate support for setting up young farmers	6	240.000	240.000
M5/2A- Improving the performance of the agricultural holding on the LAG territory.	6	678.642	678.962
M6/6B- Minorities and their integration into the local Community	0	0	10.000

M1/B6 - Stimulating the development of the South-East Baragan LAG – 20 projects submitted
As in the other LAGs, the beneficiaries being public entities, the projects submitted under this measure can have the greatest effective impact felt by the inhabitants of the region. The 20 projects submitted are aimed at modernizing public lighting systems, building sports grounds, purchasing machines and equipment for voluntary emergency services, setting up a day center for older people as well as modernizing a street. The non-refundable aid requested through the projects submitted is worth 2.006.984 euro, and the measure allotted for the implementation of the projects is 2.014.677 euros.

M2/6A Establishment and development of non-agricultural business in the LAG — 6 projects submitted. Projects addressing to different areas are being submitted: building a complex of leisure activities, wood-processing pits, a center for the maintenance and repair of agricultural machinery, but also acquisition of a veterinary ambulance. The non-reimbursable aid requested is 629.674 euros and the measure allotted for implementation of the projects amount is of 630.242 euros. The beneficiaries are 5 Commercial Societies with Limited liability (SRL) and one Individual Entrepreneurship (ii).

M3/6B Establishment, modernization or rehabilitation of worship monuments of local importance-6 projects submitted. It is the only measure on the county territory within the framework of this program that aims at intervention on religious monuments of local importance. The projects submitted under this measure are aimed at rehabilitating churches as well as restoring some church paintings. The measure is allotted 300.000 euros and the non-reimbursable amount aid requested by the projects submitted is of 297.174 euros. This projects implementation can have a major impact, providing a large number of inhabitants with improved access to religious services. The beneficiaries are units of worship covered by LAG's territory.

M4/2B - Flat-rate support for setting up young farmers – 6 projects submitted. The amount allotted for the implementation of this measure is 240.000 euros and the amount of non-reimbursable aid requested by the submitted projects is 240.000 euros.

M5/2A - Improving the performance of the agricultural holding on the LAG territory-6 projects submitted. The activities proposed by the submitted projects are aimed at achieving the objectives of this measure, they mainly concern the purchase of agricultural machinery as well as to insurance the conditions under which the work is carried out on the agricultural holding by placing lighting poles. This measure is allotted to finance the projects submitted the amount of 678.962 euros, and the amount of non-reimbursable aid requested by the projects submitted is 678.642 euros.

M6/6B - Minorities and their integration into the local Community – 0 projects submitted. The measure is allotted 10.000 euros.

Valea Mostistei LAG
53 projects were submitted, of which 42 were selected and 11 were not selected

Measure	Number of projects submitted	The amount value of the grant claimed-euro	The amount allotted through SDL-euro
M1-Promotion and support of young farmers	7	230.000	190.000
M2 - Support for initiation of the entrepreneurship and of the non-agricultural income-generating activities	5	250.000	150.000
M3- Investments support in non-agricultural activities and the rural development of micro-regions	2	398.214	397.514
M4- Investments in agricultural exploitations	11	652.047	639.512
M5- Supporting the associative forms and cooperation between the local stakeholders	0	0	60.000
M6- Sustaining the development of the LEADER zone by organizing public events	1	5.231	23.836
M7 – Investments in creating a prosperous society with a high collective responsibility level	2	48.677	50.000
M8- Small scale local development	14	880.000	930.614

M1- Promoting and supporting the young farmers -7 projects submitted, from which 4 submitted by Individual Entrepreneurship (ii), 2 by Limited Liability Companies (LLC) and one by Registered Sole Trader .The amount allocated to the measure is 190.000 EUR. The amount of the non-refundable aid requested through the projects submitted in this measure is equivalent to 230.000 EUR.

M2- Support for initiating the entrepreneurship and the non –agricultural income generating activities – 5 projects submitted . This concerns a pottery creation workshop establishment ,a photo studio and acquisition of equipment and machinery. The applicants beneficiaries are 3 Limited Liability Companies (LLC) , one Individual Entrepreneurship and one Registered Sole Trader. The amount allocated to the measure is 150.000 EUR. The amount of the non-refundable aid requested through the projects submitted in this measure is equivalent to 250.000 EUR.

M3- Investments support in non-agricultural activities and the microregion rural development – 2 projects submitted. The amount of the non-refundable aid requested through the projects submitted in this measure is equivalent to 398.214 EUR. By these projects it is proposed to be acquired the equipment and to be established a leisure activities centre . The beneficiaries are LLC-s. The amount allocated to the measure for funding the projects submitted is 397.514 EUR.

M4- Investments in agricultural exploitations -11 projects submitted. The amount of the non-refundable aid requested through the projects submitted is equivalent to 652.047 EUR. By analyzing the projects , it is concluded that the investments requested in agriculture in this Local Action Group are exclusively represented by acquisition of agricultural machinery . The beneficiaries are 6 Sole Traders, 4 Limited Liability Companies and one Registered Sole Trader. The amount allocated to the measure for funding the projects submitted is equivalent to 639.512 EUR.

M5 - Supporting the associative forms and cooperation between the local stakeholders- 0 projects submitted .To this measure it is allocated the amount 60.000 EUR and until September 2020 there was no project submitted.

M6 - Supporting the development of the LEADER area by organizing public events-1 project submitted .
Within this measure, it was submitted only one project , by an NGO , which aims at keeping the Romanian traditions and folklore alive among the children and young people . The amount of the non-refundable aid requested is equivalent to 5.231 EUR. The amount allocated to the measure for funding the projects submitted is 23.836 EUR.

M7- Investments in creating a prosperous society with a high collective responsibility level-2 projects submitted. The projects submitted in this measure aims at social services provision. The amount of the non-refundable aid requested through the projects submitted is equivalent to 48.677. The amount allocated to this measure for funding the projects is 50.000 EUR.

M8- Small scale local development -14 projects submitted. This is the measure which has aroused the most interest , especially as the beneficiaries are public institutions. By this measure, it was requested carrying out the pavements and the pedestrian walkways, a bike path, some parks arrangement, some sports fields establishing and modernizing, outfitting with equipment necessary to the public services for emergency situations and the acquisition of some backhoe loaders. By what it is proposed to be carried out, this is the measure which may have the highest impact, the objectives of the projects could influence the life quality for a very large number of the region inhabitants. The amount allocated to this measure for funding the projects submitted is 930.614 EUR and the amount of the non-refundable aid requested through the projects is equivalent to 880.000 EUR.

Colinele Argesului Local Action Group

33 projects have been submitted from which 24 selected and 9 nonselected.

Measure	Number of selected projects	The amount of the non refundable aid requested - EUR	The amount allocated by SDL - EUR
M1- Modernizing the localitaties on the Local Action Group territory	13	936.000	990.000
M2- Modernizing and establishing vegetal and	6	500.609	429.386

animal farms			
M3 – Encouraging the entrepreneurship by non-agricultural investments	4	313.630	300.000
M4- Social Investments for minorities integration in local communities	1	84.795	84.832

M1- Modernizing the localities on the Local Action Group territory -13 projects submitted. In this Local Action Group this is the measure which could have the highest impact, by the number of the inhabitants who will benefit of the submitted projects implementation results. The projects submitted aim at the backhoe loaders acquisition by the town halls, rehabilitation of the public lightening, a sports field establishment as well as some town hall premises rehabilitation and endowment. The amount allocated to this measure for funding the projects submitted is 990.000 EUR and the amount of the projects which have submitted until now is equivalent to 936.000 EUR.

M2 - Modernizing and establishing vegetal and animal farms-6 projects submitted. In Colinele Argesului Local Action Group, by the projects submitted in this measure it is intended to be purchased the agricultural machinery for modernizing and establishing the agricultural exploitations. The amount allocated to this measure is 429.386 EUR and the total amount of the non –refundable aid requested by the projects submitted is equivalent to 500.609 EUR.

M3 - Encouraging the entrepreneurship by non-agricultural investments - 4 projects submitted.Within this measure, it is very important to notice that 2 from those 3 projects submitted aim at ensuring the population access to the medical services (investments in medical centers). The amount allocated to this measure for implementing the projects is equivalent to 300.000 EUR and by the projects submitted it is requested a non refundable aid equal to 316.630 EUR.

M4 - Social investments for minorities integration in local communities-1 project submitted. Within this measure there is 7 an interest in setting up a daycare center for children. The nonrefundable aid requested is equivalent to 84.795 EUR and the amount allocated to this measure for implementing the projects is equivalent to 84.832 EUR.

Conclusions

At the level of these three Local Action Groups from Calarasi county, 144 projects have been submitted , from which 110 have been selected for a possible funding and 34 project remained unselected. The economic and administrative deficiencies of the area and the people needs were the basis for finding out the measures and the amounts allocated to each measure . It was also taken into account to be selected those measures with the highest funding percentage, as it was taken into view that the financial effort upon the applicants to be as less as possible.
The most attractive measures are those aimed at localities modernization, as without the support given, most part of the members communes were not able to carry out the investments proposed by them, due to the fact that they were not able to support such investments from the local budgets and the private investors could not have the chance to develop the activities they were carrying out or to carry out other new activities.
The analysis upon the types of eligible beneficiaries show a different ability of them to prepare the projects, the public beneficiaries having an advantage because of the qualified staff employed and the possibility to employ consultancy.
Taking into account that the amount of the non –refundable aid is sensible equal to the amount allocated for the projects funding, show that the animation activity accomplished by the Local Action Groups had an important role in involving the beneficiaries to write and submit the projects. As well as taking into account that the beneficiaries are part of all the juridical organization categories , both from the public institutions and commercial companies , sole traders or registered sole traders it is an indicator that the stakeholders who could have become interested in, benefited from the necessary information. The fact that there are not more beneficiaries applicants is due to, as it results from the assessment reports , the deficit of specialty consultants and the possible beneficiaries difficulties to carry out the eligibility conditions.

Agricultural Land Lease Analysis as a Phenomenon Continuously Connected to the Social and Economic Realities of the Romanian Society

Emil MUSAT

The Bucharest University of Economic Studies, Bucharest, Romania

Abstract

The paper analyses the way and the rhythm in which the land lease regulation has evolved, in Romania, as a legal and economic operation necessary for the reintegration in the production process of agricultural land that was returned to former owners since 1991, in order to reduce the fragmentation of agricultural land and to increase size agricultural holdings, and to streamline the agricultural activity after strengthening the segment of agricultural professionals. The land lease legsilation was adopted in Romania in response to the need to organize the agricultural activity and the land market in the context of the agrarian reform started in 1991.
By researching of the initiatives to amend the law, of the reasons invoked and of the parliamentary debates, are highlighted, at some point, the needs of the business environment represented by the land lessee, of the landowners as lessors, as well as how the legislature manages to respond to them and to keep the land lease continuously connected to the realities of the Romanian society. The social interests of each moment are also reflected. This analysis is a useful tool for an in-depth understanding of the land lease operation and for understanding how this economic phenomenon impacts the society as a whole. This paper represents an approach supporting the idea that the land lease must benefit from a special regulatory law.

Keywords: lease, history, law amendment.

Introduction

Since 1990 when the political, social and economic system changed in Romania, on the background of the ownership right reconstitution for the agricultural land in the extravilan of localities, many Romanians were in the position to become owners of agricultural land.

In fact, it was reconstituted the right of ownership over the land that had belonged to their families fifty years ago, land that had been abusively confiscated by the communist regime.

The new agricultural land owners, due to the advanced age of most of them and in the absence of specific minimum production means, could not cultivate the land, thus being removed from the production process. Given the very high sense of ownership of Romanians, especially the elderly, to ensure the reintegration of agricultural land in the production process, but also due to the lack of an adequate legal framework, the sale of agricultural land was not an agreed option, so the best option for achieving this, in the absence of a specific legal regulation, was land leasing to natural or legal persons who had the production means necessary for the land exploitation for economic efficiency. However, as there was no legal regulation in this regard either, amid skepticism by the new owners and the lack of private professionals in the field of agriculture, most of the land remained uncultivated. For example, we present the following situation:

	Agricultural area - hectares	The cultivated area with the major crops -hectares	Grain production	Wheat production
1990	14.769.028	9.402.113	17.173.539	7.289.344
1991	14.798.278	9.127.291	19.306.621	5.473.156
1992	14.790.125	8.909.111	12.288.452	3.206.382

Source: National Institute of Statistics - TEMPO online database

As can be seen, compared to 1990, the first year after the political regime changed, although the agricultural area increased, the area cultivated with the principal crops decreased steadily in 1991 and 1992, so that in 1992 it was lower than in 1990 with almost 500,000 hectares, representing 5.2%.

In this context, in 1994, the Romanian Parliament adopted the Lease Law (Law no. 16/1994 on lease), a law that tried to put order in ensuring the introduction of agricultural land in the production process by reintroducing the land lease into the Romanian legal system, an institution that had been abolished by the communists in the 1950s on the grounds that it encouraged the exploitation of man by man (art. 1 of Decree no. 115/1959 “the partition or lease of agricultural land, as well as any other exploitation of foreign labor by agricultural producers shall be prohibited”).

The Lease Law was in force for seventeen years, during which time it underwent several changes, each change reflecting how the needs of some participants active on the land market were covered, according to each time period, but also reflecting the political, economic and social challenges of Romanian society in the period prior to Romania's accession to the European Union. Each law amendment kept the lease at the forefront of operations on the Romanian land market. Currently, unfortunately, the land lease is no longer regulated by a special law. It is regulated by the Civil Code, at art. 1836 - 1850 as a variety of the lease contract.

The current state of the topic analysis

In the specialized literature, after the adoption of Law no. 16/1994 on lease, analyzes of the law were made especially from the point of view of the legal characteristics of the lease contract, and the lease was the subject of research especially from the perspective of its quality as the main factor in increasing the size of agricultural holdings.

Through the analysis of the legal characteristics of the lease contract, it is noted that although it is a contract named, with its own legal regulations, the lease contract according to the Romanian legislation is considered a variety of the lease contract. Thus, according to the provisions of art. 2 of Law no. 16/1994 on lease, "Lease means the contract concluded between the owner, usufructuary or other legal holder of agricultural goods, called lessor, and lessee, regarding the exploitation of agricultural goods, for a determined duration and at a price established by the parties" .

As legal characters (Belu Magdo, 2012), it is noted that the land lease is a synallagmatic contract (the contract is synallagmatic when the obligations arising from it are reciprocal and interdependent. Otherwise, the contract is unilateral even if its execution implies obligations on both parties), onerous (for a fee) (the contract by which each party seeks to obtain an advantage in exchange for the obligations assumed is for a fee), commutative (the contract in which, at the moment of its conclusion, the existence of the rights and obligations of the parties is certain, and their extent is determined or determinable), with successive execution, solemn (formal) (the contract is solemn when its validity is subject to the fulfillment of some formalities provided by law), non-translatable property and intuitu personae (concluded with a certain person) (Civil Code).

The initial legal regulation of the lease contained insufficiently detailed or confusing procedures, deadlines and notions, which meant that the specialized doctrine frequently included analyzes on unclear topics, especially about the submitting term and lease registering with the local council, more precisely if this term is likely to influence the contract validity or likely to influence the opposability to third parties. As the law does not clarify the above, nor does it establish any explicit penalty for non-compliance, it remained at the court discretion to decide. The text of the law contains only a general provision, at art. 24, namely "Leases concluded in violation of the provisions of this law are void or voidable". Even this legal provision is unclear, as nullity and annulment are different sanctions.

Although the registration of the land lease contracts with the local council was the subject of amendments over time of Law no. 16/1994, it was not taken into account the provision of a normative framework that would regulate the centralization of these contracts, in order to have a more complete picture of the land lease phenomenon (Luca, 2010).

Another controversial aspect in practice and which has been the subject of multiple analyzes in the specialized doctrine, is a legal provision that establishes the obligation to use the contract model provided in the annex to the Lease Law. Thus, the question arose whether the model contract in question changed the formal requirements required ad validitatem for the land lease. More precisely, if the written form as one of the conditions of solemnity, it must be that of the contract from the annex of the Lease Law (Patrascu and Berindei, 2009). The conclusion of these analyzes in the doctrine is that although the law establishes the obligation to use it, because it does not use the term "standard contract" but uses the term "model contract", in case of non-compliance can not operate the sanction of nullity. All the more so since, from the content of the model contract it results that it refers to the lease of lands, while according to art. 1 para. 2 of Law no. 16/1994 regarding the lease, the goods that can make the object of a lease contract are „agricultural lands, namely: productive agricultural lands - arable land, vineyards, orchards, vineyards, orchards, fruit bushes, hop and nozzle plantations - forested pastures, occupied lands with agro-zootechnical constructions and installations, fisheries and land improvement facilities, technological roads, platforms and storage spaces that serve the needs of agricultural production and non-productive land that can be arranged and used for agricultural production, as well as animals, constructions of any kind, machines, machinery and other similar goods intended for agricultural exploitation".

It is necessary to specify that in the Romanian legislation it is forbidden both sublease and setting up lease offices.

Also, in order to understand the existing context in the analyzed period, it is relevant to know that, after the adoption of the Land Fund Law in 1991, there were disputes in Romanian society, between agricultural land owners and the state (Rusu et al. 2011), generated mostly by the application of the law of the land fund regarding the location or the land restitution surface.
From another perspective, the land lease is seen as a legal and economic operation necessary to increase the size of agricultural holdings in Romania, after the agrarian reform of the post-communist period. Also, in the new economic, social and legal context, the reactivation of land lease was seen as a normal economic phenomenon, normality being justified both by the historical role that land lease played in Romanian agrarian relations, but especially by the experience and by the results obtained in this segment of the land market of some developed European countries, in increasing the farms size (Popescu, 2007).

Theorists in the field of agriculture, although in the legislation no distinction is made, given that the law stipulates that the natural person lessee must have agricultural training or a certificate of agricultural knowledge or agricultural practice and the legal person lessee must be subject to activity of exploitation of agricultural goods, they noticed that in practice, depending on the economic agents that lease the land, there are several types of lease:

- lease directly to the grower; the lessor cultivates the land areas with his own forces or those of the family persons, covering in full or for the most part the necessary labor force;
- lease to a person who cultivates the land areas using payed labor force;
- lease to a producer company - association or cooperative;
- lease to a company with state capital, majority state (former IAS etc.), mixed (with foreign capital participation) or private (Popescu, 2000).

Considering all of the above, it can be seen that after the appearance of the law governing the lease, the doctrine made an analysis both from a legal point of view of the contract and from an economic point of view of the phenomenon, highlighting the legal characteristics of the contract, the precariousness of the regulation of some aspects, as well as the impact that the lease has on the local and national economy by determining the increase of the size of some agricultural exploitations.

History of the amendments to Lease Law

As a result of the changes that took place in the Romanian society, in the agriculture and in the Romanian economy, new needs of the farmers and of the owners of agricultural land and other agricultural goods appeared. In order to identify how the legislator responded to these new requirements and to understand in depth the phenomenon of land lease, an analysis of the legal regulations, of the changes brought in time to the Lease Law is necessary.

To this end, the archives containing the amendments to the law, the explanatory memoranda, the opinions of the committees and the parliamentary debates will be researched.

By comparing the draft amendments to the law with the adopted normative texts, we will try to understand to what extent the legislator managed to cover with legal norms the new needs of the participants in the land lease market.

The first amendment of the Lease Law took place in 1998, by the adoption by the Romanian Parliament of Law no. 65/1998 for amendment and completion of the Lease Law no. 16/1994. The regulations regarding land lease and other agricultural goods that were adopted by Law 16/1994 took into account the historical period in which the country was at that time and were related to the tradition of our country and the provisions of common law, respectively the Civil Code. In this respect, the rules contained in the law are of particular importance in the relations between lessees and lessors and were likely to be a real support for individuals and legal entities interested in concluding leases. At the same time, these norms constitute a legal protection for both the lessor and the lessee, parties to the lease contract (Government of Romania, explanatory memorandum, 1997).

Thus, the Government proposes the following amendments to the Lease Law:

- the possibility of sublease agricultural goods;
- the possibility of assigning the lease contract to the spouse co-participating in the exploitation of the agricultural property or his descendants who have reached the age of majority;
- extending the category of natural persons who can be leased to Romanian citizens who have regained their Romanian citizenship, regardless of whether or not they have established their domicile in the country;
- extension of the category of legal persons that can be lessee to companies with part or all foreign capital established as Romanian legal entities;
- establishing the duration of the contract by the parties, without being conditioned by a legal term;
- granting the parties full freedom to set the level of the lease;
- regulation of the transmission of the lease contract for the cause of death.

After almost a year of debates, both in the Parliament and in the specialized commissions, the amendments to the Lease Law were approved by law in March 1988, being legislated that all Romanian citizens can be leased regardless of the country where they reside, as well as companies commercial companies with part or all foreign capital constituted as Romanian legal entities, these being an important step in modernizing legal regulations in the field of land market, modernization that will continue over the coming years, thus preparing Romania's accession to the European Union. Also, by Law 65/1998 the notion of lessor was introduced, allowing the parties to determine the lease and the term of its payment, and allowed the parties full freedom to determine the duration of the lease (we consider that this regulation was not favorable to the development of investments in agriculture, tenants needing long-term security in order to be able to invest in agriculture and to benefit from the fruits of the investment made). Regarding the land sublease, it was not approved, the historical argument and the fear of introducing an intermediary in the relationship between the lessor and the lessee, winning the case in the Romanian Parliament.

Considering all the above, even if the intervention on the land fund legislation was the International Monetary Fund requirement, in a broader framework that involved the restructuring of the Romanian economy (Land Fund Law no. 18/1991, art. 1-44, Law No. 169/1997 for amending and completing Land Fund Law no. 18/1991), we can say that through the amendments to the Lease Law in 1998, the Romanian legislature responded to the need of Romanian society to start the process of integration into European structures, responded to the current needs of agricultural professionals, to improve the legal instrument used to merge agricultural land, and responded to the need of the Romanian economy and agriculture to start creating the framework needed to attract investment in agriculture.

Another amendment to the Lease Law was made by Emergency Ordinance issued by the Government in 2002, four years after the previous amendment. In the Government's explanatory memorandum, the need to adopt the proposed amendments is justified by the need to promote changes in the sense that the lessee provides some guarantees in favor of the lessor.
Thus, in addition to those already provided by law, it was necessary to establish coercive measures for non-fulfillment of contractual obligations in order to determine the lessee to perform its contractual obligations. At the same time, taking into account the climatic conditions of Romania, the law will be supplemented with provisions stipulating the introduction in the lease contract of some clauses regarding the insurance of agricultural goods (Government of Romania, explanatory memorandum, 2002).

Following this initiative, the Government Emergency Ordinance no. 157/2002 which contains, among others, the following provisions: “The parties will include in the land lease contract insurance of agricultural goods clauses, which are the responsibility of the lessee” and “Leases concluded in writing and registered with the local council constitute enforceable titles for the payment of the lease on the terms and in the manner established in the contract ”. This emergency ordinance was approved by Law no. 350/2003, with some additions that do not affect the way in which the legislator complied with the initiator's request.

By Law 65/1998, which we previously analyzed, it was established at art.3 para.2 that “the tenants, natural persons, may be Romanian citizens, regardless of whether they have their domicile in the country or abroad”. This

amendment was only an intermediate step towards another amendment of the law, which definitively established that “tenants, natural persons, may be Romanian citizens or foreign nationals” and that “tenants, legal entities, may be of Romanian or foreign nationality". The Government was the initiator of this amendment, which in the explanatory memorandum made the following clarifications: in the process of implementing the acquis communautaire, Romania has assumed a series of commitments aimed at eliminating restrictions on the right of establishment and free movement of capital for foreign natural and legal persons. One of the commitments concerns the identification and elimination from national legislation of existing restrictions on foreign nationals and companies regarding the acquisition of real estate by foreigners. Thus, it is necessary to eliminate the existing restrictions in the national legislation regarding the lease of agricultural goods by foreign citizens, stateless persons or foreign companies (Government of Romania, explanatory memorandum, 2005). There were no relevant parliamentary debates.

An amendment that provoked debates and doctrine analyzes, was that of 2006 by which a model of the land lease contract was introduced in the law, to be used in the relations between the lessor and the lessee. As we have previously mentioned the legal implications, we will further analyze the way in which this regulation appeared in the Romanian legislation, the positions of the participants in the legislative process and the implications on the land market.

Thus, the initiators of the amendment were eleven senators and deputies from the Romanian Parliament. The explanatory memorandum states that the lack of a framework contract on lease, led in practice to the drafting of incomplete contracts, which led to overcrowding of courts with disputes arising from non-compliance or misinterpretation of the clauses in leases (Chamber of Deputies, explanatory memorandum, 2005). The draft law received a favorable opinion from the Committee on Agriculture, Forestry, Food Industry and Specific Services, but received a negative opinion from the Committee on Legal Affairs, Discipline and Immunities, because it was found that through the amendments proposed by the initiators, the model contract lease becomes mandatory, so that the principle of the autonomy of the will and contractual freedom is limited.

During the parliamentary debates, it was argued that this draft law it is necessary because neither the land laws nor the Lease Law no.16 provides a framework land lease and what the initiator proposes through this law is an extraordinarily great simplification of bureaucracy, including the direct relationship between the lessor and the lessor. It is a framework lease contract with which it is much easier to solve extraordinarily complicated problems that exists and come from the lease of agricultural lands (Chamber of Deputies, 2006). Another argument made by parliamentarians refers to the need to cover a gap in the lease legislation in the sense that the adoption of a model for the land lease contract would certainly help the landlords, thus eliminating the risk of concluding incomplete contracts and, at the same time, offering the possibility of using a unitary contracting method at national level.

We note that despite the fact that neither the Government nor the Legal Committee of the Chamber of Deputies gave a positive opinion to this amendment to the Lease Law by introducing a model framework contract, Parliament adopted this amendment (Law no. 223/2006), providing to landlords an instrument to cover a wide range of rights and obligations in the contractual relations of agricultural land lease.

Conclusions

In the context of the agrarian reform started in 1991 and of the new economic and political reality, when many Romanians were in the situation of becoming owners of some agricultural lands due to the reconstitution of the property right over the agricultural lands outside the localities, on the background in Romania, the Lease Law (Law no. 16/1994) was adopted as a necessity, a law that tried to put order in ensuring the introduction of agricultural land in the production process by reintroducing it in the system of Romanian Land Lease Law.

Being a new regulation, in a social, political and economic context that Romania was going through for the first time, lease as a legal operation and as an economic phenomenon was perfected over time, under the continuous action of the Parliament, that was able to identify problems regarding the land fund and the land lease, but also under the close and constant monitoring of international bodies that knew how to intervene with government authorities to determine the adoption of legal measures to restructure the economy and, implicitly, the Romanian agriculture.

As long as the lease had an independent regulation, it was managed, by successive amendments of the law, to ensure a response to the development needs of Romanian agriculture and economy, agricultural professionals being the main beneficiaries of this situation.

For 17 years, as long as the special law regulating it was in force, the land lease managed to remain continuously connected to the social and economic realities of the Romanian society. From this perspective, we believe that the current situation of land lease regulation in the Civil Code should be rethought, as a variety of location, by returning to regulation through special law, as it was until the entry into force of the new Civil Code in 2011.

Abstract

Employees are the guarantee of the company's success and survival. Their satisfaction, which is a result of fulfilment of their internal needs, contributes to the increase of economic efficiency of the company. Moreover, their work motivation determines the readiness to take diverse actions at work. Therefore, incentive systems are more and more often implemented to increase the level of employees satisfaction and their key competences such as innovation, entrepreneurship and flexibility in the enterprises. The appropriate development of such systems stimulates the actions of employees and influences their behavior to create safe work environment. It guarantees not only the improvement of health and safety at work, but most of all the reduction of the number of accidents and increase of work comfort. In the paper, an attempt was made to assess whether demographic variables affect the differentiation of the effectiveness of the non-material motivation factor that derives satisfaction from the performed work.

Keywords: Motivation, Non-Wage Factor, Satisfaction.

Introduction

Work is an essential part of human life. The desire to improve its quality increases the number of actions the employees engage in the enterprise (Kawecka-Endler, 2004; Mazur & Marczewska-Kuźma, 2015, Mrugalska et al. 2020). Therefore, the basic task of managers is to motivate their employees to perform the task as good as possible (Kozioł, 2002). However, it has to be emphasized that it is the staff who decides about their effectiveness and efficiency (regardless of the nature of the activities) (Wyrwicka, 2011; Sterna et al. 2020). Currently, more and more employers are aware that employee satisfaction, which is influenced by the increase of job satisfaction, contributes to an increase of economic efficiency of the company (Gabryelewicz I. et al., 2017). However, it has to be underlined that satisfaction is defined as: "the degree of positive or negative well-being, performed as a result of the tasks in specific physical and social conditions" (Gros, 2003). The issue of satisfaction is present in the literature and research results related to human resource management. Regardless of the fact that motivation of employees is the subject of interest of researchers from the various fields of science, no solutions have been developed to ensure satisfaction with a job well done (Sadłowska-Wrzesińska & Nejman, 2016; Gabryelewicz I. & Sadłowska-Wrzesińska J., 2016).

The aim of this paper is to determine whether demographic variables affect the differentiation of the effectiveness of non-material motivation factor – satisfaction derived from the performed work. The research was carried out in the period 2015-2017 and referred to employees working in micro and small production family enterprises in the Greater Poland Voivodeship. In the study, quota selection was used, taking into account professional activity and employment sector as well as the demographic factors of the employees.

Motivating Employees

Motivation is an ambiguous concept which is defined as the state of human readiness to take action (Koźmiński & Piotrowski, 2002). It is expressed as: "intention, will, desire, wish, interest in something" (Bartkowiak, 1995). According to Reykowski, it is "a process of mental regulation where the direction of human activities depends on the amount of energy that a person is willing to allocate to implement a given direction. It is an internal process that determines the pursuit for specific goals ”(Reykowski, 1977). Vroom defines it as "a process of making a choice between alternative forms of voluntary behavior" (Vroom & Deci, 1992). On the other hand, Griffin believes that it is "a set of forces causing people to behave in a certain way" (Sekuła, 2008; Hitka et al., 2020). It is an internal state of a person having an attribute dimension, characteristic of each of us (Borkowska 1985; Nejman & Kawecka-Endler 2014). Three levels of motivation can be distinguished (Cox & Hoover, 2005):

- subordination, i.e. carrying out the orders of the superior, who treats employees as if they could not think and reason, did not have any talents, or were not involved in the performance of work,
- goal identification is a type of investment that stimulates the employee to achieve it, and therefore, it has a positive effect on increasing motivation,
- commitment, which occurs when employees consider the company's goals as their own and understand that a good job is also in their interest.

Different types of motivation are presented in Table 1.

Table 1: Types of motivation (www.mfiles.pl)

Types of motivation	From the point of view of the scope of impact	Inner
		Outside
	From the point of view of the form	Payroll
		Non-wage
	From the point of view of the direction of impact	Positive
		Negative
	From the point of view of the manner of impact	Individual
		Team

On the basis of the applied tools, motivation can be analyzed as tangible and/or intangible. Material motivation is considered as a process which has an impact on human behavior by income from work whereas non-material motivation uses psychological features related to the internal motivation (Listwan, 2006). In the literature, there are several models of motivational process. One of them is Steers and Porter’s model which is shown in Fig. 1.

Fig. 1: Generalized model of motivational process (Adopted from: Kozioł, et al., 2000)

The model contains three basic assumptions related to human behavior such as: the influence of certain factors, relation to the goal, and being influenced. Employees have specific needs, desires and expectations that increase to a different extent. Some employees show the need for belonging and acceptance to work in a team, for others the most important thing is to achieve higher remuneration, bonuses or promotion. As soon as the goal is achieved, the stimulus stops working (Kozioł, et al., 2000). Motives, similarly to needs, can be divided into three basic groups: primary, general and secondary. Primary motives are innate and have a physiological basis whereas general motives have no physiological background and cannot be learned. The examples of general motives are: curiosity, influencing others and emotional attachment, and help to reduce tension and lead people to increase stimulation. Secondary motives are the result of learning (i.e. the motives of power, achievement, belonging, security or status) (Sikorski, 2004).

Incentive System

Incentive system is a structured set of tools and factors motivating individuals to act in the interest of the organization. Its effectiveness can be considered from the point of view of the enterprise and the employee. When we have a look at it from the first point, the degree of the achievement of objectives will be the measure of effectiveness. However, from the employee's point of view, we will talk about the level of satisfaction and contentment, or their lack (Borkowska, 1985; Rožman et al., 2017). The exemplary model of the incentive system shows Figure 2.

Motivation factors	Task working time system	Costs	Employee participation system
- working environment (social environment, company location, technical equipment), - incentive environment (material and non-material incentives), - means of persuasion (influence of superiors, information)	- catalog of task units, - formulation of tasks (function costs, order system, objectives management, situational approach), - task settlement (quantitative and qualitative reception, expert evaluation of work results, job evaluation and review)	- total labor costs (salary, insurance premiums, employee commuting, health and safety maintenance, staff training, social activities), - total cost of ownership - value of net production sold	- exclusive decisions of employees, - co-decision of employees and management, - negotiations (wages, working conditions, social matters, personnel matters), - joint control, - consulting and giving opinions

Fig. 2. Model of incentive system (Sępek, 2010)

In order to make the incentive system work effectively, it is required to have (Pocztowski, 1998):

- high level of work organization and good technical equipment,
- proper determination of tasks for individual employee teams,
- employees planned rewards,
- innovative forms of remuneration,
- defined unambiguous criteria to obtain awards.

Performed Work and Satisfaction

Job satisfaction in the workplace is related to the ability of an employee to fulfill his needs, goals, values and beliefs (Bartkowiak, 2009). V.H. Vroom defined satisfaction as "attitude". Accordingly, in the theory of expectations, in order to be satisfied you have to meet your expectations (Vroom, 1964). It is subjective feeling to: work, working conditions, payment (Kowalska, Marcinkowska, Jośko, 2010) and represents organizational behaviors, which reflect key competences such as: innovation, flexibility, and ability to development (Juchnowicz, 2013). Generally, it is a positive feeling but as it is very subjective, a similar situation may cause satisfaction to one person but not to another. It results from many factors that have another value for different people. Satisfaction may or may not arise as a result of individual requirements, expectations, or through specific experience. The individual and differentiated evaluation of factors makes it difficult to predict which activities will prove to be satisfactory for specific employees (Mrówka, 2011). The increase of satisfaction undoubtedly contributes to the improvement of employee engagement and performance. On the other hand, its decrease may increase the risk of an increase in employee turnover and absenteeism and the number of work accidents. A decrease in job satisfaction for a certain group of employees may contribute to, for example, an increase in absences, and may even become a reason for changing the workplace (Springer, 2011).

In the development of human resource management techniques, the Vroom concept deserves attention, as he perceived employee satisfaction as a consequence of, inter alia, (Sikora, 2000):

- value of the expected reward,
- effort put into achieving the desired result,
- perception of the subjective probability of success,
- assessment of the validity of the award received,

- consistency of own goal with the goal of the organization,
- lack of excessive physical overload (work not exceeding strength),
- fair and adequate remuneration to individual aspirations,
- physical working conditions that enable the objectives to be achieved and meet the needs of the employee.

The level of employee satisfaction and motivation is the subject of many analyses since the 1990s. Their results prove the existence of a strong correlation between the level of employee satisfaction and the level of motivation. For the measurement of employee satisfaction and motivation to be fully effective, it is necessary to ensure that the research tool meets the following features (Skowron, Fojutowski, Sak-Skowron, 2011):

- allowance for the identification of motivational factors and their impact on the overall level of employee satisfaction and motivation,
- determination of the level of motivation to work and the perception of the company and its management,
- determination of the most effective incentive system adjusted to the specificity of enterprises.

Satisfaction as a Factor of Motivation in Work

Methods

The research was carried out in 2015-2017 in the Wielkopolskie voivodeship. The survey questionnaire consisted of two parts, the first (marked with the Roman number I) contained 18 questions related to the workplace, while the second part covered factors of motivation to work (marked with the Roman number II). The second part (related directly to the subject matter of this study) consisted of 34 questions in which 3 areas were distinguished: non-material motivation factors, material non-monetary motivation factors, material monetary motivation factors. The answers to questions related to motivation factors can be treated as discrete quantitative variables, assigning each answer a score on a scale of 0 to 4 points. Marked scores 3 and 4 were treated as an effective motivation factor:

0 – it does not motivate me
1 - it motivates me very poorly
2 - it motivates me moderately
3 - it motivates me
4 - very motivating.

As a result of the research, the means and standard deviations for the factors motivating to work were calculated. In order to check the significance of differences in motivational factors, the Mann-Whitney test was used for comparison in two groups and the Kruskal-Wallis test for comparison in at least three groups. Correlations between workplace opinions and motivational factors were checked using the Spearman's Severity Correlation Factor Test. The value of $p<0.05$ was assumed to be statistically significant. Statistical calculations were carried out with the statistical package STATISTICA 10 PL. The Mann-Whitney test was used to determine the differences in the position of two unrelated samples when the measurable variable is described at least on an orderly scale.

Results and Discussion

The respondents were employees of micro and small family production enterprises of various industries which are presented in Figure 3.

Fig. 3: Types of surveyed companies.

In the study, quota selection was used, taking into account the type of surveyed companies and the employment sector as well as the demographic factors of the employees. 449 correctly completed questionnaires were obtained. 66.8% of men and 33.2% of women participated in the research. The dominant group of the respondents were employees aged 20-30, who constituted 39.6% of the respondents. 27.2% of people represented the group of 31-40 years, and 22.7% of people aged 41-50. Only 10.5% of the respondents were over 50 years old. A significant group were people with secondary education - 46.8%. Another group of respondents with higher education - 26.9%, and 21.8% - vocational education. The remaining respondents had primary education - 4.5% of the respondents. 35.9% of the respondents declared that they had been working in the current enterprise for at least 3 years, while 26% for a year. 25.8% of people worked for no more than 1 year, and 21.6% - for over 10 years. The remaining respondents worked for 1-3 years - 16.7% of the respondents.

The use of the Kruskal-Wallis Test was to determine the differences in the position of at least three unrelated samples when the measurable variable is described at least on an ordinal scale.

The results for the work satisfaction factor were coded as II.13. and are presented in Table 2.

Table 2: Means and standard deviations of intangible factors motivating to work

Factors motivating to work - immaterial	Factor number	n	Mean	Standard deviation
Having satisfaction from the performed work	II.13	449	2.94	1.04

Table 3 shows the means and standard deviations of non-material motivators to work on the 0-4 scale and the results of the Mann-Whitney test.

Table 3: Means and standard deviations of intangible factors motivating to work

No	Gender				Mann-Whitney Test	
	Woman n=149		Man n=300			
	Mean	Standard deviation	Mean	Standard deviation	Z	P
II.13	2.97	1.03	2.92	1.05	0.53	0.5982*

** statistically significant, p <0.05*

The data in Table 3 show that for the factor of getting satisfaction from work performed, there was no statistically significant difference in the responses of women and men.

Table 4 shows the means and standard deviations of intangible motivational factors on the 0-4 scale in age groups and the results of the Kruskal-Wallis test.

Table 4: Means and standard deviations of intangible work incentives

No	Age								Kruskal-Wallis Test	
	20-30 years n=178		31-40 years n=122		41-50 years n=102		above 50 lat n=47			
	Mean	SD	Mean	SD	Mean	SD	Mean	SD	H	p
II.13	2,76	1,10	3,16	0,93	2,89	1,09	3,11	0,81	10,90	0,0123*

** statistically significant, p <0.05*

For the analyzed motivation factor, the multiple comparison test showed a significant difference between people aged 20-30 and 31-40 (p = 0.0148). The respondents aged 31-40 indicated this factor more often than those aged 20-30.

Table 5 shows the means and standard deviations of non-material motivators on the 0-4 scale in the education groups and the results of the Kruskal-Wallis test.

Table 5: Means and standard deviations of intangible work incentives

No	Education						Kruskal-Wallis Test	
	Primary and vocational n=118		secondary n=210		higher n=121			
	Mean	SD	Mean	SD	Mean	SD	H	p
II.13	2.81	1.04	2.95	1.02	3.03	1.07	4.10	0.1286*

** statistically significant, p <0.05*

The analysis of the data contained in Table 5 shows that there were slight statistically significant differences for the tested factor, but the multiple comparison test did not show any differences between the groups.

Table 6 shows the means and standard deviations of intangible work incentives.

Table 6: Means and standard deviations of intangible factors motivating to work

No	Workstation						Kruskal-Wallis Test	
	executive n=255		specialist n=127		managerial n=67			
	Mean	SD	Mean	SD	Mean	SD	H	P
II.13	2,85	1,08	3,07	0,89	2,99	1,13	3,31	0,1912

** statistically significant, p <0.05*

The analysis of the data contained in Table 6 shows that there was no statistically significant difference for the factor gaining satisfaction from the work performed. The responses of employees working in executive, specialist and managerial positions are at a similar level.

Table 7 presents the means and standard deviations of intangible motivating factors to work on the 0-4 scale in the salary groups and the results of the Kruskal-Wallis test.

Table 7: Means and standard deviations of intangible work incentives

No	Compensation						Kruskal-Wallis Test	
	Up to 2000 PLN n=182		2000-4000 PLN n=215		above 4000 PLN n=52			
	Mean	SD	Mean	SD	Mean	SD	H	P
II.13	2,76	1,08	3,07	0,95	3,02	1,15	9,65	0,0080*

statistically significant, p <0.05

As it is shown in Table 7, it can be concluded that the multiple comparison test showed a significant difference only between people earning up to 2,000 PLN and 2,000-4,000 PLN for obtaining job satisfaction (p = 0.0080).

Conclusions

The possibility of achieving satisfaction is a determinant of motivation at work. It results from the internal needs of the employee and leads to his positive behavior. For the employer, a satisfied employee is an employee more effective and committed at the same time. The feeling of satisfaction influences lower absenteeism and greater loyalty, and also determines pro-social behavior.

The specificity of production activities based on cooperation and teamwork requires specific solutions in the field of human resource management. In practice, entrepreneurs usually use traditional motivational solutions, not taking into account the diverse and often subjective needs of employees. The appropriate development of the company determines the introduction of incentive programs that stimulate the actions of employees. For this purpose, it is necessary to prepare an individual incentive system focused on the needs and expectations of employees. The most popular, however, less and less effective way to reach the potential of motivation, is financial incentives. The entrepreneur can also use non-financial motivation factors, such as the sense of job satisfaction.

It should be noted that entrepreneurs (regardless of the legal regulations in Poland, imposing the obligation to ensure safe working conditions for employees), understand more and more that the guarantee of the company's

success and survival are employees, who should be provided with safe working conditions, enabling the development of skills (training, professional development) and increased motivation.

The presented analysis was based on the research of a relatively large number of respondents with significant differentiation. Its results allow to conclude that the analyzed motivational factor has a similar effect on both women and men. The respondents between the ages of 31 and 40 indicated this factor more often than the group of younger respondents who were in their twenties. On the other hand, small statistically small differences occurred for respondents with different levels of education and the amount of remuneration.

Abstract

Clusters are the trigger for new technology through continuous involvement in an effective approach in attracting as many members as possible to streamline industrial progress. These networks aim to capitalize on resources, the effects of results, reduce costs, improve quality, innovation, productivity and thus develop the strategies of emerging economies. Also, the economic development is in a continuous process of modernization, integration of the innovative activities through their competitive advantage. The integration of innovative clusters at the economic level brings positive effects on industrialization through technological challenges, by improving the way in which smart specialization propels this industrial sector through competitiveness. Industry 4.0 is a concept that confirms these challenges for maximizing digitization through the evolution of industrial manufacturing and harnessing the capacity of new technologies. This paper aims to highlight the importance of successful implementation of this new concept of economic development, by ensuring the factors involved in achieving the objectives related to cost, time, performance, competitiveness. The study responded to cluster managers in the northwestern region of Romania with a positive correlation of technological performance variables on competitiveness, but with a more reluctant vision of implementation in certain industrial areas on changes that may cause certain staff restructuring.

Keyword: Cluster, Digital Innovation, Performance, Competitiveness.

Introduction

Economic practices and theories implemented the national and international level give clusters the role of catalysts for competitiveness through innovation and internationalization. Each region is close to a prosperous, equitable society with a competitive, efficient and modern economy. Implementation of new technologies, intense cooperation of value chains by mobilizing industrial actors towards a circular and prosperous economy. According to the European Green Deal of 2019, it shows that "the role of clusters in the implementation of European industrial policy, they catalyze strategic and structured cooperation along European value chains; supports European policy initiatives as an important tool for promoting industrial modernization at regional level; facilitate SMEs' access to global markets and strategic value chains, encourage smart specialization and strengthen cross-sectoral cooperation, facilitating structural change and the development of emerging sectors. " We can say that at the regional level, clusters have a significant role in

RADULESCU, Rita TOADER, Florina HAHN and Izabela RUS "Influence of Technological Progress on Clusters Success" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

"operationalizing smart specialization strategies", and at the national level, clusters consider: - innovative industry - smart and sustainable economic growth

- the importance of links in global value chains
- the innovative cluster - an instrument of smart economic policy

Clusters during this period of global pandemic gaps have continued to find effective solutions to the efficiency of the mobility of industrial actors in a changing society. Considered at European level as "engine of economic development", they depend on the interaction between the business environment, academia, private sector, public environment and the availability of capital resources involving risk elements to boost economic activity, microeconomic and macroeconomic area research. Through the various European approaches, the clusters become the pillars of economic development and at the same time directing financial instruments towards an empirical research of activities.

In the current competitive situations, organizations create business models, strategies based on competitive advantage, resource efficiency, increase productivity, stimulate creativity, innovation, research among all actors involved to transfer technological progress in products and services tailored to national and global economy.

The innovative cluster is a “group with legal personality, aiming to stimulate innovation, by promoting sustained interactions between its members, supporting the involvement of SMEs in research, development, innovation, and through the effective contribution to these activities, facilitating the transfer technology, know-how, expertise, networking and dissemination of information between cluster members. ” This type of cluster offers economic progress, economic value added on competitively produced at regional level.

The new European industrial strategy on digital innovation provides support and services at national, regional and local level with 3 starting pillars: green transition, global competitiveness, digital transition.

In order to become competitive, clusters in all sectors of activity must benefit from the advantages of digital transformation, relying on a network of digital innovation centers that lead to the improvement of technological processes, products, services by using these concepts on testing, support investment, training and networking in an innovative ecosystem.

Technological evolution is a constantly evolving process that offers the possibility of human resources to use skills, abilities and competencies in the labor market. The introduction of Industry 4.0 at the cluster level offers innovative solutions for the organizations of the future through intelligent, interconnected applications. The term Industry 4.0 has its origins in Germany since 2011 as a model for modernizing the industry.

"The Industry 4.0 movement is a strategic and intentional approach to shaping the future, while accessing an industrial revolution shows us what has already changed and what are the trends in industrial change." (Https://www.greensoft.ro/industria- 4-0 /).

The customer is the one who pursues a low cost, an exceptional quality and freedom in his choice.

The use of this technology offers certain advantages, of which the most relevant are represented below:

Improved efficiency - organizations have the opportunity to maintain a high quality, a degree of efficiency maintained at the highest standards, decision-making in a shorter time.

Increased productivity - occurs more and faster while allocating resource efficiency from the perspective of cost integration.

Flexibility, agility - creating the means to carry out a manufacturing operation, a diversified range, the introduction of new products on the production line, etc.
Reduced costs - initial costs of investment, but decrease in manufacturing costs due to systems integration, data management, etc.

A better customer experience - opportunities to improve services and customer experience, more efficient delivery.

Achieving a return on investment - industry benefits, potential return on investment, competitiveness for an industrialized future.

But these advantages are also offset by some disadvantages related to technology such as:
Delimited creativity - limiting the creative process through new technology, due to the multitude of automated processes that perform work tasks, reducing staff.

Increasing unemployment - reducing human resources at the level of automated organizations.

Changes in the environment - the large number of equipment and technologies incorporated in production facilities, fuel sources, with a major impact on the environment.

Internet of things security - a keen interest in covering the gaps in internet security.

Complicated tasks cannot be performed - automation technology has failed to achieve complex production, even if it offers an increase in quality.

High initial costs - significant initial investment

Requires maintenance and training - employees must be trained, specialized in various seminars to integrate knowledge in the proper operation and maintenance of equipment. (www.greensoft.ro/industria-4-0)

"The transition from automated to digitized industry occurs in all industrialized countries, but at different rates and with different expectations from country to country.

At the Romanian level, even in Germany or France - industrial companies face challenges in terms of culture, vision or digital skills in order to start the process of data collection and automation of decisions." The diversity of the forms of expression of the intellectual creation determined in a relatively short time an accentuated dynamically aiming at the economic direction.

Following a detailed analysis of the crops it can be said that they provide advantages at national level by integrating new technological approaches.

We can say that market access, providing strategic information for business, creating human resource centers, reducing transaction costs, the existence of financial resource centers, increasing productivity and competitiveness are just some of the advantages of innovative clusters. "A strong, innovative, competitive, cluster-based industry and an efficient patent system encourage the development of an innovative network at a national and European level, as they are a means of economic recovery, opportunities for collaboration in an innovative and entrepreneurial society." (Sölvell, Ö., And Williams, M., 2013).

Investing in ecosystem focused collaboration networks such as clusters improves performance and transition of their actors towards greener and more resilient.

By implementing the innovative cluster at European level, it can be seen that it has an overwhelming effect on the growth of startups by 141% and a growth of companies by 77%, which has a positive effect on the economy, on the effects of hub development. Human resources, and in particular revenue, as exemplified by the European Panorama of Clusters and Industrial Change:

- 13,5% higher average wage
- +0.7% higher annual wage growth rate
- +0.5% higher annual employment growth rate
- 143% more global frontier firms
- 77% more high-growth firms
- 141% More rapidly growing start-ups in specialised clusters than in other locations (https://www.clustercollaboration.eu)

The situation of clusters at national level

The Cluster Police Coordination Directorate as part of the Romanian industrial policy (Industrial Policies and Competitiveness Directorate) has 76 clusters, and these in turn 47 clusters are members of the Romanian Cluster Association - CLUSTERO, an association that offers good practices and models of regional development, with large-scale representation at national, European and global level of clusters in Romania. By integrating cluster management at European level by the European Secretariat for Cluster Analysis in order to certify excellence, the following were awarded:

- 3 clusters in the Gold Labe category);
- 17 clusters in the Silver Label category;
- 58 clusters in the Bronze Label category.

In terms of geographical distribution and thematic concentrations, the clusters in
Romania is brought together in the form of regional and thematic consortia, as follows:

- "Cluster Consortium from Northern Transylvania (North West Region);
- Consortium of Clusters from Transylvania (Center Region);
- Consortium of Clusters from the North East Region;
- Consortium of "Lower Danube" Clusters (South East Region);
- Wallachia Hub (South Muntenia Region);
- Consortium of Clusters from the Bucharest - Ilfov Region;
- 'Noatex', the thematic consortium of textile industry clusters;
- Thematic consortium of wood and furniture industry clusters;" (http://clustero.eu/wp-content/uploads/2020/04/situatia-clusterelor-din-romania-aprilie-2020.pdf)

All these consortia have concluded partnership agreements at regional level over the number of CLUSTERO members, being a quasi-totality at country level of the clusters.

The following is the statistical situation of the number of companies, employees, sales and exports at the end of 2019 of the North-West region of Romania.

Fig. 1: The evolution of clusters in Romania

Source: Adapted Clustero

Following the analysis of the graph on the evolution of clusters, we can see a significant increase in 2019 in the number of clusters from 233 to 2348, even employees to over 33,000, with a turnover of over 7.6 billion lei and exports of 770 billion lei , all this shows that interest in these cluster networks is growing and with benefits for regional development.

These performances were achieved through the development of business models, various tools to support the needs of catalysts, some government policies that came to meet SMEs towards better visibility at European level. All the steps of development and integration in the network of European enterprises facilitated the participation in international conferences, innovation and internationalization audits, consultancy for accessing funds, integration of business support services, increasing the value chain at regional level, presence in Horizon 2020 projects, INTERREG, through clusters and member organizations

Research Methodology

The main objective of the research was to highlight the importance of successful implementation of new technology, the concept of economic development, by ensuring the factors involved in achieving objectives related to performance, competitiveness, cost, time, human resources, and last but not least performance.

The research is based on human resources, their behavior on technological progress, the integration of skills in the cluster, based on a questionnaire that was applied to cluster managers at the national level. The criteria in which the new technologies are applied, affiliation in consortia, excellence in management, internationalization were taken into account as criteria.

Data and Methods

The managers of the cluster members are the ones who monitor the evolution of the efficiency of the relations between the cluster members and the integrated technological performances, through the allocated financial resources, time and competitiveness.

The perception of cluster managers on the importance of performance factors and technological progress are elements that lead to increased competitiveness.

At the level of the northwest region, there are 8 clusters active in the field of wood and furniture, IT sector, agri-food industry, creative industries, renewable energies and materials. A number of 7 clusters are members of the Romanian Cluster Association, being the most performing both nationally and internationally, been awarded with gold medals 3 clusters, silver medal 2 clusters and bronze medal a number of 3 clusters.

The managers within the 8 clusters provided answers based on the questionnaire applied online, appreciating the importance of the factors on the interval l-5, where for 1 we have Total Disagreement, and for 5 we have Total Agreement.

With the help of centralized data, table 1 was made in order to achieve the vector importance, size, innovation and export.

Table 1: Qualitative analysis at regional level

	Important	Sector	Size	Innovation	Export
Wood	2,84	2,62	1,05	0,88	6,56
Research	7.43	4,89	10,7	9,43	4,52
Agriculture	5,9	3,21	10,04	8,94	0,86
Renewable energy	2,63	3,73	6,99	11,03	1,67
Creative industries	7,7	2,97	11,4	11,47	1,2
Sustainable environment	3,3	2,57	13	38,66	6,39
IT	26,9	30,1	23	28,02	49,97

Source: Eurostat (2019)

Fig. 1: Cluster members of the North-West region of Romania

Source: The authors

Based on the graph above, it can be noticed that the Mobile Transilvan cluster has the most members, followed by Transilvania IT Cluster by ARIES, on the second place. The 8 clusters within the North-West region of Romania have 362 members from various industrial fields, research and development, universities, high schools, governmental organizations, various associations, which capitalize on the interconnections related to knowledge, relationships, connections, motivation to market requirements. All these members provide information, specialized training, research, education and technical support.

The next section of the questionnaire looked at how managers have a decision-making role of the factors that lead to cluster performance and increased competitiveness at the regional level.

Testing Research Hypothesis

Hypothesis H 1: The correlation between technological progress and managers' perception of cluster competitiveness is positive and significant.

Hypothesis H 2: The correlation between cluster performance factors and industry 4.0 is positive and significant.

The research is based on the hypothesis that managers, resource efficiency influence the performance of the cluster. Investing in technological progress as an independent variable with an effect on performance, we can say that the dependent variable is performance, and these values fluctuate depending on the importance of technological progress (Popa M., 2015).

The analysis of these variables shows an abstract degree of approach to the efficiency of technological progress, cluster performance, but also a visible functional degree on the appreciation values. Depending on the abstract level, the way of their operationalization will be opened, the operationalization of the efficiency of industry 4.0 can be achieved by using an appreciation scale with which the respondents' responses on the investment in cluster development are totaled.

Industry 4.0 requires cooperation at regional and national level to develop partnerships between stakeholders in the process of clustering, industrial and technological performance in accordance with the common EU position. It will also have effects on human resources, social relations, a greater motivation for improvement taking into account the links between training programs, educational facilities, the acquisition of digital skills and social cohesion.

Technological progress is quantified by increasing productivity, increasing quality, attracting a more significant number of customers, members, which leads to a yield and at the same time to the increase of profit, innovation. It leads to an evolution of technologies, clusters, managerial decisions towards the new industrialization.

Performance, functionality can have several means of assessing managers, knowing employees, through various indicators related to how to perform activities, results, and the period of their measurement in a defined time frame.

Table 2: Frequency of responses received by cluster type

Valid	Frequency	Percent	Valid Percent	Cumulative Percent
Transylvanian Cluster Furniture	51	23,39	23,39	23,39
AgroTransilvania Cluster	42	19,26	19,26	42,65
Cluj IT Cluster	35	16,05	16,05	58,5
iTech Transilvania by ARIES Cluster	49	22,47	22,47	81,17
TREC Transylvania Energy Cluster	15	6.89	6.89	88,06
Transylvanian Creative Industries	5	2,31	2,31	90,37
CLEMS	16	8,26	8,26	98,63
Romanian New Materials Cluster	2	1,37	1,37	100
Total	215	100,0	100,0	

Source: (data resulting from the analysis of the answers received with SPSS statistical program 20,00)

There is a high interest in completing the questionnaire launched online, by the managers of the furniture cluster (23.39%), the ARIES cluster (22.47%) followed by the agro cluster (19.26%), the IT cluster (16, 05%), Clems (8.26%), TREC cluster (6.89%), creative industries (2.31%), last position Romanian new materials cluster (1.37%).

Regarding the quality (position held) of the respondents within the selected organizations, it was found that the vast majority were people with management positions, either people who are part of specialized departments or hold the status of administrator, graphic representation made in Figure 2. from lower:

Fig. 2: Distribution of respondents according to the quality held within the organization
Source: (data resulting from the analysis of the answers received with the SPSS 20,00)

The vast majority hold a management position, either as director (43%) administrator (27%) or deputy director (12%), or hold other qualities within the organization, which is why we can conclude that the data collected are representative

of the study. research, because the respondents are part of the higher, hierarchical echelon of the target group, they have technical and practical knowledge about the organizational culture.

Results

The SPSS 20,000 and Microsoft Office 10 statistical data package provide statistical tools for verifying the fidelity and internal consistency of the questionnaire, the correlation between variables as well as methods for analyzing multiple linear regressions, in which several such methods are available, as follows: (Opariuc C., 2009)

To test the fidelity of the elaborated scales (5 dimensions consisting of a number of 170 items) and the internal consistency of the questionnaire, the calculation of the internal consistency coefficients Cronbach's Alpha (α) and Guttman was used, taking into account the data distribution and their nature.

After testing the internal consistency, it resulted in a total of 170 items, a total Cronbach's Alpha coefficient with the value of .832, and for the 5 main domains a value of .763 was registered, which indicates that there is a high internal consistency.

This result was predictable, because the items were selected and adapted from other survey tools (questionnaires), used with the consent of the authors of the studies mentioned in previous theoretical chapters, items that also in these questionnaires recorded individually and as a whole, high values of the Cronbach's Alpha coefficient, which confirms the reliability of the questionnaire conducted for the research study, thus providing concrete and real data and information.

The same aspects can be deduced from the analysis of the data with the help of the Guttman model, a model that proposed fidelity coefficients in a number of 5, and are the existing lower fidelity limits, which was found to record high values, coefficients that are found in table 3, as follows:

Table 3. Reliability Statistics

Lambda	1	,666
	2	,841
	3	,832
	4	,759
	5	,845
	6	,828
N of Items		5

Source: (data analyzed in the statistical program SPSS 20,000)

The first coefficient (λ1) represents a simplistic estimate of fidelity, which is the "cornerstone" for the other estimates, once again proving the existence of the fidelity of the questionnaire.

The coefficient (λ3) is the Cronbach's internal consistency coefficient, calculated for all 171 items (.841). The fourth coefficient (λ4) Guttman is the precise one, fact for which, through statistical procedures, it turned out that the use of this questionnaire, which is faithful, consistent, is viable and will generate the data expected from the research study.

From the application of the above-mentioned statistical processes, it can be concluded that the analyzed scale is faithful, the items are correlated and have a high degree of consistency, such as the existence of true fidelity.

Following the analysis of the data from Pearson analysis, it resulted that the variables are positively correlated, an aspect that can be seen in the scatterplot graphs, correlations presented in Table 4. as follows:

Table 4: Correlations

		Investing in technological progress	**The importance of the cluster**	**Effects within the cluster**	**Cluster performance**	**Investment results**
Investing in technological progress	„Pearson Correlation	1”	,721**	,411**	,521**	,526**
	Sig. (2-tailed)		,000	,000	,000	,000
	N	215	215	215	215	215
The importance of the cluster	Pearson Correlation	,721**	1	,501**	,535**	,499**
	Sig. (2-tailed)	,000		,000	,000	,000

	N”	”215”	215	215	215	215
”**. Correlation is significant at the 0.01 level (2-tailed)”						

Source: (data analyzed in the statistical program SPSS 20,000)

It is found that we are dealing with positive and significant correlations, because the significance thresholds are lower than 0.01. At the same time, the correlation is positive, aspects resulting from the sign of the correlation coefficient and from its value.

We can therefore say that there is a moderate, significant and positive correlation between the variables, namely Investing in technological progress (0.526), The importance of the cluster (0.499), Effects within the cluster (0.472) Cluster performance (550) and Investment results.

Based on the non-directional hypotheses by which the premise of analyzing the existence of a significant link between performance variables and those of increasing competitiveness was created, by analyzing the correlation coefficients, their link was analyzed by using parametric statistics.

Consequently, being calculated the Bravais-Pearson correlation coefficient, it turned out that it records the significant value of the correlation, at a significance threshold $p < 0.01$. Up to this point, we can say that the null hypothesis can be rejected and there is a positive and significant correlation between the analyzed variables.

By applying the Kendall procedure, which is based on the analysis of pairs from two ordered sets of data, normal values with a positive impact resulted, represented according to table 5, below:

Table 5: Correlations

			Investing in technological progress	The importance of the cluster	Effects within the cluster	Cluster performance	Investment results

		N”	215	215	215	215	215

Source: (data analyzed in the statistical program SPSS 20,000)

It can be seen that the variables used to register the minimum value of the correlation, namely Investing in technological progress (0.385), The importance of the cluster (0.350), Effects within the cluster (0.404), Cluster performance (0.383) and Investment results. $p < 0.01$.

And by this process, the null hypothesis are not recognized, leading to a positive link at the level of variables and the performance of the innovation cluster.

Considering that we cannot limit ourselves only to the calculation of the coefficients, we used non-parametric methods, respectively the significance threshold was calculated, which shows that the chances of obtaining errors in the analyzed sample are quite visible. To accept the meaning, the value of the hypothesis must be below 0.05.

To test the hypotheses launched to identify the importance of the coefficient of ranks ρ, we can analyze comparatively, its value with the reference, on which occasion we used the Sperman model, due to the existence of ordinal data with a different distribution than normal.

The table above shows that the significance level for all variables is less than 0.01, which indicates that there is a probability of less than 1% that the calculated correlation coefficients lead to some sampled errors.

It can be observed that the variables used to register the low value of the correlation, respectively Investing in technological progress (0.485), The importance of the cluster (0.448), Effects within the cluster (0.495), Cluster performance (0.476) and Investment results.

Following the data resulting from the application of statistical procedures, it is found that all the links between the above-mentioned variables are positive and significant p <.01.

It is also found that the most relevant correlation between two variables is between The importance of the cluster and Investing in technological progress (.666**) and the weakest correlation is between Investing in technological progress and Effects within the cluster (.440**). Given that positive and relevant data have resulted, we can say that the hypotheses launched are confirmed.

This organization chart highlights the way in which the investment in the integration of technological progress results in the performance and importance of each node formed.(Figure 3)

Following the analysis of the resumption of the number of changes in the level of clusters, which can be significant, leads to the fact that the absolute maximum deviation of the positions of each basket has a value of .ooo. These clusters have a repetition of 9, and the minimum distance between the starting centers is 4,309.

Next we can see the initial centers and the final cluster centers to which the repetition procedure was applied and the values were adjusted according to the repetition mode, leading to an increase of values for case 2 of the final situations, and for situation 1 they were decreased. (Table 7)

Conclusions

In the activity of predicting the evolution of the factors of increasing the efficiency of human capital, with the help of models based on econometric methods, we start from the hypothesis according to which the investment in human capital will continue to have, in a predictable period of time, an increasing trend, with the involvement of organizations, cluster members and related to the national and European legislative framework in force. For relevance in the

innovative framework of the organization, the analysis of the implementation of industry 4.0 subject to research is necessary to highlight the market ballistics, the actors involved in the cluster and its performance. In the current situation when the market has a more active pace than the clusters, we can notice a certain gap in terms of competition in the market.

The role of statistical-econometric methods and models is very dynamic, with a strong impact on technology and human resources, financial resources at the cluster level, an involvement of managers in this framework of performance and market competitiveness, based on professional experience. , an opening to the new information leap, to the era of robotization and openness to international partners to facilitate qualitative results and economic progress.

Regarding hypothesis 1, we can say that it is confirmed, it can be observed in their vast majority, the intersection points between the two scales, they are located within the confidence interval, presenting a direct association.

Given the issues found, we can say that there is a positive correlation between the knowledge-based economy is a trigger for investment in human capital, respectively its development within the clusters in the chosen development region.

Regarding hypothesis 2, we can state that this can also be confirmed, due to the reasonable values resulting from the parametric and non-parametric tests performed, on the data provided by the surveyed managers.

The conclusions drawn from this research study are delimited primarily by the subjectivity of human resources surveyed, there is a fairly open attitude on the part of managers, showing a high interest in participating in this research, there are some who do not pay much attention these investments.

Although, we managed to collect data from the clusters, where we meet various types of organizations, plan an attitude of superficiality, imitating the behavior adopted by managers or officials who completed the questionnaire, because, at the time of interviews, they showed a lack of interest, a quick completion of the questionnaire, in order to satisfy the researcher.

Also, organizations that have proven to be more involved in human resource development, in allocating funds for the formation of a prosperous and efficient framework, in providing logistics and know-how, will implicitly increase their notoriety through a degree of higher competitiveness among the existing members at the market level in the North-West development region of Romania.

Although due to their diversity, the activity differs within the three analyzed clusters, the main common goal is the performance of the organization, obtained both by implementing marketing strategies, personnel strategy, innovative solutions attracted by European funding, which will add value to the activity, and implicitly a higher degree of financial performance of the company.

Evolution of The Health Care System in The USA – Obama And Trump Reforms[1]

Joanna NIZNIK

Department of Finance and Financial Policy, Faculty of Economics, Finance and Law,

Krakow University of Economics, Krakow, Poland

niznikj@uek.krakow.pl

Abstract

The evolution of the American health care system observed in recent years, caused by the reform of Barack Obama and the activities related to taking up office by Donald Trump, raises questions about the impact of the introduced changes on the health care system. In order to address the research problem, the article presents the most important stages of the development of the health care concept from the USA, the construction of the system, the evolution of the system in the years 2014-2016 and indicates the key adjustments to the system brought about by the decisions of the current president. Research methods based on inductive reasoning connected with studies of the subject literature, search of the Internet resources and available databases were employed. On the basis of information included in the aforementioned sources in the theoretical part, the analysis of a theoretical and compilation character was carried out. Within the empirical part, a secondary research was carried out, including in-depth analysis of the organisation and financing of the health care in the USA, the collected material was synthesised and the most important changes taking place in the health system were pointed out. The current shape of the health system was strongly influenced by the reform called Obamacare, which imposed on residents under threat of penalties the obligation of insurance, while at the same time introducing a whole catalogue of incentives in the form of reliefs and tax exemptions. Public funding was extended by lowering income criteria of persons covered by such assistance. The support was provided for the creation of new institutions - health platforms - to facilitate the comparison of insurance offers and the purchase of insurance. For the first time, 10 types of benefits were indicated, which must be part of every health plan (including prophylactic measures) and the only criterion differentiating the amount of health care contributions was age. At the same time, insurance companies were required to conclude insurance contracts. The American health system will evolve in the direction determined by the health policies of successive presidents and parliaments. The current measures are designed to reduce the financial burden on businesses, the insured people and insurance companies, as well as on federal and state budgets, by waiving penalties for non-insurability and by eliminating subsidies provided to insurance companies for low-income individuals, which may in the future slow down the trend of increasing numbers of people having access to medical services.

Keywords: Health Care System, Obama Reform, America Health Care System.

Introduction

The United States is the country with the highest level of development in the world, which is the only one in the group of developed countries to have a health care system that does not guarantee universal access to medical services for its citizens. The reluctance to create a universal health system is usually explained by the American culture of individualism, which means that health is not treated as a right of everyone, but as a private good, which, like all other goods, can be purchased on the market. Another reason is the resistance of influential interest groups associated with the medical professions to change the existing status quo.

It does not mean, however, that the health care system is not subject to modification. The evolution of the system observed in recent years, caused by the reform of Barack Obama and the activities related to taking up office by Donald Trump, raises questions about the impact of the introduced changes on the health care system. In order to address the research problem, the article presents the most important stages of the development of the health care

concept from the USA, the construction of the system, the evolution of the system in the years 2014-2016 and indicates the key adjustments to the system brought about by the decisions of the current president.

The Health Care System Organisation

The state's regulatory activity in the field of health care organisation involves the creation of a legal framework for the functioning of entities of different organisational and legal status and defining their mutual relations. Government agencies, headed by persons appointed by the President with the consent of the Senate, play an important role. The most important institution operating at the state level is the Department of Health and Human Services (HHS), whose tasks comprise the implementation of the recommendations of the Congress and the White House regarding finance, planning, coordination, administration, regulation and access to health services. The unit has a budget of 25% of federal spending and coordinates, monitors, and finances many state and local programmes. It also collects data concerning health.

There are organisations at the state level that cooperate with federal agencies to finance, plan, administer, and provide access to health services through Medicaid institutions, mental health organisations and public hospitals. They also monitor and support environmental activities, license medical professions, and regulate the sale of health insurance.

Despite the market nature of the health system, there are four organisations in the United States that provide a large part of the population with access to health services financed in whole or in part from public funds. Two of them, Medicare and the Federal Health Programme for Government Employees (FEHBP), are of an insurance nature. The other two, Medicaid and Children's Health Insurance Programme (CHIP), which are financed from the budget, can be used only if income criteria are met.

Medicare was established in 1966 and is a health program co-financed by the federal, state and local governments. Eligible for this program are people over 65 years of age and younger persons after kidney transplantation who require dialysis and who have specific disabilities mentioned by White (2013).

Medicaid was established in 1965 and is financially supported by federal and state funds. The poor, the disabled, the elderly covered by Medicare and those on low incomes are entitled to benefit from the indicated programme noticed Migheli and Di Novi (2017). A person can be admitted to the programme if the income per household does not exceed the amount determined by a given state and is calculated in relation to the Federal Poverty Level (FPL). The range of services available through Medicaid varies from state to state. Only non-residents are not entitled to services financed by Medicaid.

The State Children's Health Insurance Programme SCHIP (since 2009 CHIP) was established in 1997 to fund health services for children up to 19 years of age, raised within the employee family on low incomes but high enough to prevent them from taking advantage of Medicaid. Most often, the income threshold providing access to the benefits is set by the US at 200% FPL. It is a federal-state programme in which the national authorities cover on average about 72% of expenditures incurred under the programme.

A programme that substantially benefits from federal funds is the Federal Government Workers' Health Programme (FEHBP), established in 1959 as a scheme for co-financing health expenditures of the civil workers in the federal sector and congressmen. 24 health plans were distinguished under the programme, 19 - nationwide in scope. The amount of insurance premium is dependent on the adopted insurance plan. The share of public funds is, on average, about 70-75% of all contributions made by employees (Federal Employees Health Benefits Program, 2017).

A substantial part of the health insurance market is owned by private providers of insurance. In this respect, two main sectors of the market can be distinguished: the employer-sponsored insurance market and the individual insurance market.

Employers conclude health insurance agreements on behalf of their employees. The relationship between employer, insurer and healthcare providers is determined by the scope, degree and potential for combining the roles of an insurer and a provider of health services. (Robinson & Steiner, 1998). The principal forms of coordinated healthcare include: Health Maintenance Organizations (HMO), Preferred Provider Organizations (PPO), Point of Service Plans (POS), High Deductible Health Plan (HDHP) and Conventional Plan (FFS)(HMO, PPO, and POS — PROS and CONS; High Deductible Health Plan (HDHP)).

Persons who are not employees and do not meet the criteria for using Medicare or Medicaid shall conclude individual health insurance agreements. This situation is so uncomfortable that the insurance costs are higher than in the case of

group insurance. It is related to higher charges resulting from administrative costs (25-40% of total costs) as well as individual estimation of health risk or significant costs of co-payment or co-insurance.
The health insurance market is highly concentrated, with several dominant entities: Anthem Inc., Aetna Inc., UnitedHealth Group Inc., Humana Inc., and Cigna Corp. Their market share in 2016 was 80% (https://www.transparencymarketresearch.com/health-insurance-market.html).

The Health System Reform - Obamacare

President Barack Obama signed The Patient Protection and Affordable Care Act - ACA - the act on the protection of the rights of patients and access to health care called the Patients' Rights Protection Act (The Patient Protection and Affordable Care Act, H. R. 3590) on 23 March 2010, allowed for the commencement of activities aimed at the implementation of health reforms changing the organisation and financing of health care to a large extent. The aim was to establish a universal health system by expanding the number of health insurance holders. Various mechanisms have been introduced to encourage or impose certain types of behaviour on health market participants, functioning from 2014 onward.

The key elements of the new concepts include the imposition of insurance obligations on citizens or residents. New institutional solutions have been introduced, which, by adapting to the income possibilities of the citizens, have allowed those who have not yet had insurance to acquire it. At the same time, income criteria allowing access to health programmes financed entirely from public funds, i.e. Medicaid and CHIP were liberalised. Through the system of financial incentives and penalties applied to individual persons and employers, the number of insured persons was additionally increased.

Thanks to the creation of two health platforms, publicly funded and administered by government or state agencies, and jointly by federal and state agencies: American Heath Benefit Exchange and Small Business Health Options Programme (SCHOP) known as 'Exchanges' – marketplaces (The Patient Protection and Affordable Care Act, H. R. 3590), persons running small and medium-sized enterprises (employing up to 100 people) and persons concluding individual contracts were covered by the healthcare insurance. Individual states were able to set up regional health platforms and allow several 'marketplaces' with different territorial coverage to operate in the same state.

Health platforms include health plans, developed exclusively by private insurance companies, with an acceptable price and quality for low-wage consumers and an appropriate range of services. The following assumptions have been made with regard to the health plans offered by 'Exchanges' according to Manchikanti at al. (2017):

• the basic scope of 10 benefits, which must be provided by all insurers (basic health care, in-patient care, emergency care, mother and child care, psychiatric care, medicines, rehabilitation, research, paediatrics, prevention), has been established,
• patient expenditure on prevention in new health plans has been discarded to stress the role of the indicated services and to reduce healthcare costs in the longer time horizon,
• health expenditure incurred by patients from their own resources during the year has been reduced,
• annual limits on health care expenditure in health schemes have been set,
• the requirements regarding the eligibility criteria concerning the appropriate network of service providers, meeting the quality-related requirements for the measurement of the quality of services provided, the use of uniform principles of patient registration and the presentation of information concerning the health insurance agreement were introduced,
• the information requirements on redress, registration, de-registration, number of rejected claims and the sharing of costs.

The health plans offered within the framework of 'marketplaces' provide access to basic health services, reducing patient expenditure from their own resources. The maximum amount of funds allocated to health insurance may not exceed the amount equivalent to the limits set forth in the *Health Savings Account* (HSA)[2]. In 2016 it was USD 6400 per person and USD 15000 USD per family (Private Health Insurance Premiums and Federal Policy, 2016). Health plans vary only in financing the healthcare costs and fall into 4 categories. The Bronze Plan covers 60% of the cost of benefits, the Silver Plan covers 70% of the cost of services, the Golden Plan covers 80% of the cost, and the Platinum Plan covers 90% of the cost of health services under the Health Plan.

The provisions of the Health Acts have created a basic health basket in which public authorities set annual benefits and annual limits on patients' share of health care costs, however, not beyond the scope of a typical health plan offered

[2] HSA is a special account to finance health expenditure owned by a natural person; the funds on this account are not subject to taxation, the limit of funds transferred to this account is set annually.

by employers. The newly created health plans within the framework of 'Exchanges' must offer services at a level not narrower than the ones in the basic health basket.

Parallel to the health plans suggested by 'marketplaces', each state has the option to create its own *Basic Health Plans* for uninsured individuals with incomes between 138% and 200% of FPL. In such a situation, health insurance agreements are concluded which give the insured the right to benefit from services of at least the same standard as the basic basket. Simultaneously, premiums cannot exceed those paid by health platforms, and the share of costs incurred by patients from their own resources cannot be higher than the expenses of a platinum plan for persons with income lower than 150% of the FPU or in other situations of the golden plan.

The changes also included insurance companies, which were obligated to conclude insurance contracts with each person, regardless of their health condition or gender. Health plans must cover benefits in the scope of at least a basic basket with prophylaxis, there is a limit of additional payments from the insured's own funds, insurers cannot limit the duration of the insurance agreement when concluding it. The only criterion differentiating the premium level is the age of the insured. In the case of family insurance, children under 26 years of age are covered by the agreement together with their parents mentioned by Béland *at al*. (2016).

The criteria for acquiring rights to use two publicly funded programmes, i.e. Medicaid and CHIP, were made less stringent. The only criterion allowing use of the first programme is an amount of income at a level not higher than 138% of the federal poverty level noticed Courtemanche *at al*. (2017). Persons who will be entitled to benefits for the first time are guaranteed health-care services of a standard not lower than specified in the basic health basket. The Federal Government shall reimburse additional costs arising from the admission of new insured persons. Between 2014 and 2016, the federal government financed 100% of expenditures, 95% in 2017, 94% in 2018, 93% in 2019, and 90% of expenditures are expected to be covered from 2020 onwards.

In the case of CHIP, individual states have a duty to maintain the existing rules for the use of the indicated programme. As of 2015, federal co-funding for the scheme has been increased. The children with no entitlement to health care due to restrictions on the annual admission limit for new insured persons introduced in some States are permitted to seek public funding through health plans offered by health platforms.

In addition to institutional solutions, the State uses financial tools that oblige society to have health insurance. Penalising is the imposition of criminal charges on those who do not comply with the aforementioned obligation. Their amount results from the comparison of two values: a fixed amount set each year or a certain amount of income per household and the selection of a higher one. A sanction is imposed on each person in the household, up to a maximum of three times the fixed amount. This means that in 2016, for example, a person without insurance was charged with a fine of USD 695 (USD 2085 per household for at least 3 persons in a family) or 2.5% of annual income, depending on whichever is higher.

Employers who work with more than 50 employees and who do not offer group insurance are penalised by a fine of USD 2160 paid for each full-time employee (excluding 30 persons from the calculation), when at least one employee receives public funding by participating in a healthcare scheme on a health platform. The same is true when employees are covered by group health insurance and one of them benefits from state-subsidised insurance. In this case, the amount of the penalty fee is set at the lower of the two possible amounts, i.e. USD 3140 USD per each person receiving a premium surcharge or 2160 USD noticed Harrington (2010) from any full-time employee. In addition, an employer providing employee health insurance, where an employee has opted for Exchanges, should finance his or her participation in the selected health plan. In such a case, the employee's income should be lower than 400% FPL and his/her participation in the health contribution should not exceed 8% or 9.8% of his/her income. The value of the funds transferred on behalf of the employee is equal to the amount by which the employer contributes to the costs of the occupational pension scheme offered by him/her. An employer who covers expenses for the purchase of insurance by an employee is not subject to a penalty fee for employee participation in a health plan on a health platform.

In order to increase the public involvement in the health insurance system, in addition to penalties, a system of incentives linked to lending health insurance premiums to encourage its payment and subsidise the costs of health insurance resulting from co-payment, own contribution and co-insurance has been created. The right to participate in 'Exchanges' is vested only in those employees whose employers offer occupational health insurance, and their participation in the contribution is so high that it exceeds 9.5% of income. In the case of acquiring health insurance by individuals and families, premiums are credited if the income of an insured person exceeds 133% of FPL and does not exceed 400% of FPL. The amount of premium subsidy is related to the lowest cost of a silver health plan offered in a given State and is determined on a floating scale, for which the contribution to insurance costs may not exceed a specified amount of individual (family) income expressed in relation to the federal poverty rate. The amount of discount depends on the ratio of income to poverty. For example, in 2015, with an income of 150% FPL, it was 4.02%

of income, 200 FPL - 6.34% of income, and between 300 and 400 FPL - 9.56% of income (Harrington, 2010, pp. 705). In order to be eligible for co-financing of other costs related to the medical service payments, it is necessary to meet the condition of subsidising the health care contribution and the income in a household should not exceed 250% FPL mentioned Harrington (2010) (The 2015 Long-Term Budget Outlook, 2015).

A mechanism of financial support for persons and families with low income level was also introduced, consisting in the provision of subsidies to insurance companies with which health insurance agreements are concluded. Public funds reimburse 70% to 94% of health insurance costs for persons with earnings between 100% FPL and 400% FPL.

Small entrepreneurs are treated differently as compared to large and medium-sized companies, i.e. entities employing up to 50 employees, as they are not under obligation to conduct group insurance. In order to encourage employers to purchase employee health programmes, the State creates opportunities to use public funds. Employers are entitled to public aid if they employ up to 25 workers and the average annual salary per employee in their workplace does not exceed USD 50, 000. When they purchase health insurance for their employees, they benefit from tax relief. An employer with up to 10 employees with an average wage per employee of less than USD 25,000 is entitled to full government subsidies for premiums paid on behalf of employees.

New solutions include the creation of a temporary reinsurance programme for employers who insure pensioners over 55 years of age, not benefiting from Medicare. The programme reimburses employers or insurers for 80% of the value of pensioners' claims between USD 15,000 and USD 90,000. Payments from the reinsurance program are intended to reduce the cost of participation of people with high health risks in the health care system.

The introduction of the reform had to involve spending certain amounts of money on its implementation and subsidising insurers and insured persons, which should be connected with increasing public financing and thus public debt. However, estimates in this respect are divergent. The first calculations referred to the amount of additional public expenditure in the amount of USD 940 billion in the first 10 years, which was to result from the increased funds for Medicaid and CHIP in the amount of USD 434 billion, tax reliefs for small businesses in the amount of USD 40 billion, the creation of 'Exchanges' in the amount of USD 358 billion and subsidising people who would not buy insurance of USD 106 billion without the indicated support. The CBO estimated the expenditure at USD 1.76 trillion. There are also calculations, which even indicate a surplus of USD 143 billion, which would be the result of increased taxation of certain entities and reduced expenses. An increase in budget revenues was assumed due to a new tax imposed on hospitals in the amount of USD 212 billion, health plans of the highest standard of USD 32 billion, medical equipment and insurance companies of USD 107 billion, and resulting from an increase in the limit of medical deductions by 10% - USD 104 billion and an increase in the tax base of USD 64 billion. In addition Amadeo (https://www.thebalance.com/cost-of-obamacare-3306050) noticed, the plans include increased savings resulting from the reduction in drug subsidy costs for the rich of USD 87 billion, lower payments to hospitals providing services to Medicaid and the uninsured of USD 37 billion and Medicare of USD 197 billion and Medicare part of USD C 135 billion, and elimination of costs resulting from servicing loans from the Sallie Mae USD 20 billion. A comparison of spending of USD 940 billion with savings of USD 567 billion and USD 477 billion gives a surplus of USD 143 billion. The only problem is that the aforementioned measures were not implemented immediately.

It is difficult to find data to assess the changes from a public expenditure perspective. The available information is only partial. Subsidies for the purchase of insurances through marketplaces increased by $23 billion in comparison with 2014 to reach the amount of USD 38 billion in 2015, before increasing by a further USD 18 million to USD 56 million in 2016. They exceeded the assumed targets by USD 11 million in 2015 and by USD 17 million in 2016 (US Health Policy Gateway). The number of people insured with Medicaid increased by 6.1 million in 2014, by 9.6 million in 2015 and by 31 million in 2016 compared to previous years. In consequence, the spending on marketplaces increased by two-thirds due to an increase in the number of health care users thanks to ACA.

In 2016, the costs related to the payment of health care contributions subsidised through federal funds through direct and indirect contributions amounted to approximately USD 300 million. It is estimated that the tax exemption of health care contributions purchased by employers cost the federal budget about 250 billion USD, whereas crediting health care contributions amounted to about 40 billion USD, and subsidies to costs of people below 250 FPL were about 8 billion USD.

Public expenditure is reduced by taxes imposed on insurers. In 2014, the insurers who did not use 'Exchanges' paid USD 8 billion, in 2015 and 2016 USD 11.3 billion each, while those on health platforms paid USD 0.4 billion, USD 0.9 billion and USD 1.4 billion respectively (Private Health Insurance Premiums and Federal Policy, 2016).

The announcements of the liquidation of Obamacare by President Donald Trump, after taking power by him in 2016, did not materialise due to the lack of parliamentary approval for the above-mentioned reorganisations. Nevertheless,

he took a number of measures to change the health system. In October 2017, he signed a decree that abolished the refunding of costs related to the reduction of insurance prices for people with low incomes to insurers (resulting from their reduced participation in the costs in the form of own contribution and co-payment) it was mention in a book of Peal, Haberman and Abelson (2017). The Tax Cuts and Job Act, enacted in December 2017, abolished tax imposed on uninsured persons, to be enforced from 2019. It is estimated that around 13 million people will give up health insurance, which will result in budget savings of USD 338 billion said Amadeo (2018). In February 2018, the United States was allowed to specify additional requirements concerning the take-up of employment by beneficiaries of Medicare, aimed at increasing employment mentioned Pear (2018). In May 2018, a draft of the American Patients First Act was presented, which aims to reduce the cost of medicines by negotiating their price between pharmaceutical companies and Medicare as well as drafting a list of medicines (American Patients First, The Trump Administration Blueprint to Lower Drug Prices and Reduce Out-of-Pocket Costs, 2018). The Trump administration seems not to have given up its efforts to amend or repeal the ACA.

Summary

Referring to the American health care system as residual does not explain the complexity of its internal design. It is formed by a network of financially and organisationally related entities of various forms of ownership. The primary source of funding is constituted by private health insurance, but public health insurance and funds from the federal, state and local budgets are equally important. They are supported by private resources of residents.

The current shape of the health system was most strongly influenced by the reform called Obamacare, which imposed on residents under threat of penalties the obligation of insurance, while at the same time introducing a whole catalogue of incentives in the form of reliefs and tax exemptions. Public funding was extended by lowering income criteria of persons covered by such assistance. The support was provided for the creation of new institutions - health platforms - to facilitate the comparison of insurance offers and the purchase of insurance. For the first time, 10 types of benefits were indicated, which must be part of every health plan (including prophylactic measures) and the only criterion differentiating the amount of health care contributions was age. At the same time, insurance companies were required to conclude insurance contracts. Limits were set for private annual expenses of patients, and health plans together with parents could be extended to persons up to 26 years of age.

The introduction of the new system is accompanied by an increase in public fund expenditures, which should be balanced with the proceeds from fines imposed on large companies which do not offer health insurance to their employees and on uninsured individuals, as well as from taxes and fees paid by insurers and pharmaceutical companies.

Before the reforms in 2010, approximately 258,4 million people (83,7%) was insured, 106,8 million people was covered by public plans, 201 million people had private health insurance coverage, 50,3% million people was uninsured[3].

In 2019, approximately 293,5 million people (92% of population) had health insurance, 114,3 million people was covered by public plans, 217,8 million people had private health insurance coverage, 29,6 million people was uninsured noticed Keisler-Starkey and Bunch (2020).

The American health system will evolve in the direction determined by the health policies of successive presidents and parliaments. The current measures are designed to reduce the financial burden on businesses, the insured people and insurance companies, as well as on federal and state budgets, by waiving penalties for non-insurability and by eliminating subsidies provided to insurance companies for low-income individuals, which may in the future slow down the trend of increasing numbers of people having access to medical services.

Inclusive Innovation Policies as a Way Towards Inclusive Growth in CEE Countries

Dorota MURZYN

Pedagogical University of Cracow, Cracow, Poland
dorota.murzyn@up.krakow.pl

Abstract

The aim of the paper is to achieve two objectives. Firstly, it examines the level of inclusive growth in CEE countries; secondly, it explores the role of inclusive innovation policies in fostering inclusive growth. From a methodological point of view, the author uses a descriptive analysis and statistical analysis. This paper contributes to theoretical debates on inclusive growth processes in CEE countries, but it also provides policy insights on the relationship between inclusive innovation policy and inclusive growth.
CEE countries differ in terms of the level of inclusive growth, with the highest being observed in Slovenia and the lowest in Romania. We can observe an increase in the level of development in each country (in the years 2008-2018), with some developing faster than others - the highest increase occurred for Latvia and the smallest for Slovakia and Hungary. There is a need for inclusive innovation policies in CEE countries, and a wide range of such policy approaches can foster inclusive growth. To achieve such growth, it is necessary to remove barriers for disadvantaged groups, laggard firms and regions to enable all segments of society to participate in and benefit from innovation. The success of inclusive innovation policies relies on the stronger involvement of target groups and often requires strong capacity-building efforts and adequate financial support.

Keywords: Inclusive innovation policy, inclusive growth, CEE countries.
JEL codes: O20, O30.

Introduction

Innovation has long been recognised as a key driver of economic growth, but recently some see it as a way to promote social inclusion (OECD 2017). First of all, social innovation (developing new ideas, services and models to better address social issues) can help achieve active inclusion by enhancing the effectiveness of services in order to maximise a positive social impact. Secondly, innovation could serve inclusive growth through a proper innovation policy. There is a new concept emerging – inclusive innovation policies, which is understood as removing barriers for disadvantaged groups (social inclusiveness), laggard firms (industrial inclusiveness) and regions (territorial inclusiveness) to enable all segments of society to participate in and benefit from innovation (Plannes-Satorra & Paunov 2017). Although considerable research has been devoted to economic growth and innovation policies, less attention has been paid to inclusive growth and inclusive innovation policies, especially in the regions of Central and Eastern Europe.

The aim of the paper is to achieve two objectives. Firstly, it examines the level of inclusive growth in CEE countries; secondly, it explores the role of inclusive innovation policies in fostering inclusive growth. The research questions are as follows: (1) What is the situation regarding inclusive growth in Central and Eastern Europe? (2) How can inclusive innovation policies influence the achievement of inclusive growth? (3) What are the challenges associated with the implementation of an inclusive innovation policy in CEE countries? From a methodological point of view, the author uses a descriptive analysis, analysis of strategic documents and statistical analysis, such as linear ordering methods (TOPSIS). The CEE region is understood according to the OECD definition, but only EU Member States were chosen for further analysis. The study covers the years 2008-2018. This paper contributes to theoretical debates on inclusive growth processes in CEE countries, but it also provides policy insights on the relationship between inclusive innovation policy and inclusive growth.

The structure of the paper proceeds as follows. First, after a short introduction to the inclusive growth concept, the level of inclusive growth of CEE countries will be assessed. In the next part, the concept of an inclusive innovation policy will be outlined together with its relations with inclusive growth. The final section summarises the core

findings, suggests directions for future research (focusing on expanding the scope of the analysis) and provides theoretical and policy implications derived from empirical results.

Inclusive growth in CEE countries

The classical approach advanced the hypothesis that inequality is beneficial for economic development in the post-industrialisation period (Kaldor 1955). This has been challenged in the past three decades, as both theories and subsequent empirical evidence have demonstrated that income distribution has a significant impact on the growth processes. Literature concerning the impact of income inequality on long-term growth is mixed (a review of multi-faceted literature on this subject is beyond the scope of this paper), but there is growing evidence that excessive inequalities have a negative impact on human capital accumulation, and this determines their inhibitory effects on economic growth. From the other side, if economic growth is not able to stop the process of stratification of the population in terms of financial standing, it cannot guarantee the implementation of such important development goals as universal access to economic benefits, reduction of the poverty and improvement of the standard of living. High inequalities also have consequences for political stability and social cohesion, which are necessary for sustainable development. Hence, reducing inequalities has become a major concern of a development policy, and a problem that has generated interest in inclusive growth (Stiglitz 2016).

One universally applicable definition of inclusive growth has not been developed so far. OECD defines it as: "economic growth that creates opportunity for all segments of the population and distributes the dividends of increased prosperity, both in monetary and non-monetary terms, fairly across society" (OECD 2014). Inclusive growth goes beyond one-dimensional GDP growth. Employment prospects, skills, educational opportunities, health, the environment and active participation in the economy and society also matter. There are two categories of inequality which are central to discussions of inclusive growth: inequality of opportunity (in access to education, jobs, finance or the judicial system) and inequality of outcomes (such as income, wealth, health and educational attainment).

Inclusive growth is also a top priority in the European Union's overall strategy. In 2010, the European Commission placed it at the heart of its economic, employment and social agenda — the Europe 2020 strategy. The strategy was launched to help the European Union navigate a stable course towards the three key objectives of smart, sustainable and inclusive growth. Building on the Lisbon Agenda, it incorporated a new social dimension to the blueprint for EU growth, and the EU has set itself ambitious targets on inclusive growth. All EU Member States shall, among others, strive for: an employment rate of 75 per cent for people aged 20 to 64 by 2020; a school drop-out rate of less than 10 per cent; a rate of at least 40 per cent with a (tertiary) academic degree (or equivalent) related to the 30 to 34 age cohort. Last, but not least – and this goes clearly to the heart of the inclusion goal – 20 million people shall not be under the risk of poverty any more (European Commission 2010). The reduction of poverty risk is targeted at three dimensions: first, to the income poverty risk, i.e. the risk of earning less than 60 per cent of the median; second, the risk of severe material deprivation, i.e. the inability to afford some items necessary to lead an adequate life; third, to the risk of people aged 0 to 54 living in a household of low employment intensity (Frazer, Marlier & Nicaise 2010). Member States have set national targets to help achieve the overall EU targets, and they are reporting on them as part of their annual national reform programmes. Selected indicators of inclusive growth in the CEE are presented in Table 1. The CEE region is understood according to the OECD definition, but only EU Member States were taken into consideration for further analysis. The study covers the years 2008-2018. At the last indicator, there is no "target" column, because the target in this case was marked by the number of people, and to make the data more comparable, the indicator expressed as a percentage was used.

Table 1: Indicators of inclusive growth in CEE countries

Member State	Labout market			Education						Poverty and social exclusion	
	Employment rate (%)			School drop-out rate (%)			Tertiary educational attainment, age group 30-34 (%)			People at risk of poverty or social exclusion (%)	
	2008	2018	Target	2008	2018	Target	2008	2018	Target	2008	2018

**2017 data, ** 2010 data.*
Source: [Eurostat, http://ec.europa.eu/eurostat/data/database (10.05.2020)].

The situation in terms of inclusive development varies widely in CEE countries. There are countries that have already achieved most of their goals (Latvia, Slovenia), and there are those that have set those goals even at a more ambitious level than the EU (Estonia). Finally, there are those that currently (2018) perform better than the EU average (highlighted in colour). But there are also countries that still have problems in this area.

To show the position of individual countries in the field of inclusive development, a synthetic indicator was calculated using the TOPSIS method. TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) is a linear ordering method which produces a synthetic indicator of development, built on the basis of partial measures reflecting its different aspects (Hwang & Yoon 1981). This facilitates analysis of similarities of the studied objects and their linear systematisation. The construction of the TOPSIS synthetic measure is as follows (Bąk 2016):

a) normalisation of variables (quotient conversion): $z_{ij} = \dfrac{x_{ij}}{\sqrt{\sum_{i=1}^{n} x_{ij}^2}}$,

b) coordinates of the pattern (positive ideal solution):

$$z_{0j}^{+} = \begin{cases} \max_i \{z_{ij}\} & \text{for stimulant variables} \\ \min_i \{z_{ij}\} & \text{for destimulant variables;} \end{cases}$$

c) coordinates of the anti-pattern (negative-ideal solution):

$$z_{0j}^{-} = \begin{cases} \min_i \{z_{ij}\} & \text{for stimulant variables} \\ \max_i \{z_{ij}\} & \text{for destimulant variables;} \end{cases}$$

d) distance of objects from the pattern: $d_{i0}^{+} = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_{0j}^{+})^2}$;

e) distance of objects from the anti-pattern: $d_{i0}^{-} = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_{0j}^{-})^2}$;

f) values of the synthetic variable (inclusive development): $q_i = \dfrac{d_{i0}^{-}}{d_{i0}^{+} + d_{i0}^{-}}$, $q_i \in [0;1]$; The measure q_i is expressed in values from 0 to 1, with higher values indicating a higher level of inclusive development.

For research purposes, the EU headline indicators were used as variables. The included specific variables are relative rather than absolute, which made it possible to reduce the impact of interferences associated with objects exhibiting certain features confounding the analysis (e.g. much greater population than the other objects). The limited number of indicators is used to keep the concept of inclusive growth as close as possible to its meaning defined in the Europe 2020 strategy. The positions of CEE countries in terms of inclusive growth and changes in this respect for 2008-2018 are presented in Fig. 1. CEE countries differ in terms of the level of inclusive growth, the highest is observed in Slovenia, the lowest in Romania. We can observe an increase in the level of development in each country, with some developing faster than others – the highest increase occurred for Latvia, and the smallest – for Slovakia and Hungary.

Fig. 1: Linear regression models for inclusive growth (TOPSIS score) of CEE countries

Source: own elaboration.

The question arises, how can we help achieve inclusive growth and can innovation help in this? The question seems to be justified in case it can be demonstrated that there is a relationship between innovation and inclusiveness for European Union countries (Fig. 2).

Fig.2. Innovativeness and inclusiveness in the EU in 2017*

**2017 is the last year for which a social justice report was prepared, hence the analysis was carried out for that year.*
Source: own elaboration based on: Hollanders H., Es-Sadki N., European Innovation Scoreboard 2018, European Commission, Brussels 2018 oraz Schraad-Tischler D., Schiller Ch., Heller S. M., Siemer N., Social Justice in the EU – Index Report 2017. Social Inclusion Monitor Europe, Bertelsmann Stiftung 2017.

This relationship can be pre-determined by correlating the innovation and social justice indexes, assuming that these indexes are a certain approximation of the position in innovation and inclusiveness, respectively. This assumption seems justified, as is confirmed by empirical literature. The summary innovation index is a measure used in assessing the innovative level of EU Member States. In turn, the EU Social Justice Index is a kind of monitoring of

social inclusion in EU countries and is prepared taking into account issues such as preventing poverty, equal access to education, the labour market and health protection, social cohesion and intergenerational equality. This correlation shows the positive impact of care for social inclusiveness on innovation. On the other hand, an innovation policy can be an alternative and complementary tool for inclusive growth.

Inclusive innovation policies for inclusive growth

Inclusive innovation policies are defined as "policies that aim to remove barriers to the participation of under-represented individuals, social groups, firms, sectors and regions in innovation, research and entrepreneurship activities" (Plannes-Satorra & Paunov 2017, p. 6). Their goal is for all segments of society to have opportunities to successfully participate in and benefit from innovation. Inclusive innovation policies have explicit aims to contribute to one or more of the following objectives: social inclusiveness, industrial inclusiveness and territorial inclusiveness (Ibid.). These different dimensions of inclusiveness are related. When innovation capacities are not widely distributed across sectors and regions, the well-being of some groups in society is negatively affected. This is particularly true for individuals working in less innovative sectors and/or living in less innovative regions that suffer from multiple factors of disadvantage (e.g. low skills, low income), as they are less able to move to more innovative activities.

Social inclusiveness (in the context of innovation) is associated with participation in innovation activities. This means not only contributing to the processes, but also by all individuals and segments of the population benefiting from them, regardless of their socio-economic background, gender, age, place of residence, ethnic origin or disability status. It is closely related to the inclusive innovation concept. Inclusive innovations are understood as innovative solutions that include in the process of their creation groups of society traditionally not involved in development, for example the poorest (Foster & Heeks 2013). Some authors use the terms "inclusive innovation" and "innovation for inclusive growth" interchangeably (George, McGahan & Prabhu 2012). Depending on the extent of inclusion of the excluded group in relation to innovation, Heeks, Foster and Nugroho (2014) have distinguished different levels of inclusive innovation. According to them, innovation is inclusive if: the intention of that innovation is to address the needs of the excluded group; it is adopted and used by the excluded group; it has a positive impact on the livelihoods of the excluded group; it is created within a structure and a framework of knowledge and discourse that are themselves inclusive if that group is involved in the development of the innovation. The innovation systems approach shows that inclusive innovations must be fostered by means of interactive processes, where different actors play effective roles (Arocena, Göransson & Sutz 2018).

Social inclusiveness is also closely related to the inclusive entrepreneurship concept, which contributes to social inclusion to give all people an equal opportunity to start up and operate businesses. The target groups are those who are disadvantaged and underrepresented in entrepreneurship and self-employment, including youth, women, seniors, ethnic minorities and immigrants or disabled people. Most country-level evidence shows that entrepreneurs from under-represented and disadvantaged groups are, on average, less likely to operate high-growth firms, because they lack the skills, networks and access to finance needed for growth; they are also less likely to express motivation to grow their business (OECD & European Union 2019). The same situation occurs in CEE countries that have a similar pattern of entrepreneurial inclusivity for youth, women and seniors, as far as their engagement into start-ups and established businesses is concerned. However, these countries are behind Europe in the engagement of women and seniors in entrepreneurship (Pilková, Jančovičová & Kovačičová 2016).

Innovation policies for social inclusiveness aim to include in innovation activities individuals and groups that are not usually participating in innovation (e.g. women, lower income groups), so as to broaden the group of innovators. Policies addressing social inclusiveness proceed either by building the innovation capabilities of disadvantaged groups or by facilitating their access to opportunities to participate in innovative activities. Some inclusive innovation policies address labour market discrimination, which is detrimental to well-being and economic performance.

Industrial inclusiveness is understood as the extent to which the capacity to participate in innovation activities is evenly distributed across firms (regardless of their size and age) and industry sectors within a country (Plannes-Satorra & Paunov 2017, p. 11). Innovation tends to be concentrated within some firms and sectors. The uneven distribution of innovation capacities across firms has contributed to widening the gap in productivity performance between the most productive and less productive firms. SMEs in most countries are usually active in mature, traditional or low-technology sectors characterised by low knowledge intensity and weak innovation capacities. In CEE countries, only 10-40% (at an EU average of over 46%) of SMEs can be considered as innovative – they have either introduced an innovation or have some kind of innovation activity (Fig. 3). The differences between countries are, at the same time, considerable.

Fig. 3. Share of innovative SMEs, 2016 (%)

Source: Eurostat [inn_cis10_type]

Innovation policies for industrial inclusiveness aim to support innovation activities in less innovative firms (including micro-entrepreneurs, small and medium-sized enterprises and start-ups) and traditional sectors. The focus is on strengthening their innovation capacities, as well as on building an adequate business environment for innovation.

Territorial inclusiveness is the extent to which the capacity to participate in innovation activities is evenly distributed across regions within a country. Evidence shows that innovation tends to be concentrated in metropolitan areas, and spatial concentration of knowledge economy factors persists. The top 20% of regions in CEE countries account for: 56% of R&D employment (in Bulgaria, the top 20% of regions account for 90% of R&D employment, in Hungary – 85%, Romania – 64%, Czech Republic – 55%, Poland – 52%; 2016 data) and 58% of patent application to European Patent Office (2012 data). We could choose many other indicators, and most of them show that "islands of excellence" concentrate high-performance innovators. This is also confirmed by innovation research. Literature has emphasised that innovative activity is not uniformly or randomly distributed across the geographical landscape and that the tendency towards spatial concentration has become more marked over time despite a wide spread of information and communication technologies and increased globalisation (Kourtit, Nijkamp & Stough 2011).

The Regional Innovation Scoreboard, which is a comparative assessment of regional innovation based on the European innovation scoreboard methodology, has always shown a remarkable gap between capital/metropolitan regions and the rest of the country. The most innovative region within each CEE country is the capital region (Fig. 4).

Fig. 4. Regional Innovation Scoreboard 2019 – performance of CEE regions relative to the EU

■ Capital regions

Source: own elaboration based on: European Commission, Regional Innovation Scoreboard Database, https://ec.europa.eu/growth/industry/policy/innovation/regional_en (03.05.2020).

Innovation policies for territorial inclusiveness target lagging and less innovative regions, with the aim of narrowing the performance gap with leading innovation regions. They foster the innovation capacity of individuals and firms located in peripheral regions, as well as in disadvantaged neighbourhoods within large urban areas. Braczyk, Cooke and Heidenreich (1998) and Cooke et al. (2011) proposed the Regional Systems of Innovation concept to examine how governance, institutionalised learning and culture may impact innovation at the regional level.

The co-existence of multiple goals and instruments points to complexities inherent within policy mixes that present significant challenges for effective policy implementation. Policy mixes are defined as combinations of policy goals and policy instruments that emerge over time around a specific policy issue (Howlett & Rayner 2007). Specific strategies are needed to make it possible for knowledge and innovation to contribute to social inclusion and foster inclusive development. Inclusive innovation policies are complementary to other policies in promoting social inclusiveness – particularly education policies aimed at ensuring equal access to high-quality education (from early childhood education to tertiary education) and promoting high educational attainment by all segments of society. There is a need for coordination in designing a coherent and optimal set of instruments to achieve policy goals. According to Havas, Izsák, Markianidou and Radošević (2015), an innovation policy mix is dependent on the socio-economic political and historical context of the given country where it is applied. It can also be reasonably assumed that the technological position of a country should have some effect on its policy mix. From the strictly Schumpeterian growth theory perspective, it would be expected that countries at different innovation levels would have different policy mixes (Aghion, Akcigit & Howitt 2013). However, the research results show that this strictly Schumpeterian perspective is not supported by data (Izsák, Markianidou & Radošević 2013). This may not be surprising, as it has already been hinted at that policy mixes are an outcome of a variety of factors, and only one of these is technological distance. Other factors are path dependencies, policy fashions and perceptions of the best practice in an innovation policy.

Conclusion

There is a need for inclusive innovation policies in CEE countries, and a wide range of such policy approaches can foster inclusive growth. Policy instruments that address social inclusiveness include, for example, the provision of grants to researchers from disadvantaged groups, as well as mentoring programmes to tackle stereotypes or to popularise science and technology. Innovation policies aimed at addressing industrial and territorial inclusiveness can also support inclusive growth, because they shape the opportunities individuals in different firms, industries and regions have to participate in innovation. To address industrial inclusiveness challenges, innovation policies may focus on addressing the main barriers to entrepreneurship encountered by disadvantaged groups, such as obstacles to access finance, talent or other support services (e.g. through the provision of business counselling, assistance to access new markets, etc.).

In seeking to make growth more inclusive, governments should also focus on the broad policy areas: ensuring broad access to quality education and upskilling; increasing the quantity and the quality of jobs; addressing labour market insecurity and segmentation. Inclusive innovation policies, by focusing on disadvantaged groups and laggard industries and regions, are often confronted with a number of specific implementation challenges that apply less to other innovation policies. These include the low involvement of the target group in policy programmes, for example due to low awareness of their existence or low trust in governmental intervention, and the low capabilities among the target group to undertake activities promoted by the programme. In consequence, the success of inclusive innovation policies relies on the stronger involvement of target groups and often requires strong capacity-building efforts and adequate financial support. A closer connection between innovation and inclusion may give new forces to the welfare state and political democracy in the CEE region.

Innovation policy is an important element in stimulating change and directing the activities of various actors to ensure a greater degree of participation in creating innovation and the benefits from them. However, further analysis is needed to understand where and when this might be effective. There are a number of gaps in our knowledge concerning inclusive growth and how it can be fostered through innovation policy. Further empirical and theoretical development needs critical evaluation by all relevant stakeholder groups, as well as careful integration of the feedback received.

Hiding and Disliking Fashion Brands Posts or Page in Social Media Among Generation Z – Case of Poland

Magda STACHOWIAK-KRZYŻAN

Poznań University of Economics and Business, Poznań, Poland
e-mail: magda.stachowiak-krzyzan@ue.poznan.pl

Abstract

The advent of social media has revolutionized the approach to marketing activities. The presence of brands on social networking sites is not only an obligation but also a big challenge for marketers and people responsible for managing these activities. Social media provide the possibility of two-way communication, engaging consumers not only in promotional activities but also often in the process of developing new product concepts. Generally, in social networking sites, users can take steps to establish and maintain their relations with brands. They can like, subscribe or follow other pages to show their positive attitude towards brands, their support and interest. On the other hand, more and more social networking sites offer an opportunity to limit some pages activity. This means that the user can also stop displaying posts published by a brand page (for a while e.g 30 days or for forever), or can take a more drastic decision, which is removing a brand page from the likes, subscribers, or followers list. These decisions are more and more popular and based on different information and reasons. These behaviors are the consumer's direct expression that he or she no longer wants to be involved in brand communication activities. This means that research is needed to understand consumers' reasons for stop engaging in social media communication by exploring why people stop like fan pages or decide to hide activity. This study examined what drives consumers to hide brand posts and unlike brand pages on social media sites which are most often used by fast fashion clothing brands – Facebook, Instagram, Youtube, Pinterest and Snapchat. Analyzing responses from 1000 research participants using the face-to-face interview method who has ever liked a fast fashion clothing brand on social media, this study found that the intention to hide brand posts or dislike brand pages was caused by two key factors: bad consumer experience with a brand and by errors in brand communication.

Keywords: Consumer Behavior, Social Media, Social Networking Sites (SNS), Fashion Brands, Generation Z.

Introduction

Social media has revolutionized the world. Social networking sites have become not only a tool for communication, maintaining contacts and interpersonal relationships or entertainment purposes, but also a tool used for commercial purposes. According to the latest data, social networking sites are currently used by 3.80 billion users, which is 49% of the population. Facebook is one of the most used platforms all over the world. More and more companies and brands treat social media as a communication and promotional tool. Social media enable two-way communication. Recently, social media has played an increasing role in the marketing efforts of many companies because it is easily accessible to everyone in the world who has access to the Internet. Social media marketing enables direct access to the desired target group and additionally reduces the costs of marketing activities. Social media marketing uses customer engagement on social networking sites, to a brand or product. Consumers show their commitment in various ways - they like the profiles of their favorite brands, actively engage in communication activities by commenting and sharing content. At the same time, as easy as liking brand pages, consumers can hide brand posts or unsubscribe and remove brands by unliking them from their liking lists on social media (Xu et al., 2013). Such action may be the result of a continued lack of commitment or a desire to break the relationship with the brand. If consumers choose to 'hide' or 'mute' brand activity, the brand posts will not appear on their profile or wall with feeds while their relationship with the brand continues as 'fans' or 'followers' or 'subscribers'. When consumers decide to discontinue the relationship, they can remove brands from their liking lists by 'unliking', 'unsubscribing', or 'unfollowing' the brand pages (Kwon, Kim, Chung, 2020). Literature analysis revealed a lack of empirical research on consumer behavior related to unliking brand pages or hiding their posts. The aim of this article is to narrow the literature gap and provide insights for fashion brand managers and social media marketers to help them manage more meaningful relationships with consumers on social media sites.

Social media as a tool to engage consumers

Social media is defined as a group of online and offline applications that allows for the exchange of user-generated content including the exchange of knowledge and opinions (Kaplan and Haenlein, 2010). Social media comprise a variety of online information-sharing platforms including social networking sites (e.g. Facebook), content-sharing sites (e.g. YouTube, Instagram, Pinterest, Tik-Tok), collaborative web sites (e.g. Wikipedia) and microblogging sites (e.g. Twitter, Tumblr) (Yannopoulou et al, 2019). Nowadays, almost every single company is promoting its products or services on social media.

Facebook brand pages have become one of the first channels through which consumers can interact with brands directly by liking, sharing or commenting on brands' posts and messages (Machado, Antunes, Miranda, 2018). With the emergence of new social networking sites (e.g. Youtube, Instagram, Pinterest, Tik-Tok, Snapchat and others), their importance in the context of building customer engagement grew (Niyonkomezi, Kwamboka, 2020; Weitzl, Einwiller, 2018; Miranda, Antunes, Machado, 2016). The like, share and comment features of social media sites allow anyone to easily interact with a brand. A single brand post can receive thousands of comments from social media sites users all over the world who interact with the brand and other users, providing a platform for dialogue from which to easily get information and feedback. Consumers, social media sites users, can increasingly integrate and act as co-creators of brand messages. They have a great opportunity to engage and actively participate in communication on the brand's pages on social media. These actions strengthen consumers' ties with brands, turning them into committed fans (Niyonkomezi, Kwamboka. 2020).

More and more research is conducted in the context of consumer engagement in social media. Previous studies in the field of customer engagement in brand communities focused mostly on the consequences of engagement, including concepts of satisfaction (Bowden 2009), commitment and emotional attachment to the brand (Chan, Li, 2010), empowerment (Cova, Pace 2006; Fuller et al. 2009), consumer value (Gruen et al. 2006; Schau et al. 2009), trust (Casalo et al. 2007; Hollebeek 2011) and loyalty (Andersen 2005; Casalo et al. 2007). Currently, various measures are used to explore consumer engagement. Most often, researchers use the likes, shares and comments index (Vries, Gensler and Leeflang 2012; Cvijiki, Michaheles, 2013).

Predictors of hiding and unliking on social media

There is still little research conducted to identify the reasons why consumers do not want to be more long involved in the activities of brands in social media. While it is undoubtedly useful for brands to know this, it should be of interest to both academics and practitioners to understand better what motivates consumers to stop engaging with communication activities on social networks, and how brands can avoid these behaviors. These can decrease sales, levels of loyalty toward the brands and may lower positive influence on other users within the consumers' network to engage with the brands (Nitzan, Libai, 2011) because they may recognize that their friends are not following the brands through their social media profiles or no longer endorse the brands.

At the same time, it is often emphasized in publications related to research on behaviors leading to breaking relations with brands in social media (stopping liking, hiding activity) that these activities may be an extension of consumer behavior related to avoiding advertising

The most important reasons that may lead to a break in engagement are (Kwon, Kim, Chung, 2020):

- information overload,
- consumer attitude toward social media marketing,
- brand detachment,
- self-identity and social-identity expression.

Consumers today are surrounded by a great deal of information. Information overload is a determinant and direction the by-product of the information society Internet and social media sites has become an additional source of information where you can find information about products and brands. As a result, consumers and social media users very often feel overwhelmed by the overload of information. Moreover, according to information theory, humans are only able to process a limited amount of information at a time. The phenomenon of information overload is a kind of discomfort mental, related to our attitude to receiving information, permanent concentration and readiness to receive it. When a consumer feels overwhelmed by the amount of information, his purchasing decisions deviate from the norm. The consumer may feel distracted, nervous and more frustrated or irritated. The most important problem is the question of verifying this information, which of them should be considered credible and reliable, and which not. To deal with this problem, consumers use various actions, such as filtering information,

prioritizing information sources, or ignoring certain information. Concerning social media, this may just result in hiding certain information/posts or removing pages from the liking list.

Consumer attitude toward advertising is defined as a 'learned predisposition to react in a consistently favorable or unfavorable manner to advertising' (Lutz, 1985). Nowadays, consumers have become resistant to advertising, they are distrustful of it, and more and more often want to avoid it. Research shows that only one in four Poles (26%) trusts advertising (Buzz Media and Maison, 2012). Nowadays, consumers place their trust in their friends, family members or communities in social media (IR Center, 2015; Ipsos Media CT, 2014). This proves that consumers primarily trust content and information created or transmitted by other people (their friends or not) (Stachowiak, 2018). Personal information sources are more reliable and trustworthy. Consumer's attitude toward advertising plays a significant role as an indicator of their advertising avoidance behaviors. This is also reflected in social media. The most important difference is that in the case of social media, consumers themselves voluntarily consent to receive brand messages on social media (Kwon et al., 2014) by liking the page, which makes them less likely to avoid advertising than with other media.

Brand detachment is defined as 'the psychological state of distance with regard to a brand, resulting from the weakening or the dissolution of the affective bond existing between the consumer and the brand' (Pierrin-Martineq, 2004). The consumers 'relationship with brands can influence their future behaviors towards brands' communications activities (Kwon, Kim, Chung, 2020). Conducted studies have shown that consumers' previous negative experiences with brands or their marketing activities influence their willingness to accept future advertising activities (Rosengren and Dahlén, 2015). Consumer dissatisfaction can lead to avoidance (Seyedghorban et al., 2016) and further to relation break up (Mai, Coti, 2007). The literature mentions three determinants that may be an explanation for the dissolution of the relationship between the brand and the consumers: indifference, rejection and a sense of deterioration of quality (Mai, Coti, 2007). Social media enable consumers to quickly break relations with the brand by simply clicking one button – unlike, unfollow, unsubscribe. Reasons for this behavior may vary, and the most important challenge for brands is trying to identify them.

Self-expression is one of the most important functions of a brand, especially a clothing brand. Fashion is included in the category of products consumed in public. It often reflects the lifestyle, views, opinions and personalities of its users. This is even more important for young consumers. Young people through their outfit express personality and create their own identity (McNeill & Moore, 2015). Fashion is extremely important in the creation of their self-evaluation (Isaksen & Roper, 2012). For young people, personal appearance is crucial (Ceballos, Bejarano, 2018; Jurgensen, Guesalaga, 2017). Young consumers demonstrate a desire to keep abreast of the latest product and brand trends, it is a way of gaining acceptance from the environment and peers. Social media platforms are an ideal tool for self-identity and social-identity expressiveness. By 'liking' a particular brand on social media, a consumer may use that brand to reveal to others what kind of person he or she is (Kwon, Kim, Chung, 2020).

Method

Data necessary to conduct exploratory factor analysis were obtained by survey resources. The entire study concerned the communication activities of the fast-fashion clothing segment in social media in shaping the purchasing behavior of the Z generation and the results presented in the article present some of the results obtained. The measuring instrument consisted of 24 questions, including 6 demographic questions. The survey was anonymous and contained primarily closed-end, matrix and ranking questions. The results presented in the article include three survey questions constructed using a five-point Likert scale, where '1' meant a strong disagreement and '5' meant full agreement.

The study was conducted from June 2017 until January 2018. After an initial assessment, 1,000 correctly completed questionnaires were accepted for further analysis.

To identify the hiding and unlinking factors of Generation Z with profiles of clothing brand in social media analysis method was used. Exploratory factor analysis has been done. Data obtained from empirical research was statistically analyzed using IBM SPSS Statistics version 21.

Therefore the main aim of the study was to identify the role and importance of content published in social media on purchasing decisions of young consumers (generation Z) in the fast-fashion clothing market in Poland. Detailed research goals concerned the identification of activity of generation Z in social media, in the context of the decision to purchase clothing, in particular:

- the activity of generation Z on the profiles of clothing brands in social media;
- key determinants of disliking or hiding fashion brand profiles and posts in social media among generation Z.

Sample

The survey was conducted among pupils and students in Poznań. To ensure the credibility of the research, the structure of the studied population was reflected in the structure of the sample, the variables being gender, age and level of education. An example structure is shown in table 1.

Table 1 Sample structure according to age, gender and level of education (%)

Variables		Percentage
Sex	Woman	58,4
	Man	41,6
Age	16-17	2,6
	18-20	53,1
	21-23	38,5
	24-26	5,8
Level of education	Upper secondary school	15,2
	States universities	84,8

Source: own study

Result

Unliking brand pages or removing it from friends is an interesting and quite popular phenomenon among young people in Poland. More than half of the respondents declared that they had performed such an action. It happened more often to women (62.6%) than to men (49.3%).

Table 2: The phenomenon of disliking profiles of hiding posts of clothing brands in social media (%)

	TOTAL (%)	WOMAN (%)	MEN (%)
Yes. I have stopped liking or hidden brands profile or posts	57,1	62,6	49,3
No. I have never stopped liking or hidden brands profile or posts	42,9	37,4	50,7

Source: own study

When it comes to the frequency of such an action, it turns out that it is usually not a one-off action. More than half of the people who declared that they happened to stop liking the fanpage of a clothing brand on social media did so 2-3 times. Every fourth person declared that it had happened to them more times. And about 16% of respondents have done it once. There were no significant differences in gender analysis.

Table 3: The frequency of disliking profiles or hiding posts of clothing brands in social media (%)

	TOTAL (%)	WOMAN (%)	MEN (%)
once	16,3	15,2	18,4
2-3 times	57,1	58,1	55,1
more often	26,6	26,7	26,5

Source: own study

Publishing uninteresting, from the respondents' point of view, content ($\bar{x}$ = 3.33) was among the main reasons why the respondents stopped liking a given profile. Actions related to removing a brand from friends or the group of liked pages are the result of unfavorable experiences of respondents with the products of a given brand (i.e. defective products, their rapid wear, etc.) ($\bar{x}$ = 3.20). The third most important reason is too much activity of the clothing brand in social media ($\bar{x}$ = 3.04), which means publishing too often too many entries that "clutter" the wall, which means that other information important to them may become invisible, they can get lost in the crowd.

Figure 1: Reasons for not liking the profiles of clothing brands in social media ($\bar{x}$)

Source: own study

Key determinants of disliking or hiding fashion brands profiles in Social Media Sites among generation Z

To identify the key determinants of disliking brands pages or hiding posts in Social Media Sites among generation Z, factor analysis was used. In accordance with the procedure for verifying the correctness of the application of this method, firstly the results were subjected to Bartlett's sphericity test and the KMO (Kaiser-Mayer-Olkin) measure was calculated. Both the obtained measurements confirmed the basis for performing factor analysis (Table 4).

Table 4: The Kaiser-Mayer-Olkin and Barlett's test

The KMP measure of sampling adequacy		**.679**
Bartlett's sphericity test	Approximate chi-square	234.704
	Degrees of freedom	15
	Significance	.000

Source: own study

The analysis was conducted using the method of Principal Component Analysis. Based on Cattell's scree test (a scree plot), two groups of factors were created. Then, adopting a factor loading level of 0.5 as a cut-off point, all the factors were assigned into specific groups (Table 5). The two factors combined explain nearly 51% of the common variance: the first one explains 32% and the second 19%.

Table 5: Results of EFA

Items	Components/values of factor loadings	
the brand's inactivity on the social profile for a long time	0.538	-
publication of controversial material	0.613	-
unfavorable experiences with a clothing brand product (product defect, etc.)	0.731	-
lack of or inappropriate responses to requests / inquiries or criticism from fans of the brand	0.708	-
too much activity (publishing too much content)	-	0.848
publishing uninteresting materials / content	-	0.568

Source: own study

The results of factor analysis included in table 5 allow to identify the following key determinants of unliking brand pages or hiding fashion brands posts in social media among generation Z:

- Factor 1: bad consumer experience with a brand (the brand's inactivity on the social profile for a long time, a publication of controversial material, unfavorable experiences with a clothing brand product, lack of or inappropriate responses to requests/inquiries or criticism from fans of the brand);
- Factor 2: errors in brand communication (too much activity and publishing too much content, publishing uninteresting materials/content).

To sum up - for young consumers, the main reasons for unliking or hiding fashion brands profiles on social media sites among generation Z is their bad experience with a brand. It may be the aftermath of direct contact with the brand's products and general dissatisfaction with them - e.g. poor product quality or product defects. Bad brand experiences can be caused by the brand's inappropriate communication on social media. First of all, it may be the inappropriate activity of the clothing brand in its social media, including publishing inappropriate, controversial content, publishing too much content or the lack of activity and response to fan criticism. Consumers do not want to feel ignored, which is why it is so important to communicate with them also in uncomfortable situations for the brand, e.g. when they receive critical remarks or comments from their fans. Secondly, young consumers do not like or hide profiles of fashion brands on social networks, because the brand makes mistakes in communication activities - it publishes too often and too much content (generates spam on fan walls) and publishes unattractive, uninteresting content for its recipients. It is very important to understand that it is not just about communicating, but about high-quality content. Two-way communication is to bring mutual benefits, both for the sender and the recipient, therefore the content must be properly prepared and adapted to the expectations of the audience.

Conclusion

An increasing challenge for fashion brands in social media is not to gain a large number of fans, but to maintain them, in order to prevent behaviors aimed at removing profiles from the group of liked pages and hiding posts. Therefore, it is very important to find out what might be causing such undesirable behavior. This information can be extremely important in formulating a social media marketing strategy.

The findings of this study not only contribute to the theoretical understanding of the current consumers' break-up with brands on social media but also provide practical insights for social media marketers and brand managers. Consumer behavior related to disliking brand profile and hiding social media posts reflects a clear desire by consumers to avoid marketing messages and end consumer-brand relationships on social media, even though they have expressed interest in brands and have voluntarily joined them. Identifying factors influencing such behavior can help brands predict consumer behavior and prevent it in the future. Bad consumer experience with a brand and brand communication errors are key reasons for breaking consumer relationships with apparel brands among generation Z. These findings suggest that the extent to which consumers maintain a positive brand attitude and relationship strongly influences their connection with brands on social media. Clothing brands not only have to ensure the quality of their products all the time, but also the quality of their marketing activities in social media. Marketers should avoid publishing too many irrelevant posts while keeping consumers interested in their messages. The consumer's liking of the profile does not guarantee that the relationship is concluded forever, and the phenomenon of terminating the relationship is becoming more and more common.

Limitation

This study has several limitations and further investigation is still needed. One of the limitations of this study is the fact that only several, selected by author predictors of hiding behavior were analyze. Another limitation of the study is the limited sample, the results cannot be generalized to all consumers. The results cannot be also generalized to all clothing brands on the market. The survey covered the fast-fashion clothing segment. Future research might consider focusing on different market segments or specific brand. It should also be noted that the conducted research included only selected social media (Facebook, Snapchat, Instagram, Youtube and Pinterest).

Challenges for The Ferry Shipping Operation in The Baltic Sea Region in The Time of COVID-19 Pandemic

Ilona URBANYI-POPIOŁEK

Gdynia Maritime University, Poland, i.urbanyi@wpit.umg.edu.pl

Abstract

Ferry shipping is a type of maritime transportation where passengers and cargo are transported in one ship and form one market. The demand for transportation is created by two segments – people travelling in different purposes and hauliers transported cargo in trailers. Baltic Sea constitutes the prime area of ferry operation in Europe. The network of international and prime domestic ferry connections included 60 services with 116 ferries operated (ro-pax, cruise-roro i high-speed). As the ferry business is concentrated, the operations are provided by 16 main ferry operators. On international and main domestic ferry lines the traffic amounted to around 49 million passengers, 9 million cars and 3 million trailers. In previous decades changes in internal factors determining operation were to a certain extent predictable. COVID-19 epidemic started unexpectedly and created new challenges for shipowners they have to face. The latter factor suddenly hit the ferry business. The purpose of the paper is to research into the ferry operation in the time of pandemic and evaluate the activities of the operators to reduce the negative effects in turnover decline.
The paper begins with introduction (Section 1) and methodology (Section 2). The main body comprises the theoretical background of ferry shipping and presentation of the Baltic ferry operation, as well as discussed, the management of operation in time of pandemic.
The methods used in this study are the analyses of literature, analyses of original data and in-depth interviews.

Keywords: Ferry Operation, Baltic Sea, COVID-19, Ferry Carriers, Cargo Transportation, Ferry Tourism.

Introduction

Ferry shipping is well developed in many areas of the world. North Europe and Mediterranean are regions of high concentration of ferry network connections with Baltic Sea Region being one of the prime world market (Kizielewicz & Urbanyi, 2015). Ferry shipping is a type of maritime transportation where passengers and cargo form one market. The simultaneous transport of two different segments creating demand for services constitutes the prime characteristic of ferry business.

Trade relations and the volume of commercial exchange between Nordic and continental European countries influence the cargo flows in the region and constitute the regional supply chains in Baltic Sea Region. The majority of cargo between Nordic states and continent are carried by vessels, particularly by ferries and pure cargo ro-ro ships. Serry underlines that those vessels carry up to 80 per cent of total internal cargo turnover in the region (Serry, 2014).

Baltic Sea represents attractive region for maritime tourism. Passenger ferry traffic is highly developed and people undertake sea voyages for various reasons, as the needs to get to specific places, participation in mini cruise trips and conferences at sea as well as traveling for shopping and business purposes. Mini cruises, sea conferences and shopping trips are particularly popular in Scandinavian countries, Finland and Estonia.

Ferry business is sensitive to changes in the market environment. However, both segments react differently to economic shocks. Cargo traffic is strictly dependent on the economic activity and level of international commerce. In example, during 2009 crisis, due to slow down in industries and decrease in trade the majority of ferry links recorded decline of 25% in number of transported units. Particularly services between Germany and Sweden were affected by a 30% drop in cargo traffic (Market:10, 2010). It took 8 years to achieve the level of transported cargo unites before the crisis.

Cite this Article as: Ilona URBANYI-POPIOŁEK "Challenges for The Ferry Shipping Operation in The Baltic Sea Region in The Time of COVID-19 Pandemic" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The passenger segment reacts differently during recession. The latter usually is not deeply affected. Many Baltic Sea Region residents renounce longer holiday voyages to Mediterranean states or beyond Europe due to costs of stay and transport fares. They choose as destinations Aland Islands, Bornholm and Gotland, as well as ferry cruises in the region with stay in interesting places like Stockholm, Helsinki, Tallinn, Riga, Oslo or Gdansk, for example. We did not observe drop in passenger traffic in the whole region during slowdown in economy and some destinations show growth in turnover like services to the mentions islands. The fuel crises of 1974 and 1981 as well as past recession are the examples.

The COVID-19 pandemic started in Northern Europe in early March 2020 deeply affected ferry business. The lockdown particularly hit the passenger sector as the Baltic states closed the border. As a consequence of travel restrictions, the traffic was stopped and cruise trips were cancelled. Ferries operated as cargo ships only and some cruise ferries were laid up. The COVID-19 crisis that wiped out the passenger sector shows that ferry companies need both passengers and cargo to operate business profitability.

Methodology

The research concerns the impact of COVID-19 on ferry business in Baltic Sea Region and focuses on activities of ferry carriers in the time of pandemic. The prime aim of the paper is to analyse the new challenges faced by the operators and what operational solutions were implemented by them to minimize the negative effects of drop in turnover.

The research questions are formulated as follows:

- How did the epidemic affect the passenger and cargo segments of ferry business?
- What actions were undertaken by ferry carries to reduce the negative effects of COVID-19 pandemic?

The research methods were the analysis of literature concerning ferry shipping, analysis of statistics and interviews. The data were collected from the ShipPax Information, known as a reliable publisher and provider of consulting services for ferry shipping industry, as well as from interim half year reports of selected ferry operators. A detailed analysis comprises passenger traffic and cargo turnover before and in time of pandemic in the Baltic Sea Region. The study focuses also on results achieved respectively on cargo oriented and passenger oriented routes. Moreover the analysis of incomes of selected operators was conducted. The research examines the activities undertaken by prime ferry operators to minimize the negative impact of pandemic on operation results. In-depth interviews were conducted with chosen operators` representatives on -line. The questions concerned the actions undertaken by individual carrier.

The paper is organised in the following way: Section 1 comprises an introduction and a presentation of the problem undertaken in the research, Section 2 presents the methodology, Section 3 presents the theoretical background of ferry business, Section 4 analyses the ferry operation in the Baltic Sea, Section 5 discusses the operational decisions undertaken by carriers based on in-depth interviews and reports and finally Section 5 consists of conclusions and further comments.

Theoretical background of ferry shipping

There is not a uniform definition of ferry shipping and a ferry ship used in theory and practice. The reason for it is connected with continual changes of this type of ships, changes in supply and demand on ferry market, as well as approach of the authors to the presented issues. However, carriage of passengers and cargo by one ship using ro-ro technology for loading and discharging wheeled units and private cars is the prime characteristic of this maritime transport. Ferry operation is therefore defined as a type of liner shipping where passengers and cargo form one market. Ferries ply the regular routes, usually between two or three ports according to schedules. (Urbanyi -Popiołek, 2009). Similar approach to ferry business presents Kotowska, who states that the ferry shipping transports two segments: passengers and cargo (Kotowska, 2014), as well as Stapford who points out that ferries transport people, goods and vehicles over short distances by sea (Stapford, 2009).

Ferry shipping is the prime mode of general cargo transportation within the Baltic Sea Region. Cargo segment comprises different vehicles, as semitrailers, lorries, trucks and containers on roll-trailers. The function of ferries results from the economic connections between Nordic countries as well as between Scandinavia and continental Europe. Cargo traffic flows from Continent to Nordic states and vice versa are complementary to mutual trade turnover. In

mutual exchange dominate valuable commodities as automotive, electronic appliances, machinery, construction equipment, medical equipment, textiles, furniture, household appliance and medicines. The other segments are food and agriculture commodities, wood and paper products, as well as steel and semi-finished products. Presented commercial intercourse, in regard to volumes and commodity structure, is the prime determinant developing the cargo flows between continental Europe and Scandinavia and creating the demand for ferry transport of cargo.

Ferry shipping form basic transport connections in regional supply chains. Ferry links are elements of road – sea transport systems from Nordic states to continental Europe and vice versa (Daduna et al. 2012). Ferry business constitute prime elements of regional transport chains and multimodal transport systems (Paixao Casaca, & Marlow, 2009). Musso, Casaca, & Lynce describe ferry services as a segment od short sea shipping market (Musso, Paixao Casaca, & Lynce, 2010). Moreover ferry shipping is also considered as alternative for land transportation in context of sustainable transport development (Castelss, Usabiaga, & Martinez, 2012, Chen, Yang, & Notteboom, 2014). The growth of short sea shipping as an alternative for road haulage is mainly aimed at discerning social benefits resulting from lower external costs generated in maritime transport, lower number of accidents and reduced congestion (Kotowska, 2015).

The concept of carriage of valuable goods is based on house to house formula. Such merchandises generally are loaded into trucks in sender premises and unloaded in receiver place. The ferry services link the continental Europe transport system with Scandinavian roads. This maritime transport enables efficient and effective carriage of goods transported in lorries and trucks via Baltic Sea. In accordance with the scope of the article, the prime function of ferry shipping is its "floating bridge" role and it is considered as essential links in European supply chains.

Passenger traffic is the second segment of ferry industry and is usually analysed in terms of tourism functions of ferry shipping (Wild & Dearing, 2000, Kizielewicz & Urbanyi-Popiołek, 2015). Research on market segmentation has been carried out by Kizielewicz and et al. The authors analysed the generic structure of the tourist demand for ferry travel in terms of demographic variables and purchasing behaviour of passengers on-board ferries. The motives for ferry travel were defined generally as tourists, visiting relatives, business-/work-related and combinations of specified needs (Kizielewic and et al., 2017). Pantouvakis examines the factors and the ways that influence the passenger to select a ferry operator and states that ferry passengers form satisfaction perceptions on the basis of their evaluation of four primary dimensions: service quality, price, convenience and availability. (Pantouvakis, 2007).

The passenger demand is created by people travelling in different purposes, e.g. visit chosen destination in connection with various needs, package trips, shopping, business. For the purpose of this study the travellers are divided into categories (Urbanyi-Popiołek, 2018):

- Liner passengers – travellers taking a trip in various reasons (visit an interesting destination, participation in culture or sport event, visit relatives etc.), ferry crossing is only a part of whole trip,
- Cruise passengers – travellers participating in package trips of diverse nature, e.g. round trips for pleasure, trips with short stay in port of destination etc.,
- Conference passengers – participants in conferences and seminars organized on-board within liner trips,
- Shopping passengers – people who travel to purchase commodities on-board or in port of destination,
- Business passengers – passengers travelling in connection with their professional activities, in this category lorry drivers are included.

Business passengers – passengers travelling in connection with their professional activities, in this The presented selection is based on the prime factor generating the demand. In practice, assigning the travellers to given category is not clear because passengers traveling e.g. as conference participants also do some shopping and enjoy entertainment. The assignment of traveller to a given segment results from the main transport need (Urbanyi-Popiołek, 2018).

Ferry shipping operation in the Baltic Sea

Baltic Sea constitute one of the world prime ferry markets. In 2019 275,054 million passengers and 105,6 million private cars were transported in the region. The cargo traffic amounted to 11, 06 million road units. The numbers include the whole turnover with short routes between islands and mainland. On international and main domestic Danish and Swedish ferry lines (e.g. Bornholm and Gotland) important for tourism and regional transport systems, around 49 million passengers, 9 million cars and 3 million cargo units were carried (ShippaxMarket 20, 2020).

Baltic ferry business is highly concentrated. According to Shippax data, in January 2020, 16 major carriers operated on the main international and domestic markets. In terms of transport capacity and market share the leaders are Finnlines, Stena Line, Tallink Group, Viking Line, TT-Line, Color Line, Unity Line. Among others are Fjord Line, Scandlines and Polferries. The network of ferry connections included 60 services with 116 active ferries of different types - ro-pax, cruise-roro and high-speed.

Ferry business in the Baltic Sea Region includes three prime ferry markets:

- West Baltic - comprises lines from Denmark to Sweden, Norway and Germany, services from Sweden to Norway and Germany and Germany – Norway connection; the west market accounts for 54% of passenger and 62% of freight traffic,
- East Baltic - covers services from Sweden to Finland and Estonia, from Estonia to Finland and Russia; the east market accounts to 37.5% of passenger and about 19% of freight turnover,
- South Baltic/ Central Baltic - comprises lines between Sweden and Poland, Sweden and Latvia and Lithuania and the connections between Germany and Lithuania, Latvia and Finland; the central market constitutes the 8.5% of passenger transport and about 19% of freight.

These markets differ in terms of the demand for transport services and the functions the ferry lines perform. In west and south Baltic cargo turnover dominates. Both markets accounts for 81% of ferry loads in region. Most services are cargo-oriented routes. An exception are lines from Norway to Sweden Denmark and Germany where passengers traffic dominates due to tax-free sales and cruise trips offers.

The Eastern Baltic Sea is characterized by the highest concentration of ferry tourism. This is due to several reasons. Firstly, for many decades the Swedes and Finns have undertaken ferry trips due to the possibility of making purchases in the duty-free zone, which is still preserved in this area (lines via the Aland Islands). Moreover, the purpose of the journey undertaken by the Scandinavians on these routes is the journey itself and the attractions on the ferry and the shopping, not only in ferry shops, but also in Estonia and Latvia.

Ferry operators` revenues depend on sales of services. Theirs incomes comprise two different areas. The companies get their incomes from passenger and cargo segments. Revenues of the ferry company consist of:

- sales of tickets,
- sales on-board services,
- other passengers revenue,
- sales of cargo transport.

Sales of ticket is the first item of passengers revenue and include transport fares, sales of cabins and private vehicles transportation fares. Sales on-board services include sales in restaurant and shops as well as entertainment. This item is the prime revenue that flows to the company operating services on passenger oriented lines. It is estimated that sales on-board generates 30-55% of total revenues of cruise ferry. In case of ro-pax, this category has minor importance in relation to cargo transportation and has a share of 20-30% of total earnings (Urbanyi-Popiołek, 2015).

Other passengers revenues contain incomes which are not recognised as sale on-board, such as sales of packages by tour operators, transfer passengers, marketing, sales of hotel accommodation onshore etc.

The second important items are revenue from cargo segment. This incomes have a significant share on ro-paxes where cargo transportation dominates (up to 70%-80% of total incomes).

Incomes of cruise ferry operation differs in structure compared with ro-pax. On-board services generates on average as much as 40% of total revenue. Catering and entertainment generate the expenditures of passengers being the primarily source of cruise ferries income. Cargo segments amounts on average to 15-20% of this ferry type revenue.

Tallink Group is an example of carrier operated cruise ferries on passenger oriented lines. For the group passengers service is the prime source of income. Sales on-board generate more than half revenue of the group. In total, this item with ticket sales give 85% of yearly income. Freight has 11% share due to high cargo turnover on Tallinn – Helsinki route.

Alike Viking Line is a cruise- roro operator. Passenger segment generates 93% of incomes and reflects tourist feature of company`s business. The carrier offers low ticket prices and concentrates on sales at shops and restaurants. Taking into consideration the level of costs related to purchase of goods for on-board services, one can assume that the structure of operator income from passenger segment is the same as Tallink Group.

TT-Line, Finnlines and DFDS Seaways are carriers operating more cargo oriented services among others. The incomes primarily come from freights paid by hauliers. Lorries, trailers and other wheeled cargo are carried upon freight tariffs. The basic rates are charged per length of the vehicle or per unit.. Typically for liner services pricing, ferry companies charge freight additions, like Bunker Adjustment Factor (BAF), Low Sulphur Surcharge (LSS), Charge for vehicles containing dangerous goods or Peak Season Charge (Urbanyi-Popiołek, 2015).

For companies operate cruise ferries the basic are on-board services, for those having ro-paxes obviously cargo segment is essential. Cost and revenue are variables significantly influences the financial results and performance of ferry industry. The position of ferry company is inflexible due to operation the vessels on fixed routes according to sailing lists. The carriers incur costs irrespective of utilization of ship`s passenger and cargo capacity. The majority of costs in ferry business should be regarded as fixed items. The management of cost and revenue are the key issues for financial performance of the ferry operator.

Ferry shipping operation in the Baltic Sea

The COVID-19 pandemic has caused great disruption to the ferry industry. All countries in Baltic Sea Region had taken far-reaching measures which had directly influenced the ferry business. Borders were closed and Baltic states introduced entry restrictions. Furthermore, the countries were placed in lockdown.

The new situation has strongly affected the sector, however the negative impact on both segments differed. Table 1 presents the ferry traffic of selected operators and reflects the situation of the business. Passenger traffic decreased from 50 to 90% in the first half of the year compared with the same period of 2019. Cargo transportation dropped of 15-20% in numbers of trailers.

Table 1: Ferry turnover of selected operators in 2019 – 2020

Operator	H1 2020		H1 2019	
	passengers	cargo units	passengers	cargo units
Tallink Group	1 988 212	186 386	4 507 615	192 660
Color Line	621 781	85 759	1 634 408	89 503
DFDS	342 607	126 135	428 255	125 156
Viking Line	998 483	62 409	2 772 427	69 030

Source: own elaboration based on: Q2 2020 Interim Report – DFDS, Tallink Grupp AS, Q2 2020 Tallink Grupp AS, Half-year Financial Report Viking Line, 2020, Color Line Interim Report 2020.

The decrease in traffic resulted in decline in revenue. Tallink reported 3.4% fall in incomes in the Q1 from route operation and drop by 75% in Q2 compared to the same periods in 2019. The biggest contributors to the overall revenue fall were the 82% drop in shop and restaurant sales, 81% drop in tickets sales and 29% drop in cargo sales (Q2 Tallink, 2020). Viking Line results show similar decrease. Passenger-related revenue decreased by 89% during the second quarter, while cargo revenue decline by 11% (Viking Line, 2020). The other passenger - oriented carries were affected alike.

The carriers were forced to undertake actions to minimalize the effects of coronavirus crisis. The measures taken by the operators can be classified as follows:

- temporarily suspension of services and laid – up of ferries,
- streamlining of calls frequency,
- focus on cargo segment,
- restart of services and operate according to pandemic requirements,

- seasonal destinations introduced by the operators,
- reduction of the crews and ashore staff,
- state aids.

The passenger sector was hit first and foremost. The majority of passenger – oriented ferry links were suspended, and the cruise ferries were laid-up. Norway was one of the first countries in the region to close its borders. As a result, the international services operated by Color Line, Fiord Line, DFDS Seaways and Stena Line to Sweden, Denmark and Germany were temporarily discontinued, e.g. Sandefjord – Stromstad, Oslo – Kiel, Oslo – Copenhagen.

Alike ferry links from Sweden to Finland, Estonia and Latvia were suspended, as these countries sealed the borders and introduced restrictions in traveling. Helsinki – Stockholm operated both by Tallink – Silja and Viking Line, as well as Tallinn – Stockholm and Riga – Stockholm plying by Tallink are the examples. Seven of the thirteen Tallink ships were temporarily sidelined in Tallinn, Helsinki, Stockholm and Riga. Likewise four Viking Line ferries from seven were laid up from mid-March to early June. The rest of fleet operated as cargo ships.

Moreover, a number of services were ceased permanently. In the middle of March Stena Line closed temporarily passenger link between Norwegian capitol Oslo and Frederikshaven in Denmark and the ship was sidelined in Gothenburg. Later the carrier announced that the route would not be reopened when the COVID-19 crisis was over. The other permanently closed passenger – oriented ferry route is service between Trelleborg in Sweden and Sassnitz in Germany operated by Stena Line as well.

The cargo – oriented links in south and west Baltic were less affected. The passenger traffic in this region was suspended either, however ro-pax ferries operated transporting road units with cargo. The ferry connections from Germany, Poland, Lithuania to Denmark and Sweden are important elements of regional supply chains between continental Europe and Scandinavia. The economic slowdown in the Baltic states undoubtedly affected trade in the region, but the need to ensure supplies allowed for the continuity of line operation, so ferry operators servicing these countries continued to operate, albeit in freight – only mode. However, the slowdown resulted in drop in cargo traffic in this area by an average10%. In east Baltic as well as is in Skagerrak some routes operate emergency freight links subsided by the states.

On most connections, carriers have cut the frequency of trips. Rostock – Travemunde, Rostock – Gedser or Świnoujście - Trelleborg in west Baltic are the examples with average reduction by 12% in number of calls.
The COVID-19 pandemic affected the employment in ferry industry. Some operators were forced to reduce the staff.
The actions were as follows:

- Stena Line was the first major carrier that cut jobs, about 950 people employed on board and ashore were temporarily redundant as passenger traffic was stopped,
- DFDS Seaways was the next with 600 staff being reduced, however due to financial aid package from Danish government, staff was remained paid,
- Norwegian Color Line laid off temporarily 2000 people with an economic stimulus package to secure salaries,
- Eckero Line due to surplus in the on board staff terminated contracts for 300 employees,
- Tallink reduced workload and remuneration of Estonian and Latvian personnel to 70% for two months, Sweden staff to 40-50%, and Finish were on unpaid leave, except the staff on duty on vessels.

The reduction of the employment on board and ashore made it possible to cut costs in the most affected weeks from mid-March till June. It is estimated that the crew costs of cruise ferries have a 20-25% share in operating costs of the vessels. The actions resulted in average 15 % decline of operating costs, depending of the carrier. Lower operating cost savings come from the need to maintain the skeleton crew on sidelined ferries.

From the mid-June the Baltic states began to lift the travel restrictions, the passenger- oriented ferry services were gradually restarted. Among others were Oslo – Kiel operated by Color Line or Copenhagen – Oslo serviced by DFDS Seaways. Moreover DFDS included call to Frederikshaven on the latter route. The Sandeford – Stromstad route remained suspended as the latter Sweden port was located in red zone.

When analysing the management of fleet operation, it is clear that Tallink made the largest reorganisation of its network, as well as offered new summer cruise destinations. The first was the Helsinki – Riga route operated every second day by cruise ro-pax Silja Serenade, normally plying the iconic Helsinki – Stockholm service. The latter was suspended during summer season due to further travel restrictions. According to the rules travel of Swedish citizens to Finland has been

restricted. In addition to work-related or other essential travel, entry was allowed e.g. for persons who own a property or residence, however persons arriving from Sweden were encouraged to spend 14 days in conditions corresponding to quarantine.

The Stockholm – Visby route was the other new summer destination. The cruises we rounded via Marienhamn, which enables tax – free sales on board and were dedicated to Swedes. The other ferry cruises were offered on Tallinn – Helsinki - Marienhamn route and Tallinn – Turku with short call at Langnas at Aland Island for tax – free sales. Similar network for summer season offered Viking Line.

During pandemic crisis some operators were granted state aids. The ferry connections between Finland and Sweden, as well Estonia are regarded as prime elements in supply chains of essential products, as food, medicines etc. The Finish National Emergency Supply Agency came to agreement with Tallink and Viking Line to maintain a number of ships in service to carry freight. Shippers paid the ferry companies freights upon tariffs and the agency paid additional sums to ensure that the operation is not loss making. These payments covered variable traffic costs and some fixed costs, but were reduced by revenue from cargo traffic and the contribution from passenger one. The agreement comprised the operation Tallink`s Megastar ferry plying Tallinn – Helsinki route, as well as Turku-Stockholm route vessels and Viking Line ships on Turku – Stockholm line. The support was crucial to cover the operating expenses, however, there was no contribution to earnings. The measures were temporary, and valid from mid-March till mid- June. Moreover, Tallink received temporary salary compensation measures offered by the states, while Viking Line received aid from Aland provincial government. The other example is Norwegian Fjord Line operating passenger-oriented ferries. The carrier received the aid of 700 million NOK from government and two main shareholders.

State aid granted to operators was an external action, the former presented activities were undertaken by the carriers.

Conclusions

The COVID-19 crisis strongly affected the ferry industry, however not to the same extend as cruise shipping or airliners. The passenger sector was hit deeply due to restrictions in traveling, however cargo freight also dropped as the economy slow down.

The carriers have undertaken several activities to adapt to the new market conditions.

Cruise ferry operators oriented on passenger transport and on-board services sidelined the ferries and temporarily suspended the operation. Only ships with greater cargo capacity were in service and operate as cargo ships. The late spring and summer months new destinations were offered to safe the peak season and improve the incomes. However, without state aid the operation would not have been possible. The seasonal destinations were cut in September. The companies will analyse the feedback from the customers, as well as volumes, fares and on-board sales. The information will be used to evaluate what cruise destinations might be offered in the future.

Carriers to whom cargo is a core business adjusted services to customers requirements. The ferry and logistics operation have been expanded and adopted to freight forwarders and hauliers.

Customer behaviour and economic results are the key elements for the companies in the ferry industry. The COVID-19 crisis has proved once again that ferry sector needs both passengers and cargo in order to operate in the market.

Disclosure of Intangible Assets: Are We Getting Better? Evidence from Poland

Olga GRZYBEK

University of Economics in Katowice, Poland
olga.grzybek@ue.katowice.pl

Abstract

The purpose of this paper is to examine the compliance level regarding mandatory information about intangible assets reported in financial statements and its change over time. The research method adapted is content analysis of financial statements prepared by all listed IT companies in Poland for accounting years 2012 and 2017. The research tool - disclosure index - comprises all mandatory disclosures about intangible assets (34 items) according to IAS 38. The findings of this paper show moderate level of compliance with only little increase in disclosure level in 2017 comparing to 2012. Entities disclose rather general information without many details needed to deep understanding of intangible value of business. They rewrite information from one year to another and from IAS 38 to the accounting policies without adapting it to their specific. Accounting policy is very often excessively complicated because it includes all possible choices, even though they do not apply to a particular company. It should be a priority to make financial statements more user-friendly and at the same time to create stronger enforcement mechanism (for example during the external audit) to encourage companies to expand their disclosure policies.

Keywords: Disclosure, Intangible assets, Reporting pattern, Compliance level.

Introduction

This paper investigates in detail the scope of intangible assets mandatory disclosure and its change over time. The topic of disclosure is very often discussed among researchers, regulators and practitioners (Ritter & Wells, 2006; Saha, Morris, & Kang, 2019; Schipper, 2007) as it is crucial to understand the economic condition of a company. Although the need for disclosure is generally accepted, there is no agreement about the form of disclosure. Researchers argue that absent market imperfections, companies would have incentives to optimally trade off the cost and benefits of voluntary disclosure and to produce the efficient level of information to the investors (Healy & Palepu, 2001). Thus, market imperfections as well as the information gap between sophisticated and unsophisticated information users might be seen as the reason for mandatory disclosure. Nevertheless, Schipper (2007) stated that there is no agreed-upon objective function for required disclosures and no generally accepted theory of them.

IASB in *Conceptual Framework for Financial Reporting* (2018, chapter 7) highlights that presentation and disclosure of information in the financial statement is a communication tool with the primary users and effective communication needs a balance between flexibility to provide relevant information and comparability of information form period to period for a reporting entity and in a single reporting period across entities. From the insiders' point of view managers trade off between making accounting decisions and disclosures to communicate their superior knowledge of firm's performance to investors, and to manage reported performance for contracting, political or corporate governance reasons (Healy & Palepu, 2001).

Although there are some disagreements concerning overall expected disclosure, in regard to intangible assets it is desirable to disclose detailed information (Agyei-Mensah, 2019). First of all it is because of their increasing and unquestionable importance. Moreover, relatively strict requirements of International Accounting Standard 38 (IAS 38) do not allow to recognize as asset many of intangibles. At the same time expenditure to internally generate some intangibles is recognized as an expense while the same expenditure to acquire the same intangible item is recognized as an asset. It causes concern about appropriate valuation of entities and hence optimal capital allocation in economy.

Given the crucial role of disclosure for understanding the financial condition of a company, it is important to investigate reporting pattern of companies, its determinants and consequences for the market, economy and society. The literature relatively often investigates the last two areas (Gomes I., Semuel, & Devie, 2019; Ibadin & Oladipupo, 2015; Kamel & Shahwan, 2014; Omoye, 2013) whereas the empirical evidence in the first field is limited. Some previous research indicate the need for studies in the topic of disclosure pattern across years and developing the compliance with required disclosure over time (Agyei-Mensah, 2019; André, Dionysiou, & Tsalavoutas, 2018; Carvalho, Rodrigues, & Ferreira, 2016). On the one hand, researchers assume that the companies tend to maintain the disclosure level over time. On the other hand, standard setters put emphasis on the rule "comply or explain" which assumes that the companies ought to follow the requirements and if not, they should explain the reason for deviation. It should encourage the companies to improve their disclosure. The research questions of the study are as follows:

RQ1: What kind of information about intangible assets is disclosed most often / rarely?

RQ2: Is there any significant change in disclosure level of intangible assets?

This study contributes to the literature on intangible assets as it provides country-specific evidence on the compliance level with IAS 38 and its change over time. It adds to the debate about improving disclosure usefulness. The findings suggest that there is some kind of information which is generally not disclosed by companies. First of all, it concerns disclosures about intangible assets with indefinite useful lives and the amount of research and development expenditure recognized as an expense during the period. The evidence shows moderate level of compliance with IAS 38 which, considering the nature of disclosed and not disclosed information, is insufficient to a deep understanding of a financial statement.

The remainder of the paper is organized as follows: the second section provides the theoretical framework and reviews the literature on intangible assets. The third section presents the research sample and the disclosure index used in this study. The fourth section includes the empirical results. The final section summarizes and concludes.

Theoretical background

There are at least several literature reviews in the field of intangible assets disclosure (Castilla-Polo & Gallardo-Vázquez, 2016; Castilla-Polo & Ruiz-Rodríguez, 2017; Cuozzo, Dumay, Palmaccio, & Lombardi, 2017; Jeny & Moldovan, 2016). As these literature reviews summarize comprehensively the most significant research on intangible assets, in this paper I give only a brief view on the most vital issues in regard to disclosure of intangible assets from recent years.

A few theories have been used to explain the reason for disclosing the information about intangible assets. The major premise is that companies disclose information to improve transparency, legitimate their status and enhance reputation (Gomes I. et al., 2019). According to agency theory disclosure is a tool to reduce agency cost as it contributes to reduction of information asymmetry between the shareholders and the managers. Agency theory posits that disclosure is a mechanism to control managers' performance and that managers disclose information to maintain their position and compensation arrangements (Oliveira, Lima Rodrigues, & Craig, 2006).

Under the signaling theory information asymmetry is reduced by sending signals by party possessing more information to other interested parties. Disclosure of positive information is perceived as the signal about the good performance of a company facilitating its appropriate valuation. Signaling theory posits that highly profitable companies tend to disclose more information to avoid undervaluation of their shares (Oliveira et al., 2006) and to signal their excellence. It is emphasized that the signal should be favorable for the signaler (An, Davey, & Eggleton, 2011) as organizations have little incentives to report negative information (T. A. De Silva, Stratford, & Clark, 2014).

Third main theory in regard to disclosure of information is the legitimacy theory. It concerns the relationship between the organization and society at large. Legitimacy theory assumes that a company disclose information in order to be perceived as legitimate by stakeholders whereby the legitimacy status is crucial for the survival of organization. Companies ought to follow the society expectations and norms to ensure the inflow of capital, labor and customers (An et al., 2011).

It is worth noting that most disclosure literature is devoted to investigate the compliance level with accounting standards (Devalle, Rizzato, & Busso, 2016) but it is not the case of intangible assets. Regarding the intangible assets two approaches - voluntary disclosure research and compliance level with mandatory requirements research - seem to be of the same importance. Liao (2011) investigates the role of stock-based incentives in encouraging more voluntary disclosures about firm-specific intangibles and the impact of corporate governance on these incentives.

His findings suggest that stock-based incentives are positively associated with firm's voluntary disclosure about intangibles. Other studies concentrate on determinants of voluntary disclosure investigating factors that influence the level of information content. According to García-Meca & Martínez (2005) the information about intellectual capital is more specific in larger firms, more profitable and with less debt. These kinds of companies are not only more proactive in their disclosure of intellectual capital information, but are also more transparent in their communication by reporting the information on intangibles in precise and convincing way. Corporate-specific factors such as the adoption of IFRS/U.S. GAAP, industry type, and price-to-book ratio are key influences significantly associated with the level of intangible assets voluntary disclosure (Kang & Gray, 2011). Ibadin & Oladipupo (2015) reveal that age of company and the size of audit firm are positively and significantly related to overall voluntary disclosure of intellectual capital. Kumar (2013) indicates that larger firms, firms with greater ownership dispersion, and firms with lower leverage provide more voluntary disclosure of intangibles what confirms previous results obtained by García-Meca & Martínez (2005). Moreover, it appears that domestic culture does affect the voluntary disclosure of intangibles. Also Kang & Gray (2011) emphasize the influence of country-specific factors, including risks associated with economic policies and legal systems, which are found to be significantly associated with the level of intangible assets disclosure.

These results are consistent with the evidence investigating the country-level determinants of mandatory disclosure. According to the findings obtained by Glaum, Schmidt, Street, & Vogel (2013) the strength of the enforcement system and the size of the national stock market are associated with compliance. Tsalavoutas, André, & Dionysiou (2014) extend these findings by providing evidence that enforcement increases compliance because it incorporates audit components. At the country-level determinants a legal system also seems to be important. Companies form a country with a legal system of French origin exhibit lower level of compliance (countries were categorized as having legal system of English, French, Scandinavian or German origin).

At the company-level researchers indicate various factors that have significant influence on mandatory disclosure: industry, leverage, auditor type (Agyei-Mensah, 2019), financial costs (Devalle et al., 2016) and internationalization level (M. de L. R. Da Silva, Gomes Rodrigues, & Muñoz Dueñas, 2011). Azevedo, Oliveira, & Freitas Couto (2019) report that companies' size is the most influencing factor in their analysis, indicating that larger companies disclose information on intangible assets basically to reduce agency costs, political costs related to their public visibility, and in such a way manage the relationship with their relevant stakeholders.

Research sample and Methodology

The research sample is made up of all companies listed on the Warsaw Stock Exchange (Poland) and belonging to IT sector on 30 June 2019 (31 entities). I chose this branch since intangible assets are material for IT companies so I expected to observe the best practice on the market. I examined individual financial statements (IFS) as well as consolidated financial statements (CFS). Financial years 2012 and 2017 were selected to compare changes in the level of intangible assets disclosure. The research sample consists of all available financial statements prepared in accordance with IFRS (79 financial statements). To investigate the change in disclosure level over time, I decided to use matched pairs of observations for the same reporting entity being examined twice: for the financial year 2012 and 2017 (see Table 1).

Table 1: Research sample

	2012	2017	Total	Paired data
Individual FS	17	21	38	16 pairs
Consolidated FS	17	24	41	16 pairs
Total	34	45	79	-

The disclosure index is computed as a ratio between the sum of disclosure scores for checked items and the maximum disclosure level applicable to a particular financial statement. In other words, disclosure index presents the amount of information disclosed by a company as the proportion of information that shall be disclosed in its case, without penalizing for not disclosing information that is just not applicable.

$$DI = \frac{\sum_1^m d_i}{m}$$

where:

i = item analyzed
di = 1, if item i is disclosed and 0 if item i is not disclosed
m = the maximum number of items a company may disclose

There are 34 mandatory items on my checklist but not all these items must be disclosed by every company. For example if a company does not have any intangible assets acquired by the way of a government grant and initially recognized at fair value, items 24-26 on the checklist are not applicable for it. Thus, the maximum number of items this company may disclose is 31. Following the methodology of Glaum et al. (2013), companies were given the benefit of the doubt when it was not possible to determine whether a disclosure was applicable. In fact, there is no financial statement in the sample for which all items have to be disclosed (m = 34).

To minimize errors of overlooking the disclosure each financial statement was reviewed completely with special attention paid to accounting policy and additional notes about intangible assets. As there is no single accounting policy or pattern of financial statement and notes, it is impossible to make such research fully objectively. I assumed however that my approach is similar to the point of view of a diligent financial statement user. To ensure the reliability and to mitigate researcher bias, I checked every financial statement twice, where the second time was about 1 month after the first time.

Results and Discussion

The first step of my research is the analysis of disclosure of items that are regularly presented or omitted in financial statements. The checklist and the frequency of disclosure are presented in Table 2.

Table 2: Mandatory Disclosures of Intangible Assets – Checklist and the Frequency of Disclosure

Item		Disclosure requirement	% of companies disclosing item 2012	% of companies disclosing item 2017
1		distinguishing between internally generated and other intangible assets	32%	56%
2		whether the useful lives are indefinite or finite	76%	78%
3	for assets with definite useful life	the useful lives or the amortization rates used	68%	82%
4		the amortization methods used for intangible assets with finite useful lives	85%	100%
5		the line item(s) of the statement of comprehensive income in which any amortization of intangible assets is included	24%	38%
6	for assets with indefinite useful life	the carrying amount of that asset	30%	21%
7		the reasons supporting the assessment of an indefinite useful life	5%	18%
8		the gross carrying amount at the beginning of the period	100%	91%
9		any accumulated amortization (aggregated with accumulated impairment losses) at the beginning of the period	100%	91%
10		the gross carrying amount at the end of the period	97%	91%
11		any accumulated amortization (aggregated with accumulated impairment losses) at the end of the period	97%	91%
12	a reconciliation of the carrying amount at the beginning and end of the period showing:	additions - internal development	35%	64%
13		additions - acquired separately	77%	80%
14		additions - acquired through business combinations	78%	83%
15		assets classified as held for sale or included in a disposal group classified as held for sale in accordance with IFRS 5 and other disposals	60%	13%
16		increases or decreases during the period resulting from revaluations	na	na
17		increases or decreases during the period resulting from impairment losses recognized or reversed in other comprehensive income in accordance with IAS 36 (if any)	na	na
18		impairment losses recognized in profit or loss during the period in accordance with IAS 36 (if any)	100%	83%
19		impairment losses reversed in profit or loss during the period in accordance with IAS 36 (if any)	67%	100%
20		any amortization recognized during the period	100%	93%

21		net exchange differences arising on the translation of the financial statements into the presentation currency, and on the translation of a foreign operation into the presentation currency of the entity	50%	33%
22		other changes in the carrying amount during the period	100%	90%
23		a description, the carrying amount and remaining amortization period of any individual intangible asset that is material to the entity's financial statements	na	100%
24	for intangible assets acquired by way of a government grant and initially recognized at fair value	the fair value initially recognized for these assets	na	na
25		their carrying amount	na	na
26		whether they are measured after recognition under the cost model or the revaluation model	na	na
27		the existence and carrying amounts of intangible assets whose title is restricted	26%	29%
28		the carrying amounts of intangible assets pledged as security for liabilities	100%	na
29		the amount of contractual commitments for the acquisition of intangible assets.	100%	100%
30	revaluation model	the effective date of the revaluation	na	na
31		the carrying amount of revalued intangible assets	na	na
32		the carrying amount that would have been recognized had the revalued class of intangible assets been measured after recognition using the cost model	na	na
33		the amount of the revaluation surplus that relates to intangible assets at the beginning and end of the period, indicating the changes during the period and any restrictions on the distribution of the balance to shareholders	na	na
34		the aggregate amount of research and development expenditure recognized as an expense during the period	30%	18%
35	*not required*	*a description of any fully amortized intangible asset that is still in use*	*0%*	*2%*
36		*a brief description of significant intangible assets controlled by the entity but not recognized as assets*	*3%*	*2%*
Disclosure Index			**67%**	**69%**

It may be observed that companies do not use revaluation model while subsequent measurement of intangible assets. This remark confirmed worldwide findings (Agyei-Mensah, 2019; Christensen & Nikolaev, 2013; Kumar, 2013; Oliveira, Rodrigues, & Craig, 2010).

None of the sampled companies is obliged to disclose information about intangible assets acquired by way of a government grant and initially recognized at fair value. Most commonly IT companies benefit by various grants but these are usually by way of cash for financing of research and development activities.

In regard to item 23 I assume that individual material intangible asset is only this one which is recognized separately in a statement of financial position. Only one company recognized such a position disclosing necessary additional information.

There are some items with complete or almost complete disclosure in all financial statements analyzed. Commonly companies disclose the amortization method used (always straight-line), the gross carrying amount and any accumulated amortization at the beginning and at the end of the period.

Some concern arouses the low compliance level of items 6-7 for intangible assets with indefinite useful lives. As indefinite useful life may be considered as an earnings management tool, companies shall explain it very carefully.

It is not the case in my research. While companies disclose accounting policy regarding intangible assets with indefinite useful lives, they rarely indicate their nature, carrying amounts and essentially the reasons supporting the assessment of an indefinite useful life.

It appears that entities just rewrite IAS 38 requirements, often without adapting them to their own specific situation. Such behavior limits the usefulness of a financial statement as its user is not able to assess the potential of intangible assets of a company appropriately.

In the next step I computed the disclosure index (DI) for each financial statement analyzed. Descriptive statistics are presented in Table 3. It indicates that the average compliance level is 68% with only little improvement in 2017 compared to 2012 (69% and 67%, respectively). Considering the rule of giving the benefit of the doubt, it means that the companies report at most only 68% of required information being only partially compliant with IAS 38 disclosure requirements. It confirms previous findings of considerable non-compliance with accounting standards for companies claiming to have adopted them (Agyei-Mensah, 2019; Glaum et al., 2013; Gorgan & Gorgan, 2014). There was no single financial statement with all required information disclosed.

Table 3. Disclosure index - descriptive statistics

DI_2012		DI_2017		DI_Total	
Mean	0,6731	Mean	0,6893	Mean	0,6824
Median	0,6754	Median	0,7222	Median	0,7059
SD	0,1531	SD	0,1781	SD	0,1670
Skewness	-0,1140	Skewness	-1,1766	Skewness	-0,8034
Min	0,4118	Min	0,2000	Min	0,2000
Max	0,9333	Max	0,9375	Max	0,9375
N	34	N	45	N	79

To examine how financial statements of a particular reporting entity changed in 2017 compared to 2012, I use paired samples tests preceded by Shapiro – Wilks normality test. Table 4 give the descriptive statistics with more details and Table 5 summarizes the results.

Table 4. Change in DI - descriptive statistics

Change_IFS		Change_CFS		Change_Total	
Mean	0,0430	Mean	0,0585	Mean	0,0508
Median	0,0183	Median	0,0433	Median	0,0309
SD	0,1209	SD	0,1599	SD	0,1397
Skewness	0,6365	Skewness	0,7221	Skewness	0,7244
Min	-0,1731	Min	-0,2227	Min	-0,2227
Max	0,3382	Max	0,4222	Max	0,4222
N	16	N	16	N	32
DI_2017>DI_2012	10	DI_2017>DI_2012	10	DI_2017>DI_2012	20
DI_2017<DI_2012	4	DI_2017<DI_2012	5	DI_2017<DI_2012	9
DI_2017=DI_2012	2	DI_2017=DI_2012	1	DI_2017=DI_2012	3

where: Change = DI_2017 – DI_2012

I compare the disclosure level separately for individual and consolidated financial statements (IFS and CFS, respectively) and then for all paired financial statements. The average change in disclosure index is about 5pp, indicating some improvement in disclosure level of intangible assets during the research period. In most cases entities report more information in 2017 than in 2012. The change is statistically insignificant separately for IFS and CFS. Nonetheless, for paired financial statements altogether the change is marginally significant confirming slight increase in disclosure level about intangible assets within given research period.

Table 5. Significance of difference and change in DI

Variable	N pairs	Shapiro-Wilk's W statistic	p_{s-w}	Result: Are the differences normally distributed? α=0,05	Chosen test	Statistic	p	Result: Are the differences significant? α=0,05
Change_IFS	16 (14*)	0,9474	.4493	Yes	Student's	1,4212	.1757	No
Change_CFS	16 (15*)	0,9380	.3256	Yes	Student's	1,4643	.1638	No
Change_Total	32 (29*)	0,9432	.0923	Yes	Student's	2,0553	.0484	Yes

** number of differences observed between variables; for the remaining observations DI was the same in 2017 compared to 2012.*

These findings are consistent with some other research. Ragini (2012) proves the significant increase in disclosure level of intangibles (mandatory and voluntary disclosures) in three countries under review: Japan, US and India between 2001 and 2005 (about 8pp for Japanese, 7pp for US, 5pp for Indian companies). Gorgan & Gorgan (2014) find some improvement in DI without checking its significance. However, they indicate that the intangible assets disclosure level is almost constant every year (2010-2012), proving the fact that companies tend to maintain the disclosure of the same information from one year to another and even to copy the same sentences without adapting them to that particular year. These findings support those previously observed by Teodori & Veneziani (2010). Cuozzo et al., (2017) in their structured literature review identify no recent study demonstrating significant trend towards more voluntary or regulatory intellectual capital disclosure in publicly available reports. Some other researchers, although the research period comprises a few years, do not analyze the change in disclosure index over time (M. de L. R. Da Silva et al., 2011). Overall, research findings seem to confirm that there is only little change in the level of disclosure about intangible assets. Some results suggest improvement and other the opposite. However, the fact remains that contrary to the stakeholders' expectations there is no great increase in compliance level even if some improvement is noticed.

Conclusion

There are several practical implications of this study for academics, practitioners and standard setters. The study contributes to the accounting literature on mandatory disclosure and reporting behavior. The results suggest that entities are reluctant while disclosing information about intangible assets. They rewrite information from one year to another and from IAS 38 to the accounting policies without adapting it to their specific. Accounting policy is very often excessively complicated because it includes all possible choices, even though they do not apply to a particular company. As disclosure reduces information asymmetry it is important to maintain high quality of it. Auditors should pay more attention to checking the disclosures. The implications for the standard setters are twofold. Firstly, it should be noted that the revaluation model is not used at all. It has to be considered if it is needed at all, and if so, maybe the requirement of referring to an active market is too strict? Either way, it seems that the current revaluation model unnecessarily complicates the accounting standards. Secondly, as the disclosure requirements are more and more detailed, there is considerable concern about the disclosure overload (Radin, 2007; Saha et al., 2019). Instead of principles-based accounting, IFRS unintendedly transform towards rules-based standards. It should be a priority to make financial statements more user-friendly and at the same time to create stronger enforcement mechanism (for example during the external audit) to encourage companies to expand their disclosure policies.

Research limitations are related to some subjectivity in determining whether a particular disclosure requirement is fulfilled or not. To measure the DI I used a manual technique of content analysis which is related to inherent subjectivity. To limit this concern I analyzed every financial statement twice (the second time 1 month after the first one). Another limitation is relatively small sample size from only one industry – IT. Research findings may not be observed in other industries and samples.

Future research might be conducted within longer research period as well as on larger sample size. This research considers neither determinants of disclosure nor the impact of disclosure on financial market which is the relevant field of research.

Abstract

The mobile adoption in this study also known as m-learning refers to the use of personal electronic gadgets through the social media and interactions in learning process. The use of new technologies influences young generation, and learning through multimedia and web technology effectively enhances individualised learning which is becoming a popular alternative for formal education. The objective of this paper is to identify the significant determinants of the students' behavioral intention to adopt mobile learning based on the Unified Theory of Acceptance and Use of Technology model. The data was obtained from 300 students through a survey questionnaire. The questionnaire developed includes two sections, the first section consists of the demographic information of the respondents while the second section measures the factors namely the social influence, performance expectancy, effort expectancy, facilitating conditions, attitude and the students' behavioral intention to adopt mobile learning. Partial Least Squares structural equation modelling was used for the data analysis. The present study substantiates the importance of attitude on the behavioral intention to adopt mobile learning (m-learning). The findings revealed that facilitating conditions and social influence have a significant impact on the attitude towards m-learning; however, performance expectancy and effort expectancy does not have a significant impact on the attitude. The study provides prominent implications for the future research and learning apps development.

Keywords: Mobile learning, adoption, attitude, social influence, behavioral intention.

Introduction

Learning process is universal but varies from country to country. In the modern world, several new technological methods are used in learning. E-learning initiates that the learning materials are delivered by the instructor. The traditional, classroom-based teaching is replaced by the technology-based teaching (Chang, Shen & Liu, 2014). As the technology develops, new techniques are developed to suit new technology. Growth in new technology and usage by consumers increases the demand for mobile devices and usage. Mobile devices include smartphone and tablet computer. Learning through these devices can be classified as mobile learning. The mobile adoption in this study also known as m-learning refers to the use of personal electronic gadgets like smart phone, MP3 players, notebook, and tablets which uses social media and interactions for learning purposes (Athanasios & Pantelis, 2017). The use of new technologies influences young generation, and learning through multimedia and web technology effectively enhances individualised learning which is becoming a popular alternative for formal education.

Advantages of using mobile learning (m-learning) include its use anywhere, anytime by anybody, and the users can use different electronic supporting system. M-learning is developing fast and offers great value to learners (Bob Little, 2012). The use of mobile phones has gained popularity among young adults to initiate and maintain social

Cite this Article as: Ajitha ANGUSAMY, Jayanty KUPPUSAMY, Kavitha BALAKRISHNAN and Shi Jie, LIM "An Empirical Study on Attitude and Behavioral Intention to Use Mobile Learning" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

relationships (Santhalingam et al., 2011). Mobile learning has attracted the higher education organizations and has been accepted within higher education (Tan et al., 2014). Earlier study suggests that university students generally have a positive attitude towards the use of mobile devices in education and mobile learning (Liaw & Huang, 2015). Mohammad (2016) identified the factors that has significant impact on mobile learning acceptance among the higher education students and concluded that positive attitude has a significant impact on the behavioral intention to use m-learning, Crompton and Burke (2018) also provided a systematic review on the use of mobile learning in higher education. Among the research conducted on m-learning, 50% of the studies are from Asia followed by North America (21%), Europe and Australia (13%) and Africa (3%). The studies also reveal that out of 72 researches conducted all over the world, only one research is conducted in Malaysia. This indicates a need for research on m-learning in the Malaysian context, and stimulated the interest in the current study.

The main objective of this study is to determine the significant factors affecting students' behavioral intention to adopt mobile learning based on the Unified Theory of Acceptance and Use of Technology (UTAUT) model. The proposed model includes factors like performance expectancy, effort expectancy, facilitating conditions, social influence, attitude and behavioral intention.

Literature Review

Numerous models have been developed in the literature to study the effect of users' attitude and intention to adopt the latest technologies or information systems (Saroia & Gao, 2018). Technology Acceptance Model (TAM) by Davis (1989), is the key model to understand the predictors of behavior towards acceptance of the technology (Marangunić & Granić, 2015), followed by Theory of Planned Behavior (TPB) (Ajzen, 1991), Innovation Diffusion Theory (IDT) by Rogers (1995), and the Unified Theory of Acceptance and Use of Technology (UTAUT) by (Venketesh et al, 2003). Later these models are also applied in the education context. Studies that used TAM and modified models are Alharbi & Drew (2014), Hsu and Chang (2013) and Park et al., (2012) Khanh and Gim (2014). In particular, studies that addressed m-learning using UTAUT models include Liu (2008), Lowenthal (2010), Iqbal and Qureshi (2012), and Abu-A-Aish (2013). These studies revealed that performance expectancy, effort expectancy, social influence are significant factors of behavioral intention of m-learning acceptance.

The usefulness of m-learning, such as real time access, anytime, anywhere by anybody at their convenience, may improve the individual's learning efficiency, and improve their attitude towards learning. Earlier studies demonstrated the relationship between attitude and behavioral intention (Yu & Yu, 2010, Gan et al, 2017). Attitude is found to positively affect behavioral intention. The learner should have consistent attitude and eagerness towards learning and have state of mind to receive such learning materials. Attitude towards use of mobile apps depends on emotion, familiarity, frequency and eagerness, awareness of the importance of such apps and usability of the devise (Harrison et al. 2013). Student perceived mobile apps as a good source of fun and pleasures (Yang, 2013). Therefore, using the apps devise can help in achieving and increasing the output. College students are increasingly using mobile devices in their studies in or outside the classroom (Reychav et al, 2015) because mobile learning allows better flexibility and joy for the learners beyond their regular school hours (Anshari et al, 2016).

Performance Expectancy (PE) is defined as "the degree to which using a technology will provide benefits to consumers in performing certain activities" (Venkatesh, et al, 2012) or performance expectancy is defined as "the degree to which an individual believes that using the system will help him or her to attain gains in job performance" (Venkatesh et al, 2003; Kong et al, 2013). Users are ready to pay for downloading new apps if the apps bring them values like improved performance in their studies (Kang, 2014). Studies by Ju et al, (2007), Jairak et al., (2009), Khanh and Gim (2014), Sario and Gao (2018) found PE to be a significant factor of attitude towards m-learning.

Effort expectancy is "the degree of ease associated with the use of the system" (Venkatesh et al, 2003). An information system that is being used and perceived by people on the level of how easy it can be used is Effort Expectancy (Samuel & Hillar, 2014). From the previous model, the three constructs on the concept of effort expectancy are complexity, usability and also perceived usability relate. The effort expectancy is likely to most strongly affect behavior during the initial and early stages of mobile use of academic or library content, and is expected to decline over time as user gain more experience (Jambulingam, 2013). Li et al., (2008), Gao et al., (2014), Saroia and Gao (2018) in their studies found a significant relationship between effort expectancy and attitude.

The degree of user's perception towards the support and resource available in performing a behavior refers to facilitating conditions (Venkatesh et al, 2003). Iqbal and Qureshi (2012) found a significant relationship between facilitating conditions and attitude; however, Jairak et al. (2009) found that facilitating conditions does not have a significant effect on the attitude. Furthermore, past experiences and age can influence facilitating conditions on

usage. Thus, the more the experience of using the mobile learning, the stronger the effect. If no performance expectancy and effort expectancy are presented, facilitating conditions is also an important predictor.

Social value can be inferred as a person or an individual's motive of buying and using a product or even a service which depends on how they wish to see themselves or others. The individuals can disclose their self-image openly to others through their product purchasing and usage. Both old and young generations use mobile apps and consider them as trendy, and they use mobile apps to promote their self-image. Social value can be generated through friends or even through family members of the users by adopting mobile apps for learning purposes. An individual will be influenced by his/her friends or family members when they communicate with each other (Guo, 2014). By joining a social community, people will be influenced by others or even influence others of their social value. Social influence has been considered as a crucial element for decision making in sociology and behavioral science.

Fishbein and Ajzen (1975), who are the founder of the first behavior intention idea, describe intention as "the motivational factors assumed to capture and influence behavior". Behavioral intention is individual's intention to perform a given act which can predict corresponding behaviors when an individual act voluntarily (Nurdan & Nandy, 2015). According to Naincie et al. (2016), the intention of students to use mobile apps to learn a language through mobile apps is affected by their perception of ease and usefulness of mobile apps. This perspective then directly influences their behavioral intention of using mobile apps for learning.
Based on the above studies, the following hypotheses are developed.

H_1: Attitude has a positive impact on behavioral intention towards m-learning.
H_2: Performance Expectancy has a positive impact on the attitude towards using m-learning
H_3: Effort Expectancy has a positive impact on the attitude towards using m-learning.
H_4: Facilitating conditions has a positive impact on the attitude towards using m- learning.
H_5: Social Influence has a positive impact on the attitude towards using m-learning.

Methodology

Convenience sampling method was used to collect the data through survey questionnaire. The target population were the university students from different education levels namely foundation, diploma, undergraduate and postgraduate. The target respondents come from all over the country and consist of different races, backgrounds and religions to closely well represent Malaysia's population. A total of 300 responses were obtained. The questionnaire developed includes two sections: the first section consists of the demographic information of the respondents, while the second section measures the factors namely the social influence, performance expectancy, effort expectancy, facilitating conditions, attitude and the students' behavioral intention to adopt mobile learning. Partial Least Squares structural equation modelling was used for the data analysis.

Data Analysis and Findings

Demographic Profile

The results of the data analysis show that out of 300 respondents, 55% of the respondents were females and 45% of them were males. Majority of the respondents (64%) belonged to the age group of 22 and above, followed by 30% in the age group of 18 to 22, and 6% of the respondents in the age group of 13 to 17. 57% of the respondents were Chinese, 31% Malays and the remaining 12% belonged to the Indian ethnic group. In terms of education level, most of the respondents were pursing their Bachelor degree students (67%), followed by diploma and pre-university with 33% each, and 11% of the respondents were postgraduate students.

Structural Equation Modelling

Partial Least Squares structural equation modelling was used to test the hypotheses. Data analysis using the Smart-PLS was conducted in two stages. In the first stage, the measurement model was tested for its convergent and discriminant validity in order to ensure that the measured variables in the model are reliable. Then, the model was assessed to identify how well the variables were associated with one another.

Measurement Model

Values as shown in Table 1, the obtained Cronbach's alpha coefficient is more than 0.7 for all factors; therefore, the scales are deemed to be acceptable. The results shown in Table 1 indicate that the factor loadings of all the items are more than 0.7, except EE2 (0.665). However, the item is retained due to its contribution to the content validity. Two items FC3 and SI5 with standardised factor loading less than 0.7 were deleted. The AVE obtained are in the range of 0.586 and 0.697, and the CR values are within the range of 0.85 to 0.92. Thus, the convergent validity is adequate as suggested by Hair et al., (2017). Discriminant validity is assessed by using the Fornell-Larcker (1981) criterion and Heterotrait-monotrait (HTMT) (Henseler et al., 2015). The results show that all the variances extracted by the constructs (diagonal values) are more than the correlation coefficients between the constructs (off-diagonal values) indicating an adequate discriminant validity. Furthermore, the results shown in Table 3 fulfil the criterion of $HTMT_{0.9}$(Gold et al, 2001), and the $HTMT_{inference}$ that does not show the value of 1 in the confidence interval confirms the discriminant validity.

Table 1: Measurement Model

6. Social Influence	0.704 $CI_{0.9}$ (0.63,0.77)	0.692 $CI_{0.9}$ (0.62,0.76)	0.481 $CI_{0.9}$ (0.33,0.62)	0.699 $CI_{0.9}$ (0.59,0.78)	0.856 $CI_{0.9}$ (0.79,0.90)	

Structural Model and Hypotheses Testing

Structural model developed using the Smart PLS is shown in Figure 1. Bootstrapping procedure with a resample of 5000 as suggested by Hair et al., (2017) was used to test the hypotheses and the results are presented in Table 4.

Fig. 1: Structural Model

The R^2 value for behavioral intention is 0.534 and for the model to predict the attitude is 0.532, which means that 53.4% of the variation in the behavioral intention can be explained by the attitude, and 53.2% of the variation the attitude can be explained by the variations in the predictors. Since the coefficient for the attitude is positive and p-value less than 0.001, attitude has a positive impact on the behavioral intention to use mobile learning. Furthermore, social influence and facilitating condition have a positive effect on the attitude, while the performance expectancy and effort expectancy does not have a significant impact on the attitude. Moreover, the effect size f^2 for all the

significant variables are more than 0.02. Predictive relevance for the model is assessed using the blind folding procedure. Since the Q^2 for both the models are greater than zero as suggested by Hair et al., (2017), the models have predictive relevance.

Table 4: Results of Partial Least Square

H	Relationship	Beta	t-value	P Values	Decision	R^2	Q^2	f^2	VIF
H1	Attitude → Behavioral Intention	0.729	20.819	0	Supported	0.534	0.353	1.135	1

H5	Social Influence → Attitude	0.318	4.684	0	Supported	0.532	0.363	0.1	2.171

Discussion and Conclusion

In achieving the objective of the mobile learning in educational programme, it is important to understand the dimensions that affects the students' attitude and behavioral intention with regards to mobile learning. The current study intends to identify the effect of performance expectancy, effort expectancy, facilitating conditions and social influence on the attitude and the impact of attitude on the behavioral intention towards mobile learning among higher education students. Attitude is found to have a significantly positive impact on behavioral intention towards mobile learning. The findings are consistent with the studies by Yu and Yu (2010), Gan et al., (2017), Saroia and Gao (2018). This shows that students with positive attitude are more willing to adopt the mobile learning.

The results indicate that performance expectancy does not have a significant impact on the attitude towards m-learning contradicting the studies by Jairak et al., (2009), Ngo and Gim (2014), Saroia and Gao (2018). This shows that the students in this study intend to use m-learning not because they think it will help them to perform better. Another factor that does not have significant effect on the attitude is the effort expectancy. The findings are inconsistent with the studies by Li et al, (2008), Gao et al., (2014), Saroja and Gao (2018); however, quite similar to findings by Khanh and Gim (2014). The findings show that technology restrictions do not influence the attitude towards m-learning.

Facilitating conditions found to have a significant impact on the attitude in contrast to the findings of Jairak et al's (2009) study. Although the performance expectancy and effort expectancy are found in the model, they are found to have insignificant effect on the attitude; findings show that facilitating conditions are important in order for the students' attitude towards m-learning. Another factor that has a significant impact on the attitude is the social influence. The findings are consistent with the studies by Jairak et al., (2009), further supported by Abu-Al-Aish (2013) and Guo (2014), which indicates that social value has an influence on the adoption of mobile aps and other technical devices.

Through this study it can be concluded that facilitating conditions and social influence have a positive impact on attitude towards m-learning, whereas, performance expectancy and effort expectancy do not have a significant impact on the attitude towards m-learning. Furthermore, this study also reveals that attitude has a significant positive impact on the behavioral intention towards m-learning. The implications of the study illustrate that due to the exposure of the modern technology, students do not consider performance expectancy and effort expectancy as important factors for their attitude towards m-learning which in turn does not have any impact on their behavioral intention. Since facilitating conditions and social influence play a vital role in the attitude, academics and university management should motivate the students and also provide support in terms of technical assistance and ensure that students can use m-learning efficiently. This study is carried to gauge the students' perspective, hence, future studies may be done on teachers' perspective. Since not many studies have been carried out in Malaysia, more research can be done by including other variables such as academic relevance, students' academic performance and personal innovativeness.

Abstract

Concern for the environment has been growing over the years. One area of concern is the awareness towards green product. A number of studies have been done on the green product purchase decision. However, limited studies have been done from the Malaysian perspective. Therefore, the current study's purpose is to examine which factors influence consumers' green product purchase decision of Malaysian consumers. The respondents are Malaysian adults and data was collected from 181 respondents. The factors studied include social influence, green product experience, supporting environmental protection, drive for environmental responsibility and attitudes toward green purchasing. The result indicates all except for supporting environmental protection, influences the green products' purchase decision. Therefore, marketers of green product should focus on these factors in order to encourage increase in purchase of green products.

Keywords: Purchase Decision, Social Influence, Green Product Experience, Environmental Protection.

Introduction

Studies related to environment such as green product, ecological product, environmental sustainability has increased over the years since the concern for the environment is more widespread now. According to Braga Junior et al. (2014) the current consumerism of modern society affected the industry, retailers and consumers. Previous studies were done in Brazil (Braga Junior et al., 2014), India (Mishal et al., 2017; Bukhari et al., 2017; Kumar & Ghodeswar; 2015), Finland (Tarkiainen & Sundqvist, 2005), Switzerland (Tanner & Kast, 2003), Hong Kong (Lee, 2009; 2010). Comparative studies are also done such as Maram (2007) who did an East-West comparison study, Chan and Lau (2002) who did a comparative study between American and Chinese consumers. The studies in Malaysia include Mohd Nazri et al. (2016), Hasan and Ali (2015), (Nizam, 2011), (Ismail, 2015) and (Zakersalehi, 2012).

This shows the studies done is limited from a Malaysian context compared to the importance of the area of research. Therefore, this research will study on consumers' green product purchase decision and looking into factors such as social influence, green product experience, supporting environmental protection, drive for environmental responsibility and attitudes toward green purchasing to study on their influence towards consumers' green product purchase decision.

Literature Review

Researchers in green marketing research are focused in studying on green consumers decision in purchasing green products. Those who purchase green products are referred to as green consumers. Therefore, when consumers consider how their consumption pattern impact the environment and due to that are willing to change their behaviour

on purchasing, these consumers are called green consumers (Luzio & Lemke, 2013; Ritter et al., 2015). Green purchase decision is influenced by factors such as values, attitudes, information among others (Kumar & Ghodeswar, 2015). Albayrak et al. (2013) indicated that green purchase decision is related to supporting green companies, involves looking into environmental issues in purchasing green products as well as conform to the social condition. In addition, green purchase behaviour is also looking into the adoption of sustainable consumption practices (Gadenne et al., 2011; Young et al., 2010) and possibility of spending more to purchase products (Hasan & Ali, 2015*;* Essoussi & Linton, 2010).

Social Influence

According to Wahid (2011) social influence is proxy of subjective norm. Due to the impact of social influence there will be difference on how an individual acts or practices (DeLamater, 2010). Among the groups said to have social influence are companions, family, teachers, managers, proficient associates, specialists and the media (Klobas, 2001). Similar opinion is provided by Maram (2007). This is because according to Qader and Zainuddin (2011) various information regarding the product are received and shared during the interaction process. The evaluation on the product value is done continuously based on the input in the social system where comments and opinions are posted (Peattie, 2010; Tarkiainen & Sundqvist, 2005). Based on the research of Barr and Gilg (2006) and Young et al. (2010), most of the consumers in developed country have the perception on the need to adopt green lifestyle as the way to life now. Thus, through deciding to purchase green product indicates their self-image as well as their concern on the environment which also conform to the perception socially (Jamal & Goode, 2001; Qader & Zainuddin, 2011). However, Mohd Nazri et al. (2016) found social circle's relationship with green product purchase decision in Malaysia which is a developing country is insignificant. Nevertheless, a number of studies found that the social influence will affect the consumer's green product purchase decision (Kong et al., 2014; Zhu, 2013). Based on this, the following hypothesis is formulated:

H1: Social influence has significant effect on consumers' green product purchase decision.

Green Product Experience

Green Product Experience refers to learning and gaining knowledge about the product which includes ingredients, impact of product on the environment, functionality of the product among others (Laroche et al., 2001). This is supported by (Luzio & Lemke, 2013; Ritter et al., 2015). According to Khare (2014) friends also share among themselves their knowledge and the information they have regarding the green products. In addition they also learn from each other. This is also reported by an earlier study by Cheah and Phau (2011). Chen (2010) and Mobley et al. (2010) pointed out that one of the reasons that consumers purchase green products is because of their experience and knowledge about them. According to Cegarra-Navarro and Martinez (2010), due to the learning process, consumers are able to evaluate the product and know about the environmental benefits of green product which makes them to have better predisposition on it. All this effects their purchase decision, make the right choice and thus, are willing to pay higher for green products (Zhou et al., 2014). Other studies that support the that green product experience has a positive relationship with the purchase behavior are D'Souza et al. (2006), Kim and Chung (2011) and Oliver and Lee (2010). Kumar and Ghodeswar (2015) and Bukhari et al. (2017) found that green product experience has significant impact on green purchase decision although Mohd Nazri et al. (2016) found the results to be insignificant between the two factors. Therefore, the following hypothesis is developed:

H2: Green product experience has significant effect on consumers' green product purchase decision.

Supporting protection of environment

Being environmental friendly and conscious of the environmental sustainability is referred as being supportive of the protection of the environment (Barr & Gilg, 2006) Gadenne et al. (2011) pointed out that consumers become environmentally friendly in their purchase decision where they are protective of the environment. An earlier research by Lee (1990) states that consumers search for attributes that are environmentally friendly and make a difference towards environmental protection. The attributes can be in terms of product design or usage. Escalas and Bettman (2005) further indicated the products should not cause harm to animals or nature, are recyclable and causes less pollution when used. They recognise how green products play a role in increasing the quality of the environment and in turn purchase and own green products. According to Pickett-Baker and Ozaki (2008) the consumers are able to link that higher price of green products since there is will be environmental benefits through their usage. They see their lifestyle is connected to green product in a way that is environmentally friendly. According to (Han et al., 2010) consumers shows their predisposition on being environmental supportive through actual purchase of environmentally friendly products. This occurs when there is a preference on green products compared to the non-green products. Both Kumar and Ghodeswar (2015) and Bukhari et al. (2017) found supporting the protection of the environment influences the green product purchase decision. Therefore, the following hypothesis is developed:

H3: Supporting protection of environment has significant effect on consumers' green product purchase decision.

Drive for environmental responsibility

Drive for environmental responsibility refers to the commitment of customers on issues related to environmental protection. This is in addition to individual activities which can improve the environmental quality (Kumar & Ghodeswar, 2015). According to Gadenne et al. (2011), consumers know the need of their reasonability towards protection of the environment. Failure to do so will negatively affect all living being. Lee (2008, 2009) and Griskevicius et al. (2010) pointed out consumers will be emotionally involved in environmental protection and engage in conservation of the environment respectively. Kumar and Ghodeswar (2015) and Bukhari et al. (2017) found that drive for environmental responsibility influence green purchase decision. Therefore, the following hypothesis is developed:

H4: Drive for environmental responsibility has significant effect on consumers' green product purchase decision.

Attitudes toward green purchasing

Attitude based on the Theory of Planned Behaviour (TPB) can shape the actual behavioural action (Ajzen, 1991). Attitude refers to activities' consumer take in their behavior towards purchase (Ajzen, 2001). It is a quick evaluation of a psychological object which can be positive or negative. The results of the studies on attitude are mixed. Numerous studies are done to identify the role of attitude towards that green product buying behavior (Arvola et al., 2008; Smith & Paladino, 2010; Tarkiainen & Sundqvist, 2005). It is found the relationship is weak in terms of the attitude of consumers toward purchasing green products as well as the actual purchase behaviour (Tanner & Kast, 2003; Vermeir & Verbeke, 2008; Wheale & Hinton, 2007). Mishal et al. (2017) indicate that the attitude relationship towards green behavior is significant but the relationship with purchase behaviour is insignificant. However, green purchase attitude eventually leads to green purchase behaviour and it said that for a better understanding there is a need to extent the study in other parts of the world (Chen, 2007; Chan & Lau, 2002). Therefore, there is a need to study from a Malaysian context. Therefore, the following hypothesis is developed:

H5: Attitude towards green purchasing has significant effect on consumers' green product purchase decision.

Methodology

The research design of this study is the quantitative method. The respondents of this study focused on Malaysian adults. Convenience sampling is used to select the respondents. The instrument used to gather the data is through the questionnaire survey. The questionnaire is divided into three sections which are the demographic profile of the respondents, their view on the factors studied such as social influence, green product experience, supporting environmental protection, drive for environmental responsibility and attitudes toward green purchasing and finally on the dependent variable which is green products' purchase decision. The research framework is presented in Figure 1. The questions were adapted mainly from past literatures; Kumar and Ghodeswar (2015), Taylor and Todd (1995) and Wang (2014). A total 200 questionnaires are distributed to the target respondents and 181 questionnaires were received. The method of face-to-face is utilized for it and this technique would be able to reduce the doubts of the respondents. Data collect is analysed through the SPSS software and multiple regression was used to test the hypotheses.

Figure 1: Research Framework

Results

The demographic profile of respondents is presented in Table 1. Out of the total respondents of 181, 58% are male compared to 42% female. Majority of the respondents are in the age group of 21-30 years old (54.1%), followed by 31-40 years old (21%) while the lowest is from the age group of 51 years and above (1.7%). Respondents who are single is more than those who are married, which is 74% and 23.2% respectively, while those who are divorced represents 2.8%. In terms of ethnicity, the highest number are Chinese (52.5%) followed by Indian (27.6%) and Malay (17.1%) and others (2.8%). Respondent in the Bachelor level are the majority at 64.1%, followed by Diploma (25.4%).

Table 1: Profile of respondents

Demographic Characteristics	N	%
Gender		
Male	105	58
Female	76	42
Age		
Below 20	28	15.5
20-30	98	54.1
31-40	38	21.0
41-50	14	7.7
51 and above	3	1.7
Marital Status		
Single	134	74
Married	42	23.2
Others	5	2.8
Race		
Malay	31	17.1
Chinese	95	52.5
Indian	50	27.6
Others	5	2.8
Education		
SPM	6	3.3
Diploma	46	25.4
Bachelor	116	64.1
Masters	10	5.5
Others	3	1.7

Multiple regression analysis is used to test the hypotheses. The result is presented in Table 2. The r-square value is 0.552 which means that 55.2% of the total variation in consumer's green product purchase decision is explained by variables tested such as social influence, green product experience, supporting environmental protection, drive for environmental responsibility and attitudes toward the green purchasing. In addition, the F value is 43.046 and the significance value for F-test is 0.000. This indicates that the overall model is significant. This also means that at least one of the variables is significant in this study. The variables that are found to influence green product purchase decision are social influence (B= -314, p value =0.004), green product experience (B=0.169, p value =0.038), drive for environmental responsibility (B=0.326, p value =0.022) and attitudes toward the green purchasing(B=0.436, p value =0.000). This means H1, H2, H4 and H5 are supported. However, supporting environmental protection was found not to influence green product purchase decision. Therefore, H3 is not supported.

Table 2: Results of Multiple Regression Analysis

R = 743	R square=0.552	Adjusted R Square= 0.539	F = 43.046	Sig value = 0.000
Variables	B	t	Signficance	Results
Constant	.528	2.457		
SI	-.314	2.889	-.004*	Supported
GPE	.169	2.096	.038*	Supported
SPE	.116	0.849	.397	Not Supported
DER	.326	2.309	.022*	Supported
ATG	.436	3.646	.000*	Supported

Dependent variable: Green Product Purchasing Decision

Social influence (SI), Green product experience(GPE), Supporting protection of environment (SPE), Drive for environmental responsibility(DER), Attitudes toward the green purchasing(ATG).

Discussion and Conclusion

Research on environmental issues such as green marketing has increased over the years. Due to such attention, the need to identify the factors influencing green product purchase decision have motivated researchers to study on the area. This research's objective was on identifying the factors influencing consumers' green product purchase decision in Malaysia. Factors such as social influence, green product experience, supporting environmental protection, drive for environmental responsibility and attitudes toward green purchasing are considered and tested on their influence towards consumers' green product purchase decision.

The result found that out of the five factors study, four factors (social influence, green product experience, drive for environmental responsibility and attitudes toward green purchasing) influence consumers' green product purchase decision. Social influence has been found to have a significant negative relationship with consumer's green product purchase decision. This finding is different from another study done by Mohd Nazri et al. (2016) in Malaysia where the relationship is found to be insignificant. Although majority of the studies found social influence to have relationship with the consumer's green product purchase decision (Kong et al., 2014; Zhu, 2013), there are a few studies that showed societal norm to have negative influence with green purchase behavior (Connell, 2010; Lee, 2011). This is probably because consumers are not totally dependent on the view from the social groups. In fact, the more it is being said on the product, the less the consumers take into consideration to influence their purchase decision on the green product.

The findings of the study found the relationship between green product experience and consumer's green product purchase decision is positive and significant. Therefore, green product experience significantly influences the consumer's green product purchase decision. According to Cegarra-Navarro and Martinez (2010), consumers are able to evaluate the product and know about the environment benefits of green product due to the learning process. The finding of the study is line with previous studies by Kumar and Ghodeswar (2015) and Bukhari et al. (2017) where it is found that green product experience has significant impact on green purchase decision. In terms of drive for environmental responsibility, the study found there is a significant relationship between drive for environmental responsibility and consumer's green product purchase decision. Therefore, drive for environmental responsibility significantly influences the consumer's green product purchase decision. Previous studies that support the current study finding include Kumar and Ghodeswar (2015) and Bukhari et al. (2017) who found that drive for environmental responsibility has significant impact on green purchase decision. There is also a significant relationship between attitudes toward green purchasing and consumer's green product purchase decision. This means attitudes toward green purchasing does significantly influence the consumer's green product purchase decision. The finding of the study is supportive of views by Chen (2007) Chan and Lau (2002) where green purchase attitude will eventually lead to green purchase behaviour.

However, there is a no significant relationship between supporting environmental protection and consumer's green product purchase decision. This result of this research is in accordance with the finding by Mishal et al. (2017) where the consumers' environmental consciousness does not lead to green purchase intention. Earlier research by Kuhl and Beckman (1985) found cognition and behaviour's link is weak. According to them the behaviour may not be

consistent with beliefs, values, attitudes or intentions. According to Braga Junior and Silva (2013) and Braga Junior et al. (2014) showing concern for the environment is not related to green consumption or purchase of green products.

This study has contributed to the existing literature. It is critical that the firms that is involved in green products to focus on enhancing their social media to encourage green product purchase decision. However, the firms must ensure the content and the reputation of the social influencer can attract the target customers. Using reputable experts or personalities can assist customers to relate green products with environmental sustainability. By sharing such information, it can help to improve the usage of green products. Information on green product experience is essential since it can influence the green product purchase decision. Firms should identify which information are critical from the point view of customers. Only then the information can be tailored according to the needs of the target customers. Emphasis on the benefits, sharing of usable features, instructions are among the information to be considered. Firms should also identify their target customers appropriately. This is because those who support environment sustainability, are the ones that are likely to be potential customers. The more positive the attitude towards green purchasing, there is a higher chance that they will make the green product purchase decision. Therefore, the marketing methods of the green product should be attractive and convincing to ensure there is a positive feeling towards green product and this can lead to purchase of the green product. The study has some limitations. One of the limitations is the sample size which is recommended to be increased for future studies. Future study may include qualitative method or mixed mode. Other suggestions include to study on barriers to green products' consumer purchase decision.

Abstract

Optical Current Transformers (OCT) have been developed as an alternative to traditional current transformers. Significant improvements were achieved in these last years in order to find a suitable alternative to the classic measurement instruments. The development of digital technology has impacted power systems as well. Optical current transformers are an example of digital system applications in power systems. They have become more available and continue to develop over time. They are also called electronic transformers since their hardware is based on electronics. Optical transformers not only provide high accuracy but also eliminate the saturation problem that magnetic classical current transformers face. The following paper will show the use of such optical current transformer within o high voltage substation from the Romanian National Grid.

Keywords*:* Optical Current Transformers, Grid, Power Systems .

INTRODUCTION

Traditional measurement and protection systems within a substation consist of measurement transformers, such as magnetic current transformers (CT) and voltage transformers (VT). Measurement transformers are used for conversion of voltage and current from one level to another [1-7]. The primary sides of the conventional transformers are supplied by the network voltage and current [8-14]. The secondary side supplies the protection relays and/or energy measurement systems [15,16]. Signals generated by the measuring transformers are transported through electrical cables to the substation control room [17-21].

The Romanian National Transport System Operator, Transelectrica, according to its procedures and guidelines emsures granting acces to the electricity network to all paticipants. Therefore, it is imperative to know and define all energy transits between the public electric network, under the management of TSO Transelectrica and consumers and/or energy producers. [2,22,23] This is the reason why, within the substations, there have been installed protection relays but also electrical meters for settlement at the point of the electricity network where the electricity metering unit is installed [24-29].

At this moment, within the Romanin power system grid, there are two electrical substantions, in which optical current transformers are installed [30-33]. They are operating at the same time and with the same purpose as the conventional magnetic current transformers [34].

The substations in discussion are 220/110/20 kV Targoviste substation and the 220/110/20 kV Turnu Magurele substation. The optical current transformers are installed in the 110 kV voltage substations and are connected in series with the conventional current transformers for metering applications.

This began as a testing process in order to compare and verify the stability and performance of the optical technology within the Romanian power grid network.

Instrument transformers used in power systems, especially those used for metering applications, must maintain stability of measurement over time, and through different environmental conditions.

The changing of scale factor due to temperature, or scale factor drift over time and contributes to less than intended metering accuracy, impacting revenues and it may require continual calibration of revenue meters.

Some conventional instrument transformers, especially CCVTs, and some polarimetric-based optical sensor systems have experienced a drift in accuracy as they age, and due to temperature conditions.

Fig. 1: NXCT single phase Diagram

The NXCT has two major classes noted as Active or Passive. The Active NXCT is designed for metering applications. The Passive NXCT is designed for protection applications only.

The paper analyzed the connection diagrams of the NXCT optical transformers and some the learnt lesson from using the optical technology within the substation metering applications [35].

FIBER OPTIC CURRENT SENSOR OPERATION PRINCIPLES

The NXCT is a fiber optic current sensor, which produces a low voltage output in direct proportion to the primary current on the bus. This secondary voltage output can be converted to a current output using a precision trans-conductance amplifier. The system derives its measurement based on a phase shift between two optical signals in the measurement fiber that is created by the primary bus current. The sensor offers many advantages over existing types of high current measurement devices including:

- High performance sensor design
  - o True current measurement
  - o High accuracy, linearity, & stability over temperature
- No geometric dependence allows sensors to be placed anywhere around the bus
- Light weight fiber-optic design allows ease of installation & maintenance
- Sensor is immune to nearby magnetic fields. [3]

The Active NXCT is a highly linear, highly accurate fiber optic current sensor, which measures AC and DC bus currents up to 4000A for AC applications. There are three main components to the sensor: CT Electronics, Optical Modulator Box and the Sensing Loop.

Fig. 2. NXCT Diagram

The CT Electronics provide the intelligence for the sensor. The sensor module, inside the sensor chassis, contains a light source and circuitry to interrogate the return signals to derive a current measurement from the phase shift changes caused by the measured current. There is no periodic maintenance of the system.Power supplies and various types of current amplifiers can be use to interface the voltage output to conventional secondary equipment. The Optical Modulator (containing the optical Phase Modulator) is packaged in analuminum housing located in the column base The Sensing Loop starts and terminates in the Optical Modulator. The Sensing head fiber is mounted in a "donut style" housing that surrounds the bus. The sensing fiber extends from the modulator housing inside the insulator column base up through the insulator and finally into the CT ring [3,36].

Signals representing current from NxtPhase optical sensors are available in three formats: digital, low energy analog (LEA), and high energy analog (HEA). The fundamental (and most valuable) signal is the digital signal. However, given that digital signal inputs to meters and relays are in early stages of development, high and low level analog signals are available in the interim until digital inputs to secondary devices are more commonly available. Signal processing in the current and voltage electronics is inherently digital in nature and is accessible in a format consistent with IEC standard 60044-7 and draft standard 60044-8. These standards define the digital data format from the sensor electronics (contains the relevant signal information associated with several current and voltage sensors). Additional to these two standards, IEC draft 61850-9-1 and 61850-9-2 also recognize the data structure outlined in the 60044-7 and 60044-8 [4] standards, but also permit an Ethernet physical layer with the same overall data structure [37-41].

NxtPhase is one of the companies that manufacture optical current transformers in the market. The company provided a CT marked NXCT to Transelectrica for testing and installing in the 110 kV network within 220/110/20 kV Targoviste substation and the 220/110/20 kV Turnu Magurele substation [42-47].

ANALYSIS OF SYSTEM OPERATION

NxtPhase current sensing technology is based on the Faraday Effect. Magnetic field created as current flows through a conductor influences the polarization of light on a path encircling that conductor.The NxtPhase design results in superior accuracy over dynamic range, over temperature, and during vibration. The sensor measures the difference between the effect on 2 polarizations, rather the absolute effect on a single signal.

Since instalation in Romania's power grid substations, the Active NXCT for metering application did not need any maintenance work done. Figures 3 and 4 show the positioning of the OCT within the substations.

Fig. 3. Circuit Breacker with the optical transducer

Fig. 4. Installation of the optic current transformer within the substation

NUMERICAL EXAMPLES AND MEASUREMENTS

A low energy analog (LEA) signal from each sensor is available in several formats, each tailored to its specific sensor and end use. The tables below, summarizes output signals and applicable standards.The results are been presented in table 1. These signal amplitudes were chosen based on widely acceptable outputs levels from digital to analog converters.

TABLE I
LOW ENERGY SIGNAL LEVELS AVAILABLE

NXCT Current Sensor	
Metering Output	4VRMS (meets IEC 60044-8) 4VRMS (ANSI P1331)
Protection Output	200 mVRMS (meets IEC 60044-8 and ANSI P1331)

The high energy analog signal is available in a format that would typically be used for metering applications. Amplifying a current signal to be used for protection applications is possible, but is impractical as the required over range for fault currents would require a very large and expensive amplifier. In this particular situation, Transelectrica has chosen to install optical current devices only for metering applications. Low energy signals are more suitable for relaying applications. For similar reasons a 1A signal, but not a 5A signal, is available for metering applications. Table 2 below summarizes the available high energy analog signals:

TABLE II
HIGH ENERGY SIGNAL LEVELS AVAILABLE

NXCT CURRENT SENSOR	
METERING OUTPUT	1 A, 2.5VA BURDEN
PROTECTION OUTPUT	NOT AVAILABLE

CONCLUSIONS

A logical step to overcome the problems caused by electromagnetic interference on the sensor signal is to use a signal transmission that is immune to electromagnetic fields. Optical signal transmission using optical fibres are the best solution for that purpose. Normally, the optical signal is not influenced by electromagnetic fields.

The advantage of direct magneto-optic transducers using optic-magnetic active materials is the absence of additional disturbance variables caused by mechanical or electrical sensor parts such as hysteresis, saturation, induction, temperature influence and damping.

Nowadays, numerous current measurement systems based on optical devices have been developed. Optic current transformers have numerous potential advantages over conventional current transformers, depending on their sensor principle.

Potential advantages are:

- immunity to electromagnetic interference (EMI);
- high electrical insulation;
- large bandwidth;
- potentially high sensitivity;
- ease in signal light transmission;
- being compact and lightweight;
- no danger of explosion;
- ease of integration into digital control systems;
- no saturation - hysteresis-free .

The Romanian TSO, CNTEE Transelectrica SA is keen in implementing and further utilizing the optical technology for its metering applications, as it has proven to be a suitable alternative to the conventional metering possibilities.

Abstract

Authors did a critical review of the publications on negative consequences of digitalization of agriculture. Such consequences (that could threaten the food security of the country) were outlined using the methodology of institutional theory research. This problem and the role of the state in its prevention is barely explored in modern publications. Authors emphasize that modern research does not take into account the opportunistic behavior of digital technology producers in agriculture, sellers-competitors in agricultural markets, as well as political rent seeking bureaucracy, scientists and agricultural advisory service workers, who are influenced by digital technology producers. Authors claim that digital technologies in agriculture belong to Network goods and not to Public goods, so the main task of state policy for digitalization of agriculture is not to promote its spread over as large area as possible, but to protect farmers and the population from the negative consequences of its implementation. Effective digitalization of agriculture is possible only after the establishment of strong institutional environment, which would provide comprehensive and sustainable security for all businesses of the agricultural sector in conditions of the rapidly growing cyber-threats. Such environment should guarantee the country's food security.
Authors also claim that the rapid digitalization of agricultural advisory services, which are funded by the state, lost their relevance and do not require further government funding.

Keywords: Digitalization of Agriculture, Agricultural Advisory Services, Cybersecurity, Network Goods.

Introduction

The 21st century marked the beginning of the Fourth Industrial Revolution, which led to the creation of a single digital ecosystem as a result of a combination of material and virtual worlds. In these conditions, the competitiveness of any business entity or the whole country now depends on whether they use digital technologies (DT), such as 3-D Printing, artificial intelligence, the Internet of Things, energy storage etc.

The rapid spread of digitalization to all areas of human activity could not miss the most backward sector of the economy - agriculture. The introduction of DT in agriculture is associated with hopes not only to dramatically increase productivity and profitability in agriculture, reduce the risks of agricultural production, reduce resource costs, but also to solve the problem of famine on the planet, which is a possibility according to experts by 2050 due to the increase in the planet's population, limited natural resources, severe farmland degradation, adverse climate change, and environmental degradation (Clercq, 2018). According to FAO experts, digital agriculture will create systems that are

highly productive, anticipatory and adaptable to changes such as those caused by climate change. This, in turn, could lead to greater food security, profitability and sustainability. In the context of the Sustainable Development Goals, digital agriculture has the potential to deliver economic benefits through increased agricultural productivity, cost efficiency and market opportunities, social and cultural benefits through increased communication and inclusivity and environmental benefits through optimized resource use as well as adaptation to climate change (Trendov et al., 2019).

Emphasizing the positive consequences of digitalization of agriculture (DA), the euphoria from the expected incredible results of its implementation leaves negative external effects and consequences that require government regulation and prevention barely studied. At the same time, digitalization in other sectors of the economy is already gradually showing its negative side and colossal losses, for example, as a result of cyber attacks.

While the digitalization of all areas of human life is rapidly spreading on the planet, scientists are only taking first steps in the study of this process, its positive and, most importantly, negative consequences. Thus, FAO experts have only just begun to formulate the concept of realizing the potential of digitalization to improve the agri-food system (FAO, 2020).

Therefore, in our opinion, the problem of state policy for DA requires a comprehensive and in-depth use of the methodology of institutionalism as the most applied school of economic theory.

When the wrong input or methodology is chosen for research, the results will usually be wrong. Economic science, which for 200 years relied in its research on the methodology of orthodox economic theory, has moved so far away from real life that it has been unable to explain or predict the extremely devastating world crises of the twenty-first century. And only after that the scientific community appreciated the applied nature of the methodology of institutionalism, many of whose representatives were awarded the Nobel Prize for the applied value of their developments. Unfortunately, agricultural scientists, like farmers, find it difficult to adapt to innovation and rarely actually use the latest research methods. That's why, in our opinion, the problems of the state policy for DA requires a comprehensive and deep usage of research methodology of institutionalism as the most applied school of economics.

Analysis of recent researches and publications.

The DA problem is quite new and barely studied. Despite the rapid spread of digitalization, in agriculture in particular, scientists still do not have a holistic view of its challenges and opportunities (Ayre et al., 2019). At the same time, most publications on DT in agriculture are based on research either only by specialists in computer and information sciences who are poorly versed in the methods and objectives of social science research, or by specialists in social sciences (Deichmann et al., 2016; Krell et al., 2012) who do not understand the processes of DT. As Roth S. et al. aptly put it: «Most social theorists know of computers and programming languages as little as illiterate medieval farmers knew of the Bible» (Roth et al., 2012). Therefore, research results either describe the «extraordinary» technological and technical possibilities of using DT in agriculture, or look for ways to implement DA as the only way to maintain the competitiveness of farmers in national and global markets (Qiang et al., 2012; Stitzlein et al., 2020). We agree with C. Eastwood, L. Klerkx and R. Nettle (2017): «Successful complex agricultural innovations require a collaborative R&E approach».

Of particular note are the collective DA process management studies conducted by the staff and consultants of the World Bank. It is very important that their research team consisted of specialists in both Computer and Information Sciences and Economics. In particular, C.Z. Qiang, S.C. Kuek, A. Dymond and S. Esselaar summarized the experience of implementing mobile communications technology in agriculture in Africa, Asia and Latin America. They investigated the impact of mobile applications for agricultural and rural development (m-ARD apps) on «ecosystems, and business models to provide an analytical framework for policymakers and development practitioners» (Qiang et al ., 2012). Research has identified the problem of spreading programs after a pilot phase of concept testing in small target markets, when there is a transition from public to private funding. The researchers found that only «some m-ARD apps are achieving scalability, replicability, and sustainability» (Qiang et al., 2012). At the same time, they emphasize the importance of governments and donors to cover the initial capital costs of mobile communications technology providers. They also claim that «participation in modern supply chains can increase farmer incomes by 10-100 percent» (Qiang et al., 2012). However, despite the fact that the team of authors consists of specialists in the field of Computer and Information Sciences and Economics, the researchers took as an axiom the thesis that DA will only promote agricultural and rural development. And the primary role of the state in DA they see in financial support both during the pilot phase of the new ARD-m apps, and at the stage, where m-ARD apps are being scaled up and trying to enter new markets. In our opinion, any scientific and technological revolution carries great threats that need to be anticipated, investigated and secured. Precisely because the scientific community has paid little attention to the study of the negative effects of the introduction of new scientific products, the world is

now on the brink of ecological catastrophe. Therefore, the role of the state, in our opinion, cannot be limited to solving the problem of finding ways to finance the development of the country's DA.

The question of the role of corporate social responsibility (CSR) in the development of DT in agriculture is raised in different ways. Thus, C.Z. Qiang, S.C. Kuek, A. Dymond and S. Esselaar (2012) see it only in the financial support of agricultural DT producers. We are closer to the position of K. Bronson, who drew the attention of the scientific community to the unfair uneven distribution of agricultural DT between different actors in agricultural production. «Social actors shaping innovation hold a narrow set of values about good farming and good technology and their data selection choices privilege large-scale and commodity crop farmers by focusing on agronomic crop data and data mapping unusable to organize growers» (Bronson, 2019, p.1). But, in our opinion, the role of the CSR should not be limited to these two areas and needs to be significantly expanded. First of all, agricultural DT producers must carry the CSR for the consequences of introducing their product. In addition, we hold a view that contradicts the modern scientific paradigm of the concept of CSR: the state has no right to relinquish control over the activities of economic agents who advertise themselves as companies' CSR practice. The level of human consciousness is not yet ready for the introduction of the informal institution of the CSR. The moral and spiritual values, which are really adhered to by the representatives of especially big business, are far from altruistic, they are only interested in the growth of their own income, not public welfare. Even when they sponsor and patronize, they still count on how their profits will increase through such advertising.

Unfortunately, the negative consequences of DA for farmers and for society as a whole are not sufficiently disclosed in the publications. There are even fewer publications on the role of the state in eliminating these consequences (Klerkx et al., 2019) and at the same time research does not use the methodology of institutional theory, scientists are limited to using the categories «institute» and «institution».

The *purpose of the research* is to determine the role of the state in the development of DA using the institutional research methodology.

Main Material

The COVID-19 pandemic, which is destroying both the world's population and the economy, has shown the invaluable importance of digitalization of the economy to achieve all the 17 Sustainable Development Goals declared by the United Nations for the next 10 years. E-commerce, e-government, E-learning etc. received a new impetus in their development. According to the Global Information Technology Report, «full effects of new technologies such as the Internet of Things, artificial intelligence, 3-D Printing, energy storage, and quantum computing unfold… The future of countries, businesses, and individuals will depend more than ever on whether they embrace digital technologies» (World Economic Forum, 2016). Therefore, most highly developed countries, such as the USA, UK, Germany, Japan and others, have identified the digitalization of the economy as a priority for the country's development. ICTs have become a key factor in «bridging the digital divide and achieving the three dimensions of sustainable development: economic growth, environmental balance and social inclusion. They have proved to be instrumental in health, education, finance and trade, providing information and services, and have contributed to greater transparency and accountability» (ITU & FAO, 2020, p.2).

The development of digitalization in agriculture occurs in following areas: produce differently using new techniques; use new technologies to bring food production to consumers increasing efficiencies in the food chain; incorporate cross – industry technologies and applications (Clercq et al., 2018).

Studies by international organizations have shown a very uneven spread of digitalization. The researchers from ITU's Telecommunication Development Bureau examine this process by regions (Africa, The Americas, Arab States, Asia & Pacific, CIS, Europe) and by level of development (Developed/developing countries) (ITU, 2019 *b*). But then hidden from researchers is the uneven spread of digitalization within a group of countries. Thus, fig.1 shows the outsider position of most post-Soviet countries.

Fig. 1: Percentage of households with Internet in some developed countries of Europe in 2010 and 2019, %
Source: ITU, 2019 a.

A feature of DT development is the high volatility, as a result of which the new technology quickly becomes obsolete and when it becomes available to outsider countries, its usefulness is minimal. Thus, users from such countries continue to «play catch up» (Trendov et al., 2019). One such country is Ukraine (Fig . 2).

Fig. 2: Percentage of households with Internet, %
Source: ITU, 2019 a; State Statistics Service of Ukraine, 2018; Eurostat Statistics Explained, 2020.

The process of digitalization in rural areas is even slower (Fig. 3). In order to use DT in agriculture, you must at least have access to the Internet. Currently, a little more than half of the population in Ukraine has it. That is why Ukrainian farmers, who work on the 25 per cent of the world's most fertile black soil, did not have any chance to be competitive not only in the world but also in the national markets. Because «agro-holdings, with about 70 agricultural companies engaged in relative monoculture on 25 per cent of the arable land» (ITU & FAO, 2020) and who are destroying fertile Ukrainian land, in contrast to the farmers, have financial opportunities to use agricultural DT. Thus, Ukrainian farming as a result of DA is doomed to destruction.

Fig. 3: Percentage of households with Internet in Ukraine in rural areas and urban areas, %
Source: State Statistics Service of Ukraine

The main reasons for slowing down the development of the Internet in rural areas are outdated telecommunications networks, lack of electronic literacy and digital skills, low levels of computerization, low incomes, small number of information and communication technology specialists. Each country has a number of other specific reasons. For example, in Ukraine, farmers determine that the reasons for the slow implementation of DA are agricultural producers' mistrust in the effectiveness of digital technology and lack of knowledge and skills and absence of equipment (Fig. 4). Also cause inhibition of DA in Ukraine, in our opinion, is the underdevelopment of cooperatives, which would have increased the purchasing power of small and medium farmers.

Fig. 4. Factors that inhibit digitalization in agriculture in Ukraine (according to the results of a sociological survey of farmers), %
Source: Developed by the authors based on Bakun & Saiapin, 2020.

We should not forget that agricultural DT is the same product as any other, created and produced for profit. Large investments have been made in its production, from which large profits are expected. Therefore, the main goal of producers is not to increase the welfare (profitability) of farmers, but to maximize their own profits. Manufacturers and investors are extremely interested in the rapid spread of the product in national and global markets. Even aware of all the risks and negative consequences of farmers using agricultural DT, they not only advertise the incredible potential of their products, using the market asymmetry of information, but also lobby their interests in government. They resort not only to civilized methods of product promotion, but also to opportunistic behavior: logroling, bribing scientists, politicians and representatives of various public influential institutions to advertise and promote an innovative product.

Agricultural advisory services, which were once set up to advise farmers who did not have the Internet and other sources of up-to-date information, found themselves in a difficult position. Their workers are at risk of unemployment. When they were funded by the state, they did not have much motivation to provide quality, much-needed agricultural advisory services for farmers. Not surprisingly, they are now busy convincing society, scientists, and most importantly, government agencies that fund them, that in the DA their advice is especially important (Fielke et al., 2020), that without the help of agricultural advisory services technologies can lead to negative consequences (Eastwood et al., 2019).

An article by Ukrainian scientists Yu. O. Bakun and S. P. Saiapin (Bakun & Saiapin, 2020), who are employees of the agricultural advisory, is quite indicative of the real value of state-funded agricultural advisory services. They try to prove the need for agricultural advisory services for Ukrainian farmers, but when they start to provide statistics, it turns out that Ukrainian farmers underestimate the work of the services, because they do not want to receive services even on a free basis. Thus, in Ukraine, 0.15 million euro were provided from the state budget to finance agricultural advisory services for farmers and agricultural cooperative since 2019, of which only 10% were actually used (Bakun & Saiapin, 2020, pp. 84-85). Employees of agricultural advisory services, funded by the state, recognize that the system agricultural advisory services in Ukraine are ineffective and mostly formal (Bakun & Saiapin, 2020, p. 82, 90). We question the results of a survey conducted by representatives of the public organization "National Association of Agricultural Advisory Services of Ukraine", who are interested in a particular result and claim that the results of a survey showed the need for advisory services 68% of respondents (Bakun & Saiapin, 2020, p. 85).

Research Methods

In the study was used a truly invaluable discovery of institutional economics - a model of a person with opportunistic behavior, developed by O. Williamson (1985), which «involves the pursuit of the individual's interests, including fraudulently, meaning obvious forms of deception, such as lies, theft, fraud, but hardly limited to them» (p. 47). Our study takes into account the presence of opportunistic behavior:

a) of DT producers for agriculture, who are using information asymmetry in the market of agricultural DT and hide from agricultural producers during the sale of their innovative product important negative consequences of using DT, which can lead farmers into bankruptcy;

b) of agricultural producers who are competitors in agricultural markets and can use any methods of unfair competition;

c) of bureaucracy, scientists and agricultural advisory services, which are influenced by producers and investors who finance the production of agricultural DT.

Therefore, to analyze the behavior of the subjects mentioned above we are using the principle of methodological individualism, which examines society not as a faceless mass of people, but as the sum of individuals. The study is also based on the following main statements of institutional economic theory:

1. Rationality of individual assumes that every person, regardless of their status in society (for example politicians or the president of any country), in making decisions and in their actions are guided, first and foremost, by economic principle, which means comparing their own marginal benefits and marginal costs.

2. Individuals always seek to maximize their usefulness and can use opportunistic behavior to achieve it. Representatives of institutionalism and behavioral economics believe that fear is an important motive for individual behavior. Therefore, in order to prevent manifestations of opportunistic behavior, a state apparatus of violence is needed, which would guarantee the inevitable punishment of individuals for actions that harm society.

3. The state is considered not as an impersonal substance, but as a number of individuals who hold positions in the legislative and executive branches of government and who are guided primarily by their own interests (which often conflict with the public) while making decisions.
Political rent is an advantage obtained through special government benefits, subsidies, and other privileges. It is achieved through lobbying for regulations, legislation and corruption.

4. The actions of the individual are influenced by institutions – which are, according to D. North's definition (North, 1991), «humanly devised constraints that structure political, economic and social interactions». These constraints consist of formal and informal «rules of the game» that ensure order and security in the market and in society. The effectiveness of institutions depends in particular on the level of coercion used by the government.

We consider K. Kosior's categorizing of «agricultural DT», like «smart farming systems», as Public goods a methodological error (Kosior, 2019). We consider it Network goods, demand for which grows with increase of the number of its users. It is characterized by an increase in utility for an individual consumer with an increase in the number of consumers. The development of Network good requires significant initial investment, but once a sample of an innovative product is obtained, its copying and duplication require almost zero or extremely low additional costs. Therefore, its manufacturers are interested in the widest possible market coverage. The erroneous attribution of agricultural DT to Public goods leads to erroneous conclusions about the need for state participation in the promotion of this product on the market.

Results

Since DT belong to Network goods, the amount of profit of their producers depends on the scale of distribution of their product, as the cost of copying an innovative product is extremely low. This leads to fierce competition between powerful DT companies, the dominance of monopoly power in the market and the creation of large barriers for the new companies to enter this market. Therefore, the desire to win as much market shares as possible motivates DT manufacturers to use not just civilized methods of competition.

One of the methods of unfair competition used by agricultural DT producers is to reduce sales and advertising costs through the involvement of scientists, media, public authorities and influential international organizations to spread information about the benefits of DA, persuading governments and donors to reimburse initial capital costs to DT suppliers (Qiang et al., 2012). Moreover, the ability of the DT producers to impose the idea of DA as a «universal good» is so powerful that it is perceived by the world community as an axiom that does not need proof. And instead of examining the negative effects and network effects of the implementation of DA, creating a powerful institutional countering to these effects, researchers, bureaucracies and international organizations are working on ways to motivate farmers to implement agricultural DT (Stitzlein et al., 2020; Trendov et al., 2019; Ukraine 2030E, 2018).

As farmers begin to use more sophisticated DTs, they face threats they never even imagined before. When scientists and manufacturers try to adjust the design of agricultural DT to the wishes of farmers, farmers fall into the trap, because they cannot predict, for example, what cyber attacks may await them in the future and the scale of such consequences.

As the government does not study the negative effects of digitization on the economy, in most developed post-Soviet countries, the indicator «Trust, Security and Privacy» is practically not monitored and not analyzed (Fig. 5).

Fig. 5: The share of information collected on the «Trust, Security and Privacy» indicator in some developed post-Soviet countries in 2018.

Source: Developed by the authors based Yegorov & Gryga, 2019, pp. 59.

As a rule, the introduction of agricultural DT does not take place in a single farm, but in a large agricultural holding or in farms that are united in an agricultural cooperative. Such entities implement DT on large farmland. If the competition between them intensifies in the agricultural market, some of the competitors will want to resort to unfair competition and order a cyber attack on competitors - to change the dosage parameters of pesticides in their smart agricultural system for example. As a result, the crop will die in a very large area and will affect not only producers and their employees, but also a country that will not receive a significant number of agricultural products. Thus, with the introduction of DA, competition will move to another level - cyber competition, which can also be, for example, in the form of cyber raiding, when in virtual documents of ownership of land or agricultural products, a hacker can change the name of the owner. The consequences of cyber attacks and lawsuits are very costly, but scientists are not yet considering this side of the increase in transaction costs of implementing agricultural DT.

Countries cannot distance themselves from the problem of cyber threats and instruct economic entities to defend themselves. Only the state on national and supranational levels can solve this problem. It is necessary to create a cyber security team that will be responsible for the security of all economic entities.

The rapid development of the ICT industry suggests that the creation of any quality cyber defense system is an extremely short-term protection against cyber-attacks. Therefore, the creation of institutionally provided cyber

defense system on national and supranational levels is, in our opinion, a more effective mean of cyber security. This is, first of all, the creation of a regulatory framework that would provide severe punishment for cybercriminals. Protecting food security on the country and worldwide level means the punishment for such crimes should be lifelong imprisonment.

In addition to «the rising threat of cyber attacks that expand into the physical world, privacy issues, and the polarizing effects of technologies on labor markets» (World Economic Forum, 2016), each country that has its own national development characteristics may have its own specific risks. For example, Ukraine has a high potential of highly qualified IT specialists, but at the same time, incomes in Ukraine are extremely low, the unemployment rate is high, as well as the extremely imperfect legal framework for the protection of private property, especially with the help of IT technologies. This creates favorable conditions for the rapid development of cybercrime when the DA of Ukraine takes place.

The problem of CSR should be singled out, since it has now became an additional effective advertising move for companies that work with a violation of legitimacy and simple decency, and position themselves as CSR companies. This applies in particular to companies that create agricultural DT. Unfortunately, the development of STP has not changed the consciousness and behavior motives of an average person, who is stopped from criminal acts only by the fear of severe punishment. Only dreamers, like the French utopians, can believe today that the giant business sharks that invest billions of dollars are more concerned with human values, the well-being and prosperity of the planet, than their own profits. Therefore, we do not support the modern concept of CSR, which is based on the principles of voluntariness and belief in the sincerity of companies that position themselves as CSR companies. We also do not support the belief of Simone van der Burg, Marc-Jeroen Bogaardt and Sjaak Wolfert «to set preconditions for trust between stakeholders and - eventually - develop appropriate guidelines and codes of conduct for future farming digitalization trajectories» (Burg et al., 2019). The responsibility of each company and the inevitability of punishment for actions harmful to society must be established in formal institutions.

In our opinion, state-funded agricultural advisory services have outlived themselves. Today, farmers must «vote with the dollar» to determine the need for these services. The state should focus its funding on the creation of pilot DA centers at large universities, where it is possible to combine the skills of top industry experts in computer and information sciences, economics, ecology and cyber security to study the advantages and disadvantages of agricultural DT. These centers should be an educational base for current and future farmers.

Advice for farmers on the implementation and use of agricultural DT should be provided by economically and legally responsible producers - professionals who are well aware of all the nuances of their product. When purchasing an innovative product, agricultural DT manufacturers must add mandatory technical support throughout the period of use of the purchased agricultural digital technology. Observation by producers of the work of the innovation system for farmers will give full information on its further improvement.

In the 90s Ukrainians went to the United States and EU countries to study the experience of farmers, but, tasting strawberries or tomatoes without taste and smell, sincerely rejoiced that STP has not yet reached the agriculture of Ukraine and they can afford to eat an organic product. Today, Ukrainians eat the same as the population of developed countries and are willing to pay a higher price to eat organic products. We are not supporters of the idolatry of STP, in particular the digitalization of the economy. In this regard, the development of DA should be, as in medicine, under the slogan «Do no harm». DA is an objective and unrestrained process that carries both benefits and threats. Therefore, the consequences of this process need to be investigated, anticipated and directed in a useful for society way.

Conclusions

The study allows us to draw several unpopular conclusions for the scientific community:

1. In studies of the DA problem the following thesis considered as an axiom: the consequences of digitalization in agriculture can only lead to increase of its productivity and sustainability, to reduction of production costs and, consequently, to the welfare of farmers. The lack of an institutional approach and the disregard of opportunistic behavior by players in the agribusiness lead to erroneous conclusions.

2. Opportunistic behavior of producers of agricultural DT, competitors in the agricultural market, as well as political rent seeking bureaucracy, scientists and agricultural advisory services, which are influenced by producers and investors who finance agricultural DT production, can lead to irreparable consequences of DA not only for farmers and their employees, but also for the food and environmental security of the country. The current over-enthusiasm for the development of DA turns a blind eye to its future socio-economic and environmental consequences, and its scale can be catastrophic.

3. Studies of the consequences of DA should be based on a multidisciplinary approach and consider the results of experimental research of agricultural practices. To produce and implement a truly high-quality product, the DA implementation team must consist of scientists in the fields of computer and information sciences, economics, ecology and cyber security, manufacturers of these technologies and farming representatives.

4. DA can threaten the country's food security without proper institutional support, when the farmer is protected from cyber attacks, cybercrime is severely punished (up to life imprisonment), and the producer bears full unavoidable economic and legal responsibility for the quality of his digital technology in agriculture, which has a legal basis. Effective DA is possible only after the establishment of institutional environment to ensure the full and stable cyber security for agriculture in the conditions of rapidly growing cyber threats.

5. With the spread of digitalization to all areas of human life, the entry of the Internet into every family, state-funded agricultural advisory services have lost their relevance and the state should not continue to fund them. Only those counseling centers that are really needed by farmers should remain, but only with farmers willing to finance them privately.

Further DA research authors intend to continue after the creation of an effective team of researchers, which will consist of specialists in various fields of science. This will provide an opportunity to conduct a detailed study of the issues of negative externalities from the implementation of DA and to form a concept of state regulation of this process.

Abstract

The quality requirements imposed on the economic activity can be achieved only by complying with the conditions in which the equipment used in the production process is replaced, at the right time, with others that satisfy the restrictions imposed by the increase of the productivity addressed to the system. The establishment of an equipment life is a problem of economic balance. Due to the wear that occurs over time, the maintenance and operating costs increase. The costs increase until they exceed the acquisition costs of new equipment. The research methodology consists in establishing the most suitable functions for the maintenance and operation costs and for the acquisition costs of new equipment and in identifying the minimum value of the sum of the two categories of costs. For considering the real situations, a value for costs update in time is also included in this calculation. The theoretical considerations are supported by a case study in which the economic moment of replacing an equipment is established by using one of the mathematical models presented.

Keywords: Industrial Management, Maintenance and Operation Cost Functions, Equipment Life

Introduction

Among the optimal problems of economic activities is that of obtaining expected results in conditions of industrial equipment efficient operation. They can be operated rationally/ optimally until the costs for maintenance and operation exceed the acquisition cost of a new equipment. This is the moment when new equipment needs to be purchased. (Atanasiu, 2018; Nistoreanu, 2019) These statements did not consider that other equipment with superior/ improved performance may appear during the operation of an equipment and then the replacement of the existing one is made for reasons of *moral wear* and not for reasons of *physical wear*.

The problem of equipment replacement is predominantly a problem of strategic management of a company, which aims to maximize economic and financial results, as well as maintaining on a permanently competitive market. (Dragu, 2003)

The activity of equipment replacement is manifested in all areas of socio-economic life, perhaps more predominantly in the transport system due to the special safety conditions imposed by the specifics of the activity. Like any system, which is a set of interdependent objects brought together to achieve a common goal, the transport system is characterized by transport tasks, structure and technology. (Raicu, 2007)

The requirements of the socio-economic system users are more and more demanding in terms of quality and costs involved, which makes it necessary to operate the component subsystems of the economic system at the designed parameters. Productivity and quality requirements are matched by flexibility and adaptability to rapid changes in the marketplace in the face of globalization (Rădăceanu, 2008).

In this context, the equipment as parts of a complex economic system must be maintained in good working order throughout its life. This raises the question of the optimal replacement time, that time when the maintenance and operating costs together with the acquisition costs as well as the related interest rates have a minimum value. The life cycle of a product or system is a sequence of phases, each containing activities that cover the life of the system, from the initial design, to decommissioning. The life cycle scheme provides a framework for programming, conducting, controlling and supervising the system in all its aspects as it goes through different stages of development. (Ionescu et al., 2015; Roşca et al., 2014)

Any equipment gets obsolete as to its operation and maintenance if it is not properly maintained and repaired. In some situations, instead of performing the necessary repairs, it is more economical to replace the entire equipment. Often, replacement is not made because performance has dropped significantly, but due to the emergence of new equipment with superior performance (Ackoff, 1975).

In Romania, the life cycle of a system is provided in EN 50126 and incorporated into Romanian legislation under the SR EN 20126/2003 and aims to specify the reliability, maintainability and availability of the system (Ghionea, 2011).

Literature (Dima, 2007) presents several models for the renewal of the equipment. One of these is the 4 step model (Meredith and Martel, 1985) applied in the process of implementing new machines and for which the stages are defined: the management team must try to change the organizational culture of the enterprise; the management team must accept that the new machines may also have negative effects; a higher level of communication between the manager and the contractor regarding the new machinery; a change in the company's strategy as the new machines roam the roots.

The problem addressed in this paper is related to the evolution of maintenance costs to which are added the depreciation costs of the machine on which an update value may or may not act. The solution of the problem consists in finding the most suitable costs' functions whose amount should have a minimum in time.

Mathematical Models

Mathematical models that address the issue of establishing the optimal time to replace the equipment can be classified as follows:

A. models that do not take into account the variation of the acquisition cost,
B. models that take into account the variation of the acquisition cost,
C. models that also take into account cost updates.

The three models are presented in chronological order, the appearance of a new model being considered a refinement and an enrichment of the previous model. The choice of the model that will be used in the practice of optimal equipment replacement depends on the existence of statistical data (maintenance costs, as well as the variation over time of the selling price of the equipment) in the databases that define the company's activity.

A. Models that do not take into account the variation of the acquisition cost

The economic replacement time is chosen so that the amount of maintenance and operating costs and the cost of purchasing a new transport mean is minimal (Sbora et al., 1984).

In each time period, the maintenance and operating costs are known: C_0, C_1,..., C_n. For a period of n + 1 years the total costs will be:

$$C_t = C_0 + C_1 + C_2 + ...+ C_n \quad (1)$$

The first step in modeling is to determine how these costs vary over time. For this, we try to find a regression curve that tracks as accurately as possible the data recorded over time. The regression curves can be polynomial, exponential, logarithmic, etc., but their type is limited by the fact that not always the extreme point (minimum point) can be rigorously mathematically determined.

The expression of the polynomial function of the maintenance costs is:

$$y = a_0 + \sum_{k=1}^{p} a_k t^k , \quad (2)$$

with a_0, a_1, a_2,..., a_k parameters of the model.

This value is expressed by the least squares method given by the expression:

$$\sum_{i=1}^{n}\left(y_i - a_0 - \sum_{k=1}^{p} a_k t_i^k\right)^2 = U \to \min . \tag{3}$$

By calculating the partial derivatives of the adjustment function and equaling them by zero, the parameters of the model are obtained.

$$\frac{\partial U}{\partial a_k} = 0 \text{, pentru } k = 0, 1, 2, ...,p. \tag{4}$$

Model parameters are obtained by solving the system of equations:

$$\begin{cases} \sum_1^n y_i - na_0 - a_1\sum_1^n t_i - ... - a_p\sum_1^n t_i^p = 0 \\ \sum_1^n t_i y_i - a_0\sum_1^n t_i - a_1\sum_1^n t_i^2 - ... - a_p\sum_1^n t_i^{p+1} = 0 \\ \vdots \\ \sum_1^n t_i^p y_i - a_0\sum_1^n t_i^p - a_1\sum_1^n t_i^{p+1} - ... - a_p\sum_1^n t_i^{p+p} = 0. \end{cases} \tag{5}$$

In order to annihilate the influence of time variation, the condition is set $\sum_{i=1}^{n} t_i = 0$.

The exponential model of regression analysis has the form $y = ae^{bt}$ and the coefficients are given by the expressions: (Neacșu, 2009)

$$a = e^{\frac{\sum_{i=1}^{m}\ln y_i}{m}} \quad \text{and} \quad b = \frac{\sum_{i=1}^{m} t_i \ln y_i}{\sum_{i=1}^{m} t_i^2} . \tag{7}$$

Once the form of the costs' variation over time has been established, the amount of the annual maintenance and operating costs is determined. Considering that the variation of costs over time is a linear one, their total value is determined by integrating the function within the limits t_0 and t_n. For costs with a linear variation it is written: (Dinu et al., 2017)

$$C_t = \int_{t_0}^{t_n}(a_0 + a_1 t)\,dt . \tag{8}$$

Since the minimum cost must be determined by taking into account the acquisition (purchase) of a equipment, the acquisition costs (I_0) must also be added, and the following shall be obtained:

$$C_t = \int_{t_0}^{t_n}(a_0 + a_1 t)\,dt + I_0 . \tag{9}$$

The minimum cost must be found for a period of time which means the optimum time interval (t_{op}) in which the equipment must remain in service. In the equation, this is expressed by dividing both members with t_{op}. As the upper integration limit is introduced t_{op} and the lower limit $t_0 = 0$.

$$\frac{C_t}{t_{op}} = \frac{1}{t_{op}}\left[\int_0^{t_{op}}(a_0 + a_1 t)dt + I_0\right] = \frac{a_1 t_{op}}{2} + a_0 + \frac{I_0}{t_{op}} \tag{10}$$

The minimum cost for each time period is obtained by derivation with respect to t_{op} and zero equaling.

$$\frac{dC_t}{dt_{op}} = \frac{a_1}{2} - \frac{I_0}{t_{op}^2} = 0 \Rightarrow t_{op} = \sqrt{\frac{2I_0}{a_1}} . \tag{11}$$

For maintenance and exploitation costs with a parabolic variation (C_{t2}):

$$\frac{C_{t2}}{t_{op}} = \frac{1}{t_{op}}\left[\int_0^{t_{op}}\left(a_0 + a_1 t + a_2 t^2\right)dt + I_0\right] = a_0 + \frac{a_1 t_{op}}{2} + \frac{a_2 t_{op}^2}{3} + \frac{I_0}{t_{op}} . \tag{12}$$

As before, minimum is obtained by derivation with respect to t_{op} and zero equaling.

$$\frac{dC_{t2}}{dt_{op}} = \frac{a_1}{2} + \frac{2a_2 t_{op}}{3} - \frac{I_0}{t_{op}^2} = 0 \tag{13}$$

$$4a_2 t_{op}^3 + 3a_1 t_{op}^2 - 6A_0 = 0 .$$

It was obtained a third degree equation the t_{op} that is observed to have a solution in the range $\lfloor 0, t_{op} \rfloor$, but this is difficult to get.

For maintenance and exploitation costs with exponential variation (C_{te}) it is written:

$$\frac{C_{te}}{t_{op}} = \frac{1}{t_{op}}\left[\int_0^{t_{op}} ae^{bt}dt + I_0\right] = \frac{a}{bt_{op}}e^{bt_{op}} - \frac{a}{bt_{op}} + \frac{I_0}{t_{op}} \tag{14}$$

from $\frac{dC_{te}}{dt_{op}} = 0$ it is obtained $e^{bt_{op}} = \frac{I_0 b - a}{a(b-1)}$, hence the value for the optimal time of keeping the equipment in service is:

$$t_{op} = \frac{\ln\frac{I_0 b - a}{a(b-1)}}{b} . \tag{15}$$

B. Models that take into account the variation of the acquisition cost

In this case, the problem is a classical problem of economic equilibrum because the maintenance and operation costs of the equipment increase over time and the resale price decreases over time. The sum of the two functions of maintenance and operating costs, respectively resale, has a minimum after a certain number of years. Depending on the expressions used, this minimum may or may not exist. (Neacșu, 2009)

We note by $C_{mo}(t)$ the function of maintenance and operating costs; it is monotonously ascending; $P_r(t)$ – selling price after a certain time t; $P_r(t)$ it is a monotonically decreasing function.
The total cost of using the equipment for a time period t is $C_T(t)$.

$$C_T(t) = I_0 - I_0 P_r(t) + C_{mo}(t) . \tag{16}$$

And the medium cost is:

$$c_T(t) = \frac{C_T(t)}{t} = \frac{1}{t}[I_0 - I_0 P_r(t) + C_{mo}(t)]. \tag{17}$$

The minimum value is:

$$c_T^{'}(t) = \frac{t C_T^{'}(t) - C_T(t)}{t^2} = 0 \Rightarrow t C_T^{'}(t) - C_T(t) = 0 \tag{18}$$

That is for:

$$C_T^{'}(t) = \frac{C_T(t)}{t} . \tag{19}$$

In practice, $c_T(t)$ is evaluated for different values of time t and the minimum value is found. The usual forms of the P_r and C_{mo} functions are linear, exponential or exponentially negative.

a) when P_r and C_{mo} functions are linear:

$$P_r(t) = 1 - \frac{t}{\theta} \tag{20}$$

$C_{mo}(t) = k\,t$ where $0 < t < \theta$ is the time frame in which the equipment operates.
By writing the expression of the function $c_T(t)$ it is observed that the moment of the equipment's replacement is independent of t.

$$c_T(t) = \frac{1}{t}\left[I_0\left(1 - 1 + \frac{t}{\theta}\right) + k\,t\right] = \frac{I_0}{\theta} + k . \tag{21}$$

b) when P_r has a negative exponential function and C_{mo} has a liniar function by. (fig. 1)

$$P_r(t) = e^{-\lambda t} \tag{22}$$

$$C_{mo}(t) = kt\,. \tag{23}$$

In this case a minimum for $c_T(t)$ cannot be obtained.

Fig. 1 Exponentially negative functiob for P_r and a linear function for C_{mo}

c) when $P_r(t)$ has a negative exponential function and C_{mo} has an exponential function

$$P_r(t) = e^{-\lambda t} \tag{24}$$

$$C_{mo}(t) = k\left(e^{\mu t} - 1\right). \tag{25}$$

Figure 2 shows these variations from which it can be seen that there is a minimum point.

In this case the expresion of medium costs is:

$$c_T(t) = \frac{1}{t}\left[I_0\left(1 - e^{-\lambda t}\right) + k\left(e^{\mu t} - 1\right)\right] \tag{26}$$

The parameters of the model k, λ and μ can be easily determined only for small values of t (t = 3 units of time). A time unit can be one year, two years, etc. and it is conveniently chosen for calculation.

Fig. 2. negative exponential function of the P_r and exponential function of the C_{mo} (surce: processed after Dinu et al., 2017)

C. **Models that also take into account costs updates**

The purchase cost of the equipment can be very high and their acquisition is made with investments financed by bank loans. In efficiency calculation the interest rates paid on loans must be take into account. In order to make calculations with amounts paid or available in different years they must be updated with interest rates. The updating factor (f_a) for the interest rate *i* is (Popa, 2009):

$$f_a = \frac{1}{1+i}. \tag{27}$$

The total cost of maintaining and operating a transport mean for *k* years is:

$$C(k) = I_0 - S_k f_a^k + \sum_{n=0}^{k-1} C_e f_a^n , \tag{28}$$

where S_k represent the price obtained by selling the mean of transport after k years of service;

C_e – the cost of maintenance and operation in year *n* paid at the beginning of the year:

n – index for the calculation year;

k – the number of years for which the calculation is made.

Paying *C* Euro now is equivalent to paying *x* Euro at the beginning of each year for *k* years, so the updated amounts form a geometric progression. (Dinu et al., 2017)

$$C(1-f_a) = x(1-f_a^k) \Rightarrow x = \frac{C(1-f_a)}{1-f_a^k}. \tag{29}$$

After substituting the value of *C* it is obtained:

$$x = \frac{\left(I_0 - S_k f_a^k + \sum_{n=0}^{k-1} C_{e,n} f_a^n\right)(1-f_a)}{1-f_a^k}. \tag{30}$$

The part of the expression that depends on k is replaced by f(k):

$$f(k) = \frac{I_0 - S_k f_a^k + \sum_{n=0}^{k-1} C_{e,n} f_a^n}{1-f_a^k}. \tag{31}$$

The problem is to find the value of *k* for which f (k) is minimal.

Case Study

The case study addressed the issue of determining the optimal time to replace an industrial equipment when it is known that the Pr(t) has a negative exponential function and the $C_{mo}(t)$ has an exponential function.

It is necessary to find out the optimal replacement time for an industrial equipment for which the cost of the new equipment is $I_0 = 92 \cdot 10^4$ Euro and after 3 years it can be sold at the price $P_r^{(3)} = 73{,}6 \cdot 10^4$ Euro. In the first year the maintenance and operation costs are $C_{mo}^{(1)} = 26 \cdot 10^3$ Euro and after 3 years (t_n =3) they are $C_{mo}^{(3)} = 91 \cdot 10^3$ Euro. In the case study, the chosen numerical values are test data used to validate the model. The size of the values agrees with the usual practical values in the theory of equipment replacement.

As demonstrated in Chapter 2, paragraph B, the expression of average costs in this case is:

$$c_T(t) = \frac{1}{t}\left[I_0\left(1-e^{-\lambda t}\right) + k\left(e^{\mu t}-1\right)\right] \tag{32}$$

The parameters of the model k, λ and μ can be easily determined only for small values of t.

It is observed that in this case, a unit of time is one year, the period of the known data is 3 years and it is convenient for a calculation without using the electronic calculation tools. Since it is known that the variation of the sale cost after a certain number of years $P_r(t)$ is exponentially negative, it is written:

$$\frac{P_r^{(3)}}{I_0} = \frac{e^{-\lambda t_n}}{e^{-\lambda t_0}} = e^{\lambda(t_0 - t_n)}; \quad \ln\frac{P_r^{(3)}}{I_0} = \lambda(0-3) \Rightarrow \lambda = 0{,}07438. \tag{33}$$

It is known that the value of maintenance and operating costs varies exponentially ($C_{mo}(t) = k(e^{\mu t} - 1)$) and it can be written:

$$\frac{C_{mo}^{(3)}}{C_{mo}^{(1)}} = \frac{k(e^{3\mu} - 1)}{k(e^{\mu} - 1)} = \frac{(e^{\mu} - 1)(e^{2\mu} + e^{\mu} + 1)}{(e^{\mu} - 1)} = e^{2\mu} + e^{\mu} + 1 = 3{,}5 \quad (34)$$

By substituting $e^{\mu} = x$ a second degree equation in *x* is obtained, whose solutions are, $x_1 = 1.4365$ and $x_2 = -2.4365$ (a solution without a physical meaning).

$$e^{\mu} = 1{,}4365 \Rightarrow \mu = 0{,}3622 . \quad (35)$$

From expresion: $C_{mo}^{(1)} = k(e^{\mu} - 1) \quad \Rightarrow k = \frac{C_{mo}^{(1)}}{e^{\mu} - 1} = 59564{,}64 .$ (36)

After the determination of the model parameters, the function of the average cost of using the equipment can be written:

$$c_T(t) = \frac{1}{t}\left[92 \cdot 10^4 (1 - e^{-0{,}07438t}) + 59564{,}64(e^{0{,}3622t} - 1)\right]. \quad (37)$$

In table no. 1 calculations are exemplified for determining the year in which the average annual costs are minimal and therefore the optimal moment to replace the equipment that has the characteristics described in the model.

Table 1: The determination of the optimal time of replacing the industrial equipment

The notations were made: $A = (1 - e^{-0{,}07438t})$ and $B = (e^{0{,}3622t} - 1)$.

As can be seen from table no. 1, the average annual costs are minimal in the fourth year after the equipment comes into operation.

Conclusions

The management of the industrial equipment life is a problem of finding out the minimum costs that occur during the entire service. The moment when this minimum appears, in some situations, can be found when the statistical evolution of the costs involved is known, and this evolution can be modeled mathematically. If the variation of the acquisition cost of a new equipment in time is not taken into account, it was observed that for a polynomial variation of degree two or higher, obtaining the solution becomes difficult because solving the higher degree equations is difficult, and more, the solution is not unique. This leads to great uncertainty about the solutions obtained.

The mathematical models presented can be used only if the company has the statistical data required by each model. Another limitation in the application of these models is that the existence of a statistical series of data that follows a certain trend must be demonstrated. For this purpose, the least squares method can be used, in which the utility and correlation coefficients can provide pertinent information on the linear, parabolic, exponential or logarithmic evolution, etc. of data collected through time series. Data processing and storage is done through computer systems that also have maintenance and operation costs, which increases the share of operating costs of the equipment under discussion. These costs are not taken into account in the models presented but can be considered as representing a share of the costs of the equipment in question.

If the depreciation of the equipment is also taken into account, the problem becomes a classic problem of optimal, having two functions; one ascending and one descending. Even in this case the solution does not always exist and depends on the shape of the two functions. For an exponential function of maintenance and operating costs and an exponentially negative function of the selling price after a few years, the model parameters $(k, \lambda$ și $\mu)$ can be found relatively easily only for small values of t, which limits the domain of the models. This was noted and used in the case study conducted in this paper. In the case study it was observed that the replacement of the equipment must be done in the fourth year of service. In that year year the acquisition costs and those of maintenance and operation have a minimum, after which they start to increase.

In the case of models that also take into account the update of costs over time, it is noted that these models try to model as accurately as possible the situations in practice but other uncertainties arise. It is found that the optimal replacement time is not the same for the model without costs update and for the model with costs update. It is noted that the minimum value is not obtained for the same year for both models but when the cost update is taken into account the equipment can be kept in service for a longer time. (Dinu et al., 2017). For a better understanding of the optimal equipment replacement models, a cost sensitivity analysis according to the interest rates must be performed.

The originality of the paper consists in highlighting, through the case study, the limits of the equipment replacement models when taking into account the depreciation of the equipment over time and especially the shape of the function of maintenance and operating costs and the sale price after a certain number of years. Thus, the possibility of solving without the use of electronic calculation techniques only for small values of t is emphasized.

Even if each model has its own limitations, they represent a step forward in assessing the optimal time to replace equipment, as it provides a mathematical tool for decision makers and as it bring benefits to the companies using them. It is very important to collect as accurately as possible the data regarding the annual maintenance and operation costs of the equipment while their are in service.

Abstract

Public institutions are gaining in prominence as they are called upon to respond to the COVID19 pandemic. The communication between citizens and institutions is increasingly important for managing the crisis, preserving society's civic fabric, and ensuring the maintenance of trust in the aftermath of the crisis. It is relevant to look at communication in an anticipatory way because once society's normal functioning resumes, albeit in a changing environment, citizens' trust and commitment and the maintaining of civic ties are paramount. This research studies the communication patterns between citizens and public institutions in a time of crisis, evaluate the levels of trust in public institutions, as trust is a main concept and indicator in relationship building and predictor of commitment, and provides recommendations based on relationship marketing communication principles. The research was conducted qualitatively, based on 86 interviews carried out in Romania with Generation Z participants.

Introduction

Public institutions are gaining in prominence during the current sanitary crisis. The communication between citizens and institutions is increasingly important for managing the crisis, preserving society's civic fabric, and ensuring the maintenance of trust in the aftermath of the crisis. It is relevant to look at communication in an anticipatory way because once society's normal functioning resumes, albeit in a changing environment, citizens' trust and commitment and the maintaining of civic ties are paramount. The objectives of the research are to (1) study the communication patterns between citizens and public institutions in a time of crisis caused by the COVID19 pandemic, (2) evaluate trust levels in public institutions, as trust is a main concept and indicator in relationship building and predictor of commitment, and (3) provide recommendations based on relationship marketing communication principles.

Literature Review

The public sector's communication has to involve the threefold implication of public institutions at legislative, executive, and judiciary levels, in an accountable, transparent, and efficient manner. This produces a domino effect

BABA "Communication between Citizens and Public Institutions in Times of Crisis: A Study Based on a Generation Z Perspective and Relationship Marketing Principles" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

on other areas of society, such as business, academia, and civil society, empowering them to define their role and represent their interests and rights. The functioning of the public sector depends on an interwoven complexity of relationships and interactions between the executive, the legislative, the judiciary, the national, regional and local administrations, the armed forces and the police, the business, the academia, the media, the non-profit sector, the trade unions, and the religious organizations. (Uphoff, Krishna 2004)

A healthy public system is based on commitment, loyalty, credibility, and combating corruption (Dimant and Tosato, 2017). We follow the established view that there are two main influencing factors of commitment and loyalty: an attitude dimension and a behavior dimension (Day, 1969, Dick and Basu, 1994; Kiesler, 1969; Knox, 1998; Lee and Zeiss, 1980; Mowday *et al.,* 1979; Mägi 1999; Söderlund, 1999; Williams and Hazer 1986). The behavior dimension refers to the fact that people show greater commitment when making more effort to obtain something (Cialdini, 1988; Grusky, 1966; Kiesler, 1971; Söderlund, 1999). Making a sacrifice or a renunciation can lead to self-justification and increase commitment (Kanter, 1968; Farrell and Rusbult, 1981; Lund, 1985; Rusbult, 1983; Salancik, 1977). Commitment is increased when the end-user, in this case, the citizen, participates, and creates value (White, 1959; Bateson, 1985; Stott and Walker, 1995). Participation contributes to reduced perceived discrepancy between expectations and results. Therefore, people tend to give less importance to problems when investing in an outcome or course of action (Raaij and Pruyn, 1998). These findings point out that public institutions need to increase commitment and loyalty by involving citizens in a participatory, voluntary, and effort-based engagement in public consultations and policymaking.

The relationship of the citizen with public institutions revolves around the added value of the public Institution, the co-creation of value with the citizen, and trust and communication (Cătoiu and Ţichindelean, 2012; Gummesson, 2008; Payne and Frow, 2005). In the following paragraph we analyze the relationship of the citizens with public institutions through the prism of Surej's (2019) four relationship marketing pillars:

1. Trust - is the "confidence in exchange partner's reliability and integrity" (Morgan and Hunt, 1994, p.23) and it is at the centre of the capacity to develop a relationship and let it mature (Miquel-*Romero et al.,* 2014; Moorman et al., 2006; Verma *et al.,* 2016; Churchill and Surpernant, 1982). The essence of relationships and exchanges is trust, therefore the concept of trust is central in relationship marketing (Gummesson, 2008) and it applies to the public sphere through the challenge of building trust with constituents and citizens (Andrei, 2018). Trust, in the sense of delivery and fulfilment of promises, is indispensable for a healthy public sector climate. Studies using factor analysis make an attempt at measuring trust, although its measurement is difficult (Pop and Pelău, 2017). Particular care should be given to the relationship marketing approach in relation to trust, as there is an unintended consequence of making consumers more distrustful of organizations which apply its principles, because it risks to become associated with self-interested rhetoric or intrusive practices. On the contrary, trust starts with delivery of promises, cooperation, and mutual respect for each other's values. (O'Malley and Prothero, 2004).
2. Commitment - is the institution's " enduring desire to maintain a valued relationship with its stakeholders" (Verma, Sharma, & Sheth, 2016, p.209), it is at the centre of relationship marketing research (Addison, Lingham, Uslay, and Lee, 2017; Morgan and Hunt, 1994) and it has the capacity to determine the success of a relationship marketing campaign (Miquel-Romero, Caplliure-Giner, & Adame-Sánchez, 2014; Ndubisi, 2007; Moorman, Deshpande, and Zaltman, 2006). Attention is also required for the frequency of the communication flow, as private sector experience shows that a much too dense or scattered communication flow risks to produce an information overload and has counter-productive effect on commitment (Bright *et al.,* 2015; Sasaki *et al.,* 2015; Bawden and Robinson, 2009).
3. Service - the service culture aims to convince citizens that the institutions deliver on their promises. Reality looks worrying both in the public and private sectors, as levels of trust in public interventions is low (Ortiz-Ospina, 2016) and service feedback in private sector is equally disconcerting, with consumer complaints increasing in the US for example (Fournier *et al.,* 1998) and customer loyalty decreasing in the UK, as complaints management seems not be effective in generating loyalty (Management Services, 2000).
4. Information technology - in an era where privacy concerns and data theft are threats, the importance of ethical practices and of trust is crucial (Kushwaha *et al.,* 2020). Communicating with the citizen gains in importance during times when disinformation is pervasive. The communication of public institutions covers two aspects: 1) managing citizen's information in a responsible and respectful manner and 2) making use of new informational technologies and new media (Henning-Thurau and Hansen, 2000).

As indicated by Andrei (2019), there is currently a widespread anti-establishment mood characteristic of contemporary societies. Globalization has a double effect: firstly, a divisive result is characterized by disrupted traditions, and secondly, a uniting effect based on similar goods, mobility across borders, and simultaneous trans-border dialogue and exchange via the internet. There seems to be a "global mirroring of the self" (Andrei 2019, p. 304), in the sense of globalization of fears, emotions, expectations, needs, and ideas. In terms of relations with public

institutions, internationalization adds an extra disruptive dimension, namely, global events influence perceptions of public institutions and markets beyond the influence of public leaders and national market leaders. Such disruptive processes are magnified by phenomena such as fake news, internet trolling, pervasive myths, or just, plainly, criticism from other world areas.

In terms of image, a country's image consists of a real image and a projected image (Picazo and Moreno-Gil, 2017). For this reason, a regional approach is often considered to be fairer as a representation of an area (Margarisová and Vokáčová, 2016), especially for big countries with large differences between areas. Like a political campaign, in the long run, an effective country policy considers regional differences and the different interests of the stakeholders (Anholt, 2008). The so-called "halo effect" (Nisbett and Wilson, n.d.) designated the loyalty that a satisfied consumer develops towards the producer of a product or a service that they are satisfied with is applied for countries as well and can be fostered by an image branding exercise.

Communication of public institutions towards citizens has to consider whether the object of communication is services or products. Communication about services is different from communication about products because of the services' intangibility (Hill and Gandhi, 1992) and a higher level of perceived risk when accessing a service due to the lack of assurance that expectations will be fulfilled (Mortimer, 2002). The challenge of the marketer is to demonstrate benefits that are more experiential than the material in nature. Experiential marketing aims for creating pleasant, exciting, and memorable consumption experiences of products and services (Shobeiri *et al.,* 2018; Pine, Gilmore, 1998; 1999; Schmitt, 1999; Mathwick, Malhotra and Rigdon, 2001). It adds a range of sensory-emotive mechanisms added to rational and benefit-seeking motivations (Holbrook and Hirschman, 1982; Schmitt, 1999).

Services and products have different nature, symbolic meaning, and meaning that the citizen invests it with (Hakkio & Laaksonen, 1998), while the marketer acts as a mediating filter between the nature of the product and its role for the consumer (Pelau and Chinie, 2018). The development of the service sector is a defining feature of the modern economy market and it requires the continuous improvement of applications in the field of quality, manifested by a considerable evolution in terms of service quality management (Teodorescu et al., 2009). Currently, citizens have increased possibilities to review and comment on public services and goods on internet platforms. Studies show that 84% trust online reviews of services and products (Schuckert *et al.,* 2015). Word of mouth, and its electronic equivalent, online forums, is a significant differentiating factor among private brands (Shardanand and Maes, 1995), and a logical evolution will be the spread of such tools to public brands.

Emotional appeals effectively influence a favorable attitude towards services (Mattila, 1999; Zhang *et al.,* 2014). The most effective advertising strategy for services is to showcase the citizen using the service and, secondly, to show a physical representation of the service (Décaudin and Lacoste, 2018). Both ways indicate that the crux of communication in the service sector is to reassure the audience and help them identify themselves emotionally and anticipatory with the advertised service. Tangible attributes are more objective than intangible ones because they reveal themselves to the consumer's mind through the senses instead of intangible ones, which are a projection of the consumer's mind (Hirschman, 1980). The marketer has available a series of strategies for tangibilization (Hill, Gandhi 1992; Mittal, 1999, 2002; Mortimer, 2002, 2008): (1) the use of documentation to prove the service's competitive advantage or value; (2) providing visual examples of the service situation, like the way it is used or sold; (3) stressing physical components (Mittal and Baker, 2002), e.g., an ambulance for medical emergency services, a car and bags for home delivery, books and school premises for education, a fire brigade car for emergency interventions, etc.; (4) by using an established brand image (Pina *et al.,* 2006; Brodie, Whittome and Brush, 2009).

An important factor impacting the communication between citizens and public institutions is culture. Understanding the national or regional culture's specificities is crucial for designing effective services (Davis, Wang, Lindridge, 2008; Laroche *et al.,* 2000), including for public services. Hirschman and Holbrook (1982) point out these cultural differences in experiential consumption. From nation to nation, there are perceptible differences in trust, level of civic commitment, different expectations, and preferred types of confidence-building displays, such as campaigns. One of the most widely spread frameworks for cross-cultural studies was developed by Hofstede (2011). Hofstede's model contains six societal dimensions, individualism vs. collectivism, long-term orientation vs. short-term orientation, uncertainty avoidance, power distance, masculinity vs. femininity, and indulgence vs. restraint, in order to explain the differences among national cultures (Hofstede and Minkov, 2010; Hofstede, 2011; Pelau and Pop, 2018). Societal features such as individualism, masculinity, short-term orientation, uncertainty acceptance, and indulgence lead to a pragmatic approach towards public services, preferring fast delivery and electronic formulas, despite eventual risks or procedural shortcomings.

Methodology

The present article is a qualitative research, using the method of semi-structured discussion and the technique of the interview based on the conversation guide tool. Based on the research objectives mentioned in the introduction, a fundamental literature review, including COVID related literature, was carried out starting with May 2020 and until August 2020. Based on this, the following hypotheses were drawn to form the basis of the research:

H1: The communication between the young generation (Z generation) of citizens in Romania and public institutions depends first and foremost on trust;

H2: The young generation (Z generation) of citizens in Romania expects increased use of IT and electronic means;

H3: The measures undertaken by the Romanian public authorities in response to the COVID19 crisis are timely and effective;

H4: The young generation (Z generation) of citizens in Romania trust the public institutions;

H5: The young generation (Z generation) of citizens in Romania avoid the traps of disinformation in times of crisis.

In order to research these hypotheses, 86 interviews based on a conversation guide were carried out with students from the University of Economic Studies in Bucharest, Romania, throughout September and October 2020. The condition to take part in the study was to have contacted public institutions within the former 6 months preceding the study, from March onwards, since the start of the COVID19 pandemic. Several 150 students were contacted, out of which 86 accepted to participate in the study. The study's age demographics are the following:

- 79 participants are between 18 and 25 years old.
- Four participants are between 26 and 35 years old.
- Two participants are between 36 and 45 years old, and one participant between 45 and 65 years old.

Given the overwhelming majority of participants under 25 years old, the perspective obtained is characteristic of Generation Z, comprising individuals born after 1995 (Dabija *et al.,* 2017). The majority of participants are women. Most of the participants originate from Romania, Bucharest, and they live in an urban area. The interviews were conducted online with the help of e-mails. Following the answers' receipt, the authors returned to some of the respondents with additional clarifying questions in written or through Skype. Anonymity was guaranteed to the participants.

Discussion

The interviewees ranked the public services they used in the former past six months in the following decreasing order of interaction frequency: education, health, tax collection, community facilities (water supply, gas, sewage, sanitation, thermal energy, public lighting, public transport), population registration services, culture, environmental protection and restoration, and the police.

The following parameters influence the communication between the participants and public institutions in decreasing order: trust, reciprocal commitment, relationship building, direct interaction, the objective, rational attributes of the citizen's area of action, personalized interaction, national and local culture, the demonstration of the added value of the public institution's activity, negotiation and, finally, the demonstration of value-added of the citizen's request or initiative. As an example, an interviewee emphasized that, in her perception, public institutions are antiquated from both a physical and moral perspective. Based on the synergy of all these observations, H1 (communication between the young generation (Z generation) of citizens in Romania and public institutions depends first and foremost on trust) is confirmed.

Interviewees were asked to provide recommendations about the way communication with public institutions can be improved. Unsurprisingly for the nature of the sanitary crisis, an overwhelming majority of participants named the use of electronic means, such as e-mail, internet, video conferencing, web streaming, and online public administration services indispensable to better communication followed by the use of social media. A minority of interviewees mentioned the improved use of classical communication means, such as TV, radio, printed publications, and face-to-face communication. The automatization of data processing and the official documents issued, coupled with the client service's enhancement, was proposed only by two interviewees about the age group between 26 and 35 years old. We conclude that H2 (the young generation (Z generation) of citizens in Romania expects increased use of IT and electronic means) is confirmed.

When asked to evaluate the measures taken by the Romanian authorities in response to the pandemic, the interviewees considered that the most useful measures were, in descending order, the (1) possibility to work from home, including for public servants, (2) the organization of online university courses, and (3) the digitization of institutional processes, in order to avoid going to the counter, (4) the social distancing measures, including the closure of public spaces, (5) the granting of technical unemployment, (6) the postponement of fees and bank rates during the crisis, (7) the surveillance and treatment measures for suspected or infected persons and (8) the subsidies provided by the state to companies in severely affected industries. An interviewee points out that although most measures are useful theoretically, they are not implemented effectively.

Almost a third of the interviewees rate the management of the COVID19 crisis in Romania by the public institutions at 6 out of 10 on a Likert scale. A fourth of the participants rate the said crisis response at 7 out of 10 on a Likert scale. Only 10 interviewees rate the crisis response of Romanian authorities at 8 out of 10, and 3 interviewees are very satisfied with a rating of 9 out of 10. Overall, 56 out of 84 interviewees rate the crisis response over 5 out of 10, while the rest of the 30 rates it under 5, with a sixth of the interviewees giving a rating as low as 3 out of 10. The sample of 84 was retained for this, as 2 participants did not answer this last question.

Therefore, we conclude that H3 (the measures undertaken by the Romanian public authorities in response to the COVID19 crisis are timely and effective) is disproved. However, we note the positive reaction of interviewees to the measures (1) to (7) mentioned in the former paragraph and of the majority of participants being fairly positive towards the crisis response by rating more than 5 on a 10-point Likert Scale.

Interviewees were invited to rate the most common community public services according to their level of trust on a Likert scale from 1 to 10, with the results portrayed in Table 1 below.

Table 1. Levels of trust in public services (Source: data collection made by the authors)

Service	Number of interviewees with a trust level from 1 to 5 on a 10 point Likert scale	Number of interviewees with a trust level from 5 to 10 on a 10 point Likert scale	The most prominent rating of trust out of 10 (the highest proportions of participants)
Social security	36	50	6 out of 10 (aprox. a fifth of participants)
Tax collection	37	49	5 out of 10 (aprox. a third of participants)
Culture	19	67	8 out of 10 (aprox. a fifth of participants)
Urban development	40	46	7 out of 10 (aprox. a fifth of participants) 5 out of 10 (a further fifth of participants aprox.)
Education	12	74	8 out of 10 (aprox. a third of participants) 7 out of 10 (aprox. a fifth of participants)
Population register	25	61	9 out of 10 (aprox. a fifth of participants) 8 out of 10 (a further fifth of participants aprox.)
Public roads and bridges	55	31	4 out of 10 (aprox. a fifth of participants)
Environment protection and restoration	50	36	6 out of 10 (aprox. a fifth of participants)
Health	39	47	7 out of 10 (aprox. a third of participants)

Community emergency services (mountain rescuer, lifeguard, first aid)	31	55	8 out of 10 (aprox. a fifth of the participants) 5 out of 10 (aprox. a fourth of the participants)
Community services of public utility (water supply, gas, sewage, sanitation, thermal energy, public lighting, public transport)	29	57	8 out of 10 (aprox. a fifth of the participants) 7 out of 10 (aprox. a fifth of the participants)
Police	35	51	6 out of 10 (aprox. a fifth of the participants) 5 out of 10 (aprox. a fifth of the participants)
Sport	31	55	8 out of 10 (aprox. a third of the participants)

Source: Own creation.

The interviews show a high amount of trust in education and culture, most and foremost, followed in decreasing order by the population register services, community services of public utility (water supply, gas, sewage, sanitation, thermal energy, public lighting, public transport), community emergency services (mountain rescuer, lifeguard, first aid), sport and the police. The lowest levels of trust are, by far, bestowed upon public roads and bridges and environmental protection and restoration. The grey areas of trust are decreasing trust, urban development, health, tax collection, and social security. We, therefore, conclude that H4 (the young generation (Z generation) of citizens in Romania trust the public institutions) is tested and proved for the sectors of education and culture, population register services, community services of public utility, community emergency services, and, in a lesser measure, for the sectors of sport and the police. The said hypothesis is disproved for public roads and bridges and environmental protection and restoration.

The interviewees were also questioned about the fake news phenomenon. It resulted that almost half of the participants are reading only news from sources that they trust and select based on personal selection criteria. Almost a third of participants consider that they can differentiate between accurate information and attempts of disinformation. Eleven interviewees admitted to having given up all news or social media lectures, while six interviewees affirmed not trusting any source any longer. This adds up to almost a fifth of the respondents showing signs of resignation towards disinformation and a withdrawal from information sources altogether as a fatigue response. Fifteen out of the said interviewees are within the age group 18-25 years old, and only 2 are from the age group 36-45 years old. Therefore, we consider that this resignation occurs very early in the participants' lives and might pose a threat to future citizens' morale and attitude, in case this phenomenon is not curbed. In particular, in times of crisis, the disinformation phenomenon is taking dangerous, life-threatening proportions. Nevertheless, the vast majority of the interviewees acknowledge the phenomenon and build a "defense" strategy. Therefore, we conclude that H5 (the young generation (Z generation) of citizens in Romania avoids the traps of misinformation in times of crisis) that is neither proved nor disproved.

Conclusions and Recommendations

The research confirms trust as the main vehicle of communication between the young generation (Z generation) of citizens in Romania and public institutions. We recommend that that trust is built upon anti-corruption measures and whistleblowing mechanisms. Direct, personalized interaction with the young generation, particularly through the use of IT and electronic means, is a priority. The digitization of institutional processes should be a priority and facilities in terms of teleworking, unemployment safety net, and financial and fiscal mechanisms to support the youth in bridging the crisis. Positive examples such as education and culture can be emulated to conceive an action to improve urban development, health, tax collection, and social security services. Urgent intervention is needed in the area of road infrastructure, bridges, and environmental protection and restoration. Urgent measures are also required in the area of disinformation in order o prevent fake news fatigue from creating victims of resignation and civic withdrawal. We propose creating an internet policing unit, able to patrol and sanction online disinformation and intimidation.

Limitations

Given the nationality homogeneity of the cohort investigated, the research specifically aims the situation in Romania. However, a wider national study can lead to nationwide conclusive results. A deeper sociological analysis has to be made regarding whether Generation Z in Romania shares the same features as the members of this generation in other parts of the world. The historical and socio-cultural context indicates a similarity with post-communist eastern European countries. Moreover, the interviewees are students with a high level of education and scholarization. We can see that education is one of the services valued at its highest, which is both an indication of the student's perspective and a vote of confidence and appreciation for the education system in Romania, which largely subsidizes students based on filtering admission exam grades.

Abstract

In this complicated year 2020, COVID-19 made what was once optional into a mandatory part of business strategy, and 2021 will only move the needle further to the digital side. In respect to digital business in 2021, big changes will be seen coming as the post-pandemic era continues to rapidly transform the business landscape. Thus, what many considered optional became imperative overnight speaking of digital business as the majority of businesses will invest in having a full-fledged digital presence. Digital transformation involves using digital technologies to remake a process to become more efficient or effective, as digital transformation can involve many different technologies like cloud computing, the Internet of Things, Big Data, and artificial intelligence. The idea is to use technology not just to replicate an existing service in a digital form, but to use technology to transform that service into something significantly better. Therefore, we start a larger research dedicated to digital transformation and digitalization issues and their influences over the business's performances. Thus, in the beginning, this paper explains what digital transformation is, why it matters, and what its big trends are. The remaining part of the paper deals with identifying ways to find the best talent to drive the cloud and digital transformation in every business. However, businesses must make good on their commitments to embrace a digital model in order to stay relevant and competitive in today's market, as well as to provide better employee and customer experiences.

Keywords: digital transformation, information technology, cloud computing, the Internet of Things, Big Data, artificial intelligence

Introduction

Faced with unprecedented uncertainty, businesses now more than ever need their technology leaders to be resilient, agile, and future-focused. At the same time, current market, economic, and social conditions indicate this is the time for transformational, not incremental, change - and who better than technology leaders to help drive this change?

Information Technology[1] (IT) and business leaders are increasingly under pressure to find ways to apply digital practices to business processes and operations. However, many analysts point to a large divide between the goal of digital transformation and companies' ability to achieve it. This paper considers some of the biggest obstacles standing in the way of that transformation, as well as strategies to overcome them.

Digital transformation efforts are underway to varying degrees at virtually every company, with projects typically

[1] Information Technology (IT) refers to anything related to computing technology, such as networking, hardware, software, the Internet, or the people that work with these technologies. Many companies now have IT departments for managing the computers, networks, and other technical areas of their businesses. IT jobs include computer programming, network administration, computer engineering, Web development, technical support, and many other related occupations. Since we live in the "information age," information technology has become a part of our everyday lives. That means the term "IT," already highly overused, is here to stay (Source: https://techterms.com/definition/it#:~:text=Stands%20for%20%22Information%20Technology%2C%22,that%20work%20with%20these%20technologies).

Cite this Article as: Marius BULEARCĂ and Cătălin POPESCU "How May Digital Transformation Help Boosting Your Business" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

spearheaded by the Chief Information Officers[2] (CIO) or Chief Technology Officer[3] (CTO). However, these efforts are often driven in pockets of the enterprise by individual employees with expertise and passion for digital, and a vision for how it can help their company become more competitive. Dubbed "digital change agents," these individuals come from different backgrounds and skill sets, but all advocate for the same thing: using digital tools and processes to improve the business. These are the individuals in the organization who are most likely not in a leadership role, and maybe not even in a management role. But they are exceptionally passionate, informed, and experienced in digital and its impact on business and markets. They're going out of their roles to try to send that message up the corporate ladder[4].

CIOs and the Chief Marketing Officer[5] (CMO) often battle to spearhead digital transformation efforts, with the CIOs taking a technology-first approach and CMOs taking a customer experience path. Digital change agents tend to see how customers and employees are changing and that efforts need to be cross-functional. However, these individuals are not experienced in change management—one of the largest barriers to digital transformation success. Digital transformation has less to do about digital, and more about good old-fashioned change management. The common challenges for digital transformation to go enterprise-wide were all things related to the fear of executives and their colleagues - things like self-preservation, egos, and politics. Things that digital change agents aren't well-versed in how to navigate.

As 2020 comes to its end, the complete impact of COVID-19 is not fully known. But it's clear that the pandemic has significantly increased business dependency on digital technologies and accelerated the timeline for technology adoption and business digitization, presenting tech leaders with an unprecedented opportunity to help shape the future of their organization. On the technology leader's journey, the board and other C-suite executives will be critical partners.

What is Digital Transformation

We begin our research by showing what digital transformation is, why it matters, and what the big trends are, as digital transformation involves using digital technologies to remake a process to become more efficient or effective.

---

[2] A Chief Information Officer (CIO) is the most senior technology executive inside an organisation. The job title is used widely around the world in business and in government and in charitable and non-profit organisations. The role of the CIO is to help to set and lead the technology strategy for an organisation, in concert with the other C-level executives. As such, one of the many roles of the CIO it to provide an executive-level interface between the technology department and the rest of the business (Source: https://www.zdnet.com/article/what-is-a-cio-the-chief-information-officer-role-explained/).

[3] The chief technology officer (CTO) is the executive responsible for managing technology within an organisation; that can include everything from creating a technology strategy though to cybersecurity and onto product development. They need to understand broad technology trends and be able to align innovation with business goals. The CTO has overall responsibility for managing the physical and personnel technology infrastructure, including deployment, integration, systems management, and the development of technical operations personnel. CTOs also manage vendor relations to ensure that service expectations are delivered. In a sign of the increased expectations of top-class CTOs, the role is moving beyond infrastructure management and towards driving technology innovation and leading digital product development. The analyst says CTOs should be looking to evolve their responsibilities in response to the business' demands for digital transformation (Source: https://www.zdnet.com/article/what-is-a-chief-technology-officer-everything-you-need-to-know-about-the-cto/).

[4] The difference between the CIO and the CTO depends very much on the type of business we're talking about. Some businesses only have one or the other – and in these organisations, the person holding the title, whether CIO or CTO, is the most senior tech chief in the enterprise. Many big businesses, however, have both – and that's where things get complicated. In firms with both, the traditional split is that the CTO is responsible for the operational concerns associated with technology implementation. CTOs drill down into the details of technology. They have a strong systems focus and they know how technology works, making it more of a chief architect role. CIOs, on the other hand, tend to focus more on engaging with the business. So while the CTO might go and speak with vendors to source technology, the CIO makes sure the internal business gets the secure and governable systems and services it wants. In technology companies, **w**hile the CIO focuses on internal applications of technology, the CTO is very much externally focused. In these companies, the CTO – as well as being an expert technologist – becomes the external face of the vendor's technology offering (Source: https://www.zdnet.com/article/what-is-a-chief-technology-officer-everything-you-need-to-know-about-the-cto/).

[5] The chief marketing officer (CMO) is a C-level corporate executive responsible for activities in an organization that have to do with creating, communicating and delivering offerings that have value for customers, clients or business partners. A CMO's primary mission is to facilitate growth and increase sales by developing a comprehensive marketing plan that will promote brand recognition and help the organization gain a competitive advantage. In order to achieve their own goals and effectively shape their companies' public profile, CMOs must be exceptional leaders and assume the voice of the customer across the company. CMOs typically report to the Chief Executive Officer (CEO) or Chief Operating Officer (COO) and hold advanced degrees in both business and marketing. A CMO who has a strong background in information technology may also hold the job title Chief Marketing Technologist (CMT). In some larger organizations, however, those positions are separate, and the CMT reports to the CMO (Source: https://searchcio.techtarget.com/definition/CMO-chief-marketing-officer).

The idea is to use technology not just to replicate an existing service in a digital form, but to use technology to transform that service into something significantly better.

But it's not just about the technology: changing business processes and corporate culture are just as vital to the success of these initiatives. Digital transformation projects are often a way for large and established organisations to compete with nimbler, digital-only rivals. These projects tend to be large in scope and ambition, but are not without risks. While digital transformation is one of the most commonly-used - and over-used - phrases in the IT industry, definitions vary. What everyone can agree on is that, beneath the hype, the fluff and the confusion, digital transformation involves some pretty important changes to business culture.
Digital transformation can involve many different technologies, but the hottest topics right now are: ***cloud computing***[6], the ***Internet of Things***[7] ***(IoT)***, ***"Big Data"***[8], and ***artificial intelligence***[9] ***(AI)***.

How Important is Digital Transformation?

Worldwide spending on digital transformation technologies - hardware, software, and services – hit $1.3 trillion in 2017[10], according to IDC. The tech research company expects spending to almost double between now and 2021, when the total amount spent on digitalisation globally will surpass $2.1 trillion.

In a survey of 460 execs by IT analyst Gartner[11], 62% said they had a management initiative or transformation program to make their business more digital. Just over half (54%) said that their digital business objective is transformational, while 46% said the objective of the initiative is optimization.

---

[6] Cloud computing is the delivery of on-demand computing services - from applications to storage and processing power - typically over the internet and on a pay-as-you-go basis. Rather than owning their own computing infrastructure or data centres, companies can rent access to anything from applications to storage from a cloud service provider. One benefit of using cloud computing services is that firms can avoid the upfront cost and complexity of owning and maintaining their own IT infrastructure, and instead simply pay for what they use, when they use it. In turn, providers of cloud computing services can benefit from significant economies of scale by delivering the same services to a wide range of customers (Source: https://www.zdnet.com/article/what-is-cloud-computing-everything-you-need-to-know-about-the-cloud/).

[7] The Internet of Things (IoT), refers to the billions of physical devices around the world that are now connected to the internet, all collecting and sharing data. Thanks to the arrival of super-cheap computer chips and the ubiquity of wireless networks, it's possible to turn anything, from something as small as a pill to something as big as an aeroplane, into a part of the IoT. Connecting up all these different objects and adding sensors to them adds a level of digital intelligence to devices that would be otherwise dumb, enabling them to communicate real-time data without involving a human being. The Internet of Things is making the fabric of the world around us smarter and more responsive, merging the digital and physical universes (Source: https://www.zdnet.com/article/what-is-the-internet-of-things-everything-you-need-to-know-about-the-iot-right-now/).

[8] "Big Data" is a catch phrase that has been bubbling up from the high performance computing niche of the IT market. Increasingly suppliers of processing virtualization and storage virtualization software have begun to flog "Big Data" in their presentations. What, exactly, does this phrase mean? If one sits through the presentations from ten suppliers of technology, fifteen or so different definitions are likely to come forward. Each definition, of course, tends to support the need for that supplier's products and services. Imagine that. In simplest terms, the phrase refers to the tools, processes and procedures allowing an organization to create, manipulate, and manage very large data sets and storage facilities. Does this mean terabytes, petabytes or even larger collections of data? The answer offered by these suppliers is "yes." They would go on to say, "you need our product to manage and make best use of that mass of data." Just thinking about the problems created by the maintenance of huge, dynamic sets of data gives anyone a headache. Large organizations increasingly face the need to maintain large amounts of structured and unstructured data to comply with government regulations. Recent court cases have also lead them to keep large masses of documents, Email messages and other forms of electronic communication that may be required if they face litigation. Like the term virtualization, Big Data is likely to be increasingly part of IT world (Source: https://www.zdnet.com/article/what-is-big-data/).

[9] Artificial intelligence was described, back in the 1950s, by the fathers of the field Minsky and McCarthy, as any task performed by a program or a machine that, if a human carried out the same activity, we would say the human had to apply intelligence to accomplish the task. That obviously is a fairly broad definition, which is why we shall sometimes see arguments over whether something is truly AI or not. AI systems will typically demonstrate at least some of the following behaviours associated with human intelligence: planning, learning, reasoning, problem solving, knowledge representation, perception, motion, and manipulation and, to a lesser extent, social intelligence and creativity. At a very high level artificial intelligence can be split into two broad types: narrow AI and general AI. While narrow AI is what we see all around us in computers today (intelligent systems that have been taught or learned how to carry out specific tasks without being explicitly programmed how to do so), artificial general intelligence is very different, and is the type of adaptable intellect found in humans, a flexible form of intelligence capable of learning how to carry out vastly different tasks, anything from haircutting to building spreadsheets, or to reason about a wide variety of topics based on its accumulated experience (Source: https://www.zdnet.com/article/what-is-ai-everything-you-need-to-know-about-artificial-intelligence/).

[10] https://www.idc.com/getdoc.jsp?containerId=prUS43381817.

[11] https://www.zdnet.com/article/what-is-digital-transformation-everything-you-need-to-know-about-how-technology-is-reshaping/#ftag=CAD-00-10aag7e 14/16.

According to a recent survey conducted by Grant Thornton, more than two-thirds (69%) of CFOs and senior financial executives are planning to increase their investment in technologies that speed business change, and four in ten said they plan an increase of more than 10% in the next 12 months. Just under half said their companies' digital-transformation investments are meant to help them overtake their competition through differentiation.

Yet it's not all good news. Forrester recently reported that digital transformation efforts are running into roadblocks[12] amid confusion, delusion, and resistance to change (and this situation is summarized and clearly depicted bellow, in Figure 1).

Figure 1: The state of digital transformation
(Source: https://go.forrester.com/blogs/15-12-08-the_state_of_digital_business_2016_to_2020/)

Criticisms of Digital Transformation

To critics, digital transformation simply offers tech vendors another opportunity to rebrand their offerings: it's not uncommon to see systems and services being sold as the answer for digital transformation. This kind of over-selling helps explain why Gartner believes digital transformation is approaching the trough of disillusionment[13].

Tech workers also express cynicism about grand talk of digital. No technology worker spends their working day digitally transforming, rather than coding, programming, and developing. And the phrase can be applied so broadly that it becomes effectively meaningless. Hence, we don't think there's such a thing as digital transformation, but two words that people put together. There is rapid transformation that is driven by technology. Yet all change in society and business these days is impacted by some level of technology.

Why Does Digital Transformation Matter?

Such disillusionment might suggest there is little to be gained by focusing on digital transformation. But beneath the buzzwords there lies a crucial concept: digitalisation is helping smart entrepreneurs and pioneering executives to change the established economic order - and the effects are everywhere.

From Amazon's influence over retailing to Facebook's impact on publishing, traditional firms and sectors are being challenged by nimble, digitally-savvy operators. Yet, while almost three-quarters of business leaders are aware their organisation is under threat from disruption, many are not taking the risk of change seriously.

[12] https://www.zdnet.com/article/digital-transformation-gut-check-sorry-state-or-naturalselection/.
[13] https://www.gartner.com/smarterwithgartner/embrace-the-urgency-of-digital-transformation/.

Only half of enterprises see start-ups as a serious threat, according to research from Dell EMC[14], and almost one in ten do not believe they have any challengers in their market. In fact, 7% of executives say they are not concerned about the threat of digital disruption whatsoever. In these cases, a serious wake-up call is required.

What Does Digital Transformation Look Like?

Technologies from big data to cloud and from the IoT to AI are helping entrepreneurs to develop new business models and disrupt the established way of running operations. These technologies are not just the latest buzzwords, as we see tangible value coming from these technologies in terms of improving product optimisation, increasing production output, and tacking operational efficiency challenges.

So, call it what you want, but digital transformation is very much a thing - and it is something that many executives in traditional firms are still struggling to get their heads around. While start-ups thrive though their new ways of working, their innovative use of data, and their integrated approach to advanced technologies, too many traditional organisations - both in the private and public sectors - are still stuck in legacy mode. These enterprises are fixated on policy and process, rather than information and insight. Such slow-moving firms are getting left behind. Gartner says two-thirds of business leaders believe their companies must pick up the pace of digitalisation to remain competitive.

However, quickening the speed of development is tough. Digital is often viewed as a dark art that only a few experts understand. In too many cases, business leaders fill this knowledge gap with highly-paid consultants[15] who deliver the hype of digital transformation instead of measurable business value. Case studies of projects that deliver true digitalisation are thinner on the ground than the experts have you believe.

What Is Included in A Digital Transformation Project?

A genuine digital transformation project involves fundamentally rethinking business models and processes, rather than tinkering with or enhancing traditional methods. Digitalisation is not, as is commonly suggested, simply the implementation of more technology systems and services. Digital transformation should create something new: that might be an improvement to customer experience (for example by allowing customer self-service), streamlining the supply chain, or using insights from data to offer new products.

This creative requirement remains a tough ask for business leaders. Most organisations do not have a major problem generating new ideas, but many firms fail when it comes to implementing fresh business models[16] or turning good ideas into organisational objectives, according to research from Cass Business School.

This gap between innovation and execution helps explain why digitalisation and disruption are often seen as the preserve of nimble start-ups. But it doesn't have to be this way – there are great examples of digital transformation in the enterprise sector, too.

Digital Transformation Examples

In respect to our current topic, the first example comes from McDermott International. As such, McDermott International is creating a digital twin[17], which is a computer model of the oil and gas platform facilities it provides to clients. The firm envisages a 15% boost to operational margins by using the design-twin approach in key areas like predictive maintenance. Gartner believes half of industrial firms will use digital twins by 2021.

Rolls Royce's R² Data Labs initiative uses machine learning, AI and data analytics to create new services. The R² Data Labs team, which includes 200 data architects, engineers, scientists and specialist mangers, has helped Rolls-Royce deliver more than £250m in value[18] through engine-health monitoring activities in the past 12 months.

[18] https://www.zdnet.com/article/successful-iot-deployment-the-rolls-royce-approach/.

Logistics firm UPS is placing analytics and insight at the heart of business operations[19]. The firm is using real-time data, advanced analytics and AI to help employees make better decisions. The firm recently launched the third iteration of its chatbot[20] that uses AI to help customers find rates and tracking information.

In the public sector, NHS Blood and Transplant has spent the past two years pushing a digital transformation agenda[21]. Several interesting trials are currently taking place, including around the use of predictive analytics and the likely waiting time for an organ. The ability to understand organ availability has a huge impact on healthcare.

What does digital transformation mean for legacy systems?

Digital transformation might be where companies want to be, but that doesn't mean IT leaders can afford to forget about their existing infrastructure investments. Gartner says 90% of current applications[22] will still be in use by the year 2023.

This older kit can be an obstacle to change. Almost half (44%) of CIOs believe complex legacy technology is the chief barrier to digital transformation, according to the Logicalis Global CIO Survey[23], with 51% saying they plan to adapt or replace existing infrastructure as a means of accelerating digital transformation.

It is encouraging IT leaders to recognise the replacement of legacy systems with modern, cloud-based systems is not in itself an objective. This process of re-platforming is the foundation for business change, rather than the actual process of digital transformation.

Who is responsible for digital transformation projects?

As the traditional guardians of technology investment, CIOs tend to have a big say in digital change projects. Yet CIOs are far from the only executives with a role in digital transformation management, and the pressure for change has led to the rise of new C-suite specialists, such as chief digital officers[24] (CDOs).

Analyst firms fanned the flames by suggesting the appointment of CDOs could hasten the demise of the traditional IT leadership role.

Gartner originally claimed[25] a quarter of businesses would have a digital chief by 2015, and IDC said[26] 60% of CIOs would be replaced by CDOs by 2020. Right now, those predictions look way off beam. While line-of-business employees are good at buying discrete digital technologies, CIOs have the experience of integrating systems and services. In most cases, appointed CDOs work with their CIO colleagues to exploit advanced technology on behalf of the business.

In fact, CIOs have used their experience to maintain a tight grip of digital transformation. Gartner says more than half (55%) of the 300 top-performing CIOs in global businesses also hold the CDO role. Digital transformation affects the entire business and CIOs help ensure technological elements are understand, bedded down and useful.

[24] Definitions of the role of Chief Digital Officer (CDO) focus on the core responsibilities of this new executive role - the transformation of traditional operations using digital processes. CDOs aim to generate new business opportunities, revenue streams and customer services from the adoption of digital technologies. That could take any form from the relatively mundane - replacing paper forms with a digital equivalent - right through to reorganising entire business units. In reality, CDOs are business-facing individuals that often don't have a background in technology, but they're specialists in digital business models. Because the chief digital officer role is so reliant on the use of technology, there is an overlap with the CIO position - and there's some competition as a result. Yet rather than being experts in IT implementation, CDOs are commonly characterised as change agents, because CDOs can be very effective, and can initiate new approaches quickly where they buy cloud services and avoid in-house IT development in a traditional sense. CIOs remain the owners of the technology infrastructure of any company, but CDOs will have a slightly different skill set; while they won't always have the technical detail, they tend to be strong communicators. They talk about the power of disruption and get people to buy into their vision of change, and thus, the role is about more than implementing digital services (Source: https://www.zdnet.com/article/what-is-a-chief-digital-officer-everything-you-need-to-know-about-the-cdo/).

1.9. What's the Difference Between Digital Transformation and Business Transformation?

Business transformation is accelerated by and built upon digital technologies[27]. It's a sentiment that says digital, rather than being a thing you do, is a way of working. As such, we think that's the big difference: digital transformation within a business is not about putting in technology that does digital, it's more about the way that you work with those tool sand work across teams.

Digitalisation, therefore, is a way to help the business transform. Such is the potential power of disruption that debates about digital or business transformation are redundant. And thus, there isn't an IT or a business strategy; instead, there's a single digital business strategy.

When does digital transformation stop?

The answer is simple as that: digital transformation doesn't stop. Many people make the mistake of thinking of digital transformation as a discrete project. As Forrester suggests, true transformation is a journey, not a destination[28]. Digital transformation remains a slippery concept that involves the delivery of value to the business and its customers in new - and perhaps unexpected - ways.

Yet while the demand for change will keep on coming, 21% of business and technology decision makers believe their digital transformation efforts are already complete[29]. Such executives are deluded, as almost-constant strategic iteration is the new norm. Digital-led change is likely to go on forever; as such, the word transformation implies there's a beginning and an end - and there isn't. When we have projects that are badged as digital transformation with a shelf life of two-to-three years, this is not long-term sustainability; in fact, we could argue whether any digital system or service offers sustainability.

How is data transformation evolving as a concept?

Just as digital transformation constantly changes, so do its constituent elements. Right now, most business transformation activities involve the innovative use of data, whether that involves analytics, IoT, or machine learning. In many ways, as digital transformation has evolved it has become more about data-led change than anything else.

This transition can be seen in executive job titles, too. As use of the chief digital officer epithet has waned in recent years, so chief data officers[30] have become more common. In this respect, a survey conducted by Research company Econsultancy[31] tracked the use of the chief data officer title on LinkedIn for two years. In April 2016, there were 2,899 people who identified as chief data officers; by February 2018, there were 11,418.

So, the form of digital transformation continues to evolve, meaning the process of defining digitalisation remains complex and contested. The one thing we can be sure of is that transformation - in whatever form it takes - is here to stay, which means CIOs and the rest of the senior team must build a sustainable business strategy. This is the reason why the remaining part of this paper is dedicated to find the right persons that may drive ones cloud and digital transformation leading to boost businesses.

How to find the best talent to drive your cloud and digital transformation

[27] https://www.zdnet.com/article/the-new-rules-of-business-digital-transformation-must-thrive-throughout-yourcompany/.
[28] https://www.zdnet.com/article/the-new-rules-of-business-digital-transformation-must-thrive-throughout-yourcompany/.
[29] https://www.zdnet.com/article/digital-transformation-gut-check-sorry-state-or-natural-selection/.
[30] The Chief Data Officer (CDO) is a senior executive who is responsible for organisation-wide governance, management and exploitation of information. This data management and exploitation takes place through a variety of systems and services, including business intelligence, advanced analytics, data mining, and machine learning, and even artificial intelligence. CDOs should be on the look-out for ways to find opportunities for and through data analytics, whether that's predicting customer trends or finding new revenue-generating opportunities. That data might be customer data, data gathered from IoT sensors, social media, structured, or unstructured data; anything that the organisation gathers itself of buys in from elsewhere. The CDO must ensure the data is secured and maintained, but the role is not simply about deciding the technical aspects, like whether the information should be held in a data warehouse or a data lake or master data management. Instead, the CDO needs to help the business understand the value of this digital asset, enabling it to be mined for insights and competitive advantage. Data might be the crown jewels of a modern enterprise, but many businesses don't necessarily manage their information successfully. That realisation helps explain why CDOs play a key role in helping organisations take care of the information they hold and use (Source: https://www.zdnet.com/article/what-is-a-chief-data-officer-everything-you-need-to-know-about-the-cdo-role/).
[31] https://www.slideshare.net/DavidReilly1/econsultancyguidetolinkedinmarketingsolutions.

While technology and digital transformation are widely seen as critical to the success of virtually every business, in the past, CEOs and tech leaders haven't always seen eye to eye on strategy and tactics. However, success in business today, across several dimensions, is highly correlated to technology competence. Hence, the attitudes of CEOs and tech leaders are remarkably in sync about the importance of technology to enable business strategy; in fact, CEOs even say technology is slightly more important than their CIO counterparts.

This is great news for tech leaders who are shaping their technology functions to deliver significantly more value to their organizations. They have air cover from the highest levels of their companies to do so. This more integrated, strategic approach to technology can have ramifications across the organization. Digital cannot be a standalone initiative but should be embedded in the business strategy. CEOs are signalling that the technology function cannot operate as a siloed entity, struggling to get funding and support, and make a meaningful impact on the business. The invitation to tech leaders is clear: They have a critical role in developing and fostering business strategy, and their readiness to leverage technology is a key competence. The challenge is also very clear: If they don't step up, other leaders within the organization will likely take on these roles, as the role of a technology leader is not to develop a digital strategy or vision, but to embed digital in the business strategy,

As a result, most companies use a combination of talent acquisition techniques to get their digital transformation and cloud work underway. Here's a rundown of effective approaches.

IT-as-a-service (ITaaS)[32] is an operational model where the IT service provider delivers an information technology service to a business. That service could come from internal staff or from outside resources. The key is that this service is so seamless, the customer never really knows where it originates from.

To run IT-as-a-service successfully, you need talent in service and talent in technology. Nowhere is this more apparent than in digital transformation and cloud-based IT, where most companies are making major investments. Unfortunately, the talent isn't always available.

In a 2017 CFO Research Survey[33] of 123 US mid-market company financial executives, almost half (49%) said the inability to attract and retain qualified technology talent was adversely affecting their businesses.

When these executives were asked about the strengths of their internal IT staffs, they said that 40% of their talent challenges were in finding the technical and service skill sets internally to do the projects IT was being asked to do. Another 36% said that their internal IT lacked strategic planning and vision, 34% said that internal IT lacked knowledge of the business, and 33% said that IT was lacking project management skills.

Solving this talent challenge isn't easy. To meet it, CIOs consider a variety of strategies that range from direct hiring, contracting, and renting to sharing talent. The most coveted IT skills are in digital transformation and advanced skills in cloud-based technologies.

The technical skills needed for digital transformation are not necessarily difficult for IT to provide; rather it's the set of soft or interpersonal skills that facilitate digital transformation that IT lacks. Digital transformation projects[34] require significant interactions with users as they learn how to master new digitally based technologies, like document management.

Working in a collaborative and sharing service context doesn't come easy for many IT professionals, either. They may prefer to be engaged in the technical details of their work and might be protective when it comes to sharing their knowledge and skills.

At the same time, a new set of core technical and services skills is emerging in cloud computing. These skills include artificial intelligence, machine learning, and IoT. Resident IT staffs don't always have these skills.

Digital transformation and advanced cloud management techniques are areas that CIOs must address to ensure that their staff can meet technical and service needs. Here's a look at some of the talent acquisition strategies that companies are using.

Hiring

[32] https://web.archive.org/web/20160706002136/http://www.peterhinssen.com/downloads/printmedia/179/08_it_as_a_service.pdf
[33] https://www.cfo.com/it-value/2017/09/dealing-deficit-talent/.
[34] http://jarche.com/2015/04/digital-transformation-skills/.

In a 2016 Harvey Nash and KPMG survey[35] of more than 3,000 IT leaders, 65% reported difficulty hiring IT talent and said it was hurting their businesses. Data science, security, and cloud computing talent were among the most difficult areas to recruit for. All of these skills bases are directly related to digital transformation and cloud technology.

Companies have to offer attractive compensation, positions, and career paths to successfully compete in these tough talent markets. They must also provide pleasant work cultures and working conditions. Many companies use talent management systems[36] that help them forecast their staffing requirements and assist them in determining how they're going to fill talent acquisition and development needs - whether it's through outside hiring or through internal cross-training of personnel - so they can fill new roles.

Some companies also use the 'farm system' approach, where they partner with local colleges and universities. In this approach, companies serve on college and university advisory boards, assisting in the design of IT curriculum. More aggressive companies don't stop there: they provide senior staff to deliver lectures in classrooms on relevant topics and sponsor college-credit company internships for students. By interning students, the company gets to know young grads in advance of deciding whether to hire them. If a company does decide to make an offer, it is making it to a known quantity individual who has already formed professional relationships with staff. This improves the odds of a successful hire and provides a way to get new grads into productive IT roles faster.

Contracting

Contracting is another approach IT takes to solve talent shortfalls in digital transformation and cloud-based work. There are websites where you can seek IT contractors[37], but the best avenue for securing high-calibre tech contractor talent is through word of mouth or by contacting contractors you have already worked with. For one thing, you already know the type and level of work the contractor can provide. A second reason is cultural. The contractor has likely already demonstrated that they work well with your team.

When you employ a contractor, you pay top dollar for services and expect that the individual will be highly self-sufficient, with no learning curves. Accordingly, agreements with contractors should be structured to allow you an easy out at the beginning of an engagement if you discover that they aren't measuring up.

Companies also use the contractor approach when they need to fill an important position, like data scientist, but haven't been able to push it through as a permanent hire in their budgets. In such cases, they might hire a contract data scientist and decide to offer permanent employment later if the contractor's work is excellent and the budget opens up.

Renting

Although the terms 'renting' and 'contracting' are sometimes used interchangeably, they are not the same. When you rent, you are using more of a permanent outsourcing approach than when you contract. Companies rent call centres (and call centre agents). In IT, they might even opt to rent help desk staff who provide service and support for digital transformation.

Renting is more broadly utilized in advanced cloud technology. Software-as-a-service[38] (SaaS), platform-as-a-service[39] (PaaS), and other cloud-based offerings are rented via subscription or per-use prices. The understanding is

---

[35] https://www.monster.com/career-advice/article/tech-talent-gap-survey-0816.
[36] https://blog.clearcompany.com/3-ways-to-gain-a-competitive-edge-in-hiring.
[37] https://www.inc.com/drew-hendricks/10-best-freelance-websites-to-find-skilled-contractors.html.
[38] Software-as-a-service (SaaS) is the most common form of cloud computing, where you use a browser and an internet link to access a service provider's application, which is hosted and managed on its servers. You pay for the service according to how much you use it or by subscription, rather than by buying a licence and paying for maintenance, as you would with software run on premise. When people talk about on-demand software and hosted apps, they're usually talking about SaaS. SaaS has been around for years, but some view the launch of Salesforce.com's customer relationship management service in 1999 as a big moment that marked SaaS's move into the mainstream. The principle of remotely using software located on someone else's hardware goes back to the earliest days of commercial computing in the 1950s and 1960s, with the bureau and time-sharing services at LEO and IBM (Source: https://www.zdnet.com/article/software-as-a-service-saas-cheat-sheet/).
[39] Platform-as-a-Service (PaaS) is an integrated set of data management, analytics, and insight application development and management components, offered as a platform the enterprise does not own or control, may sound scary, or cryptic. Cloud computing can be broken down into three cloud computing models, where Infrastructure-as-a-Service (IaaS) refers to the fundamental building blocks of computing that can be rented (physical or virtual servers, storage and networking). PaaS is the next layer up - as well as the underlying storage, networking, and virtual servers this will also include the tools and software that

that you will be using the cloud resource for the long term.

One of the most popular cloud-based rental services for IT is in application development and testing because the cloud-based vendor furnishes the hardware and systems and you don't have to buy them.

Anyhow, we must emphasize that SaaS has had an enormous impact on the way companies consume services. As soon as internet connectivity became widely available at reasonable speed, and offered low enough latency, service providers of various kinds began offering scalable, on-demand products that were delivered over those connections.

For many observers, the modern cloud computing era dates from the launch of the first business-class software-as-a-service (SaaS) application, Salesforce.com, in 1999. But of course, there were precursors, including application service providers (ASPs) and, before that, utility computing via timesharing on mainframes. There are now thousands of SaaS applications, available from internet giants to start-ups, along with services from rather fewer providers of the other two key pillars of cloud computing: platform-as-a-service (PaaS) and infrastructure-as-a-service (IaaS).With SaaS, service consumers control their data, but everything else in the IT stack is managed by the service provider. With PaaS, the application layer comes into play, while IaaS consumers control everything from the OS layer upwards.

The contrast with traditional on-premises (or private cloud) IT is very clear: the capital costs associated with equipping and maintaining data centres full of physical and virtual servers, networking and storage are someone else's problem—and large service providers (such as Amazon, Microsoft and Google) can solve that problem far easier than the average business can. As a customer, you just pay for what you use.

The fundamental benefits of the *'as-a-service'* model are well known, and include: a shift from capital to operational expenditure (CAPEX to OPEX), often leading to lower total cost of ownership (TCO); access for businesses of all sizes to up-to-date technology, maintained by service providers that can leverage economies of scale; scalability according to business requirements; fast implementation times for new applications and business processes; freeing up staff and resources for other projects and priorities.

Sharing

Resource sharing is another approach to talent acquisition that can be used effectively in both digital transformation and the cloud. It's most often used by smaller companies, especially in the not-for-profit sector.

Here's how it works in the credit union world: Four small credit unions can't afford their own IT departments and specialists, so they band together to fund an IT budget and hire the ITers they need. They fund cost and resource-share data centre and personnel expenses, which are facilitated because they all use the same systems. IT becomes a service centre, as it now has four 'customers' whose needs it must serve. The challenge for the CIOs is to make sure that the individuals assigned to the cloud service have service and support skills that can match their technical skills. Sometimes this is easier said than done.

Final Remarks

No single talent acquisition strategy fits all companies, and most companies today use a combination of talent acquisition techniques to get their digital transformation and cloud work done. That isn't likely to change soon.

Thus, the modern workforce – and the companies that employ them - have increasingly embraced the concept of remote work over the traditional office. The benefits are well documented, including stress reduction, increased productivity, a wider talent pool, and better employee retention rates. Even so, it's important to establish ground rules to keep the remote work program effective and manageable.

Defining a clear vision of what you expect your workers to do - and a vision of where they can go and grow - helps enormously, whether they are permanent employees, contractors, or rental vendors. So does showing them that you care about their welfare/partnership, that you are committed to service in your culture, and that you appreciate the efforts they make for your company.

---

developers need to build applications on top of: that could include middleware, database management, operating systems, and development tools. And finally, the upper layer: Software-as-a-Service (SaaS) is the delivery of applications-as-a-service, probably the version of cloud computing that most people are used to on a day-to-day basis. The underlying hardware and operating system is irrelevant to the end user, who will access the service via a web browser or app; it is often bought on a per-seat or per-user basis (Source: https://www.zdnet.com/article/what-is-cloud-computing-everything-you-need-to-know-about-the-cloud/).

Conclusions

In this complicated year 2020, COVID-19 made what was once optional into a mandatory part of business strategy, and 2021 will only move the needle further to the digital side. In respect to digital business in 2021, big changes will be seen coming as the post-pandemic era continues to rapidly transform the business landscape. Thus, what many considered optional became imperative overnight speaking of digital business as the majority of businesses will invest in having a full-fledged digital presence.

As a result, digital business will be based on five key points, as follows:

- *Businesses worldwide will create digital divisions.* Digital engagement will become the number one driver of customer value in 2021, and many global organizations will join large organizations in launching data, artificial intelligence, and software-driven divisions.
- *Cloud-first strategies will dominate digital growth.* Every new digital division will embrace innovation through ecosystems, and further 50% of enterprises are expected to make cloud-centric transformation a priority, moving business-critical operational apps and all experience apps into the cloud.
- *"Buy" buttons will be everywhere.* 2021 will be a year in which businesses will toss a variety of sales channels at the wall to see which ones stick. It will be about experimenting with all these channels to build new types of direct customer relationships.
- *DOP will further replace ERP, leading to more platform innovation.* Digital operations platforms (DOP), which combine back-office business tools into a single product, were hot in 2020, and they'll continue to grow as a replacement for legacy enterprise resource planning (ERP) software. Greater DOP adoption will push vendors to differentiate their products, which is a good thing for their clients.
- *Outcomes-based pricing will grow for digital transformation services.* Businesses looking to embrace digital business strategies will be looking to lots of outside vendors, and 50% of new transformation services contracts will include a pay structure based on meeting particular outcomes.

Finally, we must add that coping with all these digital issues involves that buyers of transformation services will expect providers to bring alliances, end-to-end expertise, and software and data assets to accelerate time-to-value. Hence, consultants, tech service providers, and other agencies will need to be aware of this potential and plan budgets accordingly. While most IT and business executives believe a digital business model is critical for success, we argue that it is very important for an organization to implement a digital business model. However, businesses must make good on their commitments to embrace a digital model in order to stay relevant and competitive in today's market, as well as to provide better employee and customer experiences.

As 2020 comes to its end, the complete impact of COVID-19 is not fully known. But it’s clear that the pandemic has significantly increased business dependency on digital technologies and accelerated the timeline for technology adoption and business digitization, presenting tech leaders with an unprecedented opportunity to help shape the future of their organization. On the technology leader’s journey, the board and other C-suite executives will be critical partners.

Following the path tread by executives in tech vanguard organizations, tech-savvy business leaders should engage, enable, and support their change-driving technology leaders. Like financial literacy, tech savviness has become a key competency for all business leaders. The onus is on technology leaders to help ensure that their business counterparts are on board for the journey and that leadership teams are appropriately tech savvy.

Organizations in all sectors and geographies are entering a new volatile era, and they likely will need leaders with the vision and tenacity to drive meaningful change amid historic uncertainty. They can’t control the wind, but they can adjust the sails – but probably not by incrementally fine - tuning their strategies and technology capabilities. Faster, game-changing breakthroughs can help organizations meet the challenges of the moment - and those of the future - and technology leaders can help them make the leap from incremental to transformational.

But topics related to why CIOs must step up to lead digital transformation efforts, why the CIO is essential to digital transformation, the business executives’ commitment to digital transformation, and IT's new role (that is to build a digital society worthy of our descendants) shall be largely addressed in our future papers.

Abstract

Electronic platform environments are increasingly used as a mechanism for sharing and integrating digital services delivered to a recipient. One of the main areas where given platforms are used is public administration and implementation of processes for handling public tasks. The authors in their previous publications have shown that the previously available security models are not sufficient and the mechanisms implemented in existing environments are not supported by a formal model that would clearly allow to determine the state of safety of the environment with the possibility to dynamically integrate the services provided. Based on previously developed models, formal descriptions and research conducted by the authors, a new approach built on the mathematical lattice model was developed. In this work, the authors modelled the process to handle public tasks together with a mathematical protection model in such platforms. Then, using the lattice model, the authors proposed a safety control solution in the integration processes of electronic platforms.

Keywords: Mathematical Modelling, Electronic Platforms, Information Systems, Lattice Model, Security, Public Administration, Public Tasks.

Introduction

The authors' experience, both in research and development tasks (numerous previous publications) and in design and implementation tasks, clearly shows a lack of methodical use of the results of system analysis and mathematical modelling in designing IT systems (solutions).

The harmfulness of the lack of the above-mentioned coherence is definitely growing in the case of designing mechanisms which have a particular impact on the users' confidence in using IT solutions, i.e. solutions where the critical problem is to provide effective, user-acceptable security mechanisms. This applies to the greatest extent to processes implemented in a dispersed IT environment, such as the implementation of electronic services with the use of disciplinary and trans-disciplinary (integration) electronic platforms. The lack of security mechanisms with formally confirmed properties may lead to illegal breaches of data confidentiality, to loss of trust and, consequently, to collapse of many projects.

The use of mathematical modelling, principles of enterprise architecture and object-oriented modelling enables the development of a design method, the application of which in the design process will ensure the creation of security mechanisms with formally and unambiguously confirmed properties. The use of mechanisms, designed in accordance with the developed method, in the processes to handle public tasks by electronic disciplinary and trans-disciplinary (integration) services and platforms will contribute to the automation and the increase of security of the electronic handling of public tasks. This is feasible provided that the integration requirements expressed first in the language of the mathematical correlations are correctly reflected in the object-oriented modelling language (architectural framework) and thus taken into account in the ongoing design efforts.

In this paper the authors conducted theoretical considerations on the process to handle public tasks (Chapter 2), then modelled the processes mathematically (Chapter 3) together with the selection of a security model for the verification of the correctness of the handling process (Chapter 4). Next, in Chapter 5, the authors presented

mathematical modelling of security processes in the electronic platforms together with the security control lattice model used in the integration processes of the electronic platforms (Chapter 6). Chapter 7 summarizes the considerations and presents the usefulness of mathematical modelling, including lattice modelling, in constructing integrated electronic platforms.

Preface on the process to handle public tasks

The theoretical considerations concerning the security of the handling public tasks in the electronic service platform environment will be carried out within a certain abstract model of the electronic platform. This has been determined by: firstly, the possibility of precise, transparent formulation of problems concerning the security of the handling of public tasks and secondly, the possibility to keep the independence of considerations from detailed technical aspects of electronic platforms, which are almost continuously subject to both conceptual and technological changes.

In order to facilitate the understanding of the further development of our considerations, the formal modelling will be preceded by a short description explaining the general assumptions adopted and the subsequent steps of the public task handling, which take into consideration the above-mentioned assumptions. First of all, it should be stressed that the user (hereinafter referred to in the model as the entity) must use a dedicated electronic platform created and functioning according to the one-stop-shop principle in order to process a case, he/she is interested in, by electronic means. In general, it must be an integrative trans-disciplinary platform, as the resources needed to process any case may come from many different disciplinary platforms under the responsibility of many different administrators. Each case that can be handled electronically is assigned a single, specific public task in the platform's directory, the successful handling of which will lead to its successful processing. In practice, the user, after making sure that the case, he is interested in, can be processed via electronic means, should search the platform's catalogue for a public task identifier appropriate to the case he is processing electronically. This part of the user's interaction with the platform is usually supported, according to the one-stop-shop principle, by a special layer of the electronic platform, which makes it easier for the user to link the case to the relevant public task. Modelling and then designing such a user-friendly support layer is a very difficult, and at the same time significantly affecting the usability of the platform, undertaking.

Nevertheless, due to the specificity of its problems existing in this layer, it will not be considered further. Therefore, we will assume that the user has made proper use of this layer and, as a result, has correctly triggered a public task "responsible" for the processing of a case he/she is interested in. Each public task in the platform directory is associated with a scheme describing the process of handling this task. In other words, the above scheme is a recipe that is sufficient for the successful conducting and completion of the handling process of the public task in question, provided that the security requirements are met. We will further assume that the handling of a public task will be expressed, from the point of view of the possibility of security assessment, in the form of a process of the handling of a given public task by a given trans-disciplinary integration platform by means of a sequence of extortion, the implementation of which affects the security status of this process. As a result, the handling process is a sequence of extortions occurring alternately and the resulting security status of the handling process. Thus, if a collection of correct extortions is extracted from the collection of possible extortions, then in general (other, more practical cases will be considered in the chapter on formal modelling) it will be possible to verify the correctness of the handling process in terms of the extortions occurring in it and the achieved security status on the basis of the security rules required in a given platform.

In order to ensure safe handling of public tasks carried out by electronic means, it is necessary to build mechanisms to control a given process. These mechanisms must be placed in electronic platforms (disciplinary and integration platforms).

A disciplinary platform for electronic services - in general this is an environment for service delivery and their protection. It is limited to a single disciplinary entity (legal one, organizational one and/or public one). It has electronic services (simple ones and complex ones) and data units. In the following part of the paper, it is not important whether the services are simple or complex, they will be considered as electronic services (or even shorter services). It also defines the possible data operations, a collection of entities and security control model. Extortions that triggers electronic services from the disciplinary platform require correctness check from a security point of view.

Within the framework of electronic services on the electronic platform, a distinction can be made between disciplinary and trans-disciplinary services.

- Disciplinary service - that is an electronic service which can be provided by services from one disciplinary platform only.
- Trans-disciplinary service - that is an electronic service which requires the execution of at least one or more electronic services available in another disciplinary platform.
- Electronic integration platform - it is an electronic information system that enables cooperation of disciplinary electronic platforms.

Electronic platforms, which are considered in a given paper, are designed and built in such a way that they have functionality useful to assist a defined group of users in processing their cases within a defined scope. Such a group of users of electronic platforms have been called entities. They form the collection P:

$$P = \{p_1, p_2, ..., p_i, ..., p_I\} \tag{1}$$

The individual entities benefit from the support of electronic platforms in processing various administrative cases. They decide themselves to what extent they will use the case support within the possibilities of the electronic platform used. Making a choice - as already said - is not the subject of modelling in this paper.

The framework of possibilities to support the processing of cases in a given platform is defined by a collection of public tasks handled in a given electronic platform. Hence, the entity selects a public task that is useful for processing a given case from the collection of public tasks Z:

$$Z = \{z_1, z_2, ..., z_j, ..., z_J\} \tag{2}$$

Handling public tasks in electronic platforms

The functionality of the electronic platform includes the possibility to handle public tasks according to handling schemes appropriate for particular public tasks. These schemes form the collection S:

$$S = \{s_1, s_2, ..., s_k, ..., s_K\} \tag{3}$$

The individual handling diagrams are clearly assigned to the individual public tasks with the function π:

$$\pi : Z \rightarrow S \tag{4}$$

For further consideration it is necessary to define the electronic service, the operation and the data unit.

The electronic service is an executable resource that processes data from data units when performing operations. Electronic services form the collection E.

$$E = \{e_1, e_2, ..., e_l, ..., e_L\} \tag{5}$$

where:

E - the collection of electronic services,

e_l - l-th electronic service.

At this stage of consideration, electronic services are not considered from the perspective of simple and complex services.

The operation is an elementary executable resource that processes data from data units. They form the collection R:

$$R = \{r_1, r_2, ..., r_n, ..., r_N\} \tag{6}$$

where:

R - the collection of operations,

r_n- the n-th operation.

A data unit is an information resource for storing data. They form the collection D:

$$D = \{d_1, d_2, ..., d_m, ..., d_M\} \tag{7}$$

where:

D - the collection of data units,

d_m - the n-th data unit.

The public task handling diagram defines a sequence of extortions. Extortions, which may occur in a given electronic platform, forms the collection W:

$$W = \{w_1, w_2, ..., w_n, ..., w_N\} \tag{8}$$

The sequence of extortions, defined by the public task handling scheme, s_k defines the handling process unambiguously:

$$w_1^k, w_2^k, ..., w_n^k, ..., w_{N_k}^k \tag{9}$$

Verification of the correctness of the process to handle a public task from the point of view of security consists in checking whether all the elements of the sequence of extortion, created for a given handling process, are correct.

The correctness of extortions depends on the rules applicable in the platform in relation to individual entities. The permissions of individual entities are determined by function u:

$$u : P \rightarrow 2^W \tag{10}$$

The form of extortion depends on the model adopted to describe the process to handle public tasks in an electronic platform. Verification consists of checking whether all extortions w_n^k occurring within the sequence defined by the scheme for handling the public task, s_k which such scheme is associated with the public task pointed by the entity, are consistent with its permissions.

Selecting a security model for verification of the correctness of the handling process

It is assumed that correct extortions will carry out the public task handling process to a safe state (assuming that the initial state is safe). Therefore, it is sufficient to verify only extortions within the handling process.

Extortions may take different forms (depending on the security scheme) but for further consideration only the most complex one was selected – “electronic services, operations and data units”. In this case a sequence of extortions is

presented in the form of a sequence of triplets - data units processed within the public task handling process, operations on data units and electronic services.

Before the authors proposed their own security approach for selected scenario they performed deep analysis of available models with set of criteria based on mathematical model for distributed environment of electronic services platforms. Some available mechanisms were partially integrated as useful but not fully fitting to analysed e-services solution:

- Harrisona-Ruzzo-Ullman model – based on Lampson access control matrix,
- BLB, Biba and Dion models – data flow control,
- Denning, Sandhu and Szafranski models – lattice security models.

Mathematical modelling of protection processes in electronic platforms

The mechanism to control information security (SM) for disciplinary platforms consists of two elements:

- the data security control model (DP data protection), i.e. data access control and data flow control,
- the service execution security control model (services protection SP).

$$SM = \langle DP, SP \rangle \tag{11}$$

Data units from the D collection are assigned confidentiality classes from the collection Q, e.g. unclassified, confidential, secret, top secret. The operations from the collection R have the scopes of operations assigned to them in the collection T, e.g. reading, writing, deleting. Electronic services E are assigned categories of permissions from the B collection, e.g. common, specialized, reserved. Each entity p_i in the collection P has been assigned attributes that define its level of authority:

- the confidentiality class in the collection Q (to which the entity has access),
- the scope of operations from the collection T (acceptable for a given entity),
- the category of permissions from the collection B (indirect launch of services by the entity).

Depending on the security protection model in the given platform, the form of granting these permissions may vary.

The graphical representation of the relationship between the model elements is shown in the Fig. 1 below. Some of the terms referred to in this scheme are explained in more detail later in this chapter.

Fig. 1: The scheme of links between objects of the models.

The scheme above shows the links between the objects of the security protection model in the platform, that determine the requirements necessary to be met during the implementation of this protection.

The need to implement a public task is reported by one of the entities forming the collection P, by initiating the task selected by him. The public task is clearly assigned a scheme for handling this task belonging to the collection S. The scheme defines a sequence of extortions, which, according to the selected security model for verification of the correctness of the handling process, can be seen as a sequence of triplets - processed data units, operations on data units and electronic services (i.e. elements of the collections D, R and E respectively). This assignment of extortions to the S-collection scheme is shown as a function of α, β and γ respectively.

In the security layer in the electronic platform, it is not the specific data units, operations and services (D, R and E) that are relevant, but confidentiality classes assigned to them, scopes of operations and permissions categories (Q, T and B). Thus, the scheme illustrates these relationships by placing the symbols of the functions H_1, H_4 and G_1, which are defined further in this chapter.

And further on, as a consequence, the permissions of entities (in the model form of the u function) were indicated, referring them to confidentiality classes (Q), scope of operations (T) and categories of permissions (B), as this is the nature of granting permissions to individual entities.

Data Security Control

The DP model specifies the allowed-for-an-entity access to data units of a certain confidentiality class, the operations allowed with a certain scope and the data flows allowed between data units.

$$DP = \langle P, D, Q, R, T, \rho, \tau, HF \rangle \tag{12}$$

where:

- P - collection of entities $P = \{p_1, p_2, ..., p_i, ..., p_I\}$,
- D - collection of data units $D = \{d_1, d_2, ..., d_m, ..., d_M\}$,
- Q - collection of confidentiality classes $Q = \{q_1, q_2, ..., q_h, ..., q_H\}$,
- R - collection of operations $R = \{r_1, r_2, ..., r_n, ..., r_N\}$,

- T - collection of scopes of operations $T = \{t_1, t_2, ..., t_g, ..., t_G\}$,
- ρ - flow relationship,
- τ - operation relationship,
- HF - the functions of the model, data security model limitation generator.

The flow relationship is built on pairs of confidentiality classes: $\rho \subset Q \times Q$. The operation relationship is built on pairs of scopes of operations: $\tau \subset T \times T$

The functions of the data security control model:

$$HF = \langle H_1, H_2, H_3, H_4, H_5 \rangle \tag{13}$$

H_1- function assigning confidentiality classes to data units

$$H_1 : D \to Q \tag{14}$$

H_2 - a function determining whether an access to data unit d_m is admissible with the permissions of the entity defined by the scope of the operation q_h

$$H_2 : D \to \{0,1\}$$

$$\forall_{d_m \in D} \forall_{q_h \in Q} H_2(d_m) = \begin{cases} 1 - gdy(H_1(d_m), q_h) \in \rho \\ 0 - gdy(H_1(d_m), q_h) \notin \rho \end{cases} \tag{15}$$

H_3 - a function checking whether a flow request from the data unit d_{m_1} to the data unit d_{m_2} is acceptable

$$H_3 : D \times D \to \{0,1\}$$

$$\forall_{d_{m_1}, d_{m_2} \in D} H_3(d_{m_1}, d_{m_2}) = \begin{cases} 1 - gdy(H_1(d_{m_1}), H_1(d_{m_2})) \in \rho \\ 0 - gdy(H_1(d_{m_1}), H_1(d_{m_2})) \notin \rho \end{cases} \tag{16}$$

Access to the data is subject to appropriate permissions and the flow is allowed as in Denning model if the confidentiality class of the source object is not higher than the confidentiality class of the target object.

H_4 - a function defining for operations their scope

$$H_4 : R \to T \tag{17}$$

H_5 - a function determining whether a request to execute an operation r_n is admissible with the permissions of the entity defined by the scope of the operation t_g

$$H_5 : R \rightarrow \{0,1\}$$

$$\forall_{r_n \in R} \forall_{t_g \in T} H_5(r_n) = \begin{cases} 1 - gdy\left(H_4(r_n), t_g\right) \in \tau \\ 0 - gdy\left(H_4(r_n), t_g\right) \notin \tau \end{cases} \tag{18}$$

5.2 Service security control

The SP model controls the process of what extortion of services are allowed, i.e. what services can be used to handle the task triggered by the entity.

$$SP = \langle P, E, B, \delta, BF \rangle \tag{19}$$

where:

- P - the collection of entities $P = \{p_1, p_2, ..., p_i, ..., p_I\}$,
- E - the collection of services $E = \{e_1, e_2, ..., e_l, ..., e_L\}$,
- B - the collection of categories of permissions $B = \{b_1, b_2, ..., b_f, ..., b_F\}$,
- δ - service launch relationship,
- BF - the functions of the model.

The service launch relationship is defined in the pairs of categories of permissions: $\delta \subset B \times B$.

The functions of the service(s) security control model:

$$BF = \langle G_1, G_2 \rangle \tag{20}$$

G_1 - function assigning categories of permissions to electronic services

$$G_1 : E \rightarrow B \tag{21}$$

G_2 - the function determining whether the use of the service e_l in the process of handling a task triggered by an entity is allowed with its permissions defined by the category of permissions b_f

$$G_2 : E \rightarrow \{0,1\}$$

$$\forall_{e_l \in E} \forall_{b_f \in Q} G_2(e_l) = \begin{cases} 1 - gdy\left(G_1(e_l), b_f\right) \in \delta \\ 0 - gdy\left(G_1(e_l), b_f\right) \notin \delta \end{cases} \tag{22}$$

It is permissible to use a given electronic service in the process of handling a public task triggered by an entity when the category of permission of that entity is greater than or equal to the category of service.

5.3 Security control in disciplinary platforms

The security control model for disciplinary platforms (SM) consists of data and service security control models with HF and BF functions.

$$SM = \langle P, D, Q, R, T, E, B, \rho, \tau, \delta, VF \rangle \tag{23}$$

where:

- P - the collection of entities $P = \{p_1, p_2, ..., p_i, ..., p_I\}$,
- D - the collection of data units $D = \{d_1, d_2, ..., d_m, ..., d_M\}$,
- Q - the collection of confidentiality classes $Q = \{q_1, q_2, ..., q_h, ..., q_H\}$,
- R - the collection of operations $R = \{r_1, r_2, ..., r_n, ..., r_N\}$,
- T - collection of scopes of operations $T = \{t_1, t_2, ..., t_g, ..., t_G\}$,
- E - the collection of services $E = \{e_1, e_2, ..., e_l, ..., e_L\}$,
- B - the collection of categories of permissions $B = \{b_1, b_2, ..., b_f, ..., b_F\}$,
- ρ - flow relationship,
- τ - operation relationship,
- δ - service launch relationship,
- VF - the functions of the model.

$$VF = \langle HF, BF \rangle \tag{24}$$

5.4 Implementation of lattice mechanisms to control data and service security

When analysing the flow relationships ρ, operation relationships τ and the service launch relationship δ, it should be noted that if the condition of partial arrangement of the collection of protection classes Q, the collection of operations scope T and the collection of categories of permissions B is met, it is possible to use the lattice theory. This significantly improves the process of security verification and allows for the integration of objects data within integration platforms. The class of cases for which the above conditions are met is so large that such a case only will be considered further.

Flow relationship ρ (feedback-based, transitory and asymmetric) creates the lattice for the flow QL by partial arrangement of the collection Q. There is the supremum and the infimum for each pair of protection classes from the collection Q

The flow lattice QL is defined in the following way:

$$QL = (Q, \rho, \oplus^{Q}, \otimes_{Q}) \tag{25}$$

where:

- Q is the partially arranged collection,
- $Q = \{q_1, q_2, ..., q_h, ..., q_H\}$,
- ρ is the relationship of the partial arrangement,
- $\oplus^Q$ the operator to set the supremum of its arguments,
- $\otimes_Q$ the operator to set the infimum of its arguments,

As in the Sandhu model, it is possible to extend the partially arranged collection by a maximum element (e.g. "syshigh" in the Sandhu model) or a minimal element (e.g. "K0: uncategorized") to meet the lattice conditions.

Operation relationship τ (feedback-based, transitory and asymmetric) creates the lattice for the operation TL by partial arrangement of the collection T. There is an upper and a lower limit for each pair of operation scopes from the collection T.

Operation lattice TL is defined in the following way:

$$TL = (T, \tau, \oplus^T, \otimes_T) \tag{26}$$

where:

- T is the partially arranged collection,
- $T = \{t_1, t_2, ..., t_g, ..., t_G\}$,
- τ is the relationship of the partial arrangement,
- $\oplus^T$ the operator to set the supremum of its arguments,
- $\otimes_T$ the operator to set the infimum of its arguments,

The operation is allowed, as in the Szafranski model, if the scope of operation that is being performed is not higher than the scope of operation owned by the user.

The service launch relationship δ (feedback-based, transitory and asymmetric) creates the lattice for the launch of BL services by partial arrangement of the collection B. There is the supremum and the infimum for each pair of the categories of permissions from the B collection.

The lattice of the BL service launch category is defined as follows:

$$BL = (B, \delta, \oplus^B, \otimes_B) \tag{27}$$

where:

- B is the partially arranged collection,
- $B = \{b_1, b_2, ..., b_f, ..., b_F\}$,
- δ is the relationship of the partial arrangement,
- $\oplus^B$ the operator to set the supremum of its arguments,
- $\otimes_B$ the operator to set the infimum of its arguments,

The full model of data and service security control would consist of three lattices for the concept described here:

The flow lattice: $QL = \left(Q, \rho, \oplus^{Q}, \otimes_{Q}\right)$ [relates to data]

The operation: $TL = \left(T, \tau, \oplus^{T}, \otimes_{T}\right)$ [relates to operation]

The categories of permissions: $BL = \left(B, \delta, \oplus^{B}, \otimes_{B}\right)$ [relates to services]

Such mathematical models in the form of lattices could have been constructed both for individual disciplinary platforms and for integrated platforms - and would then be called super-lattices. These super-lattices would cover separately the three security aspects of the integrated platform.

Lattice model of security control used in processes of integration of electronic platforms

In the processes of platform integration, two different approaches are possible, which have been named (in reference to the nomenclature related to IT system design):

- diagnostic approach,
- prognostic approach.

The application of one of the two approaches has of course resulted in positive and negative effects. The selection must therefore be made on the basis of specific conditions. In general, it can be concluded that in the situation of advanced implementations of disciplinary platforms, indications are for a diagnostic approach. For initial situations, a prognostic approach should be considered.

The process of construction of the super-lattice of the integrated platform is considered below by using the diagnostic approach in the first variant and the prognostic approach in the second variant. The application of the diagnostic approach leads to a dominant definition of local area platform lattices and, as a result, to such features of the super-lattice that the constructed super-lattice can be considered as "poorly" integrated. The prognostic approach puts more importance on the requirements that are formulated before the construction of a super-lattice, and which such requirements result from the desired institutional and organizational rules. This way it is possible to obtain a structure that can be considered as "strongly" integrated.

The construction of a super-lattice with a diagnostic approach is described, in a developed scope, in the previously mentioned papers, especially in the paper by B. Szafranski.

It is assumed that the initial state of the super-lattice construction in the diagnostic approach are defined models for a specific collection of disciplinary platforms in one of two forms for a single platform:

- Two separate models, one for data security control and one for service security control.
- A single security control model for the disciplinary platform (covering both aspects of security protection).

On the basis of models for disciplinary platforms, it is possible to construct a super-lattice starting from constructing local lattices for particular security aspects (flow, operation and service launch) for disciplinary systems.

The next step is to apply the method of folding local lattices to the integrated platform super-lattice described in detail in the paper by B. Szafranski (not discussed in this paper).

By applying the prognostic approach in the platform integration process the lattice models of the domain platforms are also used and their characteristics is taken into account. But the prognostic approach is primarily to ensure that the features of the integrated platform super-lattice are those that arise primarily from the user needs defined in the institutional and organizational rules of security protection.

The process of constructing the integrated platform super-lattice is therefore as follows:

1. The formulation of requirements in the security layer resulting from the applicable institutional and organizational rules. One of the sources of identification of these requirements are possible lattice models of disciplinary platforms. But it's not the only source. The principles resulting from the institutional and organizational rules of security protection on electronic platforms being subject to integration are considered to be the main sources for the prognostic approach.
2. Construction of a super-lattices of the platform integrated in three aspects of security:
   a. the flow QL ,
   b. the operation TL ,
   c. the service(s) launch BL .

   Defining the individual elements of these lattices must take into account the requirements identified in the previous step of the process of constructing a super-lattice.

3. Construction of a super-lattice of a platform integrated in the full scope of a platform security. This chapter of the work deals with this stage of the process, as it is at this stage that there are the greatest differences from the diagnostic approach.
4. Possible construction of lattices of disciplinary platform by reducing super-lattice, in the meaning of the process described (according to work B. Szafranski, but taking into account the rule that the relations of order in the prognostic approach are to be the same in the local lattices). The implementation of this stage of the process reveals that in the prognostic approach there is a kind of reversal of the order of actions compared to the diagnostic approach. This is the concept of integrating disciplinary platforms from identified security needs and the resulting design of the super-lattice is an interpretation of the requirements that must also be included in the lattices of the disciplinary platforms.

The prognostic approach accepts the existing condition less than the diagnostic approach. The prognostic approach is more clearly based on the requirements resulting from the target intentions.

From the security point of view, the essence of the organizational system of an electronic platform (whether disciplinary platform or integrated platform) is to verify the correctness of the use of the platform's functionality by entities (from P). The rules to grant permissions to entities, resulting from the requirements of an institutional and organizational nature, determine in a very important way the effectiveness of security protection on the platform. It is only in this context that the process of verifying the correctness of the usage of the permissions granted should be considered, including the usage of lattice models. It should be noted that when applying the prognostic approach, even in the first step, rules for granting permissions to entities should be developed and they should have an impact on the design of the super-lattice. A number of policy options for the procedure for granting permissions to entities are indicated below.

The permissions (in classical variant) of the entities are granted independently for each aspect of security protection:

- (q_{h*}) - as an acceptable confidentiality class,
- (t_{g*}) - as an acceptable scope of operation,
- (b_{f*}) - as an acceptable category of permissions.

The graphical interpretation in the three-dimensional space of the above-described "extortion cubes" is the cuboid/perpendicular beginning from (q_1, t_1, b_1) and ending in (q_{h*}, t_{g*}, b_{f*}) .

Summary

The proposed security model ensures that public tasks are kept safe regardless of their complex nature and trans-disciplinary form. The security model includes mechanisms to control access to electronic services and data. Other security issues (such as managing the integrity of transactions that modify data, managing accountability, availability or system reliability) have not been included in the paper, but will be further considered by the authors.

This model may be used for service-oriented systems, in particular integration platforms, which have been designed and constructed in accordance with the architectural framework of electronic platforms described in previous publications. The proposed model is a formal representation of integration platforms of public administration in Poland, but a very similar or even identical architecture applies to integration platforms of business environments (financial, educational and insurance platforms).

The model does not force design assumptions for electronic services that do not affect security issues, but may affect the correct implementation of the service by the IT system. Such additional design restrictions may be imposed by electronic service designers in order to adequately handle acceptable (from a security point of view) cases.

The presented model covers only the area of security in the scope of authorization, i.e. verification of the permissions of entities to call up electronic services provided in integration platforms.

Abstract

Mathematical modelling is widely used by many researches to describe different mechanisms for IT systems. It was also used by authors in their previous publications to define the management model for integration platforms which support implementation of public tasks. Unfortunately, mathematical modelling is often not integrated with any real-life designing processes, so in effect it cannot be easily used to create or manage any real-life security mechanisms. In this article, the authors have decided to integrate mathematical modelling with object-oriented modelling. One of the most common object modelling languages was used – UML version 2.5.1. The authors conducted a research to select only suitable categories of diagrams to make it a more universal approach also for any new mathematical models that can be integrated into real-life scenarios.

Keywords: UML, mathematical modelling, security management, information security.

Introduction

The service and object-oriented approach is currently the most commonly used when designing or implementing new mechanisms for IT systems. UML and other object-oriented modelling languages are used to describe the whole process from system design, through security, to the build and management. It is easily understood and can be implemented into real-life systems without any significant problems.

Mathematical modelling is still used for a more formal approach when a detailed model is required. It is often used by researchers to address new requirements and it was used by the authors in the previous publication to define the management model for integration platforms which support implementation of public tasks. Still, this model requires a different presentation to make it useful for real-life scenarios.

This integration of the theoretical academic world of mathematical modelling with the practical world of object and service-oriented modelling is a common challenge. The aim of this paper is to show how to integrate a mathematical model into the UML approach and also to propose a standard approach (selected diagrams) on how to easily proceed with this kind of integration in the future.

The paper is organized as follows: first it reminds the reader the main components of the authors' mathematical model (section 2). Section 3 introduces UML modelling with criteria and the authors' choice of which diagram categories are the best to be used. It also presents approach proposed by other researchers. Sections 4-6 present the integration of the previously defined mathematical model into selected UML diagrams (static and dynamic). In section 7, the conclusions of the paper are presented.

Mathematical Model Summary

The mathematical model designed by the authors was explained in detail in previous publications, but still it is necessary to remind the reader the main concept that will be used in this paper.

Cite this Article as: Jaroslaw WILK and Boleslaw SZAFRANSKI "Integration of Mathematical and Object-Oriented Modelling in Management of Security Mechanism Designing for IT Systems" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The main element is the Security Management (SM) model for integration platforms which consists of (the model presented is a simplified version of the model from):

$$SM = \langle P, D, K, T, E, B, \rho, \tau, \delta, VF \rangle \tag{1}$$

where:

- P – a set of entities,
- D – a set of data units,
- K – a set of protection classes,
- T – a set of operations,
- E – a set of electronic services,
- B – a set of categories of an authorized execution,
- ρ – an access relation,
- τ – a scope of operations relation,
- δ – a relation of an authorized service execution,
- VF – a set of restriction functions (restriction generator for the security management model).

In the simplified version, complex services were removed as a separate model element and were replaced with just electronic services.

For the purpose of this paper, the authors only consider public tasks that can be delivered electronically by public administration. A user (defined as P – entity) can start the implementation of those public tasks (z) by selecting one of them from the public task set:

$$Z = \{z_1, z_2, \dots, z_j, \dots, z_i\} \tag{2}$$

For every public task, there is an implementation schema which describes how it is delivered (consisting of enforcements which change the security state of an electronic service platform or system).

The public tasks schema set with function connecting public tasks with the execution schema:

$$S = \{s_1, s_2, \dots, s_j, \dots, s_I\} \tag{3}$$

$$\pi: Z \rightarrow S \tag{4}$$

Based on an execution schema, an execution sequence is created with enforcements which start an electronic services execution and change security states.

When a security mechanism is designed for such a system, there are two options:

a) mechanism can check the correctness of every security state (almost impossible in the real-life scenario),
b) mechanism can check the correctness of an enforcement (if correct, it will change a secure state to another correct state from the security perspective).

Option b. was selected by the authors (based on enforcements and previously presented security model) so different security controls can be verified, such as:

- whether an entity is allowed to access selected data units,
- whether an entity has enough privileges to execute an operation (such as read, modify) on data units,
- whether an entity is allowed to provide an electronic service.

Another key element of this model is the process of designing new electronic services which are coming from different domain systems and are combined and delivered from an integration platform. In this case the security integration is extremely important to create a new security access level to data (with their operations) and services (with their functions), still keeping full compliance with domain systems security rules and limitations.

Those mechanisms were described in previously prepared mathematical model.

Object-Oriented Modelling – Diagram Category Selection

There are already many publications about security integration into UML that were reviewed and verified by the authors. Very interesting survey was published by ETH Zürich where most important conclusions are:

- UML stereotypes were selected as the most usable for security specification.
- UML behaviour diagrams were selected as most usable for security requirements specification and aspect design.
- The most common way to integrate security into modelling was by extending UML meta-language however the new meta-language should be then an appropriate alternative.

According to the authors and many other researchers the best solution was provided in UMLsec specification where security requirements were implemented into UML (using existing elements and extensions like new stereotypes). Additionally the analysis of usability of UML diagrams was conducted with below conclusions:

- Activity diagram: secure control flow, coordination.
- Class diagram: exchange of data preserves security levels.
- Sequence diagram: security-critical interaction.
- State chart diagram: security preserved within object.
- Deployment diagram: physical security requirements.
- Package: holistic view on security.

The approach presented in UMLsec and in other UML security integration models is mostly focused on a transformation from security requirements or pseudo-language into UML diagrams or simply focuses on specific security areas like:

- approach limited to access control policies,
- SecureUML which focuses only on specifying RBAC model,
- AuthUML which focuses on incorporating access control policies into use case diagrams.

According to the authors still there is no overall approach presented that is focused on the mathematical model transformation into UML security modelling and that is the reason for publishing current paper.

There are several aspects that need to be considered when integrating a mathematical model into UML diagrams:

- system elements and their reference to a mathematical description,
- system access scenarios (in this case, public task access and, as a result – verification of enforcements and security states),
- system development scenarios (in this case, the process of designing new secure electronic services which are in fact the execution of public administration tasks).

Another very import aspect is to select proper UML diagrams that are useful in the process of security mechanisms designing and allow the integration of mathematical modelling. To achieve this it is required to perform a review of categories of UML diagrams with classification and justification whether and why they can be used to translate mathematical modelling into graphical representation. Main criteria selected by authors include:

- whether it is possible to present main model elements and relationships between them,
- whether it is possible to present information on how components react to one another to reflect functions,
- whether it is possible to present information on how system state (in our case a security state) is being changed in time after specific actions.

In the UML generally we have 3 basic categories of diagrams:

- structure diagrams,
- behavioural diagrams,
- interaction diagrams.

Starting with the first category of structure diagrams which "show the static structure of the objects in a system. That is, they depict those elements in a specification that are irrespective of time. The elements in a structure diagram represent the meaningful concepts of an application, and may include abstract, real-world and

implementation concepts." In table 1 below, the most common structure diagrams (some auxiliary and not formally defined in UML 2.5 diagrams were skipped) have been presented with a short justification whether they fit the proposed criteria:

Table 1: Structure diagrams – verification

Diagram name	Short description	Justification
Package diagram	Shows packages and relationships between them.	Not fitting to any criteria. High level overview for developers.
Class diagram	Shows structure of the designed system, subsystem or component.	Basic diagram required before any action can be presented (selected).
Deployment diagram	Shows architecture of the system from deployment perspective.	Not fitting to any criteria. High level overview for software deployment.
Objects diagram	Shows instance specifications of classes and interfaces.	Not fitting to any criteria. Class diagrams are enough from the mathematical modelling perspective.
Model diagram	Shows abstraction or specific view of a system – for example architecture.	Although it does not exactly fit to presented criteria it was selected by authors as a main diagram required from the system architecture perspective.
Internal structure diagram	Shows internal structure of a classifier.	Not fitting to any criteria. Detailed decomposition into properties, parts and relationships is not required in described transformation.
Collaboration use diagram	Shows objects of the system collaborating to produce some system actions.	Specified diagram fits together with class diagram to first criteria. From mathematical modelling it is treated by authors as a complementary diagram and that is why it was not selected.
Component diagram	Shows components and dependencies.	Not fitting to any criteria. Used to create the Service-Oriented Architecture design.

This category of diagrams can be useful to present the general view of the system and place objects defined in the mathematical model there. A mathematical model is not focused usually on technical aspects of the system such as a web portal, database, backend system but rather on lower level objects (entities, data units, etc.) used in action and aligned to each other with functions. For that reason, a model diagram can be used for the high level system design but most of relationships between components from mathematical modelling can be presented in action on dynamic diagrams.

The second category are behaviour diagrams which "show the dynamic behaviour of the objects in a system, including their methods, collaborations, activities and state histories."

In table 2 below, most common behaviour diagrams have been presented with a short justification whether they fit the proposed criteria:

Table 2: Behaviour diagrams - verification

diagram name	Short description	Justification
Activity diagram	Shows sequence and conditions to coordinate the behaviour of system elements	Selected diagram as it fits the proposed criteria – it presents element activities, which collates to functions in the mathematical model.
Use case diagram	Shows set of actions of users with the system.	Selected diagram as it fits the proposed criteria – actions are created based on mathematical functions where a user (entity) is involved.
State diagram	Shows system or object states transition.	Selected diagram as it fits the proposed criteria – it is necessary to present a system and object state changes (from the security perspective).
Information flow diagram	Shows information exchange between system elements (from a high level perspective).	Diagram not selected – as detailed information flow was also not covered in mathematical modelling.
Additional state machine diagrams (behavioural, protocol, interaction)	Show discrete behaviour through state transitions.	Diagrams not selected – as base state diagram is enough from the criteria perspective.

Selected behaviour diagram can cover all three requirements defined by authors. On activity and state diagrams we can integrate component states, how and when they change, which can reflect functions. Use case diagrams can show us exactly when and how which functions and mathematical formulas should be used in system access and development scenarios.

Last category is interaction diagrams (sometimes showed as part of behaviour diagrams but we can treat them as a separate category for the purpose of this paper) which are focused on the communication and sequencing of system components over time.

In table 3 below, most common interaction diagrams have been presented with a short justification whether they fit the proposed criteria:

Table 3: Interaction diagrams - verification

diagram name	Short description	Justification
Sequence diagram	Shows message communication between objects	Although time perspective and messages are not fully covered in mathematical model it is selected to present relationships between objects from the communication sequence perspective.
Timing diagram	Shows interaction between objects with time perspective.	Time perspective was not proposed in criteria so this diagram is not selected.
Communication / collaboration diagram	Shows interaction between objects with message passing perspective.	Communication between objects is not directly covered in the mathematical model. It does not fit the proposed criteria.
Interaction overview diagram	Shows interactions through a variant of activity diagrams.	Interaction between objects from the mathematical model perspective is covered by the activity diagram. This diagram is not selected.

Most of relationships between components can be presented with behavioural diagrams but we could use for example sequence diagrams to describe in detail the process of element collaboration (placed in time). The

mathematical model proposed by the authors does not present the time perspective and that is why most of those diagrams are not selected in this paper. Based on the authors' experience, a deep dive into sequencing was not required in the mathematical model definition – although enforcements and further actions connected to them (for example an electronic service execution and access to data sets) are treated as a mathematical sequence. Detailed scenarios of how electronic services are really cooperating with each other in time is not crucial from the security perspective.

To sum up this section, the best choice for integration of mathematical modelling into UML would be behavioural diagrams. Still, some structure diagrams can be used to present a high level view and interaction diagrams when moving from only security to the full system implementation. Although behavioural diagrams were selected as best for integration process, we should always start with a general system overview and main elements definition. The same approach is used in the mathematical modelling where static elements are defined before they can be used in the dynamic approach – equations.

Integration of object oriented and mathematical modelling

This section presents how mathematical modelling can be integrated into object-oriented modelling. As we have the mathematical model prepared and UML diagrams category selected, the next steps defined by the authors are:

- based on a general process description, elaborate selected UML diagrams,
- fit mathematical equations into created UML diagrams,
- verify whether all elements from mathematical modelling have been fitted into object-oriented diagrams and whether there are no areas where they are contradicted.

This approach will be presented on the authors' mathematical model designed for management of security mechanisms for electronic service platforms. If the mathematical model cannot be fitted into the diagrams created, it means that the diagrams provided do not present proper system behaviours described by the mathematical description. This is why it constitutes a perfect verification of whether and how the theoretical approach created can be implemented into real life scenarios.

The approach presented is an example can be used by other researchers to combine two complementing approaches – mathematical (theoretical) and object-oriented (practical). This step is a direct way to create a real life implementation by building the designed system and translating mathematical equations into algorithms in any programming language (integrated into specific objects such as programmable classes and functions).

Static Diagram Integration

As it was explained in section 3 – static diagrams are the required base to define main elements before they can be used in behaviour and interaction diagrams. Every object from the mathematical model has to be defined as an object class, for example: entity, data unit, electronic service etc. In this case, a sample entity class diagram is presented below (Fig. 1) with a list of protection classes and operation levels associated with data units and execution levels associated with corresponding electronic services.

Fig. 1: Class diagram - an entity (P)

The general model diagram of the whole system (for real-life system implementation) should be also provided (Fig. 2) after class diagrams have been created. It is not connected to theoretical mathematical modelling but is necessary for a static view of the system:

Fig. 2: Integration platform model – architectural model diagram

As static structure architectural diagrams are not the most important ones from the point of view of this paper, they will not be discussed in more details (although they are necessary when building a real-life system).

Dynamic Diagram Integration

This section presents dynamic diagrams integrated with mathematical model recalled in section 2. First of all, use case diagrams are presented with high-level definitions of main actions that are allowed in the system from the perspective of an entity (P). They are then followed with detailed activity diagrams in which both design and execution of electronic services is presented with references to the mathematical model. All models are designed from the security management perspective, so some areas of real-life implementation are not covered in this paper – still presenting the approach how to move from a theoretical mathematical view to a more technical object modelling view.

First and most important activity of the entity (P) is to execute public tasks available on electronic integration platforms (Fig. 3).

Fig. 3: Public task execution (with support of electronic services platforms) – use case diagram

Static mathematical model elements were directly integrated into the model so that they can be easily created in real-life system as class objects taking part in the execution of use case actions. Dynamic operations such as – (2) getting an execution schema constitutes direct implementation of mathematical functions – in this case function π - equation No 4 from section 2. Enforcements are then transformed to low-level actions of operations (T) on data units (D) and access to high-level electronic services (E). They are verified by the security management system and if a system state is kept as safe, those enforcements are executed on domain platforms (action 4 from Fig. 3).

Next Fig. 4 presents an activity diagram for public task execution with support of electronic integration platforms:

Fig. 4: Public task execution (with support of electronic service platforms) – activity diagram

The above diagram constitutes a graphical presentation of a process described in the mathematical model mentioned in section 2 and described in detail in previous papers. Mathematical elements mentioned in this paper have been integrated into the above diagram (like data units, entities etc.) Additional elements, such as enforcements or some mathematical functions, have not been placed there as they have not been specifically introduced in the same article. Nevertheless every action element corresponds to a mathematical function – for example:

- action 2 is the transformation of a public task (z) into an execution schema (s) mathematically described by equation 4 from section 2,
- action 4 is a core verification set of functions checked by the security mechanism of the integration platform.

Next diagram Fig. 5 presents security states of electronic service integration platform (named as the system in the diagram). As described in section 2 and in the full mathematical model, the whole process starts with a secure state and every enforcement can move it to next secure state or unsecure state which means that the system was compromised and cannot be used anymore (final state). Security mechanisms are checking whether enforcements are correct or incorrect from the point of view of security (this verification is presented on different diagrams – activity and sequence).

Fig. 5: Electronic service integration platform – state diagram from the point of view of security

Next diagram Fig. 6. presents relationships between main objects from the communication perspective during execution of a public task. Although it can also cover time perspective, it will not be considered in this paper – based on an assumption that the order and time of execution of electronic services are not important from the point of view of security. Of course, it can be added later to the model – for example by allowing execution only in a specific order at a specific time of a day or week, but as it is not currently used for the real-life public administration integration platforms analysed, it is not part of this paper.

Fig. 6: Public task execution (with support of electronic services platforms) – sequence diagram

The above diagram constitutes a simplified presentation of communication between an entity, electronic service integration platform which coordinates security management and domain platform (or platforms – for diagram simplicity presented on one domain platform example). Static model elements, such as a public task or data units have been integrated into the UML diagram. Dynamic actions both from the integration and domain platforms have also been also included. Designed security mechanism and it's functions are part of integration platform security verification, sequence of enforcements is starting electronic services with data operation actions on domain platforms.

Conclusions

In the paper authors presented an approach to start with a formally verified mathematical model and then continue with a practical approach to finally allow real-life system creation. The mathematical model can be integrated into specified UML diagrams allowing not only the designing of a security mechanism but of the entire system – in this case, the integration platform environment. This approach guarantees a strong basis which is provided by the mathematical modelling and the UML representation clear to developers. Unfortunately, many newly designed systems and security mechanism are created the other way round. First, high-level architects create system diagrams and then, in some cases only, some elements are formally verified, which can result in many mistakes. When focusing on such crucial elements as security, formal mistakes can lead to a system being easily compromised -

which happens often these days. The approach presented and diagrams selected can constitute a guide for architects and researchers on how to start the integration of formal models with UML diagrams before real-life system implementations. It is not the full approach that covers all security aspects so it should be used together with other corresponding frameworks. The authors recommendation would be UMLsec but most of them finally end up with similar conclusions (for example selection of behaviour diagrams) and should be applied based on their specific focus.

Abstract

The most important food security industry is dairy. Recently, there has been an increase in the production of dairy products due to an increase in milk yield per cow. Despite the growth in production, the indicators approved in the Food Security Doctrine have not yet been achieved. Milk and dairy products produced by Russian agricultural producers are not enough to meet the needs of the population. To reduce the surplus, the state purchases dairy products from foreign countries, despite the high level of costs associated with logistics and product sales. Logistics costs can be reduced by optimizing milk delivery costs and reducing customs duties. Due to the decrease in the purchasing power of the population, the demand for dairy products is also decreasing. Despite the negative impact of the pandemic on the economic performance of the dairy industry due to the difficult situation of small businesses, the industry remains attractive for investors. The methodological basis was the works of both domestic and foreign scientists in the field of food security, logistics of dairy products and government regulation of the industry. The information base was the data of state statistics.
Use the word "Abstract" as the title for the abstract section. The abstract should be no more than 250 words. It should capture research motivation, research Design/methodology, and main findings and implications. The abstract should provide an excellent summary of the paper.

Keywords: Dairy industry, logistics, import of raw milk, food security.

Introduction

The dairy industry is the most important strategic area that ensures the food security of the country's population.

In Russia, the indicators of the Doctrine of Food Security for milk and dairy products are still not achieved. To meet the needs of the population in dairy products, measures are needed to support domestic agricultural milk producers, develop the logistics and marketing infrastructure of dairy products, and form the industry's competitive advantages. Today the dairy industry shows a steady growth in production, which indicates the possibility of choosing a strategy of behavior in the market [6].

Main Part

Various factors influence the achievement of the Food Security Doctrine indicators. First of all, there has been a decrease in the number of cows over the past decades (Figure 1).

Fig. 1: The number of cows in farms of all categories in the Russian Federation. 1990-2019

A decrease in the number of livestock in the period under review is observed both in the country as a whole and in all constituent entities of the Russian Federation. The main reason for the decline in the number of cows is the low economic efficiency of the dairy industry. During this period, the reduction in livestock was 2.6 times for farms of all categories [2]. So the greatest reduction in livestock is observed in agricultural organizations 78.6%. At the same time, there is an increase in the number of livestock in peasant (farm) households. Despite the reduction in the number of cows, there is an increase in milk production (Figure 2).

Fig. 1: Milk production in farms of all categories in the Russian Federation, 1990-2019

A sharp decline in milk production continued until 2005. As of 2019, the level of milk production has not reached the level of 1990. The structure of producers has also changed, so, if in 1990 agricultural organizations and households were engaged in milk production, the ratio was 76% to 24%, then in 2019 milk production was carried out by peasant (farm) households - 8.53% of the total production; agricultural organizations - 54.10%; household farms - 37.37%. The production of milk K (F) X over the past five years has increased by 40%, and agricultural organizations - by 18%. In recent years, there has been a steady upward trend in milk production both by agricultural organizations and peasant (farmer) households. A negative trend is also observed when analyzing the number of producers, as the number of milk producers decreased in Russia from 2017 to 2019. by more than 2900 units [4;5].

In the past five years, there has been not only an increase in milk production, but also an increase in the level of its consumption (Figure 3).

Fig. 1: Production and consumption of milk per capita in the Russian Federation, 2015-2019

On the territory of the Sverdlovsk region, there is also an increase in milk production in farms of all categories. Actual production amounted to 767 thousand tons (38.85% growth compared to 2010). According to the results of 2019, the Sverdlovsk Region entered the TOP-25 subjects in terms of gross milk production in 2019, taking the 10th ranking position.

In terms of the absolute increase in milk productivity in agricultural organizations, the TOP-10 regions are headed by the city of Moscow, an increase of +1685 kg, and the productivity was 7950 kg, But there are regions that showed a decrease in milk productivity in agricultural organizations, the largest decrease in the Chukotka Autonomous Okrug is 2582 kg, with a productivity of only 1883 kg per cow in January - September 2020.

The Russian milk market is finding optimal ways and adapting to the current situation, which is associated with the impact of COVID-19. Due to the decline in demand for dairy products, small and medium-sized enterprises in the industry will have to live in difficult economic conditions in the coming months. The pandemic has adjusted the forecasts made earlier by analytical centers based on an increase in demand for dairy products in Russia, due to the fact that in March 2020, retail chains noted a large increase in demand for shelf-stable products, including dairy products, due to the introduction of a self-isolation regime, which is typical during crises and epidemics around the world.

On the territory of the Sverdlovsk region, there is also an increase in milk production in farms of all categories. Actual production amounted to 767 thousand tons (38.85% growth compared to 2010). According to the results of

2019, the Sverdlovsk Region entered the TOP-25 subjects in terms of gross milk production in 2019, taking the 10th ranking position.

In terms of the absolute increase in milk productivity in agricultural organizations, the TOP-10 regions are headed by the city of Moscow, an increase of +1685 kg, and the productivity was 7950 kg, But there are regions that showed a decrease in milk productivity in agricultural organizations, the largest decrease in the Chukotka Autonomous Okrug is 2582 kg, with a productivity of only 1883 kg per cow in January - September 2020.

Receiving serious government support, the dairy industry remains attractive to investors. Rosselkhozbank alone, according to the chairman of the bank's board Boris Listov, took part in the implementation of over two thousand projects for the dairy industry, investing more than 420 billion rubles aimed at increasing milk production. Recently, the share of imports in the dairy market of the Russian Federation has decreased from 22% to 19%, approaching the indicators indicated in the Food Security Doctrine (no more than 10%). So, in 2020, subsidies to agricultural producers are provided within the framework of "stimulating" and "compensating" subsidies in the amount of 10.6 billion rubles, which exceeds the level of the previous year by 2.6 billion rubles. Funds in the amount of 3.3 billion rubles are also provided for the issuance of short-term loans as part of the implementation of the mechanism of concessional lending to agricultural producers, as well as funds for investment lending in the amount of 10.6 billion rubles.

It should be noted that in Russia, the per capita consumption of dairy products lags behind the EU countries. So, butter is consumed per year 2.8 kg per person, against 4 kg in the EU; cheese consumption is 6.4 kg, which is 3.1 times lower (in the EU - 20.2 kg). “According to OECD-FAO analysts, the consumption of cheese in the Russian Federation will increase by an average of 2% per year, butter - by 1%,” noted at a joint meeting of the Ministry of Agriculture of Russia with the National Union of Milk Producers, which was held on topical issues of dairy development. branches emerging in the milk and dairy products market, which is one of the most promising and interesting in the structure of the RF agro-industrial complex.

The forecast of the Ministry of Agriculture of the Russian Federation to increase milk production to 32 million tons in 2020, which is 1.9% higher (31.4 million tons) than in 2019.

The surplus of raw milk according to Rosstat in 2019 amounted to more than 3646 tons.

Insufficient production of milk and dairy products is compensated by imports. The share of imports of dairy products was 17% of the total consumption by the population.

Most often, raw milk is imported from the following countries: Lithuania, Poland, Denmark, Italy, Spain, France, Latvia and other countries.

To import milk, two main documents are required: an import permit and a veterinary certificate. At the same time, a veterinary certificate may not be required if the product contains less than 50% of animal fats, or the product is not a by-product of processing, or the product contains less than 20% milk powder.

Also, for customs clearance, a certificate or declaration of conformity, an agreement with a specialized warehouse and a customs cargo declaration are required. Also, depending on the exporting country, other documents may be required.

When importing dairy products, you must pay customs duty at a rate of 15%, as well as VAT at a rate of 10%. In Russia, a pilot project for labeling finished dairy products has been developed, which started on July 15, 2019, the project was supposed to be completed on February 29 and implemented on June 1 of this year, but the experiment period was repeatedly extended. At the end of March 2020, the Russian government, due to the threat of a coronavirus pandemic, postponed the introduction of mandatory labeling of dairy products. The marking must contain the following information: date and country of manufacture; composition; information about the manufacturer and importer; brand; product features. Since the labeling of dairy products is an expensive project, the Ministry of Agriculture proposed to partially reimburse the direct costs of labeling milk and provide producers with preferential loans.

Due to the fact that dairy products have a short shelf life, logistics costs may increase when choosing a carrier. At the same time, the transportation time is reduced from 15 to 1 day. The cost of air transportation is from 3.1 to 5.7 US dollars per kilogram of dairy products.

A large number of factors can influence the cost of milk imports. For example, the territorial location of customs, the list of the imported assortment group (the larger the list, the higher the price); packaging; conditions of transportation, including temperature conditions and others.

Despite the high level of costs for the import of dairy products, imports increased in three months of 2020 by 19.2% in physical terms and by 25.5% in value terms. The largest share of imported products is covered by Belarus, Kazakhstan, Argentina, New Zealand, Uruguay (25 countries in total).

Conclusion

The COVID-19 situation shows that a new reality is taking shape, both in trade and logistics, and in manufacturing. There is a rapid growth in the share of online sales, success awaits those companies that are ready to adapt to the new reality, build partnerships, reduce production costs and work out a development strategy.

New economic realities for milk producers around the world are causing problems due to reduced business profitability. To remain competitive, dairy companies need to organize conditions for the growth of production volumes; promote the expansion of product diversification in order to further develop the dairy subcomplex, diversify the sales channels for dairy products [3].

Abstract

The article deals with the topical issues of supply and demand for the labor of agricultural specialists. The study was based on the two most in-demand specialties: agricultural and tractor driver. The research was carried out on the basis of data from the official websites for job search, as well as data presented on the websites of the Labor and Employment Departments of the Ural Federal District. The purpose of the study is to analyze vacancies in agricultural specialties in the context of the introduction of professional standards. In the course of the research, the following methods were used: monographic research, analysis, synthesis, comparison, generalization.

Keywords: supply and demand in the labor market, vacancies, wages, agronomist, tractor driver, professional standard.

Introduction

Various factors influence the development and state of social and labor relations. On the one hand, social and labor relations are influenced by the normative legal acts of various levels, which regulate the relationship "employee-employer". An active state policy is aimed at changing and transforming the structure of the labor market. That is, the development of the labor market is impossible without active government intervention. One of the most important areas is the assessment of labor market indicators in terms of changes in the number of resumes and vacancies, both in general and by industry.

Many Russian and foreign researchers and economists dealt with the questions formation and development of the labor market. Thus, in the fundamental works of J.M. Keynes, D. Ricardo, A. Smith, J.B. Say outlines the theoretical concepts of regulating the employment of the population. In the works of Russian economists, internal, national and international problems of “the formation and development of the labor market”[1,7] are considered. In the works of foreign scientists, various job search mechanisms are considered, with the use of the Internet being the leading tool.

Significant changes have occurred in the dynamics and structure of unemployment in the last year, which is associated with the negative epidemiological situation in the region. So during the pandemic (from April 2020), “the number of unemployed registered with the employment”[4] services in the Ural Federal District has increased more than 4 times. According to the monitoring data, the results of which are presented on the official website of the Plenipotentiary Representative of the President of Russia in the Urals Federal District, as of October 6, the number of registered unemployed people left 305.3 thousand people.

At the same time, the demand for agricultural specialists is not increasing. The share of open positions for young specialists in the agricultural sector is also insignificant.

Today, there are professional standards for both professions. For the profession "Agronomist" there is a professional standard approved in 2018. The main goal of professional activity is “the organization of the technological process of growing crop products”[9]. The professional standard provides for three generalized labor functions: performance of work within “the framework of developed technologies for the cultivation”[5,6] of agricultural crops (skill level - 5); organization of products crop production (skill level - 6); management of products crop production (skill level - 7).

The main indicators, as well as directions for achieving qualification levels, indicating the names of positions, will be presented in the form of a fragment of the industry qualifications framework (Table 1).

Table 1 - Fragment of the sectoral qualifications framework for the profession "Agronomist"

Of qualifica-tions level	Name of the Generalized Labor Function	Requirements for the level of education and practical work experience	Job titles
5	“Performance of work within the framework of the developed technologies for the cultivation of agricultural crops”[9]	“Secondary vocational education - training programs for mid-level specialists”[2,8]. Additional professional education is recommended - advanced training programs at least once every five years.	- agronomist; - plant protection agronomist (intermediate qualification)
6	Organization of products crop production	Higher education - bachelor's degree; “secondary vocational education - training programs for mid-level specialists”[2,8]. At least three years of work as an agronomist with secondary vocational education No requirements for practical work experience with higher education. Additional professional education is recommended - advanced training programs at least once every five years	-agronomist - plant protection agronomist - agronomist for testing and protection of breeding achievements
7	management of products crop production	Higher education - master's degree or specialty. Additional professional education is recommended - advanced training programs at least once every five years	Chief agronomist

The information presented in Table 1 on the position of “Agronomist” is not complete in accordance with the approved professional standard and the current Federal State Educational Standard.

Table 2 : Fragment of the sectoral framework of qualifications for the profession "Tractor driver"

Of qualifica-tions level	Name of the Generalized Labor Function	Requirements for the level of education and practical work experience	Job titles
3	Performing mechanized work in agricultural production while maintaining the technical condition of mechanization equipment	Secondary vocational education - training programs for skilled workers (employees) for at least ten months. Passing mandatory preliminary (upon admission to work) and periodic medical examinations (examinations), as well as extraordinary medical examinations (examinations) in accordance with the procedure established by the legislation of the Russian Federation Availability of a tractor driver's license of categories "B", "C", "D", "E", "F"	Tractor driver of agricultural production

In the labor market, the demand for specialists of this profile is high. However, agricultural organizations still lack young specialists.

In the course of the study, the data of the sites for the selection of personnel and the data presented on the sites of the employment services of the Ural Federal District were studied for the most popular professions - an agronomist and a tractor driver.

The amounts offered of wages in the studied professions is shown in Figures 1 and 2.

Fig. 1: Salaries offered by employers of the Ural Federal District in the profession «Tractor driver»

The highest wages level are offered by employers in the Republic of Bashkortostan and the Sverdlovsk Oblast; the lowest level is in the Kurgan region.

Fig. 2: Salaries offered by employers of the Ural Federal District in the profession "Agronomist"

The level of remuneration for the profession of "Agronomist" differs significantly in the Ural Federal District. The highest level is offered by employers of the Republic of Bashkortostan, the lowest - by employers of the Orenburg and Chelyabinsk regions.

Thus, the average salary offered by employers for these positions is 10-42% lower than the average Russian level (Figure 3).

Fig. 3: The ratio of the average wages in the constituent entities of the Russian Federation and in Russia as a whole for 4 months of 2020.

The exception is the salaries offered by employers in the Orenburg and Chelyabinsk regions,

The requirements of employers in various subjects of the Ural Federal District to work experience and the level of education of applicants also differ (Figure 4).

Fig. 4: Analysis of the requirements for the level of education and work experience in the position of "Agronomist" on the territory of the Ural Federal District

No signs of discrimination were found in the analysis of these job search sites. Basically, the announcements contain requirements for the level of education, requirements for qualifications and competencies. Additionally, employers indicate the possibility of training and advanced training by candidates for the position, as well as the presence / absence of social and relocation packages.

After analyzing "the supply and demand in the labor market"[6] of the Ural Federal District, the authors came to the conclusion that there is a high level of demand for agricultural specialists. Despite the sufficient number of vacancies posted on the official job search sites, young specialists are in no hurry to find a job based on these offers. The main reasons for the unattractiveness of the industry are, first of all, the low level of wages compared to vacancies in urban areas, the lack of a developed infrastructure in rural areas and the lack of a decent level of housing amenities.

To attract young agricultural professionals to the countryside, it is necessary to implement socially significant projects at the municipal level to increase the attractiveness of rural areas. For example, such projects include the acquisition of real estate in rural areas on a preferential mortgage; provision of state support to young farmers.

The article was prepared with the financial support of the Russian Federal Property Fund. Grant «Development of theoretical and methodological provisions for the formation of a system for the reproduction of labor resources in rural areas under conditions of labor migration and demographic restrictions» 19-010-00654

Abstract

The purpose of this article is to enrich existing knowledge regarding the links between corporate social responsibility practices and their organizational resilience, and to determine perspectives and directions for further research. Corporate social responsibility is defined as all voluntary organizational activities taking into account social interests, environmental aspects or relationships with various groups of stakeholders, in particular employees. In turn, organizational resilience is the company's hidden ability to sense and correct improper adaptation tendencies and to cope positively in unexpected situations. For the analysis of the above content, scientific articles selected from the Scopus and Web of Science databases were selected, which presented practices showing the relationships between corporate social responsibility and the resistance of these organizations. The results of these investigations confirm the relationships between these constructs and their analysis has identified a research gap that can be filled by subsequent scientific interventions.

Keywords: Corporate Social Responsibility, Organizational Resilience, Sustainability, Social Resilience.

Introduction

The turbulent changes in today's business environment, caused by the economic crisis resulting from the globally prevailing coronavirus pandemic, as well as aspects such as the dynamically changing market, changing consumer needs, non-traditional competition and regulatory shocks - are increasingly forcing enterprises to pay attention to the problem of organizational resilience (Hamel and Välikangas 2003). There are different definitions of organizational resilience (OR) in existing literature. According to Gunderson and Pritchard (Gunderson and Pritchard 2002), this is the latent ability of the system to survive despite adversity, as well as to recover and maintain the existing structure after the crisis. In turn, according to Ortiz-de-Mandojana and Bansal (2015), organizational resilience is the ability of an organization to predict and respond positively to changes in the environment. They define OR as a latent structure, measured by its results. Teixeira and Werther (2013) define OR as the ability of enterprises to effectively deal with the impact of environmental changes on their purchasing power, and then implement their long-term survival and development. One of the factors that has a significant impact on building organizational resilience is the enterprise's application of practices related to corporate social responsibility (CSR) (Pal et al. 2014). CSR activities are primarily voluntary organizational actions not required by law (McWilliams and Siegel 2001), aimed at improving social and environmental conditions (Mackey et al 2007). One of the most powerful ways to make an organization stand out is by engaging stakeholders through CSR activities, thus bringing them many social benefits and values (McWilliams and Siegel 2001). The result of building an OR through CSR activities is to strengthen the profitability and financial stability of enterprises, as well as to establish significant relationships with stakeholders who, through their involvement in the enterprise, will help him avoid the negative effects of external shocks (Zahller et al. 2015).

The purpose of this article is to enrich existing knowledge regarding the links between corporate social responsibility practices and their organizational resilience, and to determine perspectives and directions for further research.

Cite this Article as: Joanna A. JOŃCZYK and Wioletta S. WEREDA“ Relationships of Corporate Social Responsibility with Organizational Resilience: A Literature Review” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The article reviews available literature selected from the Scopus and Web of Science databases, and then analyses the content of 4 selected publications. The main problem identified in the work concerned the ways in which organizations studied by scientists engage in CSR activities and the impact of these activities on building OR. At the same time, methods of measuring OR enterprises and the benefits of possessing this skill for enterprises during external crises and shocks were analysed and evaluated.

An important motivation to take up the above topic are not only the scientific interests of the author, but also the current crisis caused by the global pandemic of the COVID-19 virus, which aroused the need for organizations to review their ability to handle difficult situations. In this context, the rank of organizational resilience (OR) increases, which seems to be important not only in times of crisis, but also in times of greater stability. It is about drawing organizations' attention to the fact that they need to build internal resilience, which, combined with the CSR philosophy, can bring real added value to building a relatively sustainable balance in an ever-changing environment.

Material and Method

Criteria and search procedure

In order to find published literature on the impact of CSR on organizational resilience of enterprises, the Scopus database was searched in July 2020. Searching for literature related to OR issues began with entering the term 'organizational resilience' in the search engine of database. 528 articles were found among the publications available in the Scopus database. To locate the most relevant articles, the number of search results was limited by using appropriate search criteria, referring only to English-language articles from 2010-2020, which are in the area of business and psychology research. In this way, 150 articles were searched that addressed the issue of OR. To compare the results, articles were searched for "resilient organization". 127 articles were found in the Scopus database about a resilient organization. Then, the availability of scientific publications on corporate social responsibility was examined. The search term "CSR" was entered in the Scopus database search engine, resulting in 274039 publications. As in the case of OR articles, results filtering was used. The following criteria were used: English-language articles from 2010-2020, remaining in the research area related to business, social sciences and psychology. A summary of 7621 publications was finally obtained. The above study of literature availability in the Scopus database shows that issues related to corporate social responsibility (CSR) are very popular in available literature. At the same time, there are few publications on the issue of organizational resilience of enterprises, which may indicate that this is a relatively new research area among scientists. The last step in examining the published literature on both CSR activities and organizational resilience of enterprises was to search the articles database using a combination of "organizational resilience" and "CSR". As a result, only 4 scientific articles were compiled. To compare the results, the same search was carried out in the Web of Science database. A list of 3 articles was received, which are also in a list from the Scopus database. Finally, 4 articles found in the Scopus database were selected to analyse the content of publications dealing with CSR issues and its importance for organizational resilience. The list of selected publications is presented in Table 1. To supplement the substantive content, scientific publications on corporate social responsibility and organizational resilience, found through the Google Scholar database and manual bibliography review, on the basis of which the analysed articles were created, were additionally used.

Analysis of the content of the literature

The first article analysed concerns the disclosure of high-quality information under CSR to develop social resilience to exogenous shocks (Zahller et al. 2015). The authors of the promote and test the theory of social resistance to exogenic shocks. They assume that by disclosing high-quality information on corporate social responsibility (CSR), it is possible to achieve favourable organizational legitimacy, which in turn contributes to the emergence of social resilience to external shocks that are beyond the control of management. Perceived organizational legitimacy represents the perception by internal and external stakeholders of the company's goals and values as well as organizational activities, such as responsible use of limited resources, ethical treatment of employees and fair treatment of clients (Ayers 2014). Zahller, Arnold and Roberts (2015) define social resilience as: "the ability of human communities to cope with external shocks of social infrastructure, such as environmental variability or social, economic and political shocks" (Adger 2000).

Blacconier and Patten (1994) and Jonsson et al. (2009) also examined organizational resilience in a community context. They developed and tested the theory of social resilience using an online experiment involving 100 experienced, non-professional investors. The study manipulates two components of the quality of CSR information disclosed: accuracy and completeness. This study aims to answer the question of how high-quality voluntary disclosure of information about CSR by an enterprise can lead to economic benefits for the enterprise that discloses it.

Before designating the target research group, the researchers conducted a detailed study of 623 potential investors. The candidates had to solve the initial test and answer the control question. After this stage, 186 potential participants were rejected. In the next stage, three more difficult control questions were asked. As 322 investors did not answer at least one question, their participation in the study was abandoned. For the remaining 115 potential participants, the time in which they answered the control questions was analysed in order to examine their involvement in the task. 14 participants whose time was the shortest were excluded. One answer was rejected randomly, leaving a sample of 100 experienced, unprofessional investors who were divided into 4 groups.

The experiment consisted of two parts. In the first, participants were informed that they inherited 10,000 shares in a large company, Dryad Forestry, dealing mainly in the production of wood. The company was listed on the New York Stock Exchange. Participants received basic information about the company and economic and financial statements, as well as an excerpt from the Dryad Sustainable Development Report, which included manipulation of accuracy and completeness. After reading the entire documentation, the participants were asked to provide their assessment on the quality of investment in the company and the reliability of the report on sustainable development. At the same time, participants were instructed to assess the stability and comfort of investment as well as the integrity of the management. In the second part of the experiment, investors learned that six months had passed, during which the industry scandal that caused the shock. The company was not directly involved in the scandal, but it affected the economic results of the entire industry. Participants had the option of transferring any portion of their shares in Dryad to an indexed investment fund linked to S&P 500. Investors were asked to reassess the quality of their investments following the crisis and to estimate the time needed for Dryad's partial and full recovery of net lost income after the external crisis, as well as the maximum time that would be needed for a partial and full recovery.

The manipulated variables that scientists use to test the quality of voluntarily disclosed CSR information are the accuracy and completeness of that information. Measurement variables are two hidden structures: perceived organizational legitimacy and social resilience. Organizational legitimacy is reflected in the credibility and transparency of information disclosed by investors, as well as perceived organizational stability. All elements are

measured on a Likert scale from 1 to 7. Social resilience is examined by investors perceiving whether the company will survive an external shock and will continue to be a good investment in the future. Measured with descriptive questions on a Likert scale from 1 to 7. Divestment is measured using a position asking for the percentage of shares that a participant would transfer to a market indexed investment fund after an industry crisis. This measure aims to capture immediate volatility and perceived risk.

The results indicate that the quality of disclosed information on CSR affects the perceived organizational legitimacy, while obtaining a higher organizational legitimacy promotes the emergence of social resilience, which helps to prevent or minimize the decline in the market value of the organization in the event of an external shock. The path factor between the structure of legitimacy and the structure of social resilience was significant and positive (path factor. 865, $p = 0.002$). Drawing conclusions from the study, the authors suggest that the disclosure of high-quality information about CSR signals the respect of enterprises for social norms and stakeholders. Enterprises gain the trust and loyalty of stakeholders by showing the beneficial intentions of management and accurate and complete reports on CSR activities. Disclosures regarding CSR focus on reports on the organisation's goals and processes as well as results in terms of their impact on the environment and social well-being. Reporting focuses on outcomes and non-economic goals that are often indirectly related to financial performance through their impact on other factors such as reputation, perceived resourcefulness and credibility. Thanks to this, in the event of a decrease in the company's financial results, stakeholders are able to accept unfavourable information and support the company's operations. The quality of disclosed information on CSR indicates whether the organization is aware of its responsibility towards the environment and society. Detailed reporting and disclosure of a wider range of activities, in particular those that produce less desirable results, favours the perception of a higher quality of CSR activities. Accuracy means the verifiability and integrity of reporting, which is reflected in both the correctness and completeness of the information disclosed. Completeness covers a number of areas related to non-financial results, including environmental performance, employee health and safety, diversity, relationships with local communities, and product quality. Researchers indicate that more resilient organizations should better cope with investors withdrawing from financing their operations and recover from their pre-crisis condition faster.

Other researchers, Ortiz-de-Mandojana and Bansal (2015) in their publication entitled “The long-term benefits of organizational resilience through sustainable business practices” escribe social and environmental practices (SEP) as organizational activities that have a positive impact on society by improving the company's impact on the social and natural environment. SEP activities may include community relationships, diversity, employee relationships, human rights, product quality and safety, and environmental and corporate governance practices. SEP practices can be treated as corporate social responsibility (CSR) activities. In this article, Ortiz-de-Mandojana and Bansal (2015) assume that social and environmental practices (SAPs) help companies identify and seize long-term opportunities, as well as mitigate threats, which contributes to their resilience. The authors examine the relationship between social and environmental practices and OR hypothesize that SAP practices result in lower financial volatility, stronger economic growth and better survival rates in the long run. Ortiz-de-Mandojana and Bansal (2015) also analyse whether social and environmental (SEP) practices related to sustainable business development contribute to both short-term results and also OR. They define organizational resilience as "the company's ability to sense and correct inappropriate adaptation tendencies and to cope positively in unexpected situations." The analyses carried out in the article show that enterprises with strong SEP compared to those with low SEP show greater stability, because they can better predict threats and, if necessary, avoid those threats that will harm their financial results. According to the authors, SEPs stimulate the growth of enterprises through the ability to capture information from the environment that is crucial for their development (Nicholls-Nixon, 2005). Resilient organizations are better at acquiring and maintaining important resources needed for development, e.g. employees. Ortiz-de-Mandojana and Bansal (2015) believe that SEPs form a set of flexible resources through which organizational resilience is supported. Such resources include, but are not limited to, employees, suppliers and the company's reputation. Loyal employees who feel that the company invests in them and appreciate them will be able to adapt their working hours or remuneration to the emerging needs of the organization, especially during the crisis (MacDuffie 1995). In addition, employees of thriving companies are usually highly motivated and involved in organizational changes needed for development (Shin et al. 2012; Branco and Rodrigues 2006). Ortiz-de-Mandojana and Bansal (2015) are of the opinion that SEPs improve survival by buffering interference and reducing its vulnerability to the negative effects of the crisis. Also, thanks to social and environmental practices, enterprises become more flexible, which means that they can adapt their activities to changes in the environment much faster and at lower costs than competitors.

The authors also ask in the publication whether a compromise can be made between short-term gains and long-term resilience. They indicate the need to invest in projects and technologies that may initially generate higher costs, negatively affecting short-term profitability, but are conducive to increasing flexibility and the ability to respond to

changes in the environment, which contributes to building OR in the long term. Close monitoring of operations and disclosure of information (Gelb and Strawser 2001), employee training, achieving high quality products and investing in security (Darnall and Edwards Jr 2006) can be included in such projects.

Ortiz-de-Mandojana and Bansal (2015) show that enterprises that use responsible social and environmental practices, compared to a carefully selected control group, have lower financial volatility, higher sales growth and a better chance of survival over a period of 15 years. The authors say that the short-term approach to SEP differs from the resistance-based approach. Social resilience is not about reacting to a one-off crisis, but about continuous anticipation and adaptation (Hamel and Välikangas 2003). Scientists put 4 hypotheses in their article, which they then test in their study. Hypotheses 1,2 and 3 refer to a long period. They assume that Companies with high SEP rates experience less financial volatility (1), experience higher growth (2), have higher long-term survival rates (3), and have lower profitability in the short term compared to their peers. The authors argue that SEP practices build organizational resilience, which contributes to less volatility, strong organizational growth, greater chances of survival in the long run, and lower profitability in the short run. Researchers are testing support for hypotheses using t-tests, ANOVA and survival analysis. In order to select the research sample, the researchers used the Social Index KLD 400 and financial information from the Compustat North America database of the company, which in 1991-1993 used social and environmental practices. Enterprises were selected from the sectors represented by at least 10 companies, obtaining a sample of 195 companies. Then, from a database of 1,782 companies that are part of individual sectors, those with a high probability of being included in KLD and having the company's headquarters in the United States were selected to match them as controls for the sample with high SEP. After identifying all the data about the company needed for the study, 121 matched pairs (242 companies) were finally identified, the results of which were examined over 15 years in the years 1994–2008. Ortiz-de-Mandojana and Bansal (2015) identified several variables, using, the impact of social and environmental practices on organizational resilience in the long run was analyzed. They used rate of return on shares to measure financial volatility, covering 180 months from January 1994 to December 2008. Market data for 22 pairs was not available, which is why these analyzes were carried out only for 99 pairs (198 companies). Long-term growth was measured as the accumulation of net sales growth in 1994-2008. The authors generated a variable 0-1, indicating whether an adverse event such as a merger, acquisition, liquidation or bankruptcy occurred in business operations (1 if it occurred, 0 if it did not). All these events are associated with a lack of immunity, because they represent a significant change in the basic function and structure of the company. The time variable shows the number of business survival years from the starting point t0 = 1994 to the final observation period t15 = 2008. A scale of 0-1 was also used to identify companies in pair, a value of 1 was for companies with a high SEP, while a value of 0 corresponded to their control companies. Short-term profitability is measured by the variable ROA between two consecutive years. At the same time, the authors examined that the practices that led to building OR, including SEP activities, resulted in less financial volatility for companies using SEP compared to their counterparts. DesJardine, Bansal and Yang (2015) also stated that US companies that have invested in strategic social and environmental practices have experienced less shock and recovered faster than their peers after the 2008 crisis. In addition, the study showed that enterprises that use social and environmental practices are developing faster in the long run than enterprises that are less sensitive to issues related to SEP. Analysis of SEP in comparison with the value of net sales indicates that companies with a high SEP ratio are able to attract more customers than their peers and therefore ensure a proportionally greater market share, which also affects OR building. The authors did not find support for the hypothesis that enterprises with a strong SEP would have lower short-term results than control groups. They considered that this result is due to the short-term benefits that SEP also creates, e.g. a reduction in resource use, which improves short-term profitability. Lack of support for H4 is consistent with previous empirical studies, for example Margolis and others (2009).

Another of the selected articles focuses attention not only on the general stakeholder group as previously described work, but also includes the analysis of individual stakeholder groups. The authors Lv, Wei, Li and Lin (2019) assessed the impact of CSR on the company's results in the long term and examined how CSR associated with individual groups of stakeholders affects the organizational resilience of the company. As the definition of organizational resilience, Lv, Wei, Li and Lin (2019) accept: "the company's ability to cope positively with environmental and operational turmoil through long-term, better sales growth and financial instability". In the article, the authors present CSR activities in six dimensions, namely general CSR, shareholder, employee, business, society and the environment, and then separately examine their impact on the organization's resilience. Lv, Wei, Li and Lin (2019) analyse the impact of CSR on organizational resilience on the basis of a large sample of non-financial enterprises from China, active in 2010 - 2017. The authors obtained information on the CSR activities of Chinese enterprises mainly from the Kinder, Lydenberg and Domini databases (KLD), which provides international

assessments of the results of socially sensitive enterprises that Chinese listed companies have been required to publish. Researchers selected a group of companies from China for the study, because the Chinese market is characterized by unstable regulatory conditions, unstable industrial structure and intense competition, appearing along with the rapid development of the economy. These factors mean that Chinese enterprises are struggling with greater uncertainty in their environment and are more sensitive to changes, which is why they must particularly take care of their organizational resilience.

In the first stage of the study, scientists studied the literature published so far on the concept of organizational resilience, which contributes to high growth and low variability of the company's results over time. Then they formulated hypotheses regarding the impact of six dimensions of CSR on organizational resilience and tested them based on reports from Chinese companies.

Scientists conclude that interaction with stakeholders based on good relationships resulting from CSR activities is necessary to build OR. The core of the relationship between a resilient organization and its external environment lies in trust and reciprocity. Thanks to this, enterprises will be able to identify changes in the environment more effectively and obtain the necessary resources and support during the crisis. The important role of CSR in building organizational resilience is manifested in two aspects, namely mechanisms for increasing efficiency and securing results. The authors put forward 12 hypotheses related to six dimensions of CSR in the context of their impact on long-term growth and stability of financial results.

To confirm the hypotheses, the authors measured dependent variables, which are long-term growth and financial volatility. These variables characterize the organizational resilience of the enterprise. Long-term growth is measured by the accumulation of net sales growth over 3 years. Financial volatility is measured by the variability of return on shares. Independent variables that are characteristic of the six analysed CSR dimensions were also introduced into the study model. The variable values came from the Hexun CSR database. In addition, the authors introduced several control variables. They evaluated the ratio of the market price to the book value affecting the company's long-term results (Feltham and Ohlson 1995). They also used the Herfindahl-Hirschman index (HHI) to take into account the concentration of industry. The indicator aims to show whether the company is not a monopolist on the market, thanks to which they can maintain stable results (Ahmed at al 2014). To identify secured financial resources for possible turmoil in the environment, the authors checked sales and administrative costs, leverage and cash flow (Andersen 2012). The last control variable was the assessment of the political nature of the enterprise.

Research results indicate that involvement in CSR activities can improve the company's long-term growth and reduce its financial volatility. CSR activities help the company build its reputation and deepen social foundations. Thanks to this, companies can obtain appropriate resources and support from their stakeholders, which allows to mitigate the negative effects of system shocks, crises and threats (Ortas et al. 2014) and create opportunities for business initiatives (Ortiz-de-Mandojana and Bansal 2015). In addition, the good reputation provided by CSR contributes to increasing customer satisfaction (Singh 2016; Wand et al. 2015), which in turn affects the perceived organizational legitimacy that Zahller et al. (2015) mentioned. The authors find support in the thesis of Pal at al. (2014) that "a deep social foundation along with goodwill, brand awareness, network relationships can act as a mask that protects an organization against sudden negative events and provides its necessary time to absorb shocks and take appropriate action". Researchers say that an enterprise that engages its shareholders through CSR activities will show greater innovation. Innovation is widely recognized in the existing literature as a necessary way to achieve organizational resilience, because they can absorb and even take advantage of environmental changes by developing new opportunities (Sabatino 2016). Shareholder CSR can significantly reduce financial instability by acting as a shock absorber during a crisis and by gaining access to additional financial resources to support business operations (Gunasekaran 2011), however the research shows that this activity has relatively little impact on long-term growth.

The study indicated that CSR activities related to employees are very important in building organizational resilience. These activities include ensuring a safe and comfortable work environment, a high level of investment in remuneration and employee benefits, education and care for emotional involvement, so as to equip employees with the competences necessary to deal with environmental changes (Demmer et al. 2011; Lengnick-Hall et al. 2011). Employee CSR can bring positive and pro-innovative behaviour at work, which ultimately contributes to increased productivity (Shen, and Benson 2016). In addition, the authors note that resilient organizations involve their employees in an emotional way, thanks to which they can encourage employees to respond flexibly to environmental changes and help them identify threats faster (Wisse et al. 2018). Instead of striking or giving up work, employees in resilient organizations can demonstrate collectively commitment and cooperation, and be motivated to generate new ideas and implement various ideas that will strengthen the company's results during a

crisis. Thanks to CSR activities related to employees, organizations can strengthen long-term development and reduce financial instability caused by external shock.

The authors noticed a particularly positive impact of CSR activities on organizational resilience in the context of the business environment. Research indicates that establishing relationships with business partners, customers and suppliers, and even competitors contributes to the creation of a network in which an enterprise can obtain information, knowledge and resources from the market, and thus effectively identify and meet changing environmental needs (Wisse et al. 2018; Zhang et al. 2016). This information resource has a beneficial effect on long-term development and maintaining financial stability. Research results confirm the hypothesis presented in the article that CSR activities related to the business environment have a significant, positive impact on organizational resilience.

CSR practices related to the natural environment are actions taken by the organization to improve the environmental impact of its business activities. Reduction of dependence on natural resources, reduction of carbon dioxide emissions and pro-ecological activities makes enterprises more flexible and competitive. Companies can build a "green image" and then win public favour. Investing in CSR related to the natural environment increases investor confidence, which has a significant impact on organizational resilience.

The role of CSR related to society in building OR consists mainly of creating social reputation arising as a result of the company's charitable activities. Charity can significantly increase a company's value, strengthen its development, and gain the trust of customers (Shan et al. 2017). Positive emotions displayed by the society towards the company may contribute to alleviating the negative effects of external events. However, studies conducted by the authors show that CSR connected with society does not have a significant impact on the long-term growth of the company, which may be due to social awareness not educated in China.

Lv, Wei, Li and Lin (2019) created a publication that comprehensively shows the impact of corporate social responsibility in the context of various stakeholders on building organizational resilience. The authors argue that relationships with employees and close business environment (customers, suppliers) have the greatest impact on building OR.

Sajko and Boone (2020) in their publication investigates how the greed of CEOs affects companies' position on CSR before the global financial crisis (GFC) of 2008 and how these actions determine the organizational resilience of enterprises to systemic shocks and economic crises. The definition of greed is the "pursuit of excessive or extraordinary material wealth" (Haynes et al. 2017). Researchers are investigating whether companies with greedy CEOs and limited investment in CSR are also less resistant to environmental disturbances and how these pre-shock activities contribute to the stability and flexibility of the company in the post-shock period and thus play an important role in creating resilient organization. Scientists theorize that investments in CSR contribute to increasing the organisation's resilience in two ways. First of all, CSR helps to build stability, creating interdependencies and relationships between the company and its stakeholders, thanks to which it is possible to absorb shocks faster. Secondly, corporate social responsibility activities increase flexibility because companies with broad stakeholder involvement gain access to diverse and distinctive viewpoints, thereby increasing the set of possible adjustments to external change (DesJardine 2019).

To examine the organizational resilience of enterprises, the authors compiled selected CEOs of US public corporations listed in the S&P 1500 index before the start of the global financial crisis (GFC) in 2008. Then they combined data collected from all sources, such as KLD, Compustat, Execucomp, BoardEx, CRSP and Thomson-Reuters Institutional Holdings, and then excluded observations with missing variables and enterprises from sectors with a high level of legal regulations (e.g. from the financial and public sectors). The key factor was the approval of the CEOs for a three-year observation in 2006-2008). The list of all sample search criteria for the study was distinguished by 301 CEOs covered by the study. Scientists assume that greedy CEOs will be more likely to neglect the needs of shareholders to maximize short-term profits (Haynes et al. 2015). The researchers also expect that the low investments of greedy directors in CSR will contribute to greater losses in the short term and are associated with longer recovery times after the financial crisis. The authors make several hypotheses, which they examine in three research stages.

Table 2: Research hypotheses put forward by the authors regarding the impact of CEO greed and CSR on organizational resilience

Part I of the study	
H1	ed of the CEO will have a negative impact on the company's CSR.
H2	The relationship between the company's greed and the company's CSR will be more negative if the greater part of the president's salary is an annual bonus.
H2b	The relationship between the president's greed and CSR will be less negative if the majority of the president's remuneration had a limited share in the shares.
Part II of the study	
H3a	The greater the company's social responsibility in the period before the shock, the smaller the fall in the share price after the shock.
H3b	The greater the general manager's greed in the period before the shock, the greater the fall in the company's share price after the shock.
Part III of the study	
H4a	The greater the company's social responsibility in the period before the shock, the shorter the recovery time and the smaller the shock.
H4b	The greater the general manager's greed in the period before the shock, the longer the time.

Sajko and Boone (2020) conducted a 3-stage study to check the validity of the hypotheses. The first stage aimed to investigate how the greed of CEOs affected CSR in the pre-shock period. The research period covered the years from 2003 to the rise of the financial crisis in 2008. This section covered 301 CEOs. The study was conducted by comparing the dependent variable, which is data from the KLD database, on such issues as community, diversity, employee relations, the environment, human rights and product quality with an independent variable, which is the model of the CEO greed measure and CSR measure developed by the authors. In the next stage, the authors examined how the greed of the CEO and CSR before the financial crisis affected the company's ability to absorb exogenous shocks. The observation lasted at the turn of 2018 and 2019. This part also covered the 301 CEO survey. The study was conducted by measuring the decrease in the company's share price as an absolute percentage change between the closing price just before the start of GFC in 2008 and the lowest closing price that the shares achieved over a period of 12 months. Then, the authors compared the results with the previously developed model of greed CEO and CSR. The final stage of the study was to analyze how CEO and CSR pre-shock greed affected companies' ability to build. The third part of the study was attended by 269 CEOs and they were followed in 2009-2011. The decrease in the number of CEOs surveyed resulted from a change in their position or the collapse of the company after the GFC crisis. The authors adopted the risk indicator as the dependent variable, representing the probability that the company would regain balance during t. The observation time was 36 months.

In the first part of the study, the authors showed that greedy CEOs are less concerned about the welfare of their company's stakeholders and tend to give up long-term investments that require short-term financial sacrifices, which confirms hypothesis 1. The results also confirm hypothesis 2a, saying that greedy CEOs are more likely to neglect stakeholder concerns when their remuneration is highly dependent on annual bonuses. At the same time, the study did not indicate that the relationship between the president's greed and CSR was less negative if the majority of the president's remuneration had a limited share in shares (H2b).

In the second part of the study, it has not been confirmed that the greed of the CEO or CSR affects the fall in share prices immediately after the crisis, which is the reason for rejecting hypotheses 3a and 3b. However, when assessing the impact of the dimension of individual stakeholders on company stability, the authors noticed that companies with strong diversification practices are associated with smaller decreases. This result partly overlaps with studies (DesJardine et al. 2019), which indicated that the impact of strategic CSR has a positive effect on the company's ability to absorb shocks. The inaccuracy of analysis and results may be caused by too few samples or independent factors, such as a decrease in customer purchasing power and the supply chain after the crisis.

In the third part of the study, the results showed that companies with greater involvement in CSR before shocks have a much greater chance of recovering faster. Stock prices of companies with strong relations with stakeholders

and CSR activities were associated with higher rates of economic recovery after the 2008 GFC, while companies led by greedy CEOs were less likely to rebound from economic shock. The authors emphasize that investing in CSR contributes to increasing organizational flexibility due to its positive impact on stakeholder motivation and greater interdependence between the company and its natural and social environment. The authors find support for hypotheses 4a and 4b.

Discussion and Conclusions

Main Conclusions

Analysis of the content found in the Scopus database of literature allowed to see the directions of research on the impact of CSR activities of enterprises on shaping their OR. Based on a study by Zahller, Arnold and Roberts (2015), it can be seen that even the way companies provide information about their corporate social responsibility activities can help build OR. The accuracy and completeness of CSR reporting generates the level of perceived legitimacy of enterprises. This means that the stakeholders, based on the quality of the shared report, generate trust and favour in the company's operations. Sharing both positive and negative company results gives stakeholders a feeling that the company is honest and committed to building positive relationships with the business environment. Thanks to this, stakeholders are able to respond in a less negative way to the negative effects of external crises and shocks affecting their related enterprises, as well as to share their resources, knowledge and information to help enterprises rebuild their position after the crisis.

In turn, Ortiz-de-Mandojana and Bansal (2015) indicate that social and environmental practices, which are part of CSR activities, can generate both short-term benefits and build long-term organizational resilience. SEP practices include community relationships, diversity, employee relationships, human rights, product quality and safety, and environmental and corporate governance practices. Research conducted on American enterprises shows that enterprises that have higher rates of SEP practices are willing to increase their economic development, reduce financial instability, and have better survival rates in times of crisis. SEPs should have a particularly strong impact on employees, suppliers and customers, building the company's reputation. SEP practices related to employees have a particularly strong impact on organizational resilience. Committed and motivated employees are able to respond faster and more efficiently to changes, and are also highly flexible, thanks to which they are able to adapt their working time and remuneration to emerging changes and dangers in the company's environment. Through activities for the benefit of the community and the environment, the company gains the trust and loyalty of customers, which contributes to strengthening financial stability.

Lv, Wei, Li, and Lin (2019) examined how CSR associated with specific groups of stakeholders affects the organizational resilience of Chinese enterprises. Similarly to the study of the Ortiz-de-Mandojana and Bansal (2016) way, CSR activities related to workshops and the business environment turned out to be the most significant. CSR activities related to shareholders, society and the environment also affect the achievement of organizational resilience by enterprises, but to a lesser extent than other groups of stakeholders. Researchers indicate that building good relationships with individual stakeholder groups, resulting from CSR activities, is necessary to generate OR. Like previous researchers, the authors assess organizational resilience in terms of its long-term development and financial results. Thanks to CSR activities for individual groups of stakeholders, enterprises are able to gather resources and information on market changes from various sources. This means that each group of stakeholders is able to support the company's operations in its own way during external shocks and increase organizational resilience. The authors approach the study of stakeholder influence in a more comprehensive manner than other scientists.

In the last of the selected articles, Sajko, Boone and Buyl (2020) present a special focus on the greed of the organization's management and its CEOs. They investigate how the greed of CEOs influenced companies' position on CSR before the global financial crisis (GFC) of 2008 and how these activities determine organizational resilience of enterprises to systemic shocks and economic crises. Greedy directors are characterized by their pursuit of excessive or extraordinary material wealth, usually over a short period of time. Studies show that the CEO's greed has a negative impact on CSR activities and on building organizational resilience. The authors emphasize that the essence of building OR is investing in technologies that will negatively affect the company's profitability in the short term, but in the long run will contribute to better response to system shocks and better identification of threats. Scientists recognize that greedy directors attach less importance to taking care of relations with stakeholders

through CSR activities. These relationships are key to achieving OR because they generate access to information and other resources that may be strategic when trying to overcome the crisis.

Limitations and further research directions

In order to select articles for analysis that address the issues of both CSR activities and organizational resilience, we have deliberately narrowed the search criteria for articles in the Scopus database, resulting in 4 articles. This limitation was intended to thoroughly penetrate the issues raised due to the existing gap in the research on the relationship between CSR and the resilience of organizations and to show the actual activities of enterprises in this area. Detailed reviews of selected articles confirm the importance of the organization's resilience in the context of CSR, especially in the sphere of responsibility for results and financial stability. In addition to the Chinese company survey, other articles referred to the general stakeholder group without differentiating between the different types of stakeholders. Although research has shown evidence showing the impact of CSR activities on specific aspects of business operations, it has not been indicated how to conduct these activities. Researchers raise the benefits of corporate social responsibility in the context of organizational resilience, but do not instruct on how to achieve these benefits. In future research, it is worth considering the operationalization of ways to build organizational resilience using CSR, including all groups of stakeholders, going beyond financial issues. It is worth analysing the internal relations in the enterprise, because they have a strategic impact on building OR. It seems reasonable to examine the role of organizational culture and HRM as potential moderators in shaping relevant organizational values and engaging employees and other stakeholders in order to better prepare them to absorb external shocks. No less important is the extension of CSR practices in the context of greater attention to individual mental and physical resistance of employees. From a medical point of view, immunity means the body's ability to actively and passively protect the body against harmful external factors. We care about the body's resistance from the inside, using a proper diet and supporting ourselves with supplements and vitamins. From the organization's point of view, building its resilience should start from the inside of the company, which also includes the internal life of employees. Medical vitamins and supplements mean relationships with stakeholders as well as important resources and information from outside the organization. Therefore, enterprises should constantly strengthen organizational resilience to avoid external crises as far as possible or to pass through them in the shortest possible time, with minimal losses. It is also worth seriously to examine the organization's activities, including in the field of CSR, which could strengthen the individual physical and mental resistance of employees. Given the current time of the coronavirus pandemic, building organizational resilience of enterprises with the help of CSR seems to be not only an urgent need, but an obligation that is difficult to downplay in the context not only of the current but above all the future condition of enterprises struggling with the global crisis. In connection with the above, the author has already started work on the preparation of the project regarding the development of the concept of social organizational resilience.

Introduction

The major objective of any business is to satisfy its customers so when customers are changing, a company must learn to adapt. Change comes the opportunity to learn and prepare your work team adequately for new growths. Employers must assess the skills and tools their employees already have and look for gaps. Organizational change management is an event or program that an enterprise plans to initiate, which will cause significant disruption to their daily activities. The key challenge is reducing possible friction and resistance to change by making sure all employees understand the importance of change to the company's forthcoming growth. And, ignoring the need for change can be far more threatening to your business than the change itself.

Nowadays, new trends and technology evolve so quickly that if you don`t update, you will slip behind. So, customers' needs will continually change. Communication is faster and businesses that can't deliver quickly will lose out. To enhance organizational change management by person, group and the corporation as a whole, Wu (1984) offered practical techniques using several interventions for promoting needed changes. Three models of organizational change have been proposed by Lewin (1951): unfreezing, changeover and unfreezing again. If the change must be done, the first job is to "unfreezing", gradually softening and resolving rooted concepts; next, using them to be the basis of new approaches that you can proceed to "changeover" by these new approaches. Lippit, Watson and Wesley (1958) had ever expanded Levin's organizational change Models and classified to four sections:

1. Necessary requirements for change;
2. A certain relationship of change;
3. Strict Implementation measures of change;
4. The maintenance of steady change and
5. End of aid relationship.

The reasons for resistance are demand for security, habits and misunderstanding, which are big obstacle to change. Therefore, it is necessary to think how to reduce obstacles by: encouraging employees' participation and views, recognition and support for employees, more training courses, mutual communication and mental incentives to reduce obstacles. Lewin (1964) proposed five major interactive constructs for change, respectively, organization-wide change, transformational change, personnel change, unplanned change and remedial change.

Literature Survey

Types of Organizational Changes

With organizational change strategies, companies can avoid stagnation while minimizing disruption. However, one can't prepare without knowing what type of change is occurring. The first step is to understand what change management model exist and then figuring out what best suits your company or team.

Organization-Wide Change: Organization-wide change is a large-scale transformation that affects the whole company. This could include restructuring leadership, adding a new policy, or introducing a new enterprise technology. Achieving a successful organization-wide change demands comprehensive planning and communication throughout the organization.

Transformational Change: This specifically targets a company's organizational strategy. Companies that are best suited to withstand rapid change in their industry are quick, flexible, and prepared to transform their game plans when the need arises (Kritsonis, Alicia 2004-2005).

Personnel Change: This happens when a company experiences hyper-growth or layoffs. It is important to display genuine compassion and motivate employees to continue working hard through difficult times.

Unplanned Change: It is typically defined as necessary action following unexpected events. By setting basic change strategies in place for these situations, organizations can minimize these unplanned risks and emerge as more adaptable and resilient.

Remedial Change: Leaders implement remedial changes when they identify a need to address deficiencies or poor company performance.

Factors affecting business strategy development

From literature analysis, 11 major implementation factors were identified: strategy development, environmental uncertainty, organizational structure, organizational culture, leadership, operational planning, resource allocation, communication, people, control and outcome. Kazmi (2008) grouped these factors into three activities: activating strategy, managing change and achieving effectiveness. Further, Alamsjah (2011), Jiang and Carpenter (2013) listed the following factors as important dimensions in technology strategy development: degree of uncertainty, clarity of strategy, organizational structure, corporate culture, CEO and top management involvement, people's competencies and commitment, knowledge management, managing change, performance management, communication and development plan. The focus of this research is on the internal factors of organization changes strategy development.

What is technology strategy?

Technology Strategy is that aspect of strategy which is concerned with exploiting, developing and maintaining the sum total of the company's knowledge and abilities. It centers on the knowledge and abilities that affirm that the core of a company is what it knows and what it can do, rather than the products that it has or the markets it serves (William L. Shanklin and John R. Ryans 2015). Developing a strategy will force a company to step back from analysis of its market position and the things it sells. Getting firms to focus on technological strategy requires complementary action from the demand and supply sides. For global corporation, the pressure to improve technological strategy has to be increased through greater trade liberalization and relaxation of internal regulatory constraints to competition.

Research

Hypothesis, Background and Research Questions

Technological strategy is likely to be consistent with organizational changes, so it is expected that technology strategy will be acceptable for global corporations that focus on different strategies (Neally et al., 2001).

Hypothesis 1: The organizational changes in a global corporation will affect the technological strategy in the global corporation.

Conversely, in technology strategies where integration and simplification between functions are required, there is a possibility that low performance will have a negative adjustment effect on technological strategy (Fredrickson, 1986).

Hypothesis 2: The relationship between the technology strategy and organizational changes will be adjusted according to low performance of the corporation.

In terms of organizational changes and innovation convergence, organizations seeking innovation with new missions will have a positive adjustment on technology strategy (Burns and Stalker, 1961).

Hypothesis 3: The relationship between organization changes and technology strategy will be adjusted according to the new mission of the corporation.

Organizations tend to focus on familiar and repetitive processes, making them relatively stable, and requiring more satisfaction. High levels of satisfaction are likely to reduce the negative impact of changes on technology strategy (Nealie et al., 2001).

Hypothesis 4: The relationship between organization changes and technology strategy will be adjusted according to the level of satisfaction of the corporation.

In addition, considering the existing argument that technology strategy is a leadership activity for an entity's business areas and processes (Baines et al., 2009; Garcia & Calantone, 2002; new leadership will positively support technology strategy.

Hypothesis 5: The relationship between organization changes and technology strategy will be adjusted according to the new leadership of the corporation.

Conflicts are considered to be an inevitable part of an organizational change. It is suggested that the potential functional consequences of conflicts can work as a driving force and facilitator during the change process (Chenhal et al., 2011).

Hypothesis 6: The relationship between organization changes and technology strategy will be adjusted according to the conflicts in the corporation.

Do internal organizational changes influence the technology strategy in a global corporation?
What organizational change challenges and barriers are faced by global corporations (figure 1)?

Fig. 1: The moderating effect of Internal Organizational Changes
Source: made by authors

Case study and Statistical Data

These days, the automobile corporations' sector has become an increasingly competitive one. The environment is more dynamic, uncertain and continuously changing. These circumstances forced automobile companies like Hyundai Motors (a Korean based corporation) and Innoson Vehicle Manufacturing (a Nigerian based corporation). Although the later produces copies of original products to be launched at patent expiration, both corporations adopt more effective, unique and innovative strategies to maintain and improve their performance and to gain a larger portion of the world market share.

Methodology and Data Application

In this study, the dependent variable is "Technology Strategy", and the variance in the dependent variable is explained by the independent variable; organizational changes.

To investigation the influence of organizational changes on technology strategy development, the data is collected via an internet survey. With the use the structural Equation Model and the Change Management Model, this thesis examines the moderating impact of the internal forces of organizational changes on technology strategy development. It suggests that internal forces have a significant influence on the relationship between organizational changes and technology strategy development and that new missions and new leadership have a significant positive impact on the relationship between organizational changes and technology strategy.

Results

Under technology strategy, high levels of satisfaction and low level of conflicts has a significantly negative impact on Technology strategy. These results can reduce the flexibility and agility of organizational changes when it places too much emphasis on procedures and norms under technology strategy. The further results are going to be discussed.

Conclusion and discussion

Firstly, Technology strategy development is characterized by bureaucratic regulations in global corporations. Bureaucratic regulations consist of strict orders, contractual arrangements and the manipulation of the employee's autonomy. In this top-to-down hierarchical managing system, new vision was not well communicated or explained to the employees and little attention was paid to creating a suitable climate.

Secondly, duress and manipulation were used too much in the change process and the intrinsic values and emotions of the employees were neglected. The strategy for reducing resistance was simply pressure (Alt et al., 2003).

Thirdly, the employees were not properly empowered and involved in the change. During the planning stage, managers rarely involve employees in deciding how to handle changes. Moreover, no effective incentive system was created for those afraid of the future after the change to help them maintain confidence (Lang et al., 2006).
In order to support corporate success better, corporate communication should be closely linked to a company's overall strategy (Argenti, 2003)

Given that this study simultaneously examines the five organizational changes, further empirical work should be done to provide clear evidence for each change.

In the future, a study can be conducted among new leadership in organizations undergoing changes. The questions can focus on how leaders' function during the change process and the outcome of their efforts. It will be helpful to ask them to clarify whether their efforts are successful or not in implementing the changes, and to explain the reasons behind the success or lack of success. Besides, their evaluations of their work in the process of technology strategy development and their own opinions on how to improve and what to improve and how contribute in facilitating organizational changes.

Abstract

This study seeks to find ways to reduce accounting transparency among unlisted small and medium-sized enterprises (SMEs) and strengthen them. Korean accounting transparency increases internationality at the mid- to low-income level every year after year. Transparency in accounting will affect the information environment and capital costs of companies, ultimately serving as an important factor in Korea discount, and furthermore, it is an important issue directly related to Korea's international credibility. Research is needed to solve these problems, but the preceding study mainly developed the accounting transparency index or provided policy guidelines to improve it on the premise that the accounting transparency of our country is low.

In order to enhance the overall level of accounting transparency in Korea, it is necessary to grasp the actual state of accounting transparency of not only listed companies but also unlisted small and medium-sized enterprises and devise measures to improve them. Therefore, the purpose of this study is to identify the factors that impede the accounting transparency of small and medium-sized enterprises in Korea and to suggest measures to enhance their accounting transparency

Keywords: accounting transparency, SME, South Korea, strengthen methods and recommendations.

Introduction

This study seeks to find ways to reduce accounting transparency among unlisted small and medium-sized enterprises and strengthen them in Korea. Korean accounting transparency is international at the mid- to low-income level every year. Transparency in accounting affects the information environment and capital costs of companies, ultimately serving as an important factor in Korea discount, and furthermore, it is an important issue directly related to Korea's international credibility. Research is needed to solve these problems, but the preceding study mainly developed around the accounting transparency index or policy guidelines to improve it on the premise that the accounting transparency level of Korea is low. Non-public enterprises have a relatively small number of external stakeholders, which means less confidence in their management performance, and it is managed by practical owners rather than professional managers, which is likely to lead to more arbitrary intervention in accounting policy decisions.

In addition, major corporate decisions are concentrated on one owner, making little effort to ensure transparency in corporate accounting information, and the level of supervision and regulation by policy authorities is relatively low for them. For this reason, it is highly likely that unlisted companies will be left in a blind spot for accounting transparency as they are more widely adjusted to protect their owners' private interests than listed companies.

According to the 2019 status index, small and medium-sized enterprises account for 99.9 percent of the total number of companies and 90.2 percent of the total number of corporate workers in Korea, making up not only a large portion of the nation's national economy, but also increasing the importance of small and medium-sized

enterprises by participating in various areas to restore market functions and increase income distribution and jobs. Given the importance of these small and medium-sized enterprises, so far, most of the research on accounting transparency has been biased toward listed companies. In order to enhance the overall level of accounting transparency in Korea, it is necessary to grasp the actual state of accounting transparency of not only listed companies but also unlisted small and medium-sized enterprises and devise measures to improve them.

Therefore, the purpose of this study is to identify the factors that impede the accounting transparency of small and medium-sized enterprises in Korea and to suggest measures to enhance their accounting transparency.

.

Literature Review: Status of Small And Medium Enterprises

The Role and Importance of Small and Medium Enterprises

The Framework Act on Small and Medium Enterprises (since 2016) stipulates basic matters of initiatives to foster small and medium enterprises. Subject to this support project are small and medium-sized enterprises, which are called small businesses. Small and medium enterprises refer to enterprises prescribed by statutes for protection and fostering, and the scope standards for small and medium enterprises are prescribed in detail in Article 2 of the Framework Act on Small and Medium Enterprises and Article 3 of the Enforcement Decree of the same Act (since 2017).

According to the general standard of small and medium enterprises, the total number of industrial enterprises in Korea are presented in Table 1.

As shown in table 1, there are 3.6 million companies in 2019. Among them, 3.6 million SMEs account for 99.9 percent of the total number of businesses and 15.12 million workers, accounting for 90.2 percent of the total number of workers.

Table 1: Status of Small and Medium Enterprises (2019)

Division	All	SME	Major Company	Importance	
				SME	Major Company
Number of Businesses	3,604,773	3,600,882	3,891	99.9%	0.1%
Number of Employees	16,774,948	15,127,047	1,647,901	90.2%	9.8%

Source: The Organisation for Economic Co-operation and Development (OECD), 2020

These days, the business environment of small and medium-sized enterprises is in a difficult situation due to sluggish domestic demand, rising unemployment, foreign trade issues and several U.S. interest rate hikes. The internal environment is also noisy due to measures to resolve polarization between large and small companies and the minimum wage and welfare of workers. The minimum wage for 2018 was set to rise 10.9 percent from 7,530 won per hour to 8,350 won per hour by 2019. Under these circumstances, small and medium-sized business managers are finding it difficult to do business due to the burden of labor costs, and unemployed people are paying full attention to policies to create jobs and expand employment. However, the economy lives only when small and medium-sized enterprises live. In other words, it is also small and medium-sized enterprises that are reviving our economy.

Small and medium-sized enterprises are formed around manufacturing industries, so they do not have sufficient capital power according to Damanpour, F. (1992). Since it is established mainly in provincial areas rather than large cities due to its poor size and facilities, it plays a big role in the development of local communities and maintains relationships with large companies and suppliers by processing and delivering parts of products produced by large companies. Small and medium-sized enterprises play a key role in further developing win-win relationships by linking products produced by new research and development with large companies through relatively low costs and rapid decision-making.

Concept of Accounting Transparency

The financial and foreign exchange crisis represented by the 1997 IMF economic crisis prompted Korea to re-recognize the international community's demand for transparency in accounting information and accounting standards. Since Korea's small and medium-sized enterprises account for a very high proportion of the domestic economy, their credibility will be lost if accounting transparency is not guaranteed, making them unable to hope for stable corporate growth. It will also receive negative reviews from the international community on its accounting transparency, raising the cost of raising corporate capital. Accounting transparency reduces information asymmetry between an entity's internal managers and external stakeholders, thereby helping stakeholders make economic decisions and contributing to the efficient allocation of economic resources.

Transparency is maintained when information is pre-examined, objective and easy to understand, without concealing suitable and reliable information in relation to the recording and disclosure and predictability of information.

The IMF (Segev, 1998) defined transparency as a process that makes information accessible, visible, and understandable about existing conditions, decisions and behaviors, and said that factors such as timeliness, completeness, continuity, risk management, audit and control should be included.

Factors affecting an entity's accounting transparency can be classified into four categories (Wells, 2005). First, accounting information transparency is divided into information contents, information disclosure, and information use aspects, and second, accounting system transparency is divided into internal control systems, information systems, accounting organizations and audit systems. Third, managerial transparency is divided into corporate governance and corporate management fairness, and finally, transparency of management consciousness is divided into management philosophy and corporate culture, social responsibility performance, resource allocation decision criteria, and stakeholder respect.

Lee Sang-Wook and Chang, W. (2016) defined accounting transparency as a condition that makes the accounting process and accounting information unquestionable by fully disclosing the accounting process and accounting information when delivering accounting information to users of accounting information. In order to achieve accounting transparency, not only the contents of accounting information but also the process of accounting must be disclosed to the extent that it is unquestionable.

Kang Dong-Kwan and Jung, J. (2016) summarized the economic losses caused by accounting opacity in three ways: First, opacity deprives foreign capital of its chances of attracting domestic capital by undermining the nation's credibility, and secondly, distorts tax flows by preventing corruption such as bribery, and thirdly raises capital costs. Therefore, accounting transparency is the most important part of corporate transparency.

Lowering Factor of Accounting Transparency

We know that internal and external confidence in corporate accounting is low, but we have a long-standing practice. The efforts to set new standards run into the interests of vested interests, making it difficult to ensure success, but it is very important to instill faith in the success of the reform in those who think that change is necessary for accounting reform to succeed.

The revision of the Act on External Audit (2018) introduced groundbreaking systems such as the designation system for regular auditors, the external audit system for internal accounting management, and the registration system for auditors for listed companies, and these new systems must be operated according to their original purpose in the field to gain confidence in reform. To this end, we should also take a closer look at whether there are any problems with supervision, external audit behavior, and the way the company's governance structure works with a broader and longer perspective Sinnett W.M. and de Mesa Graziano C. (2006).

According to Lee Sang-Wook (2009), the Office PriceWaterhouse Coopers (PWC) selected five factors of corruption, legal system, economic policy, accounting and regulation that could affect the overall opacity of the country in January 2001 and calculated the opacity index for each sector, and then averaged these indices to publish the overall opacity index of each country. The opacity index consists of five sub-indexes, which are simple averages of the opacity index. As for the double accounting sector, the survey was conducted by dividing it into factors related to the opacity of accounting standards, the opacity associated with compliance with accounting standards,

and the uncertainty associated with the accessibility of financial information, and Korea ranked 31st out of 35 countries included in the survey, especially in accounting.

According to the Financial Supervisory Service, as of 2016, 89 or 66 percent of 133 companies subject to supervision were caught for accounting violations, including accounting fraud (figure 1). The share of companies caught in accounting fraud in the total supervision companies rose from 48.1% in 2011 to 66% in 2016 (Jose Daily, 2018)

The capital procurement routes of small and medium-sized enterprises can be divided into indirect financing and direct financing, indirect capital procurement routes are divided into bank loans, guarantee agencies and government policy funding, and direct capital procurement routes are divided into issues of stocks and corporate bonds. More specifically, the typical method is to provide loans based on the guarantee letter from the guarantee agency and loans from financial institutions based on the company's collateral or credit, general investors and creditors through the issuance of policy funds and stocks and corporate bonds supported by the government. Bank loans (65.9%) are the highest in each funding path, followed by policy funds (26.5%), loans to secondary financial institutions (3.4%), and overseas borrowing (1.6%). They argued that the higher the credit rating and the larger the size, or the greater the growth after the start-up, the higher the proportion of bank loans, and that small and medium-sized enterprises with lower credit ratings or smaller credit ratings use secondary financial loans and private loans (Shin Sang-Chul 2012).

As shown in Figure 2, the biggest difficulties in financing through financial institutions were high loan rates (44.2%), followed by demanding loan screening (31.8%), excessive demand for real estate collateral (19.4%), credit guarantee-oriented loans (16.3%), and lack of loan limits (15.5%). In addition, sales slump was the highest at 62.7 percent, followed by increases in raw and subsidiary materials (54.7 percent) and delays in collecting sales proceeds (30.7 percent).

Methodology: measures to strengthen accounting transparency

Improvement of Internal and External Environment

In the case of small and medium-sized enterprises, the smaller the size, the stronger the governance structure of the managers (Lee Sang-Wook, 2009), and as a result, the more influential the managers are in making decisions, such as exercising full authority, so the will of the managers is most important than anything else to strengthen accounting transparency. Poor awareness of managers is a factor that hinders efficient operation in the process of growing companies, and it is necessary to provide education to managers on management improvement.

According to Lee Sang-Wook (2009), among the many reasons why the preparation of false financial statements by managers, despite being responsible for making financial statements transparent, is that punishment for accounting fraud has been too lenient and there has been a lack of control over managers' discretion. It was also argued that small and medium-sized enterprises are still accounting to benefit from the extension of loans by financial institutions, increase of interest on loans, and decrease of interest on borrowing, and that many small and medium-sized enterprises are still not separated from ownership and management, and that small businesses are more likely to commit accounting fraud if they are immoral, so managers should take the lead in enhancing transparency of corporate accounting through proper judgment.

In order to instill in managers a willingness that securing accounting transparency can be beneficial, not loss, to the company, incentives such as granting additional points when participating in government-funded projects and financing through the financial sector are needed. In addition, when exporting overseas, foreign countries consider corporate accounting transparency important, and it is believed that government-level support should be expanded to attract many overseas investments by emphasizing this part.

Lack of Personnel and Strengthening the Internal Management System

Small and medium-sized enterprises have a small number of accounting staff and are doing other tasks at the same time, so a support system for manpower reinforcement should be established. As such, smaller companies in the internal environment use corporate expenses for the purpose of individual needs, and efforts to enhance corporate transparency are needed. For example, the entity's own efforts should be made to break away from past practices through accounting education, such as withdrawing personal expenses spent on family events from corporate bank accounts, handling non-work-related overseas airfare, hotel expenses, and personal donations.

Other ways for corporate managers to enhance transparency are to have an internal accounting management system that sets the division of duties of accounting-related executives and employees. Compared to large companies, small and medium-sized companies have relatively insufficient manpower and resources and value the performance of their operations rather than internal management, so the possibility of accounting irregularities such as embezzlement of executives and employees still exists, and the size of the company is not large, which affects the existence of the company.

Therefore, if you look at the main checkpoints that the management of small and medium-sized enterprises will check for internal control in order to prevent accounting fraud on cash and deposits, the first thing is that the fund manager and the accounting manager must separate them and control them internally through the division of duties. Second, due diligence on cash and checking the balance of bank accounts are also required without prior notice. Third, unused accounts, such as dormant accounts, are easily omitted from internal management and can be used for cheating, so they are immediately terminated. Fourth, when making cash withdrawals, control the transfer of accounts after obtaining approval from the manager. Fifth, keep separate bankbook, corporate card, seal, securities, etc. Sixth, change the work so that it is not responsible for the same task for a long time. Finally, the company will use external audits as an opportunity to check its financial status.

The introduction of the internal accounting management and control system by unlisted or non-externalized small and medium-sized enterprises will also help increase tax revenues due to transparency in accounting and tax sources. Therefore, the government needs benefits such as subsidies or tax deductions for preferential treatment for those selected for tax audits and consulting expenses spent on establishing an internal accounting management system.

In addition, the development of a company is based on the basics of human resources and the company's system from a small scale.

Based on this, the company's size and internal pool of documents grow together. The size of the company grows because if the internal workforce or system is not supported, it will hinder its efficient operation in the future.

Improvement of Consignment Work Outside

The reality is that small and medium-sized entrepreneurs with no accounting knowledge or low interest lack a deep understanding of their financial statements as they are committed to management activities for survival. For this reason, there are many hidden roles in the job of the audit agent, such as presenting reference materials and reminding them when the accounting managers of the company are weak and lack of their accounting knowledge, and maintaining transparency in accounting by explaining and persuading business owners and executives who do not understand. However, it is no exaggeration to say that most small and medium-sized enterprises are entrusted with accounting books, which hold the key to accounting transparency, and that some tax accountants and accountants prepare financial statements to meet the client's needs rather than transparent ones due to intensifying competition in accounting transparency.

Kim Ki-Young (Professor at Myongji University, South Korea) is also an external auditor and a company's request to prepare financial statements on behalf of the company.

An environment for harsh advice should be created, and auditors in practice cannot point out proper problems such as the company's request for proxy preparation of financial statements, he added, "Because of the nature of the current free-standing system, the auditor cannot make bitter remarks to the company that is a customer," adding, "If these problems are fundamentally improved, the company's financial statement preparation capacity will naturally improve." (Jose Daily, 2017).

Heo Kwang-Bok (2012) says, "For example, a system that grants certain responsibilities to accounting experts who are entrusted with accounting work and prepares a system that allows them to expand their work by selecting agents for bad bookkeeping and selecting representatives for sincere books when they are found to be responsible for accounting. “

Improving Small and Medium-sized Enterprises' Capital Procurement

To address difficulties in financing small and medium-sized companies, credit guarantee agencies operate promissory note guarantees and promissory note insurance systems in line with the promissory note system. The

promissory note insurance system was introduced by the Korea Credit Guarantee Fund in 1997 and is a system in which small and medium-sized companies pay insurance money when bills are processed by signing up for a bill that they provide goods, etc., and such a system serves to prevent small and medium-sized companies from falling into bankruptcy due to the occurrence of a bill default.

The bill system had many problems (for example, not accurate transactions), but from April 6, 2014, not only existing companies subject to external audit but also corporate operators with assets of 1 billion won or more at the end of the previous business year were required to issue electronic bills only when issuing promissory notes, so paper bills were not allowed to be issued. As a result, the number of people who are required to issue electronic bills has increased compared to past paper bills.

However, if a company provides collateral or guarantees of debt for others by company assets or promissory notes, sometimes external audit inmates are required to record future contingent liabilities in their audit reports as annotations, but small and medium-sized companies that are not subject to external audits do not have any special sanctions, which may cause concerns over their accounting transparency.

On the other hand, when a company becomes underfunded due to a sudden bankruptcy, from the perspective of a business executive, the promissory note guarantees and trade receivable insurance schemes are not the solution. Due to problems with trade receivables insurance, the effect is limited to some entities, and the effect is limited to some entities, and insurance policies are screened for high-value notes that are difficult to cover due to concerns or anxiety over the occurrence of outstanding bills, but sometimes due to misjudgment, there is no default on insurance bills, and even when the bill is uninsured, there is no default on the draft insurance policy.

In addition, the current promissory note insurance system, in which the premium rate is calculated according to the credit rating of the promissory note issuer, is burdened with high insurance fees.

Refer to table 2 and since the amount of promissory note exchanges decreased by 43.6% in 2017 compared to 2011, the current promissory note system, which includes many problems, should be improved and activated, or the policy authorities should study the substitute bill in various ways to prevent fraudulent accounting to facilitate loans through temporary financial pressure, such as reducing the bill system and preparing guarantee products.

Kang Man-Soo and Bae Jin-Sung (2017) should first implement the abolition and reduction of the bill system as a way to improve financial practices for small and medium-sized enterprises, and although the bill has various net functions through the method of corporate financing, there are also adverse effects such as one-sided promissory note practices by large companies or delayed payment between consignment and business transactions.

It is necessary to contribute to the liquidity of small and medium enterprises by transferring technology to the private sector after the establishment of a specialized institution for liquidating small and medium enterprises' financial expansion system and success case. In the short term, it is necessary to maintain the current promissory note system, and to develop a bill substitution system such as the stipulation of the expiration of the bill and the improvement of interest payment arrangements, and to successfully lead it, it is deemed necessary to absorb the bill into the products related to the credit guarantee agency (Kang Man-Soo, 2017).

Table 2: Bill Default Rate and Number of Bankrupt Companies

Division	2011	2012	2013	2014	2015	2016	2017
Bill Exchange (Billion)	5,301,061	4,341,082	3,771,402	3,178,251	2,774,317	2,513,820	2,311,919
Bill Default (Billion)	5,688	5,169	5,238	6,023	4,636	2,66	3,431
Bill Default Rate (%)	0.1	0.1	0.1	0.2	0.2	0.1	0.2
Number of Bankrupt Companies	1,359	1,228	1,001	841	720	555	494

Source: Kang Man-Soo, 2017

41.2% of the respondents requested real estate security as a source of difficulty in financing through financial institutions. Therefore, financial and guarantee institutions will make fraudulent accounting to facilitate borrowing from financial institutions in order to improve property collateral or sales-oriented backward lending practices, so financial institutions will need to make efforts by financial authorities to evaluate related financial performance and introduce index for mutual growth in the financial sector as a means of improvement, and to resolve difficulties by providing temporary factors such as loan and discount of bills and loans are temporary factors.

In the United States, Lee Jae-Yeon (2014) considers the adequacy of the business's cash flows and the nature of its managers as the most important factors in reviewing loans to small and medium-sized enterprises. The same happens in Korea. First of all, a loan is made when the size of the cash flow is sufficient to repay the principal and interest of the loan and, given the nature of the management, the willingness to repay is strong. These financial institutions are also demanding as much collateral as possible, but not 100 percent of the principal amount of the loan, so it is not absolute in deciding whether to borrow, and the types of collateral vary from account receivables to inventory assets. In the future, domestic financial institutions also need to establish credit rating models for blue-chip small and medium-sized enterprises and individuals by first evaluating borrowers' ability to repay their debts and supplement their credit risk using collateral or guarantees, considering that collateral or guarantee-oriented lending practices may negatively affect not only themselves but also the borrower and the domestic economy. In addition, for small and medium-sized enterprises and the working class who lack public information such as financial statements, there will be difficulties in applying the credit rating model, so the ability to evaluate repayment ability through rigorous business feasibility assessment and the ability to evaluate repayment will have to be enhanced considering various qualitative information such as the nature of the borrower.

As such, it was argued that the review of loans taking into account business feasibility and follow-up management aimed at collecting loans through business success would prevent borrowers from borrowing recklessly and increase the likelihood of business success rather than raising the lending threshold of financial institutions, thereby providing an important competitive edge in protecting borrowers small and medium-sized enterprises and the working class and ensuring the soundness and profitability of financial institutions in the long term (Lee Jae-Yeon, 2014).

Conclusion

As of 2019, small and medium-sized enterprises account for 99.9 percent of the total 3 640 industrial businesses in Korea, and the number of workers in small and medium-sized enterprises accounts for 90.2 percent of the total number of workers, which not only accounts for a very high proportion of the national economy, but also has a very large job creation effect. As a result, the growth of small and medium-sized enterprises will soon raise the status of the nation and be directly linked to national income. In order to foster small and medium-sized enterprises as healthy enterprises like this, we need to work together to strengthen accounting transparency and grow into sound enterprises.

The lack of eradication of SMEs' failure to properly reflect information to report their management performance to outside agencies is largely attributable to the uncertainty in accounting, which has so far become a practice. For this reason, small and medium-sized enterprises of a certain size or smaller have fewer stakeholders in financial information and relatively lower accounting reports and disclosure obligations than large companies, resulting in insufficient voluntary efforts to enhance accounting and managerial transparency.

In addition, the lack of the accounting capacity of the small and medium enterprise itself prevents it from being accounted for by the entity itself and makes it difficult for the financial institution to question its reliability, which in turn leads to distrust in the financial statements and adversely affects the measurement of the entity's creditworthiness. We looked at ways to enhance the accounting transparency of small and medium-sized enterprises by improving the problems of the bill system, the alternative bill system and the lending practices of financial institutions.

As a way to strengthen accounting transparency in this regard, first of all, small and medium-sized enterprises have a strong governance structure due to their high share ownership, and due to this phenomenon, managers exercise full power in decision-making, so it is important to secure transparency will of managers. It is necessary to expand government-level support such as granting additional points to government-backed projects or granting benefits to small and medium-sized companies when they export overseas as incentives to do so.

Second, the managers of small and medium-sized enterprises are interested in self-esteem through employee education and focus on their tasks without parallel to other tasks, which leads to long-term work, which in turn leads to the growth of the company's professional workforce. Therefore, the burden of labor costs for small and medium-sized enterprises is reduced through policies for the promotion of employment support or employment promotion support, not short-term, and the introduction of the internal accounting management system requires the provision of benefits such as subsidies or tax deductions for consulting expenses spent on the establishment of the internal accounting management system.

Third, most small and medium-sized enterprises entrust the tax agency with reporting and acting for the ledger, sometimes failing to reject the company's unreasonable demands for the evasion of the law, and the opposite phenomenon may cause the captain's agent to encourage the evasion of the law. Thus, accountants and tax accountants hold an important key to accounting transparency, and some tax accountants and accountants need policy government measures in the reality of preparing financial statements in accordance with the client's needs rather than transparent ledgers as competition in the accounting work intensifies. For example, a system that grants certain responsibilities to accountants or tax accountants who are entrusted with accounting tasks on their behalf will ensure efforts by outside accounting experts to ensure transparency.

Fourth, if small and medium-sized enterprises receive voluntary external audits, they can be given tax exemption benefits as preferential measures, reduced external audit costs such as tax credits, or directly supported measures such as tax credits, and the government pays part of the audit costs in a price-subsidized manner similar to the project to support consulting for small and medium-sized enterprises, and, as another alternative, interlinked with the existing tax investigation system so that external audits can take charge of preliminary tax audits.

Fifth, in the past, businesses disappeared countless times. However, it is now more resistant to bankruptcy protection, and it is easier to track the source of funds or the whereabouts of money than in the past due to the computerization of financial institutions and companies. It is believable that this was effective due to the introduction of the real-name system. Authors agree that the nature of the bill is the same as the past or present, and that there are many difficulties in solving the problem of the bill. However, related agencies should take the lead in resolving the capital procurement problem of small and medium-sized enterprises by improving the problematic bill system or activating the bill stand system.

Sixth, it is not easy for small and medium-sized companies to secure funds due to complicated documents and demands for collateral from companies with weak collateral when applying for loans to financial institutions to raise capital. It is necessary to supplement credit risk by using collateral or guarantee after first assessing the borrower's repayment ability by establishing a credit rating model for blue-chip small and medium-sized enterprises and individuals by breaking away from mortgage or guarantee-oriented lending practices.

Some of the limitations of this study are as follows: First, the discussions of this study are limited to unlisted small and medium-sized enterprises subject to external audit and non-external audit, and it is too much to generalize for listed corporations exceeding this category. Second, in order to enhance the practical contribution of the results of this study, further analysis of the computational system will have to be made because it cannot be addressed in this study even though it has a very significant effect on accounting transparency research. This study was conducted on the basis of statistical data and open data resources developed in various disciplines, and we hope to continue multi-pronged and continuous research on unlisted small and medium enterprises in the enterprise in the future.

maria.cristea@upb.ro

Abstract

Entrepreneurs are an important part of the economy. They allow the development of goods and services. Lately, more and more people are trying to develop a personal business, giving up the job they had, or at the same time with the job that ensures a stable income.Entrepreneurship has also developed among women internationally. The position of women is becoming more and more important, the need for her involvement in public life and in the management of organizations being necessary and undisputed.The present study follows the evolution of the winning companies of a competition regarding the granted subsidies, companies that have as associate a woman. The study shows that very few of the 21 companies have managed to achieve performance in the 5 years since they received a small financing in the form of non-reimbursable funds.

Keywords: Female Entrepreneurs, Performance, Non-Reimbursable Funds

Introduction

The presence of entrepreneurs in the economy has the effect of creating and offering goods and services and creating jobs. The activity carried out involves various taxes and duties that represent revenues for the state. Being an entrepreneur is not easy. It is much easier to be employed.

Women's motivations to join business life ranged from opportunity to necessity, the first including the desire to turn a hobby into a business, to exploit a market opportunity, while the latter referred to the lack of market flexibility. work or inability to adequately fulfill both roles - of mothers and employees. For men, being an entrepreneur is a business strategy. For women, it's a life strategy (Noble, 1986).

Because of their many obligations and roles, many women give up their ideas and do not want to try to enter the business independently. In addition, there are many other factors that influence female entrepreneurship: the influence of national wealth, social status and perception, institutional factors, family life, economic and property inequality, age, employment status, education, and personal income.

In Romania at present the presence of women in the structure of associates represents approximately one third. Thus, women are associates / shareholders within legal entities, respectively carry out economic activity in the form of Authorized person (PFA) or as a member in an Individual enterprise (II) or Family business (IF). The distribution by gender of the associates / shareholders of active legal entities and of the holders / members of PFA / II / IF is shown below (Fig. 1). The companies registered in the Trade Register that have not declared their suspension of activity and are not in any of the states that can lead to the loss of legal personality are considered active, from a legal point of view.

Unilever conducted a study in 2018 on gender equality in startups. 61% of women in startups do not think there are enough female role models, crucial at the ideas stage before a startup is even founded. Funding was one of the most challenging barriers when starting up. Gender discrimination is the main factor causing investors to finance women-led start-ups. Women complain about marginalization during dating and inappropriate treatment when they question inequality between women and men.

A study done by TinyPulse in 2017 found that startups with female founders tended to grow faster, possibly because more diverse workforces are consistently found to lead to better results.

The present study follows the evolution of some companies founded by women in Romania who benefited from non-reimbursable funds through the Female Entrepreneur program, by winning the competition launched in 2015.

Literature Review

In recent decades, the number of companies created or driven by women throughout the world has experienced significant growth.

Brush (1992) has reviewed 57 articles presenting empirical research on women business owners. The discussion concluded that women business owners are similar to males across some basic demographic factors, problems, and business characteristics, but they differ widely from male business owners across individual dimensions related to education, work experience, skills, approach to venture creation/acquisition, business goals, problems, and performance. It is suggested that the major reason for these differences is that women conceive of their businesses differently than men which in turn leads to different approaches and outcomes for performance. When a woman starts or acquires a business, the set of business relationships are "integrated" into her life.

Vasile (2014) observes that over time women have demonstrated leadership skills based mainly on communication, encouraging expression and orientation towards people, which differentiates them from men who are more task-oriented, delegated and leadership companies with three or more women in top management positions performed better than companies without women in such positions in the case of 9 criteria of excellence: leadership, vision, responsibility, coordination and control, innovation, external orientation, capacity, motivation, work environment and values.

Ahmet et all (2019) analyzed the woman as an entrepreneur in Turkey and find that having an entrepreneur(s) in the immediate family was a powerful coping strategy. Entrepreneurship was almost perceived as a family legacy for some women. Women use this class anxiety to break away from patriarchal family roles, adopting various tactics in realizing their strategy.

Cuevas si Gutierrez (2008) have observed that the differences in the characteristics and qualities of women entrepreneurs compared with men affect the behavior adopted by the former. This has been related to the different perception of every gender on the obstacles and opportunities for the development of business activity, as well as their business motivations. Women face difficulties in accessing financial resources. They adopt a business management style that is based on cultural and social values different from those of men. While women generally prefer a “transformational leadership” style, oriented towards people, and based on interpersonal relationships, men develop a leadership style oriented towards task and structures, which is supported by hierarchical and commanding relationships. Businesswomen measure the success of the business by criteria other than the strictly economic ones that are related to the reasons that determined them to create a business.

Verheul, Van Sten and Thurik (2004) find that female and male entrepreneurship are largely influenced by the same factors in the same direction. A remarkable exception is life satisfaction for which they find a positive impact on female entrepreneurship and no impact on male entrepreneurship. Another striking result of their study is the positive effect of life satisfaction on the number of female entrepreneurs, which is contrary to what is argued in the ‘social legitimation’ perspective. Hence, life satisfaction may be an important policy issue for governments aiming to stimulate female entrepreneurship.

Pandey and all (2013) studied the women entrepreneurs from developed and developing countries and they concluded that women entrepreneurs all over the world practice conventional entrepreneurship. Women more often tend to choose business due to flexibility of time and financial security. In developed countries in particular women see business as an opportunity, not a means to fulfill the basic necessities of life. Women world over do not have easy access to top management position.

Through a study conducted in 7 countries, Ifempower (2018) identified the most common and typical challenges that women entrepreneurs face when setting up and running their companies:

- ✓ employee status did not offer sufficient career prospects
- ✓ the need to be bold enough to start a business
- ✓ loss of job
- ✓ the purpose of some female entrepreneurs is to provide a solution to a problem they have personally encountered, to fill a gap
- ✓ to make real changes in society instead of working for a larger organization,
- ✓ flexibility and improving work-life balance
- ✓ appreciating individual freedom and independence
- ✓ lack of capacity to reintegrate on the labor market after maternity leave.

Gogus and all (2015) analyzed the annual 'Turkey's Woman Entrepreneur Competition' and suggested that, contrary to its overt objective of empowering women entrepreneurs, the competition can be considered to subjugate women, and reaffirm and naturalize the dominant, masculine entrepreneurship discourse.

Ramadani (2015) believes that it is necessary to implement programmes that will directly aim to improve the financial environment and provide a variety of financial instruments and impetuses that will assist women in running their businesses, because investors and banks are often reluctant to finance start-up businesses run by women, since they involve a certain degree of risk. Lack of financial support is a major problem faced by women entrepreneurs. Management capabilities that women entrepreneurs in Albania possess are related to the abilities to achieve solid communication with individuals, to generate and realize ideas and formulate goals, plans and policies, followed by their successful implementation.

Bigioi and Bigioi (2017) analyzed the diversity of management in Romania and found that the companies selected respect partially the principle of diversity. The presence of women on boards is only 25% of all members. There are some companies with a board composed exclusively of men, but no one company has only women. Regardless of the origin of the share capital, women have the same low representation.

Research Methodology

Romanian women entrepreneurs in the small and medium enterprises sector had the opportunity to win through competition non-reimbursable funds for the financial support of the businesses in which they were shareholders / associates. We will analyze the companies that won the Women Manager competition, launched in 2015.

The conditions to participate in the competition were:

- the company must have at most 3 years from the registration in the Trade Register at the date of opening the online registration application;

- at least one of the partners must be a woman and hold at least 50% of the shares of the company in the case of applicant micro-enterprises, or

- the representative of the authorized natural person (PFA) / individual enterprise (II) that carries out economic activities, to be a woman.

19 applications were submitted. The budget allocated to this program was low. Each winner could benefit from a maximum of 50,000 lei, representing 90% of the value of the investment that the beneficiary company had to make, the remaining 10% of the investment had to be covered by the beneficiary.

21 companies were declared winners of the competition.

The list of winners is available on the fonduri-structurale.ro website, which mentions DIMMMAT as a source. In this list are mentioned 2 companies out of the 19, which had not yet signed the contract at the date of publication (DIMMAT is the Department for small and medium enterprises, business and tourism)

We considered financial information for 5 years, from 2015-2019. The data were collected from the website www.mfinante.ro, data that are included in the financial statements submitted by the company according to the legislative requirements.

Of the 21 companies, for one we did not find financial information for any year (most likely the company's financial statements were not submitted); for 1 company a declaration of inactivity was submitted, and another did not have financial data available for the last year. Thus, we subjected 19 entities to the analysis.

Each entity is denoted Si, where i € {1, 19}.

The research was conducted in the following stages:
- the data was selected
- the data was been grouped according to specific objectives
- the data was processed

- the results were centralized
- the results were analyzed and interpreted
- the conclusions were drawn.

The methods by which this analysis was performed, were: investigation, identification and interpretation.

Results of the study

We analyzed for companies the indicators: turnover, profit, ROA, ROE, degree of indebtedness.
The evolution of **the turnover** is represented in figure 3.

Fig. 3: Evolution of turnover

Source: Own processing of the data extracted from www.mfinante.ro

Regarding the turnover, it is observed that there are 3 companies that did not make any sales during the 5 years.

There are companies S10 and S17 that managed to obtain a significant profit compared to other entities. Moreover, they managed to achieve higher sales from year to year, S10 has a turnover in year 5 15 times higher than that obtained in the first year.

Considering **the profit** obtained, the 19 companies had the following evolution (Fig. 4):

Fig. 4: Evolution of profit

Source: Own processing of the data extracted from www.mfinante.ro

There are 3 companies that fail to make a profit in any of the 5 years.

Considering this indicator, the same company stands out, S10 which not only has the highest turnover and growing, but also manages to cover its total costs based on sales. This way you get the highest profits. S10 manages to make a profit from year to year, the last year records a profit 11 times higher than in the first year. S17, the company with a very high turnover, is in second place in terms of profit evolution. In the last 2 years analyzed, S17 has the highest profit, after S10, but in 2019 S10's profit is only 13% of S17's profit.

As activities, the company S10 carries out Other support services activities for enterprises and the company S17 carries out Wholesale of fruits and vegetables.

Return on equity (ROE) is a measure of financial performance calculated by dividing net income by shareholders' equity. ROE is considered a measure of how effectively management is using a company's assets to create profits.

ROE= Net income/ Shareholders'equity.

Most investment books recommend an ROE of at least 15%.

We calculated ROE for the last analyzed year, 2019, as the 5th year from the date of winning the competition (Fig 5).

Fig. 5: Value of ROE for the winners of the competition

Source: Own processing of the data extracted from www.mfinante.ro

9 out of 19 companies have a positive ROE, 5 of them have an ROE of over 15% (ie 26% of the companies surveyed). The S6 company stands out from the point of view of this financial performance, but it achieves this indicator due to the losses of the previous years, a situation that makes the net profit to be higher than the own capitals. The S10 company has an ROE of about 52%.

Return on assets (ROA) is an indicator of how profitable a company is relative to its total assets. ROA gives a manager, investor, or analyst an idea as to how efficient a company's management is at using its assets to generate earnings. The ROA figure gives investors an idea of how effective the company is in converting the money it invests into net income. The higher the ROA number, the better, because the company is earning more money on less investment.

ROA= Net income/ Total assets

Values for ROA are mentioned in figure 6

Fig. 6: Value of ROA for the winners of the competition

Source: Own processing of the data extracted from www.mfinante.ro

From the point of view of the ROA indicator, 11 companies have a positive ROA. The S3 company has the highest value in 2019. The S10 company ranks third with 35% ROA.

The total debt ratio divides the total liabilities with the total assets. It shows the proportion of the assets that are financed with debt (Fig 7).

Total debt ratio =Total liabilities/ Total assets.

It is generally considered that a degree of indebtedness of less than 60% is very good and reflects a long-term balance between internal and external sources of financing.

Fig. 7: Value of total debt ratio for the winners of the competition

Source: Own processing of the data extracted from www.mfinante.ro

The S5 company has a very high degree of indebtedness, due to extremely low value assets. The S10 company has a 31% degree of indebtedness. 7 companies have a degree of indebtedness below 60% and 5 companies have values over 100%.

We defined the **function P(i),** P(i)= pi1+pi2+pi3+pi4+pi5, i={1;19}

pi1=1 if the turnover increases in 2019 comparated to 2018

pi2=1 if the the company i makes a profit in 2019

pi3=1 if ROA in 2019 >20%

pi4=1 if ROE in 2019 >15%

pi5=1 if total ratio debt is <60% and >0

The values of this function for each companies are shown in figure 8.

Fig. 8: Value of function P for the winners of the competition

Source: Own processing of the data extracted from www.mfinante.ro

The average value of the function P is 1.63. Each score was obtained as follows (table 1):

Table 1: Score obtained for function P

Score	Number of companies
0	6
1	3
2	5
3	3
4	1
5	1

The S10 company is the only one that gets the maximum score. 31.57% of companies do not meet any criteria, so they get 0 points. 42% of companies meet one or two criteria.

Conclusions

Being an entrepreneur is not easy. In a male-dominated environment, being a woman entrepreneur is even harder. It would be much better if they were encouraged by the entrepreneurial environment. Some start this experience out of necessity, others out of passion. What is certain is that some even manage to develop a profitable business. Women work in the interest of people, based on interpersonal relationships.

Their access to finance is difficult because they are women.

In Romania, the woman is an associate / shareholder / member or holder for approximately one third of the active legal companies, respectively other forms of organizing the economic activity.

One of the possible sources of financing is the non-reimbursable funds, as were those granted in Romania through the Women Manager competition in 2015, which took place in the following years under the name of Women Entrepreneur.

It is true that the amount financed is modest, but helpful for carrying out the activity.

Of the 19 companies that won the competition to finance their business, very few managed to achieve performance.

There are 3 companies that did not make any sales during the 5 years.

Only 5 companies have a financial performance measured by ROE above the minimum value. Another 5 companies have a very high degree of indebtedness.

Among the analyzed companies there is a company that managed to obtain profit every year, to increase the annual profit, to have financial performance measured by ROE and ROA, and a normal degree of indebtedness.

The financing obtained can be useful for a company to support its activity or to develop its activity. The same amount received by 19 companies generated different results. It all depends on the management and the target that each company pursues.

Acknowledgments

The article is funded by the Politehnica University of Bucharest, through the project "Engineer in Europe" online, registered at MEC under number 457 / GP / 06.08.2020, by using the fund to finance special situations that cannot be integrated in the form of financing state higher education institutions

Abstract

Hearing loss problems caused by noise are one of the 10 most common occupational diseases encountered in the European Union, and in Romania it is in the top 5. Hypoacusis (hearing loss) or deafness caused by damaging noise is one of the diseases which are identified on the European list of occupational diseases. As well as the hearing loss for those workers already affected, general noise presents additional accident risks at the workplace, as a result of communication difficulties arising from the activity itself. Also, in addition to hearing loss problems, noise causes psychosocial problems, such as stress and anxiety. Each employer is responsible for the safety and health at work within his company and for taking appropriate measures to ensure safe and healthy working conditions. In this case, the main purpose is to eliminate the risk of occurrence of occupational deafness due to exposure to noise and to maintain the productivity of the company. Safety and health at work must be an integral part of a managerial approach and this logic because it is productivity, quality and safety at work are intrinsically linked issues. The case study in this paper presents the noise risk assessment procedure, identifies workplaces where there are noise problems, workers exposed to noise and noise reduction methods where exceedances of the maximum permissible values are found.

Keywords: noise management, risk assessment, reduction methods.

Introduction

Safety and health at work are some of the biggest issues and it is completely the responsibility of the company's management to ensure that their employees are working in safe environment or not.
Some activities in the tire manufacturing can produce high levels of noise. Exposure to high levels of noise for extended periods of time can cause permanent hearing loss for employees.
Despite the fact that it is a well-known danger, noise is still a risk for workers. According to the study "Occupational morbidity in Romania in 2019" of the National Institute for Public Health, occupational deafness ranks 3rd.

The risk is not so obvious as deafness generally develops slowly and even the workers who are most at risk are reluctant to change their habits. That's the reason why it is important to reiterate the dangers of noise exposure in the workplace to managers as well as workers affected as recommended by the non-binding guide to good practice for the application of Directive 2003/10/EC.

Reducing cases of hearing loss due to noise is an essential objective for company management. Employers have a legal obligation to protect the safety and health of workers against all workplace noise risks, according to the Government Decision no. 493/2006, a decision that took over the provisions of Directive 2003/10/EC.

Noise risk assessment procedure in the tyre manufacturing

Figure 1 presents the diagram showing noise assessment procedure steps applied in a Romanian tire manufacturing as recommended by the non-binding guide to good practice for the application of Directive 2003/10/EC

Fig. 1 Noise assessment procedure steps

Performing a noise risk assessment is essential because it is the most important part of a workplace hearing and noise control program.
Article 8 of GD no. 493/2006 requires the employer to assess and, if necessary, to measure the noise levels to which the workers are exposed.

Risk assessment is fundamental for the protection of workers from risks to their health and safety arising or likely to arise from exposure to noise risk. Risk assessment shall identify workers exposed to risk from noise and determine their level of noise exposure. Risk assessment is not an end in itself; its purpose is to identify actions required when exposure action values are reached or exceeded.

Measurements and calculation of daily noise exposure in the tire manufacturing

Noise measurements were performed according to the SR EN ISO 9612:2009 Acoustics. Determination of occupational noise exposure. Engineering method.
The selection of an appropriate measurement strategy is influenced by several factors such as the purpose of the measurements, complexity of the work situation, number of workers involved, effective duration of the working day, time available for measurement and analysis.

In this case, the measurement job-based strategy was chosen from SR EN ISO 9612:2009. The principle of this noise measurement strategy is to measure random noise samples, and for better sampling, HENGs were used (HENG = homogeneous exposure noise groups) HENGs are groups of workers, composed of 1 or more workers, who have the same tasks and expected to have similar noise levels during work shifts.

The determination of the daily noise exposure levels for workers belonging to a specific HENG has to be made by means of the following next steps:

- *Evaluation of the A-weighted equivalent continuous sound pressure:*

$$L_{p,\mathrm{A,eq}T_e} = 10\lg\left(\frac{1}{N}\sum_{n=1}^{N}10^{0,1\times L_{p,\mathrm{A,eq}T,n}}\right)\ \mathrm{dB} \qquad (1)$$

where:
$L_{p,\mathrm{A,eq}T,n}$ is the A-weighted equivalent continuous sound pressure of the sample n;
n is the job sample number;
N is the total number of job samples.

- *Calculation of the A-weighted noise exposure level* of the workers belonging to a specific HENG is given by the following equation:

$$L_{\mathrm{EX,8h}} = L_{p,\mathrm{A,eq}T_e} + 10\lg\left(\frac{T_\mathrm{e}}{T_0}\right)\ \mathrm{dB} \qquad (2)$$

where:
$L_{p,\mathrm{A,eq}T_\mathrm{e}}$ is the *A-weighted equivalent continuous sound pressure* for the effective duration of the working day;
T_e is the effective duration of the working day;
T_0 is the reference duration of the working day, T_0 = 8 h.

The measurements for determining the noise exposure for tire manufacturing workers are made using the following types of equipment: dosimeters Brüel & Kjaer type 4442 and 4448; sound level meter Brüel & Kjaer type 2250. The dosimeters can be used for measurements in all types of work situations. This is the preferred method when making long-term measurements for a mobile worker, engaged in complex or unpredictable tasks or performing a large number of discrete tasks. Before each series of measurement a field calibration must be performed. In this case, the equipment used was calibrated with the Bruel & Kjaer acoustic calibrator type 4231.

The INCDPM guide to occupational safety and health regarding workers exposure to noise (2013) recommends that noise exposure assessment (measurement, determination, analysis, interpretation and reporting of results) should be performed by laboratories with competences in the field of prevention and control noise at work.

Results and discussions

Table 1 shows the results obtained for HENGs subject to evaluation whose values exceed the 80 dB (A) limit.

Table 1: Results obtained for HENGs in tire manufacturing

Homogenous exposure noise groups (HENGs)	Workers number from HENG	Daily noise exposure value calculated for HENG, $L_{EX,8h}$ dB(A)	Max. value measured, Lpeak dB(C)

These are the results of the research "Study of occupational noise and vibration exposure in tire manufacturing of Pirelli" that we made in 2017. More than half of the workers in all the production workplaces of the tire manufacturing were evaluated during the research.

According to the Government Decision no. 493/2006 on the minimum safety and health requirements regarding the exposure of workers to the risks generated by noise, the exposure limit values and the exposure values from which the employer's action on safety and health protection of workers in relation to daily noise exposure levels and the peak sound pressures are fixed as follows:

(a) exposure limit values: $L_{EX,8h}$ = 87 dB(A) and ρ_{peak} = 200 Pa* respectively;
(b) upper exposure action values: $L_{EX,8h}$ = 85 dB(A) and ρ_{peak} = 140 Pa** respectively;
(c) lower exposure action values: $L_{EX,8h}$ = 80 dB(A) and ρ_{peak} = 112 Pa***respectively.
*140 dB (C) in relation to 20 μPa.
**137 dB (C) in relation to 20 μPa.
***135 dB (C) in relation to 20 μPa.
p_{Cpeak} C = weighted peak sound pressure (Pa)
$L_{p,Cpeak}$C = weighted peak sound pressure level (dB)

If the exposure level is between $L_{EX,8h}$ = 80 and 85 dB(A) and ρ_{peak} = 112 and 140 Pa, the employer shall ensure that:

- workers who are exposed to noise at work receive information and training relating to risks resulting from exposure to noise;
- individual hearing protectors shall be made available to workers;
- a preventive audiometric test is offered to those workers identified as being at risk.

If the upper exposure action values is exceeded $L_{EX,8h} \geq$ 85 dB(A) and $\rho_{peak} \geq$ 140 Pa, the employer must to:

- establish and implement a programme of technical and/or organizational measures intended to reduce exposure to noise;
- mark, with appropriate signs, workplaces where workers are likely to be exposed to noise exceeding the upper exposure action values;
- provide for workers' entitlement to receive hearing checks by doctors or by another suitably qualified person under the responsibility of a doctor, in accordance with national law and/ or practice
-

The workers shall use individual hearing protectors, where noise exposure matches or exceeds the upper exposure action values.

Under no circumstances shall the exposure of the worker exceed the exposure limit values of 87 dB(A). If exposures above the exposure limit values are detected, the employer shall to:

- take immediate action to reduce the exposure to below the exposure limit values;
- identify the reasons why overexposure has occurred;
- amend the protection and prevention measures in order to avoid any recurrence.

Technical And Organisational Measures To Reduce The Noise Exposure

On the basis of the risk assessment, if the upper exposure action values are exceeded, the employer shall establish and implement a programme of technical and/or organizational measures intended to reduce the exposure to noise.

Article 17 of GD no. 493/2006 and article 5 paragraph 1 of Directive 2003/10/EC requires that the risks arising from exposure to noise shall be eliminated at their source or reduced to a minimum, taking into account technical progress and the measures available to control the risk at source.

The legislation in force (GD no. 493/2006 and Directive 2003/10/EC) suggests some examples of noise reduction in general.

In the paper "Managing noise exposure and prevention of the hearing loss risk in tyre manufacturing" by Platon, Badea and Ciocan (2017) are presented technical and organizational measures to reduce noise that can be applied in the tire manufacturing in particular.

Noise reduction by technical means:

- reducing airborne noise, e.g. by shields, enclosures, sound-absorbent coverings; (Sound-absorbend shielding of the grinder and tires uniformity equipment, vacuum pumps from vulcanization area, bambury engine; acoustic enclosures around PTSM; placing the acoustic barriers between the bambury working areas);
- reducing structure-borne noise, e.g. by damping or isolation; (vibration insulation of equipment is ensured by flexible mountings; mounting the noise dampers on the level of fan suction located in the roof ceiling).

Organisational measures of noise control:

- selection of low-noise equipment (use of silent tools: compressed air blowers, screw drivers, etc. and silent machines: compressors, motors, fans, etc.);
- noise can be reduced by "limitation of the duration and intensity of the exposure to noise"(Taking into account a 50 % reduction in working time only leads to a reduction of 3 dB(A));
- also, noise can be reduced by "appropriate work schedules with adequate rest periods";
- appropriate maintenance programmes for work equipments;
- workplaces where workers are likely to be exposed to noise exceeding the upper exposure action values shall be marked with appropriate signs;
- adequate information and training to instruct workers to use work equipment correctly in order to reduce their exposure to noise to a minimum.

Conclusions

Managing the occupational safety in the tire manufacturing in general and noise in particular is very important for the employer. It helps company management to achieve and maintain safe and healthy working conditions and to provide employee safety workplaces, focuses on the main noise induced hazards and indicates what needs to be done to ensure the risks of excessive noise exposure are properly controlled.

IT Security Management in Education Sector - Process Approach

Adam KOSTULAK

Institute of Informatics, University of Gdansk, Gdansk, Poland
adam.kostulak@ug.edu.pl

Abstract

The article presents a new way of managing the security of an organization's information systems. Presented Reference Model of Security Processes (RMSP) is pointed to the possibility of its use in educational organizations, as a tool for standardization based on the standards ISO 2700x family.

Keywords: IT security, Business process modeling, Process reference model, ISO 27001, Deming Cycle

Introduction

Information systems security has been a challenge in the field of scientific research for many years. There are few publications in the field of process management of the security of information systems of universities. In turn, ISO certification of university information systems is an innovative topic.

The close connection of this issue with technology means that the approach that takes into account the aspects of systems management to a very narrow extent is often dominant here. The problem of adapting security methods to the properties of the enterprise information system is so complex that it requires advanced management methods. It seems advisable to try to apply the process approach, which is currently more and more often chosen as a management method. Taking into account the direction of changes in the development of the organization, the choice of such an approach seems to be optimal, if only due to the specificity of information systems security processes in companies.

Currently, one of the key properties of information systems is data security. The intensity of intrusions to obtain information for its further use as part of economic espionage as well as simple data destruction has become a serious problem. Losses resulting from the loss of privacy of information are very painful to enterprises and often become the cause of their bankruptcy. Therefore, there is a need to create effective methods of data security management, which will take into account both the dynamics of technological progress and the development of the organization itself.

The dangers to which information is exposed essentially come down to three types of activity. It is sniffing, spoofing, and blocking access to information. These three threats occur at every level of the communication model and constitute a universal approach to building security methods. The technological model comes down to ISO / OSI standardization and concerns the hardware aspects of the IT system network solutions. It is possible to extend this model with application layers, appropriate for individual areas of information management in the company, which, taking into account the organizational structure and dependencies between individual organizational units, would give a complete model for the analysis of information processes.

Educational institutions have been developing dynamically in recent years. This entails the necessity to change the organizational structures and, consequently, to modify the approach to information systems management. The security of these organizations - mostly non-profit (public schools) - is becoming one of the most important challenges for university managers. Information security management in these organizations is a multidimensional problem and is an interesting area for scientific research. The choice of universities as a research object is also dictated by the unique properties of the structure and functioning of these organizations, unlike commercial enterprises. Moreover, nowadays public universities - whose purpose is not to generate added value - adapt quickly to the rules of the free market and require, like companies, commercially effective management methods.

Cite this Article as: Adam KOSTULAK“ IT Security Management in Education Sector - Process Approach” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Information Systems Security Management Models

There are many models for managing the security of information systems. They describe the following areas:

- dependencies between safety elements,
- dependencies in risk management,
- process safety management information systems.

The article focuses on typical normative solutions consisting in the implementation of the principle of continuous improvement, i.e. the implementation of the Deming cycle , i.e. PDCA (Plan-Do-Check-Act), which corresponds to the actual course of normative activities in the recent period, contained in ISO 9001:2000, ISO / IEC 27002:2012 and ISO / IEC 27001 standards.

The ISO / IEC 27001 standard uses the "Plan - Do - Check - Act" (PDCA) model which is applied to the entire process structure (ISMS[1]). The PDCA model takes information security requirements and stakeholder expectations as an input, and through the necessary activities and processes, provides information security outputs that meet these requirements and expectations (Table 1). An example of a requirement may be such information management that breaching its security will not lead to financial losses in the organization. On the other hand, expectation is, for example, properly trained employees who, in the event of a crisis situation, will limit its negative impact on the institution.

The proper establishment and management of an ISMS requires a cyclical approach to ensure that the procedures adopted in a given organization are documented, implemented and, if necessary, improved.

The adoption of the PDCA model also reflects the principles set out in the OECD Recommendations on which the security of information systems and networks is based. This standard provides a complete model for the implementation of the principles outlined in the recommendations on which risk assessment, safety design, safety implementation, safety management and reassessment are based. The requirements described in this standard are general and intended to be used in all organizations, regardless of the type, size and nature of the business.

Table 1: Processes of the PDCA model

Plan (establishment of the ISMS)	Establish an ISMS policy, objectives, processes and procedures relevant to risk management and information security enhancement to obtain outcomes consistent with the organisation's overall policies and objectives
Do (ISMS implementation and operation)	Implementation and operation of ISMS policies, security, processes and procedures
Check (ISMS monitoring and review)	Estimate and measure process performance in relation to ISMS policy, objectives and practical experience, and deliver the report to management for review.
Act (maintenance and improvement of ISMS)	Take corrective and preventive actions based on the results of internal ISMS audit and management review or other relevant information to ensure continuous improvement of the ISMS

Reference models in business terms are primarily used to create the foundations on which the methodology is based and the model of the modeled complexity of the reality of a given company. They represent organizational knowledge, modeling standard and define in the form of models all organizational structures of the examined economic entity. The reference model is actually an abstract structure that facilitates the creation of a solution by focusing the developer on the relevant relationships and aspects in a given organizational structure.

Minor relationships are either separated for later modification or even partially organized through such a pattern. Such a solution contains the smallest set of uniform concepts, ideas and is independent of specific technologies, standards or other implementations. The primary goal of developing a reference architecture model for the main IS security processes is to conceptualize security management in the form of related processes with a high degree of aggregation. The choice of the aggregation level is a key stage in the modeling which balances the overall simplicity and ease of

[1] ISMS – Information Security Management System

navigation within the model and the ability to reflect the major relationships between processes. The low number of top-level processes of the model allows you to easily and quickly understand the main elements of safety management.

Reference Model of Security Processes

The Reference Model of Security Processes (RMSP) described in the article is designed to assist management in the development and implementation of an effective information systems security management system. Based on an interview with the management staff of the studied universities, the functionality and impact of using the model to implement the process method of information systems management were assessed.

The model includes 6 groups of processes composed of multi-threaded processes.

Process Group A - Ensuring physical and environmental security

Process Group B - Systems and networks management

Process Group C - Information access control

Process Group D - Information systems development and maintenance

Process Group E - Information security incident management

Process Group F - Business Continuity Management

Fig. 1: Information systems security management processes

The implementation of six groups of processes takes place in a cycle (Fig. 1). This approach enables the handling of process input streams in a comprehensive manner and can guarantee the safety quality of the output streams. The process cycle schedule should be adapted to the functional properties of the facility (organization) and constitute an element of the university's information security strategy. It must be determined in accordance with the Deming cycle mechanism (Fig. 2), so that the individual stages of planning, implementing, checking and correcting the safety rules supported by the relevant processes can meet the requirements of ISO / OSI 27001.

Fig. 2: Deming Cycle - PDCA model used in the processes of information security management system ISMS according to ISO / IEC 27001

Process Group A - *Ensuring physical and environmental security.* These are processes related to the need to provide the organization with appropriate protection against unauthorized physical access and any external damage and disruptions. We distinguish between two processes and 7 activities.

Process Group B - *Systems and networks management.* These are processes that allow you to control activities related to the maintenance, operation and development of information processing infrastructure. There are 10 processes and 31 activities.

Process Group C - *Information access control* . It is a group of processes that determine the system users' rights to use information resources. We distinguish 6 processes and 25 activities.

Process Group D - *Acquisition, development and maintenance of the IT system.* It is a group of processes that define the principles of maintaining efficiency as well as extending and modernizing the system. It consists of 6 processes and 16 activities.

Process Group E - *Information security incident management.* These are processes responsible for the control and management of incidents related to threats to the security of the IT system. It consists of 2 Level 1 processes and 5 Level 2 activities.

Process Group F - *Business Continuity Management* - these are processes that implement mechanisms related to ensuring failure-free and efficient operation of the system. It consists of 1 process and 5 activities.

Conclusions

The primary activity that can direct information systems security management towards process management must be the identification and organization of security processes. Using the model of processes presented in the article, it will be possible to quickly classify security processes and prepare the organization for the implementation of ISMS. However, the implementation of the ISMS itself is not the main and obligatory purpose of the RMSP application**.** This goal is to achieve process management of the organization's information systems security area. While the ISMS is based on the process concept of the PDCA model, this is only a half-measure and can at best be a step on the way to mature process management. It should be noted that the implementation of ISMS may facilitate the path to process management, but is not a necessary step to achieve it.

The changes to be expected after the implementation of the RMSP will have several stages. The first is primarily a modification of the way of thinking about the security of information systems in the organization. Only obtaining appropriate awareness of the management staff may enable further changes towards process management. The next step will depend on the choice of an action strategy to transform the existing management into process management.

The implementation of the process management of the information systems security area of a university using the RMSP model can also take place without the need to change the structure of the entire organization into a process one. As in the case of an ISMS implementation, it can be a preparatory stage for a later transition towards a process organization.

COVID19 and Management
Impact of Covid-19 on Education Management in Lebanon

Chirine Khalil NASSAR

Ph.D. Candidate, Faculty of Business Administration, The Bucharest University of Economic Studies, Bucharest, Romania, nassar.chirine@gmail.com

Abstract

By the advent of Covid-19, education management have raised eyebrows as schools and universities were the first one to shift on computer aided learning (CAT) technologies with the vision that learning must never stop. ICT based learning methods have been widely applicable to this date. The study has been conducted to investigate the level of technologies used by instructors, assessment criteria for teachers in distance learning environment, challenges faced by instructors in integration of teaching technology and lastly challenges faced by students in distance learning programs in Lebanon. In order to investigate these specific objectives a study has been conducted where primary data has been gathered using questionnaire distributed electronically amongst the sample of n=90 students and n=90 teachers using random sampling methods with adequate ethical consent. Data gathered from questionnaires has been analyzed using descriptive statistics and frequency distribution using Ms Excel. Findings of the study suggests that students in Lebanon are facing numerous issues during their transition from conventional learning to e-learning includes accessibility to Internet, Computer, Learning Resources (e.g. Books and Curriculum), Electricity (e.g. Load shedding), Seating Arrangements at Home (e.g. chair, desk, table) and noise distraction at home (e.g. dog barking, child crying). Furthermore, findings suggests that challenges faced by teachers includes communicating with school management, electricity disruption, noise disruption challenge, children's participation in online classes , confusing when accessing student performance, difficulties using, ICT based technology, frequent communication with parents, attention distraction and lack of personalized attention. Findings of this study poses significant implications for ministry and school authorities to overcome these issues.

Keywords: Covid19, Corona, E-learning, Management, Education, Impact, Technology, Lebanon.

Introduction

The outspread of COVID-19 has also created panic, depression, and different anxiety among people across the globe (NCIRD 2020). The increase of COVID-19 has sent repercussions across the world. The public health calamities, unparalleled in our lifespans, has produced acute human suffering and deaths. The drastic increase in diseased victims and the substantial outcomes of critical patients of the infection have stunned hospitals and physicians and put remarkable stress on the health division. As governments handled with the increase of the infection by shutting down entire economic divisions and formidable extensive limitations on mobility, the healthy calamity developed into a major financial disaster which is predictable to burden civilizations for future time (Duraku & Hoxham, 2020). In response to this crisis there are numerous preventive measures taken by the countries around the world to contain the spread of COVID-19. Especially, to save future generation schools, colleges and universities have been closed which have affected more than 575 million students in 188 countries who have been directly affected by the closure of schools and universities. (UNESCO, 2020).

For specific categories of people entangled in education system is a disaster as they are unable to peruse their education in a traditional system of classroom environment. In addition to the situations caused by self-isolation at homes and other individual aspects have made parents' worried about their children future and distinctive educational requirements (UNESCO 2020). However, revival of schools and universities through opening of education institutes brings undisputable welfares to students and the broader economy but nevertheless, should be wisely evaluated against the health hazards and the requisite to alleviate the peal of the epidemic. (Schleicher, 2020).

The lockdowns in reaction to COVID-19 have interrupted standard schooling with countrywide school shutdowns in most of the MENA region countries as majority of countries. While the educational community have made coordinated efforts to keep up learning progression during this phase, children and students have had to depend more on their own means to carry on with learning privately through the Internet, television or radio. Teachers also had to adjust to new educational ideas and methods of provision of teaching, for which they may not have been educated. Specifically, learners in the most demoted groups, who don't have access to digital knowledge means or nonexistence

of the elasticity and commitment to seek knowledge on their own, are at danger of tumbling backwards (Schleicher, 2020).

Due to quarantine, the utilization of mechanization in the form of online learning has been considered the most relevant substitute to remain educational process as it is being practiced in many areas of the globe during this time. Despite the challenges in execution of online education the current need of pandemic have successfully transformed into distant or online education with drastic development in the discipline of computerized education, which, in other situations, would take a very long time (Lurvnik 2020). Evidence from Yokozeki (2020) suggests that transfer to distant learning style has also been evaluated as a better option for teachers and students to become more powerful, more productive, and improved during the time of self-isolation. On contrary, the current pandemic have raised numerous concerns amongst teachers involved in teaching procedures have been reported low-level utilization of classroom mechanization earlier to the existing situations (UNESCO, 2020). Additionally, desires for moving teaching to online style have also been announced to raise the amount of tension and depression amongst teachers in many parts of the world (Duraku & Hoxham, 2020). The COVID-19 disease has also had an acute effect on higher education as universities shut down their locations and states shut their boundaries in reaction to lockdown precautions. Though colleges and universities were quick to replace face-to-face lectures with online learning, these closures affected learning and examinations as well as the safety and legal status of international students in their entertaining state. Possibly most significantly, the calamity advances questions about the price recommended by a university education that includes interacting and social prospects along with educational content.

Relevancy of Study to Lebanon

World Health Organization (WHO) on 30th January 2020 declared the Covid-19 outbreak a public health emergency which subsequently effected delivery of education systems worldwide. In Lebanon, government on 2nd March 2020 declared a state of emergency by issuance of order of closure of education system within the country to contain the spread of virus. Both formal and non-formal education sectors were ordered to close to ensure the health and safety of future generation which effecting more than 1.2 million children's enrolled in formal, non-formal and UNRWA schools. The closure of educational institutes witnessed no trend of coming to normal, as a result Ministry of Higher Education Lebanon, launched a distance learning program for schools by giving three point agenda. First part of the agenda was promoting (a) Use of Electronic Media where national television and other private media outlets were utilized to generate awareness and provide psychosocial support for learners, parents and caretakers. Second agenda was (b) Use of internet based online platforms where technologies like Microsoft Teams was integrated with public school system. On contrary some private schools are using their own platforms. In addition, schools in Lebanon were asked to use online platforms like WhatsApp and Telegram which provided access of learning material to student. Thirdly, (c) Non-ICT methods were utilized which focusing mainly on paper-based materials. (IAC, 2020) On contrary, IAC, (2020) states that MEHE also issued instructions for teachers and academic communication on guidelines for disseminating lessons and following up with students.

Despite courageous efforts made by MOHE, in response the pandemic, the concept of distant learning is still evolving in Lebanon as the major challenges faced by distance learning includes closure of electricity across Lebanon, readiness of teachers and students to adapt to new ways of remote learning. Thirdly, restriction in movement possess pressure on students to get access to learning resources including stationary and learning utensils.

Significance of the Study

Findings of the study poses significant implications for Lebanon which is currently facing many social issues erupting from civil war, low public expenditure on education and influx of refugees. Despite all these challenges education have emerged as a major national priority for the country. Understanding of the learning management in event of pandemic will assist government in particular ministry of higher education in implementation of RACE II plan which emphasizes on inclusive education as part of their commitment towards sustainable development goals. Despite commendable efforts from MEHE by providing three-point agenda to continue education during pandemic

Research Question

- What is the level of technologies used by instructors in Lebanon?
- What are the assessment criteria for teachers in distance learning environment in Lebanon?
- What are the challenges faced by instructors in integration of teaching technology in Lebanon?
- What are the challenges faced by students in distance learning programs in Lebanon?

Methodology

The research philosophy starts with the belief which provides guidelines for the collection of data prerequisite for sourcing ideas and thoughts for the development of reliable knowledge. Research philosophy refers to the belief which provides insight on how data shall be collected, analyzed and used to achieve research outcomes. Within the scope of current research, research philosophy can be categorized into four different types which includes (a) pragmatism, (b) positivism, (c) realism and (d) interpretivism. The researcher intends to make a choice between positivism and interpretivism which are traditionally represented using quantitative and qualitative research methods. The study uses positivism research philosophy where high structured data will be gathered from participants which incorporates large sample respondents. The study uses quantitative research design which aims to explore the respondent's perspective of challenges being faced by the distance education system which is essential from education management perspective. (Saunders et al., 2009)

Backed by the positivist research philosophy, the research design provides blueprint for the collection, measurement and analysis of data. The study intends to use descriptive research design which is based upon the statistical research which describes phenomenon as it exists. (Akhtar, 2016) The descriptive research design aims to measure who, when and how the phenomenon occurs by investigating the challenges faced by distance learning and education industry as a whole. The study aims to investigate the perspective of both teacher, academics and learners where primary data has been gathered from learners engaged in distance learning and teachers involved in curriculum management and curriculum delivery using internet based technologies. It is noteworthy to examine the phenomenon in detail by describing the concerns of relevant stakeholders which includes teachers and learners who are engaged in remote and online learning caused by social isolation.

Primary data will be gathered using questionnaires as author intends to distribute two separate questionnaires, where one for teachers which aims to cover key areas like (a) level of technology used by instructors in Lebanon in post covid-19 times, (b) method of online learning, (c) assessment of student performance in remote learning and (d) challenges faced by teachers in implementation of remote learning. Similarly, another set of questionnaires will be distributed amongst students to investigate the (a) possession of adequate technological equipment and (b) challenges faced by learners. (Al-Jammal & Ghamrawi, 2013) Questionnaire will be used as an instrument where questionnaire items for each category of respondents will be developed using a close ended instrument using Thurston scale. Questionnaire items on challenges faced by students have been adapted from the previous studies of Senthilkumar & Kumari, (2020). Lastly, questionnaire items on challenges faced by the teachers have been adapted from the previous studies of Duraku & Hoxha, (2020).

The scope of the study revolves around the school students who were the first who implemented distant learning programs in Lebanon as per MEHE guidelines. Population comprises of school students which according to CERD, (2020) have number of 942 thousand students who are currently enrolled in private schools, public schools and private free schools. There are 497,530 students registered in public schools in Lebanon and there are 285339 students who are currently enrolled in private schools in Lebanon. Remaining 159462 students are enrolled in private free schools. The total sample size of n=90 students will be targeted by the author using cluster based sampling method where equal amount of respondents will be targeted from the cluster of public, private and private free schools across Lebanon. The scope of the study requires author to incorporate the opinion of teachers. According to World Bank, (2020) there are more than 80 thousand people who are associated with teaching profession in Lebanon. The study aims to target n=90 teachers working in public, private and private free schools across Lebanon using cluster based sampling technique.

Data collected from questionnaires will be analyzed using descriptive statistics and frequency distribution where pie charts will be used based upon the distribution of responses across frequency providing rationale for the analysis and discussion.

Findings

Demographics of Students

Students from different parts of Lebanon which Halba, Baalbek, Beirut, Zahlé, Baabda, Nabatieh, Tripoli and Sidon were targeted in the survey. Out of total sample of 90 respondents, 41.1% (37) respondents were male whereas remaining 58.9% (53) respondents were female as showed in graph below.

Figure 1: Gender of Respondents

Students from different family background were targeted in the survey, 48.9% (44) respondents reported having 1 to 3 family members, 34.4% (31) respondents reported having 4- family members and remaining 16.7% (15) respondents reported having more than 6 family members as showed in figure below.

Figure 2: No of Family Members

Respondents from different categories of schools were targeted in the survey by the author. 33.3% (30) participants belonged from the public school system in Lebanon, 33% (30) of respondents belonged from the private school system in Lebanon and remaining 33.3% (30) respondents belonged from the private free school system in Lebanon as showed in figure below.

Figure 3: Category of School

Students enrolled in different public, private and free private schools were asked whether they enjoy distance learning programs being started by the institutes. 68.2% (62) respondents reported that they enjoy learning from home, 8.9% (8) respondents reported that they don't enjoy learning from home. Lastly, 22% (20) respondents reported that they are not sure whether they enjoy learning from home using distance learning technologies during period of lockdown and restrictive movement.

Figure 4: Enjoy Learning at Home

Respondents of the study were enquired about the technology being used by the school for online education. Majority of the respondents which includes 61.1% (55) of respondents reported that they use Google Classroom for attending their daily classes during the lock down period in Lebanon, 21.1% (19) of respondents reported that they use Zoom for attending their classes. 14.4% of respondents reported that they use Microsoft teams. Lastly 3.3% of respondents reported that they use other software applications to access classroom and learning resources.

Figure 5: Technologies used by Schools

Respondents of the study were asked about the technology being used by school administration to share the curriculum related information. 50% (45) of respondents reported that majority of the schools used e-learning system which can be accessed using student credentials, 32% (29) respondents reported that their school used WhatsApp to share the curriculum related information. 8.9% (8) respondents reported that curriculum related information is shared on email with parents and remaining 8.9% respondents reported using other mediums for sharing curriculum related information.

Challenges Faced by Students

Figure 6: Challenges Faced by Students

Respondents were asked about the challenges faced by students during distance learning. 42.2% reported noise distraction i.e. (dog barking and children crying) moderately experienced during online learning at home. 56.7% of participants reported having moderately experienced issues of proper learning environment at home which includes having adequate furniture and desk during their online learning sessions. 51% of respondents reported having reported moderately experienced issues of access to electricity which disrupts their learning experience at home causing internet disruption. 48% of respondents reported high experienced issue of access to learning resources at home. Majority of the respondents which includes 70% of students have not at all experienced issues related to accessibility

of personal computers, tablets, phones and laptops. Lastly, 42% reported moderately experienced issues of internet disruption in some part of Lebanon.

Challenges Faced by Teachers

Figure 7: Challenges Faced by Teachers in Education Management

Respondents of the study which characterized of teachers working in different private, public and private free schools across Lebanon. Respondents were targeted with the key questions. Majority of the teachers which includes 44.2% of respondents reported that they have moderately experienced issues in communicating with school management during the tenure of working at home during lockdown. Respondents of the study were asked about the electricity disruption as a challenge to distance learning opportunities in Lebanon, 44.4% of teachers reported that they have highly experienced load shedding and power shortages which have disrupted distance learning experience caused by connectivity issues. Teachers were enquired about the noise disruption challenge faced by them, where majority of respondents which includes 41.1% of respondents reported that they have not at all experienced such issues during the distance learning implementation at home. Teachers were asked about the challenges related to children's participation in online classes where 53.3% reported that they have highly experienced issues of children participation which results in absenteeism amongst students attending online education at home. 41.1% of the teachers reported that they have moderately experienced issues like confusing when accessing student performance. 45.6% of respondents reported that they believe that many students face difficulties using ICT based technology. 41.1% of respondents reported that they have not at all experienced issues of frequent communication with parents. Lastly, 62.2% of the teachers reported having large number of students in an online classes which poses challenges such as attention distraction and lack of personalized attention to each student caused by large size of a class.

Discussion

This study aimed to examine the impact of the COVID-19 outbreak on education management and evaluate significant challenges for online learning in Lebanon situation where e-learning courses are uncommon. Thus, this study reveals both the research and practice about which elements to pay special attention to when designing online learning in this situation.

Findings of the study suggests that there are numerous challenges faced by students in Lebanon amongst which the most commonly occurred challenges occurred during the transition from conventional learning to e-learning includes accessibility to Internet, Computer, Learning Resources (e.g. Books and Curriculum), Electricity (e.g. Load shedding), Seating Arrangements at Home (e.g. chair, desk, table) and noise distraction at home (e.g. dog barking, child crying). Empirical evidence from Aboagye, (2020) shows a similar trend who investigated the challenges faced by tertiary institutions in an era of lockdown. The findings of the study suggest that one of the most common issues faced by institutes includes social issues, accessibility issues, motivation, and academic issues. Findings validate previous study conducted by Raju, (2020) findings which suggest that internet accessibility is amongst the major issue faced by students as many of the students don't have good connectivity of 4G in a rural part of the country which creates problems like buffering and laagering during live streaming of lectures. Furthermore, Raju, (2020) findings show that access to resources like books is the biggest issue as many students had to leave hostels and PGs immediately after the lockdown and could no longer carry textbooks and course material. Andersson, (2020) adapted

a holistic approach by categorization challenges that have categorized challenges into numerous types which include student, technology, institution, teachers, and support. The findings of the Andersson, (2020) studies show that the most commonly incurred challenges faced by students during the Covid-19 lockdown include motivation, conflicting priorities, confidence, learning styles, and accessibility. Sarvestani et al., (2020) findings show that infrastructure issues are one of the most significant challenges faced by students during Covid-19 amongst which the most commonly incurred challenges include internet connectivity issues, scarcity of physical space to peruse virtual education, Lack of access to school resources, lack of facilities and disconnectivity issues.

For the facilitators, it is very hard to understand the online learning attitudes since it meant coping with some flaws. E-learning is a good option in an unrealistic optimistic situation (like COVID-19), but it does not seem to be 'as good as' conventional face-to-face learning (Andersson, 2008). The physical classroom environment and face to face interaction between the students and teachers give satisfactory learning outcomes. Students work in a group, helping one another to accomplish assignments and semester projects. Moreover, during lectures looking at the professor's facial gestures and ways of describing a specific point play an important role to ease the learning. But during online classes these things are negligible (Aboagye, Yawson, & Appiah, 2020). However, developing the e-learning system helps the excellence of the educational system. E-learning is the second-best option for education institutes, as during the current pandemic situation students' learning process proceeded and students are continuing their semester without wasting their learning period. Thus, comprehending the difficulties and barriers of establishing e-learning in higher education institutions and offering practical solutions for them (Sarvestani, Mohammadi, Afshin, & Raeisy, 2019) is the current need to cope with the pandemic situation. During the COVID-19 lockdowns, virtual platforms not only served the education facilities for students but also offering many short-term certificate courses. As well as many institutes, offered different development courses to the teaching staff too (Raju, 2020).

Conclusion

It is important to address all the challenges before the pandemic situation and this effort signifies to engage the students in learning activities and keep them active and busy with studies. For example, the combined approach ought to have guided students to e-learning before you make any changes to complete the e-learning system. For students especially for school-going students, e-learning is a completely new concept and that's why in the pandemic situation they faced many issues to learn from the virtual platform. Also, most of the university students preferred to put on hold their current semester till further notice. Thus, it is necessary to consider all these problems before the implementation of e-learning in higher education establishments in Lebanon.

Future Research Agenda

Future studies should analyse these factors in-depth. Future research should investigate the student's e-learning experience after the COVID-19 lockdown. Future studies should examine the consequences of e-learning. Future studies should examine the impact of a pandemic on education in an underdeveloped nation.

Survey for Students

This questionnaire asks for your preferences about distant learning during covid-19 lockdown in Lebanon. The questionnaires aim to investigate (a) level of technology used by students and (b) challenges faced by students. Your participation in the survey is completely voluntarily and your response will benefits researcher and authorities in improving distance learning experience.

What is your gender?

Male ☐ Female ☐

Number of family members?

1-3 ☐ 4-6 ☐ More than 6 ☐

Specify the category of your school?

Private School ☐ Public School ☐ Private Free School ☐

Do you enjoy working from home during Covid-19 lockdown?

Yes ☐ No ☐ Maybe ☐

What are the technologies being used by your school for online/distance education?

Microsoft Teams ☐ Zoom ☐ Google Classroom ☐ others ☐

What are the technologies used by school's administration to share curriculum related information?

E-Learning System ☐ WhatsApp ☐ Email ☐ others ☐

Rate Challenges Faced in Access to School Distance Learning Programs

Challenges	**Highly Experienced**	**Moderately Experienced**	**Not at all Experienced**
Access to Internet			
Access to Computer			
Access to Learning Resources (e.g. Books and Curriculum)			
Access to Electricity (e.g. Load shedding)			
Proper Seating Arrangements at Home (e.g. chair, desk, table)			

Survey for Teachers

This questionnaire asks for your preferences about distant learning during covid-19 lockdown in Lebanon. The questionnaires aims to investigate (a) level of technology used by students and (b) challenges faced by students. Your participation in the survey is completely voluntarily and your response will benefits researcher and authorities in improving distance learning experience.

What is your gender?

Male ☐ Female ☐

Specify the category of your school?

Private School ☐ Public School ☐ Private Free School ☐

What is your level of education?

Associate Degree ☐ Bachelor's Degree ☐ Master's Degree ☐

Average number of students in an online class?

10-15 ☐ 16-20 ☐ 21-25 ☐ More than 25 ☐

What are the technologies being used by your school for online/distance education?

Microsoft Teams ☐ Zoom ☐ Google Classroom ☐ others ☐

What are the technologies used by schools administration to share curriculum related information?

E-Learning System ☐ WhatsApp ☐ Email ☐ others ☐

Rate Challenges Faced in Access to School Distance Learning Programs

Challenges	Highly Experienced	Moderately Experienced	Not at all Experienced
Large number of students in Class			
Frequent Communication with Parents

Abstract

The paper presents research aimed at establishing the opinion about journalists and journalism in the country covered by the so-called hybrid war waged with the Russian Federation after the illegal annexation of Crimea in 2014. An important element of the conflict is the use of disinformation. Such activities are also disseminated through the mass media and the social media. Hence, an important research goal was to establish the respondents' views on the scope and nature of fake news, as well as the impact of their distribution on the working conditions of journalists and the social perception of the profession. The study was conducted with the use of survey method in the town of Sumy, located in eastern Ukraine near the border with Russia, several days before the introduction of restrictions related to reducing the spread of the SARS-CoV-2 virus in March 2020. The main results prove that the practice of distributing fake news in Ukraine is widespread, there is a low social prestige of the profession of journalist and therefore there is a need to introduce restrictions on access to the profession.

Keywords: social communication, journalism, mass media, social media, journalistic ethics

Introduction

The research project carried out from 24 February to 6 March 2020 among 700 students of Sumy State University in Ukraine was aimed at establishing the perception of changes taking place in the system of social communication. The subject of the research was to reveal opinions on the conditions affecting the functioning of the mass media and social media. Within this aspect, it was necessary to verify the degree of approval for the activity of mass media, expressed, among others, in the authority of the journalists' profession. Beside the level of appreciation for the social role of the mass media professional, an essential task was to assess journalistic professionalism, which determines the content of media messages.

The formal authority of journalists and the perception of their professional competence were related to the issue of open access to the profession. Elements of corporative approach may contribute to the improvement of knowledge, skills and professional preparation of people willing to deal with the distribution of news in the structures of tabloidization1ed media market entities. Moreover, they may also pose a threat to the freedom of presenting views and expressing opinions, limiting the freedom of speech. The functions assigned to the independent press may be obstructed by various processes such as progressive convergence, structural concentration or tabloidization. The effects of ownership supervision, however, in many cases make it impossible to perform the control function. The local government press is an example of this phenomenon. Students expressed their opinion on the principles of activity of local administration on the media market.

The Conditions Affecting the Functioning of The Mass Media and Social Media Based on Empirical Research Conducted in Ukraine" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

One of the barriers impeding the distribution of reliable, credible and proven information is the spread of so-called fake news. Distorted, manipulated or even untrue content is not only a side-effect of the interaction of media activity with persuasive activity, the entertainment industry or achieving political goals. They also affect the main stream of the mass media. Next aim of the study was therefore to identify the perception of scale, type and social range of disinformation. Respondents shared their feelings about the segmentation of manipulated broadcasters. Ukrainian students also commented on the potential consequences of confronting traditional activities of media entities with the distribution of fabrications, misleading information and defamation, which can be both an opportunity and a threat to the mass media.

In open-ended questions asked on the day before the implementation of restrictions related to the prevention of the SARC-CoV-2 coronavirus pandemic, the students expressed their observations on the threats to modern journalism. They also presented their thoughts on combating disinformation. Sumy is a town in the northeastern part of Ukraine near the border with Russia. At the end of March 2020, 13.7 thousand students attended the Sumy State University there.

(Among the students — besides Ukrainians — there were also citizens of the following countries: Afghanistan (3), Angola (2), Anguilla - overseas territory of Great Britain (5), Azerbaijan (12), Bangladesh (4), Brazil (1), Democratic Republic of Congo (2), Egypt (25), Ecuador (3), Ethiopia (1), Finland (1), Ghana (59), India (640), Iran (1), Iraq (8), Ireland (1), Israel (1), Yemen (1), Jordan (191), Kenya (23), Congo (1), Lebanon (9), Libya (8), Mongolia (1), Morocco (15), Nigeria (238), Pakistan (4), Rwanda (2), South Africa (2), Gaza Strip (71), Sudan (1), Sweden (4), Syrian Arab Republic (3), Tanzania (38), Tunisia (6), Turkey (142), Turkmenistan (14), Uganda (1), United States of America (1), Uzbekistan (42), Zambia (10), Zimbabwe (19).

The impact of the Internet on the development of social communication

In recent years, significant transformations in social communication processes can be observed, caused primarily by computerisation in its broadest sense. Information and telecommunication technologies are nowadays one of the most important factors shaping the way knowledge and information is diffused. Phases of information technology development, starting from databases, through closed networks to open networks (Internet) are characterised predominantly by qualitative changes, which have significantly influenced the way information is distributed and access to all information resources. The Internet is undoubtedly a medium that not only has changed the world, but certainly has changed the way this world is evolving (Badzińska, 2013). Today's journalists need a wide range of knowledge, technical and digital skills. In this context, the concept of digital journalism appears here (Kawamoto, 2003). Communication online is very different from traditional communication. First and foremost, it is based almost exclusively on verbal communication, which under typical conditions only serves to convey content. The non-verbal aspect used to establish relationships and convey attitudes is limited to a minimum (Pease, 2001). Internet interactions have their own laws resulting from their asynchronous nature, anonymity and immaterialness of this form of communication, introducing interpersonal contacts into new areas where classical theories developed based on social sciences are not applicable (Juszczyk, 2011).

As Badzińska (2013) writes, "the interpenetration and unification of the virtual and real worlds is occurring today to an unprecedented extent, and hypermedia communication has become the hallmark of fundamental social and economic changes on an international scale. This is reflected both in the media and the potential for their use, in the customer and employee behaviour, in the changing approach to commercial transactions, as well as in the ways of searching for information". The concept of information society, i.e. society for which information, knowledge and all ICT techniques play crucial role, appears in scientific considerations in this context (Badzińska, 2013). As Juszczyk writes (2011), the rise and expansion of the Internet allowed to broaden the scope of freedom of speech in the world, giving the possibility to speak to those who were previously deprived of such an opportunity. The Internet exceeds national borders, competes with traditional cultural media (i.e. press, radio and television) and even absorbs them in the process of convergence, and broadens the scope of debate in countries with unstable democratic systems. Still, according to Juszczyk, it is difficult to talk about "global freedom of speech" or freedom of speech in the global dimension, because there are serious barriers on the way. Firstly, the popularisation of the Internet has aroused interest of big businesses, which create or intercept profitable (and thus popular) websites or Internet profiles, incorporating them into the market competition machine and progressive concentration on media markets. Secondly, enormous disproportions in access to the latest communication technologies, as well as in the level of education and in the development of social capital, contribute to the widening of the gap in information and knowledge resources, and thus to the social exclusion of many people in the world. This phenomenon called "digital divide" is an obstacle to the development of the idea of "global public sphere". Thirdly, the public sphere cannot exist in a global dimension, as in many countries of the world authoritarian governments are becoming various ways of limiting freedom of expression on the Internet. Fourthly, although the Internet has become a symbol of the globalisation of

communication, countries still play a significant role in shaping the so-called media order in various corners of the world, especially in the so-called cross-border network (Juszczyk, 2011).

New technologies have a huge impact on modern journalism, especially on the way journalists convey news to the world (Powell III, 2003).

The Internet has quickly redefined the way in which recipients consume messages. This activity was previously limited to reading a newspaper, listening to news bulletins on the radio or watching the news on TV. Nowadays, however, recipients can get "instant help" in the form of the latest news (literally seconds, minutes or hours ago) on the Internet or receive updates on their smartphones, emails or social networking sites (Stassen, 2010; Hoey, 2017).

The role of social media in communication processes

The origins of social media can be traced back to 1979, when Tom Truscott and Jim Ellis created Usenet, a system that allows Internet users to discuss the Internet through public news by combining the idea of Web 2.0 and user-created content (Kaplan, Haenlein, 2010). Among the first websites that can be regarded as early-stage social media are Six Degrees and Friendster. In the case of Six Degrees, the name of this site comes from the "six degrees of separation", a theory according to which each of us is only six contacts from any person on earth. The site was active from 1997 to 2001, with peaks of registered users reaching around 3.5 million. Friendster was founded in 2002 as a competitor of Six Degrees and in just a few months after its official launch it managed to attract 3 million users. Over the years, the number of users reached more than 100 million, although the reorganisation in 2011 did not allow Fiendster to compete with the new services and finally stopped offering its services in 2015 and was officially discontinued on 1 January 2019 (Kaplan, Haenlein, 2010). "I've seen on Facebook..." is a phrase often heard in today's conversations. This social medium and others similar to it were originally developed to help a person connect with friends and like-minded people. Since then they have evolved into powerful communication tools that are used by information media to interact with the audience (Stassen, 2010).

Social media can be divided in many ways depending on the specific features we are looking for. The following division comes from the user connections that exist on the websites concerned (Polańska, 2011):

- Social media (NK.pl, Facebook.com, Myspace.pl, Moja Generacja.pl, Grono.pl);
- Professional (np. GoldenLine.pl, iProfesor.pl, Profeo.pl);
- Publication (np. Fotka.pl, YouTube.com, Demotywatory.pl, Spryciarze.pl);
- Consumeristic (e.g. connected with group purchases Gruper.pl, Groupon.pl, GoDealla.pl, Kumulator.pl, MyGroup.pl, Znizkomania. pl, CityDeal.pl.)

Social media can also be divided according to their function (Networkeddigital, 2010):

- Social media for the publication of opinions and views (blogs, wiki-type websites, Citizen, Journalism) — the most basic category, its main task is to enable all interested parties to express their opinions or views.
- Social media for sharing content (Youtube, Flickr, Slideshare) - the classification is explicitly based on the idea of Web 2.0, all content that is shared by users on this type of media is available from web servers.
- Social media focused on co-creation or cooperation (Google, Docs, MMOs) — the main role is to achieve a predefined goal in the form of a result of cooperation between participants. This social media category is characterised by the formation of ad hoc communities, usually short-term, with a closed character.
- Social media focused on building and maintaining relations (Social networking, Virtual Worlds) — mainly include social networking services, consisting of building and maintaining human contacts.
- Social media focused on communication and discussion - instant messaging (Instagram, Messenger, Twitter, forums, chat) — media heavily focused on discussion and debate, one of the oldest types of networks, in the modern day Internet is often integrated with other types of social media.
- Social media focused on current events and referring to the news (microblogs, civic announcements, livecast, livestream) — reports and reactions relating to current events, focus on current events, have the form of both official alerts and private blogs or livecasts.

Over the last few years, social media have influenced various aspects of life both for individuals and society as a whole (Khang et. al., 2012).

They have led to a significant shift in mass communication towards interactive digital communication. Together with the emergence of the possibility of presenting various activities and events from private life in the media and social networks, the so-called "peer-journalism" has emerged, in which "we become self-journalists, presenting and

reporting on the experiences from our own lives, providing our own information channels for the publications we subscribe to" (Merrin, 2009). In fact, before the rise of blogs and commentaries on the Internet, the mainstream media retained their role as a guardian, belittling or ignoring stories considered unsuitable for public distribution (Farhi, 2010). The current media have developed significantly. Bloggers are playing an active role in presenting different points of view, including a large part in spreading rumours and influencing opinions about problems, events, or public people. In the process of communication, the power of persuasion has gradually shifted from media institutions to active, participatory audiences called prosumers or producers (Hermes, 2009).

With the increasing importance of social media, and more specifically the Internet in creating public opinion, a number of questions arise about the journalistic credibility, the role and significance of the journalistic profession in the modern world, as well as the truthfulness and reliability of news appearing in the mass media (Kiyan, Torenli, 2017). In the era of the digital society, where we regularly reach for information and knowledge on the Internet, and not always verifying the reliability of the sources we use, the dilemma of Internet self-efficacy arises (Rains, 2008) and the place of professional journalism in a modern world.

Journalistic ethics in the Digital Media Age

Journalism is a field of knowledge about communication among people. There are different models of journalism, however, it can be assumed that it is constructing images of reality and proposing these images to the audience, according to their needs, in the form of messages, while preserving objectivity of content and based on the competence of the authors (Furman, 2006). Journalism is also a specific profession, involved in a variety of relationships that often make it challenging to accomplish the assumed missions in this special and quite closed professional circle. Every journalist should ensure impartiality in presenting facts, moderation in expressing judgments, but also be loyal to the organisation they come from. Objectivity and balance have always been included in the principles of journalistic work. In order to achieve them, it is necessary to have autonomy, a certain lifestyle, a code of ethics, as well as an awareness of a separate identity. But the autonomy of journalistic work differs not only according to the types of media, but also their levels (local, regional, national) (Nowakowski, 2017). Journalism is considered to be a profession of public trust, so the representatives of journalism are required to have an appropriate ethical attitude and high quality services. Trust of recipients (listeners, spectators, readers) is a value that is hard to gain, but very easy to lose - the loss of credibility is a consequence of unethical behaviour (Nowakowski, 2017). As Nowakowski (2017) writes, journalism and the public relations industry are not subject to professional certification, so these are open professions, which has its consequences, for instance, related to the selection of staff, which is crucial for the quality of the profession. A great threat posed to modern journalism is therefore the presence of many non-professionals in the sector, as well as the involvement of both the media and journalists in unethical professional practices, mainly related to corruption (Nowakowski, 2017), but also to misinformation or spreading fake news (Rommer et.al., 2020; Sheares et.al., 2020; Popescu Ljungholm and Olah, 2020; Mircica, 2020; Clark, 2020; Dobson-Lohman and Potcovaru, 2020).

As Mrozowski (2001) observes, trust in journalists depends "more on how they present themselves than on what they represent. Being unable to check their reliability and honesty (truthfulness), viewers must rely on the impression they make on them, and a good impression is made when they are on-site and trying to reach different sources of information, when they get emotionally involved and can make contact with the recipient when they speak in a convincing way and have their own style. In short, the recipient believes the journalists and their relationship when they attract recipient's attention and appear to them to be an interesting personality, i.e. when the journalists create the right image of themselves". As Laskowska writes (2011), the contemporary status of the journalist's profession probably derives from the phenomenon — called by Krzysztofek (2006) — as "de-journalism" or as "disintermediation of the message". It means that due to new technologies a "living" intermediary has become unnecessary. This means that instead of a communication model: sender-medium- recipient is rather a server-customer model, which is not without significance for journalism.

Modern journalism is marked by the dynamic development of modern ICT technologies, as well as mobile devices that enable instant communication from almost anywhere in the world.

There are no other technological innovations that would have a more two-way (or even contradictory) impact on journalistic practice than the Internet. On the one hand, this medium has enabled journalistic practice, offering new opportunities for practitioners. On the other hand, it is perceived as a journalistic nightmare, resulting in a multitude of ethical pitfalls related to its ability to "instantly spread searchable information without space constraints…" (Chari, 2019). The widespread use of the Internet causes such ethical dilemmas as violating someone's privacy, displaying images of violence, spreading rumours, or trolling (Laskowska, 2011). The issue of ethics of modern journalism is also raised by Sztyber (2020). The author asks whether there is any place for journalistic ethics in modern media. As she observes, "when entrusting their attention to the media, the recipients expect the journalistic message to be truthful, and also prepared according to the rules of the journalistic craft. However, this is determined by a number of

factors — apart from legal restrictions and obligations towards one's employer — this can also be determined by the sense of duty to act in accordance with professional ethics. Reliable journalism competes today with other, mainly material values — all information is a commodity that generates income".

Perception of journalists and journalism – research results

Occupational Prestige

The students asked to assess the social reputation of the journalist profession most often considered it to be average (58.4%). The next group of respondents were those who were convinced of the high authority of mass media employees (35.1%). The rest (6.7%) believed that the reputation of journalists among the citizens is low.

Fig. 1: Opinions on the professional prestige of journalists (%).

The Trend of Prestige Change

In contrast, students who analysed the trend of prestige change were convinced of its growth (42.1%). Much fewer respondents supported a decrease in social recognition (26.7%). Every third student did not have a clear opinion on the subject (31.2%).

Fig. 2: Evaluation of the direction of social transformation of the prestige of the journalist profession (%).

Journalist Professionalism

Among the students presenting opinions on the professionalism of the journalistic environment, the majority of those who considered mass media employees to be professionally prepared for work (62%). The second place was taken

by those who could not determine the level of qualifications of journalists (23.1%). The fewest respondents indicated a lack of competence to properly perform journalistic duties (14.8%).

Fig. 3: Evaluation of the professionalism of mass media employees (%).

Access restrictions to the profession

The opinions on the legitimacy of introducing corporate restrictions on access to the profession of journalist were extremely polarised. The majority of students (75.5%) emphasised that they were necessary, even if in their basic form (e.g., the need to have a degree, membership in an organisation or professional self-government, no criminal record, etc.). Much fewer respondents (12.2%) were in favour of free access to the possibility of practicing the profession, and at the same time the harmfulness of creating any barriers. The rest of the respondents chose the answer "I do not know".

Fig. 4: Students' opinions on the legitimacy of introducing corporate restrictions on access to the profession (%).

Local government press

The press published by local government entities in the current legal status in Poland cannot reliably and impartially review the proceedings of the local administration, as the controlled entity cannot also be a controlling entity. Hence, since 1990 there has been a public debate devoted to local government media, but so far no uniform rules for the presence of local governments on the media market have been developed. That is why, the question to Ukrainian students is whether the municipal authorities should have their own mass media (local government television, radio, press, internet portals, social media, etc.)? The vast majority of respondents considered such activity to be legitimate (65.5%). The opposite opinion that deny municipal structures the right to operate in the media market, was expressed by fewer students (23.4%). The rest of them had no clear opinion on the functioning of the local government press.

Fig. 5: The respondents' opinion on the activity of municipal authorities in the media market (%).

Opinions on the nature and social range of disinformation

Disinformation Range

According to the vast majority of research project participants, the spread of "fake news" is now a common phenomenon (87%). However, its incidence was reported by only one in ten respondents (9.1 percent). In response to the question about the social range of the manipulation of the news in the media, the lowest number of people who did not have a clear view on the subject was reported (3.8%).

Fig. 6: Opinions on the escalation of disinformation spread in the media (%).

Sender Segmentation

When examining the media that are most often used to distribute manipulated messages, the respondents pointed to social media (67.2%). The second largest group of respondents were convinced that "fake news" appear more often in institutional media (press, radio, television, and editorial offices operating in cyberspace) than in social media (24.2%). The others did not know how to accurately identify the facts.

Fig. 7: Characteristics of the most common disinformation sources in the opinion of the respondents (%).

The Impact Of Disinformation On Journalism

The participants of the research project also commented on the ramifications of the distribution of manipulated news for editorial offices that function according to the ethical principles of traditional journalism. Nearly half of the respondents saw the influx of "fake news" as an opportunity for professional and reliable editorial offices to gain recipients expecting reliable and impartial information (46.2%). The contrary opinion was expressed by the second group of respondents, who considered manipulations to be a threat to editorial offices that comply with ethical standards, since, among others, disinformation devalues objective journalism replaced by entertainment (27.1%). The rest of the respondents did not consider themselves competent to express an opinion on the subject (26.5%).

Fig. 8: Respondents' opinions on the implications of spreading disinformation for editors seeking to maintain high ethical standards (%).

Summary. Opinions on threats to journalism

Dangerous Disinformation

Ukrainian students' perception of the most important threats to modern journalism was determined by answering an open-ended question about the factors posing the greatest threat to the sense of journalism and the functioning model of the media market. Most students emphasised the disinformation in its various forms. The opinions of nearly 50% of the respondents could be classified as an indication of fake news or manipulation. According to the respondents, there are many reasons why the distribution of fake news is a common phenomenon, there are many motives, methods and tools for spreading them, but the final effect on the media system always remains negative.

The statements about the "untrue information", "false information" (47 indications), "false messages" (44), "manipulation" (35), "fake news" (31), "unverified, unconfirmed, distorted or inaccurate information" (23) or "fakes" (17) were mentioned many times as the source of the crisis of journalism. This set of threats also includes: "distribution of false messages", "plagiarism", and "spreading rumours".

A Serious Fight Against Disinformation

Respondents also mentioned the Ukrainian draft law on combating disinformation among the threats to journalism. It is worth highlighting that the survey was carried out at a time when Ukraine was debating draft legislation to counteract "fake news", but which could also be detrimental to freedom of speech. Apart from the hybrid war waged by Russia (after the annexation of Crimea and the war in the east of Ukraine) and massive disinformational activities, one of the reasons for this decision was the lack of media competence of the recipients. "Volodymyr Borodinsky — Ukrainian Minister of Culture, Youth and Sports — said that more than 90% of Ukrainians cannot tell the difference between false and true information", and therefore, "President Volodymyr Zelenski instructed the government to prepare draft laws to regulate media activities in Ukraine by the end of December 2019" (Rzeczpospolita, 2019). The draft law presented on January 20, 2020 by the Minister of Culture, Youth and Sports stipulated, among other things, granting certificates of trust to the media, creating the status of professional journalists or appointing a government proxy with the right to refute false or inaccurate information and able to verify what is disinformation. "The proxy will be able to arbitrarily judge what they believe to be disinformation and issue warnings to editors who will do so. The proxy will also be able to impose financial penalties amounting to one thousand average Ukrainian salaries, i.e. currently 5 million hryvnia (about PLN 800,000)" (Andrusieczko & Kokot, 2020). The prepared solutions have met with criticism from the journalistic circles. As the participants of the 4th Polish-Ukrainian Forum of Journalists stated, discussions were held in Ukraine "on the proposal of the Ministry of Culture that wants to push through the law on combating disinformation. The idea is right, but in the opinion of journalists, the proposed solutions may significantly affect their independence. We understand the need to fight against disinformation, but this should be done by honestly joining the forces of journalists and the state, and not before a top-down regulation that may lead to the elimination of inconvenient journalists. The new Ukrainian authorities have a lot of pressure to regulate the media, they want to control it through a single institution" (4th Polish-Ukrainian Journalists Forum, 2020). The participants of the debate finally "turned to the Ukrainian authorities to refrain from adopting laws that could threaten the freedom of speech and the independence of journalists" (Karolonek, 2020).

Senders

Students participating in the research project placed the remaining threats to journalism according to a simple scheme of mass communication involving the separation of the sender, the message and the media audience.
The risk factors assigned by the respondents to the first stage of the communication process, i.e. the senders (broadcasters), can be divided into elements characteristic for journalists and media market entities. Journalists are considered both as a community (professional group) and individually as people professionally involved in the preparation and distribution of press materials. On the other hand, media enterprises are not only editorial offices, but also their ownership supervision structures.

Media Entities

In the respondents' opinion, media owners pose a threat, putting business or political goals ahead of the goal of providing the recipients with impartial, reliable and objective information. One of the reasons identified by respondents may be the conditions on the media market, including "bureaucracy of media concerns" and "dependence of media on owners" or even worse, "dependence on authorities or sponsors". Moreover, influences are a source of danger: "large corporations on news in the media" and "public relations agencies on the credibility of news" and the belief that "business people control the media".

The respondents even pointed to "mafia influence on the selection of information and concealment of inconvenient information", "manipulation caused by officials and oligarchs", "interference by magnates" and "corruption of capitalist media corporations and unethical journalists".

The stigma on journalism is also imprinted by "too much competition among the media", shaping "the desire to be the fastest in the transmission of information at all costs", which means that "journalists have to compete for the fastest access to attractive information". Yet, the main measure is "clickability rate". According to the respondents, "too many mass media also pose a threat".

The mass media in Ukraine, according to the respondents, have their own limitations: "practicing government propaganda", "hiding news that is unpopular to decision-makers", "interfering in the activities of the media of

influential people" or submitting to "government pressure". In this way, the mass media "create a framework beyond which the journalist cannot go. They build a model of "journalism based on political influence". Not only does this result in a "loss of motivation to pursue the profession" but it also poses a real danger to those pursuing the profession. This is a category defined as: "a threat to journalists due to the distribution... of truthful information".

Unethical Journalists

Over a dozen times (15 indications) the respondents explicitly mentioned "corruption" or "corruption of journalists" as a dangerous thing for the future of journalism. They described it in words: "Corruption, moral decadence, lack of rules" and "fabricating news in exchange for bribery". The threat is posed by media professionals who are characterised by "lack of ethical principles". They are distinguished by their "obliquity", "the pursuit of business and susceptibility to bribery", which results in the "transmission of false or manipulative messages upon request" or "being prepared to distribute any information, even false information". It is therefore possible to risk saying that "the greatest threat to journalism is ... journalists themselves". The outcome is an increasingly visible "lack of honest journalists" and, as a result, a "decline in the reputation of the profession", which leads to a "lack of respect among the recipients". At the same time, "the official media are becoming more and more unattractive to the audience, and the profession of journalist is becoming less and less prestigious. "The loss of credibility" resulting from "the fact that news in the media can be purchased" is accompanied by "a low level of journalism". The result is "corporate journalism", the creation of "tailor-made information" and "insufficient control in the official media to counteract false messages". The tools include "pressure on journalists from publishers (e.g. TV stations)" or "private organisations that purchase the right news. It was also mentioned that the "openness of the profession" that makes a "large number of non-professional journalists" with a lack of professional competence is dangerous ("ignorance", "poor knowledge of the mother tongue", or even "basic lack of vocabulary". Such journalists are not "objective", but "subjective", "ready to defame others through the media" and thereby lead to the "collapse of the professional image of journalism". Apart from "dishonesty of journalists" and "buying journalists", the reason why "the media and journalists lie", "falsify the reality" and "disinform" is an "unstable situation in Ukraine".

Messages (content)

The products of journalists' work, i.e. the content of the mass media, are also a threat to journalism. In this regard, the respondents mentioned "the propagation of counterfeit and manipulative information, which destroy the prestige of the journalist's profession", "an increase in the number of false information", "disclosure of unconfirmed information, manipulation", " provision of false information", "spread of false information" etc. Along with the frequently raised "lack of verification of information", there have also been allegations of submission to the convention of the "yellow press", i.e., tabloidisation, as well as the publication of "manipulations that try to control people's minds through social engineering practices".

The level of trust in journalism is also reduced by "false websites containing manipulated information", "the spread of social networks through which false information is distributed", "content spreading hatred based on nationality".

Recipients

Respondents placed some of the revealed threats to journalism on the side of the media audience. Several times "lack of trust" or "distrust of the audience" was mentioned. This category also includes the "risk of losing public trust".
The respondents explained that "people are becoming more and more educated and confidence in the media that manipulate information is decreasing", "a large number of young people are convinced that the information given to us is neither objective, nor reliable or accurate" and "if the media provide false information, people stop trusting them". As a result, "too many people no longer believe in what journalists write, and this undermines the prestige of the profession from the bottom up".

Another stage may be "aversion to the media because of their compromising activities", "dissatisfaction of the recipients", "citizens' resentment towards the media", "recipients' anger at the media for spreading false information" or "people's defiance against lies in the media". According to the respondents, there is a real "threat that people will start attacking journalists because of false information". Hence, "the threat to people in the media is the nation" and "ordinary people — because of the large number of false information spread".

Another areas of risk are the consequences of technological development. This causes that a "journalist is an outdated profession" replaced by "blogs and bloggers", often also "haters", but above all "social media" (21 indications) and "social networks that develop without the need of journalists". In this way, "traditional media are becoming a secondary focus" and "the further technological development of the Internet" makes it "common to spread news through social networks outside the official media". Therefore, traditionally perceived recipients become co-authors

of redistributed content owing to the social media, which enables "full disclosure of classified information" and "distribution of information on social networks without the participation of journalists".

The authorities' Influence

The functioning of media market entities, as well as the behaviour of recipients is affected by the political and economic environment. Therefore, another commonly mentioned threats to journalism are: "political influence", "politics", "government", "government influence" (42 indications). It is not only "a lack of interest by the government in publishing true information" or "a lack of legal protection for journalists".

The essence of the problem lies in "pressure on the journalist from the state", "restrictions on freedom of speech", "restrictions on publication rights", political manipulation", "control of the media by some influential people", "manipulation of the news or the giving of real news, but only those that have been approved by the government" or "a growing amount of information that cannot be published in the official media". The collection of these opinions is further supplemented by convictions of "political persecution" and "government pressure on journalists".

The underlying idea is that politicians and economic power centres are seeking to introduce "censorship" and "media control". This is manifested by "increasing the influence of the authorities on the activities of journalists", "blackmail and manipulation of journalists", "intimidation by the government", "distortion of information by the government" and distribution of "fake news". The consequences of these practices for journalists are "bribery or murder", "health hazard", "threat posed to honest journalists", "physical risk to journalists", "intimidation by the government" and "cruelty to truthful journalists". Examples of "punishment for telling the truth" are "falsification of cases against journalists by the public prosecutor's office", "turning indignant journalists into criminal offenders" or "prison sentences".

The claim of "limiting the freedom of the media and even threatening the lives of journalists" was repeated several times (14 indications). The following were also mentioned: "physical attack on journalists", "threat to people close to the journalist", "risk of loss of job or life", "physical violence and threats". Besides such drastic forms of violence as those described in statements such as: "if journalists tell the truth and do not accept the lies of the politicians they are supposed to describe, it can endanger their lives" or "journalists look for the truth about someone or something and then suffer from people who did not want it," the respondents mentioned other reasons why "journalism becomes a dangerous profession". Such reasons include working conditions: "There is a problem with employment for journalists", "journalists have low salaries", "a small number of jobs in the media sector", "there are many journalists now and there is a danger that there will be no jobs for them". The economic context also means that "journalists are not allowed to tell the truth, they are forced to remain silent or prepare false information". This gives rise to a "feeling of insecurity".

The external factors of negative changes in the media market identified by the respondents were also: "war and terrorism", "poor relations between countries in conflict", "introduction of states of emergency or martial law", "martial law in Ukraine", "military situation in Ukraine" and "the effects of the coronavirus pandemic, including restrictions imposed by the state authorities".

Conclusions

The aim of the research was to identify factors affecting the perception of journalism by students in Ukraine. The majority of respondents (87%) believed that in a country waging the so-called hybrid war with Russia, the practice of distributing fake news is widespread. It concerns, however, mainly social media (67%), which nearly half of the respondents interpreted as an opportunity for reliable mass media to strengthen their position. Nonetheless, the majority of respondents (75%) stated that restrictions on access to the journalist profession are necessary. The authority of a journalist in Ukraine was described by the largest group of respondents as average (58%), but with a tendency to increase social prestige.

A similar study was completed in March 2020 also among the "Polish group", which included students from the University of Silesia in Katowice as well as the "African group" composed of students from Ghana Baptist University College in Kumasi (Ghana) and Bingham University in New Karu (Nigeria).

The results obtained among respondents from Ukraine showed the highest level of disapproval towards the official mass media. They were indicated by as many as 24% of respondents as a carrier of disinformation, compared to 9% in West Africa and 4% in Poland. In Ukraine, the highest number of responses was also noted, suggesting the need to introduce restrictions on access to the profession of journalist, and responses proving the low social prestige of this profession. At the same time, Ukraine was the only research area where opinions were noted about a physical threat

to the life and health and repressions towards people wishing to perform journalistic duties in an objective and raliable manner.

Acknowledgment

The Authors would like to thank the Authorities of the Organization and Management Faculty, Silesian University of Technology in Gliwice, Poland, for funding the project.

Abstract

This research intends to analyze the level of efficiency at the hospital to increase the efficiency of productivity and industrial competitiveness, and to help realize the government's commitment to support the SDGs program. This research performed a productivity analysis following Material Flow of Cost Accounting (MFCA) which is divided into several stages, namely the planning stage (Plan), the second stage of implementation (Do), the third stage of evaluation (Check), and the last is the follow-up stage (Act). The research was conducted on financial and operational reporting data for three months and showed that the current efficiency level of Hospital X was 68.54%, indicating a high level of efficiency of the hospital. However, with the conventional method, the hospital does not know the level of inefficiency related to the environment or pollution caused by the hospital's operational activities. The implementation of MFCA resulted that the hospital's operational activities for three months resulted in a negative product of 9% of the total material input or Rp. 12,516,456 which previously was not detected by conventional methods. The results of the analysis of material flow tracing using this MFCA have the main benefit of minimizing waste thereby saving the environment from damage, thus realizing the sustainable operation of hospital X. This means that if this MFCA is applied continuously, hospital X will not only save expenses but could achieve eco-efficiency and could realize continues improvement so that in the long-term operation sustainability could be achieved.

Keywords: Material Flow Cost of Accounting; productivity efficiency; material loss, hospital.

Introduction

Indonesia as a member of the G20 is committed to supporting and achieving the SDGs, which are the global development agenda for the period of year 2016-2030. In line with Indonesia's commitment to the SDGs, Material Flow Cost Accounting (MFCA) is a technique to calculate material loss or "waste". In the current production process, generally, companies only focus on output that was produced, the output that will be transferred to the next processing processor to consumers. Waste/material loss at MFCA is all material (input) that is wasted and does not enter the output of a production process (both goods and services). The productivity improvement program through MFCA is still relatively new and has not been widely or generally known by business people and institutions in various regions in Indonesia, especially in the health service industry.

Several previous research regarding MFCA applications were generally carried out in processing (manufacturing) companies both in Indonesia and around the world, such as Western, Asia-Pacific Countries (Christ & Burritt, 2016; Darkamin & Barmaki, 2019; Tajelawi & Gharbarran, 2015; Ichimura & Takakuwa, 2013). , It was found that

Cite this Article as: Dianwicaksih ARIEFTIARA, Ria Maria THERESA and Retna SARI "Accounting (MFCA) on Health Service Industry toward Operation Sustainability" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

MFCA is a useful indicator of the company's potential growth and environmental impact. Many companies that implement MFCA could recognize losses (waste) that were previously not realized. Some of the research evidence suggests that MFCAs could improve decision-making procedures and increase profitably. The MFCA method is differ from traditional manufacturing cost of production system that allows company to trace their inventory efficiency by controlling material waste. There is still very limited research on eco-efficiency, especially in the health service industry, so it is necessary to conduct research analysis using MFCA considering the benefits it will have towards improvement to the health services (hospitals).

Hospitals as service providers in the health sector., In their business processes, a lot of material are needed as input and consume various resources to support health services. The hospital has allocated a large source of funds in investing in medical equipment, buildings, and providing other supporting facilities. These various tools, buildings, and facilities require resources to be used such as electricity, water, other supporting materials complete with certain specifications (medical supplies such as gloves, masks, syringes, alcohol, bandages, gauze, etc.), in addition to it also requires large maintenance costs as well as operational costs. Most of the operational costs are fixed costs, while hospital income is a variable, variable component, the amount of which could not be determined with certainty each month. For the purpose of going concerned, the large operational costs of a hospital make medical expenses both outpatient and inpatient expensive. In addition, if it is seen that the capacity of hospital facilities is not used optimally, hospital waste on medical supplies and water and electricity resources could have an impact on the high burden borne by the hospital, both monetary and non-monetary (negative impact on environmental sustainability). There is an urgent need to find solutions for hospitals efficiency practices/procedures/strategies, in order to help reduce operational costs so that in the end help realize the SDGs, namely health and welfare; life on land and under the sea; sustainability of the city, environment, and surrounding communities.

This research focuses on solving inefficiency problems in hospitals, analyzing the current level of efficiency of Hospital X, and identifying efforts to increase production efficiency through eco-efficient decisions using Material Flow Cost Accounting (MFCA) to improve economic, environmental performance and achieve sustainable development goals. (SDGs). This research is expected to contribute in three ways, first, this research is expected to have the benefit of helping deepen the understanding of current MFCA. This research provides a literature review regarding the application of MFCA in the service sector, namely hospitals, where as far as the researchers know, there is no literature on this matter before. This research is expected to be a literature review regarding alternative accounting methods in calculating environmental costs. Besides, this research is expected to provide empirical evidence of the benefits of MFCA in supporting environmental sustainability and increasing efficiency, productivity, and company performance. Second, as input and evaluation of the ongoing production process, to be able to identify, reduce, and manage waste/material loss to increase the efficiency and productivity of the company. The results of this research are expected to help management understand how MFCA works or mechanisms. Third, help expand the reach of the Indonesian government's program in realizing the commitment of Sustainable Development Goals (SDGs) in general, as well as the Ministry of Manpower's program in particular, namely as an increase in productivity. Finally, the results of this research are expected to contribute to the reduction in costs that must be borne by the community to enjoy health facilities. With MFCA, it is hoped that it could reduce costs and increase efficiency and productivity, so that companies no longer impose waste or material loss on end consumers, thus the price set to consumers becomes lower and more affordable. This is empirical evidence of how MFCA is applied to industry, especially industry. Health services, namely hospitals, considering that MFCA is a new method and has a very limited implementation in Indonesia.

Literature Review

Resource-Based Theory and Environmental Management Accounting

In the literature on management accounting, theory regarding company strategy, namely the Resource-Based View (RBV), argues that ownership and identification of key resources under its control could create a sustainable competitive advantage for companies, namely through the development and distribution of products or services that have distinctive characteristics to consumers (Barney, 1991; Clulow et. Al., 2007). Several studies on RBV aim to find empirical evidence of how consumers perceive the company's key resources (Clulow et. Al., 2007). Based on RBV theory, the management of corporate’s main resources is crucial. Environmental management accounting

(EMA) is a manager's tool for calculating and managing as well as providing information in order to make decisions and accommodate company interests for concerns about the social and environmental impacts resulting from their business processes (Burritt et al., 2008), and the theory focusses on both the short and long term (Christ and Burritt, 2015). Several research focuses on environmental issues have begun to emerge in the field of environmental management accounting research since 1988, although they are still small in number compared to other accounting fields (Qian et al., 2010; Madein and Sholihin, 2014)

Source: Tachikawa (2015)

Fig. 1: Development of Production Management Practices in the World

Material Flow Cost Accounting

Material Flow Cost Accounting (MFCA) is an accounting technique that calculates the amount of material loss or waste in detail in each cycle involving input, process, and output (Tachikawa, 2015; Christ and Burritt, 2015; Ministry of Manpower, 2015). This MFCA allows companies to obtain more output with minimal waste or loss of input material so that it has a significant impact on cost reduction and quality improvement (Kemenaker, 2015; Tachikawa, 2015).

Source: Tachikawa (2015)

Fig. 2: Material Flow Cost Accounting

Tachikawa (2015) explains that MFCA has advantages because its application is not limited to certain types of industry and company size, but could be applied to any industrial scope and field. Through MFCA, companies will get three benefits, namely: (1) reduced costs because MFCA is able to reduce material loss/waste; (2) increase energy efficiency, to reduce CO2 levels which are very beneficial for the environment; (3) increase material efficiency, because MFCA is able to identify the production process per-flow of material to output (Tachikawa, 2015). Christ and Burritt (2015) examined the role of scientific research in helping deepen understanding of current MFCA developments.

Methodology

Research Approach

This research uses mixed method approaches to solving research problems. A qualitative approach is used because this research was carry out focused and in-depth research on a single object of research in collecting data, this method is also called the case research method. Quantitative analysis is also used in this research to prove that the implementation of MFCA brings productivity changes for the hospital compared to before the implementation of MFCA.

Types of Data and Data Collection Techniques

This research uses primary and secondary data types. This research is divided into two stages, which shown in research design in Figure 3

Fig. 3: Research Design

Description of Research Object

This research was conducted at a private hospital located in Depok, West Java. According to the agreement with the hospital management, for the purposes of this research, the hospital's identity is kept secret. Hospital X is a relatively new hospital and is open to the public and serves various groups including Indonesian Insurance and Social Security (known as BPJS-in Indonesian terms) participants. The hospital stands on a land of +/- 2000 square meters and consists of 4 floors. The hospital's services and facilities are very complete, consisting of medical facilities in the form of dialysis; Emergency Room (IGD); Intensive Care Unit (ICU); Neonatal Intensive Care Unit (NICU); Pediatric Intensive Care Unit (PICU); Radiology; Delivery room; inpatient and outpatient rooms; Polyclinic; Pharmacy; Hemodialysis and Laboratory. This hospital was chosen because as a newly established hospital it is still looking for an effective and efficient form or design of services which in the end could calculate the price of services per patient more precisely

Finding and Result

This research was conducted in the midst of the Covid-19 Pandemic, so the data collection process was carried out online in the context of physical distancing. In accordance with the agreement with the hospital management, the scope of this research is limited as follows:

A. Operational scope: Dental Poly

B. Time: The Period of three months (in June, July, and August 2020)

C. Data: - Part of the Income Statements and Dental Poly operational Process Report

Hospital management provided data and research time to the research team for only 3 months, from June until August 2020.

Dental Poly Operational Process

The research was conducted on dental poly, where the operational process of dental poly consists of 4 main processes, namely:

A. Patient registration.

B. Patient examination.

C. Payment.

D. Pharmacy

The operational process for dental poly services could be seen in the following flow chart (Appendix 1):

-Insert flowchart here-

Hospital Operational Efficiency Level

To answer the formulation of the first problem in this research, namely the analysis of the operational efficiency of the hospital, the following data were collected regarding operational efficiency for 3 months:

Table 1: Summary of Financial Data

Financial Data Hospital X in Depok
Division - Dental Polyclinic
From June to August 2020

Information		Amount
Dental Poly Income June August		Rp 195,410,169
Cost :		
The purchase price of drugs, June to August	Rp 1,862,072	
Dental Poly Vendor Bill June to August	Rp 2,825,000	
dentist nurse salary	Rp 16,473,723	
Doctor's salary	Rp 71,793,215	
Doctor consumption	Rp 370,807	
Depreciation of Tools at Dental Clinic	Rp 8,578,231	
Depreciation of Panoramic Tools	Rp 32,031,250	
The number of costs		Rp 133,934,299
		-
Profit or Loss Dental Polyclinic June to August		Rp 61,475,870

Source: internal hospital X in Depok.

From this data, the level of operational efficiency will be calculated using the formula:

$$\text{Efficiency} = \frac{Total\ Input}{Total\ Output}$$

If this efficiency value is getting closer to 1, the hospital could be said to have carried out its operational activities effectively.

Planning Stage

This stage is the first stage in an eco-efficient analysis using Material Flow Cost of Accounting (MFCA). This planning stage consists of:

a. Determination of product or service targets.

In accordance with the results of discussions with the management of Hospital X in Depok, the planning stage begins with determining the target product/service which is the scope of research. In this research, the target of services to be analyzed using MFCA is outpatient services at the dental polyclinic. The choice of this dental polyclinic was intended because the procedures and operational scope were simpler than other services.

Fig. 4: Service Target MFCA of Hospital X

Source: Internal Hospital X in Depok

b. Determine MFCA Limits and quantity centers.

In accordance with the MFCA concept, it is necessary to determine the quantity center in implementing a good MFCA. Quantity Center is a unit within the organization which involves input, process, and output, output in one quantity center could consist of a successful product (positive product) and the rest of the material/waste (negative product/waste). If described briefly the scope of the service target in relation to input - process - output, then the dental poly service process is as shown on Figure 4.

c. Specifies the time period

Based on the agreement with the management of hospital X, it was agreed that the focus of this research was the operational process of hospital X for three months, from June to August 2020.

d. Efficiency analysis using Conventional Production Management (CPM)

The efficiency analysis of RS X Depok with conventional methods is as follows:

$$\text{Efficiency} = \frac{\textit{Total input}}{\textit{Total output}}$$

$$\text{Efficiency} = \frac{\text{Rp } 133{,}934{,}299}{\text{Rp } 195{,}410{,}169}$$

$$= 68{,}54\%$$

e. Develop a model of material flow percenter quantity

If in the previous section the quantity center that is the focus of research has been determined, at this stage it is to compile a material flow per quantity model. This stage of the research begins by identifying the activities that occur at each quantity center. Here are the details of the activities in each quantity center:

1. Quantity Center's Registration.
   Quantity Center (QC) registration is the beginning of service activities at the dental polyclinic of hospital X Depok. The activity carried out is for patients (either new or old patients) to register for service that day at the registration counter by bringing their medical card (old patient) or KTP / personal data (new patient) and insurance card (if any).
2. Quantity Center's Doctor Examination.
   The doctor's examination is the second QC in the dental polyclinic, this activity starts from the patient re-registering or reporting to the nurse on duty for the dental polyclinic to record complaints or the purpose of coming for treatment. The nurse records the patient's temperature and records the answers to patient complaints. Then the patient is waiting to be called into the doctor's examination room. After the patient has a turn to enter the examination room, the activity that occurs is that the doctor conducts interviews, asks for complaints and records in a medical record book, and performs an examination. When examining the need for drugs and medical equipment to be used, it depends on the patient's case. After the examination, the doctor will provide an introduction to supporting services (only if needed) such as laboratories, radiology (photo panoramic), and so on, if needed. The doctor after the examination will write down the examination note that day in the medical record book, provide a prescription note (if any), and write down all examination actions and drugs or treatment carried out on the treatment form as a basis for charging medical expenses or financial administration settlement by the patient. The doctor also provides a paper schedule for further control (if needed).
3. Quantity Center's Administrative Completion.
   Further activities are at QC completion of administration, starting from the patient queuing at the cashier with documents and making payments. As per the queue, the cashier serves the patient when it is their turn. The patient shows the documents such as a completed medical treatment form, drug prescription, etc. Then the cashier checks the information system, then gives the rate and calculates it. The patient then pays according to the cashier's bill, both cash, and debit then receives proof of payment and proof of payment for the purchase of the drug and drug prescription from the cashier for taking the drug at the pharmacy.
4. Quantity Center's Drug Taking.
   The activities that occur in QC for drug taking are as follows: (1) the patient goes to the pharmacy unit with evidence of drug settlement and a prescription from the doctor; (2) pharmacy officers process drug-taking; (3) verification of patient data and drugs submitted. Furthermore, after the patient receives the medicine, the dental clinic service process is completed and the patient goes home.
   The activities of each QC if described are as follows:

Fig. 5: Quantity Center MFCA of Hospital X

Source: Internal Hospital X Depok

The next step, after identifying the activities of each QC, identifies the material flow (material flow). This will be presented in the next section.

Implementation Stage:

Following are the inputs and outputs based on the material flow model per quantity center:

1. Quantity Center's Registration.
   Inputs needed in QC are paper (form) registration (for new patients), ballpoint for writing registration, electricity for application system resources on the computer, and blank medical card form to print new patient identities. The output on the registration QC is the queue number and the patient treatment form.
2. Quantity Center's Doctor Examination.
   Inputs needed in this activity are medical treatment forms, doctor services, nursing services, medical devices, electricity, water, equipment (medicine, etc.), doctor snacks, and patient snacks. The output produced in this activity is actions to patients, control schedules, drug prescriptions, and doctor's examination reports/treatment forms that contain details of the doctor's actions (bills).
3. Quantity Center's Administrative Completion.
   Inputs needed in this activity are the doctor's examination report, drug prescription, electricity, medical treatment receipt paper, payment stamp. The output produced in this activity is a receipt for payment of examination fees and proof of drug settlement and drug prescription.
4. Quantity Center's Drug Taking.
   Inputs required in this activity are drug prescriptions, proof of payment of drug payments, plastic to wrap drugs, label stickers to record drug information. The output produced in this activity is a copy of the drug prescription and the drug that was submitted.

b. Determine the tie compound.
   This stage of the research analyzes the ties in the MFCA or tie compound as a cycle of the relationship between input-process-output, described as Fig 6.

Sumber: Internal RS X Depok

Fig. 6: Tie Compound of Hospital X

In Figure 6 above, the tie compound at hospital X in Depok which is the object of the research consists of 4 tie - compounds, namely:

1. Tie- Compound Registration.
2. Tie – Compound Doctor Examination.
3. Tie – Compound Administrative Completion.

4. Tie – Compound Drug Taking.

These four tie-compounds form the basis of MFCA analysis.

c. Evaluates and filters material balances and calculates the input-output in monetary units.
   The next two steps in this research are presented in one section. Evaluation and filtering of material balances are carried out by the finance department by collecting supporting data for financial statements, namely a list of material balances. This research was conducted from June 2020, so that the material balance needed is the balance at the end of May 2020. Furthermore, the research is continued by calculating the input-output that is included in the quantity center in the monetary unit.
d. Making the cost implication (attaching the real nominal amount to the quantity center according to the accrual data)
   This step is carried out by identifying the positive and negative products of each quantity center. A positive product is the number of resources that are consumed into service components produced or enjoyed by dental clinic patients. Negative products are tracing resources that are actually wasted or waste, where these resources are not consumed in real terms to produce services. Some resource components are not available with accurate data because they are at the hospital level (not at the Poli), but from the explanation of the hospital's financial staff, a logical assumption is made.
e. Calculating waste or loss (per unit and per rupiah).
   Waste or loss is identified from the search results for each quantity center and an explanation from the hospital financial staff. Waste or loss in the manufacturing industry could be easily identified even using conventional cost calculation methods. However, this is not the case with the service industry, waste or loss could not be identified if the company uses conventional cost calculations.

The results of data collection and identification of inputs, outputs (positive products and negative products) both in quantity units and monetary units in each Hospital X quantity center are as Table 2.

f. Analysis and interpretation of MFCA results
   The implementation of MFCA in dental polyclinic Hospital X in Depok produces Material Flow data which is presented in Table 2. The operational process in dental polyclinic is simpler than other polyclinics. The efficiency level of dental polyclinic at hospital X is 68.54%, this means that the resources consumed by the dentist in 3 months are 68.54% contributing to the formation of income.

Table 2: Material Flow in monetary units

Flow No.	Process	Input	Input quantity		Input Cost (IDR)	(+) products	Persentage (+) products	Cost (+) products (IDR)	(-) products	Persentage (-) products	Cost (-) products (IDR)
1	Registration	Paper	15	rim	675,000	Registration proof	93%	627,750	Scrap kertas	7%	47,250

Source: processed data

The eco-efficient analysis is carried out as a company effort to pay attention to the impact of operational activities on environmental sustainability. Kondo & Nakamura (2005) explain that waste management and recycling procedures are companies' efforts to achieve eco-efficiency by comparing input-outputs in the operational process. Table 2. shows that the operational or service process in dental poly by tracing material flow (MFCA). From the identification process per quantity center, in a period of 3 months (June to August 2020), negative products were obtained which had never been detected by hospital X.

From the analysis of input and output, especially the identification of positive and negative products, as in Table 2 shows that the input used by the hospital for 3 months, namely Rp. 133,934,299, did not entirely produce positive products, but there was a few percent that became waste / lost/damaged, according to the MFCA concept. this is called a negative product (loss). A total of Rp. 122,517,065 was a positive product or was actually consumed contributing to services to patients during the months of June to August 2020. The number of positive products if the percentage is calculated is 91% of the total input or resources or materials consumed by the dental clinic. in the production process of its services. The research results show that Rp. 12,516,456 is a material that becomes a negative product, or in this MFCA concept, it is called waste / lost/damaged / waste/loss. If calculated, the percentage of waste/loss is 9% (see Table 2) of the total material that goes into the production process of RS X dental services for 3 months, which was previously not detected by the management of X Hospital. Even though only 9% of the total material/resources consumed are lost to waste / waste/loss, but this amount is very material if we relate it to the cumulative impact of environmental damage that may be caused, especially the waste generated by the health service industry requires more careful attention and handling.

Table 3: Comparison of Input Material Efficiency using Conventional and MFCA

	INPUT (IDR)	OUTPUT (IDR)	
		PRODUCT	MATERIAL LOSS
Before MFCA	133,934,299	133,934,299	-
	100%	100%	0%
After MFCA	133,934,299	122,517,065	12,516,456
	100%	91%	9%

Source: internal data processed

The analysis during this 3-month period is a small illustration that by tracing the flow of material as in the MFCA concept, hospital X is able to reduce resource consumption which has an impact not only on saving hospital expenses but reducing material costs from IDR 133,934,299 to 122,517. 065 (save 9%), but the expected benefit is that in the long run, it is the achievement of eco-efficiency so that it could realize the operation sustainability of the hospital. Eco-efficient is an increase in efficiency due to efforts to minimize the level of pollution to the environment.

The results of this research are consistent with Christ & Burritt (2015); Tajelawi & Garbharran (2015) by using Material Flow Cost Accounting (MFCA) so that it could help companies/organizations to create eco-efficiency conditions. This is because MFCA is indeed a tool created to encourage the achievement of eco-efficiency in organizations that allows organizations to focus on reducing material use and focus on efforts to improve the company's economic performance. MFCA improves transparency material flows and energy consumption in companies that can be a helpful tool for management (Dierkes & Siepelmeyer, 2019; Huang et.al., 2019). MFCA is the best solution where financial performance and economic performance could be synergized for continuous improvement.

Conclusion

This research intends to analyze the efficiency level of Hospital X's operation using conventional method and Material Flow of Cost Accounting (MFCA). The research was conducted for three months and showed that the current hospital efficiency level was 68.54%, meaning that the hospital efficiency level was quite high. However, with the conventional method, hospital does not know how much inefficiency is related to the environment or pollution caused by the hospital's operational activities.

The implementation of MFCA resulted that the hospital's operational activities for three months resulted in a negative product of 9% of the total material input or Rp. 12,516,456 which previously was not detected by conventional methods. Compares to manufacturing industry sector, the efficiency level on health care service industry is lower, because MFCA concept are more suitable in material waste reduction and more applicable in manufacturing sector. However, the results of the analysis of material flow tracing using this MFCA have the main benefit of minimizing waste and energy consumption, thereby saving the environment from damage, thus realizing the sustainable operation of RS X. This means that if MFCA is applied continuously, hospital X will not only save expenses but could achieve eco-efficiency and could realizes continues improvement so that in the long-term operation sustainability could be achieved.

Limitation and Suggestion

This research has several limitations, namely: data access. The research was conducted during the Covid 19 pandemic, which caused the research team could not be able to directly visit the research object so that communication and coordination with hospital management were carried out online with limited intensity and some limited data that could be accessed by researchers. Another limitation is the amount of data obtained, the hospital management limits the data to only three months and only on the dental unit or clinic, this causes some data related to operational costs at the central level that could not be traced in detail. This makes assumptions used in data analysis and discussion. The limited theoretical and empirical literature on the application of MFCA in the service sector limits the analysis of the results.

Suggestions that could be submitted for further research are to use public hospital data sources (financial reports are available) and use proxy measures with secondary data. Future research could further explore MFCA in manufacturing sector companies because the characteristics of the sector are more relevant concerning the flow of material which is the focus of MFCA. Thus it could be seen in more detail to what extent MFCA could encourage eco-efficiency.

Abstract

The paper aims to identify students' attitudes to and awareness of the retirement age and social protection, as well as their expectations with regard to educational activities in this area, the propensity for voluntary forms of savings for future retirement, trust in financial institutions. The research was carried out in 2019, using an anonymous PAPI type interview on a non-random sample of economics students (N = 382 people) who were either full-time or part-time students. This pilot study focused on theoretical questions about aging and retirement, which included personal, work, non-work, and retirement contextual factors as predictors of expected retirement age. The main questions of the study are the levels of knowledge of elementary issues about social security, young people's attitudes towards saving and investing, future retirement, care for the elderly and healthcare, health insurance. The authors also identified the level of attractiveness of studying issues related to social security for students. Studies have shown that, despite the lack of an expressive attitude to social insurance, respondents are interested in deepening knowledge in this area.

Introduction

Population aging is an inevitable prospect stemming from research on demographic change around the world. In this process, an important problem is to ensure the aging of an increasingly numerous social group, which, in the current pension system, will not provide a satisfactory replacement rate and is a threat to the stability of the public finance system, which is reported in publications. Against this background, a change in the mentality of society becomes obvious, in which the main burden of ensuring a decent retirement lies with the individual voluntary protection of retirement. A change in attitudes and awareness in this area must be done already at the stage of the younger generation, which implies the need for proper education of school and "academic" youth.

Cite this Article as: Yulia FINOGENOVA, Gulnara KAIGORODOVA, Maria PŁONKA , Tomasz JEDYNAK, Tatiana POHARCHENKO and Iryna ZELENITSA" Awareness and Attitudes of Students to The Prospect of a Secure Old Age" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Old age as a phenomenon of human life is necessarily represented by two qualitatively different aspects of its existence and scientific analysis: biological, which is expressed in a progressive decrease in the functional capabilities of various morphophysiological systems of the organs of the human body with age, and social, which is associated with natural changes in the social status of a person caused by phenomena biological aging and the necessary adaptation of the personality to these phenomena (Molevich, 2001, p. 61).
It is important to note that in modern society the very meaning of the definition of "old age" has changed (Klymeniuk, 2010, p. 56). If earlier the criterion of old age was incapacity for work, now it is a transition through the legally formalized age threshold, after which a person has the right to a pension or pension insurance payments.

For the average European pensioner, old age looks like traveling, dining out in restaurants, playing poker with friends. However, most begin to think about old age at a young age. That is why it was decided to find out what the students of Russian universities think about this.

Literature Review

The United Nations uses 60 years to refer to older people. This line, which divides younger and older cohorts of a population, is also used by demographers. However, in many developed countries, the age of 65 is used as a reference point for older persons as this is often the age at which persons become eligible for old-age social security benefits. So, there is no exact definition of “old” as this concept has different meanings in different societies. Defining “old” is further challenged by the changing average lifespan of human beings. Around 1900, average life expectancy was between 45 and 50 years in the developed countries of that time. Now, life expectancy in developed countries reaches 80 years. There are other definitions of “old” that go beyond chronological age. Old age as a social construct is often associated with a change of social roles and activities, for example, becoming a grandparent or a pensioner (Unfp, 2012, p. 20).

It's hard to disagree with Naudé, O’Driscoll & Kalliath (2009, p.11) given the trend of global aging, understanding why people decide to retire is a key issue in the 21st century for organizations, individual well-being and society. It is worth noting that, Fisher, Chaffee & Sonnega (2016, p. 230) define retirement timing as the age or relative point at which workers exit from their position or career path (e.g., early, on time, and later).

A critical question for social security policy is how program incentives affect retirement behavior (Coile & Gruber, 2007, p. 234). The importance of family values is mentioned Osborne (2012, p. 56), worldviews, and relationships can be recognized and strengthened prior to beginning retirement because this will also transfer to retirement

The thinking about pensions and more broadly about old age income security has moved in parallel with the development of the social risk management framework, especially in ensuring sustainable development. This framework provides the conceptual underpinnings for dealing with the diverse risks to which individuals or households are exposed in a world (Buzko et al., 2019, p. 9, Holzmann & Hinz, 2005, p. 37). Social risk should be understood as a legally defined probability of material insecurity as a result of a loss of earnings or labour income for an objective, socially significant reasons, as well as the need for additional costs. A situation of social risk can arise not only due to the loss of the ability to work (as a result of illness, accident, childbirth and care, old age, etc.), but also the lack of demand for work (unemployment) (Dluhopolskyi et al., 2019).

Marketing research has shown that contradictions arising at the micro and macro levels are revealed, which explains the effect of the “migration trap”; the low efficiency of using foreign labour in the Russian economy has been proved, as evidenced by the insignificant share of GDP produced by migrants and significant leaks of a part of GDP from the country’s economy through the transfer of funds to donor countries; an imbalance between the needs of the national economy for additional labour by industries and the actual use of foreign labour entering the Russian market is shown; the weak influence of the state on the national labour market and the lack of systemic regulation of the quality of training and the scope of migrant labour are revealed (Yakovleva, et. al., 2019, p.30). All this has a huge impact on the level of pension provision in the country.

From a systems perspective, the pension system is complementary to the financial system for the following reasons: pension system of any country is the channel of the cash flows of the population (savings), or “Long money”; pension system institutions play a central role in corporate governance (notably in pension funds, aimed at increasing of the shareholders’ welfare); this system encourages employees to invest in the capital of any industry (Kuznetsova & Pisarenko, 2016, p. 97).

The development of a private pension insurance system depends on life insurance companies, whose financial system must ensure the realization of financial interests, goals and objectives with sufficient financial resources through the balance and quality of financial instruments and promote capitalization (Achkasova, 2019, p. 181; Tsvetkova et al.,

2019). After all, as Achkasova (2017, p. 71) notes, the preferred indicator for assessing the financial security of the insurance market is its market capitalization. The importance of the insurance institution for the development of the economy, the social sphere of the country and its individual regions cannot be overestimated (Kuznetsova, et. al., 2019, p. 492). Insurance increases the financial protection of all its participants by reducing losses due to possible implementation of various risks and contributes to economic development by providing jobs.

Aims and Methods

The paper aims to identify students' attitudes to and awareness of the retirement age and social protection, as well as their expectations concerning educational activities in this area, the propensity for voluntary forms of savings for future retirement, trust in financial institutions.

The researched group consisted of students studying in Russia. The research was conducted in the latter half of 2019 among the non-arbitrary group of economics and administration, law and tourism full-time and part-time students in Moscow (Plekhanov Russian University of Economics) & Kazan (Kazan Federal University) within the framework of the international research project «Youth relations with the prospect of secure old age and social protection of the population» among universities in Poland, Russia, Ukraine and Lithuania.

The research was conducted using the standardized questionnaire, and the PAPI method (Paper & Pen Personal Interview), which is the form of the direct interview with a respondent, enabled us to directly explain any queries or doubts to respondents and ensured that the questionnaires would be returned. The questionnaire form included questions identifying respondents and nine specific research questions utilizing the semantic differential technique. The respondents' task was to indicate to what extent they identify with the statements located on a bipolar scale constructed on the grounds of opposing statements.

The five-point Likert scale was used for ascertaining the degree of identification, which allowed us to collect answers concerning the degree of acceptance of a given statement or opinion ranked from the complete acceptance of the first extreme statement to the complete acceptance of the second extreme statement. It is significant that the results presented in this work are based on the part of broader research and cover only the answers given to a part of the questions included in the questionnaire (Płonka, 2019; Cycoń, Jedynak, & Płonka, 2020; Płonka, Jedynak, & Trynchuk, 2020).

In the article, the authors formulated specific research dilemmas: own savings in the accounts of financial institutions, voluntary or compulsory participation in the pension system, private or public organization of the pension system, individualism or solidarity in the pension system, lower or higher basic national insurance contributions rate for the retirement insurance, the pension system different for individual social and vocational groups or uniform for everyone, the Pay-As-You-Go or the capital model of financing participation in the pension system, informal or formal education in developing the pension awareness, the pension system insignificant or crucial in the hierarchy of problems' importance, the old-age security the responsibility of the state or the family.

Data Analysis and Results

For a person to afford a decent and secure old age upon retirement, many countries use a funded pension system, when a person monthly deducts a certain amount of money from his salary, which is accumulated in his account. But the money is not just transferred to the account, but the funds that manage these assets, invest them in government securities, bonds, stocks, etc.

The current development of market relations in Russia requires a reform of the pension system, which would provide reliable social protection for the population and adequate pension coverage. The state of the pension system can be considered a crisis: retirement does not protect against poverty; the system is socially unfair; the pension fund is subsidized. To restructure the pension system, it is necessary to reform the solidarity system, create and accumulate, and promote the development of voluntary pension savings (Kozlov et al., 2017a; 2017b; Pukala et al., 2020).

About 6.4 million pensioners in Russia receive social supplements (federal and regional), which are intended to bring the level of material security to the subsistence level. This follows from the data of Rosstat, which refers to the Russian Pension Fund. And the number of such pensioners who receive additional payments is growing. From 2012 to 2019, it grew by about 20%, and the number of all pensioners in the country increased over the same period by only 10%, according to Rosstat. On average, the living wage of a pensioner was about 8.8 thousand rubles in 2019. per month in Russia. This is the threshold at which an elderly person, from the point of view of the authorities, ceases to be poor. Thanks to surcharges in Russia, poverty among pensioners has been formally completely eradicated (Ng, 2019).

Research results confirm that the key problems of the pension system are an aging nation and a huge permanent deficit of the pension fund. This is why the political decision is mature to speed up the pension reform to reduce it. Rosstat for the first time took into account the increase in the retirement age in Russia in the forecast of the demographic load until 2035. According to the average version of the forecast of Rosstat, by 2035 there will be 622 disabled people for every 1,000 able-bodied Russians, of which 391 are pensioners. Rosstat has published a demographic forecast until 2035. According to the median forecast, the population will decline from 146 million to 142.9 million (Kommersant, 2019).

To understand the future of the pension system, it is worth considering what young people think about their future pensions. It is commonly said that young people have a short planning horizon and do not think about retirement. In fact, this is not the case. In a 2008 Flash Eurobarometer survey, respondents were asked, "When you think about retirement, are you thinking about saving money or being financially dependent?". In general, the propensity to save varies from country to country, but the numbers are quite high in all countries. Interestingly, in the vast majority of countries, young people are more aware of the importance of saving than people in all other age groups.

To determine the attitude of young people to the prospect of prosperous old age and social protection of the population, a pilot survey was conducted among Russian students in November-December 2019. In the course of the research, students in the specialities of management, finance, economics, tourism, service were interviewed, among them: women - 67%, men - 33%; at the bachelor's level - 80.8%, master's - 17%, postgraduate - 2.2; full-time education - 86.8%, correspondence - 8.2 and mixed - 5%.

Many young people noted that they strive for financial well-being through saving and investing free funds. The basic principle of saving money is to learn how to save money. However, understanding is one thing, and real saving is another.

The survey results show that young people are aware of the need to save and understand their importance since 72% of respondents have their own savings. 58.2% of students' own life insurance policies, 43.4% use bank deposits, 41.2% use voluntary medical insurance policies, and 14.3% use an account with NPFs (Fig. 1).

Figure 1: Availability of insurance policies and own savings in the accounts of financial institutions

The state pension for a comfortable old age is unlikely to be enough, the respondents perfectly understand this. Only 52.2% of respondents are counting on a state pension in the future. Perhaps this is due to an increase in the retirement age, an increase in life expectancy, as well as receiving remuneration for work in envelopes and the understanding that they will be left without a pension or will receive small social assistance from the state. Besides, the World Health Organization is officially revising age standards. And now young people are considered up to 44 years old, middle-age - 44-60, elderly - 60-75; old age - 75-90, and after 90 - long-livers (Segodnya, 2015).

The authors found that 94.5% of students use the services of banks, insurance companies - 40.7%, investment companies - 11%, pawnshops - 10.4%, non-state pension funds - 6%, asset management companies - 3.3% leasing companies - 2.7% and only 0.5% of respondents use the services of construction financing funds (Fig. 2).

Figure: 2. List of institutions whose financial services students use

The changes taking place in the pension system cannot be called a full-fledged reform, so there is always a risk. Pension and tax legislation will change in the future and more than once, but the state must offer tools for accumulation and increase public confidence in them.

Although each instrument has disadvantages, the potential outcome is individual and depends on their financial knowledge (ability to use investment instruments) and motivation (Rotova & Trynchuk, 2004; Lutsyshyn et al., 2019; Komarova et al., 2019; Cwynar et al., 2019).

It's hard to disagree with Alikperova & Yarasheva (2015), Khovrak & Petchenko (2015), that the factor of citizens' trust in financial institutions is decisive in the development of the financial sector of the state, which determines the success of these institutions, as well as the level of economic knowledge of citizens (Cwynar et al., 2018; Bialowolski et al., 2020; Cwynar et al., 2020), and as a consequence, the manifestation of interest in their increase (Polinkevych & Kamiński, 2018), Suchánek et al., 2019; Vnukova et al., 2020).

Banks are perceived with the greatest confidence among all types of financial organizations - 62%, in second place are investment companies - 18.1%, mutual funds based on investment companies - 7.6%, insurance companies - 7.1%. Students trust non-state pension funds least of all - 2.7%. Do not trust anyone - 2% of respondents.

Young people are ready to invest personal funds in corporate securities - 47.3%, in foreign currency - 20.9%, alternative investments - 16.5%, government securities - 8.8%, in real estate - 4.7%, in themselves, in their education, in children - 0.5%, in precious metals - 0.5%, in the index fund - 0.5%.

Do you have a voluntary health insurance policy (VHI)? 45.1% of students answered this question in an affirmative way. Of these, the question «Who pays the cost of the VHI policy?» 55% of respondents answered that parents, 22.5% - independently, 22.5% - an employer.

The costs of purchasing a voluntary health insurance policy for working citizens should be covered (the choice of several answers) by the employer - 61.5% of the respondents think so, the state - 40.1%, the employee - 22.5%.

The authors found that 22.5% of students firmly believe that pension contributions should be voluntary, in part, another 12.3% of respondents agree (Table 1). The idea of accumulating contributions exclusively by state institutions is supported by 23.6% of respondents, another 17.6% partially agree with this opinion. There should be a systemic decision at the state level regarding the payment of pension contributions, according to 17.6% of students, and another 18.7% partially support this position. Young people, namely 16.5%, are aware that pension insurance contributions should be greater than just the contribution to the Pension Fund, and another 15.4% partially agree with this. At the same time, the vast majority of respondents 38.5% believe that pension insurance contributions should be flexible and set for certain professions, partially supported by another 16.5% of students. It should also be noted that for the majority of respondents, pension insurance contributions are an important issue, as 14.3% of students believe, and another 23.1% partially agree with this thesis.

Table 1
Respondents' attitudes to future retirement – distribution of answers (N=382)
In my opinion, pension premiums should be..., %

	agree		hard to say whether I agree or disagree	agree		
	completely	partly		partly	completely	
absolutely voluntary	22,5	12,6	41,2	10,4	13,3	absolutely mandatory
arranged only by commercial institutions	3,3	6,0	49,5	17,6	23,6	arranged by the state
dependent on citizens' discretionary decisions	22,5	11,5	29,7	18,7	17,6	be based on a system
lower than presently	8,8	13,2	46,2	15,4	16,5	higher than presently
flexibly set for particular professions	38,5	16,5	22,0	10,4	12,6	the same for all citizens
personally, I am not interested	13,2	12,6	36,8	23,1	14,3	this matter is of key significance for me

The main responsibility for caring for the elderly should fall on the state, according to 19.8% of respondents and partially supported by another 20.9% (Table 2); 15.4% (partially - 20.9%) of students are firmly convinced of this to be based on the developed savings programs; should become a subject of study at school or university, 19.8% (partially - 28%) of respondents strongly supported this idea.

Table 2
Respondents' attitudes to old age and its protection, and to intergenerational solidarity – distribution of answers (*N* = 382)
The main responsibility for care of the elderly should..., %

	agree		hard to say whether I agree or disagree	agree		
	completely	partly		partly	completely	
be assumed by children and families	5,5	8,2	45,6	20,9	19,8	be assumed by the state
be based on intergenerational solidarity and social sensitivity	8,2	9,3	46,2	20,9	15,4	be based on individual contributions and savings
be discussed within a family	4,9	12,1	35,2	28,0	19,8	be taught as a school or university subject

Under the state healthcare system, 20.3% of students admit the possibility of compulsory, but not very high, additional payments for various types of assistance, 17% partially agree with this. At the same time, 22.1% of respondents believe that medical care should be free, even if there are queues to see a doctor, 11.5% partially agree with this, and for 29.1% it was difficult to answer.

Table 3 presents the results of the perception of social insurance as an academic discipline. This discipline is necessary, 22.5% (partially 19.2%) of the respondents fully agree with this; it is not outdated, 13.2% fully agree with this (partially 24.2%); important, 15.9% fully agree with this (partially 31.9%); promising 23.1% fully agree with this (partially 22.5%); non-spectacular 17.6% fully agree with this (partially 21.4%); connected with practice, 23.6% fully agree with this (partially 26.4%); uninteresting for me, 9.9% (partially 23.6%) completely agree with this.

Table 3
Perception of social insurance as a subject of teaching – distribution of answers (N=382)
Social insurance as a subject of teaching is..., %

	agree		hard to say whether I agree or disagree	agree		
	completely	partly		partly	completely	
necessary	22,5	19,2	37,9	11,0	9,3	unnecessary
innovative	13,2	24,2	37,4	14,8	10,4	obsolete
important	15,9	31,9	32,4	13,7	6,0	waste of time
having a long-term dimension	23,1	22,5	32,4	16,5	5,5	non-developmental
attractive	9,9	13,7	37,4	21,4	17,6	unattractive
practical	23,6	26,4	32,4	9,3	8,2	theoretical
for me, interesting	9,9	23,6	39,0	13,7	13,7	for me, boring

Students believe that the subject «Social insurance» should be a necessary element of universal knowledge (Table 4); should not be taught at the secondary school level, but at the university level; for all specialities; to be more practical both in the form of seminars and practical classes.

Table 4
Respondents' expectations with regard to social insurance education – distribution of answers (N = 382) Social Insurance as a subject should .., %

	agree		hard to say whether I agree or disagree	agree		
	completely	partly		partly	completely	
be treated as an element of universal knowledge	12,6	23,1	40,7	12,1	11,5	be treated as an element of specialised knowledge
be taught in secondary schools	13,2	20,3	32,4	17,6	16,5	unnecessary at this level
be taught at a university level	15,9	25,3	33,0	13,2	12,6	trainings and postdiploma programmes are sufficient
be developed	9,3	13,2	32,4	27,5	17,6	no, it is taught to an excessive degree
be mandatory for all university courses	15,4	22,0	36,3	17,6	8,8	be mandatory only for insurance courses
be an elective subject for all university courses	19,2	21,4	34,1	14,8	10,4	be an elective subject for some university majors
be more practical	25,3	25,3	34,6	9,3	5,5	be more theoretical
be taught in the form of lectures	6,0	6,6	39,6	29,7	18,1	be taught in the form of classes

It is pleasant to note that the majority (68.7%) of Russian students are interested in deepening their knowledge of social security (Table 5), but for Polish students, this indicator is 74% (Plonka, 2019, p. 367).

Table 5
Respondents' commitment to broadening social insurance knowledge (N=382)
Respondent structure

Respondent opinions and declarations	Structure of responses [%]
I am willing to broaden my knowledge about social insurance	68,7
I am not willing to broaden my knowledge about social insurance	31,3

The results presented in the table indicate that the issue of future pension for students seems to be significant. This is confirmed by the generally accepted opinion about the importance and necessity of social insurance as a necessary component of universal knowledge for teaching, at least as a subject of study at a university for different specialities in the form of seminars and practical classes.

Discussion

Individuals face an increasing variety of financial risks (Merlo et al., 2013; Pyrkova et al., 2018; Tsintsadze et al., 2019), including those linked to their retirement. At the same time, public funding has been reduced or is strictly limited in most countries. Private insurance and pensions products, therefore, play an essential role in social and financial protection (OECD, 2008b, p. 160; Levchenko, 2015; Baranovskyi et al., 2015). Yet the public might have a low level of awareness of the risks they are exposed to and lack literacy, knowledge and skills in insurance and private pensions questions and products. This thesis is confirmed by the data shown in Fig. 1 about the students' insurance policies and their own savings in the accounts of financial institutions.

Individuals develop lifetime savings plans (Jedynak, 2019) to ensure that they will have the desired level of income in retirement. These plans are based on individuals' current knowledge and their level of understanding of financial markets (Clark et al., 2003, p. 27; Arkhipov et al., 2017; Kaigorodova et al., 2018; Horyslavets et al., 2018). In this regard, the quality of educational services should be the focus of contemporary university education (Trunina & Khovrak 2019, 401). And the role of universities in the formation of a financial culture (Trynchuk, 2011; 2017; Bucovețchi et al., 2019), a culture of green public procurement (Baranovsky et al., 2020) and the dissemination of the practice of social responsibility of financial institutions (Khoma et al., 2018; Dankiewicz et al., 2019; Glonti et al., 2020).

Financial literacy is deemed an important life competence nowadays (Cwynar et al., 2019, p.40; Mustafina et al., 2020). The need for financial education is increasingly being recognized in relation to all financial products (OECDa, 2008, p. 2). Quality education, the development of financial consumer protection, and access to financial services should be the three key drivers of financial empowerment for college students today and in retirement and will contribute to the overall stability of the financial system, underlined by three sets of high-level principles endorsed by G20 leaders (OECD, 2008a; 2008b; 2016, p. .3).

For example, the institution of financial ombudsman has been functioning in Poland for 25 years, whose mission is to take measures to protect clients of financial market participants, to represent their interests when applying the provisions of legal acts in accordance with the principles of social coexistence (Zelenitsa et al., 2018, p. 269). Particular attention in the field of insurance is focused on compliance with the rules for the sale of life insurance products and providing increased protection for consumers of the investment market for life insurance (Ostrowska-Dankiewicz, 2019, p. 168). In Russia, the institution of a financial ombudsman was created only in 2018, which carries out its activities on the basis of the Federal Law "On the Commissioner for Consumers of Financial Services" (Legislation of Russia, 2018). The financial ombudsman is independent of the authorities and carries out a free pre-trial settlement of disputes between financial institutions and their clients - individuals, thus avoiding going to court. The formation of this institution should certainly have a positive effect on the growth of trust in financial institutions and their services among not only students but the entire population.

Conclusions

With the aging population, the issue of pension insurance in many countries around the world is gaining importance. Despite the fact that the pension perspective for student youth is seen as distant, and so uncertain, it leads to a lack of proper understanding of the pension itself and pension insurance. The study shows that young people still approve of the issue of old age and consider it quite important. The vast majority of respondents, 68.7%, consider it necessary to deepen their knowledge of social security and pension protection against the risk of old age. The formation of financial culture, including insurance and pension culture, will inevitably be the key to building a secure old age because students are interested in deepening their knowledge of social insurance. This circumstance indicates the need to improve curricula, use innovative teaching methods, increase the level of practical orientation of courses.

The majority of young people (72%) strive for financial well-being through savings and are aware of the need and importance of investing in the policies of life insurance companies (58.2%), bank deposits (43.4%), private pension funds (14.3%). Students trust banks the most among all types of financial institutions. Regarding pension insurance, some respondents understand that the amount of contribution to the Pension Fund should be larger than the current one, flexible and set for certain professions.

The authors proved that the level of material well-being of student youth, changes in public attitudes and life priorities affect the vision of the prospects of their well-being. Therefore, 40.7% of students believe that the main responsibility for caring for the elderly should fall on the state, not the family.

The lack of trust in the state as the organizer of the pension system not necessarily translates to the lack of the pension awareness related with the necessity of securing the old-age in the uncertain and inefficient public finances system.

Under the educational goal, the indicated shortcomings in the pension awareness of young people should constitute the foundation for the discussion concerning planning future retirement and the values preferred in terms of pension security. Under the implementable goal, this research may be a useful instrument indicating the objectives and areas for prospective systemic changes for the benefit of developing the constructs of modern pension programmes which may, in time, transform into legislative initiatives.

Acknowledgement

The article presents the authors' results as part of a study conducted in 2019 at the Plekhanov Russian University of Economics and the Kazan Federal University in the framework of the international research project «Youth relations to the prospect of secured old age and social protection of the population» among students from Poland, Russia, Ukraine, Lithuania.

Abstract

In recent years, talent management has experienced increased attention from both scholars and practitioners. Globalization, technological developments, demographic changes, and the current pandemic influenced fierce competition for talents who will secure organizational development in a turbulent business environment. While organizations increasingly consider talent management central to the competitive advantage, only a small percentage of companies consider their talent management effective. One of the challenges is the lack of agreement both among academics and organizations on who the talent is. This paper contributes to the theoretical literature on talent management by presenting the implications of different talent definitions for talent management practice. Understanding these implications enables organizations to use talent management practices more effectively.

Keywords: Talent Management, Human Capital, Human Resource Management.

Introduction

Throughout the last two decades, organizations increasingly use talent management programs to attract, retain, and develop their talents. However, while talents are recognized as strategic resources central to the organization's competitive advantage, there is a lack of consistency in the operationalization of talent in the organization (Gallardo-Gallardo, Thunnissen, and Scullion, 2020). Also, there is a lack of sufficient empirical evidence of the effectiveness of talent identification practices (Ready and Conger, 2014; McDonnell and Skuza, 2021). Indeed, the Charted Institute of Personnel and Development (2013) study shows that only about 6% of companies consider these practices as effective. Such a belief is attributed to the lack of a conceptual consensus on who talent is in the organizational settings. Theoretical foundations for talent identification and talent definition seem to be absent in academic research, which increases conceptual confusion and limits the advancement of talent management theory. This article contributes to the theoretical literature on talent management by presenting the implications of talent definitions on talent management practice.

Approaches to Talent Definition and Their Implications for Talent Management

Although defining talent depends mostly on the organization's context, and the only correct definition of talent does not exist, adopting a specific approach to talent determines the entire talent management process. The literature review on talent management identifies three key dilemmas in defining talent. The first dilemma concerns whether talent refers to a selected group of employees (elite approach) or all employees (egalitarian approach). The second dilemma is related to understanding talent through innate abilities that K. Heller (1932) defines as higher-order abilities or

acquired competencies. The third dilemma concerns whether talent should be identified through current performance or through the potential to achieve high results in the future. These dilemmas and their implications for the concept of talent management are summarized below.

For Everyone or the Few - Egalitarian or Elite Approach?

The first question in defining talent is whether the organization should differentiate between talents and "non-talents." On the one hand, it is often assumed that every employee has talent, and organizations should develop this talent (egalitarian approach). Undoubtedly, creating development opportunities for all employees is beneficial from the perspective of motivation and involvement of a broad group of people employed in the organization. Additionally, this approach reduces the risk of identifying the wrong people. On the other hand, however, such an approach is considered ineffective and too costly (Gelens, Dries, Hofmans, Pepermans, 2013). Moreover, it calls into question the legitimacy of talent management, which becomes a new name for human resources management practice. The foundation of talent management is employee diversification, dictated by greater productivity and disproportionately greater added value provided by people with specific skills and abilities (Boudreau and Ramstad, 2005). The approach focused on a narrow group of talents (elite) dominates in talent management literature, although the authors have different interpretations of which employees should be in this group. Chuai, Preece, and Iles (2008) emphasize the need to focus on valuable and unique employees. In this case, value is understood as the potential to develop key organizational competencies, while uniqueness is expressed in the difficulty of replacing a given employee. Collings and Mellahi (2009) promote an approach focused on identifying key positions in the company that contribute to a competitive advantage and identifying people with above-average results and high potential who will be developed to take these positions in the future. Festing and Schafer (2014) recognize talents as people with above-average abilities, skills, knowledge, experience, intelligence, and development potential that significantly impact their organization's performance. Silzer and Church (2010), on the other hand, indicate the necessity to distinguish various groups of talents and individualize them according to their needs, scope, and type of development activities.

Despite the dominance (both in practice and theory) of the approach focused on selected employees or groups of employees, the elite approach raises many doubts about the cost of a potential decrease of motivation and commitment of people not recognized as talents. Those employees constitute the majority of employees in an organization. However, a review of the talent management literature shows a lack of empirical research that could confirm the negative impact of talent management programs on employees not included in these programs. Moreover, studies by Sonnenberg, Zijderveld, and Brinks (2014) and Bjorkman, Ehrnrooth, Makela, Smale, and Sumelius (2013) indicate that talent management programs significantly increase talents' motivation, commitment, willingness to learn, and intent to stay in the company, which translates into the positive financial outcomes. The authors also argue that the strategies of not informing talents about their participation in the program (some companies do not officially inform employees about talent management program) introduce much ambiguity and undermine these programs' role, mainly in terms of increasing commitment and retention of talented employees.

As already mentioned, talent management literature does not provide empirical evidence about talent management's negative effect on the motivation of non-talents. Theoretical considerations in this regard mainly use Adams's theory of justice (1965), pointing to the conditions necessary to minimize negative feelings of employees not covered by the program and suggest that this theory may become a starting point for further empirical research (Gelens, Dries, Hofmans, and Pepermans, 2013). The theory of justice assumes that an important factor of employee motivation is the employee's assessment of the ratio of his inputs and received outcomes to outcomes achieved by other employees for similar inputs. The theory of justice distinguishes between the subjective perception of justice about the distribution and allocation of resources (rewards, bonuses) in the company (distributive justice), procedures used in the distribution of these resources (procedural justice), the way organization communicates potential inequalities (informational justice) and relations between employees and supervisors expressed in openness, trust and respect (interpersonal justice). Minimizing the negative consequences of talent management programs may include the efforts to reduce the sense of injustice by increasing transparency and objectivity of talent identification and providing reliable information about the reasons for not including an employee in the talent group (and about the conditions that must be met in order to be included in the future). It is also emphasized that the perception of injustice is influenced by opened, trusted, and respectful relations with the direct manager (Lind and Tyler, 1988). A positive relationship with the manager and understanding the reasons for lack of inclusion in the talent pool are considered the most important factors that minimize talent management's adverse effects.

While the focus on a purely inclusive or exclusive approach is reported in the talent management literature, it is believed that most companies are increasingly looking for intermediate solutions. The inclusive approach might not only be impractical but often is only declarative (Kaczmarska and Sienkiewicz, 2005). On the other hand, focusing on a narrow group of talented employees (3-5%) may lead to a decrease of the motivation of employees not recognized

as talents. It is also risky to invest substantial resources in a small group of people who may quickly be lured away by the competitors. Therefore, there is an increasing interest in expanding the talent pool to other groups of employees, such as experts or young graduates. Within each group, organizations use a separate set of tools for talent identification and individualized development. Including more employees in the talent management program increases the use of the job as a primary source of development (i.e., new responsibilities, projects, rotation) and relationship-based development tools (mentoring, coaching), as they are less costly and bring tangible benefits to the organization (Garavan, Carbery, and Rock, 2012). However, including more employees in talent management programs increases managers' role in the identification and development of talents, which requires additional tools for developing and assessing managers' skills and their commitment to talent management (Gelens, Dries, Hofmans, and Pepermans, 2013).

Talent as Innate Abilities or Acquired Competencies?

Another dilemma in the talent identification process is the choice between defining talent through innate qualities or through learned competencies (knowledge, skills, and experience). The first approach concerns the definition of talent as a set of internal attributes (intellectual potential, personality traits, motivation) that undergo slight changes over time, indicating the elitism and limited availability of the talent. The second defines talent as an above-average level of competencies and the ambition and potential to develop these competencies.

The choice of either approach significantly influences the talent management practice. When the first approach is used, there is a need to pay much more attention to talent identification and selection, and to use a multi-stage process consisting of various psychological tests, identification of intellectual potential, cognitive abilities, or personality (Pocztowski and Miś, 2008; Meyers, van Woerkom, Dries, 2013). Because inborn talent is a rare commodity, the talent pool is small. The literature review shows that this approach implies assigning talents to the highest positions, and their development is mostly based on formal leadership training and intensive interactions with senior management.

The consequence of assuming that talent is a set of personality, and intellectual predispositions significantly reduce the number of people considered talents. It is assumed that investing more funds in a few talented employees will bring the company disproportionately greater financial benefits and help retain the best employees (Becker, Huselid, Beatty, 2009). However, such an approach is quite risky due to the changing pattern of behaviors of the new generations, which is reflected in their lower loyalty and increased requirements for self-development. While two generations (Millennials and Generation Z) represent an increasing ratio of the working population, a decline in their loyalty can entail a greater risk of talent loss and high financial loss due to allocating significant financial resources to developing a small group of people. On the other hand, identifying talent through innate abilities does not give employees who are not recognized as talents a chance to join the talent group in the future (regardless of their commitment and willingness to learn), which may contribute to decreased motivation and commitment of these employees.

In the second approach (talent in the perspective of competencies), identification, although not devoid of personality elements, largely consists of the diagnosis of above-average competencies - knowledge, skills, and experience that bring special value to the company's operations (Meyers, van Woerkom, Dries, 2013). Since talent is an acquired competence, talent identification criteria also include the candidate's ambitions, ability, and motivation to learn. The evaluation process includes detailed, evidence-based assessment, supported by many examples, multi-directional feedback about the candidate (360-degree assessment), and calibration meetings at various levels of the organization, aimed at in-depth evaluation discussions about candidates. This approach also increases the complexity of talent development activities, which depart from formal training and focus mainly on on-the-job learning, such as project participation, additional responsibilities and tasks, meetings with top-level management, rotation, mentoring, coaching, and facilitation sessions. The competency-based approach's main challenge is managers' increased role in talent identification, which might leave some space for subjective and incorrect choices. Silzer and Church (2010) identified the manager's lack of skills to identify talent as a key weakness of talent management programs, stressing that implementing these programs should be preceded by developing managers' abilities in two areas. The first area concerns the ability to assess employee behavior in the following aspects: (1) what to observe; (2) how to categorize these observations; and (3) how to recognize own cognitive limitations and preferences that affect the categorization process. The second area is related to the managers' understanding of the talent management role and their importance in identifying and developing talents. While the HR department plays a vital role in increasing managers' competencies in talent management, one tool that seems particularly beneficial is calibration meetings held at different hierarchical levels. Calibration meetings allow managers to compare different candidates and discuss the legitimacy of their appointments. They also contribute to the standardization of assessment standards throughout the organization.

The competency-based approach to talent has many benefits for organizations. First, it does not block people who are not recognized as talents from being nominated in the future. Secondly, talents are required to take responsibility for their development, to be more involved in their current duties, new tasks, projects, and strategic team; they are encouraged to take the initiative and participate in the decision-making process. Such engagement brings higher financial benefits than the cost involved in talent development and also reduces the costs associated with the risk of losing talents (Gelens, Dries, Hofmans, and Pepermans, 2013).

What to Measure - Past Results or Potential

Another talent identification dilemma concerns the extent to which talent is identified through an employee's past performance or the potential to achieve high results in the future. While the dominant belief is that the results of a given employee do not guarantee excellent results in the future, especially in new roles (Martin and Schmidt, 2010), in practice, companies treat results as the leading talent identification criteria (Dries and Pepermans, 2008; McDonnell and Skuza, 2021). The prevailing reason is that performance is more objective and easier to justify. Indeed, past performance becomes a more effective assessment criterion when the target position and the related requirements are known. In the early talent management understanding, which mainly mirrored succession management, such an approach was justified. However, in the current talent management practice, identifying talent mainly through the past results is questioned. Talent is increasingly identified through his/her potential to contribute to an organization's key competencies. The assessment of this potential is not related to a specific position, role (i.g. potential to move up two roles in five years) or specific future responsibilities, which are focused on individual career success (Sears, 2003; Skuza, 2018). Academic reviews claim that talent should be rather identified through the potential to become a key driver of organizational performance (Chamorro-Premuzic, Adler, and Kaiser, 2017).

There are few challenges with the identification of talents through potential. First, it requires the identification of a list of components of potential for different talent groups. Up to date, there is, however, a lack of consensus around the components of high potential in the published studies (Dries and Pepermans, 2012; Lombardo and Eichinger, 2000; Silzer and Church, 2009; Player, Randsley de Moura, Leite, Abrams, Tresh, 2019). Further, some potential components may depend on external factors (i.g., learning and motivation depend on the work conditions created by the superior), which significantly complicates potential assessment. Hence, giving candidates to the talent pool opportunity to participate in initiatives and projects outside the department and including more managers in assessing candidates' potential (through 360-degree assessment) allows for more effective identification of talents throughout the organization.

Another challenge in identifying potential comes from a lack of a common understanding of the definition of potential among the organization's managers and their inability to assess potential. Overcoming this challenge requires the centralization of the identification process, in which the direct supervisor's recommendations are only a preliminary stage, followed by multiple calibration meetings. Such meetings, as mentioned above, help establish a common understanding of the potential.

In reviewing the literature about talent potential, both academic and applied, few other questions and ambiguities emerge which call for future research: whether potential components differ by industry, culture, gender, or functional division of the organization?; which components of potential should be tested at different stages of an employee's career?; to what extent the organizational context affects the observable predictors of potential (e.g., determination and enthusiasm, willingness to take risk); to what extent potential can be developed?; to what extent a specific set of potential variables affects the effectiveness of talent management programs?

Conclusion and Implications

Talent management has been proved to increase the organization's competitive advantage, but the lack of conceptual developments of talent definition limits talent management effectiveness. Many organizations spend time and resources developing their own definitions or using studies proposed by consulting companies. The normative nature of the current publications does not explain many emerging dilemmas about talent identification. Academic publications on talent management do not specify how they understand the concept of talent (McDonnell and Skuza, 2021), and the lack of empirical studies on talent identification forces organizations to make intuitive assumptions and test different definitions of talent. Academic publications also fail to provide empirical data on the relationship between the approach to talent definition and the effectiveness of talent management.

While there is no one best approach to defining talents, organizations need to choose a talent definition that best fits their strategies and ensure that the chosen definition is clear and transparent to ensure consistency between the

theoretical assumptions and practice (Dries, 2013). Different approaches to talent have their own merits and drawbacks, and they influence talent management practices differently. For example, the focus on the small group of talents (3-5% of employees) will have different consequences for talent management than focus on a broader group of talents. In the first case, identifying talents is more centralized and usually involves the HR department and top-level managers. In this case, talent development is largely focused on leadership development training and initiatives involving top-level management. The inclusion of more talents in the program requires the involvement of managers from all organizational levels. This entails the need to improve managers' ability to identify and develop talents. Such an approach also requires changes in the broader intra-organizational environment (e.g., organizational culture).

Similar consequences may also occur when organizations define talent through innate abilities versus learned competencies. Each approach to talent definition induces different criteria of talent identification and different assessment methods. For example, competency-based assessment increases the assessment's complexity, the number of tools used to assess talent, and the number of people involved in the evaluation process. Also, while innate giftedness can be identified with relatively objective tools, knowledge, and skills are assessed mainly by observation. Furthermore, the focus on innate abilities may prevent people not recognized as talents from joining the talent pool in the future, which may significantly influence organizational efforts to reduce the sense of injustice by increasing transparency and objectivity of talent identification.

Another dilemma relates to the role of high potential in talent definitions, which requires managers' greater involvement in the identification process. Identification of high potential is particularly susceptible to subjectivity, and studies show that managers tend to follow their interpretation and intuition when evaluating candidates (Silzer and Church, 2009). Therefore, there is a growing need to include calibration meetings in the talent identification process, which helps standardize high potential understanding throughout the organization.

Further, when organizations prioritize performance criteria in their talent identification process, talent management is similar to succession management and includes identifying and developing managers for specific positions. Contrary, programs focused on identifying potential usually do not define the candidate's target position. During two to five years, organizations develop talented employees by engaging them in tasks beyond their skills, and they intensify feedback and support through mentorship, coaching, or sponsoring (Roi, 2012). Further, talent's career path is modified based on continuous tracking of talent's contribution to organizational objectives and the comparison of high potential indicators to the initial assessment (made during the program's talent entry).

In conclusion, talent management theory development depends on a better understanding of who the talent is and how to best identify talent in organizations. The variety of approaches and criteria for defining and identifying talent, and limited empirical evidence of their contribution to talent management effectiveness, leaves organizations with high uncertainty about talent management outcomes. Moreover, there is a growing challenge of identifying the right competencies, for the right roles, for the continuously changing organizational environment. Therefore, to move the talent management theory forward, it is critical to understand the definition of talent in specific organizational settings (Gallardo-Gallardo, Thunnissen, and Scullion, 2020). While the contextual dynamics of talent management explain the variety of approaches used to define talent, each approach's effectiveness is largely silent in academic literature. Thus, further studies should empirically investigate the approaches to talent definition and their consequences in a particular organizational context, which is central to the future development of talent management theory and practice.

Abstract
This article aims to uncover the key elements of learning organizations. This goal was achieved through an exploratory study conducted across 79 organizations located in Poland, Central and Eastern Europe's biggest economy. The study used a multi-step approach involving in-depth focus groups and a ranking list sent to participants by e-mail. By identifying four individual-level and five organizational-level categories, the study's outcome offers important insights on how managers perceive learning organizations. The in-depth field study is particularly important due to the recent conceptual confusion about the learning organization concept. This study contributes to academic discussions on learning organizations and offers recommendations that can be applied by companies seeking to expand their operations to Poland and other Central and Eastern European countries.

Keywords: organizational learning, learning organization, knowledge sharing.

Introduction

The topic of learning in organizations has received a great deal of attention in recent years. Growing recognition of organizational learning has emerged as a consequence of what Drucker calls the shift to "third period of change" characterized by structures based on information and knowledge (Drucker, 1988). There are many interrelated reasons behind this shift, including globalization and the technological revolution that accelerated the rate of changes in the workplace. Another reason is attributed to changes in the individual perception of the workplace. Nowadays, employees "bring more of themselves (their ideas, their feelings) to their work" (Argyris, 1991) and expect more autonomy, responsibility, flexibility, and self-development opportunities (D'Amato and Herzfeldt, 2008; Rupčić, 2019). Learning organizations are seen as a solution to those challenges, and some researchers are even more radical, stating that only learning organizations can succeed and be competitive (Senge, 1994; Huysman, 2000; Garvin et al., 2008).

The literature on learning organizations portrays the organization as a dynamic entity that gains competitive advantage from its relative ability to learn (McIntyre et al., 2012; Basten and Haamann, 2018). Despite its popularity and a proliferation of academic works that have extensively studied the learning organization mechanisms (Saka-Helmhout, 2010), the concept of a learning organization is a subject of confusion, and there is still no generally accepted operationalization of this phenomenon (Davis and Daley, 2008; Wu and Chen, 2014; Pedler and Burgoyne, 2017). Authors focus on recognizing conditions of organizational learning (Song and Chermack, 2008; Starbuck and Hedberg, 2001), identifying agents of organizational learning (Sadler, 2001), analyzing organizational learning processes (Vera and Crossan, 2007; Huysman, 2000; Jensen, 2005), or exploring learning organization outcomes

(Pérez et al., 2005; Jiménez-Jiménez and Sanz-Valle, 2011; Cheng et al., 2014; Bhaskar and Mishra, 2017; Kim et al., 2017). Although much has been written on learning organizations, there is still no instrumental and comprehensive guidance for successful learning organization implementation (Basten et al., 2015).

Notably, whereas many researchers focus on explaining what a learning organization is and how learning appears, there is a shortage of empirical research that looks simultaneously at organizational and individual-level elements that build a learning organization. Organizational learning is a process that does not happen in an individual mind but is rather developed by social interactions. Many researchers agree that organizational learning is deeply rooted in individual minds (Argyris and Schon, 1978; Senge, et al. 2012; Hoon et al., 2018, Rupčić, 2019) although for an organization to be learning-oriented, the relational and social aspects are of equal importance (Hosking and Bouwen, 2000). Research analyzing individual characteristics within the context of learning organizations is overwhelmed by studies where an organization instead of an individual is the unit of analysis. Moreover, it is difficult to find research examples that would empirically uncover employees' opinions and observations rather than reflect an a-priori reality. There is also a particular dearth of research on learning organizations in a different cultural context. For example, while scholars have increasingly investigated the learning organization concept in Western markets, there is a lack of research on learning organizations in the emerging economies of Central and Eastern Europe (CEE). The rapid political, economic, and social transformation of CEE countries such as Poland results in organizations facing different organizational learning challenges that might not follow the dominant Anglo-Saxon models (Skuza, 2018).

This article aims to uncover how managers identify the key elements of learning organizations, and we chose to focus on Poland, the biggest economy of Central and Eastern Europe. This goal was achieved through an exploratory study conducted across 79 organizations located in various Polish regions. The study uses a multi-step approach involving in-depth focus groups and a ranking list sent to participants by e-mail.

Organizational Learning

Organizational learning has been discussed for over 40 years, although it was not until the 1980s that we noted the radical growth of interest in this phenomenon (Easterby-Smith et al., 2000; Crossan et al., 1999; Crossan and Guatto, 1996). Still, however, little consensus exists on what is meant by the term of a learning organization, and still, there is no generally accepted way to research the concept (Davis and Daley, 2008; Rupčić, 2019). The definition that received a great deal of attention and that constitutes a dominant approach to learning organization was provided by Argyris and Schön, who defined a learning organization as an organization in which "members act as learning agents for the organization by detecting and correcting errors in organizational theory-in-use and embed the results of their inquiry in private images and shared maps of the organization" (Argyris and Schön, 1978, p.29). Their approach was both an inspiration and a subject of criticism. The criticism came from three different streams of research that pointed to the importance of organizational processes and context. The first one treats organizational learning as a dynamic process based on constant knowledge renewal (Crossan et al., 1995) and the spiral of knowledge creation (Nonaka, 1998; Hoegl and Schulze, 2005). The second approach stresses organizational rules, procedures, systems, or culture as critical elements of a learning organization, stating that individuals are important in the concept, but as they operate in certain organizational contexts, their behavior is conditional on a specific context (Basten and Haamann, 2018). The importance of organizational context in creating a learning organization may also derive from the assumption that different people placed in the same structures produce qualitatively similar results (Senge, 1993). The third stream of research represents a relational constructionism approach which states that knowledge exists only in relation (is not a separate product or thing) and that organizational learning might be only interpreted within social interdependencies and co-dependencies (Hoskin and Bouwen, 2000; Gergen, 1985; Reason, 1994; Bouwen and Hoskin, 2000).

The theorists of organizational learning often treat individuals and organizations as separate entities, stating that learning starts and ends in individual minds or that it is located in the organizational routines, systems, and structures (Bouwen and Hoskin, 2000; Davis and Daley, 2008; Garvin, et al., 2008). We would like to contribute to those discussions by integrating these two approaches. First, while we believe that individuals are fundamental to the development of a learning organization, we acknowledge that a learning organization's emergence is conditioned on shared learning that must result in organizational change (see Sambrook and Stewart, 2000, Yang et al., 2004). Second, a learning organization analysis must be carried within an organizational context, which strongly influences individuals' behaviors and assumptions. Such a context includes learning practices and managerial commitment, which emerge as key stimulants of any learning organization.

In this article, we understand learning organization as the one which facilitates the learning of all its members, where people cooperatively expand their capacities and challenge their patterns of thinking and collective assumptions to continuously transform their organization (Gravin, 1993; Senge, 1990; Yang et al., 2004).

Research Method

The main purpose of this study is to examine which factors contribute to the learning organization's development. Learning organization was explained to participants as an organization that 1) actively supports knowledge sharing and creativity; and 2) encourages employees to change obsolete or ineffective practices and processes to leverage organizational responsiveness to changing market trends.

Empirical studies on organizational learning are mostly designed as hypothesis testing with questionnaires that are based on theory and empirical research of other authors. As they often built on the literature from the early 2000s, they may not relate to the views and experiences that might have changed for the last two decades due to the rapid changes in the marketplace. While this is particularly true for the rapidly transforming Central and Eastern European countries like Poland, the qualitative study was designed to identify which elements are believed to contribute to the emergence of a learning organization. The study was primarily qualitative in nature since its main purpose was to uncover opinions and observations rather than reflect an a-priori reality objectively. We tried to understand a learning organization phenomenon from the managers' perspective and the meanings that managers give to their experiences in this area.

We based our research on eight focus group sessions with no more than 10 participants attending each focus group. Overall, 79 managers participated in all sessions, each lasting from 90 to 120 minutes. Focus group sessions were carried out in Poznan, although participants operated in several Polish cities (Poznan, Warsaw, Wroclaw, Gdansk, Katowice). Each participant represented a different company that employed more than 49 people.

During focus group sessions, some attempts were made to increase the reliability of responses, including asking for examples that supported participants' opinions (Suutari, 1998). Transcriptions were analyzed using content analysis by two researchers who independently coded each focus group session findings. All findings were coded in four individual-level and five organizational-level themes. Five weeks after focus group sessions, participants were contacted again, and they were asked to rank each variable according to the level of importance for the learning organization. Each participant created two rankings based on the individual and organization-level variables.

Before the focus group sessions started, respondents were familiarized with a “working definition” of a learning organization. They were also asked about factors that enhance or inhibit competitive advantage in their industries. Further, the interview was organized into two phases. First, managers were asked to identify the skills employees should possess and attitudes they should demonstrate to contribute to a learning organization development. Then, managers were asked to identify organizational practices crucial for developing such an organization. All responses were aggregated, and they were further grouped into nine themes based on the proximity in meaning. The detailed results of the study are presented in the following sections.

Results

Individual Characteristics Needed to develop a learning organization

The first part of each focus group discussion was focused on identifying the employees’ skills and attitudes needed to transform the company into learning organizations. The following question was asked: “What are the skills or competencies that employees should possess and attitudes they should demonstrate in order to contribute to the transformation of your company into the learning organization?”

The responses were coded in first-order concepts and then regrouped into four second-order themes (Table 1). Following Krippendorff’s (2018) framework for qualitative content, the analysis was applied to identify categories that were aligned with the existing literature, thus fitting theoretical considerations.

Table 1: Individual Characteristics Needed to Build a Learning Organization

First Order Concepts	Second Order Themes
Employees should: • Take a risk on new ideas to find out what works. • Invest the time in new experiments. • Take the initiative to pursue action-learning projects. • Continuously search for new ideas and solutions.	Innovativeness and Creativity

Employees should: • Actively search for information from different internal and external sources to make changes and develop skills. • Understand the value of constant learning and take responsibility for their development. • Use inter-departmental meetings as the opportunity to develop their knowledge. • Look for opportunities (new tasks, challenges) to develop skills and competencies. • Actively participate in training and development initiatives. • Actively participate in projects and different working groups to develop their knowledge. • Undertake new responsibilities to develop their skills.	Commitment to Self-Development
Employees should: • Be open to alternative solutions. • Be open to new ideas. • Not be afraid to admit the lack of knowledge. • Challenge organizational assumptions and continuously search for more effective solutions. • Discuss the weaknesses and strengths of their practices and solutions. • Be open to critical feedback and actively search for feedback.	Open-Mindedness
Employees should: • Openly communicate and share knowledge with employees from other departments. • Use social media, forums, blogs to share knowledge. • Share individual insights and knowledge openly with their coworkers. • Actively take the role of internal experts.	Commitment to Knowledge Sharing

Ranked positions of the individual variables are shown in Table 2.

Table 2: Rank Position of Individual-Level Variables

	Respondents Ranking of Individual Characteristics				**Weighted Tank**		
Individual Characteristics	No. 1	No. 2	No. 3	No. 4	Scores	Percent	Rank
Commitment to self-development	28	25	13	13	226	28.61	1
Commitment to knowledge sharing	22	28	21	8	222	28.10	2
Innovativeness and creativity	24	12	30	13	205	25.95	3
Open-mindedness	5	14	15	45	137	17.34	4
Total					790	100.00	

The first identified theme refers to a commitment to self-development, which was the most important attitude that employees should demonstrate in order to contribute to the transformation of their companies into learning organizations. Participants often mentioned that individuals should be responsible for their development and organizational learning depends on their motivation and commitment to improve skills and develop new competencies. Such observations were also noted in earlier studies (Simmering et al., 2003; Rasdi et al., 2011; Garavan et al., 2011). Managers in this study also pointed that employees should: "*look for opportunities to develop new skills and knowledge*"; "*like challenging and difficult assignments that teach new capabilities*"; "*like to work on things that require a lot of skill and ability";* or "*see learning and developing skills as important*."

The second identified theme refers to a commitment to knowledge sharing. Previous studies noted that organizational learning is not a simple sum of what individuals learn but is rather developed by social interactions (Easterby-Smith et al., 2000). In this study, participants frequently mentioned that leveraging learning orientation means encouraging individuals to interaction and dialogue. Through knowledge sharing, employees convey meaning, exchange different points of view, confront stereotypes, perceptions, and mental models. The interviewees often mentioned the need to: "*openly share information and knowledge with employees from different departments*"; "*actively search for information from different internal and external sources to make changes and learn*"; or "*participate in informal or formal initiatives to improve present or create new practices, routines, products*."

The next identified theme referred to innovativeness and creativity. According to the interviewees, a learning organization requires a constant search for new, more effective solutions and practices. Competing in dynamically changing local and global markets requires leveraging human capital's innovative potential. Innovation and entrepreneurship understood as encouraging employees to think independently and competitively are among the basic principles of the "excellent companies" (Peters and Waterman, 2004). Hamlet and Prahalad state that success requires "the capacity to bring about a revolution" that will start from organizations' middle or bottom (Hamlet and Prahalad, 1994). In this study, participants often claimed that in the learning organization, employees should: "*Take a risk on new ideas to find out what works"*; "*Be willing to invest their time in new experiments"*; or "*Continuously search for new ideas and perceptions*."

The last identified theme refers to open-mindedness, which comes from overcoming defensive behaviors, often cited by the interviewees. There are two aspects of defensive behaviors that might block the employee's learning orientation. First, people can be afraid to expose their opinions as they try to protect themselves from the embarrassment that they experience while exposing their reasoning (Argyris, 1985). The pressure to have the "right answer" as a sign of competence can block employees from exposing their way of thinking and from explaining the thought behind their opinions. On the other hand, defensive behaviors insulate people's mental models from examination (Senge, 1990), which prevents them from accepting new insights. Mental models are a perception of the reality, assumptions, and generalizations that influence how people understand the world and how they take action (Senge, 1990). During focus group discussions, managers underlined that to leverage learning orientation employees should be aware of the problem of defensiveness and understand a need for questioning mental models. They also mentioned that open-mindedness needs self-disclosure, constant inquiry, and willingness to question individual and group assumptions.

Organizational Practices That Support a Learning Organization

The second part of each focus group discussion aimed to diagnose organizational practices crucial for developing a learning organization. Therefore the following questions were asked: "What kind of practices are crucial for developing learning organizations?" and "How the organization should support individuals so they can contribute to the transformation of the company to the learning organization?"

The participants' responses for both questions overlapped. They were coded into first-order concepts and then regrouped into five second-order themes (Table 3).

Table 3: Organizational Practices That Support a Learning Organization

First Order Concepts	Second Order Themes
Managers should: • Support innovativeness by being open-minded to ideas and new solutions. • Commit to employees' development. • Create an open and trustful work environment. • See their primary task as facilitating experimentation and learning instead of controlling and knowing what needs to be done. • Understand their own limits and be open to alternative solutions. • Carefully listen to employees and respect different points of view.	Supervisor's support

Organizations should: • Encourage cross-functional teams to work on new challenges or solve existing problems. • Encourage employees to work interdependently in formal and informal teams to solve work problems and undertake new initiatives. • Encourage employees to share their ideas and exchange new knowledge. • Encourage employees to use creativity and share the outcomes of their experiments. • Systematically review successes and failures, assess them, and make the results accessible to employees. • Create and organize access to knowledge databases or/and experiences of other departments, projects, customers, competitors. • Encourage cross-functional (interdepartmental) meetings with the purpose of reviewing and discussing organizational decisions and potential areas for improvement. • Be a facilitator for knowledge acquisition from external entities.	Knowledge Creation, Internalization and Transfer
Top managers should: • Encourage open communication, creativity, entrepreneurship. • Actively support learning initiatives. • Provide vision and superordinate goals. • Create a learning culture with constant learning constituting the most important value.	Top Management Commitment to Learning
• Teams should be rewarded for innovativeness and idea-sharing. • Individuals should be rewarded for innovativeness, knowledge sharing, and taking new initiatives. • Motivational and performance evaluation systems should rely on individual development. • Failures in the application of new knowledge/new initiatives do not influence individual evaluation negatively.	Motivational system supporting learning
Organizations should: • Teach employees creativity skills and data analysis methods. • Develop employees' self-confidence, self-esteem, and self-efficacy, which are necessary for open-mindedness. • Help employees to understand defensive mechanisms and their influence on effectiveness. • Create different learning opportunities – projects, new initiatives, special tasks. • Encourage to question organizational assumptions and ineffective practices constantly.	Development of Learning Skills
Organization should: • Train employees on how to use creative techniques, data analysis methods, trend forecasting. • Develop employees' competencies that are the basis for self-confidence and self-efficacy needed for open-mindedness and inquiry-oriented behavior. • Provide workshops on internal and external issues (such as market trends, competitors' activities).	Learning Skills Development

The ranked positions of the organizational practices are presented in Table 4.

Table 4: Rank Position of Organizational Conditions

	Respondents Ranking of Organizational Conditions					**Weighted Rank**		
Organizational Conditions	**No. 1**	**No. 2**	**No. 3**	**No. 4**	**No. 5**	**Scores**	**Percent**	**Rank**
Supervisor's support	25	35	18	1	0	321	27.09	1
Knowledge creation, internalization, and transfer	19	19	32	8	1	284	23.97	2

Top management commitment to learning	19	23	17	18	2	276	23.29	3
Development of learning skills	9	2	12	31	25	176	14.85	4
Motivational system supporting learning	7	0	0	21	51	128	10.80	5
Total						1185	100.00	

According to the respondents of this study, one of the key conditions for developing a learning organization is the supervisor's support. Focus group participants agreed that the major role in fostering individual learning comes from middle or lower-level managers, who directly impact employees (Osagie et al., 2020). The issues addressed by respondents and assigned to this category portrayed managers as ones that facilitate followers' experimentation, create an open and trustful work environment, involve employees in decision-making processes, and encourage employees to inquire into the nature of complex issues and to analyze problems critically.

The next important theme refers to creation, internalization, and transfer of knowledge. This group's practices involve cross-functional teams, online knowledge sharing tools or creating networks to effectively exchange knowledge and information. Organizations should encourage their employees to be creative, experiment with new ideas, and undertake individual and team initiatives to exchange knowledge and learn from others. Other studies also supported the importance of experimentation (Birkinshaw, 1997; Lankester, 2013) and individual and group initiatives in learning and knowledge transfer (Wu and Chen, 2014). Wang and Wei (2005) believe that exploration is the source for emergent changes as it creates new knowledge that can be transformed into new solutions. Calvert and his colleagues (Calvert et al., 1994) stress that learning organizations learn faster and smarter than their competitors because they encourage risk-taking and the pursue of knowledge-sharing initiatives.

Knowledge creation involves modifying existing knowledge and present practices and leads to better decision choices (March, 1991). The benefits of knowledge creation are demonstrated in the refinement of existing knowledge and learning, which results in lower transaction costs and better decision choices. Respondents highlighted the importance of reviewing past successes, failures, and organizational decisions to improve future actions. They also emphasized the necessity for easy access to knowledge databases where employees can use and build on the experiences of other departments, projects, and various organizational stakeholders. Other studies also included knowledge creation and acquisition in their learning organization concepts stressing the importance of reflecting on past projects (DiBella et al., 1996) and assimilating knowledge from other entities (Huysman, 2000). In this study, participants also mentioned the need to: "*systematically review own successes and failures, assess them and make the results accessible to employees," "develop lessons learned repositories," and "assimilate knowledge from other organizations – suppliers, clients, business partners, and research institution."*

An equally important theme in this category was top management support for learning. The majority of respondents underlined the importance of senior managers' highest commitment to promoting open communication, creativity, entrepreneurship, knowledge flow, and shared vision. Senior managers' support was also found to be an important imperative for the learning environment in other studies (Calvert, 1994; Leitch et al., 1996; Özsomer and Genctürk, 2003; Baker and Sinkula, 2005). Authors discuss the top management role in energizing organizational learning, guiding for integrated efforts, and creating a commonality of purpose, which were also identified as important in this study.

The next important theme referred to the development of learning skills. Training and development are claimed to be a core dimension of a learning organization in a number of studies (Griego et al., 2000; Chiva-Gómez, 2004; Marquardt, 2011). Participants of this study often underlie the importance of supporting employees with the development of "learning skills." This label was adapted from the work of Tjepkema and Scheerens (1997) and Kolb and Kolb (2005). Participants stated that skill-development programs focused on expanding learning competencies and abilities help employees act proactively and evaluate experiments more effectively. In a learning organization, employees should also be taught competencies and skills that help them reflect on and articulate personal vision, understand interdependencies, and balance advocacy and inquiry (Downe et al. 2012). Participants often underlined that these competencies should be developed not only on a personal level but also practiced collectively. They also stated that the development of learning competencies are the basis for self-confidence and self-efficacy needed for open-mindedness and inquiry-oriented behavior, crucial for a learning organization.

Managers participating in this study also believed that a learning organization needs a motivational system that supports employees' learning-behavior, an observation often found in the earlier studies (Garvin, 1993; Remedios and Boreham, 2004; Chiva-Gómez, 2004; Marquardt, 2011). Interviewees stated that organizations should support reward systems that favor knowledge sharing, new initiatives, innovativeness, and entrepreneurial behaviors. They also stressed that "*failures in applying new knowledge or initiative should not influence individual evaluation negatively*," which was a common challenge in their organizations.

Overall, our study identifies four individual-level and five organizational-level themes. While they are believed to influence a learning organization development, organizational practices influence the learning organization directly and indirectly through stimulating individual skills (innovativeness and creativity, and open-mindedness) and attitudes (commitment to self-development, and commitment to knowledge sharing).

Conclusion and Implications

The primary determinant of a firm's performance is its ability to quickly respond to market changes. Post-modern organizations rely heavily on information and knowledge and their application in the decision making process. They frequently transform to be responsive and to quickly detect market changes. This naturally brings much more attention to employees, their knowledge, abilities, and motivation to continually question their assumptions and practices to search for better alternatives. It is believed that market responsiveness and organizational ability to transform knowledge into valuable products and services can be leveraged if the organization is capable of creating a learning environment (Huysman, 2000; Senge, et al., 2012; Basten and Haamann, 2018). In this study, a learning organization is defined as an organization that supports knowledge sharing and creativity and encourages employees to change obsolete or ineffective practices and processes to leverage organizational responsiveness to changing market demands. Such an organization quickly detects market changes and reacts to them faster than competitors.

This study's main purpose was to examine which factors contribute to the development of a learning organization. Our framework based on in-depth focus group discussions with 79 managers stresses the importance of individual-level qualities (open-mindedness, innovativeness and creativity, commitment to self-development, and commitment to knowledge sharing) and organization-level practices that might leverage individual learning orientation. The learning organization is an organization that continuously and intentionally reflects on those practices and investigates their influence on employees' attitudes and behaviors.

The outcome of the study is undoubtedly beneficial for practitioners that want to increase organizational responsiveness. An effective way of stimulating employees to be committed to changes, entrepreneurial behaviors, and knowledge sharing enables the transformation of knowledge into valuable products and services, which is critical for competitiveness.

This study also adds new insights to the current literature. It empirically uncovers opinions and observations about a learning organization. As little empirical studies have been published in this field in Central and Eastern Europe, the study results can be particularly valuable for researchers seeking to expand their research studies to the emerging economies of Central and Eastern Europe.

The study's limitation lies in a relatively small number of respondents that might not be representative of companies located in Poland. Further, since the focus groups were conducted only within companies operating in Poland, the results might not be applicable to organizations located in different, especially culturally distant countries. Many studies posed a series of questions about the applicability of a learning organization paradigm in various countries (Lien et al., 2007; Jamali and Sadini, 2008). Further studies would therefore be needed to ascertain whether the Polish work environment has lent a certain degree of bias to the study. Replicating the study in other cultural settings would be necessary to ensure the validity of findings.

Nevertheless, the findings of this study can be further used to create a learning organization measurement instrument. The available literature on learning organization is abstract and confusing (Pedler and Burgoyne, 2017) and pays more attention to defining and describing than measurement (Jamali and Sidani, 2008). We hope this study provides insights on which subsequent studies can be built and that it can contribute to the future development of the learning organization practice.

Acknowledgment

The study is a part of a bigger research project on organizational learning financed by the Polish National Science Centre (no. N N115 410740).

Abstract:

Social support in the working environment could be considered as one of the significant elements influencing laborers in different aspects of their work, such as work fulfillment, efficiency, and prosperity. As the literature indicates, social support in an organization comes from supervisors or colleagues. Another finding of the research is that emotional intelligence has an impact on employees' attitude, level of commitment, and on several job outcomes. The expected result is a significant negative association between supervisor support, co-worker support, emotional intelligence and turnover intentions. This study will contribute to the existing body of knowledge in the UAE and would be crucial in exploring social support and emotional intelligence related to turnover intention among employees of governmental and private universities.

Keywords*:* Turnover intention; Supervisor; co-worker; Emotional intelligence; UAE.

Introduction

In a growing economy, employee turnover is said to be an invisible enemy. It has now become a new challenge to UAE businesses, where the mobility rate of a skilled employee is notably high (Haak-Saheem and Brewster, 2017; (Ewers, 2017). It also results in a considerable loss of resources for organizations and causes great harm to their competitive positions (Ayodele et al., 2019).). The average number of years for which employees stay with organizations is 6 years; this indicates that there is a high turnover rate among the workers (Ibrahim and Perez, 2014). In another study conducted in the UAE, the impact of different factors (performance, satisfaction and job trust) on turnover intention was examined in public and private organizations. The study found that public sector workers have lower turnover intentions as compared to private sector workers (Zeffane and Bani Melhem, 2017). Similarly, a study by Al-Ali et al. (2019) on oil and gas organizations in the UAE found that turnover intention was directly and negatively associated with job satisfaction (Al-Ali et al., 2019).

Understanding the process of turnover may help companies take suitable action in order to eventually reduce the level of turnover, which will in turn lead to a reduction in costs, an improved work outcome and a high productive capacity (Hausknecht and Holwerda, 2013). The issue of voluntary turnover has been thoroughly examined during recent years. For example, experimental studies have demonstrated that a high rate of voluntary turnover is expensive for organizations since it negatively influences authoritative viability and achievement (Rahman et al., 2013). Losing a valuable worker can adversely impact an organization's competitive advantage, bringing down the morale of the rest of the staff (Agarwal et al., 2010), which in turn decreases profitability and work quality (Holtom and Burch, 2016). If a worker perceives a negative overall impression of an organization and its policies, their intention to leave an organization will increase. This, in turn, may give more impetus to search stable and secure employment.

A few factors have been associated with workers' turnover: correspondence at the workplace, work conditions, the tasks they receive, compensation/salaries and benefits (Stamolampros et al., 2019; (Hantoft and Boman, 2017; (Hsiao and Lin, 2018). Nevertheless, the social contributors of turnover received markedly less attention in academic research. Some ongoing investigations found three social components: interpersonal support, supervisory help, employee commitment, and workers' retention (Bedarkar and Pandita, 2014). Additionally, some external factors such as the key attributes of the organization, financial concerns, individual conflicts, or the chance to have more

advanced professions might push employees to leave the existing organization (Arnoux-Nicolas et al., 2016). Social support in the work environment can be considered one of the most significant elements influencing laborers in several aspects, including work fulfillment, efficiency and prosperity (Rehman, 2018; (French et al., 2018). Research has likewise recognized social factors as significant supporters of representative turnover (Brassard and Méthot, 2006).

The present study discusses three aspects and their separate integration in relation to the turnover intention. Studies by Scott et al. (2014) and Chadwick et al. (2015) reported the negative influence of co-workers' and supervisors' support on employees' intentions to leave an organization. It can be stated as an inference of the literature search that the social support, such as supervisor's and other co-workers' support, play a crucial role in an employee's intention to leave an organization (Wongboonsin et al., 2018). This notion is also consistent with Maslow's hierarchy of needs (McLeod, 2007). According to Maslow's pyramid, the need for love and belonging comes after the basic physiological and safety needs. This implies that even if a person's basic needs are being fulfilled, if their psychological needs are not met, they most likely will not be content. Therefore, in order to realize or fulfill one's talents and potentialities in a workplace, supervisors' and co-workers' support become instrumental. Since the majority of recent research has been conducted in the western world (French et al., 2018; (Scott et al., 2014; (Chadwick et al., 2015; (Lambert et al., 2016), there is a need to identify the factors that lead to employee turnover or turnover intention in the UAE, especially among high skilled professionals.

Emotions and their management have been found to have a notable influence on employees' attitudes and behaviors; therefore, they have now received increasing attention in organizational management and psychology research (Ashkanasy and Humphrey, 2011). Emotionally intelligent workers know how to perceive and use their emotions to regulate complex relationships in the workplace (Siegling et al., 2014). Thus, emotional intelligence has an impact on employees' attitude, their level of commitment, and on several job outcomes (Amjad, 2018). Furthermore, employees' physical, mental and professional development also depends on it (Luthans et al., 2014).

The role of the above components has not been previously explored in a UAE setting. Also, it is not clear how these elements interact with each other and with turnover intention, and this is the fundamental focal point of this piece of research. Exploring the idea of such relationship and whether these elements have a pivotal role in UAE would greatly help in developing proof-based management strategies that result in a decrease in workers' turnover among local workers in universities. This study will examine the individual effects of supervisor and co-worker support as well as emotional intelligence on the turnover intention process. The subjects of the study will be employees of both governmental and private universities. In the end, the findings of the study will be presented along with a comprehensive conclusion with recommendations.

Literature Review And Hypothesis Development

A. Supervisor support and turnover intentions

Lambert et al. (2016) highlighted in their study that if the management of the workplace monitors the work overload on the employee and the relationship between supervisor and their assistants, this can lead to increased employee work satisfaction and commitment to the workplace (Lambert et al., 2016). Empathy and encouragement from supervisors, or lack thereof, are often cited as the most influential factors in a person's decision to stay at or quit their workplace (Wongboonsin et al., 2018). If an employee feels that they are actively encouraged and that their supervisor openly expresses their support, they are less likely to leave their current workplace (Malik et al., 2020). Another study reported that social support such as that of a supervisor's plays a crucial role in an employee's intention to leave an organization (Chadwick et al., 2015; (Alkhateri et al., 2018). In another recent study (Alén et al., 2017), researchers asserted that social support (managers or supervisors) acts as a motivator for employees; they get intrinsic enthusiasm towards their work that helps in reducing employee intention to quit. On a similar note, Mathieu at el. asserts that a supervisor's person-oriented attitude has a negative impact on the employee's intention to leave an organization as compared to their task-oriented or leadership attitude (Mathieu et al., 2016). Based on above literature review, the first proposed hypotheis of the study is the following:

Hypothesis 1: Supervisor support has significant negative effect on employee turnover.

B. Co-worker support and turnover intentions

Beehr and McGrath (1992) described that caring, co-workers' willingness to help each other, empathy, appreciation, respect and support are beneficial in fulfilling daily activities in the workplace, and can also alleviate troublesome circumstances. Therefore, co-worker support is considered to be the most important factor that affects employees in various aspects. It is defined as colleagues' willingness to support and assist each other while performing their routine tasks, thereby reducing work stress (Beehr et al., 1992). Similarly, if one finds social companionship with the people

working alongside them, it creates a more relaxed and encouraging work environment. This in turn establishes a more personalized connection between a person and the organization, and such people are less likely to leave (Karatepe and Olugbade, 2017; (Lavy et al., 2017). (Scott et al., 2014) reported the negative influence of co-worker on employees' intentions to leave an organization.

Hypothesis 2: Co-worker support has a significant negative effect on employee turnover.

C. Emotional Intelligence and turnover intentions

Emotional intelligence (EI) is an individual's capacity to adapt to the workplace, which includes several elements like self-regulation, self-awareness, self-motivation, sympathy, and communication (Khanifar et al., 2012). It has been an area of interest for many researchers of both management and psychology. The research on this topic has evolved back in 1990 when EI's first paper was published by Salovey and Mayer, 1990. Researchers of management studies stated that EI is a predictor of workplace outcomes (Jordan and Troth, 2011). Another researcher reported that emotions are an essential part of organizations, but only a few studies have focused on their role in the workplace (Bande et al., 2015). One previously published research paper showed negative association of EI and turnover (Firth et al., 2004; (Akhtar et al., 2017). Similarly, it was also posited that the higher the emotional intelligence, the lower the workers' turnover intention (Wong and Law, 2002). Higher levels of EI are significantly associated with low stress levels, anxiety, burnout and turnover (Karimi et al., 2014). Mayer (1997) Mayer (1997) postulated that workers with higher levels of EI showed high performance and therefore they had low turnover intentions. Similarly, a study that explores the relationship between emotional intelligence and turnover intentions among nurses found emotional intelligence to have a negative influence on turnover intentions (Trivellas et al., 2013).

Hypothesis 3: Emotional intelligence has a significant negative effect on employee's turnover intention.

Employee Turnover Intention

By definition, worker turnover is the movement of employees around the labor market, in between companies and among the states of employment, unemployment and inactivity (Burgess, 1998). Employees' intention to leave an organization or turnover intention is a measurement of an organization's work plan to quit their present position (Curtis, 2019). Workers leave their jobs for many reasons, including better pay, relocation of one's spouse, unfavorable behavior exhibited by colleagues or supervisors, low job satisfaction, or in some cases, they are simply fired (Horning et al., 2019; (Goler et al., 2018).

There are two types of employee turnover mostly found in the literature: voluntary and involuntary (Memon et al., 2016). However, some authors further categorize these types into four classifications (Heneman et al., 2003; (Morrell et al., 2001) which are functional, avoidable, downsizing and discharge. Voluntary turnover is initiated by the workers themselves (Udechukwu, 2009). It is further broken down into four more categories on the basis of functionality (Dalton et al., 1982; (Abdali, 2011) and avoidability (Abelson, 1987; (Curran, 2012). Dysfunctional turnover is the resignation of a skilled employee or high performer, who is difficult to replace, which might be harmful to the company. Thus, the organization is usually focused on and concerned with retaining such employees (Allen et al., 2010; (Dalton et al., 1982; (Heneman, 2009). Functional turnover is the exit of poorly performing employees, who are not difficult to replace. This is somewhat troublesome but not harmful and could be, in a sense, beneficial to an organization (Allen et al., 2010; (Heneman, 2009). Avoidable turnover could be potentially prevented by certain actions taken by the employer, like increasing salaries, or by giving new favorable job assignments (Allen et al., 2010). Unavoidable turnover occurs in unavoidable circumstances, such as the death of the employee or the relocation of an employee's spouse (Burgess, 1998).

Involuntary turnover is initiated by the employer or organization, independent of the affected worker(s) (Morrell et al., 2001; (Curran, 2012). It is further divided into two more categories. Firstly, discharge turnover is the dismissal of an individual employee for their job problems, performance and/or discipline. It also referred to the termination of dishonest workers from the organization (Rubenstein et al., 2019). Secondly, downsizing turnover is done to improve a company's effectiveness and the growth of shareholder value. The company initiates cost-reduction or restructures the program (Holtom and Burch, 2016).

This differentiation is important for an organization to make strategies for the reduction of turnover, especially voluntary dysfunctional and avoidable turnover, as these workers are those on whom the companies invest and, therefore, want to retain (Parker and Gerbasi, 2016). There is a common misconception that all turnover is the same and that it is always negative. However, the reality is that there are different forms of it, the cost varies across the different types (Parker and Gerbasi, 2016).

Turnover intention or turnover plan is a behavioral tendency of a worker to attempt to quit their workplace. Turnover intention is one of the strongest predictors of voluntary turnover. Unlike actual voluntary turnover, it is not definite (Sousa-Poza and Henneberger, 2004). In the same way, Cho et al. described turnover intention as an employee's voluntary decision to quit their present organization (Cho et al., 2009). Extensive literature has been found in the fields of psychology and economics on the analysis of turnover intention (Sousa-Poza and Henneberger, 2004; (Cohen, 2000; (Mobley, 1977). Such intention to quit is a direct precursor and is good at predicting actual turnover (Mobley, 1977; (Steel and Ovalle, 1984). Thirapatsakun et al. (2014) divided workers' intention to leave an organization into three cognitive mechanisms: thinking of leaving the job, having the intention of looking for another job, and, lastly, having the intention of leaving the job. Thus, turnover intention directly affects the actual turnover decision, and this decision leads to various unwanted consequences, both for the company and worker.

Conceptual Framework And Theoretical Backgroud

Based on the above debates in the literature, a somewhat inconclusive relationship was found between social support (supervisor and co-worker), emotional intelligence and turnover intention. To date, very little is known about the interplay of the dimensions of workplace supervisor and co-workers support and emotional intelligence as predictors of employee turnover intentions, and there is a lack of theoretical framework. Therefore, the researcher intends to develop a conceptual model that links social support, emotional intelligence to turnover intentions to present a tool for measuring the causality between these, as shown in figure 1. On the basis of performing a thorough investigation of the recently available published literature and theories that represent social support, EI and turnover intentions, the researcher utilized the social exchange theory for social support and the Hybrid model for EI to develop this link.

The social exchange theory works on grounds of reciprocal (give and take) relationship centred on word of honour and responsibilities. The central link between public and private employee and organization is an optimistic employment association, from the perspective of an employee, which comprises of three social exchange theory concepts; organizational support, psychological contract and job security (Latorre et al., 2016; (Ertürk, 2014). In a similar way, Goleman Hybrid model emphasizes the importance of emotional intelligence and its active role in high work performance of employees and subsequent satisfaction and retention (Goleman, 1996). The implementation of such theories in both private and public sectors universities would enhance employees' performance towards their responsibilities and their pledge to the organization and will inspire them to devote their energy and determination into given task.

Figure 1 : Initial Conceptual Model for measuring the impact of component of research thesis.

Research Methodology

This will be a cross-sectional study with the purpose of investigating the effects of social support and emotional intelligence on employees' turnover intention in a UAE setting. The employees will be assessed for their turnover intention and its predictors or determinants such as supervisor support, co-workers' support, and emotional intelligence. The study will be conducted at a number of universities, including private and public universities, across the seven Emirates of the UAE. The public universities will consist of the Higher Colleges of Technology, UAE; Zayed University; and United Arab Emirates University (UAEU). Similarly, the three private universities will be the American University of Sharjah, the American University in Dubai, and Abu Dhabi University.

Approximately, more than 5000 employees are working in six universities in the UAE; therefore, when taking this number into consideration and using an OR of 0.70, it was found that a minimum of 537 employees will be required to conduct this study at a 5% level of significance or a 95% level of confidence, keeping a power of 80%. Since an online questionnaire will be sent to the employees, the anticipated response rate is 60%. Therefore, the sample size was overestimated based on the assumed response rate. Thus, after considering a response rate of 60%, the sample size was inflated to 752 in order to achieve the actual sample size of 537 employees. A multistage sampling method will be used to select the employees from the existing databases of various departments.

Expected Results and Implications

The expected result is a significant association between supervisor and co-worker support, and turnover intention. Additionally, emotional intelligence is expected to have negative effects on turnover intention behaviour. The results would support the research question, all the hypotheses, and the proposed framework for this research.

Conclusion And Future Work

In conclusion, this study would not only aim to explore the role of supervisors' and co-workers' support and emotional intelligence in employees' turnover intention but the analysis of this report will also provide a clearer picture of the turnover intention rate in UAE as well as the impact of the study's variables on the turnover intention of employees. This will be very important on a national level as most studies set in the UAE have only attempted to explore the role of job satisfaction and personal factors over the turnover intention. In order to reduce the turnover, it is crucial to explore social support and emotional intelligence, and their impact on turnover intention. Hence, it is important to apply social and emotional intelligence theories to a local setting to gain a better understanding of the underlying sociological, psychological and religious needs and aspirations of the local workforce, as these influence their intentions and decisions to search for opportunities elsewhere. Thus, this study would be crucial in exploring social support and emotional intelligence's relationship to turnover intention among the employees of governmental and private universities.

Abstract

Considered to be one of the most disruptive innovations paving the way for the development of new business models, the blockchain technology is heavily ingrained in the strategic thinking of companies that are exploring ways to unleash its power in a variety of realms. However, the adoption of blockchain technology requires an overarching approach above and beyond its technological component. Drawing on the extant management and marketing literature on blockchain technology, this paper proposes a conceptual framework for its adoption which integrates the relationships between technological, organizational, environmental factors, while also adding the consumer behavior as a standalone factor that influences the adoption of this technology. The authors took a holistic approach by incorporating both intrinsic and extrinsic factors as well as the associated complexities that ultimately influence the adoption decision-making process. The proposed framework can be used by organizations as a starting point in their journey to embracing this disrupting technology as well as by scholars willing to refine and further expand the research on the adoption of blockchain technology.

Keywords: Blockchain technology, Distributed ledger, Adoption, Consumer behavior.

Introduction and literature review on blockchain technology

The last two decades have been marked by an exponential increase in disruptive technologies and innovations including artificial intelligence, cloud computing, big data, blockchain technology. We are currently experiencing the fourth industrial revolution (Industry 4.0) that is clearly changing the way people live, think, work and relate to each other (Capgemini, 2018). The blockchain technology is considered one of the most important technological innovations and perceived as the hallmark of Industry 4.0 (Kimani et al., 2020).

In its most fundamental form, a blockchain is a decentralized database of records distributed across computational nodes and structured as a linked list of blocks, each of them including details connected in chronological order (Angelis & da Silva, 2019; Crosby et al., 2016; Lopez et al., 2020; Oh & Shong, 2017). Each block in the chain comprises transaction information which is cryptographically hashed (Rajnak & Puschmann, 2020). This technology has high capabilities and can secure the reliability and the integrity of the transaction records by having all the participants in the Peer-to-Peer network develop, record, store and verify information via a consensus mechanism (Kher et al., 2020; Oh & Shong, 2017; Rhasideh, 2020).

While the literature on blockchain technology is still in an emergent state, it is clear from early research that a broader and more holistic view is needed for organizational adoption. As with most disruptive technologies, it is vital for organizations to assess and understand the determining factors for the adoption of blockchain, together with the potential challenges and complexities associated with the exploitation of this disruptive technology. Therefore, we place our research in the context of digitalization of business models that are fundamentally changing the interaction between companies and their customers. This new competitive reality requires organizations to be agile in their quest to becoming intelligent, as their service interface will become a technology-dominant one (Toader et al, 2019). This paper is structured as follows: the first section provides an overview of the blockchain

Cite this Article as: Diana-Cezara TOADER, Corina RĂDULESCU, Graţiela BOCA,Rita TOADER Florina HAHN, Cezar TOADER and Diana IGIAN "Scrum Solo: Application in Projects with a Strong Integration Component" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

technology, the main characteristics and areas of applications. Next, we describe our research approach and provide a literature review on blockchain technology adoption where we outline the determinant factors and complexities associated with its implementation. In the following section, we present our conceptual framework for a holistic decision-making process for blockchain technology's adoption. We conclude the paper with a series of conclusions, followed by limitations and directions for future research.

Sultan et al. (2018) formalized the characteristics of blockchain into four core dimensions: immutability, decentralization, consensus-driven approach and transparency. First of all, the blockchain is temper-proof as it contains a permanent record of transactions and whenever a new block is added to the chain, it cannot be altered. This is particularly important for building trust in the distributed ledger and its records. Decentralization implies that the information can be accessed and copied by any participant in the network. Therefore, blockchain is permissionless as each party gave up control of their data and power was dispersed away from a central authority. In addition, blockchain is leveraging a consensus model which provides clear rules for verifying the validity of transactions and how information has been created by the majority of participants. Hence, blockchain allows for going beyond a simple database custodianship and focus on the usage and data manipulation as well as on how value can be best extracted from it (Corsby et al, 2016; Jannsen et al., 2020; Upadhyay, 2020). Also, since transactions are verified by a distributed network, the blockchain is perceived as being free of human errors, while also eliminating the third-party intermediaries. Lastly, transparency allows for access to a full transaction history that can be accessed by any party. Given that, trust and transparency are considered to be at the heart of its revolutionary benefits (Frizzo-Barker et al., 2020).

Since the fundamental objective of blockchain technology is to ensure transparency and substantiate accuracy of information across the digital ecosystem, its capabilities can be translated in practical applications in every industry (Sultan et al., 2018). According to Swan (2015), its benefits are more than just economic ones as they also expand into the social, humanitarian, political and scientific domains. There are three main areas that organizations can leverage when adopting this technology: currency (e-payments systems, currency remittance and transfer) with Bitcoin being the most famous illustration of how blockchain can be used for digital payment systems, smart contracts (financial markets) and social applications beyond currency and financial services. The latter can also target endless fields and industries, ranging from the legal field (notary), government applications (voting, electronic IDs), supply chain management, retail, insurance to healthcare industry (health records) (Angelis & da Silva, 2019; Crosby et al., 2016).

The blockchain technology enables new organizational forms and business models, while also facilitating the transition from hierarchical organizations to self-organizing economies. Blockchain creates a myriad of opportunities for how value can be transferred between participants in a trusted and convenient manner (Capgemini, 2018). Its advocates perceive this technology as the underpinning element for trust-free transactions (Upadhyay, 2020), while Swan (2015) advocates for its inclusion as an economic overlay to the seamlessly connected world.

Factors affecting adoption of blockchain technology

The blockchain technology has been the subject of a rapidly growing body of research in the past years. Most of the current literature focuses on the main characteristics of the distributed ledger technology, advantages and disadvantages, areas of applicability as well as the technical difficulties associated with the adoption of this innovative technology. In order to develop the conceptual framework, the authors reviewed the extant management literature and identified the main determinants of the blockchain technology's adoption. Our literature review revealed a number of diverse endogenous and exogenous factors as well as their interdependence that organizations need to consider when adoption a disruptive technology as blockchain.

We categorized these factors based on the TOE framework which was developed by Tornatzky and Fleischer (1990). This framework emphasizes the technological innovation decision-making that it is impacted by 3 determining factors: technological, organizational and environmental. The technological context relates to all the relevant technologies to the companies, both the ones that are already implemented within the organization and the new technologies that are available on the market. This factor is particularly important in the decision-making process as it establishes a limit on the scope, breadth and the pace of technological innovation that a company is able to undertake. The organizational context refers to the internal characteristics of the firm and to the amount of available resources that can be committed for technological innovation purposes (Baker, 2011). The last determining factor, the environmental one, analyzes the structure of the industry, the regulatory environment and the presence of technological service providers, and is considered a very important element in analyzing disruptive technologies (Chen et al., 2020). Besides the technological, organizational and environmental factors, we decided to further enhance this research with an element that is essential in the adoption decision-making process, namely the consumer behavior.

Technological Factors

The blockchain technology can be leveraged to solve a variety of problems across different industries by providing increased transparency, trust and reliability of data processing. Nevertheless, the complicated engineering aspects of the decentralized networks can introduce several important adoption challenges to the organizations.

a) Scalability

The blockchain technology is still considered to be in its infancy, although it has experienced a quick development in the past years. Questions over the technical scalability of the network have been raised given that this will play a critical role for high volume transactions like in the case of listed securities (ESMA, 2017). The current standard of the technology remains some way behind the levels required to support adoption in capital markets and this can put a serious strain on the further adoption of blockchain technology, especially for public distributed ledgers. The legacy transaction networks such as Visa are capable of processing thousands of transactions per second, while the two largest blockchain networks, Bitcoin and Ethereum, register way lower transaction speeds (the first seven transactions per second, while the latter can handle approximately 20 transactions every second) (Oliver Wyman, 2016; Batubara et al., 2018; Finextra, 2020). Nevertheless, according to the latest Global Blockchain Survey conducted by Deloitte (2020), 88% of the surveyed executives believe that the blockchain technology is scalable and will eventually become mainstream.

b) Standardization

Across all industries where blockchain applications proved their feasibility, many organizations have engaged in the development of standalone blockchain platforms that rely on different coding languages, protocols and consensus mechanisms. The presence of a large number of blockchain networks leads to a lack interoperability that defeats the purpose of distributed ledgers, as firms cannot exploit the network effects (Finextra, 2020). As a consequence of this lack of standardization, the stored data is not in line with the market standards and takes away consistency from basic processes like security, making mainstream adoption an almost unachievable endeavor (Finextra, 2020). The adoption of blockchain technology will require harmonized technology standards in order for the industry players to be able to focus on developing value-added services for their customers by leveraging a well-developed and secured infrastructure (Swan, 2015; Janssen et al., 2020).

c) Cost of adoption

Even if blockchain applications are expected to bring a lot of economic benefits, the initial investment may be considerable, particularly in the case of companies with massive back-office operation and complex legacy systems that would need to be replaced. This can create a lot of challenges for the current operations of those organizations besides the implied higher costs (Crosby et al., 2015; Deloitte, 2016).

Integration with legacy systems

Another potential challenge to the adoption of blockchain technology refers to the integration of the distributed ledger with the legacy systems, which are usually deeply embedded in the enterprise. This makes them critical for the everyday operations and the potential requirement to be completely restructured is definitely not an easy decision for the executives. Moreover, there is a high probability of information loss and data corruption which is discouraging more companies from transitioning to blockchain technology (Finextra 2020).

d) Security concerns

The successful adoption of this disruptive technology depends on the efficiency of the risk management associated with distributed ledgers, which is particularly important as the blockchain is part of the companies' core infrastructure. Even though the distributed ledgers are resilient, the business processes built on them may still be vulnerable to technological failures as well as cyberattacks (Deloitte, 2018). Also, since the blockchain technology is still considered to be in its infancy, the networks can still be subject to technological failures. There is a 1.5-5 percent probability of errors for each 1000 lines of code (Janssen et al., 2020).

Organizational Factors

a) Understanding of the blockchain technology and its applicability

One of the main challenges associated with the blockchain's adoption by firms, especially the small and medium ones in sectors other than financial services, is a widespread lack of understanding of how it works and how it can

be leveraged to benefit those firms (Deloitte, 2016). This fact was reiterated in a survey conducted on C-level corporate executives by the Risk Assistance Network Exchange (2020). They found that 40% of the senior managers who had not adopted this innovative technology yet do not have a clear understanding of blockchain or its benefits. This is significantly hindering a more widespread adoption of this disruptive technology.

b) New business models

Batubara et al. (2018) argued for another two main barriers to blockchain's adoption from an organizational point of view: acceptability and the need for new governance models. Indeed, the reconfigurations of the current business models might be complicated and cumbersome (Swan, 2015) and there are companies that are reluctant to the blockchain's disruptive character, since it involves approximately 80% business process transformation and a loss of control due to its decentralized network. This can be perceived as unsettling by many organizations, since it represents a massive shift away from their traditional ways of conducting business activities (Finextra, 2020).

c) Strategic orientation of the management

Clearly, the strategic orientation of the management in deciding the appropriate technology adoption path for their company is another decisive factor for the adoption of blockchain (Angelis & da Silva, 2019). Nurryev et al. (2019) argued that the strategic orientation of the management has a significant effect on the behavioral intention to adopt the blockchain technology for transactions. Moreover, Kamble et al. (2018) found that the practioner's adoption behavior gets influenced depending on how other important people to them have reacted to the usefulness of the blockchain technology. Also, Deloitte (2020) found that the blockhain sentiment among executives is following an improvement pattern, as a growing number of leaders are seeing it among the top five strategic priorities for their companies. This facilitates investment, confidence as well as the advancement of initiatives with transformational potential at the firm level.

d) Scarcity of qualified talent

Lastly, another challenge faced by the organizations is the limited pool of qualified talent required to adopt the blockchain technology. Currently, there is a shortage of adequately trained and skilled workforce who can develop and further manage the complexity imposed by the blockchain technology. According to IBM (2020), the demand for blockchain skills significantly increased by almost 2,000% in the past three years.

Consumer Behavior

Knowledge and understanding of the blockchain technology

Customers play a vital role in the blockchain technology adoption and organizations need to develop a clear understanding of its societal impact and of how this disruptive technology can benefit their customers. Some of the challenges associated with its adoption are rooted in consumers themselves. Recent studies show that there is a limited knowledge and understanding of blockchain technology among customers. When looking at the potential benefits from the consumers' perspective, the blockchain technology has the potential to ensure a high level of transparency in their purchases, reduce the transaction costs, improve their privacy as well as refine social interactions. These advantages potentially power-up consumers in their transactional encounters. Nevertheless, not many customers are aware and actively engage in the use of Blockchain-based applications (Knauer & Mann, 2020).

A survey conducted by HSBC in 2015 showed that 59% of the respondents have never heard of the blockchain technology, while 80% of those who heard of it do not really understand what this technology entails. Another report released by Bank of Canada (Schuch & Shy, 2015) shows that even though many customers had heard of crypto currency, they were unfamiliar with the basic mechanics of the underlying blockchain technology. Kumpajaya and Dhewanto (2015) empirically demonstrated that customers' knowledge of the technology is a relevant acceptance predictor. Hence, increasing the level of awareness can be critical for further adoption.

a) Resistance to change

Crosby et al (2016) argue that the adoption of blockchain technology depends on how successfully it overcomes the cultural resistance of the customers. The decentralized and distributed ledger eliminates the tangibility of the transactions through third parties, hence consumers need to gain trust in this disruptive technology. The greater freedom provided by blockchain applications comes with a higher degree of responsibility that would require a behavioral change on the customer's side. On that note, Woods et al. (2017) presented an important barrier to

blockchain's adoption, namely the security concerns. Although the blockchain technology seems to be difficult to be hacked, its decentralized nature implies that the individual nodes on the network cannot be fully secured and therefore, they are prone to be subject to malicious activity.

b) Social Influence

Social influence, reflected by the extent to which an individual places importance on the views of others, represents an important antecedent of the technology adoption behavior and on the behavioral intention to use it (Nuryyev et al., 2020). Due to the fact that blockchain is still perceived as being linked to the crypto world in the mind of many customers can be considered a reputational challenge, as the crypto world is often perceived as a venue for illicit activity (Finextra, 2020, Swan, 2015).

Environmental Factors

a) Industry structure

The blockchain technology will most likely disrupt the current industry structures due to its potential to become the new open-standard protocol for transactions, contracts and records. According to McKinsey (2018), sectors like financial services, healthcare and government are the ones capturing the greatest value from the decentralized ledger technology as their industries' functions are innately more suited to blockchain solutions.

In case the current incumbents have already adjusted their business models to enable themselves to derive value from blockchain applications and further improve their consumers' experience, then the barriers to entry for other players will be high (McKinsey, 2018). According to Varma (2019), the organizations willing to adopt this disruptive technology need to set the seal on the commercial viability of their blockchain applications in order to successfully face the competition from incumbent players who besides being powerful and rich, they are also well-ingrained in the current legal and regulatory landscape. Also, it is obvious that companies engaging in the development of blockchain solutions by themselves will face serious implementation challenges in terms of scalability and internal buy-in, as blockchain's benefits are best exploited from network effects when players are jointly creating a shared platform (PwC, 2018). Companies will be able to capture the most value from this technology by tailoring their blockchain strategy to their market position, while also taking into account the already established standards, the shape of the ecosystem as well as the legal and regulatory environment (McKinsey, 2018).

b) Legislation and Regulation

Given that the blockchain technology has assumed an increasingly prominent role in the society, its adoption across various industries and fields has caused tension, especially in the areas traditionally subject to extensive regulation, such as financial services sector (money transmission, capital raising). It is clear that the assumptions crafted in the regulations decades ago are now being challenged by the disruptive nature of blockchain technology. Even though numerous federal and state agencies recently started to regulate some of the blockchain applications, there is still a disparate approach across countries and sectors that lead to confusion on the companies' side (Dewey, 2019). Moreover, regulations around cryptocurrencies have gained widespread attention, whereas other blockchain applications are yet to be reviewed by regulators (Janssen et al., 2020). Hence, the uncertainty around the regulatory regimes and jurisdictions companies will be subject to will play a key role on the adoption of blockchain technology (Desphande et al., 2017).

In order to ensure a widespread adoption of the blockchain technology across different industries, while also protecting consumers and preventing malicious activities, a pro-innovation approach to legislation and regulation is needed (Dewey, 2019). Furthermore, regulators need to further enhance their knowledge of the distributed ledgers to be able to understand the blockchain technology, its impact on businesses and end-users as well to identify potential risks associated with its implementation (Deloitte, 2016). Lastly, Harwood-Jones (2016) argues that a wide implementation would be facilitated by tailoring and rewriting laws by considering the nature of blockchain technology as well as data security issues.

c) Governance

The blockchain technology has the potential to redesign participants' interactions in business, politics, and society due to the disintermediation at large scale, which in turn might rapidly change the underpinning tenets of existing governance models (Atzori, 2015). Currently, organizations are facing a lack of clarity on how the distributed

ledger is governed. According to a discussion paper published by the European Securities and Markets Authority (ESMA, 2016), the efficient adoption of blockchain technology relies on the development of a governance framework that addresses the liabilities of the network participants in case of error or fraud, responsibilities for the activities of the network related to regulators and customers, rules to identify authorized participants, correction mechanisms as well as penalties when rules are violated. Also, given that individual participants will most likely interact with the ledger via private keys, a governance framework needs to establish clear guidelines for the management of keys as well as protocols for loss or theft in order to avoid additional vulnerabilities of the ledger (Jannsen et al., 2017).

A proper governance framework can also ensure fair competition and orderly markets by establishing adequate levels of privacy. In the absence of proper safeguards, some participants can easily get access to information and engage in its undue exploitation that can eventually lead to market manipulation or unfair competitive practices (ESMA, 2016).

To sum up, legislation and regulation focus on procedures to be followed and the means to enforce them, while governance relates to stewardship and incentives to act on common interests. Besides creating a proper regulatory environment for the adoption of blockchain technology, governments should also play a collaborative peer role in a bottom-up governance ecosystem (Yeoh, 2017). Also, in order to realize the societal benefits imposed by the blockchain technology, clear rules, procedures and mechanisms for their implementation are needed so that the law enforcement agencies can monitor and impose penalties to participants engaging in fraudulent activities (Crosby et al., 2016).

Development of the conceptual framework

The potential of blockchain technology for creating new foundations for the economic and social systems is currently receiving significant attention from both management and marketing scholars as well as practitioners.

The emphasis of the research so far has been on blockchain technology itself and its use cases rather than on the issues around selection and successful adoption. There is a current need for a holistic understanding of the determining factors, their interaction and the challenges associated with the widespread adoption of blockchain technology.

The TOCE framework proposed in Figure 1 represents one of the first conceptual frameworks that takes a comprehensive approach by including both endogenous and exogenous factors and their relationships when considering the adoption of blockchain.

Fig. 1: The TOCE framework

The technological context encompasses the unique engineering aspects of the distributed ledger technology and the potential challenges that might delay a widespread adoption, such as: scalability, standardization, cost of adoption and the integration of the distributed ledger with the legacy systems. We also touched on the importance of an efficient risk management to address the security concerns that are raised by decentralized networks. In terms of the organizational factors, we highlighted the importance of a clear understanding of the blockchain technology, its

benefits and use cases by organizations who are willing to engage in technological innovation. However, the adoption of blockchain technology might require the redefinition of the current business models, hence the strategic orientation of the management in choosing the innovation path is essential in order to ensure the acceptability of this technology. Moreover, we also raised the issue related to the scarcity of qualified talent needed to develop and implement blockchain applications. Regarding the environmental factors, we focused on the industry structure that requires a harmonized infrastructure to ensure the interoperability of blockchain technologies. We also highlighted the need for consistent legal, regulatory and governance frameworks, that are still considered to be a serious impediment to the widespread adoption of blockchain technology.

As it relates to the research design, we have adapted the TOE framework by introducing a new theoretical perspective relevant for the study of blockchain's adoption. Therefore, the novelty of our proposed framework stands from the addition of the consumer behavior as a standalone factor that influences the adoption of blockchain technology by the organizations. Consumers are more powerful because of the blockchain technology that allow them to make more informed decisions and thus, organizations need to further streamline their customer experience to efficiently respond to their empowered customers. There are several general factors that influence customers when deciding whether to engage in activities that leverage blockchain technology that are essential for companies to understand, such as: their current state of knowledge and understanding of this disruptive technology, their reluctance to change as well as the social influence from other people in their networks.

This conceptual framework can be used by companies willing to implement the blockchain technology in order to avoid rushing headlong into a decision without gaining a proper understanding of the endogenous and exogenous factors as well as the challenges associated with its adoption. This framework draws the attention on the need to comprehend the technological and organizational aspects which significantly shape the way in which blockchain applications are implemented and how they can disrupt the current organizational processes. Companies need to conduct a strategic assessment of their business model, legacy systems and their current needs in order to ensure that blockchain is the proper change agent needed to create added-value. Given that blockchain has the potential to disrupt the current industry structures, companies need to understand how to best leverage this technology in order to successfully strive in this new competitive reality. Lastly, organizations need to gain a deep understanding of their consumers' behavior and the challenges associated with their blockchain's acceptance to be able to deliver superior value to customers through blockchain applications.

Conclusions

The journey of blockchain technology has already made the transition from theory into practice as more and more executives recognize it as a true agent of change capable of reshaping the existing business models and redefining the way in which value is transferred between different parties. Organizations are now considering it as a top strategic priority capable of streamlining a wide array of functions and organizational processes.

What management needs to consider in the adoption decision-making process is how to best position their companies to capture the greatest value from the increasing degree of service innovation through blockchain applications. This requires a comprehensive assessment and a deep understanding of the determining factors, their interdependence as well as the associated challenges with the adoption of blockchain technology.

We conducted an extensive review of the management and marketing literature on the adoption of blockchain technology from 2015-2020, which revealed that the primary focus of most research papers so far was on the technological elements. Our paper filled the current gap in the literature by providing a holistic view of the endogenous and exogenous factors that impact the organizational adoption.

The TOCE framework was adapted from the theoretical framework proposed by Tornatzky and Fleisher (1990) which analyzes the technological, organization and environmental contexts, to which we added another decisive dimension for blockchain's adoption, namely the consumer behavior. Our comprehensive conceptual framework identifies 15 determining factors that are interacting and mutually influencing each other, which organizations need to consider when deciding to implement the blockchain technology.

This study has several limitations that researchers can address in the future. First, we proposed a conceptual framework which synthetizes four main dimensions (technological, organizational, consumer behavior and environmental), that authors considered to be essential in the adoption of blockchain technology. Given the diversity of the previously described influencing factors, a more comprehensive inter-disciplinary effort is needed in order to delve deeper in the dependencies between each of the proposed dimensions. Additionally, the conceptual framework proposed has not been empirically tested, hence future research is needed to gain practical evidence across different industries.

Abstract

The main aim of the work is to analyze the human capital management of an amusement park, and the care for human capital by the park management. The present study also draws conclusions from the opinions obtained from employees, and thanks to which the park managers will be able to improve certain processes. The research methods used of the work include critical analysis of source materials and questionnaire. The research tool used in work is a questionnaire. The study examines the activities undertaken by the amusement park related to human capital management. The survey has been conducted among seasonal park employees who work at least one season. The following hypotheses are posed in the work: internal training in an amusement park is helpful in performing daily duties at work and allows employees to develop personally, long working hours drastically affects the quality of work performed by employees, which may affect customer service, as well as an amusement park is the right place to gain experience and improve the personal customer service experience.

Keywords: Human Capital Management, Human Resources Management, Entertainment, Amusement Parks.

Introduction

An organization employs the employees by carrying out a complicated recruitment process that acquires the human capital necessary for its functioning. It is essential because it should be remembered that it is not enough to hire employees who perfectly match the profile of a given position with their skills, knowledge and experience as the market situation can change dramatically. It is understood from the current situation that the recently hired employees may be worthless because they have not raised their qualifications by this time, and they have not checked whether there are any novelties on the market, so the organization may also be left behind in terms of competition. The employer needs to provide appropriate working conditions for employees so that they can use their potential and help in gaining a competitive advantage on the market, but this is only part of the tasks that the employer needs to fulfill. The employer needs to implement a system of attitudes in the organization for employees and provides the ways of engaging employees in the life of the organization. The purpose of such activities is to take care of the good name of the organization through the employees, as well as to use the full potential of the employees. The basic assumption of human capital management is the development of employees; it is a precious value for every organization and should be one of the investment priorities. The market forces the organizations to develop, so it is worth providing the most essential resource in the organization with the best possible development. The organizations should prepare development plan for employees that plan should give a chance to develop and achieve the goals of employees, it also allows to lay the foundations for the human potential expected by the organization. The proposed plan will be considered to implement as the strategy. While creating a development plan, it is worth creating a career path for the employees in specific positions, and to create such a plan, the following steps can be considered:

- create a description of the organizational structure
- create a frame of time spent by an employee in a given position or specialization
- creating a promotion system
- the employee should be able to acquire experience in working in his position
- making the possibility of participating in training for employees, and providing the opportunity to make them involved
- developing a career path

Cite this Article as: Romuald SZOPA and Michał KOT“ Human Capital Management on the Example of an Amusement Park” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The creation of a plan is designed to improve employee evaluation and improvement, but the most important element is the ability to move employees between positions. An employee who is promoted or transferred to another position in the organization is already familiar with the features of the organization and work culture. Furthermore, he/she has also acquired the skills, knowledge and experience in this organization and has already completed some training. All the factors mentioned above make it much easier for an employee to adapt to a new job and achieve better results than a person who would come from the outside and need some time to implement in the organization.

Literature Review

Human capital theory, as originally developed by Becker (Becker, 1960, Becker and Tomes, 1986, Becker et al., 1990) and more recently by the Unified Growth Theory (Galor and Weil, 1996, Galor, 2005, Galor, 2012), has emphasized the importance of human capital in explaining the demographic transition and economic growth. Many definitions can be found in the literature in connection to human capital. One of the fundamental views of human capital is the one presented by Haque and Oino (2019). They have defined human capital as knowledge and skills. These two main components are created, maintained, and, most importantly applied by the employees while performing their work tasks. Human capital management is the process of creating value in a company or organization through appropriate steps (Ingham: 2007; Ślusarczyk and Grondys, 2019; Kozicka et al. 2019). The concept of human capital reaches deep origins. According to Cadil, Petkovova and Blatna (2014), the concept of human capital is developed from a growth theory, and the relationships between the concepts and the economic growth have been analyzed for several decades. Studies completed by such researchers as Chaiprasit et al., 2020, Gorzeń-Mitka et al., 2017, Schutz (1972) and Mincer (1996) are considered as one of the most important in the context of human capital conceptualization process. Schultz (1972) relates man economic value with the concept of human capital and highlights the importance of investments in this area. Human capital (HC) is an asset for the organization or a well known intangible organizational value. Intellectual capital in the organization represents individual knowledge, skill, experiences, abilities and self-motivation (Baron A, Armstrong M 2007). Meanwhile, human capital can reflect organizational value (Wziątek-Staśko, 2014). Kaplan and Norton state that individual ideas, knowledge, innovation and how they make the decision making in working activities consider as human capital (Kaplan and Norton 2004). According to Kluþka, an enterprise is a social system that emphasizes economics and the social dimension of the enterprise -- the interests and preference human factor. Employees are the pillar of an organization. An organization cannot survive if there are no employees (Kluþka, 2011). Human capital is defined as the stock of skills and knowledge, and employees of expertise further play an integral role in increasing the productivity of the organization. These efforts have evident positive impact on the business performance being aimed at the development of professional skills of employees, including entrepreneurial ones (Stacho et al., 2019; Zainol et al., 2018). Every organization invests part of its money and resources in training its employees. Employees in turn work hard, upgrade their existing knowledge and contribute in their way to increase the productivity of their organization. This trend has risen the potential qualified staff (Tokarþíková, 2013) Consequently, it becomes one of the core reasons of current compensations and benefits programs in enterprise human capital management (Bilan et al., 2020). Human capital is the most crucial constituent of the intellectual capital of a company, as people are the ones who have the knowledge to interact with the surrounding environment. This motivates, supports and create a value for a company. Human capital plays an important role, and it deserves special attention in each of the models (Ross, Ross, Dragonetti, 1997).

Research Methodology

The research methods used in work include critical analysis of source materials and questionnaire. The questionnaire based survey has been used as a research tool in the present study. The purpose of the survey is to examine the opinions of employees about the activities undertaken by the amusement park related to human capital management. The survey questionnaire consists of thirteen main questions and five metric questions. The questionnaire has been circulated among the seasonal park employees who work at least one season. The survey was conducted to check the opinions of seasonal workers about the activities of management in terms of human capital management in an amusement park. The questionnaire has included questions related to the recruitment of employees and training courses offered by organizations. The respondents were also asked for their opinions on the remuneration and bonus system, as well as for the support of their superiors during problems encountered at work. The last questions mainly concern the opinions of employees about personal development while working in the amusement park and their opinion whether it is worth joining the employee team of the amusement park. Due to the epidemiological situation in the world, the study was conducted using an electronic questionnaire. The survey questionnaire was distributed through employee groups of the amusement park and contact on social networks with former employees of the amusement park, also due to the pandemic and the suspension of the amusement park during the survey period, it was addressed mainly to employees who worked under a civil law contract in the last three years in the amusement park. The study was conducted from July 4-11, 2020.

Research Results

Fig. 1: The ratings of the recruitment of amusement park

The first survey question is related to the first impressions of the employee regarding the organization, the employee recruitment process was assessed. While analyzing the results, it can be concluded that most employees are satisfied with the recruitment process because 48.8% of employees reveal the process as good, whereas 32.6% of employees consider it as a very good process, while only 9.3% of employees do not express positive or negative opinions on recruitment. Also, only 9.3% of employees have expressed a bad opinion about the recruitment process. The results clearly show that employees are satisfied with the approach of the amusement park to the recruitment process.

Fig. 2: The opinions of training and internal training and its impact on everyday work of employees in the amusement park

The second question is related to on-the-job training that takes place during the first hours of new employees in the amusement park. In the case of this question, the satisfaction of employees on the way of training and preparation for the position is carried out. 46.5% of employees consider on-the-job training as good, while 30.2% of employees believe it is very good, 18.6% of employees believe that it is poorly conducted and some aspects need to be improved, whereas 2.3% consider it as very bad, and the same percentage have not expressed their opinions on on-the-job

training. The next question is concerned about internal training organized by the amusement park. In the case of this question, most people are satisfied with the training offered by the amusement park, 27.9% of employees consider the training as very good, and 53.5% of employees consider it as good, and 14 % of employees have no opinion. In contrast, 4.7% of employees believe that the training does not bring anything new to them. A positive opinion about internal training among employees indicates that during the training it is possible to acquire new experience, skills and knowledge, and also proves the care of the amusement park in terms of the competences of the employees they hired. The fourth question is a continuation of the internal training survey. In this case, the employees were responded how internal training helped them in their daily work. In this regard, the opinions of employees on the training were assessed. 23.3% of employees stated the training as very helpful at work, 55.8% of employees believe that the training helped them at work. 16.3% did not have an opinion about making work easier after completing the training. In contrast, 4.7% of employees replied that the training did not help them at work. Positive results indicate that the training system offers a wide range of competences to support novice employees in performing their duties efficiently.

Fig. 3: The ratings of bonus system in the amusement park

The opinions of employees related to the bonus system in the amusement park were analyzed based on the question. This analysis gives a variety of ways, but in this question, there is a visible advantage of people who are not satisfied with the bonus system. 27.9% of employees answered that the system has good and bad, 23, 3% of employees do not have an opinion on this subject. In contrast, 16.3% of employees have a very negative opinion of the bonus system that operates in the amusement park, and 4.7% of employees are very satisfied. It can be concluded that, in the case of the bonus system, it is difficult to please each employee. Hence the results are very diverse, but there is a noticeable tendency of negative assessment, which may cause a decrease in motivation and commitment of employees while performing their duties, which may fail to achieve goals.

Fig. 4: The opinions of rotation between departments

The rotation of employees is a common element in an amusement park, so it is appropriate to ask for feedback. Most believe that this is a good idea and will allow for better use of the potential employees. Among the surveyed employees, 32.6% considered it as a good solution, 20.9% believed even a very good solution, while 25.6% believed that it is not the best idea and stated as may be problematic, and 11.6% did not express of their opinion on this. In contrast, 9.3% are entirely against rotation between departments.

Fig. 5: The opinions of long working hours and attending a large number of clients

The next question raises a significant issue that has already been raised at work, the long hours of working and attending a large number of customers that each employee can handle during the day can affect the quality of work. According to the survey among the employees, 44.2% of employees believe that it can definitely affect their work, 39.5% of employees also believe that it has an impact on quality, while 9.3% of employees believe that it does not have a negative impact on the work performed, and 7% of employees did not express their opinion. The vast number of employees believe that the long hours spent at work and the number of clients served may affect the quality of customer service. These two things will undoubtedly be influenced by increasing fatigue, this is a place that should be considered by the park management and can work with employees to find a mutually satisfactory solution.

Fig. 6: The opinions regarding the support of supervisors during a problem at work

Support from the supervisor during work is a very important issue that makes the employee feel more confident, being sure that in the event of a problem he can count on his help. In the case of amusement park employees, based on the research results, it can be concluded that the superiors definitely help with any problems encountered. Most of the surveyed employees, 86.1% answered that their superiors help, only 4.7% of the employees responded negatively

that they had not received help from their superiors, and 9.3% did not express their opinion. The results clearly show that the employees' superiors take an active part in the work and help with any problems that park employees encounter.

Fig. 7: The opinions regarding the salary of employees for their work

The ninth question is related to the correctness of the remuneration received by park employees. Almost half of the employees, 46.5% believe that the remuneration received is adequate, 20.9% believe that the employer could offer a slightly higher salary. In comparison, 18.6% of employees have no opinion on salaries, only 9.3% of employees believe that their work should be paid much higher, and 4.7% believe that they definitely receive the correct salary.

Fig. 8: The opinions of employees concerning their job satisfaction

The tenth question is the first of three questions related to the assessment of personal development opportunities while working in an amusement park. When asked if working in an amusement park is a good place to gain experience in customer service, the employees clearly answered that it is the perfect place to do so. More than half of employees, 58.1% believe that it is a very good place to gain experience in customer service, 37.2% consider an amusement park a good place, and 4.7% of employees do not have an opinion.

Fig. 9: The opinions of employees related to the acquisition of new skills in the present work

Another question concerns the development and the learning of new skills of employees. In this case, almost all surveyed employees believe that they have developed while working in an amusement park, 51.2% believe that their work has developed them, 44.2% believe that they have developed a lot while working in the park, while 4.7% of employees believe that they learned nothing while working in the park.

Fig. 10: The opinions of employees related to the recommendation of their job to young jobseekers

The penultimate question is related to the opinion of employees, whether it is worth recommending work in an amusement park for young people who are looking for a job. The majority of employees believe that they would recommend a job in an amusement park. 44.2% of employees would definitely recommend young people to try work in an amusement park, 34.9% of employees believe that they could recommend working in the park to a young person, 9.3% of employees do not have an opinion, the same number of people would not recommend working, and 2.3% of employees even advise against working in an amusement park.

Fig. 11: The opinions of employees related to the management of amusement park

The last question concerned the evaluation of the amusement park. It turned out that 48.8% of employees believe that the amusement park is well managed and caring for employees, 18.6% of employees believe that the park is very well managed. However, as many as 20.9% do not have an opinion on this subject. In the case of employees with negative opinions, only 9.3% of employees believe that the park is poorly managed, and 2.3% are very dissatisfied with the way the park is managed. The results show that most of the employees are satisfied with their amusement park work and care activities of management.

Conclusion

From the results of the research, it can be concluded that most of the employees of the amusement park mainly gain experience at work, have recently graduated from high school and do their education at universities. For the park, it may be a benefit because they acquire employees who are not yet educated and park managers have the opportunity education of employees according to their own standards. However, it can be concluded from the results of the research and the number of people employed at this age that the park management has no problem with it and this is the main direction of the recruitment team. Most of the park's employees work only for the season, which is, unfortunately, a negative situation for the amusement park, because they lose a large part of the employees trained by them after the season ends. This forces the park to create new job offers with the new season and spend money on the next recruitment of employees. The management of the amusement park is positively assessed by its employees. The results confirm that employees are covered by a good training package by the amusement park and are satisfied with it, because the acquired knowledge and skills during the training directly affect the results of their work, and also facilitate its performance. Employees are also very pleased with the opportunity to work in the park and self-development while on the job, this is definitely an essential aspect for most young people who are taking their first steps in the labor market. So, it is a huge advantage for an amusement park that most existing employees believe a place for great development. Widespread customer service during the working days is also an advantage as each employee learns to establish a relationship with the customer. The recommendation by employees to work in an amusement park is also a big advantage for the management, as the research results show that seasonal employees positively perceive most activities related to human capital management. Wages and bonuses will always be factors that do not satisfy everyone, but most of the employees are satisfied with the remuneration they receive. It can be concluded that the number of hours combined with the hourly rate and other legal aspects make employees satisfied with the wages they receive. In contrast, in the case of the work bonus system, employees have mixed feelings, but with a slight predominance of negative ones, taking into account the employees' responses, the bonus system is an issue that the park management can improve. By far the biggest disadvantage indicated by employees of the park is long working hours during the day and the influence of this factor on the quality of the work performed. Fatigue after working twelve hours or more plus working several days in a row, can cause problems for employees. Of course, employees gain a salary, while an organization can lose a lot on the quality of work and customer service, so it is worthwhile for an amusement park to think about modifying the working time of its employees to optimize working time to the quality of customer service. The research results show that the amusement park takes good care of its human capital, and employees are satisfied with their work and development opportunities.

Summary

Human capital management in the case of an amusement park is a difficult task, because the specificity of the activity requires the employment of a large number of employees in several departments, which usually need to be trained and implemented in the organization. Employees who have already been hired play a large role in introducing new employees, because they know the job positions the most, having many hours worked in previous seasons, which in most cases do not have employees at the highest management level. Training of seasonal workers is a significant factor, because they are mainly the representatives of the amusement park and they are the most common people associated with the park by customers, a lot depends on their work, approach and ability to build a relationship with the client. If seasonal workers are not involved in the work, are not properly prepared and trained to work, they may have a negative impact on the reception of the amusement park. The consequence of this may be the loss of customers, which may lead to the loss of funds necessary to maintain the park's attractions in good condition, survive the winter period, or may lead to a hole in the budget needed to prepare the park for the next season. The question was asked at work whether internal training is helpful in everyday work situations, according to employees. In the case of an organization that relies heavily on seasonal workers, it is a crucial aspect to implement employees in the life of the entire organization. They can also be used in other workplaces in the future. This is another positive aspect showing that in the case of training, the employees of the amusement park have to deal with the appropriate approach and development of human capital. In the study conducted by the author of the work, the employees confirmed that the training influences their personal development. The above work may be used by the director and managers of the park who have been observed in it. The research carried out by the author of the work shows the strengths and weaknesses of the amusement park. Conclusions resulting from the research may be necessary data for an organization in terms of human capital management. Work can also be used by sports organizations and other enterprises, because the human capital of the organization is the most important resource of any organization, and the activities undertaken in the amusement park related to the development of employees and their competencies are largely very positively received by the employees who took part in them. In summary, employees working in the amusement park are satisfied with taking up a job in this place and with the training and activities that are offered by the management in the park. They believe that the time spent as a park employee was a good experience and allowed them to acquire the necessary knowledge and competencies that they will be able to use in the further path of their professional career.

Abstract

One of the most widely used and most dynamically evolving model which intends to tackle statistical disclosure is differential privacy. The method described in this paper, based on the differential privacy principles, pro-poses adaptive metrics that together state an effective mechanism of pre-venting privacy violations by inference attacks. The method remains effective for the dynamic the information-based systems in which data volume increases and characteristics fluctuates significantly overtime and can be applied for the newly developed systems as well as already well-established systems as an additional software component.

Keywords: Differential Privacy, Information score, Risk-accuracy, Scoring Metrics, SDC Method.

Introduction

One of the most widely used and most dynamically evolving model which intends to tackle statistical disclosure is differential privacy. Published first in 2006, the differential privacy concept was introduced as a system for measuring the theoretical maximum privacy loss that an individual can experience when their private information is used to create a statistical data product (Dwork, C., 2006). The premises of the differential privacy model base on providing plausible deniability to participants by guaranteeing that the outcome of a database does not change significantly whether or not he participates.

The application of differential privacy involves several techniques, including the injection of mathematical noise in the collect data, data hashing, subsampling and randomized data injection. Finding an appropriate tradeoff between the data accuracy and anonymity while adding a noise to the data remains a challenge as datasets users need precise data to work on and the data owners need to comply with the data privacy regulations (Dzięgielewska, O., 2017).

The method described in this paper, based on the differential privacy principles, proposes adaptive metrics that together state an effective mechanism of preventing privacy violations by inference attacks. The method remains effective for the dynamic the information-based systems in which data volume increases and characteristics fluctuates significantly overtime and can be applied for the newly developed systems as well as already well-established systems as an additional software component.

Information Score Metric

Information score metric intends to determine whether the privacy of an active query *q0* made to the database *D* at time *t1* could be biased by historic queries denoted here as *Q0* for which the database transactions terminated before *t1*. The final result of the information score metric is later used as an input for the risk-accuracy metric which is used to establish a baseline for the noise added into the result of the statistical query.

Association Database Model

The idea of the algorithm of the information score metric is based on the association rule learning premises, i.e., it exploits the mechanisms of measuring the quality of the correlation between the unlabeled data – in this case the correlation will be measured based on the parameters of queries users are submitting to the database.

Definitions

The purpose of the association rule mining is to identify strong rules discovered in databases using some measures of interestingness. The measures that are going to be used for the purpose of the information score matric are:

- ***support***: *sup(X)* of an item set *X* is defined as the proportion of transactions in the data set which contain the item set, what translates to the frequency of the item set in the dataset: $supp(X)=|t \in T;\ X \subseteq t|/|T|$ (Hahsler, M., 2005),
- ***confidence***: the confidence of a rule is defined $conf(X \Rightarrow Y) = supp(X \cup Y)/supp(X)$, what translates into an indication of a positive connotation of the rule (Hahsler, M., 2005),
- ***lift***: the lift of a rule is defined as $lift(X \Rightarrow Y) = supp(X \cup Y)/(supp(X)supp(Y))$, and can be interpreted as the deviation of the support of the whole rule from the support expected. Greater lift values indicate stronger associations (Hahsler, M., 2005).

Let *P* denote the set of all the parameters that appear in the scope of the database *D*. The parameters are identified here as items. The tables T that are defined within the database *D* can be interpreted as item sets.

Let query $Q \in T$ be an item set, and *S* be a sensitivity characteristic determining the sensitivity level of the data. The query *Q* satisfies *S* if $Q \Rightarrow S$. The support of the *S* can be defined as the probability $supp(S)=Pr_{(Q \in T)}\ [Q \Rightarrow S]$.

The information score metric mechanism analyzes the potential inference between the active query itself $(q1 \in Q)$ and the active and historical queries $(q1 \cup Q0 \in Q)$. The queries $q1,\ q1 \cup Q0$ satisfy *S* if: $q1 \Rightarrow S,\ q1 \cup Q0 \Rightarrow S$.

The process

The information score metric algorithm takes an associations database as an input (AR_DB). The generic association rules creation process, that would be used to generate such a database can be described by the procedure AR_DB population, but it must be noted that the detailed AR_DB population algorithm is beyond the scope of this paper.

AR_DB POPULATION

```
1 Obtaining a raw dataset
2 Transforming the raw dataset into a numeric format
3 Computing frequent item sets with the limit set by the minimal support characteristic
4 Computing association rules from frequent item sets with the limit set by minimal confidence
5 Determining the risk profile of the associations
```

A raw data set for the researched case is the set *P* and each of the $p \in P$ has to be translated into the frequency model so that the sensitivity of each element can be determined. For the purpose of the information score metric definition, it is assumed that for steps 4 and 5 a certain threshold is set. It also must be assumed that the frequent item sets list is prepopulated by the database query parameter mappings that could be used to conduct a successful inference attack. The sensitivity of the queries should be measured as a gradient, where the associations with the high level of support characteristic, the confidence close to 1 and the lift value higher than 1, should be marked as critical risk, and the associations with low level of support, confidence close to 0 and the lift value below 1 should be at the end of the spectrum marked as low or no risk.

The AR_DB is a dynamic structure that would be repopulated at each structural change of the database itself, meaning that at every deletion or addition of the data source, the sensitivity of the associations will be recalculated. It must be noted that the detailed AR_DB population algorithm is beyond the scope of this paper.

Algorithm Description

The information score metric derivation algorithm returns a value of the information score metric (*ism*) which is used in the risk-accuracy metric as one of the inputs. The proposed algorithm in its base form analyzes only the critical correlations, but it can be adapted to consider all the sensitivity levels, therefore an optional sensitivity input in the line *i3* has been explicitly shown, however it is assumed that the default value been used in the proposed base design of the algorithm for the critical correlations. Using the sensitivity setup would require modifying accordingly the ism in case algorithm would be used without the criticality constraint.

Additional step that is not covered in the information score metric is the verification check that would intend to cover a structural change of the statistical database protected by the designed SDC method. If the structure of the database changes, then the AR_DB changes and it must be determined if after the structural change the HIST_DB (a database with previously asked queries) should be repopulated or kept as-is. Using the risk-based approach it must be established whether the changes has modified AR_DB beyond an acceptable change ratio, and therefore leading to creating a new instance of HIST_DB. The detailed method of determining the HIST_DB approach in case of the structural change is not covered in this research.

INFORMATION SCORE METRIC DERIVATION

```
        Prerequisites:
p1      AR_DB
p2      HIST_DB
                Input:
i1      P (a set of parameters of the submitted query)
i2      C (asked statistical characteristic)
i3      S (optional, default=1)
                Algorithm:
a1      if (query was asked before)
a2              return ism=ism_hist
a3      else
a4              while (AR_DB has next)
a5                      if (P and C in AR_DB_i)
a6                              add {P,C,ism=1·S} into HIST_DB
a7                              return ism=1·S
a8                      else
a9                              while (HIST_DB has next)
a10                                     if (P_hist_i,C_hist_i,C,P in AR_DB_i)
a11                                             add {P_hist_i,C_hist_i,P,C,ism=1·S} to HIST_DB
a12                                             return ism=1·S
a13                                     else
a14                                             add {P,C,ism=0} into HIST_DB
a15                                             return ism=0
```

Risk-Accuracy Metric

Risk-accuracy metric determines the ratio of the statistical noise added to the result of the statistical database query. The baseline of the noise distribution and the characteristic of the noise addition model is taken from the classical approach of the differential privacy model. The method of calibrating the randomized noise is modified by the following components:

- ***risk*** – a variable component dependent on the preset selected by the database owner characterizing the risk profile of the database. This component is strictly corelated with the information score metric, as the preset can be influenced by this metric to reflect the actual risk, calculated in an adaptive manner. The preset risk value is assigned in a numeric format within the range [0;1] where 0 renders to ignored risk and 1 to the critical risk profile of the query. The preset value is selected at the database level for each of the access roles and the value is modified at a query level after calculating the *ism* value.
- ***accuracy*** – a static component dependent on the preset selected by the database owner characterizing required accuracy level of the retrieved results. The preset accuracy value is assigned in a numeric format within the range [0;1] where 0 renders to low accuracy profile and 1 to the critical accuracy profile of the query. The preset value is selected at the database level for each of the access roles and is not modified during the database transactions.

The metric allows for better control over the risk at a query level what intents to improve the overall accuracy of the results by targeting only the queries with higher risk profile. The queries that are profiled as low-risk at the moment of the invoking the database transaction, will not be as affected by the risk component as the ones with the high-risk profile. It must be noted however, that the perfect accuracy would be only achievable if the risk factor is ignored by the database owner and the accuracy level is set to reflect actual statistics retrieved by the query. Allowing such setup would contradict the purpose of the original differential privacy model, therefore is excluded from the analyses.

Algorithm Description

The algorithm of deriving risk-accuracy metric (*ram*) should work in such a way that its effect would determine to what extent the original noise defined by the base of the differential privacy model should be changed, i.e., we

assume that the noise added in the original version determines the preset *accuracy* component at the level equal to the maximum accuracy required for the database. If the importance is transferred to the privacy of the data, the noise added to the output is modified accordingly by the *risk* component. The maximum value of the *risk* component is equivalent to specifying the *accuracy* component at the minimum level required for the database. The modification of the *risk* component may not exceed the minimum level of accuracy required for a given database. The derived values of *ram* are independent from each other in a sense that they might have the same values for different queries, but they are not dependent on the previous values returned from the algorithm.

```
RISK-ACCURACY METRIC DERIVATION
                Prerequisites:
p1      r_preset(preset of the risk component of the database)
p2      a_preset(preset of the accuracy component of the database)
                Input:
i1      P (a set of parameters of the submitted query)
i2      C (asked statistical characteristic)
                Algorithm:
a1      calculate ism for {P,C}
a2      risk=r_preset*ism
a3      if risk=0
a4              ram=a_preset-1
a5      else
a6              ram=a_preset*risk+risk
```

Applying the Metric into The Differential Privacy Model

As it was mentioned before, the differential privacy model assumes implementation of the mechanism that adds symmetric exponential noise to each coordinate of $f(X)$, where f is the query function and X is the database. The worst-case error is applied to each of the queries asked to the database. Using the proposed modified approach, the distribution of the noise added into each query would be enhanced according to the results of the risk-accuracy metric. This way, both the accuracy and the privacy of the results should be improved as the risk-accuracy factor could be calibrated accordingly per each database query.

Let's assume $D(d_q)$ is a base distribution that is used as a randomized statistical noise generation function defined as the differential privacy model noise generator, where the d_q is the base error rate. If q_n is an *nth* query asked to the database, then the distribution used to generate the noise for the q_n is denoted as $D(d_{qn})$. The method of enhancing the $D(d_{qn})$ would need to assume that for the queries with risk over accuracy weigh, the $D(d_{qn})$ is modified by introducing more noise (denoted as η) into the result ($D(d_{qn}+\eta)$) and decreasing the η otherwise ($D(d_{qn}-\eta)$).

```
ENHANCING DISTRIBUITION
                Prerequisites:
p1      D(d_q)
                Input:
i1      q
                Algorithm:
a1      calculate ram for q
a2      if ram≤0
a3              use D(d_q-ram·n)
a4      else
a5              use D(d_q+ram·n)
```

Applying the Model in A Transactional Database

The perturbative statistical disclosure control methods may either work at the data collection time, where the raw data is modified and the database stores already noisy data or as a part of the statistical derivation interface of the database, where the raw data is stored in the database without any noise added to them before the derivations. The developed method falls into the second scenario and assumes that neither the data collection method must apply any statistical control, nor the data model of the database must satisfy the statistical security-by-design measures.

The opposite approach, called local differential privacy (Kasiviswanathan, S., et al., 2008), assumes perturbing data locally before sending them into the database. The main drawback of the local differential privacy is that this approach can be applied only in cases where the data is not yet collected, therefore making it practical for new solutions. Following the approach of post-processing the raw makes the method application more universal as it can be easily applied not only into the databases that are yet to be implemented, but more importantly, it can be incorporated as an additional end-user interface for existing databases. The need of retrofitting the applications increases therefore creating a statistical disclosure control method that would work for already existing and working environments has more business impact in the current environment than designing a bullet-proof approach that

would work for future databases only. However, the main drawback of external non-custom-fitted design is increased processing time of the queries made into the database, but it's the cost that must be made as a compensation of the privacy of the statistical output.

Assumptions

Before effectively implementing the proposed SDC method into the working environment certain conditions must be met for proper application. Without following the proposed conditions below, the results retrieved from the database might be affected – in best case, only the accuracy of the data would be decreased, in worst case, the SDC method will not work and create a security breach.

The conditions that are necessary for maintain the accuracy of the results are:

- **The data** in the statistical database is stored in non-perturbed manner, i.e. the database that will apply the SDC is an effect of raw data collection. Applying said method over already perturbed data would miss the mark on the statistical accuracy, however still the results would be retrieved.

- The database has **different statistical access roles**, that have different sensitivity levels assigned to them. This way the information score metric may be used to its full potential, as the sensitivity level for a regular analyst might be different than a sensitivity level for a researcher or a data owner. Adhering the sensitivity to the business need would impact the accuracy of the retrieved output, as the sensitivity modifies accordingly the information score metric what in the end affects the error rate of the added noise.

The condition that falls into the mandatory group is **preprocessing of the association database and historical database implementation**. If the aforementioned supporting databases are not created, the proposed SDC method will not work. Whereas the historical database creation falls into the technical task only, creating the association database might be a challenging task to perform, especially for the large-scale databases. The quality of the results and the overall privacy will be affected if the association database is created without due diligence, however it must be noted that even if the associations are not created properly, the noise will still be added to the results, but the purpose of the metrics will not be fulfilled to its potential.

Process

The proposed SDC method works at the statistical derivation interface level. After a user submits a query into the database engine, the noise generation function is triggered.

In the first step the database verifies the preset for a particular database access role of a user. The preset must contain:

- *The sensitivity level* used in the information score derivation algorithm; in the base approach only the association rules will be analyzed, however by adding additional input parameter, the whole spectrum of associations could be potentially analyzed.
- *The risk level* – a component used in the risk-accuracy metric derivation algorithm to assign a base risk profile at the database level. This component is strictly corelated with the information score metric, as the preset can be influenced by this metric to reflect the actual risk, calculated in an adaptive manner.
- *The accuracy level* - a component used in the risk-accuracy metric derivation algorithm to assign a base accuracy profile at the database level.

After assigning a preset that will be used during the whole session between the user and the database, the query itself is verified in the historical database, as the information score metric algorithm recalculates the ism for the new queries only. If the query has not been found in the historical database, the associations are verified to determine the risk profile of the query. After that the ism is calculated and the query is added into the historical database along with the ism. In case the query has been made previously, the ism is gathered as an output of the historical database verification.

After the ism calculation step, the risk-accuracy metric is calculated and passed to the noise generation function as one of the inputs. After the error rate has been determined and the noise generation function has been applied over the raw output, the perturbed output is returned to the user.

The user will not receive any result from the database until the SDC process is not terminated. In case of an error occurred before the output retrieval, all the transactions made into the supporting databases that could affect future results must be rolled back, i.e., any data that has been added into the historical database must be deleted.

Fig. 1: Transaction scheme

Security features of the proposed method

Mitigation of inference attacks is the key feature of the proposed method. The main purpose of designing an adaptive SDC method was to target dynamic databases and dynamic environment, but as the differential privacy by definition is a perturbative method of the statistical protection, the coverage of the robustness to the attacks is much bigger.

Quantification of privacy loss is a desirable characteristic defined by the author mentioned in her initial idea (Dwork, C., Roth, A., 2014), however the definition is very vague, as the author stresses that the differential privacy is not a binary concept as the privacy loss of the data needs to be consumed at case-by-case basis. However, allowing the calibration of the risk and accuracy in the proposed method most definitely allows for data owners to manage the magnitude of the privacy loss and enhance the metrics accordingly to their needs.

Independent secrecy is a feature that is characteristic to the extended model and can be defined as a feature that indicates robustness against post-processing attacks. In the extended model, despite the fact that the historical data are used to derive information score metric, the outputs generated per each query are independent from each other in terms of added noise. The noise is generated specifically for each query and collecting the data from a set of queries should not reveal any statistical characteristic that could be used to leverage a successful inference attack.

Group privacy is a feature that allows to control the privacy loss incurred by groups (Dwork, C., Roth, A., 2014). This feature renders to extending the base model of the ε-differential privacy, which is bounded by $exp(\varepsilon)$: $Pr[K(D_1)\in S]\leq exp(\varepsilon)\times Pr[K(D_2)\in S]$ to $Pr[K(D_1)\in S]\leq exp(\varepsilon c)\times Pr[K(D_2)\in S]$, bounded by $exp(\varepsilon c)$, where c means a change of c items instead of one item in the original scenario. The proposed extension of the model with metrics still satisfies this feature, as the distribution function will not be affected beyond an acceptable rate.

Other Security Considerations

The technical components security is a separate area that is not covered in the scope of this paper but still states a significant part of the overall security of the proposed SDC method. The most common approach of defining security requirements for the applications is to follow one of the commonly used standards. One of them is OWASP Application Security Verification Standard, which thoroughly covers all the phases of the Software Development Lifecycle with controls to apply in certain areas of the developed solution.

There are two aspects that are critical in terms of satisfying the security of the proposed SDC at the software level: the environment and the implementation security. It must be assumed that the database environment is secured accordingly and follows best security practices, to prevent any side-channel data leakage, which would lead to releasing sensitive data, in particular:

- the statistical database, historical database and association database are properly secured at access level,
- the communication between the database users and the database is properly secured, especially important during the data acquisition process,
- the properties stored in the database that are used in the metrics derivation function and the noise generation function are protected.

It also must be assumed that the implementation of the proposed model is free from errors that would affect the security of the solution, e.g., business logic errors that would affect the processing of the data, backdoors that would intend to bypass the security mechanisms or other application-level errors mentioned in the ASVS framework.

Abstract

This article aims to highlight the importance of vision in companies that want to adopt innovation strategies, influenced by stakeholders but also the relevance of research, finding a way to analyze and classify these factors, determining the development of a company, ensuring its performance, of a high level of economic sustainability.

Innovation strategies are aimed at companies that have an orientation towards competitiveness and economic sustainability.
This article presents classifying stakeholders based on their influence and power and then understanding their motivations so that you can prioritize your efforts and resources accordingly to achieve the desired.

The article includes methods for identifying stakeholders as well as understanding the choices. It is also presented how to achieve the matrices, where our objectives are highlighted, in this way we must establish the parameters for achieving the table in order to have the real score depending on the strategy we need to adopt within the company. This score will help to implement and pursue strategic objectives.

It is very important understanding their motivations and stakeholder analysis for reveals how to adopt strategies through stakeholder analysis.
The basic objective of these companies is to focus on the most appropriate innovation strategies, influenced by key stakeholders, in relation to market needs and customer expectations but also with positive regulations, through strategic balancing.

Combining innovative strategies and their role, with understanding the factors that contribute to increasing economic sustainability, the company becomes more competitive, achieving long-term desired performance.

Keywords: Economic Sustainability, Innovation Strategies, Stakeholders.

Introduction

The innovation capacities within a company are important for the development of economic sustainability and for ensuring its long-term growth. The involvement of innovation strategies, technological development, increasingly complex market requirements but also the involvement of stakeholders in the processes of change, improvement of

RADULESCU, Rita TOADER, Florina HAHN, Constantin CUCOSEL and Alina Natalia POP "Stakeholder Analysis on the Adoption of Innovation Strategies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

a company, have now become a determining factor in the management of that company, which wants to create economic sustainability, long-term.
In order to achieve this goal, regarding the increase of competitiveness and economic sustainability, it is important to analyze the influence of stakeholders, in all that means innovation strategies and how these well-defined strategies can be implemented within the company.

In the literature, stakeholders are defined "as an interested party, as any group of persons or a person, who may affect or is affected by the fulfillment of the purpose of the corporation" Fletcher, A., Guthrie, J., Steane, P. and al. (2003).

This includes individuals, organizations and professional bodies. Stakeholders may have a positive or negative effect on the project or vice- versa, the project may have a beneficial or detrimental effect on stakeholders. They can be part of the organization working on the project, the client organization or outside these organizations, for example government, regulatory body, trades, etc.

There are different types of stakeholders. Some have a higher degree of power and can decide the course of action, approve or not decisions on a project. Another set of stakeholders can help, with their expert opinion, so consult them. Several other stakeholders need to know the progress of the work as their work begins when this work is completed. There are also stakeholders who want to know when the project will be completed. These stakeholders may be interested as a result of this project, as they can help them in their work. Not all stakeholders are equally involved or affected in the project.

All stakeholders are not equally involved or impacted in the project, the manager needs to know how to engage these different types of stakeholders. This is the main reason why it is important to have a stakeholder analysis.

Stakeholder analysis is an extremely useful technique for identifying, understanding, and prioritizing all stakeholders who can influence the business or project.

Stakeholder Analysis

The analysis of stakeholders will reveal who they are, what their needs and expectations may be, and what issues matter to them and to what degree. This analysis will tell their true level of interest and influence over project.

A thorough analysis will ensure that all affected parties are duly considered. Having access to this knowledge can greatly improve the outcomes of conflict resolution.

Stakeholder analysis will identify who exactly should be engaging, to participate during the project's execution phase - and to what extent. This valuable information can serve as the foundation for choose stakeholder and strategy.

When performed on an ongoing basis, stakeholder analysis will help to choose key stakeholder groups are changing over time - in terms of who they are, how their needs or expectations may be evolving, and how the relationship with them has improved or deteriorated.

The classifying stakeholders is so important, because it is based on their influence and power and then understanding their motivations so that you can prioritize the efforts and resources accordingly to achieve the desired outcomes.

In order to identify the problem, the planned action or the plan to be applied, it is established:

- the main stakeholders, which are those people, due to which, continuous participation, is absolutely necessary for the survival of the company; are those directly affected either positively or negatively by the actions of an organization;
- secondary stakeholders, are indirectly affected, are the intermediaries involved in the delivery process or persons involved in the implementation, start of actions, monitoring of the project, plan, etc…
- tertiary stakeholders: those who will be least affected
- key stakeholders: those with significant influence or importance within an organization; may also belong to other groups.

Stakeholder analysis helps to identify:

• Stakeholders' interests
• Potential risks and misunderstandings
• Mechanisms for positively influencing other stakeholders
• Key people who need to be informed about the project during the execution phase
• Negative stakeholders, as well as their negative effects on the project.

The differents methods to identified stakeholders

1. Team brainstorming: The idea is to come up with the longest possible list whit stakeholder and reserve judgment for the select stakeholder for the end .

2. Team members' experience: If the team has built up valuable knowledge over time, use they for the the best choice.

3. Historical data: The organization may have accumulated of data from previous projects, uses this information to train your stakeholder to efficiency and building on experience.

4. Comparable: Whenever possible, look for similar projects and identify stakeholders who may have played a key role. Maybe the same types of stakeholders will impact or be impacted by current project.

It's important to analyze stakeholders in the early stages of the project. This will allow to proactively develop a stakeholder engagement strategy, which generally produces better outcomes.

There are a number of models that can be used to analyze stakeholders, each with their own strengths and weaknesses. The most appropriate model will probably depend on the nature of your project and available resources.

Is recommended to using a combination of models to gain a more thorough understanding of key stakeholder groups and potential impact on the project.

All stakeholders have their own reasons for their individual opinions and actions. Stakeholder analysis tries to identify and interpret these motivations so that they can be adequately addressed.

Understanding your stakeholders 'motivations will help inform the type of engagement, communications and even arguments that may sway stakeholders to your side.

Stakeholder analysis helps to delimit and involve them actively, continuously, in the innovation process; their roles can be assessed according to their influence, the factors that can generate conflicts or opportunities for success, methods and tools, they can facilitate the systematic involvement, in order to obtain a sustainable improvement in the development of the innovation strategy Kimmich, C., Janetschek, H., Meyer-Ohlendorf, L. and al. (2012).

By analyzing stakeholders, the company has the opportunity to understand who are the key stakeholders, what can be the information about their contribution to the development and innovation process.

Stakeholder involvement must bring value to the company. It is essential that the people, methods and tools used, contribute with a positive, constructive and correct attitude, motivating the people involved (Fig 1. Stakeholder analysis).

Fig. 1: Stakeholder analysis (adaptation after Kimmich, C., Janetschek, H., Meyer-Ohlendorf, L. and al. (2012))

The possibles motivating a stakeholder's stance (Fig 2. Interest matrix of stakeholder)

- Financial interests: will make or lose money because of the project
- Moral and ethical values: believe the project deserves social acceptance

- Rights: the legal rights such as occupational health & safety may
- Religious beliefs: are religious beliefs shaping opinion
- Political opinions: could political opinions be triggering support or opposition to the project
- Business interests: stakeholder expectations the project to boost or shrink business revenue
- Knowledge: How knowledgeable is about the project
- Demographics: things like age, median income and access to employment opportunities can greatly affect opinions of stakeholder.
- Environmental stewardship: environmental sustainability project
- Value of ownership: does the stakeholder stand to gain or lose something of value such as their farm or the propriety
- Communication preferences: the method to communicating with stakeholders (online communications, or value face-to-face meetings).

Fig. 2: Interest matrix of stakeholder (adaptation after Coble, Yank, Coussens, Christine, Quinn, and Kathleen(2009))

Making Matrices

In the literature are presented several ways to build this tool. We will not stop at the elements of form but we insist on the elements of content.

This type of tool is widely used in the field of projects with social impact. The main objective is to standardize the presentation of the project so that similar projects carried out at different times can be compared.

Another equally important goal is to present the entire project in a single form so that team members do not have to periodically search for the necessary information, facilitate the transparency of teamwork and increase overall efficiency.

For each action alternative, a matrix is made that presents in a standardized form what needs to be done.

By drawing up a matrix, the action strategies are designed and the best strategy related to the purpose and objective of the project is chosen. First, the purpose and objective of the project are defined, all the strategic alternatives for them are elaborated, and then all the alternatives are evaluated using analyzes such as PEST, cause-effect diagram, etc.… (Fig 3. Power matrix of stakeholder (adaptation after Botten, N. (2006))

Fig. 3: Power matrix of stakeholder (adaptation after Botten, N. (2006))

In the stakeholder analysis phase, we can build a classification matrix to ensure that truly important people (key stakeholders) receive the attention they deserve from us.

The first step is to make the list of stakeholders and compile the questions that help to correctly identify the key people and understand the motivations:

1. Who is involved in the project?
2. Who can be affected by this project?
3. Who can influence this project?
4. How will the implementation, implementation or even location of stakeholders affect the implementation of this project?
5. Will there be reasons that may involve a career?
6. What are your reasons for supporting or blocking the project?

etc ...

The list is extended according to the additional information regarding the level of INTEREST and INFLUENCE that the stakeholders have in the project, and their prioritization.
We will give a score between 1 and 10 for each of these two criteria (1-lowest weight, 10 - highest weight). To point to the INTEREST column, you can be guided by the answers to the possible questions above (Tabel 1: Matrix stakeholders)

Turning to the INFLUENCE section, we can consider here the level of people within the organization, its level of authority in making decisions regarding the budget, time and resources of the project, if there are friendly relations with other key stakeholders.

The stakeholders with a maximum degree of influence and extremely interested in the project (stakeholder score 11-10), must create and maintain close collaborative relationships, must be actively involved in the analysis phase (ensuring that the project meets their needs), and informed quickly. Much of the energy and attention of the project manager in the management activities of the "stakeholders" will be directed to this group (Tabel 2: Stakeholders analysis with Action Plans).

Stakeholder with an almost maximum degree of influence or impact (stakeholder score 9-8), a high level of satisfaction must be maintained throughout the project; due to the strong influence they have in the project, we want their support to be preserved.

Stakeholders with little power in influencing the evolution of the project (stakeholder score 7-4), but extremely interested in its status and impact will have to be informed periodically; also consulting them on various problems can be beneficial in solving them.

As a last note, it is worth mentioning that the management activities of the people interested in the project represent a continuous process, which extends from the initiation phase to the closing phase.

Tabel 1: Matrix stakeholders

Number	Stakeholder	Their role in carrying out the activity	The influence of the activity on stakeholders	The influence of stakeholders on the activity
1	Actionary A 55%	Financial and technological support	10	10
2	Actionary B 35%	Financial and technological support	10	10
3	Management	Planning, organization, coordination and control	10	10
4	Administrative	Decisions, publications issued by the company, evidence of signed documentation	10	10
5	Manager IT	Technological support	9	9
6	Accountant	Financial support	9	9
7	Employees	Implementation	9	9
8	Customers	Benefits	9	10
9	Suppliers	Ensuring the necessary for services and products	8	10

Tabel 2: Stakeholders analysis with Action Plans

Stakeholder	Project impact on stakeholder	Stakeholder - level of influence on succes of project	Stakeholder´s current attitude toward project	Stakeholder Score - H=5, M=3, L=1, +=1, O=2, -=3	Action plan for stakeholder
Actionary A 55%	High (H)	H	+	11	Invite into project team at analyze phase
Actionary B 35%	H	H	+	11	Invite into project team at analyze phase
Management	H	H	+	11	Invite into project team at analyze phase
Administrative	H	H	0	10	Invite into project team at analyze phase
Manager IT	Medium (M)	Low (L)	0	4	Continue involvement on project team
Accountant	H	M	0	8	Invite at analyze phase
Employees	H	H	+	11	Invite into project team at analyze phase
Customers	H	H	+	11	Invite into project team at analyze phase
Suppliers	M	M	+	7	Continue involvement on project team

Conclusion

Effective stakeholder management is important because without stakeholders, an organization would not exist.

Therefore, it is imperative that organizations have a good relationship with both primary stakeholders - shareholders, investors, employees, customers - and the public - government and local communities - and secondary - the rest of the people directly or indirectly affected by the actions. the organization concerned.

Stakeholders are critical to the success or failure of a project. That is why stakeholder analysis is a critical part of project management as well. Stakeholder analysis will help to determine stakeholders of a project.

Stakeholder analysis is the identification and classification of stakeholders in the project. This helps project managers to prioritize stakeholders and plan for their engagement. Stakeholder Analysis also helps in understanding the communication needs in the project.

Infrastructure 2 Pedestrian System to Increase Human Life and Health Safety

Krzysztof MASLANKA

Faculty of Electronics, Military University of Technology, Warsaw, Poland
krzysztof.maslanka@wat.edu.pl

Pawel SKOKOWSKI

Faculty of Electronics, Military University of Technology, Warsaw, Poland
pawel.skokowski@wat.edu.pl

Abstract

This paper presents an Infrastructure to Pedestrian (I2P) system to increase human life and health safety. After introducing the reader to the subject of the issue, the authors motivate their research area to increase pedestrian safety on the roads. Then, the concept of the proposed method is presented. Next technical solutions for the prepared I2P system are defined and explained. Moreover, an estimation of the potential profits from the implementation of the proposed concept is shown. The article summarizes brief conclusions.

Keywords: pedestrian safety, infrastructure to pedestrian, accidents, localization.

Introduction

Every day, road users are killed or injured on the roads of the whole world. More than 1/5 of people who die on roads do not use a car, motorcycle, or bicycle - they are pedestrians (WHO, 2013). The current technical and technological possibilities related to the automotive industry and wireless communication systems create an opportunity to use them to increase pedestrians' safety as road users. The most popular ones are those responsible for communication of Vehicle to Pedestrian - V2P, Infrastructure to Vehicle – I2V, Pedestrian to Vehicle - P2V. The authors would like to present an I2P system to increase human life and health safety. The original proposal concerns a novel I2P approach to increase human life and health safety, presented in (Skokowski and Maslanka, 2020). The proposed solution may be an element of system implementations to increase pedestrian safety and allow for significant profits to secure human health and life and the consequences resulting from their loss.

Situation of pedestrian safety

People die on roads worldwide - over 270,000 are pedestrians, which accounts for over 20% of all road fatalities. Apart from deaths, over a million pedestrians are injured each year due to accidents. Based on many studies, it is possible to indicate the causes of accidents and the methods of preventing them or minimizing the probability of their occurrence (WHO, 2013; Zegeer and Bushell, 2010; Job, 2012; Peden et al., 2004; Stigson et al., 2008; Mooren et al., 2011). The most critical factors influencing pedestrians' safety are vehicles' speed, alcohol consumed by drivers and pedestrians, deficiencies in infrastructure solutions, and inadequate, insufficient visibility of pedestrians on the road. While in some cases, social campaigns and promoting road safety can make a difference, good pedestrian visibility and supplementing the infrastructure with appropriate solutions will certainly improve pedestrians' safety on the road.

The concept of the author's solution is shown in fig. 1. The proposed system is based on the communication of road infrastructure elements with pedestrian mobile devices to prevent dangerous road incidents involving them. The basic assumption is to equip the existing or newly emerging road infrastructure with devices enabling communication between pedestrians and infrastructure elements. Mobile devices equipped with appropriate wireless technologies, such as Bluetooth, 5G, or technologies developed in the future (Skokowski et al., 2017; Malon et al., 2017, Malon et al., 2018), can communicate with the infrastructure.

Cite this Article as: Krzysztof MASLANKA and Pawel SKOKOWSKI "Infrastructure 2 Pedestrian System to Increase Human Life and Health Safety" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig. 1: Proposed a novel Infrastructure 2 Pedestrian (I2P) approach for increasing human's life and health safety

In (Skokowski and Maslanka, 2020), the authors estimated the social costs in the year 2018 in Poland (Jaździk-Osmólska and Korneć, 2018; Symon, 2019), because of the accidents with pedestrians. The total cost for the three basic causes of pedestrian accidents is valued at over 600 million EUR. Considering the authors' solution, investments made in the appropriate road infrastructure can allow for huge savings. The forecasts of road accidents' costs until 2023 will amount to a total of 10 billion EUR. The proposed I2P approach has an immense application potential and can directly contribute to increasing pedestrian safety and significant social benefits. Simultaneously, it should not generate enormous investment costs and, more importantly, not for the end-users of this system - pedestrians.

Table 1: Potential profits in Poland using the I2P solution

PROFITS in million EUR / efficiency of the solution	100%	90%	80%	70%	60%	50%	40%	30%	20%	10%
Careless entering the road	414.1	372.7	331.3	289.9	248.5	207.1	165.7	124.2	82.8	41.4
Crossing the road in an illegal place	106.7	96.0	85.3	74.67	64.0	53.3	42.67	32.0	21.3	10.7
Entering the road at the red light	81.8	73.6	65.4	57.2	49.1	40.9	32.7	24.5	16.7	8.2
Total	602.6	542.3	482.1	421.8	361.5	301.3	241.0	180.8	120.5	60.3

The potential public profits using the proposed I2P solution in a million EUR for different values of its' effectiveness are shown in Table 1. It can be noticed that even for very low efficiency, the profits achieved can be huge, and the saved resources can be used for other purposes.

Technical solution for a proposed approach

Modern wireless communication systems might be used for many applications. The basis for the effective operation of I2P for increasing pedestrian safety is the pedestrian's precise location in the vicinity of the road infrastructure. The solutions currently used to determine the mobile device's position, such as GNSS signals and 4G cellular systems, are too imprecise. The new standardization solutions that are just being introduced to the market, such as Bluetooth 5.1 (Woolley, 2019), or the planned solutions in 5G systems, enable the device to be located with high

accuracy.

Positioning performance requirements have been sharpened further in 3GPP Release-17, which targets higher accuracy positioning requirements. For the Industrial Internet of Things (IIoT) use cases, the positioning error is in the range of 10 cm to 1 meter (Patel, 2020). For general commercial use cases, it is in sub-meter level position accuracy (Qualcomm, 2019). The target latency requirement is less than 100ms, and for some IoT use cases, latency in the order of 10 ms is desired. The quick work of the system determining the node's location is also significant from the point of view of the I2P solution (might be used during running or cycling).

Currently, the most accurate results from existing location systems are provided by Bluetooth. Hence, one of the basics of building the I2P system may be equipping road infrastructure elements with Bluetooth communication devices. The prepared infrastructure supported by location services using the 5G system and the I2P system could be launched as one network function. It means that it shouldn't be costly to establish such a solution (Khan et al., 2020; Zhang, 2019).

Fig.2: Proposed technical solution for Infrastructure 2 Pedestrian (I2P) system to increase human life and health safety

The pedestrian using the system has an application running on his device, which, using the location services offered by the user's end device, monitors the place where the user is, the direction in which he is moving, and the speed at which he is moving (fig. 2). At the same time, information about the road infrastructure, road, or intersection structure is downloaded. They allow us to determine whether a pedestrian is approaching the edge of the road, about the traffic lights' status at the corner, and, if possible, about any approaching vehicles. This information may come to the user's terminal from communication devices located in the road infrastructure elements or from central servers operated by the road manager in a given city or country. The data collected in this way will allow the use of intelligent computing algorithms, which will warn him, using the mechanisms available on his end device depending on the user's behavior.

The proposed I2P solution could indicate pedestrians' presence on the road through communication between their devices and the road. The infrastructure could then use communication via I2V and I2P to transmit information to connected cars. The vehicle driver would be notified with an appropriate message about a pedestrian's presence on the road despite the lack of visibility. In this case, the infrastructure can also inform a pedestrian about the situation.

Conclusions

The year-to-year social costs of each country related to the loss of life or damage to pedestrians' health connected with road accidents are huge. Nowadays, there is a need to build road infrastructure that would increase pedestrian safety. The I2P concept can prevent road accidents involving pedestrians by equipping the infrastructure with appropriate technology. The proposed I2P solution seems easy to implement, using already existing technologies. Building the system in the phase before the launch of precise 5G systems location services will require financial costs for equipping road infrastructure elements (traffic lights, lanterns, crossroads, etc.) with communication

devices and enabling location pedestrians using the I2P system. During the construction of the 5G system, it should be considered whether not to include in the tenders for frequency bands transferred to operators also the provision of new I2P services proposed by the authors. The presented estimation of potential savings shows the profits by implementing the proposed solution. The expected costs of implementing the I2P system will be much lower than the costs incurred yearly due to pedestrians' accidents, and most importantly, they will not be the same large each year. Over time, an I2P system's investment will decline and may start to generate profits in a brief period.

The novel I2P system to increase human life and health safety should be considered by relevant state authorities and institutions when developing solutions to improve pedestrian safety. Therefore I2P solution should be considered by automotive industry organizations like New Car Assessment Programme (NCAP) or car manufacturers while developing new technologies, i.e., connected cars.

Breaking Voice Authentication – Security Testing Approach

Olga DZIEGIELEWSKA

Military University of Technology, Warsaw, Poland
olga.dziegielewska@wat.edu.pl

Abstract

A couple of years ago, along with raising popularity of smart devices that promote voice authentication mechanisms, voice recognition became a buzz topic again. Not only voice patterns recognition algorithms significantly improved their quality, but also with a rapid growth in the development of sound editing tools and an outburst of the deep-fake concepts, the attack surface of voice authenticators significantly expanded. This paper describes the approach for penetration testing of the voice recognition solutions and tackles common misconceptions of voice patterns characteristics.

Keywords: Voice Biometrics Testing, Voice Biometrics Threat Modelling

Introduction

In the recent years voice authentication systems are on the raise. Along with raising popularity of smart devices voice unlock functionality, other industries started looking deeper into the possibility of voice authentication implementation for their needs as a single or a part of a multi-factor authentication, e.g. in IVR systems. As an effect the threat landscape changed.

So far there are no standardized documents explaining the approach to testing of the voice authenticators, therefore security researchers try to apply and adapt different techniques and processes when assessing the security of such mechanisms. This paper presents a proposition of an approach to security testing of the voice authentication systems starting with the threat modeling, proposing test scenarios and concluding with the risk evaluation for the identified issues.

Voice Authentication Systems

To better understand the threat landscape a security researcher or assessor must first understand the basic breakdown of the voice authentication systems and their characteristics as it provides better understanding of the potential threats.

Online systems are understood as systems, which are evaluating the samples using online database that is updated in a concurrent manner, e.g. online IVR systems.

Offline systems are understood as systems, which are evaluating the samples using offline database that is frequently physically stored on the input device, e.g. smart devices.

Active authentication or ***non-adaptive authentication*** is understood as a process in which a user is aware of the voice authentication process as he is asked to provide a voice sample during the process (Gajo, A., 2020).

Passive authentication or ***adaptive authentication*** is understood as a process in which a user may not be aware of the voice authentication process as he is not asked to provide a voice sample during the process, but the system analyzes the voice that is gathered through a different process, e.g. during a conversation with an online banking assistant (Gajo, A., 2020).

Cite this Article as: Olga DZIEGIELEWSKA "Breaking Voice Authentication – Security Testing Approach" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Playback detection or ***fingerprinting detection*** is feature of the authentication system that allows to detect the same voice sample being replayed into the input device during two independent and separate authentication processes.

Recording detection is feature of the authentication system that allows to detect the recording of a voice sample being provided into the input device. This type of feature frequently provides further breakdown portraying its accuracy when using ***collaborative*** and ***non-collaborative*** recordings. Collaborative recordings are understood as high quality recordings of a user saying his authentication quote directly to the recorder, while non-collaborative recordings are understood as low quality recordings that were grabbed without user's knowledge.

Understanding Voice Dynamics

To properly assess security of voice authentication systems it is important to understand the physical properties of the voice dynamics, including: the linguistic properties of languages the authentication system is designed for, acoustic conditions during the sampling process and the genetic properties.

The linguistic properties that need to be taken into account as a minimum are phonemes, inflexion and intonation of the covered languages. Those three characteristics help to differentiate not only the languages, but the nationalities of the sample suppliers as non-native speakers tend to mirror the inflexion and intonation of their native languages when they speak in a different language (Crystal, D., 2008).

One characteristic that is partially a linguistic and partially genetic property is the tempo, as both of the factors influence the tempo of one's speech. Another important genetic property is the genetic similarity, which can be understood as the degree to which voice of different people is similar. This is especially important for considering the corner cases in the threat modelling process as people who are related tend to have close proximity when it comes to the genetic voice characteristics.

The acoustic conditions also play a huge role in voice sampling as the background noise or the echo that is present during different phases of the voice authentication can later influence the overall security of the system.

Threat Modelling

The threat modelling process for voice authentication systems testing follows typical steps for such activities, i.e., at first the scope of the test must be determined, then the documentation analysis should be performed and, as a last step, the test scenarios are created.

Determining the scope is a crucial part of each test, but in case of the biometrics testing it is especially important to establish the project limitations as there are no standardized systematic approaches to tackle each and every aspect of the biometrics mechanisms security testing, e.g., similar to the OWASP ASVS. The main question to ask is what the purpose of the test is, as different scenarios would be developed accordingly dependent on the purpose. In case of the voice biometrics the key aspect is the validation the biometrics engine's susceptibility to attacks performed from a perspective of an external attacker. The important factor here is to determine what kind of attackers pose the most threat to the tested environment and to understand this the characteristics of the tested solution required.

What naturally follows is determining what kind of testing can be performed, i.e., white-box, grey-box or black-box. When performing testing for the biometrics product owners, the white-box approach is a feasible option, however in most cases the tester will not have access to the source code of the solution, therefore grey-box and black-box are more common.

Regardless of the selected testing approach it must be confirmed at early stages of the threat modelling which biometrics engine is used and what are its features. Getting to know what kind of the engine is in use allows to craft tool-specific scenarios.

What also helps in developing dedicated test cases is the documentation of the system, understood not only as the technical specification of the product itself, but also the actual implementation and post-implementation documentation, the risk analyses and procedural guides. The relevant supporting documentation should be identified as one of the first steps of this part of the assignment as any gaps in the received material may impact the outcome of the test, therefore should be addressed before actual testing phase. In case of the full black-box testing approach, it is most likely that there will not be any kind of documentation provided beforehand, therefore the threat modelling and the scenarios development must be based on previous experiences of this sort as no systematic standard for testing voice-based biometric authentication are formally developed yet.

The key elements to look for in the system's documentation are:

- What kind of features provides the system?
- What is the type of accepted input and the type of the provided output?
- How is the voice pattern stored in the database? How is the integrity of the pattern over time measured?
- Where is the pattern stored (product owner's side, integrator's side or the client's side)?
- Does the tool provide:
    - playback detection, also described as fingerprinting,
    - recording detection and if so, how its effectiveness differs for collaborative and non-collaborative recording types,
    - genetic similarity detection?
- If the engine can be used in the telephony systems:
    - What are the accepted telephony protocols?
    - Does the engine provide the same level of resilience against attacks using different kind of telephony protocols?
- How the supporting infrastructure architecture looks like and what kind of security protection mechanism are in use?

The last question is especially important as in the voice biometrics systems, there are usually three key elements that need to be somehow connected: the voice samples recording system, the biometric engine and the database. The interesting case are the telephony systems which use the telephony devices with conjunction of the telephony protocols as their recording system, therefore introducing more threat vectors to the initial assessment.

Except from the technical layer, the procedural layer may be also assessed as a part of the assignment. Nonetheless, it must be noted, that the procedural part may help in understanding the business need of biometrics use cases for the authentication system and also to properly assign the risk levels after a gap or vulnerability is identified but should not state a sole subject of the biometrics systems' testing. The key elements to look for at the procedural level are:

- What kind of business processes are protected by the biometric authentication?
- How does the decision tree for the processes look like?
- What are the stages of biometric pattern registration?
- What are the stages of the biometric authentication?
- Have any risk analyses been performed for the process and the selected tool? What are the results? What elements have been analyzed?

The important factor that needs to be mentioned here is establishing the relation between the product owner, i.e. the biometric engine legal owner and the entity that requested the test of the engine. If the product owner requested the test, the case is pretty transparent.

If the requestor is a different legal entity, then it is worth confirming with the client that the third-party provider is notified that the test activities will take place and that the agreement between the client and the third-party allows for such activities. It is also important to confirm the legal aspects, as in case of a gap or vulnerability identified in the solution itself, the risk mitigation falls onto the product owner and the requestor loses the control over the mitigation process, what must be taken into account.

Depending on the project scope established in the previous steps and information gathered during the documentation analysis, the threat models and the test scenarios strictly related with them can be designed.

Test Scenarios

In case of biometrics mechanisms testing, potential attack scenarios prepared and agreed with the test requestor help in understanding the real threat related with used solution. In contrast with standard approach of vulnerabilities testing it's based rather on story-telling than automatic-scans-like vulnerabilities detection.

As the previously mentioned, the fundamental division of the scope areas in case of voice biometrics testing are:
- Supporting infrastructure tests,
- Biometrics engine tests.

Additionally, the perspective of an attacker must be considered, e.g.:

- External attacked with limited resources,
- External attacker with unlimited resources,
- Internal attacker with limited privileges,
- Internal attacker with unlimited privileges.

The following pages present the general outline of the test, focused on the specific areas and more detailed baseline for the biometrics engine test.

From the requestor's risk perspective, the key part of the engagement is usually the biometric engine test scenarios covering the perspective of an external attacker.

A. Threat agent: internal or external with internal access

The table below presents base scenarios for the threat agent describes as an internal attacker or an external attacker who gained access to the internal system.

Scenario name	**Description**
Algorithm-level abuse	Targeted area: biometric engine Action: Analysing used algorithms in terms of effectiveness against the voice recognition attacks.
Source-code level errors	Targeted area: biometric engine Action: Analysing the source code of the biometric engine, including its configurations, to verify the effectiveness and security of the implementation of the algorithms and the system as a whole.
Voice pattern integrity abuse	Targeted area: infrastructure Action: Verification of the database server and the database security by analysing its configuration and performing exploitation of the attacks identified in the infrastructure that could affect the database integrity. Attempts to replace the patterns from the perspective of different roles in the system (e.g. administrator, regular internal user, external user).
Voice pattern capture	Targeted area: infrastructure Action: Traffic analysis between the system's elements. Measuring the probability of capturing the voice pattern by tapping the user's phone.
Voice pattern leakage	Targeted area: infrastructure Action: Traffic and configuration analysis covering the system's elements.
Man-in-the-Middle for registration or validation	Targeted area: infrastructure Action: Attempts to proxy the voice traffic between the user and the analysed system.

B. Threat agent: external attacker

The table below presents base scenarios for the threat agent describes as an external attacker who has only access to the input interface of the system. All of the scenarios mentioned below target the biometric engine.

Scenario name	Description
Voice pattern registration process abuse	Attempts to register a biometric pattern under various acoustic conditions (e.g., different characteristics of background noise) and technical condition (e.g., registration of samples from recordings) to verify how such cases affect the authentication mechanism.
Voice pattern reregistration	Attempts to use or bypass alternative authentication methods available in the system to modify (or overwrite) the already registered biometric pattern. Attempts to invoke parallel pattern registration for the same user ID and verifying how such action affects the authentication mechanism.
Brute-force attack	Verification of the engine tolerance when modulating / fuzzing the created pattern.
Replay attack	Performing replay attacks by recreating a previously captured pattern, including attempting to adapt the system tolerance to the patterns used (i.e. obtaining the effect of increased tolerance).
Deep-fake voice simulation	Attempts to create an AI voice avatar from voice recordings and using simulated voice in the authentication process.

The test scenarios mentioned in above can be treated as a base for the voice biometrics system testing with the focus put on the biometric engine. It must be noted that there are other aspects not covered explicitly here, e.g., hardware security, network security or database security, but the scenarios targeting the infrastructure elements are partially tackling those areas. The weight was put on the biometrics aspects testing, as those are characteristic only for such solutions and other aspects can be treated as somehow supporting elements, whose security must be assessed and comply with the standards but are not the subject of this paper.

Biometric Engine Test Scenarios Implementation

Each of the scenarios targeting the biometric engine depending on the test environment can be completed using different approaches and tools. In the sections below, a workplan's steps and tooling are proposed along with appropriate commentary regarding the implementation of the scenarios in the test environment.

The first two scenarios assume that an attacker is a person with an internal access to the environment, i.e. indicating white-box or grey-box testing (depending on the scenario). The other five assume that an attacker has only access to the input interface and has no other knowledge regarding the system.

A. Algorithm level abuse

Algorithm level abuse intents to find security gaps at the algorithmic level of the voice biometrics engine. This scenario covers analyzing used mechanisms against the current state of the voice recognition algorithmic designs and verifying the concept and the design of the algorithms, including allowed setup and use-cases.

There are no particular ready-to-use tools for this activity, as the review is performed based on the research and understanding of the current trends. The review checklists can be used to make the assessment more systematic, but the detailed steps will depend on the latest developments in the area, therefore rather cannot be standardized.

B. Source-code level errors

Source-code level errors detection aims at identification of the gaps in the implementation of the algorithms that were analysed as a part of the *algorithm level abuse* activity. It is important to note that even if an algorithm is proven to be secure, the improper implementation can introduce security vulnerabilities.

This activity focuses on the code review of the biometric algorithms however the code should be analysed as a whole, as the overall integration of the key algorithms with the system is also an important element where the security vulnerabilities may be introduced.

Another element of this activity is the biometrics engine configuration analysis. It must be understood that the implementation of the engine and its supporting system is a separate element to the configuration of the solution. In most cases the configuration of the biometric authentication system lies in the competencies of the product user, i.e. the systems can be configured differently depending on the product user's needs. A product user is understood as a party who implements the solution into its infrastructure.

The configuration review must be performed bearing in mind that the system must not only be secure but also usable, therefore setting all the parameters to provide the smallest level of the verification errors may not be a feasible option. A proper trade-off between the usability and the security must be determined based on the characteristic of the reviewed system and most likely this activity will almost always have to be done manually.

The source code review on the other hand provide a variety of tooling for static, dynamic and interactive analyses. Vast majority of them are automatic or semi-automatic tools that may miss the mark on the key aspect which is the implementation of the biometric algorithms. The algorithms implementation review should be done manually with support of the code review tools. Just as in the previous scenario, the review checklists can be used to make the assessment more systematic, but the business logic issues are impossible to be standardized in such form.

C. Voice pattern registration process abuse

Voice pattern registration process abuse targets the initiation of the biometric authentication mechanism for a particular end-user. This scenario covers:

- Registration of the voice patterns in different acoustic conditions, e.g.:
  - artificially generated or reduced background noise with varying amplitude and volume,
  - artificially generated or reduced echo,
- Registration of the voice patterns in various technical conditions:
  - pattern registration from recordings,
  - for the telephony systems: pattern registration using different parameters of telephone connection (e.g. 3G, LTE, VOIP).

There should be no direct relationship between various acoustic and technical conditions during the registration process and security of the authentication process identified, i.e., the identified authentication issues occur regardless of how the pattern was registered to pass this scenario. However, some functional errors may be identified that do not have a direct impact on system security.

To effectively execute this scenario, the tester would need access to audio devices, serving as an input (recorders) and output (speakers) and an audio editor. In case of the telephony systems testing, additionally a telephony devices and virtual audio devices allowing for coupling the audio inputs and outputs should be also used.

D. Voice pattern reregistration

Voice pattern reregistration attempts to find gaps in the processes responsible for changing the registered biometric patterns.

This scenario can cover attempts to invoke registration mechanism for a user with already registered biometric pattern and parallel voice pattern registration for the same end-user abusing the race condition on different devices.

Such behavior can be a result of the misconfiguration of the biometric engine or introduction of vulnerabilities at the source code level, therefore when testing this scenario from a perspective of an external attacker some of the conditions in which the existing vulnerability would be exploitable may remain stealth.

In general, the system should not allow for reregistration or parallel voice pattern registration. In case the parallel voice registration is not blocked, then the authentication should be possible using only one pattern – the one that has been registered as the first pattern. In such case it's also worth testing how technical errors, such as closing the connection before the pattern has been successfully registered affects the authentication process.

E. Brute-force attack

Brute-force attack verifies the engine tolerance when modulating or fuzzing the created authentication pattern. The aim of the attack is to verify how the sound distortions can affect the authentication process. There should be no direct relationship between various acoustic distortions and security of the authentication process identified, i.e. the identified authentication issues occur regardless of the distortions present to pass this scenario.

The scenario-related activities would include:

- Adding noise and sound distortion with different characteristics to the attempts to authenticate with natural voice and recordings.
- Attempts to authenticate by other people for the registered tester pattern.
- Attempts to authenticate by other people, genetically similar, e.g. twin, siblings, family members, for the registered tester pattern.

With regards to the genetic similarity recognition, it must be noted that the legal factor must be taken into account when deciding to perform such activity. It should be agreed with the test requestor whether this kind of scenario should be pushed during the testing, due to the liability reasons, in case of using voice samples that are originating from the tester's relatives which are not a party in the agreement between the test's requestor and the tester.

To effectively execute this scenario, the tester would need access to audio devices, serving as an input (recorders) and output (speakers) and an audio editor. In case of the telephony systems testing, additionally a telephony devices and virtual audio devices allowing for coupling the audio inputs and outputs should be also used.

F. Replay attack

Replay attacks are performed by recreating previously captured voice pattern of a user, including attempting to adapt the system tolerance to the patterns used (i.e. obtaining the effect of increased tolerance).

To understand the importance of this scenario it must be noted that available voice recognition tools classify their resistance against such attack in different manners. Some of them would consider the "replay" attack as reusing the identical perfect recording of a voice sample, in some cases this kind of behavior is referred as sample fingerprinting or playback resilience. Other tools would define the replay attacks as the recording detection. It is important to note the difference at the definition level, as this changes the understanding of the risk factors characteristic for the tested solution.

Another important factor to consider is the adaptivity of the authentication process. Some of the solutions, provide the adaptive mechanism that dynamically analyze the end-user's voice and other ones provide the only static phrases verification and they can be differentiated as follows:

- When there is no adaptive mechanism – static constant phrases are the key
- When the mechanism is designed as passive adaptive mechanisms, the dynamically changing phrases are used as keys
- When the voice recognition happens as the background task, i.e. during regular activities unrelated with the authentication process – an active adaptive mechanism is used.

The scenarios for the replay attack are based on the prerecorded phrases. Depending on the adaptivity of the system, the testing scenarios vary. For the non-adaptive system, the risks related with reusing prerecorded phrase is the highest among the mentioned ones, as capturing a valid pattern sample is higher.

Before performing the scenarios, sample recordings must be crafted. The voice recognition systems usually divide the recording to the collaborative and non-collaborative ones. The first type is the kind of recording when an attacker records the samples with close proximity to the victim in perfect acoustic conditions. The second type is the kind of recording captured in bad acoustic conditions, without the close access to the victim.

To test the system's actual resilience in both cases, continuous and composite recordings can be used. Continuous recordings are understood as recordings of the complete phrase at the appropriate tempo of spoken words (approx. 2.5 words per second) and intonation for declarative, interrogative or imperative sentences of the used language. Composite recordings are understood as phrases composed of different statements of the person being recorded, from recordings of different sound quality, which did not meet the standards of the tempo of speech and intonation for declarative, interrogative or imperative sentences of the used language. This kind of differentiation is needed to fully test the effectiveness of the voice authentication mechanisms in the tested solution.

As it was mentioned above, depending on the adaptivity of the system, the test scenarios vary. The table below shows a summary of the test cases for specific systems.

Test case	**System characteristic**
Attempts to authenticate with other phrases, similar in the phonetic context and using a different set of phonemes, to verify whether the biometric engine based on the user's voice characteristics will correctly recognize it	non-adaptive
Attempts to authenticate with prerecorded continuous phrases.	Non-adaptive, passive adaptive
Attempts to authenticate with prerecorded composite phrases.	Non-adaptive, passive adaptive
Attempts to use voice simulator	Active adaptive

To effectively execute this scenario, the tester would need access to audio devices, serving as an input (recorders) and output (speakers) and an audio editor. In case of the telephony systems testing, additionally a telephony devices and virtual audio devices allowing for coupling the audio inputs and outputs should be also used.

It is also recommended to modify the recordings so that the volume of the spoken phrase exceeded the volume of background noise, what can be achieved naturally in the case of recordings from close range (collaborative recordings), or by appropriate editing (non-collaborative recordings).

In some cases, recordings are detected based on the differences of the background noise before, during and after replaying the phase, therefore a special attention must be put into those aspects in the testing phase, as the proper timing of the replay may play a key role as well.

G. Deep-fake voice simulation

Deep-fake voice simulation is based on creating an AI voice avatar which simulates the natural voice of the tester. It must be noted that dependent on the languages supported by the voice recognition system, appropriate generator must be used to properly reflect the targeted phonetics. Currently available non-commercial solutions support only selected languages, therefore the risk for those languages related with attempting this attack scenario is higher.

To effectively execute this scenario, the tester would need access to the voice simulator of the appropriate phonetics, audio devices, serving as an input (recorders) and output (speakers) and an audio editor. In case of the telephony systems testing, additionally a telephony devices and virtual audio devices allowing for coupling the audio inputs and outputs should be also used.

Biometric engine test scenarios implementation

The test environment setup is a crucial part of performing tests effectively and most likely will be common for the internal threat scenarios (i.e., scenarios A-B) and the external threat scenarios (i.e. scenarios C-G).

For the testes focused on the algorithmic and the source code level, the key element is the conceptual work, therefore, no particular configuration will be required. In detecting the source-code level error, automatic tools can be used to facilitate identification of the threats that can affect the overall security of the system and the environment should be appropriately prepared to serve the needs of used tools. Except form the infrastructure part, it also must be noted that different source-code review tools require different formats of the input data, e.g., compilable source code, compiled version of the solution, or only packed sources.

For the tests targeting the external threat the setup is more complex. First of all, a set of audio recording and playing tools must be determined. Ideally, more than one device should be used to mitigate the risk of false negative cases for the device-sensitive scenarios, e.g., replay attacks. A useful tool especially for the telephony systems verification are virtual audio devices that allow to redirect the audio device’s output into the audio device’s input (e.g., VB-cable virtual audio device). This kind of behavior allows to obtain the same method of compression for the recordings used in the replay attacks what proves to be more effective solution than using external devices.

When testing telephony systems, the tester must also have access to tools or devices that are able to connect to the system using different protocols (e.g., 3G, LTE, VOIP).

It is also important to select appropriate audio editor that provides the mechanisms to introduce sound distortions, modulate the background noise levels, combine multiple recordings into one and modify their acoustic characteristics, so that they are nearly identical. Additionally, for the deep-fakes voice simulation a voice avatar generator is required. One of the most popular ones currently available for the wide public is Lyrebird, however at the current stage of the development it supports only English phonetics.

Apart for the tester's environment, it must be noted that the test requestor must set up his environment for the testing activities accordingly as well. The details should be addressed at the planning phase of the engagement however, the key part is that the environment available for testing should reflect the production setup that is under the test.

Risk Evaluation and Mitigation Steps

As it was mentioned before, the risk evaluation for the biometric authentication mechanisms strongly depend on the procedural part. Even if a seemingly high-risk vulnerability is detected when testing the biometric engine itself, the actual risk for the organization must be evaluated taking into account the business risks related with this issue. The methodology that results most useful for that kind of activities is OWASP RRM which introduces the adaptable tradeoff between the technical and the business impacts.

Proposing the mitigation steps for the identified gaps and vulnerabilities in case of the biometric engine testing can be affected by the fact that the test requestor may not be the tested product's owner. It must be established what is the relation between the test requestor, the system's configuration owner, the system's owner and the product owner. Without this, the proposed mitigation techniques can not be feasible to introduce by the test's requestor.

Conclusions

This paper proposes an approach that can be followed during the security assessments of the voice authentication systems. It should be treated as a guide during the process of determining the scope of the assessment, deploying test scenarios and estimating the risks of the identified issues. However, it must be stressed that due to the fast-evolving area which biometrics authentication, the proposed approach should be reviewed and reevaluated on a regular basis to ensure the quality of the security assessment.

Green Economy as a Part of Corporate Social Responsibility Management by using Sustainable Business Model Canvas

Małgorzata RUTKOWSKA and Anna Maria KAMIŃSKA

Department of Management and Organisation, Faculty of Computer Science and Management,

Wroclaw University of Science and Technology, Wroclaw, Poland
E-mail addresses: malgorzata.rutkowska@pwr.edu.pl, anna.maria.kaminska@pwr.edu.pl

Abstract

The article is devoted to concepts of green economy on the background of Corporate Social Responsibility (CSR). The purpose of this paper to evaluate the relationship between the green economy as a part of corporate social responsibility in management with the use of a business model. In this article, Osterwalder's business model canvas is treated as a tool that supports green economy and CSR. The article uses the descriptive method as a preliminary tool. It consisted in distinguishing and describing a specific phenomenon, which is green economy and CSR. Complementary to the inductive approach, a reduction approach was used, allowing for the verification of the obtained generalizations.

Keywords: CSR, Green Economy, Sustainable Business Model Canvas

Introduction

In recent years, the concept of a green economy has gained international importance, especially as a part of CSR. In general CSR itself (and their links with environmental effects) are currently one of the key economic problems. However, it should be emphasized that promising approaches to CSR and green economy are subject to distrust, resulting, among others, from the lack of awareness and understanding.

In Europe, Corporate Social Responsibility has gained popularity thanks to the *European Union Green Paper* titled *"Supporting a European framework for corporate social responsibility"* published in 2001. In 2002, the U.S. National Policy Association found that Europe had surpassed the United States in terms of voluntary CSR activities. In general, this is the result of a more consistent integration of CSR measures with the Corporate Sustainability approach (Schaltegger, 2020).

Increasingly, in discussions regarding social responsibility and green economy, the need for a different view of the role of the economy, or even- entrepreneurship, in social development is emphasized. Thus, the combination of Green Economy and Corporate Social Responsibility is a responsible action in dynamically developing markets. These are good business practices, the activities of which, their strategy and models are directed towards sustainable development, i.e. the implementation of economic, social and environmental goals in economic activity. Currently, in the changing economic, political and social situation, it is important for entrepreneurs to develop new procedures of conduct in which the treatment of health and the environment will be important, or even priority.

The aim of the study is to indicate the idea of a green economy within CSR. The effect of these considerations is the analysis of activities using the Sustainable Business Model Canvas inspired by the idea of corporate social responsibility in accordance with the principles of green economy.

The goal formulated in this way is determining the adopted research method, consisting in a critical analysis of the literature on the subject and participant observation.

Green Economy

There are many different definitions of a green economy in the literature. The term *green economy* was first coined in a pioneering 1989 report for the Government of the United Kingdom prepared by a group of leading environmental economists, entitled Blueprint for a Green Economy (Pearce, Markandya and Barbier, 1989). It was a consensus definition to the term "sustainable development" and the implications of sustainable development for the measurement of economic progress and the appraisal of projects and policies.

The doctrine of economics, assuming the possibility of satisfying the needs felt by the present generation at the level allowed by available civilizational development, without reducing the chances for them to be met by future generations. This definition refers to the report of the World Commission for Environment and Development, under the direction of G.H. Brundtland, in which the main focus is on intergenerational justice.

In the Agenda 21 - sustainable development objectives are included in four basic categories (Keating, 1993; Borew, 1997):

- economic goals: e.g. change in consumption patterns, international cooperation for sustainable development,
- social goals: e.g. combating poverty, protecting cultural diversity,
- environmental goals: e.g. protection of biodiversity, sustainable farming and waste management,
- institutional goals: e.g. integration of environmental policy with economic and social policy, development of scientific research for sustainable development, strengthening the role of the most important social groups in decision-making processes (Zalega 2015, pp. 5-6).

In 2008, the term was revived in the context of discussions on the policy response to multiple global crises. In the context of the financial crisis and concerns of a global recession, United Nations Environment Programme (UNEP) championed the idea of "green stimulus packages" and identified specific areas where large-scale public investment could kick-start a "green economy" (Atkisson, 2012).

The flagship Green Economy Report released by UNEP in November 2011 under its Green Economy Initiative provides a working definition of "green economy" which has since been cited in numerous other publications.

UNEP has defined the green economy as "one that results in improved human well-being and social equity, while significantly reducing environmental risks and ecological scarcities. It is low carbon, resource efficient, and socially inclusive" (UNEP, 2011).

Another definition for green economy offered by the Green Economy Coalition (GEC; a group of NGOs, trade union groups and others doing grassroots work on a green economy) succinctly defines green economy as "a resilient economy that provides a better quality of life for all within the ecological limits of the planet." (GEC, 2020).

The key question arises: Why the colour green for an economy? The colour green is symbolic of the environment and emblematic of sustainable development, hence the green economy is an economy of the environment. A Green Economy system holds a Triple Bottom Line approach that emphasizes the interdependency between “people, planet and profit”.

As defined by the European Environment Agency, “the green economy can be understood as one in which environmental, economic and social policies and innovation enable society to use resources efficiently, improving people's well-being in an inclusive way, while preserving the natural systems that sustain us” [European Commission, 2020]. Figure 1 shows the relationships between sustainable development concepts within the triune concept has been presented.

Figure 1: Relationships between sustainable development concepts within the triune concept.
Sources: own study by https://www.mdpi.com/2071-1050/12/14/5582/htm, access: 05.11.2020.

The concept of sustainable development is created through ecology, society and economy. In turn, the green economy has an impact on the circular economy which means that there is increased control over the supply of natural resources

based on renewable resources. Green economy takes due account of environmental and social externalities. The green economy focuses primarily on resource efficiency and ecosystems as the building blocks of the economy and not on inclusive GDP growth as the ultimate economic goal. Moreover, environmental degradation undermines long-term economic growth and human development [Ponomarenko et. Al., 2020].

Figure 2: Inclusive Green Economy [Own study by https://www.switchtogreen.eu/?p=147, access:5.11.2020]

The Inclusive Green Economy (Fig. 2) as an economic model differs from traditional economies in that it includes a combination of three elements: environmental, social and economic. An inclusive green economy (IGE) has evolved from the green economy. IGE is a low carbon economy, efficient and clean to produce, but it also encompasses consumption and results, based on sharing, circular, collaboration, solidarity, resilience, opportunity and interdependence. According to the IGE, it is believed that there are many different pathways to environmental sustainability [UNEP 2, 2020] The transition to an inclusive green economy requires promoting and supporting sustainable lifestyles, increasing sustainable consumption and production (SCP) and encouraging the development of eco-innovation and resource efficiency [Switch to Green, 2020]**.** Such a green approach to the economy and the indication that CSR is a part of it indicates multiple benefits, such as: economic, health, safety, social and environmental benefits. Green economy as a part of CSR is a challenge to create conditions for the growth of prosperity and the growth of social equality in the management of the economy.

Bringing the green economy to an organization that already exists is not an easy task. A suitable tool can be managing the business model so as to weave the foundations of green management to increase Corporate Social Responsibility.

Business Model Management

Business model management started in the mid-90s of the last century. The concept of the business model has been described in many different ways using different definitions and interpretations. For the purposes of this article, it was assumed that "a business model describes the rationale of how an organization creates, delivers, and captures economic, social, and other forms of values" (Osterwalder A and Pigneur Y., 2010).

There are many business models in the literature. Therefore, it will be most appropriate to indicate not what kind of models these are, but what are the criteria for their division.

In 2011, the research team, Ch. Zott, R. Amit and L. Massa analysed 103 publications on business models and distinguished 3 main perspectives of business models (Zott et. Al., 2011):

- e-business, information systems and the use of the Internet in organizations (in relation to Internet enterprises)
- innovation and technology management (technological enterprises).
- strategic- related to value creation, competitive advantage and results of enterprises (all enterprises)

When we would like to describe a business model, it is possible to differentiate components of business model definition to strategic dimensions and basic key words like (Shafer, Smith and Linder, 2005):

- strategic choices: clients, value proposition, skills, revenues, competitors, offer, strategy, branding, diversification, mission,
- value creation: resources and assets, processes and activities,
- acquisition of value: costs, profits, financial aspects,
- value network: suppliers, customer information, customer relations, flows information, products and services).

Business model, can also be defined using four questions: who is the company's customer (who?), what the company sells (what?), how does it produce products and services (how?), why its activity it is profitable (why?) The above questions create the so-called magic triangle business model that includes three key model components business, i.e. value proposition, revenue model and value chain (Gassmann et. All., 2013) (Fig. 3).

Figure 3: The magic triangle of business model; Source: (Gassmann et. All., 2013)

Based on the information above we can have business model like: open source, pay – per - use, license, freemium, crowd-funding, cross-selling, etc.

The decision which business model is applicable and how to manage it is not so easy, especially when taking into account application of green economy in an organization. Authors of this paper are proposing to use Business Model Canvas created by Alex Osterwalder. Business Model Canvas is a plain sheet with 9 fields that define 9 essential points of the business (Fig. 4).

Figure 4: Business Model Canvas [Osterwalder, 2010]

Business model canvas can be used not only to plan and create a new organization, but also to modify the activities of an already existing organization. When creating a business model canvas, it is therefore crucial to properly specify the area of value propositions so that it reflects all the values, including green economy and social responsibility. When we properly define the unique value proposition, “filling up” the remaining fields becomes simple, because we know what resources we need, the climate is our client and how to reach him, with whom we will cooperate and on what terms, as well as what our cost centres and sources of income will be.

Corporate Social Responsibility

In the literature on the subject, corporate social responsibility is understood as: "(…) a management concept whereby companies integrate social and environmental concerns in their business operations and interactions with their stakeholders" [United Nation Industrial Development Organization, https://www.unido.org/our-focus/advancing-economic-competitiveness/competitive-trade-capacities-and-corporate-responsibility/corporate-social-responsibility-market-integration/what-csr, access: 01.12.2020]. Authors of this paper suggests to consider CSR management by simple, but effective tools, like Business Model Canvas or "magic triangle of business model" as mentioned before. This kind of approach would allow to understand honestly the basics of social responsibility. The following categories CSR are distinguished, i.e.: [https://www.businessnewsdaily.com/4679-corporate-social-responsibility.html, access: 01.12.2020]:

- Environmental efforts: One primary focus of CSR is the environment. Businesses, regardless of size, have large carbon footprints. Any steps a company can take to reduce its footprint is considered good for both the company and society.
- Philanthropy: Businesses can practice social responsibility by donating money, products or services to social causes and nonprofits.
- Ethical labor practices: By treating employees fairly and ethically, companies can demonstrate CSR.
- Volunteering: Participating in local causes or volunteering your time (and your staff's time) in community events says a lot about a company's sincerity.

The basis for the concept of social responsibility is the belief that it should contribute to the growth of the company's value by creating a shared value. Corporate social responsibility is treated as a concept that proposes a modern way of thinking and acting. This approach to the issue has the potential to bring benefits to business, society and the environment. In environmental dimension of CSR most important are so called green jobs and activities which lead to decrease of negative impact of business entities on natural environment (Popławski. et al., 2017).

Social responsibility of business has become a main trend in the world economy in the 90's of the 20th century, although it was born in the 30's. Then, Howard R. Bowen described corporate social responsibility as: "manager`s duty to conduct such a policy, make such decisions and determining such directions of business activities that will be consistent with the goals and values of society" (Rabiański, 2013). Corporate social responsibility is not clearly defined either in the subject literature or in practical activity. Moreover, different interpretations of CSR are adopted in various fields of interest, and a clear evolution of the interpretation of this concept is noticed (Demków, Sulich, 2017).

Figure 5: An enterprise model based on the stakeholder concept

Source: author's own elaboration based on Freeman E. (1984).

The CSR brings to some business entities a competitive advantage, especially to these, which are able to build transparent, long-term and lasting relationships with many stakeholders. Business should also create networks with their key stakeholders, including suppliers, legislative authorities and the wider community. Such relations with stakeholders are valuable sources of information for each organization. Most of the successful companies are companies that offer good working conditions throughout the supply chain (Camilleri M.A., 2017; Paliwoda-Matoliańska A., 2014).

Recently economic development has come at the expense of the natural environment. Environmental protection and rational management of natural resources are of key importance in relation to activities undertaken as part of corporate social responsibility. Sustainability requires a change in attitudes to business, and even far-reaching political decisions (e.g. introducing environmental taxes, or public investment in bicycle paths or renewable energy). CSR coexists with "unbalanced" behaviour that eventually outgrows it. An example here are companies that sell "green", ecological products, or simply have extensive charitable programs for local? communities, and at the same time their factories are big polluters or use ineffective technology (Moj-Ogrodnik.pl).

Sustainable Business Model Canvas

Using a Business Model Canvas to for CSR gives a Sustainable Business Model Canvas, that is in general a visual presentation of an ecological and social consequences of the activity in canvas area. The aim of this specific Canvas is to reduce negative and increase positive impact on society and nature [CASE,2018].

In case of green economy, the general aim is to reduce environmental threats and ecological shortages. So the goal for Sustainable Business Model Canvas would be development of the organization without environmental degradation. The management strategy, as for a green innovation, should then include following steps in the block-areas of Business Model Canvas:

- any adjustments should be done by small and progressive modifications,
- important changes done by re-designing,
- use ecological substitutes,
- if possible- apply innovative solutions.

The result of this process would be a Sustainable Business Model Innovation Canvas with a great potential, that would lead to effective change opportunities that would result in green growth [Henriksen, 2012]. The action of reverting traditional approach to business should be coordinated in every area of Business Model Canvas, however even a small change (two, three areas) would be a great success.

Figure 6: Transformation Business Model Canvas to Sustainable Business Model Canvas

Source: author's own elaboration based on[Beers, D. Van, Grossi F., 2015]

Sustainable Business Model Canvas (Figure 6.) would be a model that supports environment by replacing for example:

- in area of value proposition: traditional shipping by transportation with less co2 emissions,
- in area of customer segments: Asia-Europe trade customers by companies with green profile (less focus on fast transport), etc.
- in area of key activities: production by retrofitting (no waste), etc.

Those changes would radically differentiate business model form the conventional operations to significantly important environmental sustainability of business. Analysing the literature, it might seem that Business Model Canvas is a simple model, which is mainly used in the case of start-ups or newly emerging organizations that must demonstrate an innovative approach to creating an organization. However, applying it to sustainable development can prove to be the key to the success of an environmental-friendly green organization.

Conclusions

By meeting the foregoing, the following conclusions shall be presented:

- Nowadays, companies are increasingly expected to conduct their business responsibly on the one hand and engage in the life of the community and the environment in which it operates, on the other hand.
- Although in the literature you can find links between green economy and CSR, it is difficult to find advice on how to implement them in the organization. The theories presented are very general.
- Green economy and CSR are the criteria for a certain, in this case ecological, action of enterprise development. The positive correlation between CSR and environmental proactivity indicates separate business models.
- Business Model Canvas transformation into Sustainable Business Model Canvas is not easy, but possible in little steps, that can be very profitable for environmental sustainability.

The use of the Sustainable Business Model Canvas business model in order to implement green economy as part of the CSR will help to meet both social and environmental challenges.

University of Lodz, Poland, E-mail: jakub.donski@uni.lodz.pl

Agnieszka BUKOWSKA-PIESTRZYNSKA

Department of Logistics and Innovations, Faculty of Economics and Sociology,
University of Lodz, Poland, E-mail: agnieszka.bukowska@uni.lodz.pl

Abstract

The aim of the article is to present the origins of the CIM/SMGS consignment note and to analyze the changes in its use. It presents the latest transport data (2016-2020), showing the dynamics of using this solution across the external border of the EU in forwarding for Russia and Ukraine. It also indicates possible reasons for the dynamics of changes in its popularity. Article refers to the use of one of the functional unification tools in the field of freight transport between the European Union and third countries. Consignment note CIM/SMGS combines the required two different legal orders into one single transport document that may be used for wagonload services and for combined transport. It avoid reissuing of transport documents on EU external border and by doing so to simplify customs clearance – the authorities from the *European Free Trade Association* customs area officially recognized it for use as transit declaration. The CIM/SMGS consignment note is significant for reducing delays in cross-border rail transport. The article uses the analysis of statistical data, applies the theoretical and empirical perspective.

Keywords: cross-border freight, international exchange of goods, railways interoperability, transport law harmonization.

Introduction

The transportation system of any country's is not a whole, neither separate nor self-sufficient. It stays in direct connection with the transport systems of other countries (usually neighboring, but also constituting a component of meta- or macroeconomic systems, i.e. cross-border logistics chains). Together, they constitute regional transport networks, which reduces them to a peculiar system of "connected vessels". Consequently, in the economic activity of transport, the legal provisions regulating transport between two or more countries are of particular importance. The solution to the need to regulate this sphere are international conventions and agreements, which are part of the international law system (Szanciło, 2013). Documents relate to both civil law relations and administrative-law issues. Therefore, in international terms, they regulate not only property relations between entrepreneurs and recipients of their services (clients), but also technical requirements, the formula of customs clearance and the organization of state borders crossing.

The preparation of the transport process means the necessity to organize and regulate a number of legal, organizational, technical and commercial issues. Their importance increases in the case of a process involving the international environment. In addition, it often comes down to regulating very specific issues, related, inter alia, to with the geographical aspect and the possible diversity of local transport subsystems. In such cases, the entire spectrum of divergent issues cannot, as a rule, be regulated by a single source of law. Nowadays, the legal systematization of the international transport process requires the involvement of international organizations, whose tasks boil down to ensuring a platform for cooperation between states and the rationalization of transport relations. This means the necessity to develop and implement normative documents.

In Eurasian East-West freight routes, there are two legal systems on the basis of which rail freight is carried out in international communication. The foundation of international rail law, applicable to goods in trans-Eurasian transport, is based on two legal acts: the *Agreement on International Rail Freight Transport* (SMGS), adopted at the conference of representatives of railway authorities of the signatory states in December 1950 and the *Convention concerning*

Cite this Article as: Jakub DONSKI-LESIUK and Agnieszka BUKOWSKA-PIESTRZYNSKA "CIM/SMGS Consignment Note as A Necessary Document in The New Legal Regime for Cross-Border Rail Freight Transport – Trends on The External Border of The European Union" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

International Carriage by Rail Convention of 9th May 1980 (COTIF) in the version of the Protocol of Modification of 3rd June 1999. The carriage of freight between Europe and Asia is governed by two different legal regimes: the *CIM Uniform Rules* (CIM) and the SMGS. At the interface between these two legal regimes, shipments have to be reconsigned and a new consignment note has to be made out. The aim of the article is to present the origins of the CIM/SMGS consignment note and to analyze the changes in its use. It presents the latest transport data (2016-2020), showing the dynamics of using this solution across the external border of the EU in forwarding for Russia and Ukraine. In addition, possible reasons for reducing the popularity of the use of the document have been identified.

Unification and harmonization of solutions for freight shipments on railways

Harmonization, as a process of making practices compatible by reducing differences in order to achieve a level of similarity between systems, takes into account the fact that some differences between systems may remain (Paise and Paise, 2013). The issue of unification of the transport law relating to cargo handling emerged in October 2003. Then, during the international transport law conference in Kiev, the program entitled *Transport and legal interoperability of CIM and SMGS* was adopted, the aim of which was the harmonization of transport documents. Its implementation envisaged two phases. First, to development of a unified CIM/SMGS consignment note, which would meet the requirements of both transport contracts without infringing the scope of their mutual responsibility (document should become a customs and banking document). Second, agreeing on a unified complaint handling procedure with regard to shipments, sent on the basis of each transport contract and relevant documents.

The project was carried out jointly by experts from the International Rail Transport Committee (CIT) and the Organization for Cooperation of Railways (OSJD). First dedicated agreement, guaranteeing the balance of interests of railways and carriers using the SMGS and the COTIF, was signed on March 30, 2006. Its purpose was to develop a joint consignment note that would enable the transport of goods between railways applying different legal systems, without the need to change documents transport at the stations where they meet (e.g. in Poland, Slovakia and Hungary), i.e. countries bordering the railway infrastructure with a track gauge of 1520 mm.

A pilot train transporting goods transported with the use of the joint CIM/SMGS consignment note was launched on 21st July 2006 from Donetsk and Nizhnedneprovsk to recipients in Germany. On 1st September 2006, the CIM/SMGS document entered circulation as a formal shipping and customs document. In 2010, the common consignment note was used for trains running on 50 routes. At the same time, more than half of the transports carried out with crossing the border of the COTIF and OSJD were made using the above-mentioned of the letter, two thirds of them were transported in containers. The rate of application of this document in Ukraine in 2010 reached 63%, and in Slovakia 30%.

The above decision coincided with the introduction of a common consignment note in all relations on the territory of Russia, then Mongolia and Moldova (2011), and in terms of transit and import also in Kazakhstan (2012). In October and November 2012, pilot container trains were organized using the CIM/ SMGS document on the route China – Kazakhstan/Mongolia – Russia – Belarus – Poland – Germany.

Years of activity in the field of harmonization of transport law has a practical economic dimension. Instead of other transport documents currently provided for under international treaties, parties to the International Convention on the Harmonization of Frontier Controls of Goods may use the CIM/SMGS consignment note as a customs document. Its use is optional, i.e. it depends on the will of rail carriers and their customers (senders and / or recipients of goods). As a rule, the SMGS consignment note cannot be used as a transit declaration in the EU. Similarly to the transit procedure, the simplification in rail transport cannot be applied in this document when there is only one railway undertaking on the EU side. Then such a letter is treated in customs matters as a typical SMGS consignment note. The use of the CIM/SMGS common document as simplification is based on the same legal basis as for the CIM consignment note. The railway undertaking that applied for the simplification in the circulation of goods becomes a person entitled to use the transit procedure along the entire route of transport of goods, to the destination railway station in another country. This means that, e.g. for a transit operation on the CIM consignment note opened in Poland or Slovakia, the railway carrier will be a person authorized to use the transit procedure until the end of the transport, e.g. to a railway station in any EU country. In 2013, already 70% of international container transport and 18% of international wagon transport in the area of operation of the CIM and SMGS regulations was performed using the joint CIM/SMGS consignment note (Committe OSJD, 2014). Figure 1 shows the geographic scope of application of regulations as of May 1, 2019.

Figure 1: Geographical scope of the application of the CIM and the SMGS

Source: https://www.cit-rail.org/media/files/documentation/freight/scopes/scope_of_application_ of_cim-smgs_2019-05-01.pdf?cid=223805 [Retrieved November 2, 2020].

In 2015, as a result of activities aimed at improving the implementation of trans-Eurasian transport, e.g. the introduction of electronic exchange of customs declarations by railway carriers operating on neighboring national infrastructures, the time necessary to implement customs procedures has been reduced. Currently, the maximum time of customs clearance of goods at individual border stations is as follows: Dostyk (KZ) – 5 hours, Ileck (RU) – 4 hours, Brest (BY) – 5 hours, Małaszewicze (PL) – 10 hours (OSJD Bulletin, 2016). In 2016, the technological service time for container trains at the hub was also shortened. Brest (BY) – up to 9 hours for reloading and up to 6 hours without reloading (OSJD Bulletin, 2017)**.**

New phase of the OSJD and CIT cooperate under the *Memorandum on Cooperation between the OSJD and CIT* signed in Ulan-Bator on 4 June 2015 leads to the unification of procedures and simplification of the exchange of goods. Cooperative efforts and information exchange were continued to design measures facilitating border crossing in international carriage by rail in Eurasia; to draft new or improve existing regulations governing international carriage of passengers and freight by rail; to step up multimodal carriage; to organize combined transport operations and high-capacity container carriage between Europe and Asia; to encourage transport of postal items in containers and transport of general freight under the CIM/SMGS consignment note. An important topic of cooperation under this project in 2019 was the transition to transport operations relying on the use of the electronic CIM/SMGS consignment note and more general paperless technologies. Joint work continues to address information exchange with customs authorities, including the scope of such information, as well as legal aspects of using electronic accompanying documents, such as resolving claims electronically based on an electronic loss-and-damage statement. Attendees of the meetings of the CIM/SMGS Working Group and the CIM/SMGS Steering Group discussed the feasibility of pilot transport operations under the CIM/SMGS consignment note that would be based on contracts of carriage under the electronic consignment note to be entered by the CIM and SMGS carriers. The project is characterized by innovative use of technology to improve efficiency and reduction of bureaucratic burdens on transport.

CIM/SMGS trends across the EU external border – cooperation with Russian Federation and Ukraine

Euro-Asian trade was largely transported by sea, according to container statistics from organizations such as UNCTAD, Eurostat, IATA, UIC and Boeing Corporation. More than 95% of the volume (in metric tonnes) and nearly 70% of the value of cargo (in USD) was transported by maritime routes. Air cargo between Europe and Asia was less than 2% by volume, but over 30% by value. Railways carried 1% of volume and more than 2% of the value (UNECE,

2020). Generally, the land transport cannot and probably will not be able to compete with the sea route in the future as the potential capacity of the land canals is limited to about 2% (physical volumes in metric tons) of the maritime transport infrastructure capacity. Nevertheless, rail connections between China and Europe are of increasing interest as they offer competitive services under certain conditions, especially in terms of cyclicality and lead times independent of weather factors. Rail transport can definitely complement the commercial offer of sea shipping and can serve to increase the reliability of production (including in the automotive and computer industries), based on Eurasian logistics chains. However, the common consignment note is important not only in trans-Asian transport (mainly China-Europe). It is also an important element of simplification in intra-European transport, between the countries included in the Common Market (EFTA) and its closest neighbors, e.g. with Russia and Ukraine.

Data collected in the study, particularly the number of CIM/SMGS consignment notes used in 2009-2019 handling freights (Figure 2) and, additionally, the number of containers transported on the basis of this document (Figure 3) clearly show a change in the tendency in the use of this tool to simplify the exchange of goods. While in the initial period (until 2015) it was popular among importers of shipments, since 2016 the share of export shipments sent by entities in Russia to the European Union has been increasing.

Figure 3: The number of containers handled in 2009-2019 by Russian Railways (RZD) on the CIM/SMGS consignment note

Source: Own compilation based on RZD data

When analyzing the latest data from January-July 2020 (Table 1), it is noticeable that the use of the CIM/SMGS consignment note has increased in popularity in transit relations through the territory of the Russian Federation, i.e. from the European Union to China (both directions). This is happening with a further decrease in the import of cargo to Russia based on CIM/SMGS common document.

Table 1: Changes in EU-Russia freight transport on the CIM/SMGS consignment note in 2018-2020

	2018			2019			7 months of 2020 (January-July)		
	Number of shipments	*Number of containers*	*Dynamics compared to the previous year (%)*	*Number of shipments*	*Number of containers*	*Dynamics compared to the previous year (%)*	*Number of shipments*	*Number of containers*	*Dynamics compared to the analogous*

The dynamics of changes in the use of the acquis of a joint document is slightly different in relation to another direction, which is the international rail freight exchange between Slovakia and Ukraine. Data relating to 2016 and 2019 regarding the application of the CIM/SMGS consignment note are included in Table 2 and Table 3.

Table 2: Changes in the freight transport on the CIM/SMGS consignment note handled by Ukrainian Railways (UZ) in 2016-2019

	2016			2018			2019			2019 compared to the 2018 (%)

Source: ZSSK Cargo data presented for CIT

The data presented in both tables shows a clear decrease in the number of shipments using the CIM/SMGS consignment note in Slovakia and Ukraine. In 2019, *Ukrzaliznytsia* – the national railway carrier of Ukraine recorded a total of 55.9% of the number of CIM/SMGS documents issued in 2016. Although at the same time, the popularity of the document with regard to import shipments increased more than 10 times. In the work of *ZSSK Cargo* – a Slovak carrier, in 2019 the number of CIM/SMGS documents was reduced by 66.9%, and the transport based on it clearly decreased both in terms of containers and wagon consignments.

The data relating to the exchange of goods by rail between Slovakia and Ukraine shows a decline in the popularity of the use of the CIM/SMGS consignment note in freight transport as well as in the transport to/from Russia. The aim of the study was to identify possible causes of this condition.

Political sphere as a determinant of shaping logistic channels supported with the use of CIM/SMGS solution

The trends that emerge from the data presented in the previous section cannot be left without explanation. It is obvious that the sphere of logistics services depends both on the institutional environment and market needs. However, due to its cross-border dimension, it remains the resultant of political influences active on both sides of the border. Attempts to evaluate economic content while ignoring its political value can only lead to an impoverished, misconceived in its foundation and misleading in its conclusions (Medeiros, 2018). Therefore, this part presents

selected issues from mutual relations between the EU and Russia, which over the past few years have influenced the shape of the current political relations, which have an obvious impact on economic relations.

The decrease in the number of shipments using the CIM/SMGS consignment note between the EU and Russia is, in part, the result of cooling mutual relations is a consequence of political events affecting the economy and changing international economic relations. The nature of the bond depends not only on the political and systemic conditions, but also on the advancement of integration processes. At the same time, the forms of institutional ties may change over time and space as a result of the development of political and economic factors. These, in turn, are often the result of current events and decisions. This is perfectly confirmed by numerous phenomena and their consequences in political relations between Russia and other countries, for example:

- between Ukraine and Russia during the so-called Maidan (November 2013 – February 2014), the subsequent annexation of Crimea and military operations in Donetsk and Lugansk,
- between the Netherlands and Russia in 2013[1)] and their aggravation after the shooting down in July 2014 of a Malaysian passenger plane, operating on the Amsterdam - Kuala Lumpur flight, with 193 Dutch citizens on board,
- between Great Britain and Russia in connection with the case of Sergei Skripal[2)].

The events that took place after 2013 radically changed Russia's position on the international arena, as evidenced by, among others:

- suspension of Russia-EU summits and other regular bilateral meetings (the last summit took place on 28th January 2014),
- suspension of talks with Russia on visas and negotiations on a new partnership agreement,
- suspension of negotiations on Russia's accession to the Organization for Economic Co-operation and Development and the International Energy Agency,
- Russia's exclusion from the G8 group,
- visa sanctions and asset freezing of entities that materially or financially supported actions destabilizing the territorial integrity of Ukraine,
- economic sanctions, for example in the form of a ban on imports of goods from Crimea and Sevastopol.

The above events are not a closed list. However, collectively they are an example of the clear influence of the political sphere as a determinant of shaping the environment in which the international trade of goods takes place and the logistics sphere functions.

As a result of political events, in August 2014, the federal government in Moscow introduced an embargo on the transport and transit of many product groups through the territory of the Russian Federation, including plant and animal origin from the European Union countries, but also from the United States, Canada and Australia. This could not be unaffected by the logistics services for the Eurasian space and resulted in the need to reconfigure the supply chains.

Economic sanctions or restrictions are often seen as especially powerful tools. They provide a tool that is used much less frequently than differentiated integration – a legal instrument that European governments use regularly to overcome deadlock (Schimmelfennig and Winzen, 2020). Currently, the scope for political influence remains of concern and the case related to the use of the “Novichok” substance against Alexei Navalny in August 2020 will, certainly, not improve political relations between Russia and the EU. For the Russian Federation the lifting of the sanctions and the normalization of relations is conditioned upon the lifting of the EU sanctions (Franco, 2018). Foreign-policy experts on both sides broadly share the view that a rapid normalization of relations is unlikely. In last two years, Russia has been sending contradictory messages regarding its future ties with the EU and the West. Similarly, the EU is also sending contradictory messages (Racz and Rai, 2018). Ukraine remains a key obstacle where no quick progress is to be expected.

Characteristically, political relations between Russia and Ukraine are also a significant factor in the decrease in transport between the EU and Ukraine, carried out using the CIM/SMGS consignment note. It should be remembered that the tense relations between Kiev and Moscow affect rail transport. In the context of the use of the CIM/SMGS consignment note, it should be noted that the cargo posted by an entrepreneur located in Slovakia to, for example, Kazakhstan or China, may – theoretically – be transported bypassing Ukraine, i.e. via Poland, Belarus and Russia. It can also be delivered along the Black Sea-Caspian southern route, which, however, will significantly reduce the transit-time due to the need to use the ferry twice between the ports of Ukraine and Georgia as well as Azerbaijan and Kazakhstan.

However, a significant decrease in shipments based on the CIM/SMGS document may be the result of the general economic situation in Ukraine. From the moment of the problems of destabilization of its situation at the turn of 2013 and 2014, this country has not reached the 2013 GDP level (per capita USD 4,030). Regarding to World Bank data, the its critical level (USD 2,125) was recorded in 2015, and then it is gradually increasing. In 2019, GDP per capita reached USD 3,659, now it is still lower even than the value from before the 2008 crisis.

Conclusion

Although the influence of the political situation on the dimension of economic exchange is difficult to overestimate, the harmonization of legal and organizational solutions, such as the CIM/SMGS consignment note, is of significant importance in handling international flows. And these exist and will be implemented to a greater or lesser extent. Tests showed the use of CIM/SMGS consignment note could reduce the standing time of rolling stock at borders from three days to 1,5 hours. This considerably would increase the competitiveness of rail freight transportation. Interest of the number of countries to create a common legal regime for rail traffic across Asia and Europe (including the countries of Armenia, Iran, Pakistan, Serbia, Uzbekistan or Turkey), increasing coverage of the CIM/SMGS consignment note on Trans-Eurasian Logistics Chains.

It can be assumed that the solution in the form of a unified transport document effectively implemented to the legal system, which is a tool to provide a quick logistic service in any relationship between the parties recognizing it, will increase the effectiveness of international exchange also in the future even despite the political obstacles. This stays in line with the expectations of the parties to international transactions and logistics operators, focused on service optimization.

Footnotes:

1) The incursion of the Dutch police on 5th October 2013 into the apartment of the counselor of the Russian Embassy in The Hague and his detention for several hours on charges of mistreating his own children sparked a sharp diplomatic conflict. Moscow reacted at the highest level – on 8th October 2013, President V. Putin demanded an apology, explanations and punishment of the guilty, while Minister of Foreign Affairs S. Lavrov suggested that Russia's relations with the Netherlands would depend on the reaction of the Dutch authorities. The Russian Ministry of Foreign Affairs found the official apologies of the Dutch minister of foreign affairs insufficient. Moscow did not consider the case exhausted. On October 9, the Russian phytosanitary inspection office *(RosSielchozNadzor)* suggested the possibility of suspending the import of Dutch flowers (worth 0.9 billion USD), and two days later announced a reduction in the list of Dutch plants authorized to export dairy products to Russia. The background of the diplomatic conflict is the dispute between the Netherlands and Russia over the interpretation and legal assessment of the actions of Greenpeace activists who on 18th September 2013, attacked the Gazprom oil rig on Barents Sea, in the Russian economic zone. Russian authorities made arrests along with the ship on the charge of piracy. The Netherlands called for the release of the ship and the mitigation of the charges, and on 4th October, after the Russian refusal, brought the case to international maritime arbitration. The Greenpeace action is therefore seen as a deliberate attack on Russia's critical interests, which requires a sharp reaction to deter any imitators.

2) On 12th March 2018, British Prime Minister T. May, in an ultimate form, demanded explanations from the Russian authorities in connection with the application of March 4th on the UK territory a combat paralyzing "Novichok" against a British citizen (former GRU officer, convicted in Russia for cooperation with British intelligence), Sergei Skripal and his daughter Julia. As Moscow ignored the British ultimatum, a series of British retaliatory measures was announced on 14th March 2018. London decided to expel from the UK Britain has 23 Russian diplomats accused of espionage, the suspension of official bilateral contacts with Russia at a higher level and a boycott by members of the government and royal family of the FIFA World Cup in Russia, as well as covert activities in the field of security. In addition, it was announced: the adoption of the British version of the so-called the Magnitsky law imposing sanctions against Russian officials; stricter legislation to combat hostile activity against the UK Britain, including tightening border controls and checks on foreigners' financial assets. British demands for an explanation from Russia were supported by the North Atlantic Council and the German Chancellor A. Merkel. The Russian authorities firmly rejected the British accusations, describing them as "a political provocation". The Russian Ministry of Foreign Affairs refused to provide any explanations until the Russian side was provided with samples of the substance used against Skripal and the British government formally initiated explanatory procedures based on the Chemical Weapons Convention. At the same time, Russian diplomacy announced that Russia would respond to possible British sanctions.

Abstract

The agri - food industries are of particular strategic interest for many governments. Policy changes in this area have direct implications for consumers, landscapes and the environment. The aim of the article is to analyse the intra EU-28 agri – food trade in the context of the EU internal policies. The dynamics of the intra EU-28 agri – food trade was analysed in terms of the changeability and differences if compared to the previous periods. The general trend line was built using the appropriate function (choosing from the exponential, linear, logarithmic, polynomial, and power functions) taking into consideration the value of the R^2 coefficient. With the help of one of the functions mentioned above, the projection of the intra EU-28 agri – food trade amount for the following two periods was made. The comparative structural analysis of the intra EU-28 agri - food imports and exports structure in 2019 showed, that the imports structure doesn't differ a lot from that of the exports one. The analysis of the intra EU-28 agri – food trade and its projections made for the following two years point to the successful implementation of the EU internal policies in general and the European Single Market and European Monetary Union in particular. It is also thanks to the worldwide reputation of EU products as being safe, sustainably produced, nutritious and of high quality. The data analysed in the article were taken from the Eurostat official web page. The time frame under research is 15 years – from 2005 to 2019 included.

Keywords: Intra EU-28, agri – food trade, EU internal policies.

Introduction

One of the most important insights from international economics is that there are gains from trade. This is why countries trade with each other; trade simply provide both ends with mutual benefits (Krugman, P. R., & Obstfeld, M., 2003). In practice, individual countries or groups of countries are to some extent integrated, i.e. their activities are carried out more intensively among themselves than with others. A substantial part of economic integration is trade integration (Fojtikova L., Vahalik B., Stanickova M., 2016). European integration has had liberalizing effects on the flows of goods and productive factors between participating economies. Integration involves an intensification of economic relationships, particularly trade relationships, in those countries which have decided to reduce or eliminate trade barriers (Mora, C.D., 2001). To continue the research in the context of the EU internal policies, it would be useful to remind, that the EU was created from the customs union founded in 1968, through a common market to an economic and monetary union, although not all member states of the EU participate in it in the same way. The growing level of economic integration in the EU enables its member states to get economies of scale effects and thus more benefits from their different economic structure. (Fojtikova L., Vahalik B., Stanickova M., 2016). Still, many economists have back and forth argued about the gains that arise from a free trade area and

Cite this Article as: Oksana KIFORENKO, Nataliia VASYLIEVA, Sergii PRYLIPKO and Oleksandra VASYLIEVA" The Analysis of the Intra EU-28 Agri – Food Trade in the Context of the EU Internal Policies" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

further on how a common currency area would be another source of continuous growth in the economy. There have also been many debates of pro's and con's with EU membership as well as what the effect has been on trade. This discussion has been further extended with the introduction of a common currency in the European Union (Buhre L. & Söderström J., 2008). That means, that the implementation of the common European currency and the European Monetary Union (EMU) is considered to be one of the most successful and influential either internal or external EU policies. The European Union's main purpose is to promote trade among its members and the introduction of the EMU aims to further integrate and facilitate trade among the member countries. By becoming a member of the customs union, trade is favoured within the custom-free area and the union's strive to eliminate all trade barriers will promote trade affinities. This in turn has led to a continuous positive trend in trade flows and has promoted the "four freedoms" which are the fundamental idea of the European Union (Buhre, L. & Söderström, J., 2008).

Recently, there has been an intense policy debate on the Euro effects on trade flows. The Euro is found to promote EU integration by eliminating exchange rate-related uncertainties. An obvious policy implication is that countries considering to join the Euro would benefit from the ongoing process of integration, but should also be wary of regarding promises of an imminent acceleration of intra-EU trade. It is generally acknowledged that the Euro-area economies become more integrated by adopting the Euro. Increased trade is one of the few undisputed gains from a currency union by eliminating exchange rate volatility and reducing the transactions costs of trade within the member countries (Serlenga, L. & Shin, Y., 2013). The extent to which member countries will benefit from EMU will be dependent on the countries' openness to trade. The more open to trade the countries are, the lower transaction costs and exchange rate uncertainty will be (Aristotelous, A., 2006).

The building process of the European Union involved the reinforcement of the common European market and the opening of a new period towards an economic and social union that would ensure a high level of employment and income, social protection and equality between all European citizens. European support policies have been a boost to the member states to reduce the existing gap between the central and northern European countries (Bolea L. et al, 2016). Lively discussions are also taking place about the effectiveness and influence of the European Single Market as a kind of either economic or trade and financial policy of the EU. In line with that, it should be said, that the European Single Market, launched in 1992 is an extension of the Common Market concept which aims at eliminating remaining obstacles to trade (physical barriers like frontier inspections, technical barriers of all sorts, fiscal barriers such as differences in indirect taxes and excise duties and national biases in public procurement) among member states of the European Union. The ultimate objective of the initiative was and continues to be the boost of economic growth by spurring competition, exploiting economies of scale and forcing companies to step up innovation and productivity. (AIER et al, 2016). Whether the EU policies and measures had practical applications, proved to be effective in case of the intra EU-28 agri – food trade, if yes – then to what extent, what trends and projections of the different aspects of the agri – food trade mentioned above are, what the possible outcomes of the said policies can be and how to make the EU a better agri – food trader – these are the questions tried to be answered in this paper.

Material and Methods

Trade has been as one of the main determinants of economic growth, given its capacity to drive production and to promote economic specialization and competitiveness of countries and the pattern of trade has notably changed over time (Bolea L. et al, 2016). Trade statistics - both detailed and general results - have proved their worth. They are an instrument of prime importance for both public and private users. For instance, they enable Community authorities to prepare for multilateral and bilateral negotiations on common trade policy, they help European businesses carry out market surveys and thus improve their competitiveness and they are an essential source of information for statistics on the balance of payments, the national accounts and short-term economic studies. This non-exhaustive list highlights the variety of users and their requirements (AEI, 1998).

The aim of the article is to analyse the intra EU-28 agri – food trade in the context of the EU internal policies. The said analysis included also the dynamics one and the general trend line building. The dynamics of the intra EU-28 agri – food trade was analysed in terms of its changeability and differences if compared to the previous periods. The general trend line was built using the appropriate function (choosing from the exponential, linear, logarithmic, polynomial, and power functions) taking into consideration the value of R^2 coefficient. With the help of one of the functions mentioned above, the projection of the intra EU-28 agri – food trade amount for the following two periods was made. Only two periods were taken to make the projection of the amount of the trade turnover mentioned above because of the uncertainty of the present situation as well as a great number of challenges the whole world is facing nowadays.

The data analysed in the article were taken from the Eurostat official web page. The time frame under research is 15 years – from the year 2005 to 2019 included.

Results and Discussion

Trade has recently showed its worth as a stabilizing source of global growth. For the European economy it is also the catalyst for the continuous process of restructuring and innovation that enables EU business and citizens to tap into the opportunities offered by an ever changing global market place (European Commission, 2015 (1)). An effective trade policy should, furthermore, dovetail with the EU's development and broader foreign policies, as well as the external objectives of EU internal policies, so that they mutually reinforce each other. The impact of trade policy has significant repercussions on the geopolitical landscape — and vice versa. Furthermore, trade policy, combined with development cooperation, is a powerful engine of growth in developing countries. The EU will continue its longstanding commitment to sustainable development in its trade policies, contributing to the newly agreed global sustainable development goals (SDGs) under the 2030 Agenda for Sustainable Development. Finally, trade policy reinforces the functioning of the EU Internal Market linking its rules with the global trade system (European Commission, 2015) (2)). To see how effective the EU policies mentioned above are and further develop the research, let's follow the intra EU-28 total agri - food trade turnover in Figure 1.

Figure 1: Intra EU-28 Total Agri - Food Trade Turnover, bn EUR

Source: author's own elaboration on the basis of the data from (Eurostat, 2020).

Having observed the data presented in Figure 1, we see, that the intra EU-28 total agri - trade trade turnover increased from the beginning of the time frame under analysis, that is from the year 2005, till 2008 included. But in 2009 we observe a decrease in the amount of the total agri - food trade turnover of 1042.8 bn EUR, which could be caused by the influence of the global financial crisis of 2008 as every sphere of activity felt the impact of the said crisis and the trade of agricultural products was not an exception. Any trade is interrelated with finance and one can't exist without the other, even the so-called barter trade, as finance is the intermadiary link between two types of goods traded. The single decrease of the amount of trade mentioned above didn't become the beginning of the downward period and we see the next increase of the agri - food trade amount of 682.4 bn EUR in the next year. Actually, in 2010 the next upward trend in the dynamics of the total agri - food trade turnover can be observed, the one that continued till the end of the time frame under analysis. As in 2009 the only decrease in the amount of the intra EU-28 total agri - food trade turnover can be observed, we'll pay attention at the biggest and the smallest increase of the said amount. We can see the biggest one in the year 2010 and the smallest one - in 2013. Taking into consideration everything mentioned above, the dynamics of the intra EU-28 total agri - food trade turnover can be roughly divided into two periods – the first one from the year 2005 till 2008 included (the upward one) and the second one – from the year 2010 till the end of the time frame under research, that is till the year 2019 included (another upward one).

The trend line built for the dynamics of the intra EU-28 total agri - food trade turnover is upward through the whole time frame under analysis. It also continues its upward direction during the following two periods taken for the

projection, that is for another two years. Only two periods were taken to make the projection of the amount of the trade turnover mentioned above because of the uncertainty of the present situation as well as a great number of challenges the whole world is facing nowadays. The trend line presented in Figure 1 was built using the polynomial function taking into account the value of the R^2 coefficients of those from the exponential, linear, logarithmic, polynomial and power functions.

Exports to the internal market (i.e. among EU Member States) constitute the bulk of EU - 28 agri-food exports (European Commission, 2017). To make our analysis more profound, let's cast a look at Figure 2, in which the dynamics of the intra EU-28 agri - food exports from 2005 till 2019 included is presented.

Figure 2: Intra EU-28 Agri - Food Exports, bn EUR

Source: author's own elaboration on the basis of the data from (Eurostat, 2020).

Thanks to the visual presentatioon of the intra EU-28 agri - food exports amount, it can be said, that the general dynamics of the said exports is very much like the one of the total agri - food trade turnover of the countries union under research. If analyzing in a more detailed way, we observe an upward trend of the amount of the agri - food export from the start of the time frame under analysis, that is from the year 2005, to 2008 included. Then we see a sharp fall of 525.6 bn EUR in the following year, being the only decrease of the amount of the intra EU-28 agri - food exports through the whole time frame under analysis. The fall in the amount of the said agri - food exports mentioned in the previous sentence didn't become the beginning of a downward trend as another increase of the agricultural exports amount can be observed in 2010, that is the next upward trend was started then being continued till the end of the time frame under research. The dynamics of the amount of the agri - food exports being analyzed was rather smooth from 2009 til 2011 included, but in 2012 the fast upward move of the agricultural exports amount slowed down and we see the increase of the said epxports amount of only 15.4 bn EUR in the mentioned year (the word "only" was used as an attribute to the said increase as the difference is very small if compared to the differences values from the other years under research). The situation repeated in the following year as well showing even smaller increase in the amount of intra EU-28 agri - food exports, that is 0.2 bn EUR. The following upward move of the exports amount was not that smooth either increasing its positive difference in 2014 and 2015, slowing down in 2016, "moving" faster in 2017 and slowing down the positive increase again in 2018 and 2019. Yet, the year 2009 is the only one with the negative difference in the amount of the intra EU-28 agri - food exports. The smallest increase of the said amount can be seen in 2013 and the biggest one – in 2006. The dynamics of the Intra EU-28 agri - food exports amount can also be divided into two periods – the first one is from the year 2005 til 2008 included and the second one – from 2010 till the end of the time frame under analysis.

The trend line was built for the dynamics of the amount of the intra EU-28 agri - food exports using the polynomial function, having tried the exponential, linear, logarithmic, polynomial and power functions. The polynomial function was given the preference because of the value of the R^2 coefficient. The said trend line is upward not only through the whole time frame under analysis, but continues to be of the kind during the next two periods taken for projection. Only two periods were taken to make the projection of the agri - food exports amount because of the changeability and uncertainty of the nowadays general situation.

The next step of our research is the analysis of the intra EU-28 agri - food imports amount dynamics, which can be ovserved in Figure 3.

Figure 3: Intra EU-28 Agri - Food Imports, bn EUR

Source: author's own elaboration on the basis of the data from (Eurostat, 2020).

The data presented in Figure 3 allow us state, that the general pattern of the dynamics of the said data is very much like the one of the intra EU-28 agri - food exports, that is - an upward trend from 2005 till 2008 included, the sharp fall of the said amount in 2009 and the following upward trend beginning from the year 2010 till the end of the time frame under research. Another similar thing between intra EU-28 agri - food exports and imports dynamics is the small increase of the imports amount in 2012 (small if compared to the differences between the other time frames) and the smallest one – in 2013. That similarity is an interesting phenomenon needed to be further researched. Another similarity between the amounts mentioned above is that the negative difference of the agri - food imports and exports amount were in the same year, that is in 2009 (imports - 517.2 bn EUR). The smallest increase of the intra EU-28 agri - food imports amount was observed in 2013 and the biggest one – in 2010 and the latter differs from the results of the agricultural exports. If we talk about the periods the intra EU-28 agri - food imports amount dynamics can be divided into, then these are as follows – the first period is from the year 2005 till 2009 included and the second one – from 2010 till the end of the time frame under analysis. Both are upward ones.

The trend line of the intra EU-28 agri - food imports amount dynamics was also built and it is also upward not only through the whole time frame under analysis and continues that way during two following periods taken for the projection, just like in the case with the intra EU-28 agri - food exports case. The trend line was built using the polynomial function having the exponential, linear, logarithmic, polynomial and power functions to choose from. The polynomial function was chosen from the functions mentioned above because of the value of the R^2 coefficient if compared to those of the other functions used for it. Only two periods of time were taken to make projection because of the same reasons mentioned while analyzing the dynamics of the intra EU-28 total agri - food trade turnover and agri - food exports.

To make the analysis more complete, let's analyze the intra EU-28 agri - food trade balance with the help of Figure 4.

Figure 4: Intra EU-28 Agri - Food Trade Balance, bn EUR

Source: author's own elaboration on the basis of the data from (Eurostat, 2020).

Having cast a look at Figure 4, one can see the extreme changeability of the intra EU-28 agri - food trade balance. Another interesting feature worth paying attention at is that in every even year we observe the increase, that is the positive difference, of the agri - food trade balance, with the only exception in 2016, in which the decrease of the said balance is observed. In every odd year we observe the decrease of the agri - food trade balance, that is the negative difference from the previous period. Such a phenomenon of seasonality of the intra EU-28 agri - food trade balance is also worth a deeper further research. The biggest positive difference, that is the increase if compared to the previous period, of the said balance can be seen in 2006 and the biggest negative difference, that is decrease, can be observed in 2007.

The trend line for the intra EU-28agri - food trade balance was built using the polynomial function, that is quite logical even without having compared the values of the R^2 coefficients of the other functions under consideration judging by the changeability of the data under analysis. But to make the conclusions unbiased, we tried the exponential, linear, logarithmic, polynomial and power functions for the building of the trend line of the intra EU-28agri - food trade balance dynamics. The polynomial one was chosen because of the R^2 coefficient value if compared to those from the other functions used. The trend line mentioned above is slightly downward to approximately the middle part of the data under research, starting being upward in about 2016. It continues its upward direction during two periods taken for the projection, in this case – two years. It means, that the intra EU-28 agri - food exports are projected to have a higher increase than the said imports, judging not only on the projection given in Figure 4 but in Figures 2 and 3 as well.

The last but not the least point of our analysis is the intra EU-28 agri - food exports-to-imports ratio, the dynamics of which can be followed in Figure 5.

Figure 5: Intra EU-28 Agri - Food Exports-to-Imports Ratio, bn EUR

Source: author's own elaboration on the basis of the data from (Eurostat, 2020).

A very interesting visual presentation of the data under analysis can be observed in Figure 5. From the year 2005 till 2010 included the intra EU-28 agri - food exports-to-imports ratio had the same value – 1.03. In the following year the said value dropped to 1.02 and remained that way through two more years, that is till 2013 included. After that, in 2014 the export-to-imports ratio increases till the value of 1.03 with the next drop in the year 2015. From 2015 and till the end of the time frame under analysis it remained at the level it reached in 2015.

The trend line for the intra EU-28 agri - food exports-to-imports ratio dynamics was built using the polynomial function because of the value of the R^2 coefficient if compared to those of the exponential, linear, logarithmic and power ones. The trend line built for the intra EU-28 agri - food exports-to-imports ratio is downward through the whole time frame under analysis and continues to be of the kind during two more periods taken for the projection making. The explanation of the phenomenon described in the previous sentence could be as follows – the tendency moves to the decrease of the difference between the intra EU-28 agri - food exports and the imports values.

As the last year in the time frame under research is 2019, let's analyze the structure of the intra EU-28agri - food trade in the year mentioned above. We'll start our analysis from the agri - food exports structure, which can be followed in Figure 6.

Figure 6: Intra EU-28 Agri - Food Exports Structure in 2019,%

Source: based on the data from (European Commission, 2020).

As a pie chart is considered to be the best tool for any structure analysis, we chose exactly the one for ours. The visual presentation in Figure 6 allows us state, that the biggest share in the intra EU-28 agri - food exports structure in 2019 was taken by "Other primary products", then come "Food preparations" followed by "Processed" agri - food products. The smallest share in the said agri - food exports structure is taken by "Beverages". Such an analysis itself may seem to be not that full at all, but it can be used for the comparison analysis of the intra EU-28 agri - food exports structure with that of the other years or countries. We'll use it for the comparison analysis with that of the intra EU-28 agri - food imports structure in 2019, presented in Figure 7.

The intra EU-28 agri - food imports structure in 2019 doesn't differ a lot from that of the exports one, that is the biggest share in it is taken by the "Other primary products" with the same percentage as in the exports. The second place in the shares of the agri - food imports structure is taken by "Food preparations", just like in the exports structure, and the percentage difference is not that big – 0.3 percentage points. The third place in the agri - food imports is taken by two products groups with the same percentage, that is by "Processed" and "Commodities". The smallest share is observed by "Beverages", just like in agri - food exports.

So, having analyzed the intra EU-28 agri - food exports and imports structure in 2019 presented in Figures 6 and 7, we can state, that the biggest share in either exports or imports is taken by "Other primary products" with the same percentage in both exports and imports. The second place is taken by "Food preparations" in both exports and imports with almost the same percentage. The third place is taken by "Processed" in both exports and imports with the adding of "Commodities" as the product group divided the third place in the imports.

Figure 7: Intra EU-28 Agri - Food Imports Structure in 2019,%

Source: based on the data from (European Commission, 2020).

Conclusions

The agri - food industries are of particular strategic interest for many governments. Policy changes in this area have direct health implications for consumers and for the welfare of farm animals. They affect landscapes and the environment like few other policy measures. The agri - food industries are critical for rural development; they provide jobs and incomes in remote regions and are often a matter of national pride. For these reasons, agriculture and food - related themes have always played relatively large roles in trade negotiations. Be it at multi -, pluri -, or bilateral level, agricultural and food - related concerns play an important role (Bureau J. et al., 2014). For centuries countries have relied on trade in agricultural and food commodities to supplement and complement their domestic production. The uneven distribution of land resources and the influence of climatic zones on the ability to raise plants and animals have led to trade between and within continents (FAO, 2003). The European Union (EU) is characterized by a high level of openness to trade, consequently increasing its member countries' vulnerability to external shocks coming from the rapidly changing global environment. Agriculture still plays a vital role in shaping Europe's future, including in the optics of the resilience of its economy (Civín L. & Smutka L., 2020). The analysis of the practical implementation of the internal EU policies, e.g. the European Single Market and European Monetary Union, allow us draw the following conclusions – the general pattern of the intra EU-28 total agri - food trade turnover, exports and imports dynamics are very much alike and can be roughly divided into two upward

periods - the first one from the year 2005 till 2008 included and the second one – from the year 2010 till the end of the time frame under research, that is till the year 2019 included. The only decrease in the amount of the intra EU-28 total agri - food trade turnover, exports and imports can be observed in 2009, having been the possible result of the global financial crisis of 2008. The trend lines for all the three data sets mentioned above were built using the polynomial functions, taking into consideration the R^2 coefficients of those from the exponential, linear, logarithmic, polynomial and power functions.

The intra EU-28 agri - food trade balance dynamics is extremely changeable. In every even year we observe the increase of the agri - food trade balance, with the only exception in 2016, and in every odd year we observe the decrease of the said trade balance. The trend line for the intra EU-28 agri - food trade balance was built using the polynomial function. The trend line "behaviour" during two projection periods means, that the intra EU-28 agri - food exports are projected to have a higher increase than the said imports.

The intra EU-28 agri - food exports-to-imports ratio had the same value from the year 2005 till 2010 included, with the drop in the following year to the value of 1.02, which remained that way during two more years. The increase in 2014 didn't last longer and the next drop of the said value was observed in the following year continuing till the end of the time frame under analysis. The trend line built for the intra EU-28 agri - food exports-to-imports ratio is downward through the whole time frame under analysis and continues to be of the kind during two more periods taken for the projection making, which, in turn, means, that the difference between the exports and imports mentioned above will lessen.

The comparative structural analysis of the intra EU-28 agri - food imports and exports structure in 2019 showed, that the imports structure doesn't differ a lot from that of the exports one and even the percentage share are the same or have small differences. The exception is the third place in the products groups share – it is taken by the "Processed" agri - food products in the said exports but by "Processed" and "Commodities" in the imports mentioned above.

The analysis of the intra EU-28 agri – food trade and its projections made for the following two years point to the successful implementation of the EU internal policies in general and the European Single Market and European Monetary Union in particular. But it is also thanks to the worldwide reputation of EU products as being safe, sustainably produced, nutritious and of high quality (Hogan P., 2018). Apart from the positive trends and projections of the agri – food trade inside the EU, there remain many threats either in the internal or external markets that could have a negative influence or even harm it. Among the so-called "old" threats one should mention protectionist policy of some countries either the EU member or non-member states. Another factor, that makes the EU market turbulent, is the unfinished Brexit trade talks. Among the so-called "new" threats, that is the ones, which came into our lives not long ago, one should definitely mention the COVID-19 pandemic, that influenced all the spheres of the human activity, changed the pattern of the global as well as internal trade and whose influence is far from being over. Nevertheless, the growing demand for food and increasing world population number are among the positive factors, that make the agri – food production and trade prosper. And the EU is among the ones who will gain from that. The safety, nutrition, production sustainability and high quality of the EU products will add to the EU agri – food products and trade success.

Changes on the 21st Century Labour Market and The Profile of the "Employee of The Future" In the Opinion of University Students and Graduates – The Representatives of Generation "Z" In Poland

Dr Magdalena RĘKAS

Wroclaw University of Economics and Business, Poland
magdalena.rekas@ue.wroc.pl

Abstract

The 21st century is characterized by the extremely dynamic socio-economic changes which affect the functioning of organizations and entire markets, in particular the labour market. Numerous trends can be observed which radically change the sphere of work and employment, i.e.: work globalization, automation and robotisation, industry 4.0, technological innovations, rapid urbanization, negative demographic changes, the increasing importance of flexible employment forms, the growing scale of self-employment and remote work, the implementation of *Work Life Balance* model, creative work, agile organizations and teams, teal organizations, etc. To a much greater extent, the appropriate human capital becomes the source of competitive advantage and business success. Organizations need motivated and committed employees presenting appropriate and diverse competences, drawing conclusions from the surrounding reality, capable of adapting to changes, creating innovations, developing products and services suitable for the increasingly diverse, demanding and knowledgeable customers. Generation "Z" is entering the labour market in growing numbers, having different characteristics from previous generations and creating further changes in employment models and work organization. The article discusses the results of a pilot study aimed at answering two research questions: What is the approach of university students and graduates representing generation "Z" in Poland to the changes on the 21st century labour market? What is the profile of the "employee of the future" in the opinion of this generation? Based on the analysis of Polish and foreign literature, the article presents a general description of generation "Z" representatives, including their values, needs and motivations as well as their behaviour on the labour market. The research findings describe the profile of the "employee of the future", including the expectations and characteristics of an employee representing generation "Z" university graduate, which should constitute an important element in developing a correct HR policy in an enterprise.

Keywords: labour market, factors of the labour market changes, generation Z, profile of the employee of the future

Introduction

The scientific discourse is increasingly focused on the problem addressing generational differentiation of employees in contemporary organizations. Young people with relatively short work experience or recently entering the labour market – referred to as generation "Z" remain, in many respects, radically different from the more mature, in terms of age, employees (Wiktorowicz, 2016). At the same time, the galloping dynamics of changes can be observed on the 21st century labour market. Many experts wonder whether human work will be totally automated in the near future. Will there still be a place for people on the labour market, and if so, what role they are going to play? The report published by *Infuture Hatalska Foresight Institute* entitled "Employee of the Future" (2019) highlighted that, according to 15% of the respondents, the ongoing technological and economic changes open up new opportunities on the labour market, while 85% of the respondents recognize threats to human labour resulting from work automation as well as the risk related to disappearance of some of the occupations performed today. The approach towards the aforementioned transformations occurring on the 21st century labour market varies significantly depending on the generation active on this market (Weingarten, 2009). It should also be adopted that along with generation "Z" gaining the dominant position on the labour market, the model of work may also change.

Basically, there are four generations functioning on the modern labour market. The source literature provides diverse terminology referring to a given generation as well as different dates regarding their year of birth. E. Hetig (2019), after Lain-Kennedy, identified the following generations: Baby Boomers, generation "X", generation "Y"

Cite this Article as: Magdalena RĘKAS " Changes on the 21st Century Labour Market and The Profile of The "Employee Of The Future" In The Opinion Of University Students And Graduates – The Representatives Of Generation "Z" In Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and generation "Z". The representatives of the first group, i.e. people born in 1946-1964 are slowly retiring to be replaced by the next generation - generation "X" (people born in 1964-1985). They, in turn, have to face the challenges of working with the next generations: "Y" (people born in 1985-1995) and "Z" (people born after 1995 to 2010). Since 2010, generation "Alpha" has been identified to constitute the resources of future employees (Thompson Augusto dos Reiss, 2018). Each of these generations has been shaped by various social, economic, political, cultural and technological events, and thus their members differ in many characteristics, including the ones referring to professional life. Therefore, they present different approaches to work, to understanding development, loyalty, dedication of working time and organization. For an employer, a team made up of workers diverse in terms of age, covering representatives of different generations offers access to a wide range of competences and experiences, increases creativity and multiplies methods of solving problems, but it is also a challenge to create an appropriate intergenerational management system. Thus, the "employee of the future" will evolve depending on the scenarios offered by the labour market development and the generations that dominate it at a given moment.

The purpose of the article is to attempt answering the following questions: What is the attitude of students and graduates representing generation "Z" in Poland to the changes on the labour market in the 21st century? What is the profile of the "employee of the future" in the opinion of this generation? Due to different characteristics of this generation, it seems reasonable to find out, already today, the attitudes and expectations of generation "Z", as that will allow businesses and institutions to prepare for the new model of the "employee of the future".

The article has been prepared based on the analysis of Polish and foreign literature and the analysis of research reports, in particular the 2018 research report published by *Infuture Hatalska Foresight Institute* entitled "Employee of the Future" (2019) and the author's own pilot studies. The research consisted of two parts. The first part addresses the research methodology and the description of the target group. The second part presents the results of pilot studies conducted in June 2020 using a survey questionnaire.

Changes on the labour market in the 21st century and generation "Z" in the light of source literature

The research carried out by many authors, including: Kultalathi S. et al. (2015), Lieber L.D. (2010), Luscombe J. et al. (2013), Lyons S.T. (2015), as well as the experiences and opinions of employers indicate that the current situation on the labour market is largely influenced by intergenerational differences and the simultaneous functioning of several generations of employees. The subject of the study is generation "Z", which is also called: "generation V", "generation C", "generation Cox", "internet generation", "homeland generation" or "Google generation", as well as the "mobile generation" or the "selfie generation" (Kapil Y. et al., 2014) living in the Internet and the social media. This generation is aware that their world is a digital environment which affects their features and adaptation to life.

Various studies analysing generation "Z" (Ozkan and Solmez, 2017; Seemillee and Grace, 2016; Merriman, 2015) highlighted several important characteristics of this generation, such as:

- they are digital natives attracted by an immediate reward;
- their attention focus time is 8 seconds comparing to 12 minutes characteristics for generation Y;
- they are more interested in experience and expert knowledge than in general knowledge, they are more flexible;
- they are identified as loyal, compassionate, thoughtful, open-minded, determined;
- they are valued as a competitive, spontaneous, adventurous generation curious about the world;
- the difficulties they perceive include: uncertainty about the future, high individual expectations and concerns;
- they prefer to shop online because of such factors as: the Internet impact, product description, external factors, deals and product identity.

M. Diaconu and A. Dutu (2020), in turn, identified the characteristics of generation "Z" in the context of their approach to the labour market, which should be taken into account by employers when managing a diversified team and developing rules for the functioning of intergenerational teams:

- they intuitively satisfy their continuously changing needs;
- they should be part of the solution as they dislike things being imposed on them;
- they show respect and loyalty before asking for it;

- they accept social learning, learn directly, expect full commitment, prefer learning by acting rather than listening passively, focus on designing their own life journey and career, they are not interested in syllabuses and understanding general knowledge;
- they can manage time in virtual space;
- technology is an extension of their identity, hence they are capable of managing skilfully the increasingly complex tools;
- they are strongly attached to, e.g., a technology manufacturer and are dependent on personal phones;
- they pose a clear challenge for companies in the sense of self-confidence and self-motivation, far from being naive and detecting dishonesty quickly;
- healthy food preferences are important to them;
- they are optimistic about their financial future, use financial advice mostly from their parents and are careful when spending money, often make savings out of caution;
- they are ideal patients of the future due to their openness to stress measurement technology and genetic mapping technology;
- they are in favour of online shopping over the phone as they can easily compare prices and make the right choice; smartphone is a tool which helps them make transactions and take decisions;
- their goal is the career top salary level approximately 3 times higher than the one earned by those currently employed;
- they enjoy travelling and operate effectively in both local and global space, thus they expect employers to provide them with the opportunity of choosing their place of work in the world;
- they inherited scepticism from their parents, but not pessimism, they are the generation which emphasizes happiness and openly expresses their dislikes;
- they have the ability of processing information faster than other generations, provided they find them interesting;
- they rely heavily on social media for social as well as school/university and later professional contacts;
- they prefer online interactions with friends over face-to-face ones; they favour messaging over calling by phone or e-mailing;
- social media are very important to them;
- they are better at multitasking than the preceding generation Y;
- they do not favour starting work as early as possible and are increasingly using the online version of vocational training to the detriment of classical education;
- they earn a living as a result of their own efforts at a young age working under fixed-term contracts;
- they strive to perform work being their passion.

Demographic and generational changes represent one of the factors having impact on the labour market transformation, which has been particularly intense since the turn of the 20th and the 21st centuries. This transformation is present in the economic, technical, social and demographic spheres and has a fundamental impact on the entire national economy as well as the individual components of its structure. Taking the classical approach, the changes on the labour market and also in individual industries are influenced by the following factors: technological, social, environmental, economic and political ones (Samuelson and Nordhaus, 2008). As A. Tomanek (2010) emphasizes, technical progress, globalization processes and negative trends in population changes constitute the essential development challenge for the labour market. B. Stopczyński (2015) indicates that the volatility of the labour market is influenced by the global competition, the development of information and communication technologies, including the Internet and technological development. R. Dylkiewicz (2013) highlights that it is globalization characterised by strong intensity which exerts the greatest impact on the labour market. This is due to the elimination of barriers resulting in a uniform global economy, influencing the supply of labour and its demand. On the other hand, O. Blanchard (2006) argues that the situation on the labour market is the consequence of many factors, often closely related to one another. In the study by M. Rękas (2019) it was indicated that technological, social, environmental, economic and political factors result in the emergence of new challenges regarding the approach to work in the 21st century as well as the characteristics and competences of the "employee of the future".

A different classification of the factors responsible for changes on the labour market in the 21st century was proposed in the study carried out by *Infuture Hatalska Foresight Institute*. It distinguishes 3 groups of factors, depending on their perception by employers, employees and labour market experts, i.e. (Employee of the Future, 2019):

- "Now" factors – this is a group of change factors that are felt and noticed by employees and employers right now and currently have the strongest impact on business, labour market or the desired employee competences. This group includes such factors as, e.g.: rapid technology development, mobile internet,

digitization and automation of work, cloud computing, Big Data, urbanization, consumerism, generational changes in the work environment, flexible working conditions.

- "New" factors – this is a group of change factors which are increasingly felt and noticed, but they are in the initial stage of development. This group includes such factors as, e.g.: growing social inequalities (including the NEET generation), freelancing economy, work life balance, silver economy, increase in life expectancy, minimalism, expanded virtual reality, lifelong learning, women empowerment gender parity, the idea of sustainable development.
- "Next" factors – this group of change factors is made up of trends that are already taken into account, but are sometimes approached as the future ones. The following factors are included here: artificial intelligence and machine learning, monitoring and controlling, cybercrime, climate change, zero waste economy, overpopulation, teal organizations, sharing economy.

The above classification of the factors responsible for changes on the labour market was also used in the author's own pilot study.

Research Methodology and Description of the Group of Respondents

The research was conducted following the below stages:

1. The analysis of the selected source literature and research reports published by Polish and foreign institutions in the defined research area, which allowed systematizing knowledge, identifying the research problems and planning the research.
2. An in-depth debate involving students from the "Economicus" Science Club and the students of Wrocław University of Economics during didactic classes – based on a detailed scenario developed on the basis of experiences and conclusions from the literature and the available research findings – preliminary qualitative studies which allowed formulating questions provided in the survey questionnaire.
3. Conducting questionnaire survey among students and graduates of universities representing generation "Z" – quantitative research.

The performed quantitative research was of pilot nature, and its objective was to provide answers to the following two research questions.

- What is the approach of university students and graduates representing generation "Z" in Poland to the changes on the 21st century labour market?
- What is the profile of the "employee of the future" in the opinion of generation "Z" representatives?

In order to obtain answers to the aforementioned questions a quantitative research tool was used, i.e. a survey questionnaire which allowed collecting information by applying the indirect measurement method. The survey was conducted on-line from 10th till 21st June 2020. It was provided by sending a special generated link to people from a random research sample covering university students and graduates in Poland representing generation "Z" and residing in Poland.

The questionnaire included personal information section and 29 questions divided into 4 areas: value of work, expectations when choosing a job, factors of changes on the labour market and their perception, the attitude of generation "Z" towards changes on the labour market in Poland within the coming 10-15 years. These areas allowed identifying the characteristics of the "employee of the future" in the studied group. Therefore the questionnaire provided questions about job expectations, employee competences, the labour market and its change factors, along with the current situation on the labour market related to SARS-CoV-2 pandemic and the respondents' attitudes towards the changes they anticipate in the future. The respondents were asked about the value of work for them, if they have any professional experience, what their attitude to work is, whether they are attached to the current place of employment, how they imagine the possibility of retraining, what values they follow when choosing a job and what they find important at work. Next they were asked about the factors changing the labour market and their preferences related to choosing an employer. The subsequent section included questions about the characteristics and competences of the employee of the future. The respondents were also asked to provide information about their personal feelings regarding the impact of SARS-CoV-2 pandemic on the labour market. In this section the respondents were also requested to comment on their current or future decisions regarding employment. The personal information part included a question about the respondent's age, which allowed excluding questionnaires filled in by the representatives of a different generation. It was adopted in the study that the research sample covers the representatives of generation "Z" born after 1995, who were between 18 and 25 years of age at the time of the study.

Before conducting the survey, the respondents were informed about its purpose and ensured that the survey was completely anonymous. In the course of the survey no irregularities or technical disturbances occurred. 150 fully completed questionnaire sheets were collected as a result of the conducted pilot studies. The Table below presents the research sample in detail.

Table 1: Detailed research sample

No.	Specification	Possible answers	Number of provided answers	Value in total answers
1.	Gender	**woman**	**86**	**57.3%**
		men	64	42.7%
2.	Age	**18-25 years of age (generation Z)**	**150**	**100%**
3.	Studies	in the course of the first cycle degree programme	40	26.7%
		in the course of the second cycle degree programme	**67**	**44.7%**
		completed studies (graduates)	43	28.7%
4.	Form of studies	**full-time studies**	**95**	**63.3%**
		extramural studies	55	36.7%
5.	Education at the time of completing the survey	primary	0	0%
		vocational	0	0%
		secondary general	23	15.3%
		secondary vocational	18	12%
		bachelor's degree	**61**	**40.7%**
		master's degree	37	24.7%
		engineer's degree	11	7.3%
6.	Place of residence	village	18	12%
		city up to 50 thous. inhabitants	18	12%
		city up to 100 thous. inhabitants	**47**	**31.3%**
		city up to 250 thous. inhabitants	26	17.3%
		city over 250 thous. inhabitants	41	27.3%

Source: Author's compilation

The analysis of the above Table shows that women dominated the research group (57.3%). The distribution of provided answers is almost fifty-fifty, which significantly reduces the probability of collecting erroneous information that could result from the gender factor alone. Students accounted for 71.4% and graduates for 28.7% of all the respondents. The group of students was dominated by the second cycle degree programme students. 63.3% of the respondents represented the students or graduates of full-time studies. 40.7% of the respondents covered by the survey had already obtained the bachelor's degree, thus they were the first cycle degree programme graduates. Based on the place of residence, 31.3% of the respondents resided in cities of up to 100,000 inhabitants and next the inhabitants of cities with the population of over 250 thous., i.e. 27.3%. The research was conducted as a pilot study and will be repeated on a larger research sample after obtaining additional funding within the framework of the research project implemented by Wrocław University of Economics. The research will be extended by quantitative studies covering the representatives of generation "Z", regardless of the level of education, and also by qualitative studies (interview) among the employers currently employing representatives of the surveyed generation. It will allow developing the map of gaps between the expectations and the actual employment conditions on the labour market. In addition, it will help determining the impact of the prolonged SARS-CoV-2 pandemic on the situation and attitudes of both sides of the labour market – employers and employees representing generation "Z" in the perspective of the deteriorating economic conditions and the situation in many industries.

Research Results – generation "Z" and their attitude on the 21st century labour market and also the profile of the "employee of the future"

The conducted survey was focused on seeking answers to two research questions: *What is the approach of university students and graduates representing generation "Z" in Poland to the changes on the 21st century labour*

market? The following research hypothesis was formulated in relation to the defined research problem: Students and graduates representing generation "Z" are open to changes on the labour market and will create a new model of the "employee of the future" presenting a different approach to the value of work than the previous generation.

The second question was: *What is the profile of the "employee of the future" in the opinion of generation "Z" representatives?* regarding which the following research hypothesis was formulated: Among the characteristics of the "employee of the future" representing generation "Z" the most important ones are: work is a passion at the same time, development and no stress at work rather than earnings are crucial, they are familiar with the Internet and digitization since birth, hence remote work is the desirable form of employment for them, they are open to transformations in the world, primarily the ones resulting from technological changes, they remain highly sensitive to ethics and care for the environment.

The results of the author's own research allowed verifying both research hypotheses. The Table below presents the results with the highest indications. The obtained answers allowed creating the "employee of the future" profile representing generation "Z" in relation to the respondents, i.e. university students or graduates.

Table 2: The "employee of the future" profile represented by generation "Z" in the surveyed group

Employee's approach	Generation "Z" employee profile in the light of own research
The attitude of generation "Z" and the value of work	
• Which approach to work does the respondent identify with the most?	• Work should be a passion (49%)
• Has the respondent ever taken up a job in his/her life? If so, for what purpose?	• Yes, to increase income (44%)
• How important is work in life for the respondent? *On the scale from 1 the least important to 5 the most important*	• important for 52% of the respondents (average 3.8)
• How important is the amount of earnings for the respondent on the scale from 1 the least important to 5 the most important?	• important for 46% of the respondents (average 4.3)
• Which of the elements of work is the most important for the respondent in performing work?	• no stress (36%) Additionally: permanence and stability of employment as well as developing skills and qualifications (both elements came second, 22% of the responses each)
• Is job satisfaction more important for the respondent than earnings?	• rather yes (47%) • yes (24%) Positive answers: 71% of the respondents
• Does the respondent think that the current number of hours devoted to work is too high?	• Yes (52%)
The expectations of generation "Z" when choosing a job	
• What is the most important for the respondent when choosing a job? *On the scale from 1 unimportant to 6 the most important*	• Earnings are most important (average 5.14) • Development and improvement (average 5.02)
• What form of employment is the most attractive for the respondent?	• Running one's own business and part-time work (the same results - 31% of responses each)
• Which statement does the respondent identify him/herself the most? a) An employee should adapt to the labour market. b) The labour market should adapt to an employee.	• The labour market should adapt to an employee (64%)
• What is the most important for the respondent in his/her professional career? a) Security and stability of employment	• Security and stability of employment *(flexicurity model)* and performing work which allows career development

b) Performing work which allows for career development (promotion) c) Control over the performed work, duties and working hours d) Earning the highest possible income	(the same results - 43% of responses each)
• What are the crucial factors for the respondent when choosing an employer? a) offered high earnings b) company reputation (only the best are employed) c) company ethics d) independence of the position at work	• Company ethics (50%)
• What does the respondent want to gain from professional work? a) Change the reality b) Be innovative and creative in return for high earnings c) Work at a high position in an attractive organization d) Be proud of work in a socially engaged organization	• High position in an attractive organization (34%)
• How does the respondent see his/her work in the future?	• I am part of an organization that puts people and common good first (32%) • I am part of the continuously developing innovative and international ecosystem using ultramodern technology (31%)
• What should the enterprises of the future do according to the respondent?	• Bring the greatest possible benefits to the environment and reduce negative impacts on the environment (33% of the responses) • Feature high social awareness as the primary goal of business (32% of the responses)
The factors of changes on the labour market as assessed by generation "Z"	
• Does the respondent believe that dynamic changes are taking place on the labour market?	• Yes (86%)
• Which group of factors (technological, social, environmental, economic and political) influencing changes has the greatest impact on the labour market transformations at the time of conducting the research in the opinion of the respondent?	• *Technological factors* (47% of indications)
• Which of the *technological factors*, according to the respondent, have the greatest impact on the changes taking place on the current labour market (indicate 3 answers)	• mobility and digitization (57% of indications) • automation and robotisation, including the development of artificial intelligence (53 % of indications) • fast development of technology (51% of indications)
• Which of the *social factors*, according to the respondent, have the greatest impact on the changes taking place on the current labour market (indicate 3 answers)	• Generational changes on the labour market (48% of indications) • *Work life balance* (45% of indications) • Aging society (44% of indications)
• Which of the *environmental factors*, according to the respondent, have the greatest impact on the changes taking place on the current labour market (indicate 3 answers)	• Climate changes (47% of indications) • Urbanization (42% of indications) • Depleting natural resources (37% of indications)
• Which of the *economic and political factors*, according to the respondent, have the greatest impact on the changes taking place on the	• Powerful corporations (59% of indications) • Social inequalities (52% of indications)

current labour market (indicate 3 answers)	• Immigration crisis (36% of indications)
The attitude of generation "Z" towards changes which according to them will take place on the labour market in Poland in the coming 10-15 years	
• Which of the factors: NOW, NEW, NEXT may have the greatest impact on changes on the labour market model in Poland within the coming decade?	• NEXT (59% of indications) and among them: artificial intelligence, machine learning and climate changes (37% of indications each)
• What does the respondent feel when thinking about the future changes on the labour market related to technological and economic development?	• Believes that he/she can manage the new tasks (41% of indications)
• Which 3 most important competences will the "employee of the future" have to present on the future labour market in Poland?	• Ability to cooperate with others 75% • Ability of active learning 66% • Digital skills 49%
• Which of the new organizational and employment models is the most groundbreaking in the respondent's opinion?	• Remote work (64% of indications)
• Does the respondent feel attached to his/her current place of employment?	• Yes and rather yes (43% of indications)
• Would it be easy for the respondent to take up a new, better job at the expense of retraining?	• Yes and rather yes (67% of indications)
• Does the respondent believe that SARS-CoV-2 initiated another revolution in the labour market?	• Yes and rather yes (86% of indications)
• Does the respondent think that the labour market in Poland has ceased to be the "employee's market" as a result of SARS-CoV-2 epidemic?	• Yes and rather yes (70% of indications)

Source: Author's compilation

The research findings presented in the above Table indicate that the value of work has been redefined. Generation "Z" definitely perceives work as an element related to carrying out their passion and thus bringing satisfaction, which is a completely different approach to the role of work in human life comparing to other generations. Generation BB was dominated by the attitude "I work to survive", generation "X" representatives identified themselves with the statement "I live to work", generation "Y" "I work to live", whereas generation "Z" is the first generation which desires to combine work with passion.

In the question *"What is the most important for the respondent when choosing a job?"* the respondents were asked to evaluate the following elements: earnings, form of employment, mobility, development and improvement, creativity and influencing climate change. The survey covered these characteristics which were considered the most important in the light of the source literature review and the results of foreign research, in particular the Employee of the Future report (2019). According to the respondents, earnings constitute the most important aspect when choosing a job (139 indications), development and improvement were ranked as the second (132 indications), the third position was taken by the form of employment (115 indications), the fourth – creativity (111 indications), with mobility to follow (107 indications). Influencing climate change was listed as last since only 86 people considered it the characteristic which they take into account when choosing a job.

It is worth emphasizing that people from generation "Z" are not particularly eager to work full-time, on the contrary, they perceive running their own business as the most attractive form of employment, which offers an opportunity to decide about the time and amount of work, and if they decide to take up employment they prefer a part-time option. They value freedom in deciding about themselves and their working time. For an employee representing generation "Z" earnings are important when choosing an employer, however, while performing the job the absence of stress at work is the most important value. In turn, their career expectations are focused on job security and stability (the component of the *flexicurity* model), but also on performing work which provides an employee with development and promotion possibilities (they strive for a high position in an attractive organization). The attitude of generation "Z" representatives also confirms their high sense of ethics and appreciation for the ecology oriented operations of the enterprise they work for. People from generation "Z" are attached to such values as flexibility and freedom of work, they find professional development opportunities highly important.

The employee of the future representing generation "Z" expects to be part of an organization that puts people and the common good first, and also a part of the constantly developing, innovative and international ecosystem, using ultra-modern technology – this finding confirms the openness of this generation to the world and, at the same time, the very important role of technology, which they deal with since birth and are aware of its development in the future, hence working with robots is not a scary vision for them. It should be highlighted that they expect to work remotely, as it offers them a specific space to operate, they are also ready to retrain and change the sector. This approach allows for a new definition of work in the 21st century, i.e. work is no longer a place where a person spends 8 hours every day, but a collection of activities performed from anywhere in the world, also from home. For generation "Z" online communication is a normal form of contact and a part of their everyday life. The study identified three most important competences sought on the future labour market that form a coherent entirety in relation to the characteristics of the discussed generation and the results of provided responses about other aspects.

People from generation "Z", as confirmed by the research findings, are aware of the changes on the labour market in the 21st century and, in their opinion, the group of technological factors will have the greatest impact on the labour market transformations in the years to come. The rapidly advancing technological changes do not pose a problem for generation "Z", moreover, the majority of this generation representatives are not afraid of the changes, they even believe in being fully capable of dealing with the new tasks. It is also worth emphasizing that, in their opinion, it is the market that will have to adapt to them and not the other way round, thus a company which will not notice generational changes on the labour market may have a problem with recruiting and retaining employees.

Generation "Z" also confirms that they can quickly analyse information and draw conclusions. In the face of the existing threats – the current SARS-CoV-2 pandemic, generation "Z" perceives risks, and above all notices the change in the nature of the market situation from the employee's market to the employer's market but, nevertheless, detects opportunities for the market and business development in a properly selected model of work organization, i.e. the already mentioned remote work. The obtained findings of the author's own research are largely consistent with the characteristics of generation "Z" presented in the cited source literature, in particular in the article by M. Diacon and A. Dutu (2020) and also in the *Infuture Hatalska Foresight Institute* report entitled "Employee of the Future" (2019).

Conclusion

Beyond any doubt the world is already speeding so fast that the model of the "employee of the future" will continue to evolve. Undoubtedly, generation "Z" will be an important subject of this model and, due to a number of specific and completely different characteristics than in the case of previous generations, will present a specific challenge for employers. Diverse attitudes and values of work, different expectations than the ones already known form the labour market characteristic for generations BB, X and Y cause that employers will have to learn how to recruit, work with, retain and motivate employees representing generation "Z".

It is worth observing that, at the international level, a great deal of research has been carried out in different national contexts to identify the characteristics of generation "Z". Interestingly, the results of these studies are also sometimes different from the ones indicated in the presented study. This variability of findings is directly determined by cultural factors and national context in which each study was conducted. Further research will certainly allow for much better understanding of the characteristics and behaviours typical for generation "Z" representatives, entering the labour market more and more boldly and in greater numbers, and will also determine further changes on the labour market in the 21st century.

The presented research is a pilot study and should be approached within the constraints resulting from a reduced sample of respondents. In the near future the study will be extended to cover a more representative sample size. Further research direction will take the form of a comparative study in intergenerational contexts to allow providing knowledge for the development of human resources policy and managing multigenerational employee teams.

Acknowledgment

The project is financed by the Ministry of Science and Higher Education in Poland as part of the program entitled "Regional Initiative of Excellence" 2019 – 2022 project number 015/RID/2018/19 total amount of funding: PLN 10,721,040.00.

New Transformations and Challenges for Human Resource Management in the Public Sector

Charbel EL AMMAR
PhD Candidate, Bucharest University of Economic Studies, Romania
charbel.alammar@gmail.com

Abstract

The main idea of public management is that management methods in the private sector are superior to those in the public sector and can be borrowed. The public sector is considered less innovative, overly bureaucratic, rigid, expensive and too centralized. Increasing the performance of human resources in the public sector is still the subject of extensive debate and study. The modernization of the administration must be guided at all times by the need for good management of the money coming from the contributions and efforts of citizens, by increasing the effective accountability of its organizations and by decentralizing services, measures that can contribute to the implementation of modern management, which can encourage the necessary effort to adapt the public sector. This empirical research aims to identify and analyze new transformations and challenges for human resource management in the public sector compared to private organizations. The comparative analysis of human resources in the public and private sectors is based on the thorough analysis of the literature and identifies the differences in organization and management of staff in the two types of organizations.

Keywords: Human Resource Management, Public Organizations, Staff Management, Recruitment.

Introduction

Moving from a stable organizational context, marked by the civil service system, human resources management is now evolving in a hybrid environment, which combines the values and principles of public and private action. The challenges are considerable to move from a simple management of personnel files to a genuine human resources management, focused on the skills and motivations of the staff and enabling the implementation of an integrated and coherent human resources policy, in relation to with the strategic orientations of the organization. Practices inspired by the new public management have a lasting impact on the functioning of public organizations, especially in developed European countries. These practices are carefully constructed as opposed to the classical bureaucratic model, considering the market model as the key to solving public problems. While it is undeniable that the new public management and its various applications have allowed public organizations to make significant progress (Giauque & Emery 2008), they have nevertheless been seriously criticized, especially on the grounds that these methods violate specific public values, the democratic logics that regulate their operation and, finally, they aimed to reduce administrations to simple enterprises dominated by market requirements.

Research Methodology

The main objective of this empirical research is to make an in-depth analysis of the literature in order to identify the main transformations and challenges that have occurred in recent years in human resource management in the public sector compared to private organizations. In this sense, the literature review of the main articles was used, as well as of the main studies and researches that approach the targeted topic. A comparative analysis of the differences and similarities between human resources in public and private sector organizations was included, which incorporates an analysis of recruitment processes, human resources management, retirement and fixed-term employment contracts in

public and private organizations.

Literature Review

Most analysts believe that it is necessary to rethink public organizations by integrating the best of the two: the traditional administration and the private enterprise. This hybrid view is shared by well-known specialists in administrative sciences (Aucoin, 1997; Pollitt & Bouckaert, 2004) or organizational sciences (Olsen, 2006). Thus, the concept developed by Denhardt and Denhardt (2003) and formulated in response to an exaggerated management, is built around the following guidelines:

- ✓ Serving citizens, not consumers;
- ✓ Pursuing the general interest;
- ✓ Prioritizing the valorization of citizenship and less of entrepreneurship;
- ✓ Thinking strategically and acting democratically;
- ✓ Recognizing that imputing is not an easy task;
- ✓ Serving rather than to leading;
- ✓ Valuing people, not just productivity.

This hybrid institutional model depends, more or less, on the country and the organizations analyzed, on the administrative reality in which public agencies are currently evolving. The many reforms that have affected public administrations have transformed the working environment of employees, projecting them into a new era, known as post-employment service. They are currently facing new employment conditions and new ways of working, which aim to make the public service more efficient. But these changes have a strong impact on their identity and motivations at work. The typical conditions of the civil service, typical of the old civil service statutes, have been largely abandoned in Western countries, starting with the appointment of civil servants for life, as well as by the very name of civil servants, renamed civil servants.

Thus, the hybrid institutional model described above translates into an environment called post-employment, whose main features are:

- ✓ public servants are employed under conditions close to the private sector, but benefit from the guarantees of public law (Demmke, 2004);
- ✓ enthusiasm is provided by an entrepreneurial spirit (Farnham et al., 2016), which respects the values characteristic of the public ethos and the principles of public law (legality of administrative action, equal treatment, proportionality, etc.)
- ✓ orientation, evaluation and reward according to the quality of their services and the performance achieved (Villeneuve, 2006), incorporating the expectations and legitimate requirements of the beneficiaries of public action: citizens-clients.

Post-employment service appears explicitly not only in the literature (Schedler & Proeller, 2000), but also in international public service modernization projects. This hybrid public function, halfway between the pure logic of the market and the classical one, of the public administration, induces new behaviors, based on competencies that more or less successfully combine the qualities of the traditional "bureaucrat" with those of the successful private sector employee.

Public officials are usually required to be "customer-oriented", fully respecting the equal treatment of beneficiaries. Influenced by this new institutional and organizational context, the practices of public human resources management are thus necessarily transformed, which determines the emergence of significant challenges.

The public management of human resources remains determined by the legal bases, statutes and other regulations regarding the personnel, which condition the modalities of action. On the other hand, it must also meet the requirements of the organization, providing concrete solutions to help better fulfill its missions and challenges, trying to make better use of the strategic leverage effect (Emery & Giauque 2003).

Thus, significant difficulties arise, starting from the fact that planning and strategy are often missing or are expressed in general terms, making any operationalization difficult. Added to all this is the fact that many strategic plans are more like public marketing than a real will to strategically steer. From the moment the human resources management passes from the purely administrative stage to a true management of people, it becomes obvious that the role of the hierarchy is central, because it is the one that will select, frame, appreciate, value, develop and promote staff, based tools provided by the human resources service.

Many studies have considered staff quality as a moderating variable essential for human resource management practices to lead to increased performance (Vermeeren et al., 2008). This dimension of public leadership is all the more critical as the evolution due to the new public management is based on an increased delegation of responsibilities and a greater margin of maneuver granted to public managers, although practice shows that this transfer of responsibilities it is less obvious than it seems (Broucker, 2008).

In particular, this delegation can bring about a form of public service explosion, with public officials being treated very differently from one department to another, without these differences always being legitimized by objective elements. In this way, a neosubjectivity in the public service appears, subject to the arbitrary power of a hierarchy that demonstrates an excess of autonomy.

The era of automatisms (salary increases, career development, etc.), a feature of the public service, seems less and less adapted to a rapidly changing world and constantly changing public organizations. Thus, a good human resources management system should highlight the positive behaviors that contribute to the quality of the services provided, the collaboration between staff members and the efficient use of available resources and intervene to improve dysfunctional behaviors (Tataru, 2019). In fact, this means avoiding automatic mechanisms, assigning the same salaries and promotions to everyone. The problem also lies in the fact that the end of automation means moving to a dynamic system, whose criteria must be clearly defined and rigorously applied, without which the public administration risks entering a form of revived internal clientelism. In this respect, the analysis of remuneration practices by performance is particularly illustrative of the difficulties encountered by the public administration.

The access to the public service was based on objective qualifications, attested by official diplomas, necessary to fulfill the different tasks of the positions that compose it. Since the 1980s, this logic of "diploma" has been gradually replaced by that of skills (Boyer, 1998; Horton et al., 2002). It was thus found the emergence of competency benchmarks to stimulate the development of professional development in the public service, in which the isolation between ministries, for example, is classically significant (Rouban, 2007).

The definition of competencies shows that this challenge will not be easy to overcome, the public management of human resources being faced with a very important sophistication of its activities, especially those of involvement, training and professional development. Indeed, if a competence is contextualized by definition, then each environment requires specific competencies, which must be identified and described. The activity of civil servants is not easy to appreciate, due to the complexity of the activities performed and the multiple relationships between functions, but this cannot justify ignoring this central process of this management. Individual and group performance management systems, based on clear objectives and precise indicators, undoubtedly indicate the way forward. This is reflected in the OECD reports on remuneration for performance, which argue that not only can financial rewards have a positive impact on the motivation of civil servants, but also on the process of completing the action to which they are confined and at the end of which each civil servant knows his goals and goals. it can be included in the most general missions pursued by its service (Reichard, 2002; OECD 2005).

A group of authors (Desmarais et al., 2012) note that in recent decades most OECD countries have introduced many changes in the management of their public sector, bringing it closer, from this point of view, to business management. These reforms, more or less radical, based on a critique of bureaucracy, can be largely related to the new management and the new public management. They pursued similar objectives, such as decentralizing decision-making power, improving public sector performance and attractiveness, reducing costs, and so on. In this way, the outline of a new public management of human resources was drawn, built largely as an opponent of the bureaucratic model and characterized by contractual labor relations, flexible remuneration and especially the generalization of remuneration based on performance, emphasis on professionalism of politics. At the same time, this unequivocal vision hides significant differences in the reforms undertaken. Thus, the principle of career civil service is present in many European countries, and with some notable exceptions, the unilateral appointment of civil servants is the rule in many countries.

However, the countries that have committed themselves to extreme reforms are ultimately a minority. The reforms undertaken differ from country to country, so it should be noted that, beyond certain managerial convergences, changes in personnel management in public organizations remain strongly contingent on the institutional conditions, culture and administrative traditions of each country, or even levels of governance.

It is not uncommon for human resource management reforms not to have the desired effects in terms of effectiveness or to remain only formal. But beyond the difficulty of sustainably transforming practices, human resource management reforms also remain the paradoxes and tensions to which civil servants are subjected and have to work (Emery & Giauque, 2007). The analyzes also highlight the flaws of coherence of impulsive and contextual changes. These changes are accused of fueling a crisis of values and public ethos.

The study undertaken by Desmarais et al. (2012) aimed to take stock of the reforms carried out in an international perspective, with emphasis on the dimensions related to the management of public organizations. Specifically, he focused on four empirical researches. The study began with an analysis of the effects of changes in the public sector.

De Chatillon and Desmarais (2010) were interested in the effects of changes related to the new public management on psychosocial risks. If the negative effects of the new public management in terms of workload and pressure on employees have been mentioned in the literature based on qualitative analyzes, this study is innovative by quantitatively analyzing the impact of these changes on suffering at work, especially burnout, in a local French community. The analysis, conducted on a sample of 1118 public employees, highlighted the impact that the new public management had on burnout through its effects on the workload of employees and the climate of psychological violence. The second research focused on managing change in the public sector and, in particular, on the roles and identity construction of intermediary managers in the change process within public authorities.

Fergelot and Alis (2012) highlighted the way in which intermediary managers are at the same time actors and objects of the transformations induced by the reforms that are adopted in public services. This qualitative research, conducted in two French public authorities, describes and models the role of managers in the development of sensemaking and sensegiving, to legitimize, implement and assume change. Following the analysis of these two dimensions of the role of managers in the context and process of change, the text provides avenues for research for exploration.

The third research, conducted by Moreau et al. (2012) analyzes a developing phenomenon, that of the impact that public-private partnerships have on the behaviors and positioning of employees, who become responsible for managing public services in a strictly private and commercial legal framework. The results show that public-private partnerships generate trials: evidence, experiences, which initially result from a strategy to exclude more recalcitrant employees, and then encourage managers to seek a compromise to bring their private business world closer to the specific civic world. public service. Thus, a policy of developing a proximity management can result in a mixture of values, favorable to user satisfaction.

A more recent study, which examines the introduction of a logic of skills in the public sector, was conducted by Ben Hassine et al. (2012). The text proposed an approach aimed at establishing a profile of skills in this sector in Tunisia. The results showed that there was a tension between "bureaucratic" skills, associated with a tendency to verticalize relationships and compliance with administrative procedures, and managerial skills, related to the search for a better exchange of information, with an emphasis on ethics and management skills development, on vision and piloting public policies. Thus, it was observed that the Tunisian government wanted to identify within it the means to reinvent bureaucratic solutions by adapting them to the challenges of the new public management. The study concluded with two texts with reflections related to the remuneration of performance in the public sector.

The second reflection, authored by St-Onge and Buisson (2012), proposed a balance of knowledge about remuneration by merit in the public sector. After describing what happened in the public sector in the United States, the United Kingdom and in terms of remuneration based on individual performance, the article presented a summary of the results of studies that analyzed the impact of remuneration by merit in the public sector. The authors then found that remuneration by merit in the public sector has similar limits to those identified in the private sector, but that, in addition, the public sector offers additional specific constraints. This raises the question of why more states persist in adopting and maintaining it.

To explain this paradox, the authors turn to the perspectives of institutional and conventionalist theories, which show that the adoption of a management practice does not derive only from its supposed or objective "technical" performance. Finally, the study proposes promising research avenues to better understand the issues and challenges of

merit-based pay in the public sector. Current and future changes in human resource management in public organizations make these issues an emerging area of research in the field of management sciences. The study also demonstrates the diversity of issues and challenges posed by these changes. Beyond the analysis of the effects of new practices, the research now focuses on an analysis of the hybridization of human resources management practices, which occurs as a result of juxtaposing bureaucratic and managerial models and to define management models specific to the new public management.

Comparative Analysis of Differences and Similarities between Human Resources in Public and Private Sector Organizations

The main differences in the organization of human resources in the public and private sectors concern the fundamentals of the relationship of subordination, the methods of recruitment methods and the conditions of remuneration. In the private sector, the sources of labor law emerge primarily from the contract. Even if labor law must comply with certain external rules (constitution, ratified treaties, laws, etc.), the essential foundation of labor law is the will of the parties, whether it is expressed in the relationship between employer and employee or through a collective delegation: national interprofessional agreement, national branch convention, enterprise or establishment agreement, etc. The competition, regardless of its modalities (by test, based on the title, internal, external, etc.), is the standard recruitment norm in the public service. This way of recruiting is a way to avoid favoritism.

Devetter (2004) recalls that "before the generalization of competition, recruitment in the public service remained for a long time marked by nepotism and clientelism". This is not the only way, because other systems have been used in the past (or still are), such as elections, drawing lots or co-optation. The competition rule responds, moreover, to the requirements of anonymity, foundations of public office: an official is a person who holds a position, it is recruited based on his skills and abilities and not based on his name, rank, wealth, family his or his system of relationships. Given these criteria, the competition is distinguished as an ideal selection tool, because it is based on the assessment of the candidate's skills.

If private sector recruitment meets a number of requirements, such as non-discrimination, the relevance of the information requested, loyalty to the candidate, the obligation to formalize the recruitment in writing, the employer is free to recruit whenever he wishes. This freedom meets the objectives of the enterprise, which are fundamentally different from those of the public service. The latter is in the service of the general interest, while the company's objective is - in economic terminology - to combine the factors of production to achieve maximum performance (Dima, 2018). The free choice of recruitment is the corollary of the company's raison d'être. Once the terminology problems are overcome, there are many commonalities and many similarities between the public and private sectors, when the structures are of comparable size. If the ways of recruiting in the public and private sectors are different, the similarities become clearer when it comes to managing staff, or giving up.

With regard to staff management, the big difference between the public and private sectors concerns joint administrative commissions, which have the power to issue opinions on the careers of civil servants under the statute and to meet in the disciplinary board in case application of sanctions. The Joint Administrative Commission is consulted on all matters affecting the careers of officials: position (relocation, secondment, making available), career (promotion, promotion through the list of skills, tenure) and sanctions discipline. In practice, this committee has a greater role in decision-making than advisory: its opinions are followed by overwhelmingly overwhelming effects. It should be noted, moreover, that trade union representation is more rigid in the private sector than in the public sector. The rigidity of staff management under the statute is often opposed to the greater freedom that staff managers would have in the private sector, especially when there is a need to stop working with an employee.

Frequently advanced evidence is the growing temptation to use untrained staff in the public service, especially in limited-term or rapidly changing positions. Or the flexibility of the private sector, compared to the public sector, comes more from different cultural contexts, than from a greater ability to give up a collaborator. Whether in the public or private sector, collaboration between an employer and an employee can be concluded in three forms: end of contract, career or resignation.

Retirement, the end of the contract (fixed-term contracts are not the prerogative of the private sector, the public service can use them, and do not hesitate to do so), resignation are significantly comparable situations in terms of personnel

management in both sectors. The difference between the two systems is found more in the licensing procedures. With regard to dismissal for economic reasons, this notion has no equivalent in the public system. The closest thing is the law on the release of cadres, which although it is a simple law, is enough to "dismiss" officials. The comparison between the public and private sectors must be made on the basis of dismissal for personal reasons (labor law) and professional incompetence (civil service status).

The fixed-term contract does not offer human resources managers in the company more flexibility than the one available to the personnel managers under the statute. Both labor law and civil service status distinguish between dismissal for misconduct and dismissal without fault. With regard to the latter, the finding of professional incompetence or the inability to work due to a long illness leads to dismissal, both in the private and public sectors.

In public organizations, the duration of the career is that of the professional life of the civil servant: the time within them coincides with the long period of bureaucracy, accompanied by the stability and continuity of the rules. In the private sector, short time and market responsiveness take precedence, determining the strengthened and continuous link between activity and contract. The time perspective of the official coincides with the duration of his career. This explains the heated nature of the debate on the issue of retirement age in the civil service and in the case of assimilated staff. All this is encouraged, as promotion is largely done according to seniority. This specific relationship with time can be observed and vice versa, in the sanctions that can be applied to an official in case of disciplinary misconduct: removal from the promotion table, demotion from the echelon, temporary exclusion, ex-officio retirement, respectively so many ways that affect career time.

The job guarantee is more applicable to the position than to the person holding it and is a guarantee of independence, neutrality and impartiality. Acting on behalf of the state, serving as such the general interest, the official must be protected from partisan interests. Offering a job for life removes his concerns from the need to find a professional backup solution.

Officials are extremely reluctant in the face of any confrontation, for example in situations where they are brought together to decide on a debate and / or a conflict. This does not mean that they are foreign to the concept of conflict, struggle, influence, observed as much in the public sector as in the private sector, but the expression of conflicts has the vocation to be suppressed, deaf, discreet. Raising one's voice is a mistake, a signal for a career and inadequacy for leadership or senior management positions. This is why public service rituals are poorly adapted to certain ways of meeting people in the private sector, especially those in which the arguments are opposed before a choice can be seen. Joint meetings between staff representatives and management are very illustrative of cultural differences in conflict management. Even if they belong to the public service, employees 'representatives are imbued with a union culture, which results from workers' demands and therefore has a sincere, direct, sometimes abrupt way of expressing themselves.

Compared to them, management representatives use rather codified, allusive language and are often shocked by the turn of joint meetings, even when the positions of staff representatives are, more often than we think, more moderate than their expression. The aversion to confrontation of officials is the corollary of their relationship with time, which is calibrated with their career. Destined to stay in touch with each other for decades, they are unlikely to significantly damage their relationship. Particularity in the public sector is therefore an exacerbated aversion to confrontation, even if the latter remains the most effective way of resolving conflicts. And this time the staff manager under the statute must take into account this dimension: to avoid the frontal solution of the problems in question or the opposition of the people or to engage in a pedagogical activity in order to make the confrontation finally accepted or tolerated.

Conclusion

The fact that there are more similarities than differences in personnel management in the public and private sectors calls for convergence in the training of management staff, managers and directors. One might imagine that the lack of the instrument of financial differentiation in the hands of public sector management underestimates the importance of training in human resource management and management in general. But the opposite is true: this is due to the fact that staff managers under the statute have fewer tools at their disposal and that they should be specially trained in this regard. Persons under the statute have specific motivations, which should not be overlooked. Often, officials have a keen sense of the general interest, of the public service, of the mission in which they compete. As such, they can be

strongly mobilized towards goals, provided that these goals are either relevant to their status and that the forms are met, that their motivation is stimulated. This is why the training of civil servants should be enriched with knowledge and experience from the sociology of organizations, the sociology of professions, and even anthropology. Rituals, codes, professional culture have as much the right to be studied and taught in the public service as in the private sector.

Abstract

Nowadays, eco (green) investments have been recognized as a key element in the transformation from a brown to a green economy. Eco-investments can be applied to all sectors of the economy, and all its dimensions: social, economic, and ecologic; Eco-investments are the applicable result of sustainable development actions among European Union countries. This paper presents the role of eco-investments among the EU member states and statistical analysis. This study is based both on qualitative and quantitative research methods. Then, the eco-investments on the European Eco-Innovation Scoreboard tool have been also analyzed, and the results were also presented. Source material for the examination were secondary data. As a result of this research, the leading eco-innovators were identified among factors influencing this type of investment.

Keywords: eco-innovation, green early-stage investments, Eco-IS.

Introduction

In recent years, the term 'eco-innovation' has been increasingly used. The definitions of eco-innovation seem to be quite general and, thus, many kinds of innovation can be defined as eco-innovations. Eco-innovations can contribute to the renovation of the whole innovation system, taking into account social, ecological, and economic aspects. Among the very important are green jobs, which can be seen also as a sustainable development factor (Sulich 2018) and an eco-innovation which contribute to the real economy sphere and protection of the natural environment (Sulich et. al., 2018).

Eco-innovation plays a key role in promoting and implementing green growth because it promotes all forms of innovation that reduce environmental impacts and strengthens resilience to environmental pressures (Park, Bleischwitz, Han, Kyung, and Joo). These pressures caused by human activity are called an anthropopressure, but seen both as a challenge and a set of ideas for the new entrepreneurship in EU countries (Sulich et. al., 2018).

This article reviews the results of eco-innovation in the EU Member States in terms of the total value of green early-stage investments (per capita). They are part of eco-innovation inputs which comprise investments aiming to trigger eco-innovation activities.

The Essence of Eco-Innovation

The definitions of eco-innovation seem to be quite general meaning and are the important issue of further classifying eco-innovations to better understand their specific characteristics. There is no commonly agreed definition of eco-innovation, therefore this article presents only the most important of them. According to the classical definition of eco-innovation, it is a new product that provides value for the customer and business, while significantly reducing the negative impact on the environment (James, 2001). Eco-innovation is most often understood as innovation (that is, changes in technology, organizational structure, and management of the company which is designed to eliminate or at least reduce the negative impact of business on the environment (Witkowski, 2008).

Cite this Article as: Małgorzata RUTKOWSKA and Jolanta PAKULSKA "Green Early-Stage Investments in the EU Member States" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Eco-innovation refers to all forms of innovation – technological and non-technological – that create business opportunities and benefit the environment by preventing or reducing their impact, or by optimizing the use of resources. Eco-innovation is closely linked to the way we use our natural resources, how we produce and consume, and also to the concepts of eco-efficiency and eco-industries. It encourages a shift among manufacturing firms from "end-of-pipe" solutions to "closed-loop" approaches that minimize material and energy flows by changing products and production methods – bringing a competitive advantage across many businesses and sectors [http://ec.europa.eu/environment/pubs/pdf/factsheets /eco-innovation/en.pd, access: 11.11.2018].

Pro-ecological innovation (eco-innovation) is also any innovation, implemented following applicable law, which brings benefits for the natural environment - in particular in the form of minimizing the consumption of natural resources per unit of manufactured product and minimizing the release of hazardous substances into the environment during the production of the product and its use and afterward. Use (Reid A., Miedziński M., 2008).

This article assumes that eco-innovation is "Eco-innovation is any form of innovation aiming at significant and demonstrable progress towards the goal of sustainable development, through reducing impacts on the environment or achieving a more efficient and responsible use of natural resources, including energy" (European Commission, 2007).

Eco-innovation in the EU Member States

The researches on the eco-innovation level in the EU Member States is provided since 2010. The data is collected by the Eco-Innovation Observatory, which is an EU initiative focused on the research of eco-innovations in the European Union. The results of this research are a yearly ranking called the Eco-Innovation Scoreboard (Eco -IS) (Szpor, Śniegocki, 2012).

The Eco-IS is the synthetic index, consisted of the 16 indicators divided into five groups (Eco-innovation inputs, Eco-innovation activities, Eco-innovation outputs, Resource efficiency outcomes, Socio-economic outcomes) [1]. In our analysis, we are interested in the first group (Eco-innovation inputs). The index for this area is calculated based on three indicators: government investments in environmental and energy R&D, green early-stage investments, and total R&D personnel. We analyzed the last indicator and we study the relationship between this one and Eco-innovation inputs and between this one and the Eco-IS.

Thanks to this shape of the index, various aspects of eco-innovation can be presented. The index is important information for each country about an eco-innovation level (Kobryń, Prystrom, 2017). The Eco-IS showed us how the level of eco-innovation distinct from the average for the EU Member Stated because this average is always 100 [2].

Earlier research by one of the authors showed that the level of eco-innovation in the European Union member states is very diverse. This diversification is reduced; it is difficult to say whether it will be a constant tendency. The Eco-IS indicator for individual countries ranged from around 40 to almost 190 (see Figure 1).

In 2018 the most eco-innovative country was Luxembourg, Germany, Sweden, and Finland. These countries have a value of the index is above 120 and are counted among the eco-innovation leaders. On the other hand, there were Hungary, Slovakia, Romania, Malta, Poland, Bulgaria, and Cyprus, whose index is 80 and belong to the countries catching up on the eco-innovation group. In the middle, there is the largest group of countries included in the group of advocates of eco-innovation where the index value ranges from 81 to 119. Over the years, the group of eco-innovation leaders has remained more or less constant. A slight shift is generally recorded with an indicator of around 120. Similarly, the situation is in the other groups. However, some countries have shifted significantly in ranking over the years.

Eco-innovation Inputs

Eco-innovation inputs are one of the five areas included in the Eco-IS construction. It includes investments (financial and human) to trigger eco-innovation activities. Eco-innovation inputs comprise investments (financial resources, human resources, technical resources) that provide an initiative for eco-innovation activities at companies, research organizations, and other institutions. Thus, eco-innovation investments are an important determinant of eco-innovation performance at the level of companies, sectors, and countries. This indicator contains (Giljum, Lieber, Doranova):

1. Governments environmental and energy R&D appropriations and outlays (% of GDP).
2. Total R&D personnel and researchers (% of total employment).
3. The total value of green early-stage investments (USD/capita).

Table 1: Indicator group: Eco-innovation inputs

Name of the indicator	Short description	Unit of measurement
Governments environmental and energy R&D appropriations and outlays	The relative priority is given by governments to invest in research and development in the areas of energy, including renewables, and the environment	Percentage (of GDP)
Total R&D personnel and researchers	Indicator of the knowledge and research capabilities of a country. Since the data for R&D personnel involved in eco-innovation or environmental or cleantech research is not available, the generic indicator is used	Percentage (of total employment)
The total value of green early-stage investments	The value of early-stage investments in cleantech industries	USD/capita

The eco-innovation rate in the EU Member States is characterized by very large variations (from 0 to 287). In most cases, countries take similar positions in terms of both indicators. Although there are large discrepancies in some cases. The biggest difference was in the case of Estonia, which ranked 21 in terms of Eco-IS overall, while 8 in terms of Eco-innovation inputs. A much smaller difference was recorded for Greece (positions 19 and 9), Luxembourg (positions 1 and 11), and Italy (positions 8 and 17).

Table 2: Comparison of country positions in 2018 according to Eco-IS and Eco-innovation inputs

The EU Member States	The position of the country in terms of Eco-IS overall	Country position in terms of Eco-innovation inputs
Austria	5	10
Belgium	18	13
Bulgaria	27	26
Croatia	17	23
Cyprus	28	28
Czech Republic	13	14
Denmark	6	2
Estonia	21	8
Finland	4	4
France	7	3
Germany	2	1
Greece	19	9
Hungary	22	19
Ireland	14	15
Italy	8	17
Latvia	20	22
Lithuania	16	20
Luxembourg	1	11
Malta	25	27
Netherlands	15	12
Poland	26	21
Portugal	12	18
Romania	24	25
Slovakia	23	24
Slovenia	10	6
Spain	11	16
Sweden	3	5
United Kingdom	9	7

The total value of green early-stage investments

The total value of green early-stage investment is the indicator that shows the value of early-stage investments in cleantech industries. The total value of a green early-stage investment is very diversified in EU countries (from 1 to almost 400). In many countries (especially in the initial years of the research period) there is no data on the subject under study. At all times, Finland, Ireland, Sweden, United Kingdom, Germany are at the forefront. At the other end of the ranking, Poland, the Czech Republic, and Greece are permanently present. Similarly, as in the case of Eco-IS overall and Eco-innovation inputs, countries rank in the ranking. Fig. 3 shows clearly how large discrepancies are found in this indicator and indicates how much more do the countries at the bottom of the rankings have to do in this respect.

The positional statistical measures were used to present the degree of differentiation of the total value of a green early-stage investment. In this case, we can see that a value deviates significantly from the others we cannot use classic measures because it can create problems of interpretation. Therefore, we used positional measures, to determine which we take into account not all but the selected values. The analysis was based on range and quadrant deviation, which suits the best for this analysis (Pułaska-Turyna, 2011).

The range from the sample is a measure showing the difference between the smallest and the highest value of the indicator being examined. The higher this indicator, the less evenly distributed the level of ecological innovations, and the greater is the dispersion of the values of individual countries' indicators around the average level of eco-innovation. The smallest difference is noted certainly when the range is 0, which in practice does not occur. In the case of the European Union Member States for the total value of the green early-stage investment, it can be concluded that the range is very huge. The highest range was calculated for 2010- 2012 (371), but in 2013 this indicator has decreased, but in the next year the range has risen significantly again. In 2014-2016 this indicator has decreased significantly, but in 2017 – 2018 has risen significantly again.

An indicator that can tell us a bit more is the quadrant deviation which is equal to half the interquartile range and measures the diversity of only a part of units after the rejection of 25% of units with the smallest values and 25% of units with the highest values. Therefore, we receive information on the diversification of the level of eco-innovation, in 50% of the EU Member States at the level closest to the median. The level of diversification is smaller than all EU Member States. In this case, the decline in the diversification has been observed already since 2015, and the trend has not changed in 2017, but in 2018 has risen significantly again.

The total value of green early-stage investments (per capita) versus Eco-IS inputs and Eco IS-overall

The Pearson correlation coefficient was used to investigate the relationship between the total value of green early-stage investments and Eco-IS inputs as well as between the total value of green early-stage investments Eco-IS overall. Aside from 2014, there is less correlation between the total value of green early-stage investments and Eco-IS overall than between the total value of green early-stage investments and Eco-IS inputs. In 2014, this correlation is almost the same. In 2018 correlation between the total value of green early-stage investments and Eco-IS inputs is smaller than in prior years, and the correlation between the total value of green early-stage investments Eco-IS overall is much smaller.

The correlation between the total value of green early-stage investments and Eco-IS overall in 2010-2015 is quite strong, as it remains at 0.75-0.84, in recent years the relationship has weakened and reached values below 0.7, which should be interpreted as a moderate relationship. In contrast to the above, the correlation between the total value of green and the Eco-IS inputs is constantly at a fairly strong level (0.82 - 0.88). This means that with the growth of the total value of the green early-stage investment, both Eco-IS overall and Eco-IS inputs should analogically grow.

Fig. 5: Pearson correlation between the total value of green early-stage investments and Eco-IS inputs and Eco-IS overall

Source: *own calculations based on Ranking Innovation Union Scoreboard, https://ec.europa.eu/environment/ecoap/indicators/index_en (access: 20.2.2020).*

Conclusions

Based on the above analysis, the following conclusions were adopted:

1. The eco-innovation rate in the EU Member States is characterized by very large variations and the total value of the green early-stage investment is very diversified in EU countries.
2. Most often there is a smaller relationship between Eco-SI and the total value of greenery.

The limitation of this paper is the scale of the eco-innovations which is related to the wealth of each member state but was not indicated in the paper. Although there is a group of well-developed countries, which are leaders in expenditures on eco-investments and eco-innovations, they are also leaders in the transformation towards a green economy. Further research directions for this paper can cover a more detailed area of the economy - the Environmental Goods and Services Sector and can be focused on the direct relations between indicators of eco-development and innovations. Such direction of future research can provoke more managerial implications and recommendations for the policymakers.

Motivation of Employment Personnel in the Public Services Sector

Charbel EL AMMAR

PhD Candidate, Bucharest University of Economic Studies, Romania
charbel.alammar@gmail.com

Abstract

Motivation at work remains a key concern for any organization, whether public or private. Its presence among employees is likely to increase the performance of the organization, while its absence leads to the opposite. Motivation stimulates effort and the adaptation of effective behaviors to individuals at work. One of the first tasks of any manager is to motivate his employees to provide as much effort as possible, thus motivating all employees in the chain. Employee motivation is a process of stimulation of them by the organization through the management factors for fulfilling the tasks that come from the job description at a level of performance meant to lead to the achievement of the organization's mission. In this context, the article aims to conduct an empirical theoretical research on motivation of personnel in the public organizations. Thus, it conducts an in-depth analysis on main theories related to human resources motivation and presents the concept and dimensions of work motivation in the public services sector.

Keywords: employee motivation, human resources, public organizations, work attitude.

Introduction

The process of training human resources revolves around motivation. This is the psychological factor that determines the activation of performance and efficiency. Motivation in human resources means motivating people in their work. It does not mean, first of all, to reward her money, but to improve the mental/social representations regarding the work, the organization in which it takes place and the products obtained through the respective activity. An individual's motivation for work means the certainty that he will obtain, by performing work under established conditions, elements that will satisfy his own needs. The value system is involved in the motivation, which gives a precise meaning to the consequences of the employees' behavior and influences the degree of individual freedom to adhere to certain values.

In the organizational context, motivation is a conditioned factor of the performance of each component of the organization, the spring that pushes it to act in a certain way, its internal state, which animates and determines its behavior, and motivation is the process by which managers it determines the subordinates to achieve the best possible performances, giving them grounds to act in this respect.

The existence of an efficient and democratic administrative structure is one of the most important criteria that define the modernity of a country. The functioning of a modern, flexible and efficient public administration is an essential condition for the structural transformation of the Romanian society, for the achievement of a profound reform in all fields of socio-economic life, for the increase of the citizen's role in decision making. The public administration must be able to face the challenges it has to face, which is not possible without the help of an honest and well-trained professional apparatus. The very quality of public services depends on the quality of the employed staff's activity. The employed personnel have a special significance, because their activity is nothing but the ensemble of the activities carried out in order to carry out the public services, and in the last instance of the general interest. But in order to carry out quality activities, employees must be motivated. They must satisfy certain needs through the activity they carry out within an organization or within the institution where they work.

Literature Review

Research in psychology and management in recent decades converges towards consensus supporting the idea that motivation at work results from the interaction of the individual and his environment, according to Lewin's behavioral equation that the behavior of the individual is a function of two variables: his personality (P) and its environment (E). (Bakari et al., 2017) Therefore, motivation is above all an individual phenomenon, each individual is unique thus having different needs, expectations, values, history, attitudes and objectives. (Stepanova et al., 2018) Being an internal process that only the individual can control, motivation is a challenge for managers, they can influence it, for the benefit of the organization, creating a work environment that supports and inspires employees a high level of motivation. The motivation is therefore intrinsic land. (Deci & Ryan, 2010) But external forces bring to trigger the behavior, to orient it, to invigorate it, to maintain it in order to achieve the expected objectives. In public administration, human resources are a particularly important issue, as even the best administrative laws cannot give the expected results if those who apply them, civil servants, do not have adequate training.

Approaches to understanding and explaining motivation are different because many theorists have developed their own opinions and theories about motivation. They approached motivation starting from different points of view, from ideas determined by the socio-economic and political conditions existing at that time. None of the approaches can be considered the most correct and comprehensive. Each contributes to the understanding of human behavior and has its limits. The study of the epistemology of the theories of the organization highlights numerous theories on motivation. Many of these theories can be divided into two broad categories, each with a number of other concepts:

1) **Process theories of motivation focused on explanations of motivation** that emphasize how people are motivated. There are four important theories that describe how and when a person goes through the motivation process:

- Needs - objectives theory of motivation: Theoretically, motivation is triggered by a need that must be transformed, through a series of stimuli, into a behavior aimed at supporting, or accepting, another behavior that aims to meet the goal of satisfying the need.
- Vroom's theory of expectation: This theory is also based on the premise that needs give rise to human behavior. However, Vroom's theory introduces in the motivation process the problem of the force that it has, respectively the desire that a person has to follow a certain behavior (Parijat, & Bagga, 2014).
- Equity theory: J. Stacy Adams, the founder of this theory, found that when employees feel that they have been treated unfairly compared to their colleagues, they will act in a certain way, changing their behavior (Adams, 2005).
- Porter-Lawler's theory of motivation: Describing more fully the motivation process than other theories, Porter and Lawler believe that needs give rise to human behaviors and that the effort to accomplish a task is mainly influenced by the perceived value of the results (Khan, 1993). embracing the behavior and the perceived probability that the behavior will give rise to these results.

2) **Content theories of motivation: human needs.** There are explanations of motivation that emphasize people's inner traits. They focus on knowing people's needs and how these needs can be met. To this end, a series of theories have been devised to help managers better understand these needs:

- Maslow's hierarchy of needs. Maslow's concept of the hierarchy of needs argues that human beings have five basic needs, ranked according to their importance and the order in which people generally strive to meet them: physiological needs, security or safety needs, social needs, needs for consideration and needs for self-improvement.
- Alderfer's theory. Responding to a series of criticisms of Maslow's theory, Alderfer explains human needs and divides them into three basic categories: necessities of existence, needs of association, and needs of development.
- Argyris' theory of the maturity-immaturity spectrum. Also providing information about human needs, this concept focuses on the personal and natural evolution of people to explain human needs. Thus, as people mature, they show increasing needs for sustained activity, have deeper interests, are able to adopt a long-term perspective, are more self-aware, and have better control over their own destiny.
- McClelland's theory of acquired needs. It is a theory that explains human needs and focuses on the desire for achievements, power and association that people manifest as a result of the experiences they live in life. This theory focuses on three of the many needs that arise throughout life: needs for achievement (the desire to do something better or more efficiently), needs for power (to control, influence, or be responsible for others), and association needs (desire to maintain close, friendly personal relationships).

From a management perspective, motivation is one of the four interdependent activities of the influencing function - leadership, motivation, communication and consideration of groups - which are performed by managers to guide the behavior of members of the organization to achieve its objectives.

Work Motivation in the Public Services Sector: Concept and Dimensions

One of the important questions raised by public management is whether individuals behave differently when working for the public or private sector. If it is accepted that a person's behavior depends on his individual characteristics and his environment, then it is a question of knowing, on the one hand, whether the motives, values and needs of civil servants are different from those of employees in the sector. private, and on the other hand, if the environment of public organizations provides a solid institutional framework similar to that of private organizations in order to motivate their employees and therefore to trigger the best performance (Brewer & Brewer Jr., 2011).

Traditional theories of motivation at work have provided important theoretical tools, so-called determinants, most of which are based on neoclassical assumptions that the individual, being rational, systematically seeks to maximize his personal benefits. Following the neoclassical paradigm, rational choice theories or public choice argue that the behavior of individuals at work, both in the bureaucratic system (public) and in the market system (private), is transformed by maximizing their own interest, because individuals are selfish and tend to behave like stowaways (Weibel et al., 2010). These are stereotypes that implicitly suggest that public and private sector employees are identical; they respond directly to the incentives offered to them, as well as to the opportunities and constraints of the organizations in which they work.

This stereotypical view of public organizations has been criticized and rejected by many authors in public management (Hondeghem & Vandenabeele, 2005; Perry et al., 2010; Brewer & Brewer Jr., 2011, etc.). while it is true that public or private employees may respond to incentives that are offered to them, however, depending on the values that predispose an individual to work in a sector, an incentive may be the basis for motivated behavior in a given sector, and not in another sector. For example, private agents can be animated mainly by utilitarian incentives, while civil servants are animated by normative and emotional incentives.
