Unlike private organizations that seek to maximize their profit and therefore their own interests, public organizations aim to defend the general interest, to ensure collective well-being. It is therefore normal for public officials to be particularly motivated by community or collective motives. The collective interest must take precedence over the personal interest, although the latter always exists in any official, as is the case with all individuals. As a consequence, theories based on self-interest could not provide reasons to analyze the motivation of employees, in particular public sector employees. (Moynihan & Pandey, 2007)

Scientific papers suggest that work motivation of public sector employees is very different from that of private sector employees (Ciobanu et al., 2019, Cornean, 2020). Research on motivation in the public sector has shown that it results from the interaction between the individual characteristics of the employee and the organizational environment. These two broad categories of behavioral determinants are used as a tool in identifying and understanding the motivating factors of work in public services. Studies show that the individual characteristics of public sector employees and their work environment are different from those of the private sector. (Brewer & Selden, 1998) Therefore, certain sources of motivation of public servants seem to be different from those of private sector employees. From the two categories of determinants of work motivation, **four variables can be retained: employee motivations; work context; job characteristics; attitude towards work.**

These four variables of individual characteristics and organizational environment will be further analyzed in terms of involvement in the motivation of work in the two sectors - public and private - to highlight the differences between them:

a). Employee motivations.

They derive from the individual characteristics of the employees. Research has shown that civil servants' motives are more oriented towards the ethics of good consumption, the spirit of sacrifice and altruism that converge with the state's mission focused on satisfying the general interest and ensuring collective well-being, while the motives of private sector employees are to maximize their own utilities, thus attaching greater importance to financial rewards (Crewson, 1997), which is in line with the goal of private organizations, which is to maximize their profit.

Studies have shown that public sector employees are more motivated by a sense of usefulness to users and the support of their neighbor, a willingness to serve the state and contribute to the defense of the collective interest or

through intrinsic rewards (Perry & Wise, 1990). Unlike their private sector counterparts, public officials they seem to be little motivated by extrinsic monetary rewards.

In support of this assertion, we recall the empirical work of Buelens and Van den Broeck on 3,314 private sector employees and 409 public servants in Belgium (Buelens & Van den Broeck, 2007). In the same vein, Houston's work indicates that civil servants place greater value on intrinsic incentives that provide a sense of self-fulfillment, while private sector employees attach more value to extrinsic elements, such as a high level of income (Houston, 2000).

Other research has shown that public sector employees attach more importance to higher needs (needs for fulfillment, autonomy, self-actualization and development) than their private sector counterparts. Public sector employees are more motivated by content jobs, recognition, interesting work and the opportunity to learn new things. (Jurkiewicz et al., 1998)

It can be noted, as a conclusion of this research, that individuals with a pro-social behavior, wanting to put themselves in the service of the public interest, to support the disadvantaged, to contribute to the well-being of others, are much more likely to integrate into public organizations, while individuals who are motivated primarily by the care of defending their own interest, of maximizing their own utility, are more inclined to integrate into private organizations. Therefore, studies have shown that individuals who place great importance on money seek to integrate into the private system in which they are confident that they will be better paid than in the public sector. In other words, the assertion that people tend to choose organizations that are compatible with their own values or motives and in which they can meet their needs is learned.

b). The work context.

It refers to the characteristics of the organizational environment in which people work. According to Perry and Porter (1982), the work context is limited to issues that are found in both the immediate and the extended environment of the employee. The immediate environment refers to the interpersonal relationships of the employee with colleagues and the hierarchical superior, as well as to the work environment that these relationships create as a friendly atmosphere and the conditions of physical work environment (conditions of sound, thermal, visual, atmospheric hygiene and general condition of the work space, office location, cleanliness, comfort). The extended environment includes elements of job security and stability, the reward system, goal setting, formalization, fairness and procedural justice (the way agents are treated and the way organizational rules are administered).

The work context of public organizations is often perceived as fundamentally different from that of private organizations, due to the fact that their missions and functions are different. Thus, the public sector has the task of fulfilling social missions, promoting collective well-being, protecting the population and providing society with public goods and services that, due to the externalities that cause them, cannot be easily provided on the market. (Wright, 2007)

Instead, private organizations aim to maximize their profits and, by rebound, must be productive and competitive (Dobrin et al., 2015). A number of researches have pointed out that there are more ambiguous objectives in public sector organizations than in private enterprises, making it difficult to mobilize civil servants by providing accurate information on objectives and achievable organizational performance, organizational commitment, as well as reducing the motivation of public officials.

The hierarchical level is also considered as one of the major determinants of the differentiation of motivation in the two sectors. The organizational structure of public organizations is considered to be heavier than that of private organizations. Thus, public organizations have the highest level of formalization, scriptology and centralization (Buelens & Van den Broeck, 2007).

However, civil servants are likely to be motivated to achieve their performance goals because they place more importance on their job, due to the fact that they work for the state, which provides very important public services to society. As a consequence, they are likely to consider the provision of such services to the community as a personal duty. The works of Jurkiewicz and Brown (1998) pointed out that civil servants are more motivated by job security and stability compared to private sector employees, who are much more interested in high incomes.

c). Job characteristics

The activities required by a person's job in an organization are usually summarized in a formal description in the job description - an organizational document that lists the activities to be performed by the person in the job and is also

specified responsibilities and limits of competence. An unclear job description can be confusing to employees and cause them to lose interest in the job. When properly designed, job descriptions communicate to employees what the job is, set performance levels that employees must maintain, and act as a guide that they must follow to help the organization meet its goals (Girneata et al., 2015). Therefore, posts must have certain characteristics capable of creating the conditions that give rise to greater motivation. The most motivated employees work better. This evidence has led various researchers to highlight the motivating factors.

This theory of job characteristics describes the conditions that a certain job must offer to arouse the interest and motivation of the employee. From this point of view, motivation is born from the balance between three psychological dimensions: work must be capitalized; the person must feel responsible for his results; the person must be constantly informed of his results. According to Hackman and Oldham, the more the three dimensions are satisfied, the less the employee will be absent and will have the desire to leave the company, in addition he will be motivated and efficient.

Some studies suggest that civil servants are more likely to feel that their tasks are important and challenging, because public organizations provide employees with the opportunity to address important social issues (Perry et al., 2010). Indeed, public sector employees may be motivated because they have the feeling that the tasks they perform have a considerable impact on improving the living conditions of society, especially the most disadvantaged people, or contribute to ensuring a certain degree of social equity.

In addition, given the multiple functions of the state and given that public bodies often have more influential missions and a greater impact on society than private enterprises, public posts can be challenging and require a variety of skills. And if the mission of the organization is important and in harmony with their own values, the tasks entrusted to them will also be perceived as important.

However, a number of researches have shown that civil servants think that the private sector has a better chance of providing interesting jobs (Buelens & Van den Broeck, 2007). The public sector would, in principle, is characterized by administrative posts that are likely to have more routine activities, while the private sector, through productive posts and those related to the marketing and sales function, involves several challenges.

Other research has not found differences in the characteristics of public and private sector jobs. Thus, for example, the results of the research undertaken by Rainey and Bozeman (2000) reveal that civil servants face the same level of difficulty in some tasks as their counterparts in private enterprises.

Also, in both the public and private sectors, routine tasks with non-precise objectives have a negative effect on motivation, while specific and clear tasks reinforce it. Perry and Wise (1990) suggest that civil servants feel that their tasks are more important and contain more challenges than private sector employees. This feeling results from the perception that they work for organizations that have more functions and provide public services that are very important for the population.

However, these characteristics of the public sector position (variety of skills, importance of the task) that favor motivation sometimes seem to be in contradiction with the work context that is not always favorable (such as through multiple, ambiguous and contradictory objectives, procedural constraints, centralization thus reducing the level of autonomy and identity of tasks in the public sector).

In conclusion, it appears that the differences in job characteristics between the public and private sectors exist mainly due to differences in the employment context of each sector and the importance of tasks (public sector tasks generally have a considerable impact on the functioning of the company).

d). Attitude towards work.

It is one of the variables on which researchers rely to determine whether civil servants behave differently from private sector colleges. The differences found in the motivation of public and private sector employees, as well as in their work context, translate into the adoption of different attitudes and behaviors at work.

In general, job satisfaction analyzed as the main attitude towards work results from the congruence between employees 'expectations from their job (employees' reasons) and what they receive (work environment). Thus, numerous sources of job satisfaction are: salary, promotions, job security, supervision, work group characteristics, participation, organizational structure and organizational climate. In the literature, the comparison of the two sectors - public and private - is at the center of contradictory debates.

Most of the work on attitudes towards work identified a low level of satisfaction with public officials, argued by the cumbersome organizational structure of public organizations, procedural constraints, ambiguous and sometimes contradictory objectives that hinder the factors that could contribute to job satisfaction. civil servants (such as the opportunity to perform altruistic tasks, to contribute to collective well-being. It should be emphasized, however, that studies that found civil servants to have a lower level of job satisfaction used to measure job satisfaction. In general, specific factors of work, such as: promotion perspective, salary level, autonomy in work, however, these facets of work seem to be frustrating in the public sector, especially due to the lack of autonomy in work generated by procedural constraints and political interventions. papers with the same research topic found contrary results, respectively, showed that civil servants are generally more satisfied with their job (DeSantis & Durst, 1996).

Although empirical studies have provided varying results regarding the difference in job satisfaction of civil servants and private agents, they do not suggest a large gap between the two sectors. Related to this aspect, there is the impact of another concept, namely "employment" which is, along with satisfaction, an important attitude in determining the behavior of individuals at work (Ritz, 2009). Numerous empirical researches on the comparison of organizational employment between civil servants and private sector employees has found contradictory results, depending on the context of the economic, social and cultural environment of the organizations included in the samples of research undertaken.

A number of studies have highlighted, through a comparative analysis, that the level of organizational employment of private sector employees is higher than the level of employment of its public sector counterparts. Some research papers have found, among other things, that the employment of public managers is positively related to continuous employment, respectively their desire to remain in the organization, but does not necessarily translate into the decision to make considerable efforts for the benefit of organization (Balfour & Wechsler, 1991).

Other empirical research has led to results according to which civil servants are much more engaged in their work than their private sector counterparts. Such a level of commitment may be due to the fact that civil servants do not have rational reasons as the only source of motivation, but normative and affective reasons. These studies have shown that civil servants are employed in their organization especially under the impact of motivating factors towards work in the public sector.

Conclusions

Knowing the reasons that generated the behavioral actions of employees gives meaning to the managerial activities within any organization. Knowing these reasons can be the generators of increasing the efficiency of actions and can contribute to the prediction and understanding of human behavior, as well as to decipher its moral value. In organizational theory, and later in human resource management, motivation has been related to operational effectiveness in the work of individuals, often being linked to an instrumental logic. Currently, there is a change of perspective: professional success is due to motivation and not just skills proven by the individual.

The motivating factors that could lead to the increase of the subjective value of work, taking into account the particularities of different situations and people, are non-pecuniary factors. Among these can be mentioned: appreciating the success of employees, setting goals that lead to competition, permanent information on the financial situation, informing the stage of achieving objectives, encouraging personal initiative, imprinting a climate of autonomy, freedom, creativity, care for the professional future, acquisition of intelligence.

Motivational theories emphasize either that staff have different needs that must be met and depending on their satisfaction they will be more or less motivated to work hard to achieve goals, or that motivation occurs in the work process, which leads to the conclusion that the work must be designed in such a way as to be as attractive and motivating as possible for the person submitting it. Thus, the public management has an important role, namely to identify the system of needs for each team or for each civil servant, in order to use the most appropriate ways to motivate. Among the ways that can be used in the motivation process can be mentioned: salary as a means of motivation, position as a means of motivation, objectives as a motivating factor, alternative work programs and total quality management.

Abstract

The purpose and the objective of this paper are to examine the essence of the social responsibility concept by way of an example of a respected Serbian company doing business in the insurance industry, with a special focus on the opinions and attitudes of Generation Z. The objective of this paper is to examine the availability of information concerning CSR activities in the local community, as well as the broader one, with a special emphasis on its development, as well as aid in the spheres of culture, science, and education, sports and assistance for the socially disadvantaged. This objective is to be achieved using quantitative research and individual interviews. The road to a proper strategic direction is paved by linking company work with responsible business and adequately communicating with target audiences. This paper underlines the significance of informing the target population factually and in a timely manner, resulting in comprehensive and transparent information about the CSR activities undertaken in the insurance industry.

Keywords: Socially Responsible Business, Organisational Support, Business Competitiveness, Generation Z, Insurance Industry

Introduction

In companies with a modern approach to CSR activities, it is believed that young members of Generation Z should participate in many activities and initiatives, especially those that require digitalisation and complete robotisation of the business process. One of the suggestions being made is the so-called responsible organisation and turquoise management model, which is increasingly being seen as a response to the views of the younger generation (Sobotka, 2019).

Within 'today's modern framework, the so-called responsible and self-aware companies' model is based upon self-aware people employed by the company itself. They are the ones who create their own work environment rather than being mere observers (Ohme, 2018). The development of such a direction is based upon increased care and readiness to act. This type of company is characterised by a low tolerance to every possible aspect of dysfunction in business.

The turquoise management model is based upon three core foundations: self-organisation, integrity and evolution. The self-organisation is formed as a type of negation of the hierarchical model of management where it is given to each employee to manage, whereby each employee takes responsibility equally, as all is based on mutual trust. Integrity presupposes the abolition of boundaries between the 'employees' professional and personal lives, which is believed to achieve the best possible business results, as no form of employee imperfection is covered up. Finally, evolution views the company as a living organism moving in a certain direction. Regardless of the long-term business goals, a company primarily depends on the signals received by its immediate environment and the actions of the company team (Laloux, 2018). Younger generations, among others, the Z one, would fit perfectly within the above-

mentioned company business models, as they strive for self-fulfilment in a way requiring internal motivation for all CSR activities in the company, as well as active business creation.

Companies that achieve good financial results allocate significant funds and resources to CSR activities in order to improve relations with employees, care for the environment and, generally, when it comes to relations with the immediate and wider community. In the long term, the means allocated can become a significant strategic advantage in achieving a more efficient corporate image and improving relations with shareholders, as well as improving opportunities to attract new employees (Manokaran et al., 2018). Interestingly, the author Friedman (2017) believes that the management of any company only has a single obligation, and that is to maximise the profits of owners and shareholders, and that social issues should be voluntary actions of free-market systems, rather than business issues. According to one study (Lim & Greenwood, 2017), CSR communication developed from one-way to two-way (correlative). In this way, companies and their brands have been allowed to increase the commitment of shareholders to caring for consumer motives and needs. If consumers identify the basic motive of companies as providing services to others, they can develop positive feelings and attitudes to CSR projects undertaken by those companies (Peloza, Ye & Montford, 2015).

It is believed that the increased popularity of CSR activities within the insurance industry is related to the intention of insurance companies to strengthen their business image within their long-term business engagement (Okhrimenko & Hranchenko, 2018). CSR is a modern tool intended to improve the sustainable economy as well as a resultant CSR philosophy of the leading industries of every economy with the aim to provide innovative know-how techniques and practices that lead to economic development (Popovic-Sevic & Bajalski, 2019).

Experts believe that the share of the insurance industry in the GDP sphere may increase to a significant 7% by 2020, with such a share being associated with an increase in net premiums as well as a remarkable increase in the number of companies offering insurance services (Trynchuk et al., 2019). Interestingly, the increased numerical presence in the insurance industry (Sulkowska & Cycon, 2017) does not directly contribute to increasing awareness and insurance culture among insurance users, with most of them viewing CSR activities in the insurance industry exclusively as a trend (Khoma et al., 2018). Unfortunately, this is evidenced by a lack of financial investment in CSR activities of the insurance industry for a long period of time (Makarenko et al., 2018).

When it comes to insurance companies, all three target groups – employees, clients, and potential investors are important for determining CSR activities. In this sense, it is considered that the greater the trust in the insurance company, the more impact it will have on the market value of that company (Szczepanski & Switalska, 2018). This consequently means that CSR activities in insurance are not just a trend, but rather a necessity for insurance companies.

In summary, it is of special importance to identify the impact of CSR communications on Generation Z, as not only are they the second most numerous demographic, but their purchasing power has been said to be the greatest (Fromm, 2018). The main goal of this research is to examine the impact of CSR communications on Generation Z consumers, their purchasing habits, as well as on special connections to brands in the insurance industry.

Generation Z

Modern technologies have caused the younger generations to be continuously exposed to, and under the influence of numerous sociological and technological challenges in their immediate environment, which has resulted in the acquisition of new skills and knowledge necessary for access to most information systems. Full automation of activities, the use of artificial intelligence systems and digitalisation have become omnipresent in all spheres of production and services processes, as well as in the everyday lives of consumers.

Gen Z is the first generation that has never experienced life before the Internet, and its members are defined as a kind of digital nomads (Akcayir et al., 2016). This means that this generation is the first in a series to which information technology is accessible from an early age, which has had revolutionary consequences on the lives of its members – ranging from various social interactions to mental health, as well as behaviour in their private and professional lives (Carbonell et al., 2018). This has the further consequence that Generation Z cannot be technologically dependant, for the simple reason that information technologies have been an integral part of their lives from their very beginning.

Generation Z is also called by other names, such as“postmillennials“", “ the digital generation“, “dotcom generation”, “e-generation”, “switchers”, etc. It is also known as Generation C. The members of this generation are also better versed in the use of various information gadgets. Instead of traditional toys, they prefer the use of electronic gadgets, cosmetics and branded clothes as children (Peszko, 2018). They are a kind of digital immigrants, communicating in a digital language in almost all spheres of their activities. They spend a lot of time in front of the screen (computer, laptop and mobile phone), mostly using chats and various forms of social networks as a means of communication. They prefer the content found on the Internet, spending much time surfing it and watching YouTube videos. They are proponents of the digital way of learning, preferring to use short educational videos and short online workshops (Tick,

2018). The use of computers has become a part of their daily lives, even while at home. Television is completely obsolete to them, replaced by the world of the Internet.

Generation Z is thought to have $29-$143 billion in consumer purchasing power, and its members even control about 93% of the purchasing decisions of their families. Also, they are recognised as the most diverse generation by ethnicity and sexual choices, and is therefore considered to be fairly free-spirited (Grace & Seemiller, 2016).

Compared to previous generations, Generation Z has different conceptions on the topic of relationships, communication and mutual activities. Why is it so important to differentiate between various generations of consumers? Simply put, it is because all generations are intertwined, connected in everyday life through living and working together, communicating with each other. Finally, there are differences in the motivational wheel as the initiator of the communication process, when making important life decisions, but also when it comes to different types of purchases, differences that are obvious in the behaviour of consumers of different age groups (Csobanka, 2016). It is believed that members of each generations are interconnected primarily owing to shared experiences, mainly through customs, various cultural events, economics and politics, popular culture… All experiences in regular and emergency situations make them a unique group, not by age, but in a sociological sense.

It is believed that the development and application of modern technologies will affect many sociological and economic changes and open numerous ethical problems in the future for the following reasons (Mesko et al., 2017): (i) they will occupy all areas of human existence and functioning, allowing access to even the most sensitive personal information of technology users; (ii) robots will most likely replace humans in areas where they were not present until recently (such as activities that require much more mental and creative work). Looking at Generation Z, predominantly users of modern technologies, it is able to offer the following:

- Expeditious feedback with the aim of communicating with other parties – modern technologies provide the ability to see and talk online, along with other global forms of communication;
- Complete independence in terms of access, work and further provision of information – they provide space and 24-hour independent communication in all areas of life and work.
- Increasing the effectiveness of work on online platforms – technical devices will replace humans in many activities, which will automatically mean less work for people;
- Enables further development and expansion of online education – in addition to online studies, the Internet is an excellent platform for independent learning and upgrading specific skills and knowledge.

What else defines and characterises Generation Z? They are highly intelligent, but it is noticeable that this does not transfer to emotional intelligence. They are more inclined to diverse activities compared to previous generations. Despite the fact that they are generally able to perform several activities simultaneously, their concentration drops over time, so long-term memory is a problem. They may live a happy life, but their values are derogated. Their present is completely virtual and strictly controlled – if they are not online, they almost do not exist! In that sense, there is an important paradox – a virtual presence on social networks means that they are not alone, but on the other hand, many members of Generation Z are very lonely.

One study found that this generation feels constant pressure from a variety of sources, be it poverty, school, unequal economic opportunities, war, etc., and that members of this cohort feel that they live extremely stressful lives (Global Millennial Viewpoints Survey, 2019). They are characterised by impatience and egocentrism; they love everything with an immediate nature and outcome (Yuliana, 2018). They start, but also complete many things later than the previous generations, beginning with separation from the immediate family, completion of formal education, finding and retaining a job, forming a marital union, expanding the secondary family, and so on (Bencsik et al., 2019).

Everything in the lives of the Generation Z is consumeristically “fast” – frequently changing partners, places of residence, workplaces and more. In this context, many describe them as an unstable generation living with constant fear, despite their flexibility. They are described as a generation with a heightened degree of depression, isolation and laziness. As a result, they seldom get attached, both to people and things. Another issue with Generation Z is the form of direct communication and acceptance of criticism and suggestion in the workplace, resulting in a reduced loyalty rate and often a lack of basic responsibility for undertaken activities (Ray & Singh, 2018).

Many resent Generation Z for their narcissism and their noticeable lack of empathy compared to previous generations. They do not have strong relations with their primary families, which was not the case with their predecessors. The opinion of their peers is more important to them, often excessively so. In that sense, media channels, as well as their representatives (celebrities and blogger) are the ones exercising a lot of influence on them. In an educational sense, they prefer independent learning styles where reading is cast down to a secondary position (with new reading strategies being present) and with physical activity playing a significant role. As a consequence, they are structured by images, with the text being of secondary importance, reading being done “between the lines”, thus being faster and more efficient. Thus, those belonging to Gen Z are further confirmed to receive text simultaneously – they can process a lot of information at the same time.

Those belonging to Generation Z like various media channels that combine writing, images and videos, all in order to be able to express themselves through them. For members of Generation Z, Facebook is long since obsolete, and almost all of them have left it and are instead widely found on Instagram, Line, Tik-Tok, Snapchat, YouTube, WhatsApp, Jott. They choose social networks that store content only 24 hours a day. To them, writing and sharing texts on social networks is almost unknown – instead, video, photo and audio content are shared.

All these characteristics are extremely important for companies that deal with CSR and want to share their values with their customers, including members of the Generation Z, in a certain manner. Consequently, companies will recognise the necessary method of adapting the news and content of a certain socially beneficial activity, in order to get the attention of these young people. With the rapid changes in IT technologies and communication with their customers, many companies will find it necessary to transform their appeal to their target audiences.

CSR Perception of Generation Z

In the era of high information technologies, young members of Generation Z are changing society, but society is transforming them as well, through a various set of socially responsible activities. The sociological environment is of great importance for members of Generation Z who prefer to work in a team. Since those belonging to this generation are quite confident in themselves, they want some kind of a secure future. They know that work is important in that sense, for the sake of achieving their life ambitions. If not realised, it can make them very unhappy. If they are in any way unhappy or dissatisfied at their workplace, they have no problems leaving it and very quickly starting business activities elsewhere. They are fiercely independent and intolerant of authority of any kind, and they do not have cut out or defined relations with any particular generational group that came before them.

In terms of consumption, Gen Zers want to be actively involved. One study found that as many as 48% of teenagers receive pocket money on a regular basis, which they proceed to spend according to their style and tastes (Olczyk, 2018). Despite the fact that Generation Z is not overly focused on advertisement messages, it cannot be said that they pay no attention to them at all.

According to one research, Generation Z prefers creative approaches to company strategies to regular ones (Stupinska, 2018). Namely, they are more oriented towards companies through which they are given the opportunity to influence the development of certain matters within the company (31% of Gen Zers versus 25% of Gen Yers). Young people value the ability to demonstrate originality and style with every socially beneficial CSR activity, with different opinions being maximally respected – that is definitely the way to gain the full support of Generation Z. The thing that Generation Z certainly has in common with the generation that preceded it is that they strive for education, but also for entrepreneurship. They are not afraid of challenges and are ready to face completely unpredictable situations and work-related tasks, as well as to try finding the best possible solutions in the shortest time frame possible.

Given the experiences of financial institutions, it is certain that the industry is facing intense competition. The financial and even insurance sector is continuously faced with the most diverse technological challenges, which are an important factor in the industry.

Numerous changes in the business environment are forcing financial institutions to innovate with their products, which is to say, their offers, in order to maintain a competitive advantage (Miletic et al., 2018).

It is indisputable that the younger generation would prefer to be informed about all CSR activities performed by a financial institution through a system of various social networks, as that medium is the one they are most receptive to (Dootson et al., 2016). In that sense, it is necessary to regularly update content posted on social networks, all the while increasing interaction with the youngest users.

Gen Zers correspond with institutions in a very analytical and pragmatic manner. Thus, companies communicating their CSR values should modify their communication with Generation Z in three ways (Francis & Hoefel, 2018):

- Access to activities through co-participation, rather than through possession of things or events.
- Clarification of CSR activities through the possibility of preserving the wholeness of each individual.
- Approach to all socially responsible activities through the ethical prism of business.

The thing that Generation Z finds most important when it comes to CSR activities is the accurate and faithful presentation, whether pertaining to the actions of a company or an individual. Insisting on authenticity, but also on preserving the freedom of communication, marks the tendency of the members of generation Z to freely express their opinions and attitudes, with the aim of better understanding others. By using the Internet, Generation Z wants to demonstrate its freedom, but also to express theiropposition to gender divisions, as everything to them. They have an interest in those companies in which state-of-the-art IT technology is at the forefront and where jobs are based on a multitude of projects. They also like to work at, and highly value companies where co-working is an option (Ozkan & Solmaz, 2015).

Companies should focus on some of the special characteristics of Generation Z, which is to say constant and ethical communication, as well as dialogue. This generation does not like confrontation and wishes to express its uniqueness in a pragmatic manner. That is why they are called "identity nomads." However, for the sake of some common interest, they are more than willing to mobilise their own resources and join the majority, which may have a different attitude from their own at a given moment (Francis & Hoefel, 2018). The same study showed that they are ready to boycott companies whose campaigns or any other activities are associated with racist, homophobic and unethical actions.

In accordance with the above, members of Generation Z expect open and clear communication from companies, and should they have certain inquiries or objections to their activities, they will demand their efficient resolution. They presuppose a dialogue with companies that is devoid of all stereotypes and desire pragmatism at all costs. This further means that, when communicating its CSR values, a company should clearly discern the ideas and values of Generation Z, and adapt its messages to its value system. This is especially challenging for large companies that face a number of ethical challenges in doing business, as there is a preconception that big brands are somehow less ethical compared to smaller ones. In that sense, it is of the utmost importance to communicate all activities with Generation Z, without exceptions. Communicating with members of Generation Z, along with everyday technological and other challenges, brings with it numerous new advantages of transforming communication that should be wisely marketed.

Methodology

The research was conducted in order to determine the attitudes of the respondents about their perception of the insurance company (hereinafter the Company) as socially responsible. The company is a leader in the insurance market in Serbia, with about 3,000 employees. It covers the entire insurance market, and its organisational structure consists of the General Directorate and the main insurance branches in 29 of Serbia's largest cities and more than 600 points of sale. The Company was founded 45 years ago, and since its establishment, in addition to its core business, it has invested significant funds in the development of the community, trying to reinforce its brand and the trust of its users and the citizens of Serbia.

In the 15/05 – 23/05 2018, extensive research was conducted with the aim of reviewing the attitudes and experiences of Serbian citizens in the insurance market, as well as the perception of the Company as socially responsible. The research covered different categories of the population according to gender, age, occupation, work status and income. All respondents live and work in the territory of the Republic of Serbia, excluding Kosovo and Metohija. In this paper, the authors will mainly focus on the views of the youngest respondents, most of whom belong to Generation Z (as part of the survey sample), but will not discard the rest of the sample.

The size of the research sample was 1054 respondents, of which 48.8% were male and 51.2% female. By age the sample was structured as follows: 18-29 years old - 18.3% of respondents; 30-44 years old – 24.7%; 45-59 years old – 27.0%; and 60+ 30.0% of respondents. The percentage of respondents who didn't go to school, have not finished primary school, or only finished primary school, as well as those who completed a two-three-year secondary school is 52.1%. Those who have finished a four-year high school, gymnasium and specialisation make up 31.0% of the respondents, and those with a completed university or college make up 16.9%. Of the 1054 respondents included in the survey, 260 belong to the youngest group of respondents, 18-29 years old, which includes Generation Z.

By employment status, 10.8% of respondents are employed in the public sector, 1.3% work in the social or mixed sector, 28.0% in the private sector, 22.4% are unemployed, 25.8% are pensioners and 1.1% are farmers. Pupils and students make up 6.2% of respondents, informally employed (undeclared labour) 2.2%, while a further 2.2% of respondents did not wish to answer the question pertaining to their employment status.

Those who have no income make up 26.0% of the respondents, while 6.9% of them earn up to 15,000 dinars. Those whose income amounts to 15.001 to 29,999 dinars comprise 29.1%, 30,000 to 49,999 16.2%, while those with incomes that are equal to or exceed 50,000 dinars make up 2.9% of respondents. There were also 18.9% of those who did not want to answer this question. By place of residence, 60.8% of respondents live in urban areas, while 39.2% of them belong to the rural population. Regionally, 21.3% live in the Belgrade Region, 28.1% in Vojvodina, 28.9% in Western Serbia and Sumadija, while 21.7% live in Eastern and Southern Serbia.

The method of data collection was PAPI, a quantitative research in the form of personal interviews where well-trained interviewers had a printed questionnaire from which they read the questions to the respondent and filled in the answer. The data entry software used was WARP IT, a professional licenced market research program with a wide range of options when setting up a project. SPSS was the software used for data analysis. In order to control the credibility of the answers and the obtained results, repeated interviews of 20% of respondents were conducted. Poststratification was conducted in order to eliminate non-responses due to refusal of interviews, the variations of poststratification being age and education. The margin of error is 1.3 p.p. for an incidence of 5%.

Categories that did not wish to provide answers were excluded from the analysis when cross-referencing the variables.

When cross-referencing the variables, the "didn't go to school, have not finished primary school, or only finished primary school, as well as those who completed a two-three-year secondary school" represents the "primary school" category. The category "four-year high school, gymnasium and specialisation" was compiled into the "secondary school" category.

In the segment of employment status, the categories employed in the social or mixed sector, farmer, and informally employed (undeclared labour), as well as those that earn upwards of 50,000 dinars are low-frequency categories (<5%) and are observed indicatively when cross-referencing variables. The Chi-square test was used to prove the second hypothesis.

Hypothesis 1: Generation Z lacks information regarding CSR activities in the local and wider communities.

Survey question 1: How familiar are you with the CSR activities of the Company in the local and wider communities?

Survey question 2: Does the Company aid the development of the local and wider communities?

Survey question 3: Does the Company aid the development of culture?

It is believed that managers within the company should know and understand the cultural characteristics of their consumers/users in order to adequately implement their CSR strategies in the long run (Hur & Kim, 2017). In addition to the form of communication through a country's cultural sector, the manner in which a company determines its priorities when it comes to its relations to CSR initiatives in the cultural sector is of the utmost importance. In this context, the importance of the manner in which companies communicate CSR information is particularly emphasised (Ott & Xiao, 2017). It is a common belief that, in a way, it is the responsibility of companies to spread cultural sustainability among their own shareholders, as well as to put forward innovative projects in direct cooperation with the local community (Tamagnini & Baldo, 2019).

Survey question 4: Does the Company support science and education in society?

Survey question 5: Does the Company aid socially disadvantaged people?

Survey question 6: How should the Company aid socially and materially disadvantaged people?

Survey question 7: Does the Company promote sports?

Survey question 8: Which projects should the Company support?

Hypothesis 2: There is no statistically significant difference in the answers of the respondents depending on their education level in relation to the variable: When choosing an insurance company, I take into account whether it cares about the local and wider communities.

Survey question 9: When choosing an insurance company, I take into account whether it cares about the local and wider communities.

Data Analysis and Research Results

Table 1: Social community development by the Company across the regions

Company – social community development	Urban	Rural	Belgrade	Vojvodina	Western Serbia	Eastern and Southern Serbia	No income	Less than 15k	15-29,9k	30-49,9k	Over 50k
Yes, but I am not familiar with the project.	27.6	24.4	29	22	33.1	20.2	24.8	19.2	23.2	32.2	30
Yes, I am familiar with a specific project.	0.2			0.3							3.3
It doesn't help the community.	17.5	25.1	17.4	18.2	28.2	16.2	24.5	26	19.9	19.3	20
I don't know if it helps the community.	54.8	50.5	53.6	59.5	38.7	63.6	50.7	54.8	56.9	48.5	46.7

The largest number of respondents stated that they did not know if the Company was helping the community, almost 50% if respondents in all target groups. The vast majority of respondents living in urban areas (99.2% of them) do not know the names of the projects that contribute to the development of the community and that the Company supports, as opposed to only 0.2% who do. When it comes to respondents whose income is more than 50,000 dinars, the result is somewhat better, so that 3.3% of respondents are familiar with specific projects with which the Company helps the community, but the vast majority, 96.7% are not. Some 32.2% of people who earn between 30,000 and 50,000 dinars say that they do not know the exact names of the projects that the Company supports, aimed at developing the social community, but that they do know the Company helps. In Belgrade, almost 60% of respondents claim that they do not know if the Company helps the community, while the percentage of respondents who claim the same in Eastern and Southern Serbia is 63.6%.

Table 2: Responses across various age groups regarding the Company's projects in local and wider communities

	18-29	**30-44**	**45-59**	**60+**
Yes, but I don't know about a specific project.	24.4	27.7	29.5	23.5
Yes, a specific project cited.	0	0	0.4	0
No	21.9	23.5	18.9	20.3
I don't know.	54.8	48.8	51.2	56

Table 2 shows that those belonging to the youngest group of respondents and Generation Z are 3.3% and 5.1% less aware of whether the Company aids the development of wider and local communities compared to the 30-44 and 45-59 years of age groups, respectively. The youngest group either thinks that the Company does not help, or do not now of it helps to a greater extent than these two mentioned age groups of respondents. From the data provided, it can be seen that 24.4% of respondents aged 18-29 have information that the company Company helps the development of the local and wider communities, while 76,7% either think that the Company does not help, or don't know if the company helps.

Table 3: Responses across various age groups regarding the Company's support for cultural programs

	18-29	**30-44**	**45-59**	**60+**
Yes, but I am not familiar with a specific project.	25.5	25.8	24.9	22.7
Yes, specific project cited.	0	0	0.4	0.6
No.	16.7	16.7	21.1	17
I don't know.	56.4	57.8	53.7	59.6

The attitudes of those belonging to the youngest group of respondents, to which Generation Z belongs, are almost identical to those of the 30-44 age group, so that 25.5% of them say that the Company aids culture, but cannot cite a specific project. There is a significant disparity when it comes to answers of different age groups of respondents when they say that the Company does not help culture. There, 21.1% of the respondents aged 45-59 gave such an answer, which is 4.4% more than respondents of all other age groups, even the youngest, the subject of this paper. This question is also answered negatively by all age groups. Some 16.7% of the respondents aged 18-29, including those belonging to Generation Z, stated that the Company does not help the development of culture, and 56.4% did not know whether the Company helps the development of culture.

Table 4: Responses across various age groups regarding the Company's donations to science and education programs

	18-29	30-44	45-59	60+
Yes, but I am not familiar with a specific project.	24.7	22	23.5	19.4
Yes, specific project cited.	0	0	0.4	0.6
No.	18.6	25.1	23.2	18.4
I don't know.	56.7	52.9	53	61.6

Respondents belonging to the youngest generation, Gen Z, are more aware than other respondents that the Company aids science and education in the community (24.7% of them). However, here too, the negative result is clearly dominant, so that 18.6% of them are explicitly of the opinion that the Company does not help the development of science and education, and as many as 56.7% are do not know whether the Company helps science and education. Respondents aged 30-44 and 45-59 mostly said that they did not know whether the Company helps science and education. The least informed are the respondents over the age of 60, with 61.6% of them saying that they did not know if the Company helped science and education in society.

Table 5: Responses across various age groups regarding the Company's contribution to socially disadvantaged people

	18-29	30-44	45-59	60+
Yes, but I am not familiar with a specific project.	25	22.7	26.3	19.3
Yes, specific project cited.	0	0.4	0	0.6
No.	16.7	23.6	21.8	20.9
I don't know.	58.3	53.5	51.9	59.2

The attached table shows that 58.3% of respondents aged 18-29, including Generation Z, do not know whether the Company helps socially disadvantaged people, while 25% of respondents in that age group are aware that the Company helps, but cannot cite a specific project. That is 2.3% higher than in the next age group (30-44), while results are the worst in the 60+ age group, 5.7% lower than with the youngest respondents.

The Company mainly conducts a CSR project for socially disadvantaged people from the categories listed as answers to the respondents. By far the largest number of respondents, 72%, answered that they did not know how the Company should/could help the socially disadvantaged.

About 4.4% of respondents feel that funds should be allocated to humanitarian actions, while almost 3% believe that the Company should finance soup kitchens and 2.7% who think that it should help single mothers and pregnant women. Other respondents answered as follows: construction of shelters 2.2%, financial assistance to the needy 2.1%, assistance to refugees 1.8%, and the same percentage assistance to the poor. Assistance to the disabled – 1.7%, pensioners – 1.6%, assistance to the Roma – 1.5%. Some 1.1% saw free schooling as an area that could use the Company's help, while the fewest number of respondents saw the Red Cross as being in need of help, only 1 % of them.

Table 6: Responses across various age groups as to whether the Company's is socially responsible

	18-29	30-44	45-59	60+
Yes, but I am not familiar with a specific project.	26.6	26.5	32.6	24.4
Yes, specific project cited.	0	0	0	0.3
No.	17.7	17.7	20.07	21.8
I don't know.	55.7	55.7	46.7	53.5

The youngest respondents here have identical results as the respondents aged 30-44, with 26.5% of them perceiving the Company as socially responsible, but cannot cite a specific project. It is interesting that a greater percentage of respondents aged 45-59 see the Company as socially responsible, by a margin of 6.1%. When it comes to the oldest category, however, 2.1% hold that view when compared to the 30-44 age group. As the table above shows, an identical percentage of respondents aged 18-29 and 30-44 answered "no" and "I don't know", constituting the majority in both categories, with 17.7% of them feeling that it wasn't, and 55.7% not knowing whether the Company was socially responsible.

Table 7: Responses across various age groups as to whether the Company is sports donor

	18-29	**30-44**	**45-59**	**60+**
Yes, but I am not familiar with a specific project.	30.6	25	29.8	23.4
Yes, specific project cited.	1	0.8	1.1	1.9
No.	14	23.1	22.5	17.4
I don't know.	54.4	51.2	46.7	57.3

Table 7 shows that 30.6% of respondents aged 18-29 are aware that the Company helps sports, while 54.4% of respondents of that age are not, while 14% think that it doesn't. For the first time, the youngest generation can name a specific project, 1% of them. The lowest percentage of positive answers about whether the Company helps sports is in the group of the oldest respondents, 23.4% of them. However, the highest percentage of those who could name a specific project, 1.9%, is also within this age group.

Graph 1: The types of sport projects supported by the Company

Looking at Graph 1, it can be concluded that as many as 84.5% of respondents do not know which sports projects the Company should launch and support in the local and wider communities. The largest percentage of those who commented on specific projects that the Company should support, 6.6% of respondents, thought they should sponsor young athletes/talents, 4% felt they should invest in sports facilities, while 2.1% stated that the Company should support sports clubs. Sports events – 0.9%, other – 0.8%, youth sports – 0.6% and sponsorship of sports events – 0.4%.

The correlation between the level of education under the sample (youngest respondents and Generation Z) and the attitude to the following statements was tested: When choosing an insurance company, I take into account whether it cares about the local and wider communities. Chi-square test was used to test the hypothesis H2: there is no significant statistical difference in the answers of the respondents based on their education level in relation to the variable: When choosing an insurance company, I take into account whether it cares about the local and wider communities.

Table 8: Age group 18-29, education level

	Number
No education, unfinished primary school, primary school, high school 2-3 years	54
4-year high school, gymnasium, specialisation	143
College, university +	63
Total by column	260

Table 9: Data on respondents' attitudes towards the statement

	Yes, but I am not familiar with a specific project	Yes, project cited by name	No	I don't know	*Total by lines*
No education, unfinished primary school, primary school, high school 2-3 years	12	1	16	25	54
4-year high school, gymnasium, specialization	27	1	30	85	143
College, university +	15	1	14	33	63
Total by columns	54	3	60	143	260 (total)

Table 10: Results on the attitudes of the respondents regarding the statement and the relation with education level

	Yes, but I am not familiar with a specific project	Yes, project cited by name	No	I don't know	***Total by lines***
No education, unfinished primary school, primary school, high school 2-3 years	12 (11.22) [0.05]	1 (0.62) [0.23]	16 (12.46) [1.00]	25 (29.70) [0.74]	54
4-year high school, gymnasium, specialization	27 (29.70) [0.25]	1 (1.65) [0.26]	30 (33.00) [0.27]	85 (78.65) [0.51]	143
College, university +	15 (13.08) [0.28]	1 (0.73) [0.10]	14 (14.54) [0.02]	33 (34.65) [0.08]	63
Total by columns	54	3	60	143	260 (total)

At a significance level of 0.5, the following results are obtained: The Chi-square statistic is 3.7998. The P-value is .703743. The result has no significance at $p < .05$., which means that they are independent variables. This confirms H2: There is no statistically significant difference in the answers of the respondents (youngest respondents and Generation Z) depending on their level of education in relation to the variable: When choosing an insurance company, I take into account whether it cares about the local and wider communities. The Chi-square test of independence showed that there is no significant connection between education and the conditionality of the choice of an insurance company by its care about the local and wider communities.

Conclusion

Based on the research results obtained, it can be concluded that the general hypothesis that Generation Z lacks information regarding CSR activities in the local and wider communities is confirmed. The answers of the respondents from Generation Z to the questions asked confirmed that the Company primarily does not have a satisfactory and efficient way of communicating its CSR activities to the public, especially not to members of the youngest generation, which also includes Generation Z. This resulted in the highest percentage of negative answers to all questions asked. The answers to the questions whether the Company helps the local and wider communities, whether it aids science and education, culture, sports and socially disadvantaged people are all mostly negative. Between 14% and 18% of Generation Z believe that the Company does not help the local and wider communities, science and education, culture, sports and socially disadvantaged people. The vast majority of Generation Z, 54% to 58% or more of respondents, do not know whether the Company helps the local and wider communities, science and education, culture, sports and socially disadvantaged people.

The fact that 17.7% of Z generation members do not see the Company as socially responsible and 55.7% of them do not know the answer to the question, indicates that more than 73% of the youngest generation of respondents do not perceive the Company as socially responsible, which is another confirmation the fact that the Company does not adequately communicate the projects it implements, and thus the general hypothesis that Generation Z lacks information in the field of CSR activities in the local and wider communities is confirmed. While the fact remains that the state is obliged to take care of education, pensioners, Roma, poor people, refugees, pregnant women, single mothers, soup kitchens, there is a great lack of funds in the local and wider communities that the Company also recognises and wishes to direct its CSR activities there and contribute, being a part of the solution of the problem. However, the research says that the vast majority of respondents do not know how to determine in which segment of socially vulnerable people they should direct their CSR activities. This also indicates a lack of information in this area.

When asked which projects the company should support in the field of sports, the vast majority of respondents (84.5%) answered that they did not know. This result also indicates that there is a lack of information and that there is no real communication on the topic of sports. The Company is actually present in most sports, and the result is still "I don't know".

The "I don't know" answers are above 50% of all answers in the group of the youngest respondents, to which the Generation Z belongs, is also the dominant result of all survey questions: How familiar are you with the Company's CSR activities in the local and wider community; Does the Company help the development of the local and wider communities; Does the Company help the development of culture; Does the Company help science and education in society; Does the Company help socially disadvantaged people; How should the Company help socially and materially disadvantaged people; Does the Company support sports and which sports projects should the Company support?

Considering the above and the fact that the first hypothesis was confirmed, the conclusion is that communication is a factor of the utmost importance in the CSR strategy of any organisation. It is necessary for every organisation that wants to present itself as socially responsible to inform all participants about its CSR strategy and implementation of specific projects in a transparent, adequate, understandable, honest and timely manner. This holds especially true when it comes to young members of the local and wider communities, with an emphasis on Generation Z.

The limitations of the research are reflected in the impossibility to examine a larger number of respondents at the same time, to repeat this research in an identical manner, but with a larger number of companies, and subsequently compare the results. It is possible that there are certain companies that are more clearly positioned as socially responsible, which would be useful for comparing and once again proving the need for timely and accurate information about CSR activities of the Company to the public through all channels of communication. As Generation Z is demanding, it is necessary to take all measures in a timely manner in order for companies to be perceived as socially responsible for what they do and how they behave, but also for how much attention they pay to transparent, adequate, understandable, truthful and timely informing of the public, which is another important aspect of CSR.

A Comparative Analysis of Factoring Market in Poland and the EU before and during the Time of COVID-19

Maciej TOKARSKI

WSB University in Torun, Poland
maciej.tokarski@wsb.torun.pl

Abstract

Factoring companies have been supporting Polish entrepreneurs in running their business for over 25 years. They finance their development and provide resources to meet the most urgent needs. They enable the conversion of receivables resulting from issued invoices into cash. This allows you to effectively secure financial liquidity and avoid payment gridlocks. Their services are already used by 22 thousand. companies in Poland. Factoring is the most dynamic section of the Polish financial services market, the volumes of factoring turnover has been steadily increasing since 2008. Unfortunately, the recent lockdown suppressed this dynamic trend and factoring was also affected by the slowdown. The present article is aimed at a comparative analysis of the factoring markets in Poland and UE.

Keywords: business financing, assignment of receivables, factoring market, Poland COVID-19

Introduction

Short term financing is vital for the financial survival of any company, because very often they are facing deficits of cash during their activity. Therefore a company has to identify the optimal solutions in order to cover those (temporary) deficits. A good solution to this problem is the financing with receivables using factoring (Benea, Duma, 2013). A well-organised financial services market providing access to a wide range of range of financial instruments is a prerequisite enabling enterprises to function smoothly and expand. Many SMEs confront problems when attempting to gain access to external funding because of the difficulties faced by financial institutions in producing consistently reliable risk-assessment processes. Particular problems for firms may be experienced in the management of working capital. In an attempt to alleviate such problems many firms have considered alternative forms of finance – factoring - by pledging an important element in their working capital, that of accounts receivable. The incidence of asset based finance – including factoring – has been increasing rapidly over the past decade and factoring is specifically targeted and suitable for smaller businesses.

Factoring is currently considered to be a flexible short-term financing source which also represents an alternative to a bank credit. It is also a safe instrument which allows the entrepreneur to improve or even regain financial liquidity. Factoring is also a very important tool of managing the receivables in a company. In times of recession mostly small and medium enterprises are put at risk of financial liquidity loss due to the lack of payment of a counterparty. A limited access to the traditional current financing in the form of bank credits and a weaker market position of SME, confronting bigger enterprises, decreases the possibilities of obtaining longer payment terms of trade credit. From that point of view, settling the receivables on time and securitization against the default risk of buyers are extremely important and quite often determine the ability of the company's survival in the market.

Factoring market in Poland grows very dynamically. Its strength is its high efficiency in solving the everyday business problems. The safety of trading and, consequently, increasing company's liquidity is crucial point for the development of any business. Factoring meets these needs (Czternasty, Mikołajczak, 2013).

The present article is aimed at a comparative analysis of the factoring markets in Poland and EU. As a result of the analysis, the hypothesis that in the considered period the factoring market in Poland saw a fast growth has been confirmed. Not only did the factoring turnover grow, but also the number of enterprises using the services of factors was on the rise. Research methods include literature and general statistical analysis of financial data (EUF, FCI, PFA and The Polish Central Statistical Office).

The concept and definition of factoring

There are many definitions of factoring in source literature and business practice. The official definition of factoring created for banking purposes by the Bank of France in 1973 states that it is a business arrangement between the supplier and the factor, under which the supplier assigns its accounts receivable to the factor that undertakes to collect them and pay the supplier, even if the actual debtor is late on payment (Deschanel, J. P., Lemoine, L, 1993). The essence of factoring is best captured by a definition that describes the facility as a purchase by the factor of supplier's short term receivables arising under transactions other than the purchase of services or goods for private consumption or from a hire-purchase arrangement, in order for the supplier to be paid on time or for the risk of debtor's insolvency to be transferred to the factor (Salinger, 1999).

Factoring refers to the phenomenon where a company (the adherent) sells its accounts receivables (the invoices showing the debts owed by its clients) to a financial service company (otherwise called factoring companies or factors) at a discounted rate (a little cheaper than the exact amount stated on the invoice), which will be paid immediately the status and creditworthiness of the debtors are ascertained by the factor. This allows for the uninterrupted running of day to day operations in the company, while passing off the burden of debt collector to the factor (Chirkunova et al., 2016; Dorfleitner et al., 2017; Protopappa-Sieke and Seifert, 2017).

Mian suggested a simple definition of Factoring being company's sale of its accounts receivables to a financial institution other than its captive one (Mian, 1992). Sopranzetti defined Factoring through the eyes of service providers, the Factors, being a financial institution that are in the business of buying and managing other firm's accounts receivables whereas through a typical Factoring contract the Factor bears credit risk and the responsibility to monitor the credit quality of the outstanding accounts receivable (Sopranzetti, 1999).

Soufiani defined Factoring as an economic decision whereby a specialized firm undertakes the responsibility for the administration and control of a company's debtor portfolio enabling the company to sell their accounts receivables at a discount in exchange for cash (Soufiani, 2002) .

Factoring, a form of asset-based finance, is often referred to as current-asset financing (Bakker, Klapper, & Udell, 2004; De Vries & Cameron, 2003). In factoring, funding, usually cash, is extended based on the discounted value of trade debtors. In addition to providing funds, factoring firms usually provide debt chasing and collection services for firms as trade debtors are exchanged for cash (Klapper, 2006).

Factoring is not a loan and there are no additional liabilities on the balance sheet of the company, although it provides financing of working capital. In addition, factoring is often done "without recourse", meaning that the factor that purchases the receivables assumes the credit risk for the buyer's ability to pay. Hence, factoring is a comprehensive financial service that includes credit protection, accounts receivable bookkeeping, collection services and financing (Klapper 2005).

The factor has three main functions such as:

- financing (pay their clients for their invoices as they are issued);
- providing services (collect payment from their customers, provide advice to clients on credit management, pursue late payers);
- protecting the client against bad debts.

Factoring increase working capital of a firm without increasing the liabilities of a firm's balance sheet since factoring isn't a loan. Factoring provides firms with comprehensive financial services which may consists of credit services, receivable bookkeeping, collection services and financing. Factoring firm assess the creditworthiness of the client firms' customers (Klapper, 2006). Factoring is especially important for SMEs since they have difficulty in accessing bank financing due to the weak credit history and inadequate collateral and assessing creditworthiness of their customers (Bradic-Martinovic et al., 2015). Factoring allows SMEs to reach funding faster and less costly way than bank finance.

From the above definitions, it is obvious that:
1) The scope of Factoring is mainly focused on the finance function despite its extended range of services.
2) Factoring is more suitable to SMEs rather than to the large corporates.

Factoring in Poland

The law in Poland does not specify whether factoring is a banking activity. Hence factors in Poland do not need the permission of the National Bank of Poland in order to trade nor do they need to obtain a permit from the Polish Financial

Supervision Authority. This creates ideal conditions for the development of the factoring market, in which Polish entrepreneurs are more and more eager to engage in. Factoring agreements have to be in accordance with the provisions of the Civil Code (the Act of 23 April 1964) or since 2005 article 1: 102 (1) Principles of European Contract Law. There isn't a ban on the assignment of receivables in general, although in practice a ban on the assignment of receivables to commercial contracts is becoming more and more common in Poland. The law governing the assignment of receivables is within the Code of Civil Procedure, and results directly from article 509 §1 of the Civil Code (Stecki, 1996; Kruczalak,1997; Kreczmańska-Gigol, 2006). Internationally, the most important source of law is the Convention on International Factoring adopted by the International Institute for the Unification of Private Law - UNIDROIT in 1988 at the International Diplomatic Conference in Ottawa (Sommer, 1998; Puławski, 2018). The Convention contains 23 articles grouped into four chapters (UNIDROIT Convention on international factoring). In addition to the Convention, the UNCITRAL - Convention on the Assignment of Receivables in International Trade from 2001 is also used as an international source of Law on Factoring. Convention on International Factoring defines the factoring contract as a contract whereby the client transfers to the factor the receivables from the concluded basic sale agreement with the debtor, where the factor performs at least two of the following functions:

1. Financing the client, including loans and advance payments;
2. Keeping accounts related to receivables;
3. Collection of receivables,
4. Provision against the risk of non-payment of receivables.

Poland's factoring market compared to other countries of the EU

The factoring services are used by the enterprises from the developed and developing countries (Klapper, 2006). According to the data of the EU Federation for the Factoring and Commercial Finance Industry, the majority of the EU countries noted an increase in the factoring turnover since 2009. In the majority of countries, factoring is a common financial service. In Poland it was spread by banks in the 90's of the 20th century. Next, then on-bank factoring partnerships started to be created and their factoring services developed dynamically. The factors both on the demand and the supply sides condition the development of factoring services. On the side of the entities offering factoring services one may enumerate: the type of the entities offering factoring services, their number, size, the turnover they generate or the range of services they offer. Legal regulations promoting the development of alternative financing are also important (Keczmańska-Gigol, 2015).

The portfolio of products offered by Polish factors is comprehensive. Both the independent factoring entities and the banks deliver the broad range of 'classic' factoring facilities, as well as tailored ones (Tokarski, 2005; PFA: Polish Factors Association; Czarecki, 2007).

• Domestic factoring

– Non-recourse factoring
– Recourse factoring
– Collection only
– Reverse factoring
– Maturity factoring

All of these services are delivered either as notified or non-notified type. The most common payment terms: 30 to 90 days.

• International factoring export

– Export, non-recourse factoring based on two-factors' system
– Export, recourse factoring based on two-factors' system
– Direct export factoring
– Collection only

The most common payment terms: up to 180 days.

• International factoring import

– Import factoring, backing the co-working export factor (cover and collection)
– Collection only

The table 1 shows detailed information about factoring turnover by country in the 2011-2019 years, together with year on year growth rate, GDP penetration and market share.

Figures collated by the EUF's Economic and Statistic Committee for 2019 show an 8% growth year on year in factoring turnover in EU countries, with the total now exceeding 1,9 trillion euro. It was the 11th consecutive year of growth and the third where the yearly increase was higher than the 6 years' market compound annual growth rate (7%). This figure confirms how factoring is playing an essential role in financing companies' growth, outpacing the progress that might be expected simply from good economic conditions in the EU.

The high level of concentration shown by the EU factoring market in previous years also in 2019 remained unchanged, with the top five countries of France, United Kingdom, Germany, Italy and Spain together representing 75% of the total EU market. And in 2019, for the first time, France overtook the United Kingdom to become the no. 1 country by volume in the EU factoring market.

The table 1 shows detailed information about factoring turnover by country, together with year on year growth rate, GDP penetration and market share. This year's GDP penetration ratio was again higher than last year's (11,3% comparing to 10,9% in 2018), and there were again wide variations between countries. The lowest GDP penetration ratio was in Luxemburg (1%) and the highest in Belgium (18%). The dominant type of factoring was domestic, representing 80% of total turnover, unchanged from the previous year. In 2019 the growth of international factoring was slightly higher than that of domestic.

At the end of 2019, the estimated value of funds advanced by European factors to their clients exceeded 274 bn euro, showing a year on year increase of 14%. These advances were secured by assets valued at 331bn euro (increase by 7% y/y). The ratio between advances granted and security values equals 83%, and it reflects low risk profile of factoring transactions.

In conclusion, statistics collated for 2019 shows that factoring is still developing much faster than the EU economy. It is a source of funding for growing number of companies and also provides them additional benefits – such as popular risk coverage (in case of nonrecourse factoring), accounts receivables portfolio management and a soft collection service.

Table 1: Total factoring volume in EU by country (in Millions of EUR)

Country	2011	2012	2013	2014	2015	2016	2017	2018	2019	GDP penetration 2019	Market share 2019

Source: author's own calculations on the basis of data from the EU Federation for the Factoring and Commercial Finance Industry.

Over the last 10 years Polish factoring has grown fivefold. The average annual growth dynamics reached 20% and this is the dynamics that other countries cannot boast of. Unfortunately, the recent lockdown suppressed this dynamic trend and factoring was also affected by the slowdown. However, the market remained in the black, although to a lesser extent than in the previous years. In the first half of the year the market noted 2.6% growth rate. Europe, which brings together 2/3 of the sector, remains the dominant factor for the development of the global factoring market. Poland takes strong 8th place it enjoys the best growth dynamics among the leaders. The share of factoring turnover in GDP in our country amounts to 13%, while in the entire Old Continent it reaches 11.3%, and in the world it amounts to 4%. There are around 60 factoring institutions at the Polish market, among which the greatest share of the market belongs to institutions, which are members of Polish Factors Association (The Polish Central Statistical Office, 2020). In 2019, 22,083 customers (29.0% more than in the previous year) used factoring services.

Table 2: Total factoring volume in Poland (in Millions of EUR)

Year	Total factoring volume	Number of customers (factorers)
2008	11,486	4432
2009	11,997	5 206
2010	16,210	5 622
2011	17,900	6667
2012	24,510	7688
2013	31,588	8472
2014	33,497	10 242
2015	35,020	12 650
2016	39,756	14 806
2017	44,300	15880
2018	56,474	17917
2019	66,141	22 083
GDP penetration 2019	13.00 %	
Market share 2019	3.50 %	

Source: author's own calculations on the basis of data from the Polish Central Statistical Office and data from the EU Federation for the Factoring and Commercial Finance Industry (https://euf.eu.com/total-factoring-volume-data/poland-20-poland.html)

The service of factoring, thanks to the constant financing of receivables, prevents the creation of payment backlogs enabling the regulation of liabilities on time and, as a result, improves the financial liquidity of economic entities. Itis thanks to these above-mentioned reasons that the use of the service of factoring is larger in Poland than in the other countries of the EU (NBP– National Bank of Poland, 2015).

The market in Poland still enjoys considerable growth potential, if only because there have been over a million business entities operating in the micro, small and medium-sized enterprises segment alone. It is easy to calculate that the factors service less than 1% of enterprises. Hence, it is necessary to develop products tailored specifically to companies from this sector and promote them effectively, especially for those who do not keep full accounting records. The factoring offer which is available on the market might be considered mature. Factors providing it offer a full range of products and the quality of their services meets the requirements of the worldwide standards.

The Polish factoring industry needs more educational and promotional activities to mature, because this facility cannot function properly without informed and knowledgeable entrepreneurs. Entrepreneurs should above all understand that factoring is as much a solution to their cash flow problems as a source of supportive services, which are equally advantageous as the purely financial benefits of factoring. These educational activities should be addressed not only to entrepreneurs as the potential users of factoring, but also to factors and debtors.

The international Covid-19 pandemic is shaking the whole world. This is an unprecedented health crisis that affects all of us. The shock to our economy is tougher than in 2008 and will have devastating economic and social consequences across Europe.

The data collated by the EUF shows that in 2019, factoring and commercial finance volumes in the EU grew overall by 7.9% to reach €1.91 trillion. This rate of growth, which equalled that seen in 2018, again clearly outpaces the increase in GDP in Europe. Funding of €275Bn is supporting around 280,000 European clients, helping them to deliver growth,

employment and business success. With factoring and commercial finance now representing around 11.3% of EU GDP, this is an increasingly powerful and vital contribution to EU economic development. Besides Europe remains the first economic zone in the world for factoring with two-thirds of the global total.

The statistics of European factoring are generally good in the first quarter of 2020. However, with the economy coming to a sudden halt, and in the absence of invoices to finance, they should be expected to decrease sharply from April

Factoring in the time of COVID-19

Data gathered on the European factoring market for H1 2020 has shown, for the first time in 11 years, a decrease in factoring turnover of 6.0% year on year. The total factoring turnover reached €853 billion compared with €911Bn in H1 2019. Information received from country members' organisations indicates that this drop is principally the result of national lockdowns, and in some countries of the impact of government measures to sustain enterprises and especially their treasuries. What is interesting is that the decrease in factoring turnover was almost in line with the reduction in EU GDP of 6.3%. This is why this year's GDP penetration ratio was similar to last year's (11.1% compared with 11.2% in 1H 2019); normally we see factoring growing faster than GDP (EUF Newsletter, Spring 2020).

The trend differs between countries, but 3 of the top 5 European factoring markets received the hardest hit. The biggest falls were observed in (EUF Newsletter, Spring 2020):

- UK, with 14% decrease year on year, significantly greater than its GDP reduction of 7.7%,
- Italy, with a 13% decline, whilst GDP shrunk nearly 11%,
- France, with a 10.2 % fall, compared with a 9.3% reduction in GDP,
- Portugal, (not the one of the largest markets) fell 9%, and GDP was reduced by 7.1%,
- Belgium with a 5% turnover reduction and an 8% decrease in GDP.

The principal causes of these reported falls were:

- decreased client turnover,
- insufficient, poorly targeted or belated government interventions.

Despite this difficult business environment, there were also countries where a yearly increase was reported:

- Netherlands, where turnover grew 4.6%, when GDP decreased by 2.6%,
- Norway, which saw 2.6% of growth, when it experienced an almost 13% decrease in GDP,
- Poland, which grew by 2.4% whilst its GDP fell by 2% (although when we exclude the increase in turnover of one main member, the overall market decreased by 2%, in proportion to the GDP decrease),
- Denmark, 1.7% growth against 2.6% GDP reduction,
- Germany 1.6% growth compared with a 4.2% fall in GDP.

The data from the German and Polish markets indicate that in both countries the support measures taken by their governments have helped to soften the economic impact of lockdown and to minimize its effect on the supply chain.

The leader of the European market is France with almost 18% of the market. Next there is Germany with 15.8%, followed by UK 15.3%, Italy 12.5% and Spain 10.2% respectively. These top 5 countries represent 71.7% of the EU factoring market.

Conclusion

The basic problem preventing the correct development of enterprises is lack of capital. Capital shortage is often a result of the payment gridlock, which emerges as an effect of bad management of trade credit. The tool used to improve cash flow is factoring. Around the world, factoring is a growing source of external financing for corporations and small and medium-size enterprises (SMEs).It is currently considered to be a flexible short-term financing source which also represents an alternative to a bank credit. It is also a safe instrument which allows the entrepreneur to improve or even regain financial liquidity. It is also a very important tool of managing the receivables in a company. It is a financial service providing liquidity to the real economy as it involves the payment of invoices before their final due date. Factoring is widely accepted as an alternative financing source, and used in almost every industry that sells business-to-business or business-to-government. One of the biggest advantage of factoring is the improvement of financial

competitiveness by the increase of liquidity and enhancement of cash-flow patterns of businesses (Milenkovic-Kerkovic, T. & Dencic-Mihajlov, K. 2012).

The Polish factoring market has come a long way from a modest beginning to a very dynamic development which has been observed for many years. Factoring is not only becoming more and more known, but also more and more appreciated as a quick and easy source of financing for the current operations of enterprises

Factoring is the most dynamic section of the Polish financial services market, the volumes of factoring turnover has been steadily increasing since 2008. Polish business had effectively examined factoring as financial instrument. Remembering that Poland is the 6th economy in the Europe and there are over 2 million of businesses entities, the demand for factoring may be very strong. The current number of factoring clients extends 22 k, thus the potential is still large, the number of the clients looking for factoring may amount to 100 000. Such a bound was reported from the factors and fin-techs servicing the micro businesses (The Polish Central Statistical Office, 2020). The increase in factoring popularity is based on clients' demand more than just short -term financing but also a helping hand in decreasing the risk level in day-to-day operations. What should be noted here, factoring market approaches to the matured stage. Polish factors offer a full range of products derived from trade receivables model and the performance of the services' quality correspond to the world standards. Market looks attractive, there is still room for new players and new. Poland remains an exceptional place for doing factoring business.

In July 2020, the European Commission approved the Polish factoring-based support program for enterprises affected by the coronavirus epidemic. Poland is the first European market where the aid for companies will be based on factoring. The value of the support program amounts to EUR 2.6 billion, *i.e*. PLN 11.5 billion. The scheme was approved under the Temporary State Aid Framework. It will provide further support to companies which were severely affected by the effects of the coronavirus pandemic. Factoring is going to be used as the measures which will allow the enterprises to meet their liquidity needs as well as it will help them stay in business during this difficult time. The program, which is implemented by Bank Gospodarstwa Krajowego (BGK), will be available to enterprises of all sizes and it will provide guarantees for both recourse factoring and reverse factoring. BGK will enter into portfolio agreements with factors (banks or factoring companies) and it will grant them guarantee limits. Factors will be able to use these limits and provide BGK guarantees to entrepreneurs for the granted factoring limits. The cooperation between BGK and the factors will ensure liquidity for companies and it will enable the on-going settlements of liabilities (https://ec.europa.eu/commission/presscorner/detail/en/IP_20_1402).

Factoring is a financial service whose application leads to the shortening of the cash conversion cycle thanks to which it is possible to improve the corporate financial liquidity. Due to its complex and multidimensional character it allows for a better trade liability management as well as for the protection against the risk of debtors' default. Factoring will be in high demand during and after this crisis, as banks pull out of credit facilities, especially SMEs and companies looking for new alternative sources of working capital financing. With the significantly increased volatile business environment, companies will look to mitigate the risk of their receivables. When exploring liquidity options during these tumultuous economic times, companies should remember to consider all financing options at their disposal. For companies with accounts receivable, factoring arrangements and other receivables financing structures may provide a much-needed source of liquidity. Factoring ensures solvency to businesses and frees them from problems involved in paying their liabilities, helping them to focus on the core business.

Abstract

The use of modern digital technologies in the process of tax administration not only opens up new opportunities, but also creates additional tax risks for the state and taxpayers. The article presents a study of tax risks under the conditions of the digitalization of the economy. The purpose of this study is to identify and systematize tax risks and to work out criteria for tax risk assessment in the context of digitalization. The study used the methods of logical and systems analysis of tax risks under the condition of the digitalization of the economy; content analysis was employed to analyze the available literature; the best practices of tax administration digitalization were summarized; the practice of using digital technologies to minimize tax risks was explored.

Keywords: Tax Risks, Digitalization, Risk-Based Approach, Tax Administration, Tax Risk Management, Digital Technology.

Introduction

A transition to a qualitatively new level of interaction between tax authorities and taxpayers is due to the development of information technologies and their adoption by tax authorities.

As digital technologies are penetrating the life of society and are getting actively employed by tax authorities, new risks are emerging for the state as well as for the taxpayer. A transformation of tax relations is happening under the influence of the challenge of economic digitalization and contemporary fast changing trends in the digital economy. Among the key ones are:

- first, the transformation of traditional industries and companies and ubiquitous use of the internet: business models are evolving as their number grows; growing spread of digital goods and services. As of January 2020, the number of internet users totalled 4.5 billion people globally; 3.8 billion of them were social media users. In Russia, 118 million people, or 81% of the country's population, use the internet; the number of social media users reaches 70 million, which is 48% of the country's population. E-commerce sales in Russia have been growing year-on-year: 487.83 billion roubles in 2013; 616 billion roubles in 2014; 732.67 billion roubles in 2015; 868.67 billion roubles in 2016;– 1,035.8 billion roubles in 2017; 1,285 billion roubles in 2018 (RAEC, 2019).

- second, the development of digital platforms and the use of big data. This drives the transformation of relations in the sphere of taxation and the growth of cross-border transactions that take place on cross-border platforms that are invisible to regulators and tax authorities. In the consumer-to-consumer (C2C) market, users engaged in e-commerce are spread among the following platforms: 65% are based on Avito, 39% on Youla, 22% on Vkontakte, 9% on Instagram, 8% on Irr.ru, 6% on Odnoklassniki, 6% on WhatsApp, 5% on Facebook Messenger; 5% on Auto.ru, 4% on Drom.ru, 2% on Telegram, 2% on Viber. In 2018, the big data market garnered 38 billion dollars globally, growing to 46 billion dollars in 2019.

- third, the development of robotics, M2M (machine-to-machine), artificial intelligence (the Higher School of Economics expects the global robotics market to reach 147 billion dollars by 2025, China accounting for 30% of the

Cite this Article as: Olga SINENKO and Igor MAYBUROV "Tax Risks in The Context of Digitalization of The Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

world's robotics technology market by 2022 (Abdrakhmanova G.I., 2019). According to RLMS, 26.5% of employees in Russia work in jobs with high levels of automation (over 70%) (CMASF,2018).

- fourth, the development of the cryptocurrency market (an increase in the volume of capital flows bypassing the traditional banking system) (shadow online transactions). Today, there are over 1,300 cryptocurrencies (their cumulative market capitalization has been growing year-on-year, reaching the present value of over 597 billion dollars: Bitcoin's current total value is 259.6 billion dollars; Ethereum's value is 72,9 billion dollars; Bitcoin Cash is worth 57.8 billion dollars, Ripple and others are valued at 46 billion dollars.

On the one hand, the digital economy trends described above create new opportunities for taxpayers and the state, but on the other hand, they are a source of new tax risks for all parties involved in tax relations. Tax authorities are trying to embrace the ongoing processes by creating various online services for more convenient communication with taxpayers and are using automated systems that improve the quality of tax control. Taxpayers, too, are looking for ways to reduce their tax charges. For example, the website of the Russian Federal Tax Service had over 145 million unique visitors in 2018 and 160 million in 2019. Between 2015 when automated tax control systems in Russia were launched, and 2019, the number of dummy companies (so-called fly-by-night companies) halved. Today, there are 120,000 of them, which is 3.2% of all businesses. At the start of 2016, there were 1.6 million fly-by-night companies. The number of VAT refund claims filed by high-risk organizations has reduced 15-fold. The factors listed above fuel the reduction of the number of companies engaged in the shadow economy.

The size of the shadow economy and the actual number of self-employed individuals in Russia remains highly debatable. Additionally, blogging and ecommerce social media are gaining in popularity (an Instagram influencer with 150,000 followers whose posts garner an average of 15,000 likes is paid around 15,000 roubles for a promo post).

Methodology

They key research methods are content-analysis, synthesis, and comparative analysis. An analysis was done of tax risks amid the digitalization of the economy. When conducting the research, types of digital tax risks were identified and systematized; areas subject to each type of risk were located through relevant qualifying elements. Criteria for tax risk assessment in the context of digitalization were devised. Content analysis was conducted of the literature on the subject and the best practices of the digitalization of tax administration were summarized. As a result of the analysis, the main components of digital technology application with the goal of tax risk minimization were identified. The analysis utilized data from the websites of the tax authorities in Asia-Pacific countries and academic journals.

Research

1.Tax risks. The majority of researchers agree that tax risks emerge, on the one hand, as a result of what the state does and, on the other hand, as a result of taxpayers' own actions. Tax authorities define tax risk as the risk of illegal actions by taxpayers who look like an attempt to extract unfair tax benefits and go "beyond the execution of their right to determine the tax base and/or calculate the amount of tax to be paid". Approaches to defining the concept of "tax risk" are summarized in Table 1. Tax risks faced by taxpayers are largely due to their desire to minimize their tax liability (Sinenko, O. Mayburov, I., 2017). As an outcome of risk exposure, additional tax charges, fines and penalties might be imposed.

Table 1: Definitions of the concept of "tax risk"

«Tax risk» of the state	«Tax risk» of the taxpayer
Probability of tax revenue loss as a result of tax minimization schemes used by taxpayers thanks to loopholes in tax legislation (Gashenko, Irina V., Zima, Yulia S., 2019)	Probability (threat) of additional tax charges, penalties and fines being imposed as a result of a tax audit following disagreements between taxpayers and tax officers as to how to interpret tax legislation, which could result in bigger tax burden for the organization.
Possibility of failure to meet collection targets for total tax revenue and specific taxes.	Possibility of financial and other losses for the company as a result of tax payment and optimization in monetary terms
Failure to meet tax revenue targets, including as a result of the use by taxpayers of "legal" tax minimization	Possibility of growth of tax liabilities and, consequently, lower financial potential of the taxpayer

schemes (Tkacheva, T., Afanasjeva, L., Goncharenko, L., 2019)	(Gubar, E. A., Zhitkova, E. M., Kumacheva, S. S., & Tomilina, G. A. (2019).

Source: compiled by the authors

Most of the researchers agree that it is impossible to mitigate completely the impact of tax risks even under the conditions of digitalization. The ongoing digital transformations highlight the timeliness of identifying, assessing, monitoring and forecasting tax risks faced by the state as well as by taxpayers. Tax risks in the context of digitalization can, therefore, be defined as risks that occur for the state or the taxpayer under the conditions of the development of the digital economy and/or risks that occur because of the adoption of digital technologies by tax authorities. As part of this study, tax risks were identified that emerge as a result of digital economy trends. The results of the attempt to prove a connection between the influence of digital economy trends and negative outcomes for taxation and tax administration are presented in Table 2.

Table 2: Relationship between digital economy trends and tax risks

Digital economy trends	Tax risks
Ubiquitous use of the internet: evolution of business	Transactions executed via P2P services, social media channels, international job boards are difficult to control, which results in tax evasion (due to the problem of identifying such entrepreneurs and controlling their business operations)
	Tax base is diluted; virtual tax havens emerge; tax revenues decrease as a share of corporate incomes is taken out of the jurisdiction of national tax laws (duty-free import).
Growing spread of digital goods and services	Decrease in tax revenue from sales of traditional goods and services; Tax evasion as sellers of digital goods and services are hard to track down and identify
Use of big data	Tax base can be expanded by means of digital data.
Digital currency and development of cryptocurrencies	Increase in cash flows generated by trade in cryptocurrencies bypass the traditional banking system, — tax administration becomes more complicated.
Use of robots, M2M, artificial intelligence	Tax revenues are reduced thanks to robotization.

Source: compiled by the authors

The analysis enables one to name the following key tax risks for the state that emerge in the context of digital economy: the risk of illicit business operations being conducted over the internet (through social media channels, P2P services etc.); the risk of tax evasion due to the difficulty of identifying online sellers of digital content; the risk of tax base shrinkage due to the cheapness of digital goods and services; the risk of tax evasion by crypto entrepreneurs; the risk of tax revenue reduction as a result of robotization etc (Sinenko, O. Mayburov, I., 2019).

2. Utilization of digital technology in tax risk identification. In the course of tax administration, it is critical for tax authorities to promptly identify and assess the impact and probability of tax risks. Effective tax risk management depends on a combination of methods and activities that make it possible to forecast the occurrence of risk events and take steps to mitigate them. In order to improve the effectiveness of the identification and assessment of tax risks in the course of tax administration, digital technologies are finding ever wider application globally. This study contains a comparative analysis of technologies that are employed in tax administration within the following categories: blockchain, robotic process automation, artificial intelligence, chat bots, biometric identification etc. Table 3 presents the results of the analysis of digital technology application in tax administration in Asia-Pacific countries.

Some countries in the Asia-Pacific have not only automated elements of tax control in order to minimize tax risks, but are also embracing robots and using the benefits of artificial intelligence and biometrics. Communicating with taxpayers and consulting them on tax issues has been delegated to chat bots in many countries.

Digital communication between tax authorities and taxpayers is developing rapidly and becoming more advanced. To study digital tools and methods of tax control, data from the official websites of the tax services of Asia-Pacific countries were used to produce a summary of the practice of digital technology application by the tax authorities of Asia-Pacific countries (valid for 2019). Fiscal authorities in all countries of the Asia-Pacific region use third-party information, including big data, on the income and transactions by taxpayers to assess tax risks. The pioneers in this field are South Korea, the US, Singapore, and China. Artificial intelligence and big data are starting to be used not only for assessing but also for forecasting tax risks.

Table 4: Application of digital technologies by Asia-Pacific countries (as of 2019)

Digital technology	Country	Methods and practices in use
Digital communication with taxpayers	USA	Mobile application «IRS2Go app», virtual services (video conference calls)
	Singapore	Digital system «CorpPass», «myTaxPortal» website.
	China	«Alipay», «WeChat»
Preliminary calculation of VAT refund	Chile	An application creates a VAT return file on the bases of electronic tax documents
	EEU	Belarus: «EEU Taxpayer (Web)» software, Kazakhstan: via "Taxpayer's Logon" etc.

Electronic document workflow (electronic invoicing)	China	GTS (Golden Tax System)
Artificial intelligence, big data, internet-of-things	USA	IBM's Watson supercomputer – analysis of tax returns
	South Korea	«Tax secretary», AI for forecasting tax risks
	Australia	Alex the chatbot that provides consultations to tax payers
	China	Data from biggest corporations is used to analyze tax risks
Social media monitoring for tax purposes	US, China	Social media monitoring to detect tax evasion, including crypto transactions

Compiled by the authors using data from websites of national tax authorities

Digital technologies enable tax authorities to tackle a wide spectrum of tasks associated with the detection and mitigation of task risks and to transform conceptually the paradigm of tax administration. Despite the fact that Russia does not lead the way in digital development, the Russian government is trying to address the problem of tax risk management amid digitalization. The evolution of the digitalization of tax administration in Russia pursuing the goal of tax risk minimization is presented in Table 5.

Table 5: Evolution of digitalization of tax administration in Russia (1991 -2020)

Year	Changes in the system of tax administration in the context of digitalization
1991	Introduction of individual taxpayer identification numbers (ITIN)
1992	Testing of elements of AIS-Nalog system.
1997	First version of open website of State Tax Service of Russia goes online
1998	Start of mass issuance of individual taxpayer identification numbers to private individuals
2002	– Adoption of digital document management as an operational standard for territorial tax authorities; the option of electronic filing of tax returns become available
2003	–the Unified State Register of Taxpayers can be accessed remotely; – one-stop-shop for company registration.
2010	Tax arrears reminder notices are now sent to taxpayers through their accounts on the tax service's website;
2011	– Nalog-Servis system is launched (provides services of entering tax return data, printing of tax reports etc.); Federal Information Address System.
2012	– Electronic registration service is launched; – Private individuals can create taxpayer accounts on the website of the tax service; – Official online invoice templates are introduced
2013	– Launch of pilot version of VAT-2 automated system
2014	– Launch of automated system Nalog-3; – Launch of taxpayer accounts for businesses on the website of the tax service
2015	– Launch of taxpayer accounts for sole traders on the website of the tax service – Launch of automated system VAT-2.
2016	– Introduction of online cash registers; Introduction of RFID tags; Launch of tax monitoring.
2017	Launch of taxpayer accounts for foreign companies
2018	– Launch of information system "Unified State Register of Taxpayers and Civil Registration"
2019	– Introduction of special taxation regime for self-employed individuals (mobile application "My Tax")
2020	– Launch of State Information Online System of Accounting (Financial) Reports

Compiled by the author using data from the official website of the Federal Tax Service at: https://www.nalog.ru/

It has to be noted that the adoption of digital technologies positively impacts the efficiency of tax authorities. According to the Federal Tax Service of the Russian Federation, the time spent on tax audits has been declining year-on-year, the number of on-site tax audits decreased more than seven-fold between 2011 and 2019, while the number of inconclusive tax audits halved. In 2019, the share of tax audits that were found to be invalid was 0.36% of all tax audits conducted, which is almost half the 2011 number. Between 2011 and 2019, the number of inconclusive on-site tax audits in Russia decreased from 772 to 358. Between 2011 and 2019, the effectiveness of tax audits improved: the share of audits that found irregularities increased from 62.8% of the total number of tax audits in 2011 to 96.9% in 2019 (FTS, 2020).

The introduction of tax monitoring in 2015 enabled the Russian tax authorities to make tax audits 30% less labor intensive. As of January 2020, 95 companies accounting for 30% of the country's tax revenues were engaged in tax monitoring.

Thanks to the implementation of the online cash register project in Russia, average sales per cash register doubled between 2017 and 2019. Online cash registers are used by over 1.5 million taxpayers. As of January 2020, there were over 3.2million online cash registers in use in Russia. Thanks to RFID implementation, excise duty collection has increased 40%; over 10,000 companies and sole traders take part in the tagging system, 24% of them are recently registered entities, which implies that they are out of the shadow market. Since the launch of the project, the number of fur garments registered in the tagging system has increased by 51%, customs duty payments increased 80% - from 38.7 million dollars to 69.6 million dollars.

Demand for mobile phone applications released by the Federal Tax Service is attested, among other things, by the number of downloads in the Google Play Store: Moy Nalog (My Tax) has been downloaded more than 500,000 times; Nalogi FL (Taxes Private Individuals) – over 1.1 million times; Lichnyy Kabinet Predprinimatelya (Business Account) – over 150,000 times; Proverka Kassovogo Cheka (Check Your Receipt) – over 120,000 times etc. Additionally, Russian taxpayers have been actively using services available on the website of the Federal Tax Service, the evidence of which is the number of visits: "Check the accuracy of invoices" – over 5.4 billion hits; "Find out the ITIN of a private individual" – over 393 million hits, "Personal account of a private individual" – over 24.2 million hits; "Transparent Business" – over 5 million hits; "Personal account of a sole trader" – over 1.3 million hits etc. Such efforts help increase the amount of collected tax payments without increasing the tax burden on taxpayers. For example, in 2013-19, VAT revenue increased 140% (Sinenko, O.A., 2020).

For the sake of a systemic approach to tax risk detection, the Federal Tax Service of Russia plans to create a virtual transaction environment – a digital eco-system that would consist of a number of connected elements: the digital environment of the taxpayer, the digital environment of the tax authority, and the tax administration environment. Along with the benefits, the employment of digital technologies by the Russian tax authorities has brought about some negative impacts and new types of tax risks, both for the tax authorities and taxpayers.

3. Classification of tax risks in the context of digitalization. The incorporation of new digital technologies into business processes and the system of tax administration in Russia provides evidence for the considerable potential of tax base expansion and tax revenue growth. On the one hand, there is stronger tax control; on the other hand, new types of risks emerge that are associated with the application of digital technologies in the economy as a whole and by tax authorities in particular.

Risk management effectiveness is largely determined by the precision of tax classification that makes it possible to identify risks and organize risk management efforts. In this study, a classification of task risks in the context of digitalization was built on the basis of criteria that were developed by V. G. Panskov. He systematized tax risks by factor of occurrence and by type of consequences for the state and the taxpayer. Viewed from the perspective of consequences, tax risks can be acceptable, critical and catastrophic. By this criteria, risks for the taxpayer are classified into four groups: risks of an audit by the controlling authority; risk of heavier tax burden; reputational risk, and risk of prosecution. Building upon the principles of tax risk classification by V. G. Panskov, the authors have systematized the identified tax risks for the state (Table 6) and the taxpayer (Table 7) in the context of digitalizsation

It has to be noted that as part of this study, new tax risks for the state caused by internal factors include those risks that are associated with the digital transformation of the tax authorities, the adoption of digital solutions for tax administration. Tax risks for the state caused by external factors include the risks associated with the impacts of digital economy trends on the national tax system. Additionally, the list of tax risks has been expanded with general risks of digitalization that are associated with the introduction of digital technologies in the business processes of the Federal Tax Service of Russia.

Table 6: System and assessment of tax risks for the state in the context of digitalization created in order to optimize the work of the Federal Tax Service of Russia

Risk description	Probability of risk occurrence	Degree of danger of losses
Tax risks caused by internal factors		
Risk of tax evasion by small businesses due to high cost of equipment (online cash registers, RFID tagging, digital workflow)	L	CA
Risk of a fictional tax debt because of fly-by-night companies reporting all business transactions, in order to conceal a tax gap from tax authorities etc.	L	C
Risk of minimization by the taxpayers of their tax liabilities (for example, by registering as a self-employed individual)	L	C
Tax risks caused by external factors		
Risk of illicit activities conducted over the internet (through social media channels, P2P services)	HL	CA
Risk of tax evasion by users of international freelance platforms	L	C
Risk of loss of control over transactions concluded via online cross-border platforms	L	C
Risk of tax evasion due to the difficulty of identifying online sellers of digital content	L	C
Risk of tax base shrinkage due to the cheapness of digital goods and services and elimination of middlemen.	L	C
Risk of tax evasion by crypto entrepreneurs	HL	CA
Risk of reduction of revenues from personal income tax and insurance contributions as a result of robotization and automation	L	CA
General risks of digitalization		
Cyber risks	U	CA
Operational risks (technical failures and breakdowns)	L	A
Risks associated with lack of digital presence of some taxpayers	U	A
Risk associated with lack of internet connection in some parts of Russia	L	A

Note: unlikely (U); likely (L); highly likely (HL); acceptable (A), critical (C) and catastrophic (CA)

The principles of a risk-based approach to taxpayers in Russia were laid down back in 2007 in the Concept of Planning On-Site Tax Audits. The principles were originally applied to VAT payers. Today, the Federal Tax Service of Russia is capable of implementing the risk-based model of tax administration on the basis of big data analysis using data on cashless payments, information retrieved from online cash registers, electronic invoices, RFID tags. As part of this study, an analysis was conducted of tax risks faced by taxpayers in the context of digitalization within the existing legal framework. The identified tax risks are systematized in Table 7.

Table 7: Tax risks for taxpayers in Russia created in order to optimize the work of the Federal Tax Service of Russia

Group of risks	Risks for taxpayers
Risks of audit by controlling agency and of heavier tax burden	Risks stipulated by the Concept of Planning On-Site Tax Audits
	Risks associated with online cash register malfunction
	Risks associated with the adoption of electronic document workflow systems (electronic invoices, electronically submitted VAT returns)
	Risks caused by technical failures and incorrect data in the course of communications between the tax service and other government agencies (the Federal Service for State Registration, Cadastre and Cartography and the traffic police)

	Risks of obtaining unjustified tax benefit
	Risks of tax optimization by splitting up a business
	Risks of crypto transactions (purchase of cryptocurrency, exchanging one cryptocurrency for another or for fiat money, paying for goods and services with cryptocurrency, cryptocurrency mining)
	Risks associated with earning an additional income (selling goods through P2P services, social media channels, doing jobs found on freelance platforms etc.)
Risks of prosecution	Risks associated with mandatory tagging of goods
	Establishment of fly-by-night firms for the purposes of tax evasion
	Major tax fraud by a corporation
Reputational risks	Risks of being blacklisted as a dishonest taxpayer
	Cyber risks due to the threat of data theft/loss and disclosure of confidential tax information

Source: compiled by the authors

When managing tax risks, it is critical to identify which tax payments that are affected by emerging risks. The results of an analysis of the impact of digital risks faced by taxpayers on tax revenues in Russia are presented in Table 8.

Table 8: Impact of digital tax risks for taxpayers on main tax payments in Russia

Risk	VAT	Excise duties	Corporate Income tax	Property taxes	Personal income tax	Land tax	Vehicle tax
Risks of incorrect operation of online cash registers	■	■	■		■		
Risks associated with introduction of electronic document management systems (electronic invoicing)	■	■	■				
Risks caused by technical failures and incorrect data in the course of communications between the tax service and other government agencies				■		■	■
Risks associated with crypto transactions (purchase of cryptocurrency, paying for goods and services with cryptocurrency, cryptocurrency mining)	■		■	■	■		
Risks associated with earning an additional income (selling goods via P2P services, social media etc.)	■		■		■		
Risks associated with mandatory tagging of goods	■	■	■				
Cyber risks due to the threat of data theft/loss and disclosure of confidential tax information	Loss of reputation and competitive edge						

Source: compiled by the authors

Conclusion

To sum up, it should be noted that tax risks associated with the development of the digital economy are caused by the emergence of new business models and ways of earning income, the virtualization of goods-for-money exchanges (creation of digital currencies, digital goods and services), the digitalization of industries and of the system of tax administration (use of robots, artificial intelligence, machine learning). The study of tax risks in the context of digitalization proves the necessity of the transformation of tax administration. This applies to individual procedures addressing specific taxes as well as to the improvement of the entire mechanism of tax administration. We believe that in order to tackle the problem of tax risks it is necessary to constantly monitor emerging digital tax risks. The problem can be solved if digital transformations are accomplished that imply full transparency of economic processes for the state and if a new level of trust between society and the state is reached.

Abstract

This article deals with an actual question of a significant decrease in fish stocks of the entire World Ocean. In this regard, there is a massive resettlement of invasions and zooplankton, which is the main reason for the decline in fish catch in various parts of the world of fishing. The main method of resettlement of invasive migrants is ballasting and deballasting of sea vessels, where in the ballast waters of the vessel these biological creatures of various sizes begin to fight for their existence, destroying all life on their way in the waters of the new habitat. The damage to the global economy over the past 30 years in the decline in fishing is about $ 5 trillion. Along with financial losses, ballast water contaminated with harmful viruses: cholera, plague, hepatitis, Covid-19 and its modifications can lead to a pandemic on a planetary scale, considering that the Covid-19 virus, according to the latest updated data from scientists from a number of countries, is viable in wastewater for up to 48 hours. One can imagine what consequences could threaten all of humanity. It is no coincidence that for all shipowners of the World Marine Fleet it will is necessary to re-equip ballast systems in accordance with the updated International Standard D-2 until 2024. Currently, more than 70 thousand seagoing vessels should be re-equipped at various shipbuilding and ship repair yards. According to our approximate calculations, the total amount of the re-equipment is about 7 billion dollars. Scientists and engineers of the Danube Institute of National University "Odessa Maritime Academy", including the authors of the article, invented a unique installation for disinfection and purification of ballast water in accordance with the requirements of the updated standard D-2. All the main costs for the production of the presented installation were worked out in detail according to the existing labor standards of the Izmail shipyard. The selling price of the newly manufactured installation is $ 169,000, well below current world prices. The results obtained show that with the help of the above processes in the manufactured installation, practically the entire line of life-threatening viruses are destroyed in ballast wastewater.

Keywords: water resources, Covid-19, invasive species, ballast water, standard D-2, safety of navigation.

Introduction

The world maritime fleet is currently experiencing significant economic difficulties associated with the re-equipment of the ballast system of each seagoing vessel. This new requirement arose due to the huge losses of water resources of all coastal countries of the world ocean, which found its expression in the IMO (International Maritime Organization) normative document [1], which is mandatory for all shipowners.

The damage that has been caused to aquatic flora and fauna on a global scale over the past three decades is estimated at $ 4-5 trillion, which cannot be accurately quantified. Cargo transportation by sea and river fleet from year to year, practically increases in all directions of the sea routes of the World Ocean, with the exception of the period of the global pandemic Covid-19, there is a steady decline. The intensity of cargo transportation by water assumes a significant increase in ballast water discharge and reception in different parts of the World Ocean – this is dictated by the safety of navigation. After unloading cargo in ports, the draft of the vessel is significantly reduced, which leads to a violation of its stability, and in order to restore this stability, the vessel takes outboard water into the ballast tanks, thereby increasing the draft. The frequency of ballasting and deballasting depends on the intensity of the work of the vessel and weather conditions. During this period of ballast operations, the plankton, zooplankton, neoplankton, and phytoplankton, which is the food for many fish and marine animals, move but there is also another side of the danger of its migration in ballast waters. This danger is associated with its survival in an alien habitat, where it mercilessly destroys the flora and fauna, causing irreparable damage to the economy and ecology of many countries of the world.

Cite this Article as: Nataliia TIRON-VOROBIOVA, Anatoliy DANYLYAN, Valentyn CHYMSHYR, Igor MASLOV, Andrii NAYDYONOV and Olha ROMANOVSKA "Scrum Solo: Application in Projects with a Strong Integration Component" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In the process of implementing the new requirements for the ballast water of sea vessels, unique installations have appeared to destroy various invasive bioorganisms, harmful viruses, the latter being extremely dangerous for human life and health. Suffice it to recall the dire consequences of the cholera pandemic in the period 70-71 years of the 20th century, raging simultaneously in different parts of the world: Ukraine, Odessa region, the coast of Peru, the islands of Haiti and a number of African countries. *Cholera vibrio* in these countries was in coastal waters for a long time, constantly threatening the population. Undoubtedly, it can be concluded that simultaneous contamination could only occur when ballast water was discharged from sea vessels with a clear violation of the discharge distance from the coastal zone. Detection of the hepatitis virus in sea waters is quite frequent, and modern installations certified by the IMO and international supervisory authorities are capable of destroying them. In this regard, it is appropriate to recall the information received from scientific sources that the Covid-19 virus survives in wastewater for 48 hours and its entry into the body of aquatic fauna, waterfowl is unpredictable in its consequences.

Presentation of The Main Material

The main problem that the authors of the article raise in this work is relevant today in all countries involved in sea transportation. The purity of the water space and the ecological health of the flora and fauna of the World Ocean can be possible only with a sharp decrease in the migration of various invasions in the ballast waters of ships. Statistics and analytics constantly carried out by IMO, speaks of significant volumes of transported ballast water, it is about 5 billion tons per year, and 1 m3 of ballast contains about 50 thousand species of zooplankton, which causes irreparable damage to marine and river fauna, it is more than 200 billion dollars per year. In the Azov-Black Sea basin Russia and Ukraine have reduced the catch of sturgeon and mullet over the past decade by 12 times, completely disappeared: the Black Sea ancheus, chirus, flounder in the Black Sea have become a rarity. Canada during this period, has reduced the catch of sturgeon more than 5 times, the Atlantic from year to year, reduces the catch of valuable fish species, which brought billions of dollars in profits to the leading fishing countries.

Phenomena such as the massive release of whales and dolphins on the shore caused the disruption of the location apparatus of these sea animals, where parasitic worms penetrate and block its work. Colonies of these worms are constantly found in ballast waters when samples are taken on ships by onshore laboratories.

The latest IMO requirements, which regulate the quality of ballast water for ballast water discharge in accordance with International Regulation D-2 with the wording: Ballast Water Treatment System (BWTS), also determine the terms for the conversion of ships until 2024. In this regard, at present, more than 70 thousand sea vessels are subject to complete reconstruction of the ballast system.

According to our calculations, the financial costs in the segments of the world marine fleet are: TAM (Total Addressable Market) – total target market – 4.9 billion dollars; SAM (Served / Serviceable Available Market) – available market size – $ 1.47 billion; SOM (Serviceable and Obtainable market) – realistically achievable market size – $ 0.3 billion [2]. The last meaning determines the real possibilities of the ship repair facilities of Ukraine for the re-equipment of the ballast system of sea vessels. Currently, the shipyards of Ukraine have successfully begun this work, having re-equipped 6 sea vessels of foreign companies, there is a fairly large volume of incoming orders from ship owners in future. This big work in the World Marine Fleet is due to be completed in September 2024.

The scientific and engineering team of the Danube Institute of National University "Odessa Maritime Academy" (DI NU "OMA"), created the installation in accordance with the new requirements of Rule D-2, which was patented and successfully tested in the laboratory of the institute [3].

Fig. 1: Installation for purification and disinfection of ballast water, developed in the DI NU "OMA"

1 – dispenser of chemicals; 2 – ballast tank; 3 – coarse filter; 4 – ballast pump; 5 – unit ultraviolet UV radiation; 6 – block of electrohydraulic impact; 7 – self-emptying nanofilter for fine cleaning; 8 – stop valves of the ballast system; 9 – electric gate valve EA-220; 10 – pressure sensor [4]

In Fig. 1. a schematic diagram of the installation of a sea vessel, proposed by the developers of the institute, is shown. On any seagoing vessel, the amount of ballast is up to 30% its deadweight, and the time for complete ballasting of the vessel takes 10-14 hours, which requires, with the installation of new modern systems for cleaning and disinfecting ship ballast, in no way to reduce productivity and not to increase the time for receiving ballast and discharging it. Ballast is received directly from the ballast tanks, where the ballast water is preliminarily treated with special reagents. Now hypochlorite is widely used instead of chlorine, which actively destroys the metal of ballast tanks by corrosion. According to the patent, we proposed to use iron chelate, which is several times superior in its action to hypochlorite, without exceeding it in price. From the ballast tank through a coarse filter with a screening out of large invasive bioorganisms of 300 microns or more, then it passes water through a pump, which creates a pressure in the ballast system of no more than 3 bar, disinfecting water through a cassette set of UV lamps located in the direction of water movement, which then enters the electric hydraulic shock unit where there are constant pulsating electric discharges in the form of lightning, which can destroy most of the living microorganisms in the ballast water. The next stage of processing begins in the nanofilter with automated cleaning of its filter elements by blowing them with compressed air. The created filter is able to purify water by screening out various inclusions up to 2-3 nanometers, without significantly increasing the resistance to water movement. Purified and disinfected water is discharged overboard.

In the process of testing the installation, an ozone generator was additionally introduced, which made it possible not to use the remaining expensive modules: nanofilter and electrohydraulic shock. The developers of the installation proceeded from the concept of sufficiency and cost savings. In this simplified form, the installation reached ballast water treatment rates in full compliance with the new Regulation D-2. This begs the question: "Why were the other two modules designed?" Analyzing the situation with the constant tightening of requirements for the ballast water of ships (every 5 years), and understanding the growing costs of re-equipment of the ballast system, it became obvious to create a universal installation taking into account the growing requirements. The Covid-19 pandemic also made adjustments to the creation of a full-fledged installation. It became known that viruses, dangerous to human life and health, are widely spread in ballast waters. The versatility of the installation is confirmed by its ability to disinfect waste water using the other two modules, which gives a complete guarantee of the destruction of the entire line of viruses. Scaling the size of the installation taking into account its performance, it can be successfully applied at the wastewater treatment plant of any metropolis.

At the beginning of this year, the development team of the installation of the DI NU "OMA" tried their hand at YEP Starter – the International Entrepreneurship Program, putting forward their own project "BWTS" (Ballast Water Treatment System). YEP Starter is a 3-month startup incubation program supported by the United States Agency for International Development. USAID is an independent government organization run directly by the US Secretary of State. The startup was supported by the Ministry of Education and Science of Ukraine, the Ministry of Foreign Affairs of Estonia and the University of Tartu, and the Ministry of Digital Transformation of Ukraine. For 3 months, the institute team diligently performed various tasks, attended lectures and used the acquired knowledge to develop their project. The team successfully passed the YEP Starter incubation program and received a prize in the form of Personal Mentorship, the team was invited to take part in the next stage – the PreAcceleration Program [5].

The Izmail shipyard showed interest in the production of the installation under the patent of the institute developers, providing partial financial assistance in the creation of a laboratory installation, which made it possible to conduct research in a simplified version using two modules (UV and ozone module), this showed the effectiveness of the created laboratory installation in accordance with the new requirements. Due to financial difficulties, the developers of the Danube Institute cannot continue in-depth research using the other two modules. One of them – the module of electrohydroimpulse at present will be replaced by a module of a nanosecond corona multipulse electric discharge, which specialists of the Institute are currently working on. The new module is able to improve the quality of ballast water disinfection until the complete destruction of the entire line of viruses. Tests carried out in one of the laboratories in Ukraine showed the complete destruction of *E. coli* colonies in water. The consumed electricity for disinfection of $1m^3$ of water is reduced by 3 times and amounts to 0.1 kW, which in ship conditions for an average large-tonnage vessel will amount to 2 thousand kW of power of marine diesel generators 1300 kW of electricity savings, which is equal to saving diesel fuel for 1 hour of operation of the new module – 260 liters, or $ 205.

Research and development work on the installation continues, the developers are improving the installation, having received the approval of the management of the Izmail shipyard, which is currently re-equipping sea vessels with foreign-made installations, which are supplied directly by the ship owner. All the installations installed by the factory belong to Wärtsila, they are recognized in the World shipping market as the most reliable and high quality ones. The selling price of this installation is too expensive and not affordable for many shipowners. Today, the scientists and engineers of the institute are faced with the most important task to achieve complete superiority of the domestic installation not only in terms of performance, but also in price, in contrast to foreign analogues. For this purpose, in the first approximation, the price of our installation was calculated for its production at the Izmail shipyard. The new legislation of Ukraine in 2020 on taxation of private industrial enterprises of the category of an existing plant was taken into account, where the list of taxes includes the following items: the rate of income tax – 18%; military tax – 1.5%; tax on dividends – 5%; value added tax (VAT) – 20% of the amount of sold products, but after the goods cross the border, the amount of VAT is refunded to the payer; unified social contribution (USC) – 22% from the wage fund; environmental taxation (ecotax) – 1% of the profit.

Factory calculation of monthly installation production costs [6]:
1. Pipeline and fittings - $ USA 3000
2. Automation equipment - $ USA 6000
3. Installation of an ultrahigh corona electric pulse voltage 50 000 kW. - $ USA 50,000
4. Self-discharging nanofilter - $ USA 35,000
5. Ozone installation - $ USA 25,000
6. Ultraviolet UV disinfectant - $ USA 10,000
7. Chemicals for the trial period - $ USA 2000
8. Materials for electrical installation work - $ USA 8000
9. Indirect costs - $ USA 10,000
10. Creation of design and working technical documentation - $ USA 5000
11. Wage fund for workers in various specialties (10 people) - $ USA 10,000.

Total: $ USA 169,000 price with a full set of installation modules.

The calculation of profit is obtained from the difference in the base price of similar installations on the World market, taking into account the deadweight of the vessel, which can be taken with a certain error as the average market price of $ USA 250,000, then 250,000 - 169,000 = $ USA 81,000. From the profit received, it is necessary to pay general taxes 26% = $ USA 21,060 then the net profit will be 81,000 - 21060 = $ USA 59,940, which is quite consistent with the European level of profitability. In Ukraine, the selling price of manufactured products can be set by the manufacturer, which is often not justified when, in the pursuit of excess profits, a non-marketable price is set and the goods lose their liquidity. It is obvious from the calculations that it is more profitable for the plant to produce our installation in a simplified version without two innovative modules.

In creating their own installation, the developers of the institute analyzed in detail a number of foreign analogues such as: Optimarin (Norway), OBS / OBS, Alfa Laval (Sweden), Pure Ballast 3, TeamTec OceanSaver AS, Ocean Saver, Sunrui (China), Bal Clor, Ecochlor , Inc (USA), Ecochlor, Erma First (Greece), Erma First FIT and others. The result of the analysis showed that many foreign installations are focused on the D-2 standards with no prospect for the next 5 years after 2024 [7-9].

Conclusion

The installation developed and patented by the developers of the DI NU "OMA" based on the results of laboratory studies, has shown its competitiveness in the BWTS market in its simplified version. The installation flexibility allows to use a full set of modules without additional configuration, by automatically connecting and disconnecting them. This installation, with a certain scale of it, is capable of disinfecting and purifying wastewater from city sewage treatment plants. With the use of a corona nanosecond electric pulse discharge, this installation (its module) is able to reduce the energy consumption of ship power plants by three times. The use of an innovative module of an electric pulse discharge will destroy the entire line of harmful viruses that are dangerous to human health and life.

The Changing Role of Human Resource Management

Daniela MARGARIT(RUSE)
Polytechnic University, Bucharest, Romania
Email:rusedaniela@yahoo.com

Liviu Daniel GHICULESCU,
Polytechnic University, Bucharest, Romania
Email: daniel.ghiculescu@upb.ro

Abstract

Given that resistance to change can play a major role in determining how a company operates, it is necessary for those involved in change management to find solutions to avoid mass resistance when a change occurs. The most important aspect to consider is the communication about the need for change, the impact and the benefits it brings to the organization as a whole.

Keywords: Human Resources Management, Companies, Teleworking, Employers.

Introduction

People are the common and vital resource of all organizations, are the ones who ensure survival and development in a long chain of competition, in all areas. Resistance is a natural reaction of employees when faced with changes.

Change is uncomfortable and requires, every time, new ways of thinking and performing tasks at work, mentioned in "Management.How you can reduce employee resistance to change"

https://www.colorful.hr.

Human resources specialists believe that a good management of change must aim to create a favorable environment and anticipate employees' needs in transit periods. Human resources management encompasses most of the human-oriented activities, with objectives from the conception, design, use, maintenance and socio-human development.

Change generally requires continuous adjustment of life. The process of change is often irreversible, moving the individual from the state of comfort to an aspirational one and realizing a dream. In an organization, things are absolutely the same, the small difference being its size and its ability to adapt to external conditions, from the environment in which people work while maintaining internal stability. You don't have to be a visionary for the change-stability relationship to be balanced, the identity of the organization is important, the flexibility to adapt to advanced technologies and the existence of an employee reward system that equally reflects priorities, organizational values, as well as the needs of individuals that forms the organization.

Human Resources Management in Romania

Human resources management encompasses most human-oriented activities, having objectives derived from the conception, design, use, maintenance and socio-human development. This type of management has evolved substantially, has developed high competence in multiple ways. Most organizations use human resources specialists, by outsourcing this service, which, in the past, was a self-standing department within the entity and directly subordinated to its management.

A number of activities are carried out to ensure long-term and beneficial relationships between the employee and the employer. These activities developed in Romania immediately after opening the borders and with the Romanian market being captivated by multinationals and brands with capital and conduct, allowing management to develop in all aspects. Human resources management existed in Romania, but it was not called so, nor did it have an acute

Cite this Article as: Daniela MARGARIT(RUSE) and Liviu Daniel GHICULESCU "The Changing Role of Human Resource Management" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

need to direct and orient the human resource and is mentioned in the book “Human resources management” written by Păunescu I. (2000).

Human resources management has evolved substantially, has developed high competence in multiple ways. Specialists develop methods of finding and hiring people with the required skills, looking at the organization's future projects and trends, the number of employees needed and the type of skills and competences that any vacancies require. All this work is the definition of human resources management, more precisely, all the activities oriented to the provision, development, motivation and maintenance of human resources within the organization, in order to achieving, with maximum efficiency, its objectives and meeting employees' needs.

Rigorous human resource management requires effectiveness in activities relating to:

- the flow of staff – which involves not only recruitment and selection, but also the pursuit of post adaptation socialization, internal promotion;
- leaving the organization;
- performance evaluation;
- feeds-back, both from the business entity seeking personnel and from the employees, whether personal, team or organizational objectives are achieved or not, rewards and benefits;
- defining posts, organization chart, areas of responsibility, training teams or working groups and training of employees;
- keeping employees engaged and involved in decision-making activities, the development of bottom-up and top-down communication, maintenance of procedural accuracy and organizational ethics, mentioned in “Labor force in Romania. Employment and unemployment in 2019”, National Institute of Statistics, https://insse.ro/cms/ro.

These tasks can only be successfully completed if there is "someone" (a person, team or department) capable of, at least, to:

- identify how organizational objectives can be understood and interpreted in their interdependency to the level of the objectives of each individual employee;
- understand and identify the internal drivers of employees;
- identify the need of knowledge and skills necessary for the staff to achieve the objectives;
- establish the set of measures, to optimize them (understanding the nature of all organization activities and methods of professional development of employees);
- know how to serve all the skills of the employees to the organization and take steps to reduce thosebehaviors that are at odds with the goals of the organization.

The gap between the quality of employees and organizational objectives, between the goals of the employees and those of the organization, it is what human resources management really means.

Most of the time the organization goals change much faster than people's ability to adapt to these changes and is mentioned in the book “Human resources management” written by Păunescu I. (2000). As it grows and develops, any organization faces problems with the need for human resources.

The objectives pursued by human resources management are:

- Increasing efficiency and effectiveness of staff (increase of the productivity);
- Reducing absenteeism, fluctuation and the magnitude and number of striking movements;
- Increase employee work satisfaction;
- Increase the capacity to innovate, solve problems and change the organization.

The statement that human resources management is the only road to success is certainly exaggerated, but it is perfectly true that a just management of human resource allows to obtain competitive advantages that can place the firm in a higher position on the market.

The management of the change

As for any need involving a process of finding problems and identifying solutions and for change, there is a management that has the same feature as research and finding the problem, finding the right solutions, solving and moving from the current state to the desired state. In the situation addressed, the focus is on the broader impact of

change in particular, on people and how they, as individuals and teams move from the current situation to the new one, mentioned in "Management change" 5 principles of organizational strategy, https://www.austral.ro/blog.
The change in question could vary from a simple process change to major changes in the company policy or the change of the required strategy, if the organization wants to reach new limits. In the management of the change, it is important to realize that there will be a response to change and let's think about the reaction in the report with the change, passive - we're waiting to see what's happening or active - we're engaged to achieve the desired goal.

When an organization opposes change, it often means that it agrees to achieve a goal in one way, the one originally proposed or the one the organization is already accustomed to. But the adaptation of an organization to change is influenced by two main aspects: our expectations of a certain situation and what happens in reality. The greater the difference between the two, the harder it is for us to adapt. Organizations capable of adapting will prosper in conditions of uncertainty and chaos. Companies run by leaders with an adaptable attitude will not complain of failures, they will recognize the situation, learn from mistakes and then continue to go further (fig.1).

Fig. 1: Categories of interest that control the process of change is mentioned in the article: (2015)" The *role of* human resources management in the context of change" [online] accessed May 2020 http://andrei.clubcisco.ro

Human resources in Romania in the context of the pandemic crisis.

Changes in the structure of society as a whole but also in the way companies operate, have put a mark on work organization (open-ended, full-time and fixed-time employment contracts), which are abandoned in favor of new flexible forms of work that benefit both the employer and the employee.

Although the legislation is constantly amending and supplementing, flexible forms of work such as teleworking or home-work, in the context of the pandemic crisis of COVID 19, have partially resolved the continuity and balance in the economy, mentioned in "Labor force in Romania. Employment and unemployment in 2019", National Institute of Statistics, https://insse.ro/cms/ro

However, the rules to be followed in order to implement these flexible forms of work create numerous problems. Not all employees are ready for such work, cannot adapt and individual employment contracts don't have rigorous clauses in this respect. Flexibility at work has several advantages for employee, the salary package is becoming more complex and more tailored to market needs, negotiation power is transferred from the employer to the employee, costs are more effective and improves employee satisfaction and is mentioned in the book *The New York Talent Management Manual: Recreation Organizational Excellence Handbook*, written by Berger, D et al (2003). In addition, mobility also has benefits in kind with favorable tax treatment: "gift tickets, car usage for personal purposes or holiday vouchers".

Not all areas are ready to adopt this kind of work. Not all employees are ready to work from home. At this time, changes have taken place in every respect worldwide. The imminent threat of an unknown enemy, in this case SARS-type virus, its way of spreading determined long series of decrees to force companies to adopt measures in order to make the employees activity more flexible. But here is how a crisis situation puts a sufficiently high pressure so it can force us to find quick solutions, and this acceleration of what is shown, in many respects, to be progress (the best example is the digitization of some procedures and services), will bring long-term benefits.

It is also true that for very many employers not much will change, not if the legislation does not make the necessary updates and changes. Not all firms will want to invest in more effective measures to protect employees from the risk of contamination, and the likely fines from ITM(Territorial Labour Inspectorate) will not prove viable unless there are clear provisions in the law.

Although we do not like it, in the next few months and even more, social distancing will say its word, we will still have to try to work without exaggerating in terms of socialization and avoiding larger groups of people. Therefore, work at home will be kept high, because there will also be many employees who will request to continue working from home, out of fear of being left without work, or of fear of illness.

Moreover, companies have had the opportunity to test the extent to which employees can do their work from home and also assess the extent to which this change has been cost-effective for the company. Investment in people has proved to have a good effect over time. The employee felt valued and made more effort to develop the company. Valuable individuals understood that they can grow with the business, being motivated in all respects.

Those who did not agree with the company's policy or did not comply with the requirements of the management, were willing to leave, to star over under other conditions and the remaining ones have helped to solve some difficult situations the company faced. This approach, based on investment in current employees, has good long-term effects. Filling vacant positions will be easier because employees will have other roles in the company, some of the more important ones they could only dreamed of and they are now doing it with passion, mentioned in "European Union law", https://eur-lex.europa.eu.

In addition, they have already adapted to the working environment and have already delivered results in a certain area, so they are more likely to manage in a new one. In this way you can prevent problems that may arise when hiring a new employees, like the inappropriate attitude, the lack of flexibility or the lack of focus on results, because you already know them.

More than 51% of the companies made portable devices available to employees, which allows internet connection via telephone networks for business purposes and over 85% use computing techniques, like personal computers, desktops, portable computers, tablets or smartphones and is mentioned in the book *General Community Law*, written by Tancu, D. (2007).

These data relate in particular to enterprises with more than 10 employees, with main activity in manufacturing, construction, trade and services. Thus for those companies which insured the transport of employees or settled travel payments, for those offering a warm meal, or 1-3 hours of disconnection in the gym, for those who paid exorbitant rents for large spaces, ensuring all the comfort to their employees, for them there were certainly cost reductions from the start.

For employees who did not receive such benefits, there was an increase in income, the latter having no longer to pay for the daily transport to and from the place of work, eliminating the daily costs of lunch, the stress of waiting at public transport stations, the daily temptation to buy "something" seen at a colleague or suggested by a tiring ad. This is another factor that will make many employees to take home work into account, even after the end of the state of emergency, and companies should be prepared and open to such proposals.

Large companies have given up large offices, using virtual offices where only one employee takes orders, answer the messages, receive the mail and distribute it diligently. Companies can reinvest the money saved in new technologies that make work at home easier, communication with employees, business partners and even customers. It is already expected to be registered, in the next year, a major increase of people who will still want to work from home and companies wishing to keep their employees will have to accept such requests and remember the recent lesson: only those who adapt quickly are overcoming the crisis.

Many employers have been unconfident about telework or work at home, but this crisis has driven out skepticism for many of them. They had the opportunity to test, see and convince themselves that work from home comes with more benefits and that doesn't mean that those working from home no longer work or are no longer as efficient. On the contrary, in countless situations, and again depending on each field, work at home will be much more efficient for many employees and will bring much better results to the company. It is a time when attempts are being made to preserve business and to invent ways of resisting.

The increasingly common career process, the professional retraining which occurs when we, as people, want a partial or total change in the field of activity which is increasingly taking place at a time of crisis. Reconfiguring the professional road when we believe we have chosen the wrong road, it no longer applies at this time, although we believe that we have potential and ideas for another area, we have no choice now. What is happening in the labor market was a rapid learning process in crisis conditions but a process that will benefit those companies that have understood how much this transformation can help them, or they will hasten the end of the inadaptable ones mentioned in the article *Europe, from one way ticket to migration in a circuit from one state to another*,written by Bechir, M. in Adevărul newspaper.

Many of the companies that were not ready for work from home and they have not even made any efforts to digitize quickly, to ensure that they support their employees in terms of work at home, have seen a drop in labor productivity. Due to the situation created by the pandemic, the closure of some businesses, the rethinking of others, the migrant workforce returned to the country. At this point, the restart of the economy is being considered, so we will have to have a plan with arguments prepared and a speech explaining the benefits of these changes, especially because of the trend of people, generally speaking, to be closed to the new and to resist change and is mentioned in the book *Labor market, restructuring, employment, unemployment*, written by Osoian, C. (2005).

Automation and modern technologies will speak more and more.The flexibility of working hours will no longer be for most of the companies just a way to try mark a trend, somewhere in the distant future, but a concrete reality demanded not only by employees, but also by legislation.

Change - the survival of organizations

It is known or more understood that the survival of an organization depends on change, which can be divided into four levels (fig.2):

- change in knowledge,
- a change in attitude,
- how to change the behavior of individuals
- as well as changes in the behavior of the group or organization.

Fig. 2: The relationship "Time - Difficulty" in producing a change is mentioned in the article (2015) "*The role of* human resources management in the context of change" [online] accessed May 2020 http://andrei.clubcisco.ro

The easiest changes to make are with knowledge, followed by changes in attitude. Attitude structure differs from knowledge structure, knowing that they are emotionally positive or negative. As far as behavioral changes are concerned, they are much more difficult and time consuming than the other two mentioned above. Changes in group and organizational performance are probably the most difficult and time consuming. The survival of an organization may therefore depend on the degree to which behavioral sciences are able to resolve conflicts between understanding change and implementing it, mentioned in "Management change" 5 principles of organizational strategy, https://www.austral.ro/blog .

Control of the change process

We seem to tend to believe that organizations are the ones changing but in reality change is always achieved by people, which is why to achieve effective change, the focus is primarily put on people.

William Bridges – who dedicated his career to research into how change affects us – says "changes are not the problem, but the transition. The change is a new laptop. The transition is the attempt to use it."

Change means doing things differently, seeing things in a new way, adapting to surprises and ideas with unexpected results.

Any significant transformation first creates "problems" to the people and then to the organisations in which they work. Jobs are changing, new skills and capabilities need to be developed and employees will find themselves in an uncertain situation. Responding to these problems in a reactive way, on a case-by-case basis, puts the speed, morale and results of a team at risk.

Principles of the basic change

The goal setting helps to establish performance indicators and how to measure the achievement of the goal. This also involves identifying the resources and people who will facilitate the process and support the team's effort. When you establish a solid basis in the process of change, you will have more clarity and ease for successful implementation.

The power of example - the top of the organization

Because change is inherently difficult for people at all levels of an organization, when you are in the process, all eyes will head to the CEO and leadership team for help, support and direction. The leaders themselves must first adopt the new changes to motivate the rest of the team by example.

Planning

Regardless of the size and impact of what is changing, a more or less formal, flexible plan is needed to ensure the operation of the measures. The establishment of human resources is the first step in the plan and the time allocated for implementation is also done at this stage.

Communication

The best decisions are made through communication, an attitude that strengthens the team and helps them understand and implement the new situation. Top-down communications are designed to provide employees with the right information at the right time and request information and feedback.

Monitoring

In the process of change, it is important to make sure that actions happen as planned, or at least that you are informed when things do not work as planned. At this stage, make sure that the budget, the allotted time, and the quality indicators you have set are respected. Also the change brings with it a lot of resistance from people, make sure that they have constant support in going beyond this stage.

Anticipate the unknown

No program of change is exactly in line with your plan, no matter how well it is made and perhaps this unpredictability is precisely the charm of the changes.

Reward the success

The work team will feel appreciated, proud of the effort, will feel that their work has counted and will be much more motivated to deal with future changes in a proactive and enthusiastic way.

Clear Goals, Major Changes

While they are constantly changing, the goals of HR management show that an increasing number of employers have taken significant steps in the process of managing change through specific activities of human resources management. Most of the time, the training process is considered decisive in this effort. The long-term objective is to make all workers aware of the reality of change and the need to work together regardless of the differences between partners.

Attracting the human resource, the potential skilled for each job, provides an increasing number of contemporary employers with the possibility of better control and further reducing operating costs. Keeping specialists for as long as possible so that investment in their training and specialization can be amortized is another important objective.

The potential advantage is to reduce fluctuation and increase efficiency, continuity and productivity. Different schemes of change are being developed, flexible working hours, the traditional time of start and end of the daily 8-hour program may vary, short working week (compressed), distance work (home).

An indicator by which the effect of a positive environment in the organization can be measured is the quality of life of employees and their jobs. Quality of life can be defined as the degree to which employees can meet their needs (self-esteem, sentimental belonging and self-realization) at work. In these circumstances, it is an effective human resources management department that provides the process of motivating workers to induce a desire to achieve performance and provides stability for staff.

Last but not least, the motivation, the establishment of forms of direct, indirect and performance criteria reward is a clear and constantly changing objective. Ensuring the quality of working conditions through participatory and responsible involvement in the work, achieving adequate satisfaction, reducing stress and accidents at work or occupational disease hazards, make that organization a wanted one, making the role of the HR manager much easier.

The human resources policy formulated by the organization's management, guides the work of each employee. This requires the elements of this policy to be detailed and implemented at every level of the hierarchy. The establishment of a fair human resources policy must take into account the importance of human resources, the responsibility of the management and the objectives in this area.

Conclusions

At a time when most companies are facing great problems with human resources and when statistics rank us as the top of the export of skilled personnel, it is important to clarify what is going on and what direction to follow in the area of human resources, mentioned in "Professions, employees and employers face-to-face-to-digitization", https://www.zf.ro.

The world of human resources is extremely dynamic, so it is good not to approach forecasts for long periods. However, the next period will continue to be in a growing shortage of staff, the statistics on
the departure of Romanian workers from the country continue to remain at the same level, so the range of options for employers will remain at most as small.

The importance of human resources and their management will increase as a result of the companies demand, which have reduced their activity and have chosen to resist or develop other lines. The need for people is not simple, it comes to a package with qualifications and motivation.

If the workforce chooses to leave, we will import work from outside the European Union to cover immediate needs, but with fabulous costs for employers.

Small and large firms will approach the motivation technique for ambitious young people who want to feel that they make the difference, that the purpose of the work is respected and due to them. It is true that large organizations do not have concurrent on the motivational chapter, they offer in addition to stability, salaries and benefit packages that are more attractive to a young individual. As always, fair reward for work, recognition and appreciation, investment in training and development, the fact that man is man and can be wrong will be successful.

People are in constant search, are being eaten by the illusion of a higher salary, but they also want a balanced working time, they want conditions, they want respect, they want flexibility and they want to get to work easily. Qualities, and if he approaches, the individual cannot adapt then he has a choice, resists (not much) and does not yield, or goes into a new search.

At the time of this work, the effect of the coronavirus pandemic changes a lot of life at work in some cases forever.

In Romania, however, telework was the common alternative during the pandemic, whereby employees continued their work from home. Many employers have convinced themselves that work from home can be at least as productive as work at office. Of course, it cannot be carried out permanently, but digitization could be, in the future, another approach to avoid human contact in the event of a health emergency. And this could rethink the entire organization chart of companies and institutions.

The current situation has happened unexpectedly and suddenly, tens of millions of people around the world have been finding themselves in the situation of working at home the next day. The companies rushed to adopt fast remote work solutions, consisting mainly of video and conference platforms, alongside the phone, chat, WhatsApp,

email and collaborative solutions such as Google Docs, one Drive or similar. And in general, these platforms, plus some specialized on a case-by-case basis, have proved quick and easy to implement.

Beyond the logistical issue of their adoption and large-scale implementation (licensing purchases, initial user training, phone or laptop purchases or tablets in some cases), the real difficulty of making the transition to this way of working has proved to be different. One of the mindset and psychological adaptation.

We all received what we wanted (work from home) before the pandemic, but after a while it was no longer comfortable because it was not a choice was sudden imposition and without preparation. The human resource has adapted, we have found solutions for anything, simpler or more complex, cheaper or more expensive, but unfortunately not in all areas of the economy and is mentioned in the book *General Community Law*, written by Tancu, D. (2007). Employees will need to adapt to the new context, business travel will be significantly reduced, online meetings and videoconferencing become a normality and also show their efficiency, they may never recover again.

The fact is that in the coming period, companies will show more concern for employees, and so they will appear in the top of the most wanted jobs in the future. It is a quality that you can get very hard and that involves a fairly high cost of time, money and resources. As for the human resource, it has discovered dormant skills and competences, so it will have to adapt even more to evolve.

Development of Approaches to Ensuring Tax Security in The Region

Elena A. MURZINA

Volga state university of technology, Yoshkar-Ola, Russia, elena.murzina@gmail.com

Marina S. SHEMYAKINA

Volga state university of technology, Yoshkar-Ola, Russia, sh.marina.s@gmail.com

Abstract

The article reveals the tasks set before the formation of a tax control system in order to ensure the tax security of the region, the following: ensuring the established amounts of tax revenues to the budget, reducing tax arrears, increasing the effectiveness of tax control, improving the tax culture of taxpayers, implementing the principle of conscientious taxpayers, reducing the number of complaints and appeals of taxpayers. The author of this article considers it strategically important to increase the efficiency of tax control not through the application of tax sanctions, but through preliminary prevention of tax violations, informing taxpayers about potential risks, and building a comfortable business climate. The latter is especially relevant in the current epidemiological situation.

Keywords: Economic Security, Tax Security, Tax Control, Tax Security Risks, Tax Risk Management.

Introduction

Tax control tools ensure the effectiveness of the implemented regional tax policy. The strategic result of its development is an increase in tax revenues going to the budget, as well as the prevention of tax risks and threats. The level of tax security of the regions depends on the efficiency of organizing the implementation of tax control.

The main activity of the tax authorities at present can be designated cameral control, which involves conducting more detailed tax audits. The tax authorities of the constituent entities of the Russian Federation use automated cameral controls. The effectiveness of the on-site inspection depends on the quality of the desk audit, since a plan of the on-site audit is formed based on the results of the desk inspections.

Monitoring, collection of indirect information and its assessment are given an important place during the audit. In particular, on the basis of information obtained from external sources, the directions of actions of the tax authorities are determined.

It is not always possible to bring the taxpayer to justice. With the system of responsibility currently in force, many participants in tax relations, from an economic point of view, it is more profitable to apply the scheme of tax evasion, even if there is a risk of prosecution. In this case, the tax authorities need to analyze tax optimization schemes in order to form and apply measures to prevent and eliminate the identified tax violations.

Review of literature

Considering the current state of research on the selected topic, we note the following. Among Russian scientists, theoretical and practical aspects of state support were considered with varying degrees of completeness in the works of O. Ponomareva (2017), V.I. Boboshko. (2017), Bykovskaya Yu.V., Ivanova L.N., Safokhina E.A. (2018) and a number of others. The named authors focus on certain aspects of the state support mechanism, including its individual measures. The issues of assessing the effectiveness of state support are raised in the works of V. Barinova (2018), E.R. Dadashev. (2020), Baranova S.V. and her co-authors (2020).

Including in the context of a coronavirus pandemic in the work of N.S. Bezugloy. and Shamray I.N. (2020). To a lesser extent, the system of assessing state support for small business has been studied in the work of S.A. Anokhina. (2020). It seems interesting to study the dynamics of indicators of small business activity in the regions of the Russian Federation using neural network modeling of small business entities Yu.V. Kuznetsova. (2017; 2020) and Perova V.I. (2020). Nevertheless, the proposed method can only identify regions with a low level of clustering of small business entities, but not the effectiveness of state support in relation to these entities. It should be noted that some authors made attempts to form a certain integral indicator reflecting the level of formation and dynamics of development of the small business sector (Burov V.Yu., Kaibalina N.B. & Ortykov A.U. (2020)). This is undoubtedly of interest, but it is not comprehensive and does not reflect the effectiveness of government support. An interesting study summarizing government support measures is the Review of international practice of supporting the economy and

Cite this Article as: Elena A. MURZINA and Marina S. SHEMYAKINA" Development of Approaches to Ensuring Tax Security in The Region" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the population in the fight against the coronavirus pandemic, which was prepared by a team of scientists from the Institute for Social Policy of the HSE University (2020).

It can be noted that in Russian studies, it is precisely the integrated approach to the methodological provision of state support that is not sufficiently represented, and many problematic issues still require comprehension and search for new scientific approaches, including the absence of an economic and mathematical justification for the conscientiousness of an entrepreneur's behavior.

Foreign authors in their research focus on efficiency criteria (economic, social, budgetary) (Sternberg R. (2017), Kadirbeyoğlu, Z., Adaman, F., Özkaynak, B., & Paker, H. (2017)). For example, Fuller T., Moran P. (2016) distinguishes such a criterion as the significance of government support measures among its recipients. Speaking about the practical implementation of the results of foreign research, it is especially worth highlighting the PART (Program assessment rating tool) system (USA), aimed at monitoring and assessing the effectiveness of state support. This system is complex in nature, summarizes a significant amount of factor indicators and gives, as a result, a report on the effectiveness of state targeted support programs. Nevertheless, this program allows you to analyze the results as a fait accompli, but not to form preliminary forecast values of the effectiveness of state support.

It is planned to use the technology of distributed ledgers (blockchain) as the main toolkit for the implementation of the project. Blockchain has not received wide, deep coverage in scientific literature, especially the use of this technology in the sphere of the functioning of the system of state support for business entities. The main research in the field of distributed ledgers is focused on several projects, such as: Masterchain (2020), Waves (2020). However, none of them is considering the possibility of using it in the field of state support, methodological approaches to using this technology are also not being studied.

Methodology

Let us formulate the main provisions of the proposed approach to solving the problem.

Provision 1. Measures of state support for small and medium-sized businesses should be differentiated in relation to each region, their volume and content should be assessed from the standpoint of:

1) admissibility in each specific region in the context of ensuring the economic security of the region;

2) sufficiency for each specific business entity (and at the same time not be redundant);

3) the effect of the application should be determined by quantitative indicators.

Provision 2. A necessary condition for the effectiveness of state support should be the absence of abuse by the recipients of funds. The recipients of state support funds should be exclusively conscientious entrepreneurs - subjects of the ecosystem of small and medium enterprises. Accordingly, we propose to introduce, substantiate and quantify the category of “conscientious entrepreneur” for the purpose of obtaining state support. For this purpose it is proposed:

1. Explore the content of the category "conscientious entrepreneur". It should be noted that the term "good faith" also takes place at the legislative level: a) for example, it is found in the Civil Code of the Russian Federation, a number of other regulations), b) in tax legislation, the very concept of "good faith" is taken into account in relation to taxpayers (good faith or unscrupulous taxpayer).

2. Within the framework of our research, the sign of “conscientiousness” is considered not as a qualitative one, but primarily as a quantitative characteristic of an entrepreneur - a representative of small or medium-sized businesses. Accordingly, it is proposed to develop a system of quantitative indicators to assess the "good faith of an entrepreneur" and, as a result, the formation of a passport of a bona fide entrepreneur

3. A quantitative assessment of financial and economic activities and confirmation of the status of a bona fide entrepreneur is the basis for the provision of state support.

Provision 3. Balanced government support for the ecosystem of small and medium-sized enterprises should be built using distributed ledger technology (blockchain), which in relation to the task at hand has the following advantages:

a) the immutability of the entered initial data on potential recipients of state support;

b) a single format for the accumulation, systematization and analysis of data;

c) transparency of the registered information for all interested parties;

d) exclusion of corrupt practices when deciding on the provision of state support;

e) the possibility of registering information on the financial and economic activities of a business entity, coming from all controlling bodies of state power (subject to the gradual deployment of the all-Russian system);

f) the use of smart contracts to automate the procedures for determining recipients

g) the use of smart contracts to track the acceptable and sufficient volumes of government support;

h) the reliability and invariability of the effectiveness of the implemented measures of state support.

Общий план работы и ожидаемые результаты:

Results

Using the proposed methods, the following were obtained:

1. Scientific substantiation of the prospects and economic effect from the deployment of comprehensive balanced state support for the ecosystem of small and medium-sized businesses within the constituent entity of the Russian Federation, the Federal District, Russia. Formation of the methodological base of the study, substantiation of the use of economic and mathematical research methods and analytical tools of a comprehensive system of balanced state support for small and medium-sized enterprises, including the creation of its strategy that ensures sustainable socio-economic development of the region and its municipalities in the search for a balance of the regional ecosystem.

2. Analytical study of the use cases of distributed ledger technology (blockchain) for project tasks. Analysis of existing information and analytical systems used by government authorities for the implementation of distributed ledger technology. Determination of the optimal technological platform for solving the problems of providing balanced state support for the ecosystem of small and medium enterprises. Analysis taking into account the possibility of practical implementation of the use of smart contracts in the Etherium, Masterchain or Waves blockchain.

3. Development of basic principles for the application of a balanced state support system for small and medium-sized enterprises. Building a differentiated model for regulating the processes of state support for small and medium-sized enterprises, taking into account the socio-economic development of regions. Scientific substantiation of a differentiated approach to obtaining government support measures for small and medium-sized businesses, taking into account the entrepreneurial integrity index.

4. Research of the content of the category "conscientious entrepreneur" in order to develop a system of quantitative indicators of "conscientious entrepreneur".

Conclusion

Tax control tools ensure the effectiveness of the implemented regional tax policy. The strategic result of its development is an increase in tax revenues going to the budget, as well as the prevention of tax risks and threats. The level of tax security of the regions depends on the efficiency of organizing the implementation of tax control.

The main activity of the tax authorities at present can be designated cameral control, which involves conducting more detailed tax audits. The tax authorities of the constituent entities of the Russian Federation use automated cameral controls. The effectiveness of the on-site inspection depends on the quality of the desk audit, since a plan of the on-site audit is formed based on the results of the desk inspections.

Monitoring, collection of indirect information and its assessment are given an important place during the audit. In particular, on the basis of information obtained from external sources, the directions of actions of the tax authorities are determined.

Abstract

Music is an integral part of life, a major mark in representing the culture and tradition of a society. Tourism, being a globalized process bringing out different people together, takes hold of music too in its inter-disciplinary journey, through Music Tourism. Connecting people around the world through the music festivals, help in the sustainable development of the process of globalization. Music therapy, a major way of treatment, dated back to ancient Gods to the modernity, can also be considered as a major part of the cultural tourism. This study focuses on music, rather than being a mere art form, shares its part with tourism promoting equally in the entertainment arena, economic sphere and in the health-induced fields.

Keywords: Music, Music Tourism, Culture, Tradition, Music Therapy.

Introduction

Music, in all its rights has its universal way to mark the cultural expressions. It can be considered as one of the major factors affecting the culture and tradition of a society. It varies according to different cultures, which are cherished for their aesthetic values. Music has been bound basically to rituality and sociality. And so, music was considered as a performance of power, representing a particular group. Especially, while looking onto the cultural side of a group, music can be taken as an order of expressing their emotions in a proper way. Even though, it was given such an emphasis on that sphere, by now, music is seen as a part of our everyday lives, where most of the people are on an urge of being a part of music, via listening, singing, forming groups worldwide. The soothing effects the music produces, creates a relaxing atmosphere and paves the way for seeking pleasure through its performance**.**

While talking about the rituality and sociality of music, it has been a major factor defining the ritual side of a society. Music was used as a major source for ecclesiastical purposes, by the churchmen. And rather than focusing on its importance in the church, it was also used by certain tribal groups to express their emotions through their songs. As a matter of consideration, music for them was a way to celebrate their ritualistic performances, and for the minority groups, music was used as a weapon against the ones who opposes their freedom of rights. So music as a genre, is considered as evolved from culture and a part of culture, itself. Music, having a therapeutic implication, is a major arena where people look into for pleasure seeking, enjoyments, etc. And this ranges from the classical styles of music including the Western classics, Carnatic music and Hindustani music to the punk- rock styles which are being considered as the popular music forms of the time.

Discussion and Results

Music Tourism

Music tourism is a tourist entity where the people/tourists travels to a place to listen to music performed on festivals. This, as an entity has been promoted by many people all around the world, since it is not only considered as an entertainment arena, but also a way for the local authorities of the place at which the musical festival being held, to live through. During early times, music was basically accepted in its classical or traditional forms. But with the arrival of modernity, there happened a great distinction between classical and popular music. The upper class elites

went to see the musical performances in huge theatres on festivals. And by the time, the middle or lower classes get used to the hallway or street singing. As tourism as an institution started into being, music as a form of cultural art was also used as a medium to entertain people. Even though music had only been a way of entertainment, it was used as a way to make money too. Tours for the foreigners as part of music festivals were for the promotion of music, fan club and in achieving economic prosperity.

Music works as a narrative for the tourists since it shows out different cultures, and helps in a cultural interaction with the inter-disciplinary fields too. Since music passes out the boundaries, it attracts the tourists who come to know of the tradition of a particular place and identity. Music can be considered as a product of tourism, which can also be a tool to study it. World music genres and their importance in the Diaspora communities or Ethnic communities such as African, Caribbean, Indian, etc, should also be focused on, while talking about music tourism. The third world countries are the major ones who focus on the enhancement of this, due to their need of the appraisal of their own culture to the ones who battle against them and also in an urge to earn money. Music tourism can also be taken as a great opportunity for the ones around the world to establish themselves and showcase their talents. It also contributes the local employment of people over a place and in the promotion of their culture and tradition as well. This phase of tourism started out in the West and later on, was carried away by other countries too.

Major groups or music festivals to be mentioned are given below:

Name of Band/ Festival	**Place of origin**	**Year of origin**
Jam band phenomenon	California, US	1960
Summerfest	Milwaukee, US	1968
New Orleans Jazz and Heritage festival	New Orleans, US	1970
Rio Carnival	Brazil	1723
Notting Hill Carnival	London, UK	1966
Love Parade	Germany	1989
Montreal International Jazz Festival	Montreal, Canada	1980

Music tourism was also promoted in many states of India and the major musical festivals taking place annually, are as follows:

Name of Band/ Festival	**Place of origin**	**Year of Origin**
Desert Camping Festival	Thar Desert, Rajasthan	2018
Dhrupad Mela	Varanasi, Banaras	1989
Sunburn Festival	Vagator, Goa	2007
Ziro Festival of Music	Ziro Valley, Arunachal Pradesh	2012

Music Therapy and Cultural Tourism

As the Seventeenth Century playwright, William Congreve has said, 'Music has charms to soothe the savage breast, to soften rocks or bend a knotted oak'. Music therapy works accordingly, where music, as a medium is being used to address the emotional, physical and other needs of an individual or a group. This therapy not only helps in the treatment process of a particular aged people, but also for the people of all ages. A disturbed mind can be treated by making a distraction on it, with the soothing melodies, and that's what the music therapists do. Cultural tourism provides this sort of facilities for the tourists so that the long- travelled tourists could sit back, relax and have a relief on their stress. Also, the people who had to suffer from Stroke, head injuries, Alzheimer's disease, Autism, heart disease, Cancer, Dementia, etc are being treated with music, nowadays. The universal nature of music helps it to transcend the individuals across all background and ages.

The Receptive Music Therapy, which guides the patients to listen to live or recorded music and Active or Expressive Music Therapy, which engages the clients in the act of making music and producing songs ,are both being used in the tourist' sessions, where basically the tourism supports the former one, the most, because it is more time-saving

than the other. In Kerala, Swathithirunal Kalakendram Music Therapy Foundation at Kozhikode district is considered as a centre of music therapy, which beholds twenty years of experience. In the treatments over there, it is an interpersonal process in which therapist uses music and all its elements to help those undergoing pressure to maintain good health. The basic advantage of these kind of places or this particular therapy is that it helps in the reduction of a number of anaesthetics and the decrease in the length of proceedings, number of employees and equipments of high cost, and moreover an effective way for the reduction of stress, strain agitation, etc.

Music therapy is not a matter that has just happened to form, all of a sudden. But it was used as a healing implement for centuries. Apollo, Greek god of music and medicine, connected these two in the curing of diseases, followed by Aesculapius, who cured diseases of the mind by using song and music. And this same method was used in Egyptian temples too. Even in the Bible, David playing harp for King Saul has been mentioned, and then comes Hippocrates who had played music for mental patients. So music therapy is one of the effective ways used by the ancient legends and the ones now, to cure many mentally and physically ailed diseases, which can be more strongly recommended to be taken, a part of the cultural or music tourism, rather than just giving an inferior position.

Conclusion

Music can be one of the major cultural areas that the field of tourism has to rely on, since it is a part of the cultural space existing in the world that defines different societies, different people and different cultures. Tourism, basically an inter-global process, takes the help of music to be a part of the entertainment industry as well as in the promoting an economic prosperity for the third world countries. Music festivals conducted annually, or on a six- months' basis are given much importance by the tourists all around the world, because they find it a greater chance to get to know the other people and their culture. So it helps in an interaction around the globe, or maybe we can call it as an effective process of globalization too. Music therapy in tourism is also an effective way to attract the tiresome tourists, who wants to get a relief. Therapeutic sessions of music are being held nowadays, all around the globe, which also helps in promoting the inter-global relations and in the universal spread of peace and calm with the magical power of music.

Abstract

The current situation in the world economy is characterized by instability and lack of progressive movement towards social well-being. A sharp decline in interest rates and concessional government financing of large socially significant enterprises led to the emergence of enterprises that are highly likely to be unable to pay off their debts. The COVID-19 pandemic has led to an increase in the number of zombie businesses and an increase in their debt. It should also be noted the emergence in the world economy of states that are similar in their characteristics to zombie enterprises. The main distinguishing feature of these countries is the inability to pay off their debts through the economic activities of their economies, since the debt of these countries exceeds their annual GDP. At the same time, due to securitization, zombie enterprises and zombie countries issue various financial assets, including bonds, which are bought by solvent and well-known companies such as Apple. In this regard, it is relevant to search for a model for the distribution of zombie assets of economic entities.

Keywords: zombie enterprises, zombie countries, financial instruments, bonds, junk bonds, GDP, infection model

Introduction

The current economic situation is characterized by instability and lack of a stable movement towards general social well-being.

The situation has worsened significantly as the COVID-19 epidemic spreads around the world. Most enterprises around the world have experienced difficulties related to their economic activities. However, the scale of these difficulties is highly industry specific. For example, the majority of IT companies not only did not suffer, but were also able to increase sales volumes, since during the lockdown the consumption of services which can be obtained remotely increased. At the same time, travel service companies and airlines experienced a catastrophic drop in service volumes, and many were on the brink of financial ruin.

The financial crisis has made the problem of zombie companies urgent, which are companies that cannot pay off their existing debt, and the available income is used to pay off interest on loans.

For the first time, the concept of zombie companies appeared in connection with the outbreak of the financial crisis in Japan, when the bubble burst in the financial and real estate markets. Low interest rates gave rise to inefficient companies that, despite their inefficiency, continued to function. Also, Japanese banks, in the absence of highly profitable projects, continued to finance ineffective zombie enterprises. Also, Japanese banks found themselves in a situation where potentially large losses on previously issued loans forced banks to continue financing some of the zombie enterprises. All this led to the fact that in the early 2000s, the total share of zombie enterprises was about 30% of the total number of all Japanese enterprises. Zombie-owned assets accounted for 15% of all assets in the Japanese economy (Hoshi & Kashyap, 2011).

The largest number of zombie enterprises was observed in those sectors of the Japanese economy in which there was no fierce competition from foreign companies. In those industries in which there was significant competition from foreign companies, the number of zombie enterprises was lower.

Cite this Article as: Kirill Kurilov and Anastasia Kurilova "The Problem of Zombie Businesses in The Global Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

At the same time, zombie companies hindered their existence from the development of healthy companies by obtaining affordable financial resources and ensuring at their expense the hiring of qualified personnel with a higher salary. The increase in the number of zombie enterprises in a sector of the economy leads to the fact that viable companies are forced to reduce investment and hiring.

At the same time, the emergence and growth of zombie enterprises negatively affected the productivity of other enterprises. According to Caballero, Ricardo, Hoshi & Kashyap, 2008, the increase in the number of zombie companies in several sectors of the Japanese economy led to a drop in productivity in those sectors. Thus, the lack of market competition and the forces of "creative destruction" defined by Schumpeter led to a prolonged stagnation in the Japanese economy. If the Japanese government had not prevented the bankruptcy of inefficient enterprises, the economic growth, according to Caballero, Ricardo, Hoshi & Kashyap, 2008, would have been higher. For example, the Japanese economy in the 1990s grew by an average of 0.5% per year, while the US economy during this period grew by 2.6% per year. Thus, the Japanese government and banks by supporting economically inefficient enterprises, on the one hand, avoided a possible hard and short recession in the Japanese economy, and on the other hand, generated a new series of problems associated with a long gradual stagnation, a decrease in economic efficiency and a prolonged absence of economic growth for a long period.

Summing up the Japanese experience, we can draw conclusions about the reasons for the emergence of zombie companies.

Firstly, the main reason for the emergence of zombie companies is the low level of interest rates on attracted debt financing, which leads to a significant increase in the ratio of equity and debt capital, which, in the event of a tendency of rising interest rates, turns out to be one of the main reasons for the emergence of financially insolvent companies.

Secondly, an indirect reason for the appearance of zombie companies is the increase in the volume of bad loans in the composition of bank portfolios, while banks, in order to avoid declaring losses, continue to provide financing to insolvent companies in the hope that in the future their financial condition will improve and they will be able to return previously attracted debt financing and interest.

Third, it is the government's desire to avoid significant social and economic upheavals in society by any means. As a result of government actions, some insolvent enterprises receive state support. At the same time, support measures are usually implemented not based on the principle of the future efficiency of the enterprise and the possibility of restoring solvency after receiving financial support but based on the principle of too big to fail.

It should be noted that the problem of zombie enterprises is typical not only for the Japanese economy, but also for the world economy. So in China, the rapid economic growth and government support measures associated with the policy of stimulating production have led to an increase in the number of zombie enterprises, a characteristic feature of which has become excess production capacity in the steel, cement, and aluminum industries.

The main feature of Chinese zombie companies is that they are owned by the state, the activities of zombie companies are carried out in those industries where there is an excess of production, they provide significant employment and a large share of regional GDP, their efficiency is quite low, each of these enterprises has a significant volume corporate debt. A drastic cut in funding for Chinese zombie businesses could lead to production shutdown and collapse (Guangyuan, 2015).

A difficult situation has developed in other world economies as well. A sharp 10-fold decrease in the US Federal Reserve rate from 2.5% (12/19/2018) to 0.25% (03/16/2020), as well as a significant period of low interest rates, in effect from 01/30/2008 to 09/26/2018, brought to life in the United States, see figure 1 for an epidemic of zombie enterprises.

Figure 1: Dynamics of changes in the US FRS rate, in% (prepared on the basis of data from the Federal Reserve System, 2020)

According to Lee & Davis, 2020, with the onset of the COVID-19 pandemic, almost 200 large enterprises and companies in the United States have joined the ranks of zombie enterprises. The total number of zombie enterprises whose shares are included in the Russell 3000 index reaches 527 enterprises, while the total volume of liabilities of these companies has grown from $ 378 billion to $ 1.36 trillion. US dollars.

At the same time, Lee & Davis, 2020 note that at the peak of the financial crisis of the 2000s, the debt burden of zombie enterprises reached only $ 500 billion. Thus, the debt burden of zombie companies has more than tripled. Among the American zombie companies are quite large players such as the aircraft manufacturer Boeing, the travel company Carnival, Delta Air Lines, the oil and gas company ExxonMobil and the largest and oldest retail chain in the United States Macy's.

It should be noted that the United States fits the definition of a zombie enterprise, since the US GDP has been less than the US debt since 2012, see figure 2., and in 2020 the national debt exceeded GDP by 31.01%. The average growth rate of the US debt to GDP ratio from 2000 to 2020 is 3.6% per year. If debt continues to grow at this rate, then by 2030 debt will exceed US GDP by 86.52%. Given the state of the US economy, it should be noted that this debt is unlikely to be repaid soon. At the same time, a decrease in the volume of attracting debt financing from the United States may entail disastrous consequences for the US economy and labor market. Thus, in addition to zombie enterprises in the world economy, one should recognize the existence of zombie countries that cannot exist normally without attracting debt financing and will not be able to significantly reduce the amount of available public debt.

Figure 2: Dynamics of the ratio of the US dollar to US GDP, in%, prepared based on data from the Federal Reserve System, 2020)

At the same time, a significant indicator, more than 100%, of the debt-to-GDP ratio characterizes a fairly large number of countries, including China, Great Britain, Italy, etc. see figure 3.

Figure 3: Debt to GDP ratio for countries with a value of more than 100%, in% (prepared based on data from the Federal Reserve System, 2020)

The global ratio of public debt to world GDP is currently 300%. Thus, in order to pay off public debts, the whole world needs to pay three full annual GDP, which in a real situation is hardly possible.

The situation is aggravated by the fact that the debt of zombie enterprises and zombie countries is acquired by other economic actors. For example, large companies such as Apple or Google are actively buying bonds on the US financial market, including high yield bonds, which are characterized by high yield and high risk. In particular, Apple has about $

78.74 billion in corporate bonds, Facebook has $ 10.7 billion, and Google has $ 23.7 billion (Obukhova & Pakhunov, 2020)

Also, many countries are buyers of bonds of other countries, investing part of their reserves in bonds of countries, including the United States, see figure 4.

Figure 4 - US Lender Countries, January 2020, $ billion (based on data from the Federal Reserve System, 2020)

Formulation of the problem

Thus, a network of assets is formed, based on bad debts of borrowers, which is unlikely to be repaid in the future. At the same time, a chain of "contaminated" assets is formed whose owners may not even be aware of the existing problems with these assets. Given the potentially wide range of owners of such assets, the problem of bad debts, zombie enterprises and zombie countries are currently quite relevant.

The greatest danger is the gradual infection of economic agents with the assets and derivative assets of zombie enterprises and zombie countries, see figure 5.

The mechanism of this infection is due to the possibility of converting non-market obligations into market ones through securitization by issuing bonds and other financial assets. Financially stable and efficient enterprises by acquiring financial assets of zombie enterprises and zombie countries become risk carriers of issuers of financial assets. In this regard, it is relevant to model the process of contamination of economic entities with other economic entities with bad debts. Analyzing figure 5, we can conclude that this mechanism of infection is similar to infection during an epidemic characteristic of biological subjects.

Figure 5: The mechanism of infection of enterprises with assets of zombie enterprises and zombie countries (prepared by the author)

Results

Considering the mechanism of infection like biological organisms, when describing the infection model, one can use the appropriate models of the spread of the epidemic, for example, the classical SIR model proposed by W. Kermak and A. McKendrick in 1927. In accordance with this model, the entire population of biological subjects is divided into three groups.

The first group (Susceptible) is biological subjects susceptible to infection, but not infected, that is, the number of uninfected by the time t, S (t);

The second group (Infected) are biological subjects infected by the time t, I (t);

The third group (Recovered) are biological subjects who have recovered from the disease by the time t, R (t).

The epidemic model is described using the following differential equations:

$$\frac{dS(t)}{dt} = -\frac{\beta S(t)I(t)}{N}; \tag{1}$$

$$\frac{dI(t)}{dt} = \frac{\beta S(t)I(t)}{N} - \gamma I\ (t); \tag{2}$$

$$\frac{dR(t)}{dt} = \gamma I(t); \tag{3}$$

where: β is the frequency of contacts between representatives, $\gamma = 1 / T$, while T is the time of illness.

A similar and other model for assessing the epidemic can be used in assessing the consequences of "infection" of economic entities with primary toxic assets of zombie enterprises, zombie countries, as well as their derivatives.

Conclusions

Summing up the above, we can draw the following conclusion. The turbulence of the global economy, as well as the crisis caused by the COVID-19 pandemic, is leading to the emergence of many zombie enterprises. It should also be noted the emergence of zombie countries whose debt is several times higher than their GDP of these countries and most likely cannot be repaid in the coming years. At the same time, zombie economic entities issue various financial assets that are acquired by other economic entities, including those with high solvency and widely known in the market, such as Google and Apple. Thus, there is a transfer of part of the risks of bankruptcy of zombie economic entities to efficient and solvent enterprises. In turn, economic entities (individuals and enterprises) who buy, for example, Google and Apple stocks and bonds become carriers of the risk of zombie economic entities. This mechanism is like the infection of biological subjects during an epidemic. Therefore, there is a potential for predicting the consequences of the epidemic of the emergence of zombie enterprises and zombie countries for the world economy.

Abstract

The debt market is currently characterized by the growth of bad debts of the corporate sector and states. A particularly alarming trend is in the corporate sector, which is seeing a rise in the number of zombie businesses, which are businesses that cannot pay off payables and only pay interest payments on them. The negative point is that these enterprises issue financial assets, including bonds that are bought by well-known and large companies such as Apple, Facebook, Google, etc. Thus, toxic assets are spreading throughout the economy, spreading the risks of insolvent economic actors throughout aggregate. In the context of the growing risks of massive non-payments, the relevance of the formation and use of the financial strategy of the enterprise, adapted for zombie enterprises, increases.

Keywords: zombie businesses, financial strategy, junk bonds, financial investments

Introduction

The debt market is currently characterized by the growth of bad debts of the corporate sector and states. A particularly alarming trend is in the corporate sector, which is seeing a rise in the number of zombie businesses, which are businesses that cannot pay off payables and only pay interest payments on them. So, according to Lee & Davis, since the beginning of the COVID-19 pandemic in February-March 2020, almost 200 large American companies have joined the ranks of zombie companies. The total number of such companies in the Russell 3000 index, which includes 3 thousand of the largest traded American companies, reached 527, and the total volume of their liabilities compared to the end of last year increased from $ 378 billion to $ 1.36 trillion.

Figure 1: Growth in debt of the largest US zombie enterprise, in billions of US dollars (prepared by the author based on data from Lee & Davis, 2020)

Cite this Article as: Kirill Kurilov and Anastasia Kurilova "Approaches to Shaping the Financial Strategy of Zombie Businesses" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Among the zombie companies were such major players as the aircraft manufacturer Boeing, the cruise company Carnival, the airline Delta Air Lines, retailer Macy's and the oil and gas corporation ExxonMobil. The concentration of zombie enterprises in various sectors of the economy is shown in figure 2. As you can see from figure2, the largest concentration of zombie enterprises is in the industrial sector.

Figure 2: The concentration of zombie enterprises in various sectors of the economy, in% (prepared by the author based on data from Finbox, 2020)

In addition, there are a number of countries that are actively attracting financing from the external market, the volume of debt of which exceeds the annual GDP of this country. At the same time, the debt of these countries continues to grow. Striking examples are Japan, whose external debt is already more than 2 times higher than its annual GDP, as well as the United States, whose external debt is 31% higher than its annual GDP.

On the negative side, the liabilities of these enterprises are bought by well-known and large companies, in particular, Apple has about 78.74 billion USA dollars in corporate bonds, Facebook has 10.7 billion USA dollars, and Google has 23,7 billion USA dollars. In addition, the reserves of these companies are placed in government bonds, including US bonds (Obukhova & Pakhunov, 2020).

Thus, toxic assets are spreading throughout the economic entities, spreading the risks of insolvent economic entities to the entire population.

Formulation of the problem

In the context of the growing risks of massive non-payments, the relevance of the formation and use of the financial strategy of the enterprise increases.

First, the financial strategy of the enterprise is necessary for zombie enterprises, which in the process of its implementation can restore their solvency, profitability and pay off existing debts. Such changes take place in the process of company restructuring, which is the most important mechanism of modern financial strategy.

The restructuring process is due to a certain impact of external and internal factors, which take into account with the help of the necessary set of measures of an organizational, managerial and financial nature, which must be carried out in the company in order to strengthen its market position and implement strategic objectives.

The development of a financial strategy in many companies is associated with the need for restructuring, choosing the form of its implementation, assessing the likelihood of results (forecast and financial analysis) and efficiency.

Results

The financial strategy is developed in accordance with the global objectives of the company's economic strategy. In the process of its development, the main trends in the development of finance are predicted, the concept of use is formed, the principles of financial relations with their partners are outlined.

There are five key elements that are relevant to financial strategy:

the goal is the effective development of the company;

time - long-term benchmarks;

direction - financial activities;

mechanism - financing;

conditions - internal and external environment.

One of the main functional goals of a financial strategy is to maximize the company's market value. The financial strategy solves the problems that ensure the financial stability of the company in the modern market conditions of management. This is a fairly good tool that allows the company to develop in a clearly defined direction and achieve ever better results.

Financial strategy provides:

formation and competent management of financial resources;

identifying the most important areas of activity and focusing efforts on their implementation;

maneuverability in using the reserves of financial management;

compliance of financial activities with the economic condition and material capabilities of the company;

objective accounting of the financial and economic situation and the real financial situation of the company in the year, quarter, month;

considering the financial capabilities of the company and its competitors;

identification of the main threat from competitors, mobilization of forces to eliminate it and choice of directions for financial actions;

identification of the most effective areas of investment and concentration of financial resources in these areas;

creation and preparation of strategic reserves;

ranking and gradual achievement of goals.

The main tasks of the financial strategy include:

identification and specification of ways to successfully use financial opportunities;

formation of promising financial relationships between the company and third parties;

provision of operating and investment activities with financial resources;

analysis of economic and financial capabilities of potential competitors, development and implementation of measures to ensure financial stability.

The development and implementation of a financial strategy, as the basis of a company's financial planning, is based on the use of the following tools:

financial management: financial analysis, budgeting, financial control;

financial services market: securities, factoring, leasing, insurance.

From the standpoint of strategic management, there are usually three main groups of objects of strategic management:

the company as a whole;

strategic economic zone;

strategic business unit.

In the system of this management, there are usually three main types of strategies:

corporate strategy;

functional strategies;

strategies of individual economic units (business units).

The corporate strategy determines the prospects for the development of the company. It is aimed at fulfilling the company's mission and most comprehensively ensures the implementation of the main goal of operation - maximizing the welfare of owners.

At the corporate level, the strategy covers such important issues as the choice of types of economic activities, ways to ensure long-term competitive advantages of the company in the relevant product markets, various forms of conglomerate reorganization (mergers, acquisitions), the principles of allocation of all main types of resources between individual strategic zones of management and strategic economic units. The development of corporate strategy is carried out mainly by the top managers of the company.

Functional strategies are formed, as a rule, for the main types of the company's activities in the context of the most important functional units. The main strategies at this level include financial; marketing; production; innovative.

The strategies of business units (business strategies) of a company are usually aimed at solving two main goals:

ensuring competitive advantages of a specific type of business;

increasing its profitability.

When developing a financial strategy, an enterprise should use the following principles:

considering the company as an open system capable of self-organization;

considering the basic strategies of the company's operating activities;

predominant focus on the entrepreneurial style of strategic financial management;

highlighting the dominant areas of strategic financial development;

ensuring flexibility in the financial strategy;

highlighting the dominant areas of strategic financial development;

providing alternatives to strategic financial choices;

providing the developed financial strategy with an appropriate organizational structure and organizational culture;

focus on the professional staff of financial managers in the process of implementing the financial strategy;

considering the level of financial risk in the process of making strategic financial decisions.

Regarding the formation of the financial strategy of zombie enterprises, it is necessary that the financial strategy of the enterprise be aimed at increasing the solvency and increasing the profitability of the enterprise. To do this, it is

necessary, first, to assess the existing financial strategy to determine the mistakes made in its formation and to form a new financial strategy based on new goals and objectives.

Figure 3 - The process of adjusting the financial strategy of the enterprise (prepared by the author)

After the formation of the financial strategy of the enterprise, it is necessary to assess its effectiveness using the golden rule of economics:

$$Tp > Tr > Ta, \qquad (1)$$

Where:

Tp - profit growth rate;

Tr - the growth rate of sales;

Ta - the growth rate of the advanced capital.

If, as a result of the development of a financial strategy, this ratio does not correspond to that recommended in this model, the strategy or part of it must be changed in order for it to fulfill the main goal - to ensure maximum efficiency of the enterprise.

Conclusions

Summing up the above, we can draw the following conclusions. The number of financially unstable enterprises that can be classified as zombie companies is growing. Along with this, the debt of these companies is growing significantly, which, through securitization, is transformed into financial assets, which are gradually spreading throughout the financial market, transferring risks to other well-known and solvent enterprises. This problem is common all over the world; Japan, China and the USA are experiencing problems with zombie companies. Therefore, it is necessary to transform the economic activities of these companies by transforming the financial strategies of these enterprises in order to increase their efficiency and solvency. The formation of an updated financial strategy for most zombie enterprises is a chance for their transformation into a solvent and profitable enterprise.

The Tourism Impact on The Residents' Life Quality – Case Study

Abstract

Tourism is a fast-growing sector at national level, but also at global level. This growth has generated positive externalities, but also some negative ones. This study aims to understand how the (negative) impacts of tourism are perceived by residents of the Sé parish, and how they affect their quality of life.
To achieve the main objective of the study, a face-to-face survey was carried out among the inhabitants of the parish of the Sé. The answers of 234 participants were collected and then analysed in the SPSS statistical software. The results obtained prove that the residents have quality of life, are satisfied with the conditions of their environment, noting also that these two variables are related to each other. However, it was not possible to correlate residents' perceptions regarding the role of tourism activity. Through the results obtained it is expected that tourist entities and bodies evaluate, the growth and maintenance of tourism, but also all the issues that are directly or indirectly related to it.

Keywords: Gentrification, Tourist Pressure, Overtourism, Quality of Life.

Introduction

In recent years, the tourism sector has contributed to the financial balance between imports and exports in Portugal. In 2019, according to INE, more than 29 million guests were registered in hotels, generating a total of 77.8 million overnight stays, which corresponds to an increase of 7.4% and 4.3% respectively, compared to 2018, being responsible for the entry of 4.3 billion euros in the country.

These figures are mainly due to the commitment to diversify the tourist offer of the various destinations, to the emergence and improvement of the support infrastructures and to the commitment to the qualification of the tourist product. From this perspective, the range of countries issuing tourists has diversified and domestic tourism has grown. In 2019, the domestic market contributed with 26.1 million overnight stays, representing an increase of 5.9% over 2018, which corresponds to 33% of the total overnight stays for the year. The city of Porto is no exception. Due to its location, its gastronomy, the Port wine, its natural beauty, its culture, and heritage and also its hospitality, climate, low cost of living in relation to the reality of tourists, as well as the increase in low-cost flights, more tourists choose to visit the city and stay overnight.

However, despite the growth in revenue and the improvement of infrastructure and services in cities, tourism also has a less positive side. One of the biggest problems caused by tourism is the (lack of) quality of life of city dwellers who constitute themselves as tourist destinations. Cities suffer from an excess of tourists, which leads to various problems in terms of infrastructure capacity, the sustainability of the city itself and with the residents themselves and may even lead to a deterioration in the relationship between tourists and residents.

Cite this Article as: Pedro LIBERATO and Ana SILVA "The Tourism Impact on The Residents' Life Quality - Case Study" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Doxey (1975), cit. in by Zaidan & Kovacs (2017) published "Irridex", a theory on residents' attitudes towards the presence of tourists and the way they change and move from feelings of acceptance and welcome, to feelings of irritation and boredom, as the number of tourists increases in relation to the local population, to the point where these attitudes would result in antagonism between the two parties. Rosenow & Pulsipher (1979) emphasise that the negative impacts/results of tourism are associated with seasonal tourist pressure, hostile tourist behaviour and environmental impacts.

To make the whole picture worse, regulation of the sector is failing to keep pace with the great growth that has been seen, leading to disparities and conflicts between the parties. Due to the growth in demand from the city of Porto, there are situations of eviction of residents, from their homes, to create tourist accommodation offered on digital platforms.

Being the parish of Sé the cradle of the city of Porto, a crossing point between the city centre and the Ribeira area and due to the landscape, it provides, many tourists are attracted to visit it, which may harm the daily lives of the inhabitants. This is the starting point for this research work, to assess whether tourism and the number of tourists present in this historic area harms its inhabitants and in what way. This will be done by analysing the inhabitants' perception of this sector of activity and how this perception influences their quality of life, seeking to identify the day-to-day activities that will be most affected by tourism.

Literature Review

In the 1970s, several authors warned of the more negative side of the continuing growth in demand for international travel and tourism. All of them state that if tourism demand continued to grow, such growth would require careful planning and management so that the effects of mass tourism on the environment and societies would be minimised. Young (1973) cit. in by Gossling, McCabe, & Chen (2020), predicted several social, environmental, and economic consequences for destinations that did not control growth and did not carry out regional planning and management. Turner and Ash's (1975) cit. in Gossling, et al. (2020), stated that tourism demand would begin to be met also by lower social classes, making demand so high that destinations would be unable to meet it. Many studies point to several negative effects caused by tourism. In this article, 4 of these negative effects will be addressed, gentrification, touristification, tourism pressure and overtourism.

Gentrification and touristification

The concept of gentrification has been much studied and has evolved over time for several years. See that for Glass (1964) cit. in Fernandes, Carvalho, Chamusca, & Pinto (2018), this definition emerges as the process of changing an urban area conducted through the entrance of more residents and/or users of the city. For Rose (1984) cit. in Fernandes, et al. (2018), gentrification is related to chaos, presenting different forms and in different locations. For Benediktsson et al (2015) cit. in Fernandes, et al. (2018), this concept emerges as an idea of segmentation, and finally, for Lees, Shin & Lopéz Morales (2016), gentrification is the process of social recomposition of the population of a given territory resulting from urban transformations and associated with a gradual replacement of poorer residents by groups of higher socio-economic status, which has been becoming more complex. The phenomenon has been spreading, either through its occurrence in territories around the world or through its progressive increase in scale.

One of the causes for the emergence of this process are the new users who long for new services, leading to the disappearance of older shops and restaurants (Burnett, 2016, cit. in Fernandes, et al., 2018), giving rise to new offers influenced by tourism demand, such as souvenir shops, local accommodation, among others.

However, several authors, such as Zuk et al. (2015) cit. in Fernandes, et al. (2018), argue that the whole gentrification process is difficult to evaluate, since it may vary in terms of the time it takes to occur, in its causes and actors involved. But in the end, three conditions will always be met, the existence of empty or undervalued buildings in each area, the preference for urban life, and the existence of (gentrifiers) gentrification agents (Hammett, 2001, cit. in Fernandes, et al., 2018). Other research shows that there are fluctuating movements of these gentrification agents, the most important being tourists and students (Gotham, 2005; Smith, 2005, cit. in Fernandes, et al., 2018). This happens because both tourists and international students, when using certain places of a city during their stay, leave their mark. Although they are in a limited space and time, they will modify them thus leading to gentrification as a process of urban modification.

It can be said that one of the main causes of gentrification in several cities today is tourism and the volume of people it transports every year globally, thus giving rise to the term tourist gentrification. Tourist gentrification can be defined as the process of gentrification accelerated by the tourist activity (Gotham, 2005; Cócola Gant, 2015, cit. por Mendes,

Amílcar, Carreiras, & Guimarães, 2016), since recreation companies and tourist spaces are created and introduced that will transform cities (Gotham, 2005, cit. por Cordeiro, 2018).

Since tourist gentrification is a process of replacing local genesis (residents, commerce, among others) to give way to the economy of tourism, one of its consequences is touristification. Touristification is a current gentrification process that manifests itself in the significant expansion of tourism in a certain area, both on the supply side, with services, equipment and tourist accommodation, and on the demand side, where the city becomes seen and sought after as a tourist destination (Mendes, 2017, cit. in Cordeiro, 2018). It is basically the loss of identity of a certain place to the detriment of the tourism sector and tourists.

From this point of view, the gentrification of tourism and, consequently, the touristification are translated into the appropriation of urban spaces for tourism (Oliveira, 2017), where there is the displacement of the poorest classes to more peripheral areas to give way to housing for tourism purposes, substitution of local commerce to give way to souvenir shops, specialization of city services in the area of tourism, among others, where everything becomes tourism.

Tourist Pressure and Overtourism

Mass tourism is an increasingly recurrent phenomenon, often involving the arrival of large numbers of tourists to small areas, which has a major impact on the area of arrival and leads to increased pollution, waste, water consumption (which adds to the needs of the resident population), putting infrastructure and habitats under great pressure (WWF, 2020).

This mass arrival of tourists can be measured through the Tourist Pressure felt in the destinations. Tourist pressure can be defined as the number of tourists/visitors, existing in a certain place and time, in relation to the number of inhabitants of that same place. Several studies have associated perceptions of tourism with visitor density/agglomeration, stating that tourism pressure is a psychological rather than a measurable construction (Neuts, Nijkamp, & Van Leeuwen, 2012, cit. in Gossling et al., 2020). This is a phenomenon in which the greater the number of tourists, the greater the tourist pressure felt in a defined territory. If tourism pressure increases consecutively, it could be considered as a scenario of over-tourism. To better understand the consequences of Tourist Pressure, and its increase, this new concept, overtourism, will be addressed.

The term Overtourism has been defined as the situation in which part of the local population feels that their daily lives and quality of life are diminishing due to tourism, leading to the emergence of forms of resistance or protest directed at tourism, tourists, legislators, or stakeholders (UNWTO, 2018, cit. in by Gossling, et al., 2020). As the local population will resist tourism, another problem arises linked to overtourism, the degradation of the value of the experience to the tourist. For Pasquinelli, & Trunfio (2020) overtourism is "a multifaceted phenomenon in terms of the increase in visitor numbers and their temporal and spatial concentration, the influence of tourist behaviour on the quality of urban life (such as noise, vandalism, among others), and the physical impact and urban transformation (such as the exploitation of natural resources and tourism)". It is the cause of several problems such as overcrowding of public spaces; the spread of the impacts of visitors' inappropriate behaviour; the physical touristification of the city centre and other frequently visited places; the eviction of residents from their areas of residence to make way for tourist accommodation; the pressure on the local environment (waste, noise pollution, and use of natural resources) (Koens et al, 2018, cit. in Pasquinelli, & Trunfio, 2020), the weakening of socio-cultural cohesion and transformation of the social character of many cities (Peeters, et al., 2018, cit. in Pasquinelli, & Trunfio, 2020).

In short, overtourism is a phenomenon that involves the number and density of tourists in a certain area, the social, cultural, economic and/or environmental changes caused by tourism, and the (positive or negative) sociopsychological responses among residents triggered by these changes (Gossling, et al., 2020).

It can be concluded that overtourism, as well as tourist pressure, are phenomena that can be considered psychological, since their existence depends on the perception and evaluation of tourism and its effects by the local population.

Quality of Life

The theme quality of life has been studied by several authors. It is important, first of all, to stress that the authors of the studies on this subject use "quality of life" and "well-being". For Delibasic, Karlsson, Lorusso, & Rodriguez (2008) cit. in Mathew, & Sreejesh (2017), quality of life is presented as the degree of well-being felt by a person or a group of people. The World Health Organization (WHO) cit. in Mathew, & Sreejesh (2017), also defined quality of

life and presented it as the set of perceptions of individuals about their position in life, according to the cultural context and value system in which they live, in relation to their life goals, expectations, standards and concerns.

Sirgy (2001) cit. in Rivera, Croes, & Lee (2016) defines quality of life as a dynamic connection between material wealth, social conditions and physical well-being (including work, income, social support, health conditions, personal and family life), and a precondition for achieving happiness.

The measurement of quality of life in general or related to a particular area of life, such as social life or family life, is usually performed using objective and subjective indicators (Sirgy, Meadow, & Samli, 1995, cit. in Uysal, et al., 2016). These two indicators are considered to be the two dimensions of quality of life.

The quality of life (or well-being) can thus be divided into two dimensions, the objective dimension and the subjective dimension. The objective dimension is made up of indicators that the individual does not control, i.e. those that are independent of him or her, and may include the individual's income, basic needs, physical health, standard of living and crime (Stiglitz et al., 2009, cit. in Croes, et al., 2018). Regarding the subjective dimension, this is composed of indicators that capture self-reported responses to individual happiness and satisfaction, highlighting a list of capabilities, functionalities and needs (Stiglitz et al., 2009, cit. in Croes, et al., 2018), including satisfaction with family, work, community or life in general (Andrereck, & Jurowski, 2006; Diener, & Suh, 1997, cit. in Uysal, et al., 2016).

However, both dimensions have criticisms and limitations. In the case of the objective dimension, the main limitation is that objective indicators may not accurately reflect people's experience of well-being (Andrews & Withey, 1976, cit. in by Woo, Uysal, & Sirgy, 2018). In relation to the subjective dimension, the main criticism is that feelings and emotions are a mental evaluation of an objective condition, not the condition itself. Since individuals are socially capable of adapting to their situation, after their adaptation they perceive a satisfactory quality of life, eventually affecting their quality of life and the evaluation of it (Croes et al., 2018).

From the moment a city/area becomes a tourist destination, the life of the residents of that city is affected by tourism on an economic, socio-cultural and environmental level (Andereck et al., 2005; Harrill, 2004; Moscardo, 2009; Nunkoo & Smith, 2013; Sharpley, 2014; Sirakaya, Teye, & Sonmez, 2001; Uysal, Woo et al., 2012, cit. in Uysal, et al., 2016). Several studies attempt to understand the relationship between the impacts of tourism and residents' attitudes towards tourism development (Uysal, et al., 2016). Research around this theme has shown that, according to the level of development of the destination, residents' attitudes towards economic, socio-cultural and environmental factors tend to change from positive to negative (Uysal, Woo, et al., 2012, cit. in Uysal, et al., 2016) and, consequently, the different levels of tourism development will affect, in a different way, residents' quality of life (Uysal, et al., 2016). Allen, et al. (1988), cit. in Uysal, et al. (2016), acknowledge that host communities benefit from tourism development in the early stages of the destination's life cycle, but that this benefit diminishes as it moves into more evolved stages.

Objectives, Hypotheses and Methodology

Objectives and Hypotheses

The main objective of this research is to study the influence of the perception of the inhabitants of the region under study, in relation to tourism, on their quality of life incorporating both tangible and intangible items. The specific objectives are: i) to evaluate how tourism activity affects the inhabitants of the Sé; ii) to perceive whether the inhabitants have a good perception of tourism activity; and iii) to evaluate the quality of life of the inhabitants (tangible and intangible).

Based on the specific objectives, the Research Hypotheses were developed:

- Hypothesis 1 - Tourism has a positive impact on the lives of the inhabitants;
- Hypothesis 2 - A better perception of tourism by the inhabitants leads to greater satisfaction;
- Hypothesis 3 - Greater satisfaction is synonymous with better quality of life;
- Hypothesis 4 - The city's inhabitants have a good quality of life.

Methodology

The research used a quantitative approach, where a questionnaire survey was applied and this was based on the questionnaire used in the research "Tourism impact and stakeholders' quality of life" by Woo, E., Uysal, M., & Sirgy, M. (2018). The questionnaire was applied to residents over 18 years of age in the municipality of Sé. The questionnaire was introduced door to door and in total the answers of 234 inhabitants were collected, this sample representing an error of 6.15% for a 95% confidence level.

The normality test was carried out for the three variables that make up the various hypotheses, which made it possible to understand which tests should be carried out to analyse the validity of the research hypotheses. It was concluded that all the variables under study did not follow a normal distribution. The Chi-square (adherence) test for a sample was carried out in order to understand the impact of tourism on the lives of inhabitants and whether they had a good quality of life, the Linear Regression test and the Spearman Correlation Coefficient, in order to verify the correlation between the perceptions of the impacts of tourism on the lives of inhabitants and the inhabitants' satisfaction in relation to the environment, as well as between the inhabitants' satisfaction in relation to the environment and the generalised satisfaction.

Results

Characterisation of the sample

Most respondents were women (71.8%). Most of the sample was older, 39.3% were aged between 55 and 65 and 23.5% were over 65 and with a lower level of schooling, 32.9% of those surveyed were in the 1st cycle only. Regarding the professional situation, 50.9% were employed and had “Other” as sector of activity (53%) with an income of between 500 and 1000 euros (52.1%).

Table 1- Characterization of the sample

Gender	Frequency	%
Female	168	71,8
Male	66	28,2

Analysis of the Hypotheses

For the analysis of hypotheses 1 and 4 the Chi-square (adherence) test for a sample was performed, as well as an analysis of the frequency table obtained with this test. For hypothesis 1 the items in group 2 of the questionnaire "Perception of the impacts of tourism on the lives of inhabitants, in economic and non-economic terms" were analysed and for hypothesis 4 the items in group 4 of the questionnaire "Generalised satisfaction" (quality of life) were analysed. For this test, it was considered that all values have the same probability of occurring.

With the Chi-square (adherence) test for a sample, carried out for the "Perception of tourism impacts", a Chi-square value of 211,607 and p of 0,000 (Table 2), i.e. less than 0.05, was obtained. This means that there is sufficient statistical evidence to reject the null hypothesis, i.e. the data obtained is not consistent with the expected distribution. It has been found that the values that occur most are those below 3, i.e. inhabitants do not perceive tourism as having as many positive impacts on their lives as expected. In short, it was found that hypothesis 1 of the study was not validated.

In relation to "generalized satisfaction" (quality of life), the values obtained by performing the Chi-square (adherence) test for a sample, were for the Chi-square of 235,872 and for p of 0,000 (table 2), again a value below 0.05, which means that there is sufficient statistical evidence to reject the null hypothesis, i.e. the data obtained are not consistent with the expected distribution. As in hypothesis 1, it was also important to analyse the frequency table obtained in the Chi-square test. Observing the frequencies obtained, it can be seen that the values that occur the most are those above 3, with a percentage of about 91% of the responses obtained above 3 points, which means that inhabitants feel that they have a good quality of life. It can be stated that by analysing the values obtained in the Chi-square Test, hypothesis 4 was validated, since most of the respondents and their answers were positive (>3) in relation to the items in this variable.

Table 2: Chi-square Test Results obtained for the exposed variables

	Perceiving the impacts of tourism on life in economic and non-economic terms	**General satisfaction**
Chi-square	211,607	235,872
gl (degrees of freedom)	27	14
Significance Sig.	0,000	0,000

Source: Own elaboration

For the analysis of hypotheses 2 and 3, the Spearman Correlation Coefficient and Linear Regression were used. To analyse hypothesis 2 it was necessary to compare and analyse the items of group 2 of the questionnaire "Perception of the impacts of tourism on the lives of inhabitants, in economic and non-economic terms" with the items of group 3 "Satisfaction of inhabitants with their surroundings". To analyse Hypothesis 3, the items in Group 3 "Satisfaction of inhabitants in relation to the environment" were compared and analysed with the items in Group 4 "Generalized satisfaction".

Regarding hypothesis 2, the Spearman Correlation Coefficient was carried out and a p-value of 0.001 was obtained, which shows a high dependence between the variables, however, the R-value is -0.212, which shows the existence of negative correlation: when the values of one variable increase those of the other decrease - weak, due to its value being higher than -0.300. If the p-value is less than 0.05, this means that there is sufficient statistical evidence to reject the null hypothesis, that is, the variables are not independent.

Table 3: Results obtained for Spearman's Correlation Coefficient between "Perception of the impacts of tourism" and "Satisfaction with the environment

		Perceiving the impacts of tourism on life in economic and non-economic terms	Satisfaction of inhabitants with their surroundings
Perceiving the impacts of tourism on life in economic and non-economic terms	**Correlation Coefficient (R)**	1,000	-0,212
	Sig. (2 ends)		0,001
	N	234	234
Satisfaction of inhabitants with their surroundings	**Correlation Coefficient (R)**	-0,212	1,000
	Sig. (2 ends)	0,001	
	N	234	234

Source: Own elaboration

In order to better understand the relationship between the variables under study, it would be necessary to carry out Linear Regression. However, it was not possible to proceed with the study of Linear Regression, since two of its assumptions were not verified, namely the fact that there is no linear relationship, given the dispersion of the variables, and the fact that the Durbin-Watson test presented a value not comprised between 1.5 and 2.5, as the value obtained was 0.600. It can be seen that there is a correlation between the variables, however, there is no linear relationship. Although there is dependence between the variables, it was found that the existing correlation was negative and what hypothesis 2 studied was a positive correlation. It can be said that hypothesis 2 was not validated.

Finally, for hypothesis 3, the Spearman Correlation Coefficient was also performed and a p-value of 0.000 was obtained, which indicates the existence of a very high dependence between the variables; however, the R-value obtained was 0.264 (<0.300), which shows the existence of weak positive correlation. The obtained p-value is less than 0.05, which means that there is sufficient statistical evidence to reject the null hypothesis, i.e. the variables are not independent.

Table 4: Results obtained for Spearman's Correlation Coefficient between "Environment Satisfaction" and "Generalized Satisfaction"

		Satisfaction of inhabitants in relation to the environment	Generalized satisfaction
Satisfaction of inhabitants in relation to the environment	**Correlation Coefficient ®**	1,000	0,264
	Sig. (2 ends)		0,000
	N	234	234
Generalized satisfaction	**Correlation Coefficient ®**	0,264	1,000
	Sig. (2 ends)	0,000	
	N	234	234

Source: Own elaboration

As in hypothesis 2, Linear Regression could not be carried out because there was no linear relationship and the value of the Durbin-Watson test was not accepted (0.708). Thus, there is a (positive) correlation between the variables, however, there is no linear relationship.

Taking hypothesis 3 into account, it can be said that it has been partially validated, since the variables are dependent on each other (even if little) and there is a direct correlation (positive), that is, when the values of one variable increase the values of the other also increase, a relationship which was intended to be tested in this Hypothesis.

Conclusions

Several limitations and negative impacts have arisen from the growth, for some, of tourism that has been excessive in recent years. One of the parties most affected by this unregulated growth is the inhabitants of tourist destinations and, consequently, their quality of life. While many cities already take the well-being of their inhabitants into account when thinking and planning the development of their tourism sector, others are still in a very early stage.

Following this line of thought, the present work was elaborated with the intention of perceiving how the inhabitants of the tourist destinations, in this case the inhabitants of Sé (Porto), perceive the tourist activity, and to find evidence that confirms the influence of the perceptions of tourism on the quality of life of the inhabitants. The term quality of life in this work was evaluated considering several material and non-material indicators of the life of the inhabitants. Through the analysis of the results obtained it was found that the inhabitants of the area under study do not perceive tourism as the source of positive impacts on their lives, however, it cannot be said that tourism is a source of negative impacts. A more in-depth study in this area would be necessary. It was also found that the relationship between "Perception of the impacts of tourism" and "Satisfaction with the environment", contrary to what was expected, is negative. This negative relationship happens a lot because the results obtained for the variable "Perception of the impacts of tourism" were negative, contrasting with the positive results obtained for "Satisfaction with the environment". Thus, both hypothesis 1 and hypothesis 2 were not validated.

On the other hand, hypotheses 3 and 4 have been validated, because in relation to hypothesis 3 it was found that the variables are positively correlated, i.e. higher satisfaction corresponds to better quality of life, and in relation to hypothesis 4 it was found that the values that occur the most are those above 3, which shows that the inhabitants surveyed have quality of life.

Relating the hypotheses tested to the specific objectives to be achieved in this work, it was found that these were only partially achieved, since it was not possible to clearly perceive the impact of tourism activity on the inhabitants of the area under study, nor was it possible to perceive whether the inhabitants have a good perception of tourism activity. However, it was possible to evaluate the quality of life of the respondents and their satisfaction with the environment, and that a greater satisfaction of the inhabitants leads to a better quality of life. It is possible to state that, in general, the inhabitants surveyed are satisfied with their quality of life, classifying it as being good in most aspects, and with their environment. However, there is still no predominant opinion regarding tourism and its impacts.

Abstract

This paper indicates changes in movement of employees in a selected organization as a management problem in the 21st century. The rotation in this industry was characterized. A proposal for a tool designed to counteract employee rotation was presented. An analysis of the staff shortage occurring in a commercial bank was carried out using a case study.

Keywords: Rotation, Employee, Present Day, Management, Socio-Economic System.

JEL classification: A11, A13, D31, E24, E32, L26, M12.

Introduction

Proper human resource management results in a synthetic diagnosis of an employee in the light of the overall organizational system. An exemplary contemporary manager, a rational manager with the ability to manage a culturally diverse team should be prepared to adequately respond to the problems of the 21st century (Rubenstein-Montan et al., 2001). One of the significant problems in banking is the growing staff movements, which are an obstacle to the proper functioning of the team inside and outside the organization in terms of the key - quality customer service. The times of crisis and the deteriorating situation of the "bank's customer portfolios" mean that the needs of the bank's employers and the customers themselves are not met. Staff shortages arise, bank employees fail to achieve their sales targets, they quit without taking any action that would be the basis for remedying the current state of affairs. The reasons related to this aspect of the problem may be of various organizational nature. The organization may have team problems with the proper motivation of the employee and frequent sick leave (Kirsch, 1996; Miciuła, 2018). There are banking teams that periodically recruit people for given positions, they are unable to keep a good employee in their current workplace. Staff shortages increase the risk of proper customer service. All activities aimed at assessing the rationalization of the resulting phenomenon and introducing changes to restore the assumed banking structures should be performed (Knights and Willmott, 1999).

Literature Review

Labor movements (fluctuation)

The enterprise should have the required number of people employed, in the event of its absence, it is planned to hire new employees, i.e. recruitment (Zeffane and Morgan, 2003). Recruitment consists in finding suitable candidates with the appropriate qualifications for a specific job position (Snell, 1992). The departure of employees for maternity and paternity leaves and call-up to military service is one of the reasons for employee movements, the

Cite this Article as: Ireneusz MICIUŁA, Henryk WOJTASZEK and Paweł STĘPIEŃ "Employee Rotation as A Contemporary Management Problem" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

nature of which is temporary. The employer is obliged to employ an employee in the previously held position. Termination of the employment relationship may take place only for the following reasons: in the event of bankruptcy or liquidation of the workplace, then the employee is entitled to a monthly severance pay, for economic reasons, organizational, production or technological changes, then the employee is also entitled to a monthly severance pay due to the fault of the employee, then the employer has the right to terminate the employment contract without notice.

Professional promotion is the transfer of an employee to a higher position. It is associated with a change of position, an increase in remuneration, but also greater duties and greater responsibility.

An employee's departure from work may be due to a number of reasons:

- inappropriate interpersonal relationships in the enterprise,
-hard working conditions, work harmful to the employee's health,
- change of the employee's place of residence,
- undertaking an independent business activity by the employee,
- the possibility for the employee to obtain better working conditions, the possibility of faster promotion, the possibility of taking full advantage of the employee's professional qualifications.

Demotion is a kind of punishment for an employee, it is a punitive transfer to a lower job position, and thus a reduction in wages and job prestige. Demotion is the opposite of promotion.

The retirement of an employee who meets the retirement requirements. The employee is then entitled to severance pay, which is a gratuity in connection with the end of work. Retirement for a disability or retirement pension is the reason for permanent employee movements.

Dismissal of an employee is also a permanent nature of employee movements. Dismissal is a measure of last resort, used when other measures have not produced the expected result. Termination of the employment relationship may take place: by mutual agreement of the parties, by termination of the employment contract, without termination of the employment contract, disciplinary dismissal. The death of an employee obliges the employer to pay a death benefit to the employee's family. The amount of the death benefit depends on the period of employment of the employee (Stoner and Wankel 1992). Employee turnover at a certain level is a natural process like a business cycle (Baldwin et al., 2003). On the other hand, many factors affect above-average employee migrations.

Rotational fluctuation of banking employees

Frequent changes in the workplace of banking employees are associated with staff changes, moves and negative rotation, i.e. as a result of a progressive threat to the rotation of the 21st century.
The concept of negative rotation was explained as a set of employee activities performed consciously or not, more often at the initiative of an employee, which resulted in the dismissal of a job by moving to another bank with a more attractive spectrum of operation from the employee's perspective.
The concept of rotational fluctuation of banking employees has been characterized as a specific system of mass dismissal of banking employees and the search for a better alternative solution, which is a significant problem threatening efficient management in the 21st century. The effects of this phenomenon are limited staff resources in bank branches, observed more and more often in banking structures (Gray and Vander Wal, 2012). The figure number 1 shows a diagram of the proposed remedies for employee turnover problems.

Fig. 1: Scheme of suggestions for fixing the problem of employees

Source: own study

In order to solve the above problem, it was suggested that the Bank's Management Board implement the employee retention plan and coaching. The consequence of this action is that the employee will remain in the workplace and release a sense of usefulness in the position held. Managers forget how important a role is to properly motivate an employee, increase relationship and mutual cooperation. It was recommended to introduce trainings in the field of fluctuation rotation, which would be an activity supporting management and showing the threat to today's banking organization. The awareness of this growing phenomenon should be increased (Gołębiewski, 2001; Wojtaszek and Miciuła, 2019).

The traditional definition of job rotation is the planned change of specific jobs by selected employees or groups of employees. The rotation is indicated by the number of employees who voluntarily left the organization, were made redundant, retired or died in the course of their work. Rotation changes the human and intellectual capital of an organization and affects performance. Turnover has a direct impact on costs, both in terms of reducing wages and greater expenditure on recruiting employees. In colloquial terms, job rotation may be associated with employment fluctuation - staff (staff) rotation understood as the arrival and departure of employees from the place of employment (voluntary or involuntary). Until recently, job rotation was associated only with positive changes, which resulted in promotion, gaining new qualifications and gaining new experience (Nowakowska-Grunt et al., 2020).

The problem of employment liquidity in banking is actual in practice. Banks, despite high unemployment and educated specialists in this field, still have problems with finding suitable employees. Even if the organization finds an employee who will meet its needs, a problem in the long run may arise when such an employee is retained in the organization. The reasons for the rotation may be different, depending on the employer or forced by the market situation. Rotation, i.e. the movement of employees, and more precisely their arrival and leaving work at a certain time (Wojtaszek and Nejman, 2015).

The departure of an employee is considered as:

- voluntary, i.e. caused by his resignation. It is influenced by such factors as: the atmosphere at work, ties between the supervisor and colleagues, and the use of more attractive work.
- voluntary, i.e. independent of the employee himself, resulting from decisions of superiors or unexpected actions of the bank's structures. We include here:
- dismissal of an employee caused, among others, by staff reduction,
- liquidation of a given job,

- expiry of a contract that was signed for a specified period,
- disciplinary dismissal,
- resignation under duress,
- implementation of some project,
- employee aging,
- retirement or disability pension,
- illness or death of an employee.

The most important internal causes, apart from natural reasons related to retirement or special leave, include:

- change of the organizational structure and related reorganization,
- lack of motivation, low salary, bad atmosphere, communication disruptions
- errors in management,
- poor working conditions, insufficient tools necessary for work and protection social,
- lack of clearly defined evaluation criteria,
- low efficiency of employees due to burnout or excessive burnout workload.

The more important external causes include:
- company mergers,
- strong competition,
- modern technologies,
- new labor markets for employees.

Rotation as a negative phenomenon:

- costs incurred by the company in connection with the dismissal of an employee,
- costs incurred by the company in connection with hiring a new employee (e.g. training costs), who may not be suitable for the position,
- the lack of a person employed at a given position contributes, inter alia, to not carry out a project within a specified period,
- routine, habituation and lack of motivation to act due to not moving inside the company,
- a high level of staff mobility rates indicates improper management of the organization.

In practical terms, the analyzed phenomenon shows a rotation resulting from the termination of an employment contract initiated by the employee himself. Banking employees complain on internet portals about high employee turnover in their banking branch. The problem affects more and more banks nowadays. Bankers share their information, exchange views on various job-related portals, thus exchanging information. Too much pressure from the management on the implementation of sales plans while maintaining the highest possible ratio of adapting the offer to the customer's needs often results in failure to meet the sales goals (Pocztowski and Miś, 2000; Pocztowski, 2003).

Results of the Research

Network management of the 21st century solution. Organization map.

An organization map is a tool that, with the help of built-in statistics, shows the roles of employees, the work of departments and the entire company, the flow of resources and places where they are blocked. The map of the organization enables the mapping of the informal structure of the company, i.e. the actual practices of employees, which allows for the proper planning, implementation and monitoring of activities preventing excessive and costly employee rotation (Stabryła, 2006; Kabus and Miciuła, 2019). The most commonly used organization map charts describe how to create and interpret network analysis deployments to help solve common problems in companies and organizations (Gray and Vander, 2012; Hejduk, 2016). These diagrams present an example of modern management through the use and development of employees' knowledge, human resources management by reducing the costs of leaving and replacing employees (Miciuła and Miluniec, 2019). Also this support sales management by increasing cross-selling and extended sales, and developing effective sales channels. The audited banking unit lacks network management that would solve the problem. The network map counteracts the fluctuation problem by suggesting the creation of conditions in which employees have a sense of using their own potential and a satisfactory comfort of work resulting from the proper workload, transparent communication and satisfactory

relations with management and colleagues. An increase or a financial gratification does not necessarily solve the problem of employee rotation (Rokita, 2005).

To sum up, thanks to the mapping of the actual practices present in the company and the possibility of their multi-level interpretation, the organization map is a tool that allows you to reduce employee turnover and significantly reduce its negative consequences, unfortunately it is not used in the analyzed bank (Wojtaszek, 2016; Kadłubek and Miciuła, 2019).

Analysis of staff shortages in a commercial bank - case study

For the purpose of examining this issue, questions were built, which were answered on the basis of participant observation, which served as a tool in the study. The question was posed: what elements significantly affect the emerging problems of staff shortages in the examined commercial bank? The survey was conducted in April 2014, summarizing the last 6 months of work for the commercial bank under study.

A research hypothesis was adopted - informing that the main cause of staff shortages is the lack of couching, motivation and communication disruptions. The results of the study made it possible to attempt to test the hypothesis and indicate possible areas for improvement.

A survey was conducted among bank employees (of the entire operating department). The survey was conducted among 22 people, of which 18 people (81% of the population) are men and 6 people (19% of the population) are women. The respondents were divided into four age groups:

- 20-30 years - 9 people, which is 40.9% of the studied population,
- 31-40 years old - 5 people, which is 22.7% of the studied population,
- 41-50 years old - 6 people, which constitutes 27.3% of the studied population,
- over 50 - 2 people, which constitutes 9.1% of the studied population.

The presented data show that the greatest number of people is 20-30 years old, as much as 40.9% of the surveyed population, and the fewest are employees over 50 years of age.

Higher education is the minimum requirement for employment in the analyzed bank. All respondents have higher education in banking.

The figure number 2 shows the reasons why employees terminated their employment relationship. People who witnessed the above-mentioned event, but were not a party to the dismissal, also answered this question.

Fig. 2: Reasons for employee rotation by age group.

Source: own study.

The figure 2 shows bank employees by age and their percentage share due to: coaching, disruptions, implementation of plans and layoffs.

The conducted survey allows you to consult employees who are working and those who no longer work. Regardless of the age, the majority of employees claim that there is a lack of coaching and disruptions in the surveyed banking branch. The tendency to implement sales plans with the age of given employees in terms of feasibility becomes lower in implementation. The layoff process is a side of all employees in the age range, both those profitable for the organization and those not profitable. It is likely that employees who did not meet their sales plans have been fired, and employees who have pursued these plans have moved to more attractive jobs. Employees aged 41 and over 50 do not implement sales plans. Another question among the respondents was the information on the reasons for the failure to implement the assumed team plan (figure 3).

Fig. 3: Reasons for failure to implement the team plan

Source: own study

The main factor independent of team work planning is employee turnover due to layoffs, as many as 68% of respondents were terminated their employment contract. Among the examined factors, the following are parallels: lack of motivation and communication disorders. It was noted that the correction of not only unrealized sales, but also rotation can be disruptions in communication and lack of motivation. Support no meals in only 8 percent of the study population.

Another question among the respondents was the information on the absence of employees (figure number 4). The survey shows people who have an established employment relationship but are not present at work. Most of the respondents showed that this is due to communication disruptions. Communication disruptions may include various factors, such as the lack of information about the bonus, incorrect information about the incentive system, and the inability to rationally plan the holiday. It is natural that, according to the Labor Code, an employee is entitled to a vacation. On the other hand, the practice and the personnel of the branch show other components of these situations. On the other hand, 37% indicated that the reason was a lack of motivation. Among the respondents on sick leave, there is one person who does not significantly affect the resulting problem of employee rotation. It was assumed that the employee who is on sick leave is in fact sick and cannot get to work

Fig. 4: Reasons for absenteeism of employees at a bank branch

Source: own study.

The most common work disruptions were the lack of coaching, in the audited entity there is no basic fulfilled communication principle, such as a conversation between employees and superiors, and vice versa. This is a factor in which 62% of respondents indicated the main cause of communication disruptions (figure 5). A disturbing element is the extended working time, although it ranked in the 15% position, however, in combination with others, it may become a threat to the entire banking organization.

Fig. 5: Types of communication disturbances

Source: own study.

Summary

The hypothesis posed makes it possible to state unequivocally that the main factor causing staff movements or rotation in the examined banking branch are communication disruptions, lack of coaching and lack of motivation. It was noticed that the sales plan is implemented by young people in the age group from 20 to 40 years, as well as these people more often decide to change jobs.

In the aspect of dismissals, age ranges do not matter, it only matters who was a party to the notice. In the study of the parties to the dismissals, the aspect of the subjectivity of the dismissal was not distinguished, but the information was provided resulting from participant observation, which indicates the dismissed persons - those who did not implement their sales plans and those who departed - those who implemented their sales plan. The emerging problem of staff movements in the form of dismissals of employees, regardless of the initiating party, causes serious disturbances in the operation of the banking organization in the 21st century. Until recently, the organization was prepared for positive rotation activities related to promotion, absence of an employee for the duration of training. A

crisis situation, unfavorable quotations of funds, low quality of the client's portfolio, and the lack of his creditworthiness cause the deepening dissatisfaction of both the bank employee and the manager, which results in a staff change involving the termination of the employment contract of one of the parties, usually a profitable employee. The cyclical lack of full staffing of bank employees leads to customer neglect.

There are modern tools of the 21st century supporting counteracting the situation of employee rotation in the form of organizational maps in the field of network management, but they are not applied in the audited bank. The bank's management board should consider the possibility of using the above-mentioned tool.

Employees need coaching, "positive conversations" and, above all, support from the management. All kinds of disturbances should be dealt with on an ongoing basis. The employee should be appreciated, feel about himself as an important entity of the organization. If symptoms of negative rotation or any personnel changes were observed, all actions should be taken to detain the employee. If the banking unit is not able to organize a remedial program to retain the employee, it can use ready-made solutions offered by specialized units dealing with, for example, network management, including an organization map, which significantly contributes to overcoming the research problem.

Funding

The project was financed within the framework of the program of the Minister of Science and Higher Education in Poland under the name “Regional Excellence Initiative” in the years 2019–2022, project number 001/RID/2018/19.

Towards Life Cycle Perspective In Activities of Small and Medium Enterprises In Poland

Jolanta BARAN

Silesian University of Technology, Gliwice, Poland
jolanta.baran@polsl.pl

Abstract

The growing needs of enterprises in the integration of environmental life cycle aspects into product development, related to the implementation of new legal regulations, result in the searching the relevant tools to meet these needs. The aim of this study is to present the conditionings for the inclusion of the life cycle perspective in activities undertaken by SMEs, as well as to analyze possible barriers and eco-design procedures in terms of its application by small and medium-sized enterprises.

Keywords: Small And Medium Sized Enterprises, Life Cycle Assessment, Ecodesign, Environmental Aspects

Introduction

In the structure of small and medium-sized enterprises in Poland according to the predominant type of activity, the number of entities that conducted service activities was dominant, constituting 56.4%, especially in the field of trade, repair of motor vehicles - 27.7%. There was also a significant share of entities that declared predominant type of activity related to construction - 12.2%. Industrial activity (mining and quarrying; industrial processing; production and supply of electricity, gas, steam, hot water and air for air conditioning systems and water supply; sewerage, waste management and remediation activities) was conducted by 31.4% of entities (including mainly the companies in the area of industrial processing - 28.1%) (Determinants of the entrepreneurship, 2018).

Small and medium-sized enterprises in their activities deal with issues related to environmental protection. This is reflected in particular in the implementation of actions resulting from legal regulations, to avoid possible penalties, but also in taking non-obligatory initiatives (Jonek-Kowalska, 2014). Activities undertaken in the field of environmental protection and environmental management in response to the negative impact on the environment generated by the enterprise, or resulting from other incentives, include among others (Baran, 2013):

- keeping records and calculating fees for discharging gases or dust into the air, discharging sewage into waters or into the ground, water abstraction and waste storage (beyond the scope of general use),
- payment of fees for the use of the environment (for the introduction of gases or dust into the air and storage of waste) (Ustawa Prawo ochrony środowiska, 2001).
- paying fees for discharging sewage into waters or into the ground and water abstraction (Ustawa Prawo ochrony środowiska, 2001).
- payment of product fees and the recycling fee and keeping records of packaging, introduced electrical and electronic equipment, batteries and accumulators, obligation to organize and provide access to the collection network for end-of-life vehicles, preparation of reports,
- in the field of waste management - keeping waste records, preparing the required statements and information, hazardous waste management programs, developing documentation needed to apply for permits, permits, decisions, implementation of obligations related to the BDO, i.e. the database on products and packaging as well as waste management.
- in the field of water and wastewater management - preparation of water reports, hydrogeological analyses, determination of pollution indicators,
- in the field of air protection - preparation of documentation necessary to apply for permits, as well as to notify installations, preparation of reports on emission management, PRTR (The National Register of Pollutant Release and Transfer) and KOBIZE (The National Centre for Emissions Management) reports, measurements of pollutant emissions and the effectiveness of devices reducing emissions,

Cite this Article as: Jolanta BARAN "Towards Life Cycle Perspective In Activities of Small and Medium Enterprises In Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- in the field of protection against noise - noise analyses, measurements of emissions and noise levels,
- in the field of investment planning - preparation of reports on the investment's impact on the environment, development of project information sheets, post-implementation analyses of projects, ecological reviews, projections of the investment's environmental impact, conducting environmental audits,
- in terms of requirements related to Integrated pollution prevention control permits - preparation of documentation necessary to apply for integrated permits, conducting environmental studies, comparing the proposed solutions with the best available techniques BAT, developing adaptation programs,
- in the field of greenhouse gas emission trading system (EU ETS) - preparation of documentation necessary to apply for permits to participate in the greenhouse gas emission trading system, monitoring of emission levels, settlement of emission allowances, preparation of reports,
- implementing and maintaining an environmental management system or an integrated management system,
- applying for financing of pro-ecological projects – for example from National Fund for Environmental Protection and Water Management.

These activities largely cover responsibility for negative environmental impact, enforced in accordance with the "polluter pays" principle. The activities of enterprises and their effects on environmental protection are monitored in the scope, which is mainly related to the manufacturing of products. That is reflected in reporting and payment of fees for using the environment beyond the scope of general use. In many cases, especially from the point of view of small and medium-sized enterprises, this approach has so far been sufficient, as it corresponded to the level of formal requirements. However, environmental protection law, as well as the theory and practice of enterprise management, are evolving towards taking into account environmental aspects not only at the stage of product production, but also at other stages of its life cycle. In recent years, legal acts, both Polish and EU, have been implemented, which define requirements relating to stages of the product life cycle other than manufacturing for some product groups, e.g. packaging, electrical and electronic equipment, batteries and accumulators, motor vehicles.

The use of a product life cycle assessment broadens the perception of a product's environmental impact and enables a relative assessment of the achievement of the Sustainable Development Goals SDGs. Companies and researchers are becoming more and more aware that engineering activities require a sustainable approach in the face of the growing demand for products created within sustainable development (Sarkis, 2001). However, this approach is still not used more widely in enterprises, especially in the sector of small and medium-sized enterprises SMEs. According to the Commission Recommendation of 9 April 2013 on the use of common methods to measure and communicate the life cycle environmental performance of products and organisations (2013/179/EU) (Commission Recommendation, 2013), most SMEs do not have the knowledge and resources necessary to provide information on environmental performance in life cycle. That is why it is so important to provide support for enterprises in this area. This is due to the complexity of the issue of incorporating environmental aspects into design, as well as because of the still relatively small, though increasing, ability to use this approach in the activities of enterprises.

Compared to large enterprises, SMEs tend to have limited human, knowledge, and financial resources (Michna and Kmieciak, 2020; Ates et al, 2013). On the other hand, they are less formalized and more flexible, thanks to which they have the ability to adapt faster to changes in the environment (Michna et al, 2020).

The aim of this study is to present the reasons for the inclusion of the life cycle perspective in activities undertaken by SMEs, as well as to analyze possible barriers and eco-design procedures in terms of its application by small and medium-sized enterprises.

Rationale for including environmental aspects throughout the life cycle of products in small and medium-sized enterprises

The environmental life cycle of a product is a consecutive approach, with interrelated stages, starting from the research and development phase, acquiring and processing raw materials needed to produce a specific product or provide a service, through the production or service provision phase, product use, up to the disposal of consumer waste.

The first of the important reasons for integrating the life cycle perspective into the activities of small and medium-sized enterprises is the development of legislation in this area. Even if a company only supplies components for the production of a regulated product for another company, the requirements increase along the entire value chain.

Table 1 lists products for which certain environmental protection requirements are present in the legislation in relation to different stages of the life cycle. Three main stages are included - the production stage (the stage of

implementation of technological processes and all auxiliary processes), the use stage (stage related to energy supply, water consumption, maintenance, renovation, regeneration, repair, etc.), post-consumer waste management stage (including e.g. landfill, waste treatment).

Table 1: Life cycle stages of selected product groups for which legal, Polish and / or EU solutions, regulating environmental protection procedures were applied

No	Name of the product or product group	Legal acts obliging to take into account the impact of products on the environment at the stage of use or management of post-consumer waste	Life cycle stages		
			Raw material and material acquisition	Using	Post-consumer waste disposal
1	Packaging: plastic, aluminium, steel, from paper and cardboard, of glass, made of wood, multi-material	Ustawa z dnia 13 czerwca 2013 r. o gospodarce opakowaniami i odpadami opakowaniowymi (Dz.U. 2013 poz. 888) (Ustawa, 2013) Ustawa z dnia 11 maja 2001 r. o obowiązkach przedsiębiorców w zakresie gospodarowania niektórymi odpadami oraz o opłacie produktowej (Dz.U. z 2001 r. Nr 63 poz. 639) (Ustawa o obowiązkach przedsiębiorców, 2001)	X		X
2	Lubricating oils		X		X
3	New pneumatic rubber tires and used pneumatic tires		X		X
4	Equipment operating on the temperature exchange principle (e.g. refrigerators, air conditioning equipment, heat pumps)	Directive 2009/125/EC of the European Parliament and of the Council of 21 October 2009 establishing a framework for the setting of ecodesign requirements for energy-related products (ErP directive) (UE L 285 z 31.10.2009, p. 10-35) (Directive, 2009) Directive 2011/65/EU of the European Parliament and of the Council of 8 June 2011 on the restriction of the use of certain hazardous substances in electrical and electronic equipment (OJ L 174 z 1.7.2011, str. 88-110) (Directive, 2011) Ustawa z dnia 11 września 2015 r. o zużytym sprzęcie elektrycznym i elektronicznym (Dz.U. z 2015 r. poz. 1688) (Ustawa, 2015)	X	X	X
5	Lighting equipment (e.g. fluorescent lamps, LED)		X	X	X
6	Large and small electrical and electronic equipment (e.g. household appliances, washing machines, dryers; watches, irons)		X	X	X
7	IT and telecommunications equipment (e.g. telephones, printers, personal computers)		X	X	X
8	Consumer equipment and photovoltaic panels (e.g. radio, TV sets)		X	X	X
9	Electric and electronic tools (e.g. drills, saws, sewing machines)		X	X	X
10	Toys, recreational and sports equipment (e.g. consoles, video games)		X	X	X
11	Medical devices (e.g. cardiology equipment, dialysis equipment)		X	X	X
12	Monitoring and control instruments (e.g. smoke detectors, heat regulators, thermostats)		X	X	X
13	Vending machines (e.g. vending machines for dispensing products, money)		X	X	X
14	Industrial and portable batteries and accumulators	Ustawa z dnia 24 kwietnia 2009 r. o bateriach i akumulatorach (Dz.U. z 2009 r. Nr 79, poz. 666) (Ustawa, 2009)	X		X
15	Motor vehicles and three-wheeled mopeds	Ustawa z dnia 20 stycznia 2005 r. o recyklingu pojazdów wycofanych z	X		X

		eksplo23atacji (Dz.U. z 2005 r. Nr 25, poz. 202) (Ustawa, 2005)			
16	Sale of food	Ustawa z dnia 19 lipca 2019 roku o przeciwdziałaniu marnowaniu żywności (Dz. U. 2019 poz. 1680) (Ustawa, 2019)		X	X

The production stage of products is subject to legal regulations aimed at reducing the environmental impact of production processes along the entire supply chain. These regulations apply not only to producers who produce a specific product for which the environmental impact is determined, but also to those involved in the acquisition of energy resources, metal ores, chemical raw materials, precious and semi-precious stones, other resources, processing of these raw materials, the use of secondary raw materials and manufacturing of materials.

As shown in Table 1, there are also more and more solutions aimed at reducing the environmental impact after the end of use of products. This applies, for example, to packaging, tires, electrical and electronic equipment, and motor vehicles. Additionally, solutions are implemented to reduce electricity consumption at the stage of use of energy-related products. This applies to such product groups as refrigeration appliances, washing machines, dishwashers, air conditioners, fans, hot water boilers, TV sets, fluorescent lamps, electric motors, external electric power supplies, water pumps, circulation pumps, the so-called set-top boxes.

Taking into account the list of products presented in Table 1, it can be concluded that the problem of considering environmental aspects at various stages of the life cycle concerns mainly to large enterprises and concerns. Small and medium-sized enterprises are however suppliers of components for the production of products manufactured by large enterprises.

In addition to the applicable legal regulations, a motivating role in carrying out the analysis of the impact of the life cycle on the environment is played by activities in the field of product development and improvement, that is, identifying opportunities to improve the environmental performance of products at various stages of their life cycle (ISO 14044, 2006; ISO/TR 14062, 2002), mainly as part of eco-design.

Supporting decision making in industry, governmental or non-governmental organizations (e.g. in strategic planning, setting priorities, implementing changes taking into account the impact on the environment) is another premise for conducting an environmental analysis of the product life cycle. Applications of life cycle assessment in the area of environmental management systems and tools include, inter alia, environmental management systems and environmental performance assessment, for example, identification of the significant environmental aspects of an organisation's products and services, integrating environmental aspects into product standards, environmental communication (ISO 14044, 2006), and product evaluation under GPP.

The above-mentioned applications of environmental life cycle analysis of products are followed by its use for marketing purposes (ISO 14044, 2006) (e.g. as part of the environmental labelling system, preparation of environmental statements or environmental declarations, as well as CSR (Corporate Social Responsibility) reports).

The system-wide nature of the life cycle perspective means that its inclusion in the procedures used in other methodological approaches to environmental analysis can be a complementary factor in the environmental impact assessment (EIA), the economic side of environmental management (EMA), policy evaluation (recycling models, etc.), Sustainability, Substance and Material Flow Analysis (SFA and MFA), Hazard Assessment and Risk Management of Facilities and Facilities, Product Responsibility, Supply Chain Management, Life Cycle Management (LCM), Project Descriptions, Life Cycle Thinking, Cost Analysis life cycle (LCC) (ISO 14044, 2006).

Moreover in December 2015, the European Commission adopted the EU Circular Economy Action Plan to boost employment, growth and investment, and develop a carbon neutral, resource-efficient and competitive economy. On 4 March 2019, the European Commission Report on the implementation of the Circular Economy Action Plan (COM (2019) 190 final) was presented. It states that the circular economy is now an irreversible global trend on a large scale. However, much effort is still needed to intensify EU and global action, fully close the loop and take advantage of the competitive advantage that the circular economy provides for EU enterprises. In this context, a further challenge is for the circular economy is to be at the heart of the EU's industrial strategy, which will enable a closed loop in new areas and sectors. The product life cycle assessment should become the norm and eco-design rules should be extended as much as possible (COM (2019) 190 final). With this message, a new Circular Economy Action Plan was developed (COM/2020/98 final). It sets out a sustainable product policy framework covering the design of sustainable products, empowering consumers and public buyers, and a closed loop in production processes. Key product value chains have also been identified for electronics and ICT (Information and Communication Technologies), batteries, accumulators and vehicles, packaging, plastics, textiles, construction and

buildings, as well as for food, water and nutrients. Actions are also proposed to reduce the amount of waste, adapt the closed loop to the needs of people, regions and cities, and take into account the global context of the implemented solutions (COM/2020/98 final) (Baran, 2019).

However, the inspirational role of the above-mentioned approaches is often not yet reflected in practice of Polish SMEs, due to both the constant need to overcome barriers that are generally associated with environmental protection measures and the specific problems of carrying out a life cycle assessment.

Barriers of life cycle perspective implementation in SMEs

Introduction a life cycle perspective in SMEs involves the use of analytical methods based on life cycle assessment. It is necessary to determine the impact of specific product and process solutions on the environment.
Barriers to using LCA, affecting the limitations of the inclusion of a life cycle perspective, lead to lost opportunities for improved environmental decisions. Potential concerns that affect the use of LCA methods include the aspects pointed in table 2 with considering possible solutions.

Table 2: Barriers of life cycle approach-based methods implementation

Barriers	Description	Considering possible solutions
Resource requirements	- Required know-how - Time consumption - High costs	- Outsourcing of life cycle approach expertise, acquiring the know-how from outside - Searching for external financing options - Estimation and comparing the costs and benefits of external and internal expert LCA services
Data requirements	- Difficult data collection procedures in practice - The need for internal training to collect good site-specific quality data - Inconsistent data - external and internal - Lack of internal procedures for collecting life cycle data - Data are not available at the needed level (e.g. geographic, process) - The range of LCI databases vary in design, format, and quality - Data not available in the value chain	- Joining in developing databases with data that have been vetted within the industry - Development and implementation of internal procedures and data collection systems adapted to the needs of LCA
Increasing number of methodologies, standards and programs containing methodological recommendations	- The problem with determining the appropriate methodological approach needed in a given situation	- Developing know-how - Trainings
Limited guidance	- Problems with the application of complicated methodological procedures in available programs (e.g. concerning recycled content) - Methodology in continuous dynamic development	- Employees trainings - Developing cooperation with partners in the value chain – especially with suppliers and clients
Uncertainties over implementation of results	The results of an LCA may suggest a change in a company's operations. Dedicated competence groups within an organization are somewhat reluctant to changes and particularly changes that don't evolve from activities within the group itself	- Implementation appropriate knowledge management approach to life cycle-based activities - Stimulating LCA understanding in the Human Resources area

Validity	Power of and value provided by LCA would increase significantly if it were validated – additional costs and requirements	- Analysis of the possibilities of validity and selection of the best solution
Scientific basis	Life-cycle studies that do not follow the steps of a traditional LCA may be criticized as lacking scientific support	- Cooperation with science - Development of internal know-how
Transparency	Existing standards and guidance provide some guidelines, which, if followed, will ensure consistency, but for some issues, the standards are silent or ambiguous, leaving room for the use of an extensive range of methods. Many of these methods lack transparency on core methodological issues, making it difficult to compare them with other methods	- Organization needs initial analysis before conducting LCA-based analysis - Adaptation of the methodology used to the needs
Absence of perceived need	Many companies do not see how lifecycle thinking can be applied to their specific operations - or even the benefits of doing so. Many potential users are unaware of how life-cycle approaches can aid in decision making. Documentation of performance improvements can be tedious and resource intensive, but may be necessary to verify the results of changes resulting from life-cycle thinking.	Options for integrating or at least considering LCA analytical approaches and results in conjunction with other environmental and decision making tools will be needed to show how LCA can contribute to improved decisions.
Organizational structures	Often, life-cycle practitioners are functionally a part of a company's environment, safety, and health division - separated or disconnected from the process design and product development departments. Thus, the knowledge of the life-cycle practitioners is not shared with developers, and the developers may not be aware of how life-cycle thinking can be integrated into design and development.	- Introduction of a new department dealing with sustainable development - Appropriate department empowerment because many internal parties need to work together to implement LCA-related projects providing the required resources for the sustainability initiative including time and educational resources - Participating actively in setting up the strategic sustainability goals of the organization - Communicating explicitly throughout the organization regarding the sustainability aims in an effective and clear manner - Involving actively the employees with regard to ideas and suggestions for the use of life cycle approaches

Ecodesign as a tool for incorporating a life cycle perspective in small and medium-sized enterprises

Figure 1 shows the general model for integrating environmental aspects into the product design and development process, with guidance for small and medium-sized enterprises. Suggestions to apply solutions in small and medium-sized enterprises result from the need to take into account the realities of running a business in the SME sector.

Typical stages of the product design and development process	Recommendations for small and medium-sized enterprises on integrating environmental aspects into product design and development
Planning	– Initial problem analysis (formulated in relation to a specific goal and requirements) in the context of existing conditions (including time frames, financial constraints, external factors). – Decide whether to carry out the eco-design procedure on your own or consider involving an external expert. – Organization of possible training for staff or sending employees to training.
Design assumptions	
Conceptual design	– Initiating and conducting activities aimed at identifying concept solutions. – Caring for commitment to the search for solutions of a carefully selected, properly motivated team. – Initial analysis of the availability and adequacy of internal resources as part of the potential implementation of individual solutions. – Application of simpler analytical methods - qualitative and semi-quantitative in order to estimate the environmental impact of the considered solutions.
Design concept	
Detailed design	– Development of selected design concepts using the design tools used so far, or considering the purchase of e.g. new software. – Ensuring the creation and maintenance of an internal database for the implementation of a specific solution.
Design solution	
Research/prototype	– Verification of the achievement of the ecodesign goal and ensuring that at this stage there is communication between employees responsible for design and sales.
Prototype	
Production and introducing to the market	– Ensuring that the launch of the product on the market is accompanied by carefully prepared information addressed to customers.
Product	
Product overview	– Periodic reviews of both the product design and development process and its results.

Fig. 1: General model of integrating environmental aspects into the product design and development process with recommendations for implementation in small and medium-sized enterprises.
Source: on the basis (ISO/TR 14062, 2002; Baran, 2013).

It is particularly important for small and medium-sized enterprises to decide whether to carry out the eco-design procedure on their own or with the involvement of an external expert. The first solution is a more demanding approach, the barrier to its application is primarily the need to have specialist knowledge in the field of estimating the impact of the life cycle on the environment, including knowledge of appropriate software and the ability to select appropriate research methods. While large enterprises have organized research and development departments and laboratories, thanks to which the implementation of new solutions is easier, it is much more difficult in enterprises without such departments and experience. In this case, it is worth considering involving an external expert, especially if a life cycle assessment is required. If, on the other hand, ecodesign will be carried out by employees of a given company, then it is necessary to appoint a carefully selected design team composed of people responsible for design, production, financial and marketing aspects. It is also important to involve top management (Baran, 2017).

In small and medium-sized enterprises that implement the ecodesign procedure on their own, special attention at the stage of conceptual design should be paid to initiating and conducting activities aimed at identifying concept solutions (Baran, 2015). It is worth using tools and methods that stimulate creativity, including heuristic methods,

such as brainstorming or unorganized thinking. A less formal approach in contacts between employees in small and medium-sized enterprises as compared to large enterprises seems to be an opportunity to obtain the appropriate results (Jonek-Kowalska, 2019).

Another important issue at this stage for small and medium-sized enterprises is the analysis and assessment of the availability and adequacy of internal resources as part of the potential implementation of individual solutions. This is all the more important as small and medium-sized enterprises usually have less financial resources, which limits the possibilities of implementing some solutions.
At this stage, it is often necessary to carry out a life cycle environmental analysis. Faced with the complexity and high level of difficulty in carrying out a life cycle assessment, small and medium-sized enterprises, if possible, may use simpler analytical methods - qualitative and semi-quantitative, to assess the environmental impact of the solutions considered.

Overall, ecodesign (at all stages of the presented model of the ecodesign process) can be supported as part of the environmental management system and in this respect the recommendations of PN-EN ISO 14006 can be used, which provide guidelines to assist the organization in establishing, documenting, implementing, the maintenance and continual improvement of ecodesign management, which is treated as part of the environmental management system. It is intended for the use by those organizations that have implemented an environmental management system according to PN-EN ISO 14001, but it can also be useful in other management systems. These guidelines are applicable to any organization, regardless of its size or type of business.

Conclusions

Environmental aspects relating to the entire product life cycle in the design and development of products is increasingly becoming a necessity. At the same time, small and medium-sized enterprises are forced to respond to legal requirements regarding the environmental aspects of the products for the production of which they supply components. Large enterprises with R&D departments separate in their structure are able to respond faster and more adequately to the need to meet new legal requirements, while a less formalized or informal, more intuitive approach to product design and development in small and medium-sized enterprises can be perceived as a weakness when it is necessary to use a complex procedure and complicated test methods that may be resistant on first contact. In addition, the use of cost-intensive design solutions as well as the purchase of software supporting the design process is more achievable for large enterprises that have greater access to capital. In small and medium-sized enterprises with fewer employees, there are also fewer opportunities to delegate selected employees who are involved in fulfilling time-consuming duties, to additionally carry out the eco-design procedure. There are also concerns about potential unwanted knowledge transfer in the event of the possible involvement of external experts. These problems, when confronted with the still low ecological awareness of the society and the perception of environmental protection primarily as a cost, require a special approach both in the development of legal solutions that should take into account these difficulties of small and medium-sized enterprises, proposing instruments to facilitate their implementation, as well as in the field of offering small and medium-sized enterprises practical solutions supporting ecodesign.

Abstract

Technology transfer is of particular strategic importance, as technology is a catalyst for the socio-economic development of economic actors at home and abroad. Technology consists of a pool of knowledge and know-how, acts as a catalyst for healthy and competitive international trade, and is linked to the commercial needs of industrial enterprises. Sectors of economy, regions and national economies in general need effective planning of research activities and management of production, from the research laboratory to the market of knowledge-based products. The tasks of creating an institutional environment for technology transfer in Russia actualize the need to develop recommendations for improving the efficiency of technology transfer, which is the subject of this article.

Keywords: Innovation, technology transfer, efficiency, technologies, Russian economy.

Introduction

From a legal point of view, technology consists of the set of intellectual property rights and the tangible holders in which it is expressed. From the economists' point of view, technology is an incentive for competitive (e.g. international) trade, linked to the commercial needs of industrial enterprises, Sectors of the economy, regions and national economies in general need effective planning of research activities and management of production, from the research laboratory to the market of knowledge-based products.

Thus, the objects of transfer (transfer) of innovative technologies are, first, the rights to the protected results of intellectual activity and means of individualization (article 1225 of the Civil Code of the Russian Federation) and, second, the material carriers in which they are expressed.

Definition of the category «technology transfer»

Let us further indicate different approaches to the definition of the category «technology transfer». In the most common variant in various scientific and methodical sources, the transfer of technologies is the «process of involving technological innovations in market relations» and is literally translated as «transfer of technologies in the direction of application of knowledge», «the process of transferring technologies from one field of activity to another or from one field of application to another» and is:

- a process of realization of scientific and technological achievements in products and services offered to the market;

– using of intellectual property developed and tested in some fields (in some enterprises) and in other fields (enterprises).

Development of technology transfer mechanisms in Russia

Considering the emergence and development of technology transfer mechanisms, it is worth noting the key importance for its development of the economic restructuring that took place in Russia in the early 1990s.

In the Soviet economy, the invention (technological development, technology) was, a priori, the property of the State; then, tried and legally secured methods were proposed for bringing the invention into practical activity. At the same time, the economic effect of the use of innovations was not a decisive criterion for its introduction into industrial production (which can be considered in both positive and negative context); instead the term «introduction» was used (technologies, inventions, new technical solutions, etc.), which were carried out within the framework of the existing management system with the assigned formal functions of purpose, planning, control, motivation, etc. Unlike the term «transfer» discussed above, it has an emphasis on «transfer», which can be carried out both within administrative procedures and spontaneously, under the influence of economic interests of spontaneous economic agents.

Mechanisms of technology transfer

The general legal framework for the implementation of technology transfer processes in Russian legislation is regulated by the Decree of the President of the Russian Federation of 1 December 2016 #642 «Strategy of Scientific and Technological Development of the Russian Federation» where the formation of an effective system of communications in the field of science, technology and innovation, etc. the formation of a system of technology transfer, is defined as one of the main directions and measures of implementation of State policy in the field of scientific and technological development.

At the same time, legal and methodological documents such as the Model Regulation «Intellectual Property Policy for Universities and Research Organizations», Recommendations on Management of Intellectual Output Rights in Organizations, Recommendations on Management of Intellectual Output Rights and Tools for Customization in Regions, and «National Standards: Technology transfer. General provisions» (GOST R 57194.1-2016), «Technology transfer. Technological audit» (GOST R 57194.3-2016), «Technology transfer. Results of intellectual activity» (GOST 57194.2-2016) are used.

Legislative and infrastructural framework of technology transfer in Russia

The analysis of the legislative and infrastructural framework of technology transfer processes raises many questions, particularly with regard to mechanisms for diffusion of innovation. The development of the IP market is a key element in the utilization of national scientific capabilities. Despite some transformations in Russian legislation in the field of protection of IP facilities, the legal and regulatory framework still has a number of «shadow parties» requiring further clarification and refinement.

Thus, the existing legal norms define the relationship of the organization with the external environment, covering those spheres of activity which have a connection with commercial secrecy. Such relationships are largely determined by long-standing personal contacts and informal relationships. The introduction of the most flexible IP market regulation still remains a pressing issue: restrictions on the application of antimonopoly legislation in the area of IP regulation should be removed. A balance must be struck between the inadmissibility of unfair competition and the interests of the right holder in the protection of IP objects. Legal uncertainty about IP facilities reduces the intensity of technology transfer.

The issue of VAT taxation of the transfer of rights to IP objects remains unresolved. The position of the Plenum of the Russian Federation (Decision of 30.05.2014) is that, in accordance with paragraph 1 article 146 of Tax Code of the Russian Federation, which defines as the object of the VAT levy the actions on the provision of services, should be taken into account that the concept of «service» presupposes the transfer of patents, licenses, trademarks and other civil-legal obligations. The Tax Code of the Russian Federation does not explain whether VAT should be withheld if the difference between the amount of income received from the assignment of the property right and the cost of the acquisition of the claim is negative or nil (art. 155 of the Tax Code of the Russian Federation). There is no official position on this matter.

It is important to note the lack of sufficient attention by law to the regulation of licensing relationships. The execution of the license agreement is an important stage in the process of transferring rights to the use of IP objects. The efficiency of the transfer of IS objects depends on the proper execution of all the terms of the agreement. According to art.1237 Civil Code of the Russian Federation, control over the execution of the license agreement is entrusted to the licensor on the basis of the licensee's account of the use of the IP objects. The lack of capacity of the right holder to control access to the IP facility leads to litigation.

Support for technology transfer mechanisms

Direct support for applied research and development is currently being used in Russia, but practice shows that this type of support is not very effective and accounts for a small share of total government financial support for commercial innovation in industrialized countries. For this reason, there is a need for a method to encourage investment in research, which will have a significant impact on the quantity of research and development undertaken.

It seems that the innovative system of Russia has been characterized earlier and continues to be characterized by the approach called «repulsion from technology». This implies, first, significant investment in a large number of potential innovation processes; secondly, increased attention at the initial research stage of innovation; thirdly, the fact that the technological process is beginning, In fact, from scratch, it ignores lessons learned in other areas of activity.

In addition, there is currently no body responsible for technology transfer in the Russian Federation; the software-targeted method of technology transfer management is not sufficiently used, etc.

This leads developers, technology implementers, and other transfer participants to the disappointing conclusion that investment in technological solutions can in most cases not be commercially viable, economically efficient. The challenge is to develop a technology transfer mechanism that can be quite successful.

Reasons for technology transfer' ineffectiveness

The number of enterprises from the scientific and practical fields involved in technology transfer to the real economy is not commensurate with their counterparts abroad. Nor is there a clear positive development in the number of such enterprises in Russia. The current situation is largely due to the fact that there are barriers to the effective operation of the DOT in the process of technology transfer, namely:

1. Lack of communication between innovators (universities, academia) and the business sector on the demand for and supply of business-relevant products from the science and education sector. Many universities do not monitor market needs and do not assess research opportunities leading to commercialization of the results of their intellectual activities.
2. Often innovation is not ready for market entry because of the weak economic component, that is, the mechanism of entry of an innovative product into the market is not sufficiently developed (lack of innovation infrastructure supporting the commercialization of innovative products).
3. The low level of developer activity in patenting their inventions, which reduces the benefits of intellectual property results' commercialization, as proprietary these type of results do not become a commercial product and can only be used in the development of technological processes.
4. Lack of initiatives and insufficient training of research teams in decision-making on commercialization of Reeds and their transfer to the real economy.

Ways of improving the efficiency of technology transfer

The following groups have been identified as possible ways of improving the efficiency of technology transfer processes in the Russian economy: legal, organizational and infrastructural, economic and personnel.
1. The legal enforcement of the regulation of IP transfers in the Russian Federation should aim at developing and adopting the necessary standards and norms in accordance with the objectives of the innovative development of the economy.
2. Establish a framework that should methodologically form an ecosystem of innovation for technology transfer.
3. Creation of a map of transfer efficiency criteria for various economic entities, as well as methodological recommendations for the establishment of such enterprises and the legal and organizational organization of their activities; Methodological aspects of performance assessment for investors and technology owners (i.e., actual business models).

4. Development of professional requirements for the competences of technology transfer specialists.
The proposed measures would significantly improve the efficiency of the technology transfer process, create a continuous flow of high-tech developments, reduce transaction costs and improve the overall dynamics of innovation.

Assessing Innovation Performance Through *Ex-Ante* and *Ex-Post* Patent-Based Measures

Francesca MICHELINO*, Antonello CAMMARANO and Mauro CAPUTO

Abstract

The paper analyzes the relationships between *ex-ante* and *ex-post* measures for innovation performance based on patent data. Results provide suggestions for innovation managers on the leverages to be operated during the innovation process for obtaining high valuable patented technologies.

Keywords: innovation performance, patent data.

Introduction

Innovation is more and more acknowledged as the only tool for companies to compete in a sustainable way (Michelino et al., 2019). Patents are universally acknowledged as the main output of technological innovation (Patel et al., 1995; Michelino et al., 2015) and are commonly used as a way for proxying both innovation activities and innovation performance. Yet, among the most interesting indicators for measuring innovation performance we find the so called "*ex-post*" measures, which are available years after the application of the patent.

The aim of this paper is to analyze the relationships that *ex-post* indicators have with *ex-ante* ones, which are immediately available when the R&D efforts for producing the patented technology are put in place. Indeed, if such relationships exist, innovation managers and decision makers can select the more adequate *ex-ante* indicators for obtaining high valuable patents also according to *ex-post* ones.

In what follows, first a literature review of patent-based metrics for innovation is presented. After a methodological section, results are presented and discussed. Conclusions close the work.

Literature Review

The use of patent data to measure innovation has multiple advantages: patent data are widely acknowledged by scientific literature (Burhan et al. 2017; Caputo et al., 2019; Grupp, 1992; Johnstone et al., 2012) since they cover decades of innovation activities (Griliches, 1990), are publicly available, allow access to a wide range of objective and standardized information, are continuously updated (Belderbos et al., 2010). Indeed, patent indicators are able to cover many different aspects of innovation (Squicciarini et al., 2013), from technological acknowledgement to scientific content, from knowledge base breadth to market success. Among patent quality indicators, a distinction is made between *ex-ante* and *ex-post* indicators, according to the possibility of determining the measure before or after the date of publication.

Ex-ante measures

Ex-ante indicators are available at the date of application of the patented technology and contain information on its potential value.

The number of claims determines the boundaries of the exclusive right in terms of legal protection and defines the scope of the patent, i.e. its potential uses/products/applications, whereas the breadth of the patented technology can be measured looking at the number of different knowledge domains (Squicciarini et al., 2013).

As to backward citations, from one side, the absence of citations to previous patents defines the originality of the technology since no previous art is found for the technology (Cammarano et al., 2019). On the other side, the

Cite this Article as: Francesca MICHELINO, Antonello CAMMARANO and Mauro CAPUTO "Assessing Innovation Performance Through Ex-Ante and Ex-Post Patent-Based Measures" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

existence of citations to non-patent literature (NPL) and research papers defines the scientific content of the patent and its complexity (Callaert et al., 2006).

Looking at the technological areas of the patent (Lerner, 1994), the presence of new combination of knowledge domains denotes the capability of creating new architectures and developing architectural innovation (Guan and Yan, 2016; Verhoeven et al., 2016).

All these indicators can be modulated by innovation managers by addressing R&D efforts towards new technological areas, relevant scientific issues and borderline knowledge. Therefore, the main advantage of such measures is that they are directly manageable already during the innovation process. Yet, the information provided by them is mainly related to the potentiality of the technology and not to the actual success it can have.

Ex-Post Measures

Ex-post indicators overcome the problems of *ex-ante* ones, determining the actual impact of the patent in terms of both technological and market success.

Indeed, many authors define the technological acknowledgment of the patent through the number of forward citations received from other patents, which attest the validity of the new technology (Hall et al., 2000; Cammarano et al., 2017a; Ahuja and Lampert, 2001). On the other side, the market success can be defined by the number of patents generated by the applicant after the focal patent and recalling it as a priority, i.e. the numerosity of the patent forward family (Squicciarini et al., 2013; Harhoff et al., 2003).

Obviously, the fact that the applied patent is actually granted by the receiving office is a measure of effectiveness of the innovation process. Yet, even granted patents are sometimes lapsed by the assignees when the benefits deriving from the exclusive right ownership are valued lower that the costs for maintain it: therefore, the payment of renewal fees is a direct measure of the value that the owner of the patent directly attributes to it (Squicciarini et al., 2013; Svensson, 2012).

Even if *ex-post* indicators are capable to provide information on the actual success of the patent, their definition is possible only years after the publication and decision makers are not able to directly modulate them during the innovation process. For this reason, finding statistically significant relationships between such indicators and *ex-ante* measures can provide a guide to managers and decision makers concerning *ex-ante* measures to focus on in order to obtain adequate *ex-post* indicators.

Methodology

Data and sample

The research is performed on patents filed by R&D-intense IT hardware companies from 2000 to 2009 and thereafter granted. The industry was selected since intellectual property plays a central role in this sector: patents are a means of appropriation of innovation (Pavitt, 1984) and can be employed to study innovation practices (Cammarano et al., 2017b). The choice of the years of analysis depends on the need for evaluating *ex-post* patent quality indicators, with 2009 being the latest period for which information is available in the PATSTAT version available for the authors. The firms were selected from *The EU Industrial R&D Investment Scoreboard*, which annually reports the ranking of the worldwide top R&D spending companies. In particular, only those repeatedly included in five subsequent scoreboards were considered, in order to include the firms showing a continuous commitment to innovation.

A total of 1,705 patents applied by 60 companies is found.

Variable definition

Consistently with literature, the following *ex-ante* indicators are included in the work:

- **scope**, defined as the number of claims reported in the application;
- **breadth**, defined as the number of international patent classification (IPC) codes within the patent;
- **originality**, a dummy variable assuming a value of 1 if no patent backward citations is reported in the application, 0 otherwise;
- **scientific value**, calculated as the number of NPL backward citations reported in the application;

- **architectural capability**, a dummy variable assuming a value of 1 if the combination of IPC codes reported in the application is new-to-the-world, 0 otherwise.

Similarly, *ex-post* measures are defined as:

- **technological value**, defined as the number of external forward citations received five years after publication (i.e. self-citations are excluded);
- **market value**, defined as the number of family patents, i.e., the number of patents applied within 5 years from application defining the focal patent as a priority;
- **internal value**, a dummy variable assuming a value of 1 if renewal fees are paid eight years after publications, 0 otherwise.

Statistical analyses

Firstly, in order to find relationships between *ex-ante* and *ex-post* quality measures, Pearson's correlations are performed. Thereafter, regressions of *ex-post* indicators using *ex-ante* ones as predictors are used to find linear dependency relations.

Moreover, by performing Ward cluster analysis using *ex-post* indicators as clustering variables, different clusters of patents are found characterized by different values of such metrics: a one-way ANOVA is therefore performed to find whether significant differences are found among the clusters also as to *ex-ante* indicators.

Finally, principal component analysis is performed to find the latent concepts behind the different performance indicators, trying to summarize the information they contain and finding redundancy among the metrics, i.e. whether different indicators measure similar concepts.

Results

In Table 1 means and correlation coefficients are reported for the variables under investigation.

Technological value is positively associated to breadth and negatively related to originality: patents receiving higher technological acknowledgment are those with a wider knowledge base, but also those relying on an already strong prior art. Indeed, original patents, i.e. patents that do not cite previous patented technologies, may be related to newer and more risky technologies that can turn into failures.

Market value is positively related to breadth and architectural capability and negatively associated to scope: a wider base of knowledge together with the original combination of knowledge areas turn into technologies that can be usefully employed in different contexts, generating future generations of patents from the focal one. On the other side, if a patent is already defined with a wide scope, i.e. if many different claims are reported, the recourse to a wide patent family is not necessary, being the focal patent a multi-purpose technology.

Internal value is positively associated to patent scope and negatively related to originality and scientific value: multi-purpose technologies are highly valued by their owners, as many applications and products can be derived from them. On the other side, the riskiness associated to radical new, science-based technologies makes patents less appealing for companies, especially when short-term results are pursued.

In Table 3 the results of cluster analysis performed using *ex-post* quality indicators as clustering variables are shown, together with one-way ANOVA significance.

Cluster 1 is characterized by the highest internal value, whereas technological value is on average with that of the sample and market value is very low: for this cluster only scope among *ex-ante* indicators is significantly higher than the average value of the sample, confirming the fact that patents considered a good investment for companies are those featured by many claims and representing multi-purpose technologies.

Cluster 2 is characterized by average market values slightly higher than those of the whole sample, while the other two *ex-post* metrics are below average. These patents have higher values of originality and scientific value, i.e. these are the riskiest technologies. If such riskiness turns into failure in most cases, when this does not happen a market development of the new technology can be observed.

Cluster 3 is featured by higher values of all three *ex-post* indicators if compared to the total sample: such highly valuable patents are characterized by a wider knowledge base and the original combination of technological domains. Including different technological areas into the new technology and combining them in a new-to-world way results in high quality patents.

In Table 4 the results of principal component analysis are shown as to the first four factors, whose eigenvalue is greater than or equal to 1. Moreover, the graphical representation of the quality metrics in the first factorial plane is reported in Figure 1.

The first factor is highly associated to breadth and architectural capability (*ex-ante*) and technological and market value (*ex-post*): combining many different knowledge domains within a single patented technology in a novel way is confirmed as the most significant strategy to pursue high technological and market value.

The second factor is positively associated to originality and scientific value (*ex-ante*), but negatively to internal value (*ex-post*), confirming that the high risk associated to new-to-the-world technologies relying on a complex scientific base often turns into patents that are lapsed by the owner after some years.

Conclusions

The work provides suggestions on the relationships among *ex-ante* and *ex-post* indicators of innovation performance, the former being immediately available but providing information only on the potential value of the patented technology, the latter being capable of defining its actual value but requiring a long period of time to be calculated. In this way the paper contributes to knowledge advancement in innovation management, providing useful insights to decision makers on what leverages operate *ex-ante* in order to obtain high *ex-post* performances.
Relying on patent data - which are standardized, publicly available and verified by independent third parties - yields objectivity to the work, but also limits it only to the technological dimension of innovation. For this reason, future

developments will be addressed towards the inclusion of non-patent indicators of innovation success, such as percentage of revenues deriving from new products, in order to verify the existence of relationships between innovation outputs and financial outcomes.

Abstract
The research aims to test an original cost of quality (CoQ) calculation in an innovative organisation operating in the European defence industry. Our methodology embraces the identification, classification and estimation of CoQ – based on business process mapping and accounting data exploration – as well as a structure and ratio analysis thereof. The main findings show that CoQ constitutes over 39% of operating costs of the company which is the subject of our study, and they are present in nearly all business processes. We find a very high share of compliance costs (>84% of total CoQ), and only a minor percentage of non-compliance costs (<8%), which is a positive phenomenon. The processes that generate most CoQ are the design and development process and the maintenance process. The presented ready-to-use tool allows for the measurement and management of CoQ, and can contribute to controlling and value-based management solutions. Being the first such case study in the high-tech defence industry, our research paper not only fills the gap in academic literature, but has valuable implications for practitioners as well.

Keywords: Cost of Quality, Cost Calculation, Defence Industry, Innovative Organisations, Management Accounting.

Cost of quality and its calculation

Cost of quality (CoQ) is a term defined by Juran (1951) and means an instrument for measuring quality. New definitions of the term have appeared in secondary sources in the years since. Feigenbaum (1961) – the quality guru – believes that these are costs related to pro-quality activities such as prevention, assessment, control testing, and debugging, whereas Groocock (1974) argues that these are costs incurred for defective production and those that would not have occurred without quality assurance activities.

Crosby (1979) points out that quality does not cost anything, but what is costly is the lack of it – that is, doing the work improperly the first time. Oyrzanowski (1984) defines quality costs from the resource-oriented point of view – as outlays on: obtaining a certain level of quality, analysing costs, and carrying out activities aimed at minimising them, whereas Horngren et al. (1997) define them as costs aimed at preventing low quality and those which result from insufficient quality. Bland et al. (1998), on the other hand, define them as costs that constitute the difference between the actual production cost and the cost that would have arisen if there had been no system failures or employee error. Their definition suggests looking at quality costs in terms of opportunity costs.

Zymonik (2003), in turn, presents a marketing orientation by defining quality costs as the consumption of resources needed to generate value for the customer – expressed in monetary units – that the customer is able to accept. For Wood (2007), CoQ is a cost related to the achievement as well as the lack of the desired level of quality of services and products. From an accounting point of view, CoQ is the sum of all compliance and non-compliance costs, where compliance costs are those incurred for the prevention of poor quality and non-compliance costs are those resulting from a lack of appropriate quality of products and services, Mukherjee (2019).

CoQ forms the basis of the CoQ calculation, which is used to measure, record, monitor, analyse, interpret and manage them, Malik et al. (2016). The aims of that calculation are indicated, among others, by Toruński (2012): assessment of management system efficiency, creation of a basis for quality improvement programmes, the identification of key areas and processes that require improvement, and an increase in goodwill. In addition, the CoQ calculation is used to measure the efficiency of an organisation and also helps to increase profitability and competitiveness, Jafari and Rodchua (2014), Malik et al. (2016).

The CoQ calculation models developed mostly apply to enterprises in the industrial sector; examples of these are studies from the wood, metallurgical, machinery, furniture, automotive and food industries, Harrington (1987), Pole (2003), Chopra and Garg (2012), Malik et al. (2016), Teli et al. (2018), Pristavka and Koloman (2018). These models most often include assumptions, the structure of CoQ, and sources of information on CoQ, as well as bodies responsible for the calculation of CoQ, Sadkowski (2019a). However, to the best of our knowledge, there are no scientific studies that would test the calculation of CoQ in the defence industry. This study therefore contributes to filling this research gap.

It should be stressed that CoQ calculation is a management accounting tool, which means that there are no legal norms that would oblige enterprises to implement it in their accounting systems, nor are there any regulations that shape it. The optional nature of its application means that only a few organisations have decided to implement it. On the other hand, the discretion of its structure provides an opportunity to create original and innovative tools.

The awareness of the existence of CoQ is confirmed by almost every entrepreneur; however, most of them do not want to expose themselves to additional costs and labour outlays related to keeping an account of these costs. This is surprising because, by doing so, organisations deprive themselves of a number of possible benefits, such as gaining a competitive advantage, improving the quality of services and products offered, or increasing the efficiency of processes. The economic balance associated with the implementation of the CoQ calculation clearly shows that the sum of potential benefits far exceeds the costs of its implementation, Jafari and Rodchua (2014), Murumkar et al. (2018), Elsharif (2019).

The role of CoQ and its measurement in innovative organisations

The efficient management of costs and the processes that generate them has a critical impact on the achievement of an enterprise's goals. One of the most important systems in an organisation in particular – a management system that controls processes and the activities that create them – requires the supply of information on costs, to be collected in accounting and controlling subsystems. In innovative enterprises, information on CoQ is all the more important, as these types of costs are generated in almost all business processes of those entities.

The processes of enterprises (especially innovative ones) should therefore be systematically measured on the basis of established efficiency measures. The ISO 9000:2015 standard "Quality management systems – Fundamentals and vocabulary" stresses that the measure of process efficiency is expressed by the degree to which the quality goals they contain (which must be measurable) are achieved, ISO (2015).

CoQ, which is the main element of CoQ calculation, make it possible to assess the degree of achievement of quality goals, Sadkowski (2015). Measuring these costs in innovative enterprises, such as those operating in the high technology sector, is a significant challenge for managers because the costs in question can be hidden in all processes operating in those entities, Yang (2008), Murumkar et al. (2017).

Mukherjee (2019) points out that it is CoQ analysis that determines the assessment of process efficiency. Reliably conducted, it allows one to: determine the amount and structure of CoQ, determine the dynamics of its changes in the studied periods, identify the places where it arises, take corrective actions, optimise costs, increase the efficiency of management systems, and improve the quality of processes as well as products and services provided to customers, Sadkowski (2019b).

In summary, CoQ calculation is a very important tool which supports effective management in innovative enterprises. Its skilful use supports the achievement of competitive advantage, increases the effectiveness and efficiency of processes, and improves the quality of products and services offered, Jafari and Rodchua (2014), Murumkar et al. (2018).

CoQ calculation in an innovative organisation – a case study from the EU defence industry

Subject and context of the research

Aerospace and defence [1] is a high-tech industry that has become a critical part of the global infrastructure, economic growth, international trade, and globalisation, and plays a vital role in national security, Briones-Peñalver et al. (2020). The defence sector itself is actually part of the latter – a larger structure in the security sector of a nation, Chuter (2011). This is why it is directly affected by national security policy and indirectly affected by invisible pressure from social-economic policies and the development of information technology, Wang et al. (2018). From the perspective of the population as a whole, the security sector is the foundation of the state's stability – hence security in daily life

is a precondition for economic and political development and a well-functioning security sector is therefore fundamental to a country's success, Chuter (2011).

At regional level, the defence industry is important to the competitiveness of EU industry as a whole because of factors related to technological and economic policy. After all, the main goals of the European Union's industrial policy include: support for scientific and technical progress, which determines the competitiveness of Community products; support for the development of so-called strategic industries, that is, those which ensure the share of production of new generations of products based on modern technologies on global markets (which are important for defence) as well as prestigious industries such as information technology, biotechnologies, space research and technology, the aerospace industry, and nuclear energy. The competitiveness of the European defence industry is also crucial to the credibility of the Common Security and Defence Policy, Defence Industry (2020). Figures demonstrate that this is an important sector for the economies and societies of the EU Member States – with a turnover of EUR 97.3 billion for 2014, directly employing 500,000 people, and creating 1.2 million indirect jobs, Defence Industry (2020).

The European defence sector is currently facing challenges such as market fragmentation and falling defence spending, Defence Industry (2020). Like other industries, it needs to move towards increasing efficiency in order to provide the best value for money to its customers while protecting the interests of its shareholders. Hence, inasmuch as is the case with enterprises operating in other industries, efficient management, including cost optimisation – especially in critical organisational processes such as quality assurance – is crucial here. Efforts to monitor quality management systems and to ensure product quality are enormous in the defence industry, Thomas (2006). This is due to technological sophistication, the rigours of stringent practices, and control within the supply chain, which all serve to create a significant challenge to quality assurance functions in general, Thomas (2006).

In many respects, the defence sector is a peculiar market that differs substantially from many other industries of the economy, Castellacci & Fevolden (2015). First, defence companies are heterogeneous and produce in several different industry segments, Hall et al. (2010). Second, they invest heavily in R&D and innovation, but the lag between input and output of the innovative process is often very long, González & López (2013). Third, the industry is heavily regulated and protected, and public instruments such as R&D procurement and offset agreements are commonly used to support national interest and domestic firms, Guay & Callum (2002).

The enterprise which is the subject of this study competes in the defence sector and is part of a corporation operating in one of the EU Member States which brings together several dozen industrial plants and research centres of key importance to the national defence industry. It is one of the largest defence solutions providers in Europe. The company's core business is the creation, production and sales of optoelectronic products for the military and, to a limited extent, for the civilian market. It is a large enterprise [2], which is in fact a research and production centre, where all products created and sold are the result of the work of the corporation's own research and development facilities.

Optoelectronics, and more broadly photonic techniques, have been identified as key technologies for the development of many fields of technology, PPTF (2015). The 21st century is expected to be the century of "light". Photonics [3] is currently one of the fastest growing fields of science, and – as a high-tech industry – it is characterised by a high degree of globalisation and rapid diffusion of innovation, www1 (2018).

The analysed enterprise is a highly innovative organisation from a technological point of view, and this is what it builds its competitive advantage on. Technological innovation is a crucial competitive strategy for companies in the defence industry, and public policies that support R&D investments and close cooperation between private firms and public science and technology organisations play a particularly relevant role in this sector, Castellacci & Fevolden (2015). The managers of the enterprise are aware of that, as evidenced, for example, by its organisational structure, human resources management policy, and its relational capital. The company has its own R&D and innovation department, which introduces innovative projects to the company, obtains external funding (both domestic and foreign), and is fully responsible for the overall management of projects commissioned to the company as part of competitions. Approximately 40% of the company's employees carry out tasks in the field of R&D. The company has won numerous competitions within the framework of programmes supporting innovation related to the development of modern technologies, obtaining funding for projects in the field of scientific research or development work for the benefit of national defence and security. Most of these projects are carried out in consortia, consisting of units of the arms industry, universities (mainly technical) and private entities.

The result of extensive cooperation between the enterprise and the academic community is, among other things, the research presented in this article in the area of CoQ and its calculation. It shows that the company not only engages

its resources in product and technological innovations (which is obvious in this industry), but is also open to organisational and management innovations.

The selected enterprise is a case study which is representative of innovative organisations for research into CoQ for at least three reasons: (1) it is an enterprise operating in the high technology sector, which requires numerous product and technological innovations that must be driven by above-average quality; (2) it operates in a strategic industry from the point of view of national defence and, as such, must meet the highest quality standards in order to deliver the expected value for the customer; and (3) it has quality assurance systems (such as the ISO-certified quality management system), suitable organisational structures and competent human resources in the area of quality. For the above reasons, CoQ should be present in almost every process of the enterprise's operations, thus constituting an important component of its economic balance. That balance, on the other hand, is both a result and a factor determining the company's competitive position. As a participant in the international market, the company competes with foreign companies, which often have a decisive advantage in terms of financing (national defence sectors are usually financed by a fixed percentage of a given country's GDP), have a wider market and have greater opportunities for lobbying at the international level. The challenge of Industry 4.0 must be added to these market conditions (as well as the announced Industry 5.0), which poses not only a qualitative challenge, but – above all – a financial/investment (cost) challenge.

Industry 4.0 is seen to represent the transformation of organisations to digitalise their entire manufacturing process and its environment. It is anticipated that advancements in Industry 4.0 will lead to dramatic improvements in the flexibility, efficiency and automation of manufacturing, Bibby & Dehe (2018). They are welcomed by manufacturing organisations who are continually aiming to "eliminate unnecessary production costs; improve manufacturing process and business performance; increase throughput; reduce cycle times and maintain quality" in order to operate in changing manufacturing environments, Cottyn et al. (2011, p. 4397).

Therefore, quality management together with cost management (understood as cost optimisation while maximising the value for the customer) may constitute an important source of competitive advantage for enterprises operating in the European defence sector, an example of which is the company which is the subject of this study.

Research Methodology

Estimating CoQ is a process that requires the following assumptions. The studied enterprise must have a quality management system confirmed by an ISO certificate, maintain comprehensive bookkeeping, and provide access to its sensitive data (i.e. quality book, process map, unpublished financial data, and data from the accounting system). Full cooperation between the studied entity and the person(s) responsible for the implementation of the CoQ calculation is necessary. CoQ arises in processes implemented by innovative enterprises. The adopted cost categories include prevention costs, appraisal costs, internal failure costs, external failure costs, and other CoQ. Prevention costs are the costs related to providing the conditions for meeting quality requirements in the implemented production and service processes (e.g. costs of employee training). Appraisal costs are costs incurred to ensure that the requirements in the processes are met (e.g. audit costs). The costs related to irregularities that occurred before the product was delivered to the customer are the costs of internal failure (e.g. the cost of a defective product), and those detected after the product was delivered to the customer are the costs of external failure (e.g. warranty repairs). Other costs of quality include costs that cannot be assigned to compliance costs (the cost of prevention and appraisal) and non-compliance costs (the costs of failure), e.g. the cost of environmental fees.

The first stage of estimating CoQ is related to the analysis of a map of processes of the studied enterprise. On the basis of the analysis, it will be possible to indicate a potential CoQ that is hidden in the processes under way, and to place them in the identification form presented in Table 1. At this stage, consulting the Quality Management Systems Officer, as well as the accounting department, is recommended.

Table 1: Cost of quality estimation form

Name of the process	Name of the cost	CoQ category	The amount of the cost	Source document	Additional information
process No. 1	Cost No. 1				
	Cost No. 2				
	Cost No. n				
process No. 2	Cost No. 1				
	Cost No. 2				
	Cost No. n				
process No. n	Cost No. 1				
	Cost No. 2				
	Cost No. n				

Note: own elaboration.

The CoQ items identified require actions related to estimating their amount, assigning them to an appropriate cost category, and indicating the source document. Therefore, cooperation with the accounting department of the studied entity is of vital importance. Significant remarks concerning the calculation of the costs in question should be included in the "Additional information" column. The CoQ estimation form prepared in this way constitutes the basis for the implementation of subsequent stages.

The second stage consists of preparing a CoQ matrix and ordering the CoQ identified in a model of their structure. At this point, it is necessary to use the financial data on CoQ drawn from the CoQ estimation form. The CoQ matrix should contain aggregated CoQ for the entire period under consideration. The matrix form is presented in Table 2.

Table 2: Matrix of cost of quality

CoQ	Basic (operational) processes	Management (strategic) processes	Auxiliary processes	Total	CoQ structure analysis
Prevention costs					
Appraisal costs					
Costs of internal failures					
Costs of external failures					
Other CoQ					
Total					
Analysis of the structure of processes generating CoQ					

Note: own elaboration.

The CoQ matrix is a source of information about the amount of costs incurred, their structure, as well as the share of those costs in individual processes of the enterprise: fundamental, management and auxiliary. The information obtained will allow for the identification of the areas of activity that generate the highest CoQ and require optimisation actions.

The last stage of the research consists of carrying out a ratio analysis of CoQ, consisting of 13 measures. They have been collected in Table 3.

Table 3: Ratio analysis of cost of quality

No.	Name of the indicator	Formula
1	Indicator of the share of CoQ in total costs	W_{QC1} = (CoQ/Total costs)*100%
2	Indicator of the share of compliance costs in CoQ	W_{QC2} = [(Prevention costs + Assessment costs) / CoQ]*100%
3	Indicator of the share of non-compliance costs in CoQ	W_{QC3} = [(Costs of internal errors + Costs of external errors) / CoQ]*100%
4	Indicator of the share of prevention costs in CoQ	W_{QC4} = (Prevention costs / CoQ)*100%
5	Indicator of the share of assessment costs in CoQ	W_{QC5} = (Assessment costs / CoQ)*100%
6	Indicator of the share of costs of internal errors in CoQ	W_{QC6} = (Costs of internal errors / CoQ)*100%
7	Indicator of the share of costs of external errors in CoQ	W_{QC7} = (Costs of external errors / CoQ)*100%
8	Indicator of the share of other CoQ in CoQ	W_{QC8} = (Other CoQ / CoQ)*100%
9	Indicator of the share of the number of non-compliance cases in CoQ	W_{QC9} = (Number of non-compliance cases / CoQ)*100%
10	Indicator of the share of CoQ in sales revenue	W_{QC10} = (CoQ/Sales revenue)*100%
11	Indicator of the share of CoQ in net profit	W_{QC11} = (CoQ/Net profit)*100%
12	Indicator of the share of non-compliance costs in net profit	W_{QC12} = [(Costs of internal errors + Costs of external errors) / Net profit]*100%
13	Indicator of the share of CoQ in operating costs	W_{QC13} = (CoQ/Operating costs)*100%

Note: own elaboration.

The result of the ratio analysis of CoQ will be information on the percentage share of particular quality cost categories in the total costs, as well as the relationship between CoQ and particular items of the profit and loss account, i.e. sales revenue, operating costs and net profit. Determining the right conclusions will allow for conducting activities aimed at optimising costs and processes.

The assumptions for the CoQ estimation procedure and CoQ calculation, as presented here, have been used in an attempt to apply them to the defence industry enterprise operating on the territory of the European Union which is the subject of this study, which has made its proprietary data available for research purposes. The results obtained have been collected in the next part of the article.

Results

The identified quality cost items of the studied enterprise have been consulted with the accounting and controlling departments. As a result of this work, a CoQ estimation form has been created and used to prepare the CoQ matrix for 2019 presented in Table 4.

Table 4: Matrix of cost of quality of the organisation for 2019

CoQ [in EUR]	Basic (operational) processes	Management (strategic) processes	Auxiliary processes	Total	The share of CoQ categories in the structure of CoQ [%]
Prevention costs	4,152,979.22	628,634.54	4,857,675.51	9,639,289.27	52.00%
Appraisal costs	2,601,875.26	435,532.45	2,908,925.50	5,946,333.22	32.08%
Costs of internal failures	-	-	160,436.86	160,436.86	0.87%
Costs of external failures	1,021,688.70	-	281,031.62	1,302,720.32	7.03%
Other CoQ	-	1,020,831.75	467,910.84	1,488,742.58	8.03%
Total	7,776,543.18	2,084,998.73	8,675,980.32	18,537,522.24	100.00%

The share of processes in the structure of CoQ [%]	41.95%	11.25%	46.80%	100.00%	x

Note: own elaboration.

The estimated CoQ for 2019 in the enterprise amounted to EUR 18,537,522.24. The largest categories therein are prevention costs (52%) and appraisal costs (32.08%). The share of other categories was as follows: other CoQ 8.03%, costs of external failures 7.03%, costs of internal failures 0.87%.

In order to obtain the full picture of CoQ, in particular the processes of the organisation, the authors have prepared an extension of the CoQ matrix, which is presented in Table 5.

Table 5: Extended matrix of cost of quality of the organisation for 2019

CoQ [in EUR]	**Basic (operational) processes**				**Management (strategic) processes**		
	Commercial process	**Design and development process**	**Business development process**	**Production process**	**Management process**	**Quality management process**	**Economic and financial process**
Prevention costs	1,551,103.95	2,237,636.00	242,174.91	122,064.36	187,205.38	191,997.17	249,431.99
Appraisal costs	-	2,237,636.00	242,174.91	122,064.36	55,677.43	-	379,855.02
Costs of internal failures	-	-	-	-	-	-	-
Costs of external failures	-	-	-	1,021,688.70	-	-	-
Other CoQ	-	-	-	-	1,020,831.75	-	-
Total	1,551,103.95	4,475,272.00	484,349.82	1,265,817.41	1,263,714.56	191,997.17	629,287.01
The share of processes in the structure of CoQ [%]	8.37%	24.14%	2.61%	6.83%	6.82%	1.04%	3.39%
CoQ [in EUR]	**Auxiliary processes**						
	Logistics process	**Personnel management process**	**Maintenance process**	**Internal control system process**	**Quality control process**	**Environmental management process**	**IT systems management process**
Prevention costs	-	244,538.39	4,280,445.89	-	-	-	281,031.62
Appraisal costs	807,599.46	160,436.86	655,824.45	85,046.42	1,200,018.32	-	-
Costs of internal failures	-	160,436.86	-	-	-	-	-
Costs of external failures	-	-	-	-	-	-	281,031.62
Other CoQ	-	454,003.85	-	-	-	13,906.99	-
Total	807,599.46	1,019,415.95	4,936,270.34	85,046.42	1,200,018.32	13,906.99	562,063.23

The share of processes in the structure of CoQ [%]	4.36%	5.50%	26.63%	0.46%	6.47%	0.08%	3.03%

Note: own elaboration.

The processes most burdened with CoQ in the organisation are auxiliary processes – 46.80% (in which maintenance costs dominate, constituting 26.63% of all CoQ) and basic processes – 41.95% (the vast majority concerning the design and development process, constituting 24.14% of CoQ). Only 11.25% of quality-related costs arise in strategic processes, mainly in the management process (6.82%).

The data obtained in the CoQ matrix, as well as information from the financial statements of the enterprise, were the basis for the ratio analysis, the results of which have been collected in Table 6.

Table 6: Ratio analysis of cost of quality of the organisation for 2019

Indicator	Value of the indicator
Indicator of the share of CoQ in total costs	36.79%
Indicator of the share of compliance costs in CoQ	84.08%
Indicator of the share of non-compliance costs in CoQ	7.89%
Indicator of the share of prevention costs in CoQ	52.00%
Indicator of the share of appraisal costs in CoQ	32.08%
Indicator of the share of costs of internal failures in CoQ	0.87%
Indicator of the share of costs of external failures in CoQ	7.03%
Indicator of the share of other CoQ in CoQ	8.03%
Indicator of the share of the number of non-compliance cases in CoQ	0.0004%
Indicator of the share of CoQ in sales revenue	32.38%
Indicator of the share of CoQ in net profit	287.16%
Indicator of the share of non-compliance costs in net profit	22.67%
Indicator of the share of CoQ in operating costs	39.15%

Note: own elaboration.

The most important findings from the ratio analysis of CoQ of the studied defence industry organisation include:

- at least 1/3 of all costs of the studied enterprise are related to quality,
- a very high share (84.08%) of compliance costs in the CoQ structure,
- the small share of non-compliance costs (7.89%) in total CoQ,
- the negligible impact of errors on quality-related costs (0.0004%),
- CoQ have a significant impact on the operational activities of the organisation and its financial performance.

In summary, the high level of involvement in prevention and assessment activities visible in the calculated indicators is a desirable phenomenon and reflects very well on the cost and quality strategy implemented by the enterprise. The

above is also confirmed by the low indicators related to non-compliance cases.

Conclusions and Recommendations

The implementation of the CoQ calculation in the selected defence industry enterprise has made it possible to sort out the problem of costs related to quality in that entity – to highlight their scale and structure, to identify priority areas for the management of this cost group, and perhaps to define new tasks for controlling.

The results of the research confirmed the critical importance of CoQ in innovative enterprises. On the other hand, the implementation of the CoQ calculation developed in the high-tech industry (photonics), in the European defence sector – to the best of our knowledge – is the first scientific examination of its kind, which offers a valuable contribution to scholarship as well as business practice.

As for the latter, the authors recommend that the organisation should take measures aimed at optimising its fundamental and auxiliary processes, in particular the design and development process and the maintenance process, which are the largest sources of CoQ. Moreover, maintaining a high level of prevention and appraisal costs, which effectively prevent the occurrence of non-compliance cases, is recommended. In the case of enterprises marked by a high percentage of CoQ (as is the case with the studied entity) and such diverse types of costs present in various business processes, we strongly recommend that the organisation use IT programmes based on artificial intelligence to identify the CoQ, which will allow the process to be automated, Sadkowski (2020).

Referring to the current economic circumstances, the pandemic-induced crisis seems to have created suitable conditions for the implementation of QC innovations due to the general pursuit of savings and cost optimisation. Our CoQ calculation is such an innovation. An additional justification for its implementation in the studied organisation is the fact that photonic enterprises operate in international markets, while being strongly embedded in global value chains, www1 (2018). This strong dependence of the enterprise's activities on other participants of the supply chain, who are already reporting operational problems (problems with timely delivery), seems to imply a need to take proactive action in logistics and quality control processes in order to ensure business continuity.

CoQ calculation is an innovative tool for measuring CoQ in the processes of high-tech enterprises operating in the defence industry. The skilful use of this tool will allow for the optimisation of the level of these costs and an increase in value for the organisation's stakeholders.

Endnotes

[1] According to Global Industry Classification Standard (GICS). Aerospace & Defence industry comprises manufacturers of civil or military aerospace and defence equipment, parts or products; it includes defence electronics and space equipment, https://www.msci.com/gics.

[2] Net revenue from sales – EUR 57.25 million; ROE – 7.4%; ROA – 5.5%; ROS – 11%; employment – 630 FTE as for 2019.

[3] Optoelectronic devices are introduced to various fields of science and economy as measuring or execution equipment: from geology to agriculture, to medicine, to power generation, to transport, to manufacturing systems, and – more recently – to the entertainment industry

Abstract

The study examines beneficiaries' expectation in relation to returns generated from pension fund investment in Nigeria. This study investigates the perceptions of contributors of pension fund from the various investments by Pension fund administrators (PFA). The study adopted survey design method using questionnaire to establish the expectations of pension fund beneficiaries on the returns generated on their contributions. The population of the study consists of active pension contributors, retirees of Federal and State Polytechnics in the South-Western state of Nigeria, PFAs and Pension Fund Custodians staff respectively totaling 13,528. Sample size of 389 was drawn using Taro Yamane method of sample size selection technique on margin of error of 5%, where 98.7% of the entire research instrument was returned. Data collected were analyzed using both descriptive and inferential statistics. The descriptive statistics consists of mean and standard deviation while Kruskal Wallis test, a non-parametric test for mean difference in response approach was used to infer. The study concluded that expectations vary from beneficiary to beneficiary but, with general expectation of reasonable returns on investment of their contributions by pension fund managers. The study therefore, recommend that pension managers should, as a matter of diligence, invest pension funds into portfolio that will make for stable value of pension for contributors at retirement.

Keywords: Beneficiaries' expectation, Pension fund investment, Pension fund administrators, Return on investment.

Introduction

The goal of any efficient pension scheme is to provide succor to retirees at old age. In the case of Nigeria, the new Contributory Pension Scheme (CPS) was established to give retirees a good lease of life after their productive years. S. 86 of Pension Reform Act (PRA) 2014 expressed unequivocally the need to invest pension contributors' fund so as to provide pensioners with pension that will sustain them at pension age. Before now, Nigeria pension system adopted defined benefit plan (DB) until 2007 whereby government employees in the Federal, State and Local government levels were paid a lump sum gratuity and regular monthly pension payment to retired employees in the

public sector. The private sector employers and employees put contributions in the National Social Insurance Trust Fund (NSITF). Lump sum pension payments were then given to retired employees. From 2004, after the enactment of Pension Reform Act (PRA) 2004, Contributory Pension Scheme was established. The scheme is a fully funded, defined contribution (DC), privately managed and based on individual accounts known as Retirement Savings account (Stewart & Yermo, 2009).

The expectation of pension fund contributors is sacrosanct. They anticipate receipt of their pension as at when due at retirement. They also expect that the value of their pension will also be enhanced by returns generated from the investment of their contributions while they are still in service. Despite generally positive findings linking pension system development and economic growth, there have also been plenty of disappointments. In too many countries, pension fund investments remain highly concentrated in bank deposits and traditional government bonds, contributing little long-term funding for development – as well as delivering disappointing investment returns and therefore pensions (Morales, Fuentes, Searle & Stewart, 2017).

The Act also encourages the contributors to add voluntary savings to the mandatory 8% contribution by them and 10% by their employers (PRA 2014, S. 4(1). To make this happen, the Act stipulated that the funds should not lie fallow in the hands of the administrators to make the expectations of pension contributors achievable. The funds' administrators are mandated by the Act to invest in specified investment outlets (PRA 2014, S. 86 – 90). Such investment is expected to generate further income for the contributors and recorded in their retirement savings account (RSA) and regular information on returns from these investment sent to the contributors every quarter.

Managing and administering pension funds have continued to pose a major challenge to the government of Nigeria. Pension which guarantees employee succour in his or her inactive years is critical to the sustenance of life of the individual at old age (Nkanga, 2005). In the Nigerian society, most workers who contribute to pension scheme suffer from poor management of these pension funds (Akowe, Ocheni & Daniel, 2015). It was also found out from PenCom (2019) report that many state governments defaulted and are still defaulting in the remittance of deducted pension contributions of their employees, as well as in the mandatory employer's contributions. This has been a great challenge for getting these funds into the RSA. It is the funds that are available that will be invested as pension assets on behalf of the contributors.

PRA (2014) section 83(3) provides for monitoring of the investment area to which pension funds should be applied. This is to guarantee that pension funds are well secured and do not reduce in value before the time the contributors become retired to draw fund from their RSA. There is the fear of efficient investment of pension funds by the pension managers. This necessitated the provision of Amended Investment Regulation (2019) by PenCom. The Regulation instructed each PFA to establish an Investment Strategic Committee and a Risk Management Committee in compliance with Section 78 of PRA (2014).

This study therefore looks at the expectations of the pension fund beneficiaries in relation to the returns generated by PFAs on the investment of their pension contributions. The study delve into the expectations of beneficiaries, who are contributors and retired persons, on the benefits derivable from investing their pension fund in the investment portfolio stipulated in S. 86 of PRA (2014), and the transparency that attend to the returns on those investments.

Literature Review

Existing literature were reviewed to assess efforts made by previous studies on what work have been done on the expectations of pension beneficiaries on returns form investment of pension funds. Amao (2008) serialized the Nigerian Pension Reform Act (PRA) 2004 and discussed the likely effect of the Act on Nigerian employees. The paper is exploratory in nature and it identified the inherent challenges for the future successes of the new scheme to include social implications on employees, higher life expectancy and lower fertility, increase in population of pensioners, lower pension compared with higher standard of living among prospects and challenges.

Ahmed and Oyadiran (2013), in their study on the impact of 2004 pension policy on the welfare of Nigerian civil servants in some selected ministries, obtained responses by questionnaire using random sampling modus operandi, discovered that the implementation of the contributory pension scheme (CPS) had significantly improved the welfare of civil servants. Their study furthermore revealed that the CPS has not addressed the problem of sharp practices and inadequate budgetary allocation and as such, the new pension order has not been able to surmount these challenges being experienced by retirees in Nigeria.

According to Egbe, Awogbemi and Osu (2013), there is need to diversify a portfolio before it can be optimized. This is first step in the right direction for plausible investment. The main objective of diversification is the reduction of variability of portfolio returns without necessarily losing the anticipated rate of return. Thus, the main reason for

achieving optimal diversification is knowing the nature of relationship of the portfolio and not component securities in the portfolio. The purpose of allowing these funds and assets to be applied as stated above is to reduce the challenges posed by the time value of money, provide a better welfare to the contributors who are to receive their pension whenever they are due. Where voluntary funds are paid into the Retirement Savings Accounts (RSA), PFA is tasked to invest such funds in profitable investments. The choice of investment windows by the managers poses another challenge in pension fund administration.

Anazodo, Ezenwile, Chidolue and Umetiti (2014) examined the effect of new pension scheme on retirees in Nigeria. Their study employed qualitative and exploratory research design and descriptive analysis to examine the issue of the new Contributory Pension Scheme (CPS) as it relate to how retiree received information on the pension managers operate. The study concluded that most retirees are not privy to how pension managers, to whom their funds were entrusted, operates and that the ecological nature of Nigeria may place a challenge on the instituted regulations to check and safeguard retirees' fund.

Biobele (2015) examined pension fund accounting and pensioners' wellbeing in Nigeria looking at their sustainability and life expectancy. The study adopted the survey design by administering questionnaire to evaluate the perceptions of pensioners on the effect of pension fund accounting to their wellbeing. A sample size of 400 respondents comprising of 135, 132 and 133 respondents from Oyo, Anambra and Kano states respectively, taken from three geo-political zones was collected. Judgemental sampling technique was adopted for selecting respondents from the states. Ordinary Least Square (OLS) was used to analyze the data obtained for the study. The study revealed that accounting for pension fund significantly have effect on pensioners' wellbeing. Collective bargaining between pensioners and pension fund administrators have also been identified as a source of pensioners' sustainability.

Reis, Silveira, Braga and Teixeira (2015) looked at the effect of pensions and retirement on the social welfare of households in Brazil's Minas Gerais State. Their study used a methodological approach hinged on propensity score estimates using p-score and p-smatch2 packages earlier adopted by Becker and Ichino (2002), and micro-data from the National Household sample survey, Pesquisa National por Amostra de Domicilios (PNAD). The study found out that retirement income and pension are vital contributors to beneficiary's household income, specifically for beneficiaries of low-income households. The study concluded that there is a positive effect of social security on the incomes, access to knowledge and conditions of living of households used in the study.

However, Andonov and Rauh (2018) revealed that there is dependence of institutional investors on past performance in setting expectation of future return. The study employed statistical testing on real return versus expected return on pension investments to analyze its data. The study found that asset class around 22% weight of variation in portfolio expected returns, creating a large role for the difference in assertions concerning returns in the different classes of asset. The study also discovered that unfunded liabilities are positively correlated to the portfolio expected returns. This is in line with the assumption that 'fiscally entangled' government is faced with pressure in maintaining greater anticipated rates of return. The study also found that the expected returns in risky asset classes like real assets, public equity, hedge funds and private equity are significantly and positively correlated to the past return.

It was found out that most literature studied (Becker & Ichino (2002); Amao (2008); Ahmed & Oyadiran (2013); Egbe, *et al* (2013); Anazodo, *et al* (2014); Biobele (2015); Reis, *et al* (2015); Andonov & Rauh (2015) were unable to establish the core expectations of pension beneficiaries (contributors and pensioners) to have reasonable returns on the pension funds invested by pension managers on their behalf. This study have therefore examined the expectations of these beneficiaries on the pension fund investment returns as stipulated in S. 86 of PRA (2014) and as contained in the investment guidelines issued by PenCom in Nigeria.

Materials and Methods

This paper adopts survey research design. Quantitative method of data collection and analysis was used to explore the outcome beneficiaries' expectation and return of pension fund investment taking South-West Polytechnics in Nigeria into consideration. The target population consists of 4672 pension fund beneficiaries in five (5) Federal Polytechnics, 7500 in twelve (12) State Polytechnics domiciled in South-Western part of Nigeria, 1,208 of twenty-one (21) Pension Fund Administrators (PFA) and 148 in four (4) Pension fund custodians (PFC) domiciled in Nigeria. Proportional allocation method of the Stratified sampling technique was used to derive a sample size of 389 using Taro Yamane sample size calculator from the combined population of 13,528, where 98.7% of the research instruments was returned. However, PFA and PFC staff were included in the study based on the fact that they are also part of pension fund beneficiaries, thereby justification of inclusion. Summary of the questionnaire distribution to target sample can be evidenced in table 1.

Table 1: Questionnaire Distribution to selected institutions

Strata	Population	Sample Size*	Proportion (%)	
Federal Polytechnics	4672	134	34.45	
State Polytechnics	7500	216	55.53	
PFAs	1208	35	9.00	
PFCs	148	4	1.03	
Total	**13528**	**389**	**100.0**	

**Using the Proportional Allocation technique.*

The data collected through the structured questionnaire was collated using spreadsheet and analyzed making use of descriptive and inferential statistics through Statistical Package for Social Sciences (SPSS). The expectations of the pension fund beneficiaries and returns of pension fund investment in Nigeria as opined by the beneficiaries, PFAs and PFCs was analyzed using weighted average score technique as depicted in the research instrument. The weighted average technique comprises of threshold at which the decision of the selected items of the test instruments lies. The frequencies on variables of expectations was scored by assigning 1 to Strongly Disagree, 2 to Disagree, 3 to Indifferent, 4 to Agree and 5 to Strongly Agree. Reversed questions were coded otherwise.

The weighted averages score was ranged in the following ways;

Strongly Agree (SA) = 4.5 - 5.0; Agree (A) = 3.5 - 4.4; Undecided (U) = 2.5 - 3.4; Disagree (D) = 1.5 - 2.4; Strongly Disagree (SD) = <1.5
The weighted frequency (WF) per items can be expressed in equation (4) as;

$$WF = (1 \times F_1) + (2 \times F_2) + (3 \times F_3) + (4 \times F_4) + (5 \times F_5) \quad (1)$$

$F_1, F_2, \ldots, F_5$ represents individual frequencies attached to the likert scales of SD, D, I, A and SA respectively. Hence, the weighted average (WA) score will then be calculated as;

$$WA = \frac{WF}{n} \quad (2)$$

Where n ≡ total number of responses

The Kruskal Wallis H statistic of mean rank for several groups is given as

$$H = \frac{12}{N(N+1)} \sum_{i=1}^{g} n_i (\bar{R} - \bar{R}_i)^2 \quad \sim \quad \chi^2_{(g-1)} \quad (3)$$

Where;
H is the Kruskal Wallis Test statistic,
N is the total number of samples
g is the number of groups representing the 5 point scales from the research instrument
$\bar{R}$ is the overall mean
$\bar{R}_i$ is the average rank responses per items.

The weighted average score technique coupled with Kruskal Wallis H test for difference in mean response was used to confirm if there exist mean difference in respondents' expectations on the returns generated by PFAs on the investment of their pension fund investments.

Results and Discussion

2: Descriptive Statistics of Beneficiaries Expectations

Item Nos.	Beneficiaries Expectations	Mean	Std. Deviation
1	Contributors' monthly contributions are invested in income-yielding investments as contained in PRA (2014)	4.38	.697
2	Contributors experience increase in the amount in their retirement savings account (RSA) due to investment of their monthly contributions by the PFAs	4.31	.847
3	Retired personnel receive regular payment of their pension amount from their PFAs	3.00	1.276
4	There is diminution in the value of equities invested in, due to market dynamics which have caused retirees to lose part of their RSA balance between the date of retirement and the date of receipt of lump sum/first pension	3.94	.967
5	Retirees' risk appetite is not as high as that of the active contributors going by the general retirement age (60years and above)	3.63	.928
6	There is adequate compliance with the framework and implementation guidelines for RSA Retiree fund whose main objective is to ensure that retirees' pension does not lose value after commencement of monthly pension	3.44	1.118
7	All income earned from investment of pension fund are credited to the individual RSA of beneficiaries as specified by Pension Reform Act (PRA) (2014)	4.00	1.276
8	There is safety and maintenance of fair return on amount invested on behalf of contributors by PFAs	3.38	1.220

Source: Field Survey, 2020.

Descriptive statistics of table 2 indicated beneficiaries' expectation on the pension fund invested. Mean response of 4.38 in item 1 implies that beneficiaries agreed that contributors' monthly contributions are invested in income-yielding investments as contained in the PRA (2014). Mean response of 4.31 in Item 2 showed an agreement that contributors experience increase in the amount in their retirement savings account due to investment of their monthly contributions by the PFAs as they were indifferent (mean response = 3.00) on the opinion that retired personnel receive regular payment of their pension amount from their PFAs.

Taking the value of equities of item 4 into consideration, beneficiaries agreed on the mean response of 3.94 that there is diminution in the value of equities invested in, due to market dynamics which have caused retirees to lose part of their RSA balance between the date of retirement and the date of receipt of lump sum/first pension; as retirees agreed based on the empirical analysis of item 5 that their risk appetite is not as high as that of the active contributors going by the general retirement age of 60 years and above.

In addition, pension fund beneficiaries were indifferent on mean response of 3.44 about the adequacy of compliance with the framework and implementation guidelines for RSA retiree fund as evidenced in item 6, but agreed on mean response of 4.0 in item 7 that all income earned from investment of pension fund are credited to the individual RSA of beneficiaries as specified by Pension Reform Act (PRA) (2014). On the safety and maintenance of fair return on amount invested on behalf of contributors by PFAs in item 8, beneficiaries were indifferent on whether or not there exist safety and maintenance as evidenced from mean response of 3.38.

Table 3: Kruskal Wallis H test for Difference in beneficiaries expectations and Returns of Pension fund Investments

Item Nos.	Safety and maintenance of fair return on amount invested on behalf of contributors by PFAs [b]		N	Mean Rank	Test statistics [a]
1	Contributors' monthly contributions are invested in income-yielding investments as contained in PRA (2014)	Strongly Disagree	24	288.50	237.278 (4) [0.000]

		Indifferent	120	202.10	
		Agree	72	240.50	
		Strongly Agree	96	228.50	
		Total	**384**		

( ) parenthesis represents degree of freedom; [ ] parenthesis represents p-value
a. Kruskal Wallis Test ; b Grouping Variable

Empirical analysis of the Kruskal Wallis H test for difference in beneficiaries expectations and returns of pension fund investments in table 3 indicated a statistically significant difference on the opinion of beneficiaries with respect to how their contributions are invested in income-yielding investments and safety and maintenance of fair return on amount invested on behalf of contributors by PFAs, $\chi^2_{(4)} = 237.278$, $p < 0.05$ with a mean rank of 288.50 for strongly disagree, 88.50 for disagree , 134.90 for indifferent response, 323.50 for agree and 288.50 for strongly agree.

Kruskal Wallis H test also showed a statistically significant difference on increase in the amount in retirement savings account due to monthly contributions by the beneficiaries between the safety and maintenance of fair return on amount invested on behalf of contributors by PFAs, $\chi^2_{(4)} - 261.318$, $p < 0.05$ with a mean rank of 288.50 for strongly disagree, 176.50 for disagree, 82.10 for indifferent response, 288.50 for agree and 246.50 for strongly agree as evidenced from item 2 of table 3.

It was also evident that opinion of respondents on regular payment of pension by beneficiaries was statistically different between the fair returns on the amount invested by PFAs, $\chi^2_{(4)} = 261.318$, $p < 0.05$ with a mean rank

of 12.50 for strongly disagree, 200.50 for disagree, 142.50 for indifferent response, 244.50 for agree and 255.50 for strongly agree as depicted on item 3 of the aforementioned table.

Kruskal Wallis H test result also showed a statistically significant difference in diminution of equities invested between the safety and maintenance of fair return on amount invested on behalf of contributors by PFAs, $\chi^2_{(4)} = 76.972$, $p < 0.05$ with a mean rank of 180.50 for strongly disagree, 176.50 for disagree , 180.50 for indifferent, 136.50 for agree and 264.50 for strongly agree as evident in item 4.

In addition, it cannot be overemphasized that high in retirees risk appetite and the returns on amount invested was statistically significant $\chi^2_{(4)} = 108.084$, $p < 0.05$ with a mean rank of 360.50, 240.50, 170.90, 188.50 and 144.50 for strongly disagree, disagree, indifferent, agree and strongly agree respectively. Hence, retirees risk appetite is as high as that of the active contributors going by the general retirement age of 60 years.

Empirical result of analysis also indicated from the Kruskal Wallis H test on adequate compliance with the framework and implementation guidelines for RSA retirees taking into account the safety and maintenance of fair return on amount invested on behalf of contributors by PFAs was statistically significant based on the $\chi^2_{(4)} = 66.085$, $p < 0.05$ with a mean rank of 348.50 for strongly disagree, 172.50 for disagree , 163.70 for indifferent response, 216.50 for agree and 186.50 for strongly agree.

On the Kruskal Wallis H test of the item 7 of the table, analysis indicated a statistically significant difference on the manners at which income earned from investment of pension fund are credited as specified by the Pension Reform Act (PRA) taking the safety and maintenance of fair return on amount invested on behalf of the contributors by PFAs into consideration, $\chi^2_{(4)} = 120.640$, $p < 0.05$ with a mean rank of 12.50, 140.50, 202.10, 240.50 and 228.50 for strongly disagree, strongly agree, indifferent, agree and strongly agree respectively.

Conclusion and Recommendations

Hence, empirical analysis of the result findings cannot be neglected as beneficiaries expectations are high in the area of the returns received or to be received from their pension fund investments from the respective PFAs attributed to each beneficiary and the pension fund custodians. However, result also showed that expectations vary from beneficiaries to beneficiaries, which depends on how the respective PFAs manage the financial returns of the beneficiaries. This portends that the performance of Pension managers differs. Some are more diligent and calculative as far as risk on investment is concerned. The result of the study is in tandem with Anazodo, Ezenwile, Chidolue and Umetiti (2014). The study recommends that, for pension contributors and retirees to repose confidence in the way their funds are managed, their funds should be invested in safe investments where risks on investments are professionally calculated, reasonable income generated from such investments. It is also expected from the PFAs, transparent accountability posture to the operation of the pension fund management devoid of misappropriation. With these, the expectations of pension beneficiaries will be very close to accomplishment.

Abstract

The article discusses competitiveness at the present stage. The analysis made it possible to systematize the views of individual domestic and foreign authors on the disclosure of the concept of competitiveness, methods of its assessment. The authors formulated a definition of the competitiveness of enterprises, taking into account the level of offenses in foreign economic activity and highlighted other approaches to the definition of the concept of competitiveness: legal, mathematical, socio-psychological, organizational and managerial, economic and financial. The article considers factors and conditions influencing competitiveness, including the region, through indices of comparative advantages. The Bell Balassa Index, Lafey Index, PCA Index, WEF Competitiveness Index were considered. Global Overview, "Growth Index.

Factors that represent potential threats to Russia's foreign economic security include health and primary education, labor market efficiency, technological readiness, business and macroeconomic environment.

Disclosing ensuring the competitiveness of enterprises taking into account countering violations in foreign trade activities, the classification of violations in foreign trade activities was clarified.

Keywords: Competitiveness, Economic Security, Foreign Trade, Threats, Risks

Introduction

The study of the category "competition" is devoted to a considerable number of studies, however, the essence of which is not unambiguous and a single system of views on its content, forms and types has not yet been developed.

To solve this problem, it is necessary to understand what is meant by competitiveness at the present stage. The analysis carried out as part of the writing of the work made it possible to systematize the views of individual domestic and foreign authors on the disclosure of the concept of competitiveness, the methodology for assessing it.

A number of authors, speaking of competition, imply some kind of rivalry - the independent rivalry of two or more persons Stigler J. (2000).

Later, the authors specified that rivalry arises among buyers, indicating certain conditions for its occurrence. So, A. Smith in the work "Research on the Riches of Peoples" wrote - "competition will now begin among buyers if there is a reduction in supply, which will entail an increase in prices," but when the supply is too high, the price will fall the lower, the more competition between sellers, "or, depending on how quickly it turns out for them to sell this product" (1997).

Marshall A. connects competition with the struggle for rare economic benefits and, as a way of acquiring them, for consumer money. This conclusion follows from the logic that most of the benefits (goods, services, resources) are rare in the sense that their number is less than the potential need of society. In this regard, the owners of these benefits have the opportunity to distribute them, while pursuing their benefit, setting conditions, for example, the required level of prices, quality, etc. As a result, they have the opportunity to decide who to provide the benefits to, and to whom to refuse it (1993).

In the development of the idea of unity, stability, as well as deterministic equilibrium in conditions of perfect competition, Blaug M. put forward the theory of general equilibrium (1994).

One of the first economists - representatives of the functional approach is J. Schumpeter. As a distinctive criterion of competitive market, its ability to initiate new achievements of scientific and technological progress is highlighted (1982).

Del Bosco, B., Chierici, R., Mazzucchelli says, If to speak about the indicators characterizing the level of economic security of the region and factors, influencing on it some authors note, for assessment of the impact of the external economic safety and assessment of competitiveness of the region, it is possible to estimate influences of separate economic indicators (a gross regional product per capita, direct foreign investments per capita, the average monthly nominal salary of the permanent worker) on export of goods per capita of the region. At the same time the used regression model confirms that all above-mentioned indicators have positive impact on export and trade activity at the regional level of the country. However the level of influence of these indicators on export of goods is per capita various. Results of work show that influence of direct foreign investments on export activity wasn't significant. The gross regional product positively influences this indicator. The average monthly nominal salary of the permanent worker per capita has the smallest impact on export of goods (2019).

Some authors suggest using thresholds of indicators characterizing the level of economic security in their calculations. So, A. Burmisova (2016) and Fadeev Yu.N. (2016) use an approach that consists in comparing threshold values of indicators. At the same time, these values are calculated on the basis of international experience.

The works of S.Yu. Glazyev, A.N. Illarionov, V. Medvedev, E.A. Oleinikova, V.K. Senchagov, A. Orlov and others (2004 , 1997,2005) are devoted to the assessment of economic security of economic systems of various levels.

S.V. Hooke notes that in assessing the system of indicators characterizing economic security, in addition to generally accepted significant parameters, it is necessary to evaluate the areas of the region's economy that are most exposed to threats [(2008), to which, in our opinion, the sphere of foreign economic relations belongs.

Most studies assess the level of national and regional economic security in the following areas: living standards, production, demography, financial sphere, ecology, law and order, scientific and technical potential (2008).

At the same time, as a rule, domestic economists identify the following types of security on the principle of the most vulnerable spheres of life: production, financial, food, demographic, scientific, technical and social security.

Among the components of national economic security V.A. Oleinikov mentioned the following: investment, financial, price, currency, information, scientific and technical, energy security, as well as the security of the stock market, credit and banking system, material spheres of economy, foreign economic activity, etc. (2004)

According to V.E. Manevich, the large size of net exports does not indicate good economic health, but, on the contrary, a narrowing of the domestic market. "Net export is the transfer of the domestic economy to the foreign economy, and net import is the transfer of the external world to the domestic economy." He proposes "to halve energy exports without the slightest harm (and with great benefit) to the economy." (2004)

Model

As a result of studying the opinion of various authors, the author's definition of the competitiveness of enterprises engaged in foreign trade activities was formulated.

By the competitiveness of enterprises engaged in foreign trade activities it should be understood that competitiveness is the result of a well-thought-out, targeted policies that take into account the external and internal factors of the economic entity at the macro and micro levels, which are in constant competition, in which the independent actions of each of them exclude or limit the possibility of each of them unilaterally to affect the general conditions of circulation of goods in the external commodity market in the context of the globalization of the economy and the

strengthening of the role of multinational corporations, and with strict enforcement of the legality of foreign trade activities and respect for the economic security of the State.
Based on the analysis of monographic and other scientific sources on this topic, it is proposed to distinguish other approaches to the definition of the concept of competitiveness: legal, mathematical, socio-psychological, organizational and managerial, economic and financial.

The legal approach describes this concept from the point of view of legal science, emphasizing the exclusion or limitation of the possibility of destructive manifestation.

The mathematical approach considers competitiveness as a model for managing the external and internal factors of an economic subject at macro and micro levels and describes them in terms of lifetime.

The organizational and managerial approach consists in determining the competitiveness in terms of the organizational and legal form of the design under consideration.

Socio-psychological analyses the activities of economic actors in terms of their rational economic behavior, the result of well-thought-out, targeted policies.

The economic and financial approach considers competitiveness as the conquest and expansion of business in the market of goods and services, including in foreign trade activities.

The study of the principle and methods of assessing the comparative advantages of enterprises in foreign trade activities is based on various reasons for the emergence of comparative advantages in certain sectors of the economy: differences in the endowment of production factors, differences in production technologies, different levels of investment in labor, differences in the principles of the economic structure of countries (from the tax system to state programs of support and stimulation of production), political conditions in the country.

Among all known methods of measuring comparative advantages, the concept of identified comparative advantages was most popular, the idea of which is based on the premise that if a country has a comparative advantage in a given industry (for a given product), this will be expressed in the country's foreign trade, export specialization in a given industry.

The authors considered factors and conditions influencing competitiveness, including the region, through indices of comparative advantages. The Bell Balassa Index, Lafey Index, PCA Index, WEF Competitiveness Index were considered. Global Overview, "Growth Index) (1965 < 2002, 1992).

It was noted that economic security also affects the competitiveness of the region and the state as a whole. In turn, economic security indicators will show control (border) points of improvement or deterioration of economic security. Foreign economic security plays an important role in this process.

As part of the study, the authors formulated taking into account the stated direction, the definition of the competitiveness of enterprises, taking into account a separate, but important factor - this is the level of offenses in foreign economic activity.

Results

Potential threats to foreign economic security included:

- Health and primary education (rating - 54). The factors that led to this value of the rating are life expectancy (years), the number of TB diseases, the prevalence of HIV;
- Labour market efficiency (rating - 60). The assessment used factors such as employee-employer cooperation, the cost of excess labor, the impact of taxation on incentives to work, reliance on professional management, the country's ability to retain and attract talent;
- Technological readiness (rating - 57). The following factors influenced the formation - availability of the latest technologies, absorption of technologies at the firm level, foreign direct investment and transfer of technologies, international Internet traffic, traffic volume per user;
- Business (rating - 71). Data on the number of local suppliers, the level of cluster development, the depth of the value chain, the willingness to delegate authority were used;
- Macroeconomic environment (rating - 53). The following factors were used in the calculations - state budget deficit, inflation, sovereign credit rating.

Disclosing ensuring the competitiveness of enterprises in the framework of countering violations in foreign trade activities, the authors clarified the classification of violations in foreign trade activities.

The developed classification of offences in foreign trade activities is presented in Table 1.

Table 1: Classification of offences in foreign trade activities

Criteria	Characteristics
By the sphere of emergence in the sphere of economic activity	against public danger
	against public health and public morals
By severity	of low gravity
	moderate severity
	heavy
	Particularly grave
By the degree of public danger	minor violations
	gross violations
On the object of encroachment	encroaching on the movement of goods
	infringing on the procedure for the registration of goods, their movement under customs procedures and the implementation of customs control measures
	encroaching on the provision and use of benefits
	encroaching on customs charges
	encroaching on the normal operation of customs authorities
By form of wrongful act	action
	inaction
By types of legal liability	administrative responsibility
	criminal liability
By amount of damage	minor damage
	average damage
	major damage
	causing particularly serious damage
По характеру криминализации	Activity permitted by law, with elements of destructive activity
	Activities prohibited by law
	Activities not prohibited by law, with elements of destruction
According to the status of subjects of offenses in the field of foreign trade	Offences committed by foreign trade economic entities in the export of goods, works, services
	Offences committed by foreign trade economic entities in the import of goods, works, services

Note of the Criminal Code of the Russian Federation - Criminal Code of the Russian Federation
Administrative Code of the Russian Federation - Code of Administrative Offenses of the Russian Federation
The developed systematization will make it possible to study violations in foreign economic activity both in general and in individual elements, predict the extent of their spread, and contribute to the neutralization of the determinants and socio-economic consequences of these phenomena.

Conclusion

In the context of increasing globalization processes that contribute to the growth of competitiveness of developed economies, the issues of ensuring Russia's foreign economic security (given its very low competitiveness indicators) remain relevant.

At the same time, taking into account the variety of manifestations of illegal acts in the field of foreign economic activity, their conjugation with other economic offenses, other subjects of investigation, it becomes an important task to determine their destructive influence on the economic security of the State. The developed classification makes it possible to streamline offenses in foreign economic activity by the nature of the impact, which creates the prerequisites for the formation of effective strategies for comprehensive counteracting existing offenses in the foreign trade activities of economic entities.

Application of Selected Models and Methods of Graph Mining on the Example of the Analysis of Publication Links

Zbigniew TARAPATA
Military University of Technology, Faculty of Cybernetics, Warsaw, Poland
zbigniew.tarapata@wat.edu.pl

Abstract

The paper deals with specific group of methods of graph and network mining related to the so-called community detection (clustering). Presented methods was discussed and divided into four groups: node-centric, group-centric, network-centric, hierarchical-centric. The characteristics and properties of several methods from each group were discussed. In many cases, attention has been drawn to the computational complexity of the methods presented and ways of improving it. An extensive example of the use of selected methods for the analysis of publication cooperation of employees of a research institute is presented.

Keywords: graph mining, community detection methods, link analysis, clustering.

Introduction

Data mining consists of many data analysis techniques. Its primary purpose is to discover hidden and useful relationships between data from a very large collection. Graph mining, which has gained in importance in recent decades, is one of the innovative approaches to explore a structured data set represented by graphs and networks (Rehman et al (2012)). It is used in various fields, such as bioinformatics, chemical reactions, program flow structures, computer networks, social networks, etc. Different methods of data mining are used to extract graph-based data and perform useful analysis of this data. Different approaches to graph and network (weighted graphs) exploration are proposed in the literature (Rehman et al (2012), Tang and Liu (2010)). Each of these approaches is based on classification, clustering, or decision trees. This paper focuses on a specific group of methods of graph and network mining related to the so-called community detection.

The first section presents the taxonomy of community detection methods in graphs. Selected models and methods of community detection are presented. In the next section there is an example of the application of the described methods to evaluate the publication links between the employees of the Institute of Computer and Information Systems of the Faculty of Cybernetics, Military University of Technology, Warsaw, Poland. The paper ends with a summary and conclusions concerning the described models and methods and their applications.

Selected methods of graph and network mining

Discussing selected methods of graph exploration focused primarily on the methods of detecting communities (communities, groups, clusters - these terms will be used interchangeably) with certain properties. Communities are subsets of entities, among which there are relatively strong, direct, intense, frequent, or positive ties Wasserman and Faust (1994)). Networking interaction provides useful information on the relationships between the entities.

Methods of detecting communities (groups, clusters) can be divided into 4 categories (Drif and Boukerram (2014)):

- node-centric (each node (vertex) in a group meets certain properties);
- group-centric (considering connections within a group as a whole; the group must meet certain properties);
- network-centric (take into account the weights of edges and vertices and divide the whole network into detachable subnets);
- hierarchical-centric (creating a hierarchical community structure).

It should be noted that many of the described models and methods have their computer implementations in numerous of packages and environments, such as R, Python, Gephi, Neo4j, etc. (Neo4j (2020), MCL (2020), Modularity (2020), Markov Clustering (2020), MCL2 (2020), Gephi (2020)).

In further consideration, we will assume that we have a given undirected unigraph $G = (V, E)$, where V – set of nodes (vertices), and $E \subset \{\{u,v\} : u,v \in V\}$ set of edges. Undirected unigraph is a graph where there is at most one edge (undirected link) between each pair of vertices. If there is an edge between a pair of vertices, we say that these vertices are adjacent to each other.

We will also accept the following indications: number of vertices $n = |V|$, number of edges $m = |E|$. In some models we will assume that the vertices or edges of the graph have weights assigned to them. Then, when it is important, we will emphasize it.

Below, the definitions of several terms that will be used in the further part of the study are reminded (they concern the undirected unigraph G).

Subgraph of graph G is the part of the graph that is based on a selected subset V_p of vertices G and all edges between vertices belonging to V_p.
A *full subgraph* (clique) in the G graph is called a graph where there is an edge between each pair of vertices (all vertices are adjacent).

A *connected graph* is a graph in which there is a path (sequence of alternate vertices and incidents edges with them) between each pair of vertices. In other words, we can move between each pair of vertices in the graph.

The *connected component* of graph G is the maximum subgraph of this graph, which is a connected graph.
Edge connectivity $ec(G)$ of graph G, is the minimum number of edges whose removal results in graph disintegration (i.e. the graph ceases to be connected when these edges are removed).

Cut in graph is a set of edges, the removal of which causes the graph to become disconnected.
Min-cut S is a cut with a minimum number of edges. For a non-trivial graph (with more than 1 vertices and edges) there are: $|S|=ec(G)$.

The *degree* of the vertex in graph G is the number of edges incidental to this vertex (in the case of unigraph, it is the number of neighbours of the vertex under consideration).

Node-centric community detection methods

This group of community detection methods is based on some specific properties of the vertices (nodes) in the graph. The most common characteristics of vertices in the graph are degree, radius, closeness, betweenness, clusterization coefficient, hubs and authorities, PageRank (Bartosiak et al (2011)). From the point of view of detecting communities, the characteristics of a subset of vertices are important, based on selected characteristics of vertices.

Methods based on the concepts of *k-core, k-plex, k-brace*

The methods of this group are based on the definitions of the terms: *k-core, k-plex, k-brace*, which are presented below.

k-core (Ugander et al (2012)): subgraph of graph G, in which each vertex connects to at least k vertices of the group (there is a degree of k).
k-plex: for a group with n_s vertices, each vertex should be adjacent to no less than n_s-k vertices in the group.
These two definitions are complementary, i.e. k-core is $(n_s$-$k)$-*plex*.
k-brace (Ugander et al (2012)) is a variety of k-core. Instead of a vertex degree, the definition uses the concept of edge embeddedness. *Embeddedness* $Em(e_{ij})$ of e_{ij} edge connecting two vertices i and j is the number of common neighbors of vertices i and j, i.e.

$$Em(e_{ij})=|V_i \cap V_j| \tag{1}$$

where $V_i = \{j \in V: e_{ij} \in E\}$, and $|x|$ describes cardinality of the set x.
k-brace of graph is a graph created by repeatedly removing all such edges e_{ij}, for which $Em(e_{ij})$ is less then k, and then removing all components connected to vertex. To characterize the final result of the edge-removal process and to better understand the essence of the k-brace, let us assume the following definitions.

Let $H = (W, F)$ be a subgraph of $G = (V, E)$, where $W \subseteq V$ and $F \subseteq E$, and each edge in F has both vertices in W. Then we define the set of subgraphs $B_k(G)$ of graph G: we say that the subggraph H belongs to $B_k(G)$ if (i) each edge of H belongs to at least k different triangles (the triangle in the graph is a 3-element clique) in H, and (ii) each vertex in H is incidental with at least one edge in H. It can be shown that the k-brace is in fact a specific part of $B_k(G)$ (Ugander (2014), Ugander et al (2012)).

You can see that for all graphs, the k-brace is a subgraph (k+1)-core: because every vertex in the k-brace is incidental with at least one edge, and each edge of the e_{ij} has connection $E_m(e_{ij})$ equal to at least k in G, hence all vertices in the k-brace must have a degree equal to at least k+1 in G. The inquisitive reader should have no problem answering the important question whether each edge in the k-brace belongs to at least k triangles in G.

The complexity of k-plex and k-core determination algorithms is $O(m+n)$. The complexity of the algorithm for determining the k-brace is $O(m^2)$. Because the k-brace is a subgraph of (k+1)-core, it is better to determine (k+1)-core first, and then to determine k-braces in them.

Clique Percolation Method (*CPM*)

One of the methods of grouping in graphs is *Clique Percolation Method* (*CPM*) (Palla (2005)). The problem of determining the maximum clique in the graph, or a clique of k size (k is the number of vertices of a clique) is a known problem belonging to the NP class of computational complexity and is used as a subproblem of *CPM*. Therefore, different polynomial approximation algorithms are used to solve the problem of determining the maximum clique or clique of size k (Wu and Hao (2015)).

The idea of the *CPM* algorithm (for a given network and fixed k) is presented below:

1. Find all cliques of k size in the network.
2. Build a cliques' graph. The vertices of the cliques' graph are the cliques determined in the 1 step, and two cliques are adjacent (connected by an edge) if they have k-1 common vertices.
3. Each connected component in the cliques' graph creates a community (group).

Group-centric community detection methods

Group-centric community detection methods are based on the structural properties of the part of the graph G (e.g. subgraph of G). This group of models and methods can include: *quasi-clique* determination methods (Palla (2005)), *Highly Connected Subgraphs* (*HCS*) (Hartuv and Shamir (2000), Huffner et al (2014)), *Markov Clustering* (*MCL*) (Azad et al (2018), van Dongen (2000)).

Quasi-clique determination methods

Subgraph $G_s(V_s,E_s)$ is a quasi-clique if there is a condition:

$$\frac{2|E_s|}{|V_s|(|V_s|-1)} \geq \gamma \tag{1}$$

where γ is the given density of the quasi-clique and the denominator means the maximum number of edges (degrees) in G_s.
A greedy approach can be used to determine quasi-clique (Pattillo et al (2013)):

1. Starting with a vertex with the highest degree, expand it with vertices that can contribute to a larger quasi-clique.
2. Continue until you cannot add more vertices.

Highly Connected Subgraphs (*HCS*) method

In this method, the term *Highly Connected Graph* is used: graph with n>1 vertices is highly connected, if its edge connectivity $ec(G)>n/2$.

Highly Connected Subgraph (*HCS*) is such a subgraph H of graph G, that H is highly connected.
The *HCS* algorithm identifies highly connected subgraphs as clusters. The idea of the algorithm is as follows:

1. Find and delete *min-cut* in G getting a set of subgraphs $\{H_1, \ldots, H_t\}$ relating from the cut removal (cut in graph is a set of specific edges in G (removing these edges we disconnect a graph G)).
2. For each subgraph H_i, $i = 1,\ldots,t$ check if it is strongly connected, i.e. if there is a condition $ec(H_i) > n/2$:
   a. If yes, give a subgraph H_i as cluster;
   b. Otherwise, repeat *HCS* algorithm on the H_i subgraph (recurrence).
3. Repeat steps 1÷2 until there are no more subgraphs.

The calculation time of the *HCS* algorithm is limited by $2Nf(n,m)$, where N - the number of clusters found, $f(n,m)$ - the computational complexity of the algorithm for determining the min-cut in the graph with n vertices and m edges. The quickest deterministic algorithms of finding the min-cut in an unweighted graph require $O(n^2m)$ steps, and for weighted graphs – $O(nm+n^2\log n)$ (Stoer's –Wagner's algorithm (Stoer and Wagner (1994))). Another proposal to solve the min-cut problem is a randomized Karger's algorithm (Karger (1993), Karger and Stein (1996)). It is based on the idea of the so-called *edge contraction*. Edge $e(u,v)$ contraction consists of replacing vertices u, v, which are its ends, with a vertex w, removing all edges between u and v and the "surge" to the vertex w the edge that occurred u, v. The complexity of the Karger's algorithm is $O(n^2m\log n)$, and the probability of not finding the min-cut is equal to: $\left[1-\binom{n}{2}^{-1}\right]^T \le \frac{1}{e^{\ln n}} = \frac{1}{n}$, where $T = \binom{n}{2}\ln n$ is the number of runs of the edge contraction algorithm.

Markov Clustering (*MCL*) method

Markov Clustering (*MCL*) is an algorithm based on the simulation of stochastic flow in graphs (Azad et al (2018), van Dongen (2000)). The algorithm is based on random walks on graph G; visiting a dense cluster, we will not likely leave it until many of its vertices have been visited. The MCL algorithm simulates the flow inside the graph and promotes the flow in the strongly related part of the graph and degrades this flow in the weakly related part of the graph, thus determining the clusters in the graph. The size of the flow is proportional to the weight of the edge, which affects the probability of its selection when walking on the graph (this probability does not depend on how to get to a given vertex, hence the Markov model).

Network-centric community detection methods

Network-centric community detection methods consider edge and vertices weights and divided network into disjoint subnets. Grouping is based on: similarity of vertices (central similarity measures: degree, radius, betweenness, closeness, clusterization coefficient, Hubs-Authorities, PageRank) (Bartosiak et al (2011), Ferrer et al (2009), Tang and Liu (2010), Tarapata (2007)), latent space model (Salter-Townshend and McCormick (2017), Tang and Liu (2010)), block model approximation (Tang and Liu (2010)), cut minimization (Karger (1993), Stoer and Wagner (1994), Tang and Liu (2010), Wu and Hao (2015)), modularity maximization (Blondel et al (2008), De Meo et al (2011), Gach and Hao (2014), Newman (2006), Traag et al (2019)).

k-means method in graphs

The method is based on the *k*-means method known from data mining (Ferrer et al (2009)). In this method the definition of the function of distance (similarity) between grouped objects (in the graph: vertices) is important (e.g. the length of the path in the graph is measured by the number of edges in the path; the length of the path in the network is measured by the sum of weights of the edges occurring in the path; the shortest path is the one whose length is the smallest). The most commonly used distance functions $dist(i,j)$ between two vertices i and j are:

- length d_{ij} of the shortest path in graph (network) between i and j, i.e. $dist(i, j) = d_{ij}$;
- Jaccard's distance (similarity): $dist(i, j) = \frac{|V_i \cap V_j|}{|V_i \cup V_j|}$;
- cosine distance (similarity): $dist(i, j) = \frac{|V_i \cap V_j|}{\sqrt{|V_i| \cdot |V_j|}}$;
- features based on the largest common subgraph, the smallest common supergraph, graph editing distance (Schenker et al (2005)),

where V_i described in **Error! Reference source not found.**.

The idea of *k*-means method in graphs (Schenker et al (2005)) is modification of standard *k*-means method (Ferrer et al (2009)):

1. Select *k* vertices (e.g. randomly) and each of them set as the initial centroid (the central vertex of each *k* cluster);
2. Create / count clusters by assigning vertices to the nearest (in the sense of the $dist(\cdot,\cdot)$) centroid function;
3. Designate new centroids in clusters (designation of a new centroid in a cluster is to determine such a vertex from the cluster, for which the average or the sum from the values of the distance function $dist(\cdot,\cdot)$ to the other cluster vertices is the smallest);
4. Repeat steps 2 and 3 until there are no more changes in the clusters or the assumed number of iterations is reached.

The complexity of the *k*-means algorithm in the graph is equal $O(n^2+nm) + N\left(O(kn)+O\left(k^{-1}n^2\right)\right)$ where N is number of iterations in algorithm.

Louvain modularity method

Louvain modularity method (Blondel et al (2008)) is used to detect groups/clusters/communities. The most important of these are the communities in large networks. This is one of the most popular methods of determining clusters. The essence of the method is to optimize modularity as the algorithm advances. Modularity is a value on a scale from -1 to 1, which measures the density of the edge inside the community to the edge outside communities. Optimization of this value results in the best possible grouping of vertices of a given network, however, going through all possible iterations of vertices in a group is impractical because of time consuming (the problem of determining maximum modularity is NP-hard to calculate), therefore heuristic approaches are used. The idea of the method comes down to two steps:

- small communities are first located by local optimization of modularity at all vertices of the network,
- then each small community is grouped into one vertex (the so-called "community") and the process is repeated.

Greedy algorithm has computational complexity $O(n \log n)$, where n is the number of vertices in the graph.
The Louvain method has a lot of improvements and modifications, which the works treat, among others (De Meo et al (2011), Gach and Hao (2014), Traag et al (2019)).

Hierarchical-centric methods of community detection

The aim of this group of methods is to build a hierarchical community structure based on the network topology. One of the best-known methods of this group, which is based on the so-called edge betweenness, is Girvan's-Newman's method (Girvan and Newman (2002)).

Girvan's-Newman's method

Edge betweenness, used in the method, is based on the number of shortest paths between all pairs of vertices passing through the edge: a given edge is the more important the more the shortest paths pass through it. As a reminder: the measure of betweenness for vertices is based on the thesis that a vertex is more important in the graph, the more the number of shortest paths connecting any two vertices in the graph passes through it.

Girvan-Newman's method uses the observation that the edges between groups usually have a greater value of edge mediation than inside groups.

The idea of the algorithm is as follows:

1. Calculate the edge betweenness of all edges in the network.
2. Delete an edge e_{bet_max} with the highest value of the betweenness measure.
3. Recalculate the edge betweenness for all edges affected by edge removal e_{bet_max}.
4. Repeat steps 2 and 3 until no edges are left.

The Girvan's-Newman's algorithm has a complexity $O(m^2n)$.

Application of models and methods of graph mining for the analysis of publication links

The results presented in this section concern scientific publications (chapters in monographs) between 2015-2018 of the employees of the Institute of Computer and Information Systems (ISI) of the Faculty of Cybernetics, Military University of Technology, Warsaw, Poland (http://isi.wat.edu.pl) (number of chapters: 164).

The data (in BibTex format) was converted to the weighted graph format (network) read by the software Gephi (Gephi (2020)), in which the analyses were made. The analyses were carried out using the Louvain method implemented in Gephi and by determining the value of *k*-core and *k*-brace (Ugander (2014), Ugander et al (2012)) for different values of *k*.

Graph of publication links was constructed in a following way:

- the collection of graph vertices are the authors of the publication (employees) who had at least one publication,
- an edge (*x, y*) is added between such a pair of authors *x* and *y*, who had at least one publication in common,
- the edge (*x, y*) weight is the number of common publications by authors *x* and *y*.

It follows from the way the graph is constructed that if a vertex is isolated (i.e. not connected to any other vertex, i.e. the degree of that vertex is 0), it means that the author either published it himself or with co-authors who were not ISI employees.

Example of exported BibTex records for a chapter in the monograph is presented below:

Fig. 1: Graph of publication cooperation between the authors (from ISI) of the chapters in monographs between 2015-2018. Number of vertices *n* = 42, number of edges *m* = 64. The number of clusters is 15, of which 5 are multi- faceted (vertices coloured the same colour belong to the same cluster). The size of the vertex is proportional to its degree, the "thickness" of the edge is proportional to its weight;

Source: own elaboration

Fig. 1 shows the network of links between the authors of the chapters in the monographs between 2015-2018. Number of vertices *n* = 42 (number of employees who had at least one publication as a chapter in the monograph), number of edges *m* = 64 (number of pairs of employees who had at least one joint publication as a chapter). The number of clusters is 15, of which 5 are multi-faceted (vertices colored the same color belong to the same cluster). The size of a vertex is proportional to its degree (i.e. the number of employees with whom a given employee had joint publications), the "thickness" of the edge is proportional to its weight (i.e. the number of joint publications between a pair of employees). The graph analysis shows that the chapters in the monographs were created the vast majority in five groups of co-authors (number of clusters). The most numerous of these groups (blue) has a number of 9 (central vertex: A. Najgebauer), but judging by the "thickness" of the edge in the 8-person group (violet, central vertex: M. Kiedrowicz), there were most publications of this type. These conclusions can also be confronted with the data in Table 1.

Fig. 2 shows the *k*-core of the graph in Fig. 1. According to the interpretation (subsection 2.1), the *k*-core will indicate those authors of the publication who had at least one publication in common with other authors in the *k*-core. For example, the 3-core (Fig. 2c), "filters" the graph of publication links to such a subgroup of authors, in which each of them had at least one common publication, with at least 3 authors of this group: e.g. Dariusz Pierzchała has at least one common publication with 3 authors of this group (these are: Zbigniew Tarapata, Andrzej Najgebauer, Krzysztof Chlebicki, Tadeusz Nowicki). Fig. 2 shows that such connections among the authors of the chapters are strong.

Fig. 2: Graph filtering results from Fig. 1 to *k*-core: (a) 1-core, (b) 2-core, (c) 3-core and (d) 4-core; Source: own elaboration

Fig. 3 shows the *k*-brace of the graph in Fig. 1. In this case we also have interesting interpretations and results. Namely, the *k*-brace "filters" such vertices from the graph that if two employees (authors) had at least one common publication (edge in the graph and the *k*-brace between them), each of them had at least one joint publication, with at least *k* the same authors. For example, in Fig. 3c, Zbigniew Tarapata and Andrzej Najgebauer are in the 3-brace and are connected by an edge (they had at least one common publication). This means that each of them had a common publication with at least three of the same authors (Fig. 1 shows that they were them: Rafał Kasprzyk, Ryszard Antkiewicz, Dariusz Pierzchała, Wojciech Kulas, Michał Dyk). Let us also note that each *k*-brace is a subgraph (*k*+1)-core.

Table 1 shows the values of basic measures of vertex centrality measures in the graph in Fig. 1. While the vertex degree measure is interpreted as the number of authors with whom a given author has published (vertex in the graph), the weighted degree measure is interpreted as the number of all co-authors' publications of a given author (sum of the weights of incidental edges with a given vertex). From the point of view of the betweenness measure, the most important is the vertex (author) that would take part in the "association" of the largest number of pairs of co-authors. Considering the measure of closeness, the most important is the author who is closest (in sense of publications) to all other authors. More about vertex centrality measures in graphs and their interpretation can be read in (Bartosiak et al (2011)).

Fig. 3: Graph filtering results from Fig. 1 to *k*-brace: (a) 1- brace, (b) 2- brace, (c) 3- brace;

Source: own elaboration

Table 1: Values of basic vertex centrality measures from Fig. 1. Three vertices (authors of publications in chapters), for which the value of the appropriate measure is the highest, are marked in bold. Zero vertexes, i.e. authors who have not co-authored publications with other ISI employees, are not included; Source: own elaboration

Summary

The problems of graph mining are of growing importance in the analysis of large data sets, often automatically acquired and processed from electronic sources. Several implementations of methods of solving these problems and description of their practical applications causes that the field of graph exploration is constantly developing. This can be seen in the intensity of scientific publications, scientific conferences held in this or similar areas, especially in the last twenty years.

The paper presents only selected models and methods of graph mining. The reader interested in this subject is referred to the review and application literature (Drif and Boukerram (2014), Kumar aet al (2016), Schenker et al (2005) , Tang and Liu (2010), Wasserman and Faust (1994)).

The analysis of relations between the authors of the publication presented in the study and the designated characteristics of groups of authors or individual authors (e.g. vertices isolated in graphs from subsection 3 do not directly testify to the quality of publication. They reflect the emerging in the institute of the research subgroups that have joint publications, not the quality of their work.

Application of the FMEA (Failure Mode and Effects Analysis) Method for the Analysis of Effects and Errors in the Transport of Dangerous Goods (a case study)

Ryszard BUDZIK

Opole University of Technology, Opole, Poland.
r.budzik@po.edu.pl

Abstract

In the article, the issue of safety in the transport of dangerous goods by rail has been presented. Based on the example of one of the largest enterprises dealing with rail transport in Poland, the analysis has been conducted on errors arising during the loading, carriage and unloading of dangerous goods.
In order to carry out the analysis, the FMEA (FAILURE Mode and Effects Analysis) method has been applied. The use of the FMEA method has demonstrated the main importance of the human factor for the level of safety in the transport of dangerous goods by rail. The application of the FMEA method for the analysis of safety in the X company in the transport of dangerous goods by rail has enabled the creation of risk tables that have contributed to the introduction of principles on minimizing risks in the transport of dangerous goods.

Keywords: FMEA method, transport of dangerous goods by rail.

Introduction

Transport, in Latin "transport – to carry, to freight", is an activity related to the movement of people, cargo from point A to point B with properly selected means of transport.

Nowadays, when the time is the main factor in transferring goods from place A to place B, road transport has dominated the transport market for carriage of various goods.

At any time, when thousands of tons of different goods are being transported around the world, the problem is safe transport of dangerous goods with an adequate level of safety. From the point of view of carriage of hazardous materials, an alternative for road transport is rail transport.

One of the main factors distinguishing the mode of transport is the range of cargo movement. Taking into account the range, transport can be divided into short- and long-distance transport. Long-distant transport is divided into air transport, water transport, road transport and rail transport.

Rail transport is the oldest mechanized form of transport used primarily for the carriage of bulk cargo. In particular, freight rail transport is profitable for distances starting from several hundred kilometers. Rail transport has a number of advantages:

- high load capacity,
- relatively short delivery time,
- technical reliability of the means of transport,
- from the point of view of safety, a lower risk of an accident, collision,
- lower transport rates per kilometer compared to road transport.

Long-distance rail transport is still being developed, the example of which can be the Moscow-Vladivostok railway with the distance of 9259 km. The major significance of this railway is the transport of goods from China to Europe.

Security in Rail Transport

Securing the cargo plays the major role in transport. It depends on the proper protection whether the goods will be delivered to the indicated place in perfect condition.

Cite this Article as: Ryszard BUDZIK " Application of the FMEA (Failure Mode and Effects Analysis) Method for the Analysis of Effects and Errors in the Transport of Dangerous Goods (a case study)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The consequences of inappropriate security are often large material losses. An undesirable effect of inadequate protection during transport is an accident. According to the correct security procedures, various loads are protected with adequate nets, straps, mats, chains and ropes. In rail transport, cargo is secured not only against movement but also against theft.
Dangerous goods carried by the means of transport are classified in terms of physical, chemical and biological properties. Also, goods transported by rail may possibly pose a threat to the health and life of people involved in the transport of dangerous goods, they may also cause significant losses in the material and environmental spheres.

According to RID (in French: Le Règlement concernant le transport international ferroviaire des marchandises dangereuses), it is the regulation for the international carriage of dangerous goods by rail, based on the Directive 2008/68/EC of the European Parliament and the Council of Europe on the inland transport of goods. (Directive 2008/68/EC of the European Parliament on the inland transport of dangerous goods. 2008).

The RID regulations, among others, specify what dangerous goods are not allowed for international transport and which are allowed and under what conditions.

According to RID, there are 9 classes of dangerous goods. These are explosives, gases, flammable liquids, flammable solids, materials susceptible to self-ignition, water reactive materials, oxidizing materials, radioactive materials, corrosive materials, various hazardous materials and objects.

Legal provisions for the transport of dangerous goods

The main principles for the international transport of dangerous goods by rail have been included in the RID regulations, Annex C to the Convention of International Carriage by Rail. The Convention was written in Berlin on 9 May 1980. RID is in force in all European countries. The participants in the transport of dangerous goods by rail are obliged to adapt to and obey the rules dictated by RID.

The general rules dictated by RID in the event of a hazard are presented to all the participants in the transport of dangerous goods and are as follows:

- to apply all possible measures to minimize the effects of the event,
- the obligation to immediately notify relevant emergency service,
- to provide the necessary information for an effective rescue operation.

The analysis of effects and errors in the transport of dangerous goods by rail according to the FMEA analysis (a case study)

The subject to the analysis is the transport of dangerous goods by rail in the X company. The X company carries dangerous loads in the area of Poland, Belarus, Czech Republic, Ukraine and Germany. The X company has their own rolling stock, all the attestations and certificates related to the security of the transport of dangerous goods. The security in the X company is ensured by a range of procedures, instructions aimed at specifying and indicating appropriate operations concerning the secure carriage of dangerous goods; the analysis of types and effects of possible errors has been carried out (Kosiorek D.: Jakość w teorii i praktyce zarządzania organizacjami. “Zarządzanie i finanse” No. 11 Part 1,2013; Rychły – Lipińska A.: FMEA . Analiza rodzajów błędów oraz ich skutków. “Zeszyty Naukowe Wydziału Nauk Ekonomicznych Politechniki Koszalińskiej” No. 11,2007;
Urbaniak M.: Zarządzanie jakością. Teoria i praktyka. Difin. Warszawa 2004).

In order to improve the safety of the transport of dangerous goods in the X company, the analysis of the types and effects of possible errors has been carried out according to FMEA.

The FMEA method is to prevent the effects of hazards which may occur during the transport of dangerous goods by rail.

The hazards which the FMEA analysis relates to occur at the stage of:

- loading and unloading of dangerous goods,
- carriage of goods,

Critical threats which may occur are as follows:
- train derailment,

- a collision with another train, a motor vehicle at a crossing, wild game,
- leakage of a tanker or a load unit.

Lesser rank threats include:
- inadequate security,
- inappropriate marking of dangerous goods,
- incorrect connection of loading/unloading devices.

Irregularities that may affect safety are:
- incorrectly written documentation,
- illegible marking,
- human error.

In practice, the application of the FMEA method for the analysis leads to the determinanion of the threat-effect-cause relationship. For each hazard, its cause or effect, the criteria are defined given the value in the range of 1 to 10.

In Tables 1, 2 and 3, the criteria and weights for hazards, hazard effects and frequency of hazard occurrence are presented based on practice.

Table 1: Criteria for the probability of hazard detection (weight, ranking).

No.	Effectiveness of hazard detection	Weight, Ranking
1.	Complete uncertainty	10
2.	Very faint uncertainty	9
3.	Faint uncertainty	8
4.	Very little uncertainty	7
5.	Little uncertainty	6
6.	Average uncertainty	5
7.	Moderate uncertainty	4
8.	High uncertainty	3
9.	Very high uncertainty	2
10.	Highest uncertainty	1

Table 2: Criteria for the probability of hazard detection (weight, ranking).

No.	Effectiveness of hazard detection	Weight, Ranking
1.	Dangerous, with warning	10
2.	Dangerous, no warning	9
3.	Very serious	8
4.	Serious	7
5.	Moderately serious	6
6.	Not very important	5
7.	Unimportant	4
8.	Trivial	3
9.	Very trivial	2
10.	No effects	1

Table 3: Probability and frequency of hazard occurrence (weight, ranking)

Probability of hazard occurrence	Frequency of hazard occurrence	Weight, Ranking
very high – very frequent hazards	once a week once a month	10 9
high – frequent hazards	once a quarter once every six months	8 7
medium – occasional hazards	once every nine months	6

	once a year once every 1.5 year	5 4
low – relatively low hazards	once every 2 years once every 2.5 years	3 2
distant – unlikely hazard	once every 3 years	1

In the X company, as a result of the FEMA analysis, 25 hazards have been identified based on practice:

- incorrectly compiled shipping documents and specifications,
- inadequate selection of personnel,
- lack of a sufficient number of employees responsible for the transport process,
- poor mental and physical condition,
- lack of staff training in OSH
- failure to comply with internal regulations and orders,
- training in the transport of dangerous goods inconsistent with applicable regulations,
- lack of appropriate training in the transport of dangerous goods,
- illegible marking of dangerous goods,
- improper securing of dangerous goods,
- inappropriate selection of the rail car for the transport of dangerous goods,
- collision with wild game,
- collision with another train,
- collision with a motor vehicle at a crossing,
- leakage of a tanker,
- leakage of a load unit,
- damage to train control mechanisms,
- failure of the breaking system,
- damage to the sheathing of a car or a locomotive,
- damage to railway traffic control devices
- poor condition of the railway infrastructure,
- train derailment due to human error,
- train derailment for reasons beyond the carrier,
- natural disasters.

On the basis of the points in the ranking assigned to the occurrence of the specific hazard (Z), effect of hazard occurrence (S) and control of hazard detection (W), the risk has been created which is the product (L) of the above ranking ratings.

$$\mathbf{L = (S) \times (W) \times (Z)}$$

Number L may take values from 1 to 1000. On the basis of long-term observations in the analyzed X company, it has been concluded that number L = 100 is significant for the safety of the rail transport of materials. It has been stated that each determined L value higher than 140 means a critical hazard for the transport of dangerous goods by rail.

The matrix of L risk is presented in Table 4.

Table 4: Risk classes and the risk level

No.	Risk class	"L" risk	Risk level
1.	I	L<100	No risk, or a very low risk of hazard occurrence
2.	II	100<L<140	Steps to eliminate the risk of hazard must be taken
3.	III	L>140	With an increase in the number to more than 140, very high hazard, including the critical one

In order to obtain the specific numbers of risk (L) in the X company, the table has been compiled containing information on what L numbers can be assigned to the specific hazard. Based on the FEMA analysis, the criteria for assessment of the degree of risk have been created. L number higher than 140 amounts to the critical hazard. L number lower than 100 means there is no risk of hazard occurrence. The risk is acceptable.

Typical two examples of hazards out of 25 threats which may occur in the transport of dangerous goods by rail in the X company are presented in Table 5.

Table 5: Exemplary hazards that may occur in the transport of dangerous goods.

No.	Hazard	Possible effects	Control measures (detection)	Z	S	W	Z	Recommended control measures
1.	Poor mental and physical condition	Threat to life and health	Control before and during work by the manager	4	6	7	168	L higher than120. Critical hazard. Controls ought to be introduced
2.	Poor condition of the railway infrastructure	Risk of an accident	Reporting on bad condition to superiors	2	6	7	84	Threat of bad condition, reporting to the infrastructure manager

Summary and conclusions

In the analyzed company, the research results on the application of the FEMA method have been specified. With this method, one may easily determine which hazards should be eliminated first.

Based on the conducted analysis of safety in the transport of dangerous goods by rail in the X company, the following conclusions have been drawn:

- 1. The application of the FMEA method has shown mainly the importance of the human factor for the level of safety in the transport of dangerous goods by rail,
- 2. The transport of dangerous goods by rail is a complex and responsible process and constantly changing regulations, new forms of security, methods of loading and unloading, force companies to continue training in this field,
- 3. The effects that may be due to inappropriate transport may concern every person and also the surrounding environment,
- 4. The application of the FMEA method for the analysis of safety in the X company has resulted in the creation of the risk table and the risk tables have contributed to the introduction of principles for minimizing risks in the transport of dangerous goods by rail in the X company.

Abstract

The aim of the study is to verify the pricing of assets in the Polish capital market using CAPM extended version. In the research, in addition to market risk in the form of a beta coefficient, the variables adopted for the model were the fundamental ratios used to analyse profitability, ROA and ROE. Market risk was considered in a variance and downside framework. For calculating the downside risk the Harlow and Rao formula was used. The subject of the research were stocks of the companies with various capitalization and across different industries, belonging to the large, medium and small indexes and equally-weighted portfolios based on these stocks. Two-factor models for quarterly returns were estimated in a two stage procedure in which cross-sectional regression was applied. The regressions give an evidence of existing positive risk premium for market risk both in conventional and downside approach For all samples of companies downside beta is a little better risk measure than the conventional one. The findings of our study indicate also that the ROA and ROE ratios proved to be valid factors in the risk-return relationship. Profitability ratios considerably outperform market beta coefficients as factors explaining average returns on the Warsaw Stock Exchange. Mean returns in the capital market are much more responsive to the financial performance of a company, especially ROE, than to the market index. The highest explanatory power have models for portfolios, large and medium stocks and with downside beta and ROE ratio. The results show that the combination of financial analysis' factors with downside risk measure contributes to a better understanding of capital asset pricing.

Keywords*:* Downside beta, CAPM, ROA, ROE.

JEL Classification*:* G12, G32.

Introduction

The study of share prices in the financial markets is as old as the financial markets themselves. The growing importance of financial markets and financial institutions in the economy means that research on share prices is

Cite this Article as: Anna Rutkowska-Ziarko and Lesław Markowski "Profitability Ratios and Downside Risk in Asset Pricing" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

an important area and will continue to be so in the future. Fundamental analysis is the oldest tool for analysing stock prices in financial markets (Ritchie, 1996).

Profitability and cash flow analysis has a special place in the fundamental analysis of the stock market. It is believed that the increase in share prices and dividends paid by the company is related to the ability of enterprises to generate profit and to maintain positive cash flow.

An alternative approach to the pricing of financial assets is highlighted in Markowitz's portfolio theory (Markowitz, 1952; 1959) and the model of valuation of capital assets. This model was developed independently by Treynor (1961), Sharpe (1964), Lintner (1965) and Mossin (1966).

These models assumed that for a market in equilibrium the average rate of return on shares depends on the risk incurred by the investor. The risk was measured by the variance in returns. For variance, the risk of the investment portfolio can be easily determined based on the correlation between returns on shares. This approach is easy to apply in practice. In the calculus of variance, positive and negative deviations from the average rate of return are treated in the same manner, which is not consistent with the assumption that the investor prefers to own more than less. In response to this, asymmetric risk measures such as semi-variance were developed in the capital market studies (Hogan & Warren, 1974). The downside measure of co-occurrence replacing covariance is the lower partial moment. It is worth emphasizing that when determining variance and covariance, the reference point is always the average or expected rate of return. However, different target points can be chosen for determining the lower partial moments. Many approaches to calculating them have been proposed in the literature (Bawa & Lindenberg, 1977; Harlow & Rao, 1989). Research on the use of downside risk measures and the Downside CAPM (D-CAPM) model includes works (Estrada, 2002; Post & Vliet, 2006; Momcilovic et al., 2017). Barucci and Fontana (2017) put forward that expected returns change over time and a risk premium for downside risk is generated. They offer an explanation for changing risk aversion in time. Investors have low risk aversion after a rise in share prices and high-risk aversion after declining in prices.

Irrespective of the one-factor CAPM with a classical and downside risk approach, the Arbitrage Pricing Theory (APT) was created, which significantly enriches the structure of capital asset pricing. APT indicates the existence of risk factors other than volatility. It is, on the one hand, a competitive theory and on the other a theory expanding CAPM. (Ross, 1976). According to APT, rates of return on shares depend on several factors that are sources of systematic risk, which can be considered as a combination of elements of portfolio and fundamental analysis in the process of capital assets pricing. Fama and French (1992; 1993; 2018) made an important contribution to the development of multi-factor models and APT. Their model is based on a variance as a risk measure added to CAPM other than beta coefficient risk factors such as firm size and book-to-market. Zaremba and Czapkiewicz (2017) found that profitability factors ROA and ROE have a statistically significant impact on rates of return in emerging markets

Considering the market factors and fundamental factors, this paper attempts to specify multifactor models in the classic approach to risk and models based on downside risk measures. As a statement of the financial performance of the company, the profitability ratios ROA and ROE are taken. The two-factor models based on one profitability ratios and alternatively classical and downside beta coefficients are estimated. We assume, that the profitability ratios are one of the most important reasons determining the level of rates of return on the capital market. The aim of the study is to verify the pricing of assets in the Polish capital market using CAPM extended version.

The article is organized as follows. First, the downside risk measures were introduced in Section 2. Section 3 describes the data set, the method of portfolios formation and the results obtained were discussed. We conclude in the last Section.

.

Theoretical Background

CAPM is still one of the fundamental theories and tools of risk assessment. However, its standard version is subjected to continuous modification by taking into account additional risk factors. These factors may prove the effectiveness of assets management and, thus, the financial condition of the company.

Florio and Leoni (2017) showed that companies with a good quality of risk management are in good economic condition and their market position is better. Accounting variables are a valuable support to market beta in risk analysis (Amorim, Lima & Murcia, 2012). They analysed the relationship between information from financial statements and systematic risk in the Brazil financial market. In addition, this article gave a wide review of literature and studies on that topic. Nekrasov and Shroff (2009) highlighted the utility of accounting information

as risk factors. The co-movement between the ROE of a firm and the market ROE were considered. Cambell, Polok, and Vuolteenaho (2010) appreciated the role of accounting information in the calculation of the cost of equity and the risk analysis. They study the influence of stock cash flow on returns in the capital market and provide an example of the application of accounting risk measures using the Morningstar stock-rating system. Morningstar Inc. argues that accounting data may better reveal information about the long-run risk and cost of capital than CAPM.

The correlation between market risk and accounting information was also analysed for emerging markets. Er and Kaya (2012) analysed the Istanbul Stock Exchange and found the impact of EBIT divided by net sales on market beta. They did not use ROA or ROE. Toms (2012; 2014) proposed the accounting-based risk (ABR) model as a contrast to CAPM. The ABR model focuses on revenue and cost behaviour and the impact of that on the accounting rate of return.

The role of financial ratios in multi-factor models is still developing. Fama and French (2018) proposed six-factor models with cash profitability and operating profitability**.** Ahsan (2013) showed that a portfolio based on ROE can generate positive abnormal returns, but higher ROE does not guarantee higher returns from a security. He considered NYSE, NASDAQ and AMEX stocks and annual company performance. Zaremba and Czapkiewicz (2017) tested explanatory power of four popular factor pricing models in emerging European markets. They analysed about 100 anomalies documented in the financial literature. Out of wide range of variables they used as well the profitability factors like ROA and ROE. Considering these ratios they found positive differences between means that significantly different from zero under the equal-weighted and capitalization-weighted portfolios.

CAPM is a theory describing the risk-return relationship in the light of the postulate according to which variance is the only accepted measure of risk. For this reason, testing the asset pricing model has been widely criticized as not being sufficient to determine the cost of capital. The downside risk is intuitively based on investor aversion to potential deviations in the form of losses rather than profits. In addition, the return distributions are not usually normal or at least symmetrical. Many CAPM validity tests conducted on developed markets found the advantage of CAPM downside beta coefficient over classic CAPM (Post & Vliet, 2006). Ang, Chen and Xing (2006), using common stock quoted on NYSE, AMEX and NASDAQ, provided strong evidence that investors require a premium for downside risk and verified that assets with high downside betas obtain high average returns. Models with downside betas have higher explanatory power than traditional CAPM for NYSE stocks (Chen et al., 2009). Tsai, Chen and Yang (2014) investigated whether the expected returns depend on CAPM and downside betas. They used a dynamic conditional correlation (DCC) model and, for a sample of developed countries, they revealed that the downside betas explain a substantial part of the volatility of expected asset returns better than CAPM betas. In emerging markets, Estrada (2007) indicated that the Downside-CAPM much more explained the risk-return relationship than the traditional CAPM, particularly in asymmetric return distribution. Estrada proposed a new formula of downside beta and verified its utility in asset pricing. Alles and Murray (2013) concluded that downside co-skewness was a significant measure in cross-sectional regressions in contrast to the downside beta. These results were confirmed in the Korean stock market (Thuy & Kim, 2018). Extensive research in emerging markets such as Slovenian, Croatian and Serbian demonstrated that the downside risk is the variable that statistically significantly explain mean returns (Momcilovic et al., 2017) Significance of downside risk in asset pricing was examined on the Chinese stock market (Ali, 2019). This research showed a positive risk premium for downside variability in the medium and long term. Therefore, we considered risk analysis in two approaches: variance and downside risk. Recent research into accounting-based downside risk and cost of capital was conducted by Konchitchki et. al. (2016). They proposed a measure of downside risk - accounting-based downside risk. The accounting-based downside risk is the proportion of lower and upper variances of ROA. It contrasts the meaning of downside risk compared to our approach. Rutkowska-Ziarko (2015) and Rutkowska-Ziarko and Pyke (2018) identified a positive correlation between the quarterly profitability ratios (ROA, ROE, ROS) and the quarterly average rates of return for companies listed on the Warsaw Stock Exchange.

In the current study, we use the concept of Harlow and Rao (1989) for downside risk. In addition, quarterly information on company performance was used, whereas most studies employed annual data. In this article, we suppose that fundamental variables have better explanatory power of average rates of return for larger and medium firms compared to smaller firms.

Research Methodology

According to the classic CAPM, the main source of risk is the economic situation of the market as a whole, which is reflected in the market portfolio, including all available assets. In practice, stock indices are an approximation of such a portfolio. The main, systematic measure of risk is the beta factor, which expresses the sensitivity of

changes in a given asset to changes in market conditions. The CAPM postulates a linear function between expected returns of assets and the systematic risk expressed by beta coefficients. This relation can be given as follows:

$$E(R_i) = R_f + \beta_i\big(E(R_M) - R_f\big) \quad (i = 1, \dots, N) \tag{1}$$

where $E(R_i)$, $E(R_M)$ are the expected return on asset *i* and the market portfolio, respectively; R_f is risk-free rate; β_i is beta coefficient for asset *I*, which reflects the sensitivity of a given asset to changes in the stock index as a proxy of market portfolio.

In contrast, downside CAPM (D-CAPM), unlike the classic approach, identifies risk only as deviations below the assumed rate of return. Downside risk measures base on semi measures like semi-variance of returns and co-semi-variance or, more generally, lower partial moments (lpm) of degree n (with $n \geq 1$) and defined as:

$$lpm_i{}^n = \frac{1}{T-1}\sum_{t=1}^{T}(lpm_{it})^n\ , \tag{2}$$

where:

$$lpm_{it} = \begin{cases} 0 & for\ R_{it} \geq \tau \\ R_{it} - \tau & for\ R_{it} < \tau \end{cases} \tag{3}$$

and R_{it} – rate of return on asset *i* in period *t*; T - length of the time series.; τ - target rate. An important issue for assessing downside risk measure is the target rate, which means the required rate by the investor. The theory distinguishes many forms of downside beta coefficients, differentiating them from the formula and the target rate. In a case when the required rate τ equals risk-free rate and $n = 2$, the downside beta coefficient can be written as follows (Hogan & Waren, 1974; Bawa & Lindenberg, 1977):

$$\beta_i^{HW} = \beta_i^{BL} = \frac{E\{(R_{it}-R_f)\cdot\min[(R_{Mt}-R_f),0]\}}{E\{\min\,[(R_{Mt}-R_f),0]^2\}} \tag{4}$$

and the special case of above coefficient where the target rate is zero (Li & Galagedera, 2008):

$$\beta_i^{HW}\big(R_f = 0\big) = \frac{E[R_{it}\min(R_{Mt};0)]}{E[\min(R_{Mt};0)]^2} \tag{5}$$

Harlow and Rao (1989) developed the problem of lower partial moment as the *n*th order generalised lpm. They indicate that investors' risk assessment of securities should take into account various acceptable target rates. One such level for determining the downside measure is the average rate of the market portfolio. The downside beta of the Harlow and Rao formula is given by using the covariance between asset *i* and market portfolio:

$$\beta_i^{HR} = \frac{E[(R_{it}-E(R_i))\min(R_{Mt}-E(R_M);0)]}{E[\min(R_{Mt}-E(R_M);0)]^2}\ . \tag{6}$$

In this research, formula described in (6) was employed to calculate the downside betas to study the risk-return relationships.

Research Results

The study sample employs securities listed on the Warsaw Stock Exchange. The dataset consists stocks quoted in the WIG20, mWIG40 and sWIG80 indices. The WIG20 index is based on the value of a portfolio of 20 major and most liquid companies on the WSE, the mWIG40 index comprises 40 medium-sized companies and the sWIG80 index comprises 80 smaller companies listed on the WSE. The selection of companies from such various indices made it possible to consider the impact of company size on the risk-income relationship. The sample time period of quarterly returns starts from January 2010 to December 2017. The full-time series in the analysed period were characterized by 62 stocks: 10 from the WIG20, 21 from the mWIG40 and 31 from the sWIG80 indices. The sample includes a set of stocks mixed in terms of size and across different industries. In the study, we used data for companies from almost all industries, excluding the financial sector.

Besides individual securities, equally-weighted portfolios are also analysed in this study. Portfolios are formed from securities sorted in ascending order by the average return. Each portfolio consists of 5 securities and is formed in a rolling procedure. In that way for the entire sample of 62 securities, 58 portfolios can be created. For two

separate subsamples of 31 large-medium securities and 31 small securities, 27 portfolios are formed in each of them.
The market-wide WIG index is used as the market portfolio approximation. Two well-known profitability ratios (ROA and ROE) from quarterly financial reports are taken. All data were obtained from the EMIS database. EMIS provides access to information on over 145 emerging markets.

The study of relations between risk measures and expected rates of return is carried out in a two-step procedure. In the first stage, based on all observations of the sample, the risk measures and ratios (β_i, β_i^{HR}, $\overline{ROA}_i$, $\overline{ROE}_i$) are estimated using single linear regressions and formula from section 2. In the second stage cross-sectional multiple linear regression model relating mean returns to risk measures is used (Estrada, 2002). Two versions of two-factor CAPM are proposed. Each type of model includes two sets of variables. The first constitutes a classical or downside beta coefficient and the second comprises company characteristics in the form of the average return on assets ratio (ROA) and average return on equity ratio (ROE). The idea of combining financial ratios with downside risk is a new one. The specific combination of proposed risk factors is unique just for this paper. The testing cross-sectional multiple regression equations are as follows (Estrada, 2002):

$$\bar{R}_i = \lambda_0 + \lambda_1\hat{\beta}_i + \lambda_2\overline{ROA}_i + \eta_i; \qquad (i = 1. \dots . N) \tag{7}$$

$$\bar{R}_i = \lambda_0 + \lambda_1\hat{\beta}_i + \lambda_2\overline{ROE}_i + \eta_i; \qquad (i = 1. \dots . N) \tag{8}$$

$$\bar{R}_i = \lambda_0 + \lambda_1\hat{\beta}_i^{HR} + \lambda_2\overline{ROA}_i + \eta_i; \quad (i = 1. \dots . N) \tag{9}$$

$$\bar{R}_i = \lambda_0 + \lambda_1\hat{\beta}_i^{HR} + \lambda_2\overline{ROE}_i + \eta_i; \quad (i = 1. \dots . N) \tag{10}$$

where $\bar{R}_i$- means rates of return for the *i*-th security or portfolio; β_i, β_i^{HR}, $\overline{ROA}_i$, $\overline{ROE}_i$, are the estimates of risk measures for the *i*-th security or portfolio; $\lambda_0, \lambda_1, \lambda_2$ - structural parameters, η_i - random variable term of *i*-th security or portfolio.

From the relationships (7-10), some testable implications can be formulated. The risk premium denoted by parameters of λ_1 and λ_2 associated with all risk measures should assume significant and positive values. Finally, the constant term λ_0 should significantly differ from zero and correspond to the actual risk-free rate.

The estimation of extended CAPM was preceded by the analysis of correlation coefficients between average returns and systematic risk measures and fundamental ratios, separately for individual securities and portfolios. Tables 1-6 show the Pearson correlation coefficients between market betas and profitability ratios.

Tab.1: Correlation coefficient between risk measures for all individual stock companies

Notes: *, **, ***, indicates significance at the 10%, 5% and 1% level respectively.

There is a positive and significant correlation between average rate of returns and the average values of the profitability ratios (ROA and ROE) and betas for the sample of all stock companies under study. The power of correlation is higher for equally-weighted portfolios compare to individual stock companies. In the same time there is no significant correlation between market and accounting risk factors, both for portfolio and individual stock companies.

Similar results have been obtained for the sample of large and medium stock companies. In this case, all risk factors were significantly correlated with the average rate of returns. The correlation for portfolios was stronger than for individual companies. The classical beta (β) and downside beta (β^{HR}) have not any connection with the average rate of return on the capital market. Whereas the significant correlation between returns for stock companies and average accounting profitability was observed.

The correlation analysis exhibits the positive and statistically significant relationships between mean returns and classical and downside beta coefficients both for individual securities and portfolios. The analysis also shows the strong positive correlations between profitability ratios and mean returns and these measures considerably outperform market beta coefficients in the overall samples securities and portfolios. The findings of this study indicate that returns are much more responsive to the level of fundamental data than the market condition. Stronger relationships of this type were observed for portfolios, which was expected. In addition, the results show no relationship between market measures and fundamental measures for individual securities, which generate the possibility of treating the latter as additional information necessary for asset pricing.

The results of multivariate cross-sectional regressions defined in equations (7-10) for all securities and equally-weighted portfolios are given in Tables 7 and 8. The beta coefficient and downside beta of the HR formula are significant variables in explaining mean returns of these investments. Investors are rewarded for classical and downside systematic risk in the shape of a positive risk premium which ranged from 0.0138%-0.0169% per quarter for individual securities and 0.476%-0.0525% per quarter for portfolios. The findings are consistent with the results of Mamoghli and Daboussi (2010) who identified positive and significant premiums for classical and downside betas in cross-section regression analysis when the mean returns of portfolios were regressed over the above-mentioned risk measures. However our results did not confirm the findings obtained by Galagedera (2009) and Thuy and Kim (2018) who found that the beta and downside beta were insignificant and co-skewness outperformed these risk measures in explaining the variation of average returns.

When the tools of fundamental analysis are included together with CAPM and downside betas the average values of ROA and ROE ratios proved to be valid factors illuminating the risk-return relationship. In all regressions, estimates of risk premium for these variables were significantly differ from zero at the 1% level. Correlations

between the ROA and ROE ratios and mean returns testify that these factors are more influential than beta coefficients in explaining of mean stock returns. The risk premiums for portfolio investments are much higher than for individual securities and ranged from 3.4389% to 3.4909% per quarter for ROA and from 1.5970% to 1.6145% per quarter for ROE. For explanatory power two conclusions should be drawn. Firstly, models containing average ROE have more explanatory power than models using ROA ratio. The first models explain about one-third and the second models explain about one-fourth of variability in mean returns of securities. However, models with ROA and ROE for portfolios have the average R-Squared values about 0.79-0.82 and 0.70-0.73, respectively. Secondly, downside CAPM have slightly higher explanatory power than classical CAPM, both for individual securities and for portfolios.

The two-factor cross-sectional regressions were repeated for a subsample of large and medium stock companies and separately for small stock companies. The results obtained for large and medium stocks included in Table 9 very closely resemble the results received for the whole sample. The impact of risk factors on the expected rates of return was positive and statistically significant at the level of 5% and 1% for the beta and average ROA and ROE ratios respectively. The explanatory power of these models is higher than the results obtained for all securities and it varies from 0.338 to 0.389. Similar to the previous results for all securities the best model for explanatory power was the equation using the downside beta of the HR formula and the average ROE ratio. All estimates for portfolio investments are statistically significant at 1% level (Tab.10). Particularly noteworthy is the downside CAPM with ROE ratio for which the highest level of explanatory power was 0.851. The results show a stronger effect on stock prices caused by changes in return on equity than return on assets. Increasing profits from equity generate higher demand for shares of a given company and thus higher prices of these shares.

As shown in Tables 11 and 12 the significant risk factors for small stock companies turned out to be the ROA and ROE ratios. The values of the risk premium for these factors were higher compared to large and medium companies and ranged from 1.4674% to 1.5543% quarterly for average ROA ratio and from 0.9293% to 0.9708% quarterly for the ROE ratio. For portfolios the values of risk premium were significantly higher than for individual securities and ranged from 3.4242% to 3.68% and from 1.835% to 1.891% quarterly for average ROA and ROE ratios respectively. In contrast to models based on portfolios, the results for individual securities models show that investors are not rewarded for classical and downside betas as the systematic risk measures. Market risk premiums for beta and downside beta of HR formula are positive but not statistically significant. The implication is that average returns of small companies are less sensitive to general market conditions than other-sized companies which may indicate the importance of company size in the assets pricing. Regardless of the size of the company the explanatory power of models with downside beta is higher than in the models with the CAPM beta.

Conclusions

This paper analysed the impact of two sources of systematic risk in capital investment mean returns. The first is the market beta coefficient in the classical and downside approach and the second is fundamental factors in the form of average profitability ratios ROA and ROE. The Harlow-Rao formula was used to determine the downside risk coefficient. These measures were adopted as independent variables in cross-sectional regressions of extended versions of CAPM relative to quarterly mean returns of individual companies and equally-weighted portfolios. The research sample included large, medium and small-sized companies.

There are some important theoretical and practical implications of this study. The study and its results indicate that the beta coefficient in the downside framework is an appropriate measure of risk for explanations of average returns regardless of the size of the company. For small companies, downside beta is an even better risk measure than the conventional counterpart, which was confirmed specifically by estimates for portfolio investments based on these companies. Investors are rewarded by a positive and statistically significant premium for the acceptance of CAPM beta and downside beta. This means that stocks or portfolios with higher classical or downside betas generate higher mean returns. This conclusion is consistent with many recent studies and gives strong evidence for using CAPM with lower partial moments in addition to classical CAPM. Moreover, results show that the mean return as a threshold rate is relevant to make capital investments decision.

Correlation analysis and two-factor models demonstrate the advantage of fundamental factors over market risk coefficients, both in the conventional and the downside approach. The average ROA and ROE ratios were more strongly correlated with mean investment returns than beta coefficients. The estimates of the premium for profitability ratios were statistically significant in models based on securities and portfolios for various sizes of the company. However, the values of these premiums for small companies were relatively higher than for large and medium companies. R-squared values were higher for the sample of large and medium stock companies compared to small companies. It should be emphasized that the two-factor models with ROE ratio had the highest explanatory power of variability of returns exceeding more than 80 percent for portfolio investments. This research, conducted on the Polish capital market gives stronger evidence of the significance of economic analysis in asset pricing. The company's ability to generate profits and the efficiency of managing its assets is important for investors in the capital markets.

Abstract

The global economic crisis as a result of Covid-19 might increase the risk of employment insecurity and poor quality of life among young adults. This study evaluates the influence of the Covid-19 pandemic on employment insecurity and quality of life among young adults. Covid-19 pandemic is negatively affecting the global economy given that majority of business establishments and companies are compelled to temporarily shut down. As a result, some establishments or organizations are unable to meet up with the financial responsibilities of their companies. Therefore, workers are being laid off temporarily or permanently, businesses and companies are downsizing, cost of goods and services is spiking. Consequently, there is a further increase in employment insecurity among young adults. Hence, there is a likelihood of a reduction in the standard of living for the young adult population. A collective effort by the government and major stakeholders is required to ensure rigorous enforcement of Covid-19 precautionary measures. Additionally, adequate social or welfare support should be put in place for individuals who have lost their jobs and low-income earners. This will help minimize the severity of the economic crisis and employment insecurity among young adults globally. The study culminates with directions for further studies.

Keywords: Covid-19, Global Economy, Employment Insecurity, Young Adults, Informal worker, Quality of Life.

Introduction

The Covid-19 outbreak has continued to escalate across the globe, leaving affected countries and her citizens economically, socially, and mentally devastated. In fact, the effect of the Covid-19 pandemic has been reported to reduce global economic growth by 3.0 to 6.0 % in 2020. There is a likelihood of partial recovery of global economic growth in 2021, if there are no records of re-infection otherwise known as a second wave or even a third wave (Jackson et al., 2020). However, the inability to work towards preventing a second wave of the virus might further increase the risk of economic instability and insecurity globally. In as much as every affected country is putting in the effort to curtail the spread of the virus, it is important to note that policymakers and major stakeholders across the globe are confronted with the dilemma of securing the health of the public through enforcing physical distancing, closure of social activities, and certain related business activities. Sequel to these, they are faced with the unintended economic meltdown, which in turn poses a threat to the global economic growth (Ozili, 2020).

Unarguably, the inability to curtail the spread of the infection or virus might worsen economic recession across the globe (Açikgöz and Günay, 2020). Invariably, the human cost in terms of loss of lives is likely to negatively affect

global economic growth. Furthermore, there are chances of the heightened poverty level, career-derailing, job losses, social unrest, increased cost of goods and services. According to Jackson et al. (2020), the global market might diminish by 18% in developing countries whose economies depend greatly on trade.

Amidst the global unrest and economic crisis caused by the sudden outbreak of Covid-19, more concerns need to be channelled towards young adults (WEF, 2020). The pandemic has no doubt ensued to unexpected disruption of many lives globally, through inflicting of psychological stress arising from imposed physical distancing (Dong and Bouey, 2020). Considering the ripple effect of the pandemic, there are speculations of deepening economic crisis on numerous sectors of the world economy (Walker et al., 2020). Hence, there is a likelihood of increased unemployment rate and implications for incurred debt. These are likely to result in inter-generational issues which may further serve as a threat to the well-being of youths and future generations (see Figure 1). Hence, this study intends to evaluate the global effect of Covid-19 on young adults. Its further sorts to evaluate the consequences of the global economy on the employment rate and quality of life of young adults.

Fig. 1: Predicted Shrink in Economy in Different Regions (by percentage)

Source: WEF, 2020

Literature Review

The incidence of Covid-19 has tremendously transformed from a public health concern to the global economic crisis. According to Kumar (2020), the current pandemic is one of the worse global experiences since World War II. In the quest to flatten the curve of Covid-19 spread, countries were compelled to adapt to stringent measures which required international travel bans, border closures, closures of business establishment and social activities, and enforced quarantines. These adapted measures have created an uproar in the global market and further escalates the risk of massive global recession. Irrespective of the length and severity of the pandemic globally, different regions across the continent are forecasted to experience a shrink in economy.

The economy shrinkage forecasted for different regions across the globe was triggered by the shutdown of the global market. Concurrently, the shutdown enforced in different regions affected the global market and these has led to a massive disruption in the supply chain (Ling and Wahab, 2020). As a consequence, there is a decrease in the Gross Domestic Product (GDP) of most countries across the nation (The World Bank, 2020). Table 1 presents some of the global economic factors of the Covid-19 outbreak in all regions across the globe.

Table 1: Global Economic Factor of Covid-19 Outbreak

Sub-Sahara Africa	Asia and Pacific	Middle East & North Africa	America	Europe
Since March 2020, Crude Oil price has continued to drop GDP downturn Economy recession A massive decline in agricultural productivities Nearly 24.3 million tourism-related jobs are threatened Unemployed has escalated from 6.2% in 2019 to 7.8% in 2020 Expected yearly revenue from oil sales is predicted to decline by 48% monthly	Export services such as international accommodation services, food serving services and tourism are all under heated pressure to lay off staffs A decrease in the export trade of oil services Disrupted labour movement and supply chains Sectors highly reliant on automobiles, pharmaceuticals and electronics supplies are under intense pressure Heightened prices of surgical supplies Unable to resume normal working hours	40% drop in the trade market An expected increase in drop specifically electronics and automobile products Intense disruption and decline in supply and demand chains Heightened risk of job loss A collapse in demand and a decrease in the supply of crude oil Increases risk of GDP decline Expected to lose approximately 42 billion dollars this year.	68.2 million citizens have filed for unemployment insurance 20 million jobs lost Disruptions in supply chain Harsh contraction of financial situations Extremely globalised economies and integrated cross-border supply chains Heightened share of services sector of GDP in advanced economies	EU economy growth shrunk by 8.3% in the 1st wave of Covid-19 outbreak. Predicted to reach 11% during the second wave Shrunk in energy prices Approximately 5.5 million job loss

Source: The World Bank (2020)

Subsequently, millions of individuals have been put out of jobs since the first quarter of Covid-19 outbreak across countries due to the uncontrollable economic meltdown (World Economic Forum (WEF), 2020; International Labour Organization (ILO), 2020). Observably, young adults are considered one of the most vulnerable in terms of jobs lost during this pandemic. Young adults in the context of this study are referred to individuals between the ages of 15-25 years. As at 2015, statistical evidence indicates that young adult between ages 15-24 years makes up to 1.2 billion (17%) of the global population. The data is forecasted to increase to 1.3 billion by 2023 (United Nation (UN), 2020).

The increased rate of unemployment among young adults during the pandemic remains worrisome. The fact that young adults make up 17% (1.2 million) of the world population is a global concern (UN, 2020). Over the years, the young adult unemployment rate in the labour force has been quite low. Furthermore, young workers are expected to experience more difficulty in accessing the labour market in 2021 prior to the pandemic as shown in Table 2.

Table 2: Global Youth Unemployment Prior to Covid-19 Pandemic

Source: ILO (2020)

Majority of young adults are mostly non-skilled workers, self-employed or unemployed. Figure 2 gives an insight into the labour market involvement and socio-economic status of young adult across different regions of the world (ILO, 2020).

Fig. 2: Global Labour Market of Young Adult, 2019

Source: ILO (2020)

The shutdown of most business sectors worldwide has led to downsizing of companies, laying off staffs and temporary and/or permanent closure of business outlets. As a consequence, there is a further negative economic impact on young adults in 2020 and beyond. Table 3 shows the trend in decline rate of employability to population ratio between young adults (18-25 years) and older adult 25-29 across different regions and sub-regions worldwide from 1999, 2019 and 2023. This was reported prior to the Covid-19 outbreak. The labour market is predicted to remain unfavourable to young adult (18-25 years) through to 2023 (ILO, 2020).

Source: ILO (2020)

Data generated from ILO (2020) indicated that before the Covid-19 outbreak, young adults were highly employed by the most hit sectors during the Covid-19 outbreak. Four of the most disrupted sectors include accommodation, food and services, wholesale and retail trade, these sectors amongst others are said to have experienced a massive economic output downturn during the outbreak. As a result, young workers employed in any of these business establishments are confronted with either temporary or permanent job loss, reduction in working hours or slash in income. Table 4 shows the informal sectors engaging young workers in the labour market and the severity of Covid-19 outbreak on these sectors in term of the economy globally during the Covid-19 outbreak.

Table 4: A Global estimation of young workers employed by Unskilled Sector Hit by Covid-19

		Baseline employment estimates for 2020 (before COVID-19 crisis)		
Economic sector	Impact of crisis on economic output	Level of employment (millions)	Share in global youth employment (%)	Share of young women in total youth employment (%)
Wholesale and retail trade; repair of motor vehicles and motorcycles	High	74.8	17.5	41.7
Manufacturing	High	59.2	13.8	36.9
Real estate; business and administrative activities	High	16.4	3.8	43.8
Accommodation and food services	High	28.1	6.6	50.8
Transport, storage and communication	Medium-high	21.0	4.9	16.4
Arts, entertainment and recreation, and other services	Medium-high	28.4	6.6	60.3
Mining and quarrying	Medium	2.9	0.7	22.6
Financial and insurance services	Medium	4.6	1.1	54.7
Construction	Medium	33.1	7.7	5.4
Agriculture, forestry and fishing	Low-medium	123.7	28.9	36.0
Utilities	Low	2.0	0.5	21.3
Public administration and defence; compulsory social security	Low	8.6	2.0	33.3
Human health and social work activities	Low	11.8	2.7	74.2
Education	Low	13.2	3.1	69.5

Source: ILO (2020)

A comparison between high, medium and low-risk rate (percentage and number) among young and older adult across different regions and income groups clearly indicated that young adults are highly vulnerable to job loss during Covid-19 outbreak globally (ILO, 2020).

Invariably, since the onset of Covid-19 and given the constant decline in economic output of business establishments, millions of young employees have been thrown out of jobs thereby losing their source of income globally. The severity of the economic impact is highly dependent on region and income groups (see Table 5). Understandably, young workers from low income earning region and sub-region may endure even worse predicaments than young workers from high income earning regions. Besides, gender disparities due to social and cultural barriers may further heighten the risk of job loss for young adults in the Middle East and North African (MENA) regions. Bearing in mind that young adult from MENA region accounts for the highest number of unemployed young workers (51%) (WEF, 2020; ILO, 2020) followed by Sub-Sahara Africa and Central Asia prior to pandemic even complicates their situation during and/or post Covid-19 period.

In view of the current economic turmoil across countries, young adults are likely at the verge of experiencing long term negative consequences from both pre and post Covid-19 outbreak. The implication of decline in revenue from oil sales, manufacturing industries, agricultural farming, import and exports of goods and services, and tourism and travels threatens the employability of young workers in the labour market who have reportedly lost their jobs (The World Bank, 2020). Above-mentioned economic sectors were major generating income source for young employers across all regions and sub-region prior to Covid-19. In other words, most of the highly affected sectors employed a huge population of young adults. Therefore, the contracting economy has made it very difficult for affected sectors to strive given decline in productivity and cash flow. These have led to downsizing of companies resulting in compounding of the unemployment challenge for young adults (employed, self-employed and job seekers) (Ozili, 2020; ILO, 2020).

The fact that young adults are disadvantaged in terms of proper education and formal skills may narrow the opportunity for young workers in the labour market. Consequently, the inability to predict the extent of the severity and duration of the Covid-19 outbreak in aforementioned regions would continue to narrow the opportunities for young adults in the labour force. Hence, young adults from regions and sub-regions of very low to moderate-income groups and low employment rates before the pandemic are even at increased risk of extreme poverty.

Table 5: The global unskilled young workers and Adults in Percentage and Actual Numbers

Methodology

Due to the dearth of study and the importance of the investigated topic, a narrative review method was adopted. A total of 21 articles were selected from 35 articles extracted from PubMed, Science Direct and Springer from September 2020 to October 2020. Irrelevant and duplicated articles were removed after screening. Articles with a focus on the global economic impact of Covid-19 and employment insecurity for adults and young adults were considered for this study. Furthermore, relevant information was extracted from Report paper published by ILO, UN and other global economic forums in the cause of this study. Inclusion criteria were also limited to articles that evaluated the impact of unemployment on young adults with a focus on young adults aged between 15-24 years. Both qualitative and quantitative focused papers were included (Nier et al., 2020; Krishnan and Wahab, 2019). Additionally, papers that evaluated the impact of Covid-19 on the global economy of travel and tourism, food supply and sports were respectively included in the study. Articles not published in English language and articles published before the year 2020 were respectively excluded.

Result and Discussion

Result

Since the outbreak of Covid-19, individuals have been compelled to practice physical distancing and confinement across the continent. These measures are considered the most logical and safest strategy to prevent the continuous spread of the virus (flattening the curve). Quite a number of businesses and productive activities were confronted with economic stagnancy, and are unable to meet up with the financial obligations to staffs and the company as a whole. As a result, there are reports of temporary layoffs, downsizing or closure of companies and businesses, and this further heightens the risk of employment insecurity among young adults. ILO (2020) established an estimated value of 178 million young adult populations across different regions earned their income from adversely affected sectors as a result of the Covid-19 backlash. Sectors such as retail trade, accommodation and food services are experiencing an economic downturn. Nearly, 17.1% of the young adult population across the Middle East and North Africa, Asia and Pacific, Europe, America and Sub-Sahara Africa world have reportedly lost their jobs since the outbreak of Covid-19 (ILO, 2020). An insight on statistical evidence of young workers who have stopped work since the onset of Covid-19 pandemic and those who worked prior to the outbreak is presented in Figure 3. This illustration is based on gender and income groups.

Fig. 3: Global Rate of Young Adult Who Stopped Working since Onset of Covid-19 Outbreak
Source: ILO (2020)

According to ILO (2020), the global working hours of young adult dropped by 7% by each day every month during the first and second wave of the pandemic. After adjustment, the working hours subsequently increased to 14% per day every month. The loss in working hours evaluated covered all outcomes such as part-time, lay-off, reduced working hours, unskilled workers, unemployed worker, and self-employed. Apparently, every lost working hour per day and month translates to a loss of 400 million full-time jobs per 48 hours a week. In essence, all affected region except the Middle East and North Africa (data not present) experienced at least a two-digit loss in daily revenue from labour except for America whose losses were adversely higher compared to other regions (Refer to Fig 4 & Fig 5)

Fig. 4: Labour Market Impact of Covid-19 from a Global Perspective
Source: ILO (2020)

Fig. 5: Labour Market Impact of Covid-19 from a Global Perspective

Source: ILO (2020)

The fact that young workers are highly employed in the sector mostly affected during Covid-19 further exacerbate their vulnerability towards poor income, lack of adequate social and legal job securities. The global economic effect of Covid-19 continues to escalate the unemployment rate of young adults and induce a low quality of life (see Table 6).

Table 6: Global Effect of Covid-19 on Young Adults Employment and Impact on Quality of Life

Source	Global Region	Young adult unemployment during the pandemic	Impact on quality of life
David et al. (2020) WEF (2020)	Sub-Sahara Africa	• Approximately 20 million young workers ages 15-24 years will lose their jobs • The jobless rate reached 7.8% in 2020 from 6.2% in 2019 • Young adult expected to experience low income and lack of social work security • Difficulty to gain access into a new job due to low education • Maybe disadvantaged to more career opportunity and growth • Difficulty to access new job for informal workers due to socio-economic status, ethnicity, gender diversity and location • May endure lower pension	• Increased socio-economic inequality (extreme poverty) • Social unrest • Increase the risk of domestic violence for female
ILO (2020)	Asia and Pacific	• 10-15 million young workers are likely to permanently lose their jobs • 12% of young adult stop working since the awakening of pandemic • Drastic slash income • A continuous decrease in working hour by 6.5 per 48 hours a week which may escalate to 13.5% with prolonged pandemic • Youths informal sectors might shift to informal sectors	Decrease mental well-being due to stress of working hours loss and slash in income.

		• 92% loss in productivity and 91% financial downturn for self-employed young adults • Unfavourable working hours without befitting income	
WEF (2020)	Middle East & North Africa	• Low chance of employment in the labour force, risk of unemployment is five times higher compared to older adult • Tighten opportunity for women in this region to participate in the labour market • Women working in Agricultural and other sector are likely to experience harsh working condition with no social security	• 14.3 million people to fall below the poverty level • 1.9 million people are expected to become malnourished • Risk of mental health concerns • Gender-based violence is likely to exacerbate among young women in this region
Gould and Kassa (2020); Jackson et al. (2020)	America	• The unemployment rate increased from 8.4% to 24.4% from spring 2019 to the first quarter of 2020 during the pandemic • Leisure and Hospitality are the most hit sector with a high proportion of young workers, hence this sector experience 41% job loss • Drop in working hours by 13.1% due to lockdown measures • Difficulty to secure a new job post-Covid-19 pandemic, as newly available jobs may require formal employees	Long term negative impediments which may lead to
Jackson et al. (2020); ILO (2020)	Europe	• The young adult jobless rate reached 17.3% in June 2020 from 7.7% in 2019 • Long term unemployment challenge which may include poor salary earning through-out lifetime. • Less future opportunity in terms of career growth • Securing a new job during a pandemic will negatively influence income power	• Low income earning power result in high dependency on parent which further leads to delayed marriage for affected individuals • It also causes a risk of low fertility in women • Poor mental well-being

Source: ILO (2020)

In order to protect the future of young adult, it is imperative for government and major stakeholders across nations to join forces and establish regionally tailored policies that will aid in cushioning the current and predicted adverse effects of the increased unemployment rate, income loss and extreme poverty level on young adults in and outside the labour market. Table 7 presents the recommended policies peculiar to different regions to aid in minimizing the effect of the global economy on young adults.

Table 7: Regionally Tailored Recommended Policies

Source	Region	Recommended Policies to Cushion Effect
WEF (2020); ILO (2020)	Sub-Sahara Africa	• Government to develop inclusive business models that expedite young people's transition to the formal economy • Young adult empowerment programs in terms of training and provision of financial assistance to set them up at the end of the training. • Policies to protect unskilled workers against exposure to hazardous and unfavourable social security • High-tech enhancement training programs for the young adult to enable them to fit into current working condition induced by Covid-19 on the labour market
Jackson et al. (2020); ILO (2020)	Europe	• Set up skilful programs to aid young workers to escape long term consequences of unemployment • Set up a social scheme to help young adult gain financial assistance during and post-pandemic • Policies to regulate for standard income-earning power for a young adult who get into the labour force at an earlier age
ILO (2020)	Asia and Pacific	• The government should lend financial support to some affected sectors such as healthcare. • Establish policies that will protect unskilled workers from last in first out • Lend support through to enterprises and jobs • Lend financial aid to self-employed young adults • Embark on youth-targeted employment programs to help young adult gain access into the labour force
UN (2020); WEF (2020)	Middle East & North Africa	• Loosen up on cultural and social barrier limiting female gender from employment • Policies to protect unskilled workers especially female gender in this region. • Set up a social scheme to accommodate the inclusion of informal employees back into the labour market, through the provision of training • Provide financial support to vulnerable individuals
Gould and Kassa (2020); Jackson et al. (2020)	America	• Set up policies to accommodate waiver of work history for the affected individual might aid cushion the effect on job seeking young seeking adult • Improve on social welfare scheme to enable both employed and job-seeking individual access to social support

Discussion

Unarguably, the measures besought in controlling domestic and international spread of the Covid-19 virus across the world have resulted in global economic crash (Ozili and Arun, 2020; ILO, 2020). The global economy came to a complete standstill during the first wave of the pandemic. Infact, the drop in oil price due to decline in demand and increase in supply was catastrophic for many oil based economy. Little or no demand for tourism due to closure of international and domestic borders both by air, road and sea, disruption in agricultural farming due to interruption of export and import services, reduced manufacturing outputs due to imposed movement restriction orders were the bane of the pandemic (The World Bank, 2020; WEF, 2020; Osman et al., 2020).

Apparently, the disruption in the flow of the global market affected the GDP of major regions such as Sub-Sahara Africa, Asia and Pacific, Middle East and North Africa, Europe and America. Hence these regions are expected to experience a shrink in the economy during and after pandemic (see Figure 1). As a result of the current global economic recession, millions of individuals have been affected through job losses, income loss or slash and cut-down of working hours. However, young adults within the age of 15-24 years are observed to be the most affected population during the pandemic (ILO, 2020).

Young adults have been one of the most marginalized populations in terms of unemployment and socio-economy inequalities over the years prior to the pandemic (see Figure 2). Even-though a large population of a young adult are

employed in the informal sector (see Table 2), majority of them have to endure terrible working condition which exposed them to hazardous and harsh working environment with poor payment (ILO, 2020; David et al, 2020). During this pandemic, young adult population are twice at higher risk of job loss, income loss and loss in working hours than older adult (see Table 2). During the pandemic, an estimate of 17.1% of young workers has been thrown out of jobs (see Figure 3). Meanwhile young workers in the workforce experience daily loss of working hours amounting to increased risk of losing their job permanently globally (see Figure 4 & Figure 5).

Apparently, Covid-19 pandemic poses a long-term threat to the global economy through the lenses of employment insecurity. Amidst the risk of job loss and other chains of a negative effects, comes a decreased standard of living. It is an established fact that, once the source of income of an individual is negatively affected then the standard of living also becomes affected (Belayeth Hussain, 2020; Ali et al., 2020; Buheji et al., 2020; Gössling et al., 2020; Ozili and Arun, 2020). The consequences of unemployment on a standard of living are indicated in Table 6. In nutshell, there is a dare need to put in place mitigating measures to assist young adult globally as shown in Table 5. It is believed that if these measures are properly implemented, it will guarantee a considerable reduction of the impact the pandemic on young adults.

Conclusion and Recommendations

The restraining order of movement control and compulsory or temporary closure of some business outlets and companies have undoubtedly escalated the workers' laying off and job insecurity among young adults. The stringent policy control measures implemented to aid minimize the spread of Covid-19 have led to a massive disruption in the global market. Most affected sectors were the main driving force of the labour market and global economy over the years. Young adults employed by these establishments have been subjected to severe losses in jobs, income and working hours. Young adults have become the most vulnerable due to their unskilful nature and lack of adequate social security in their workplace. Furthermore, young workers who are self-employed started experiencing a decline in productivity and income exposing them to instant loss of income as well. This is a very challenging time for young adults across different regions. Considering young adult prior to Covid-19 experienced difficulty in gaining access into the labour force, Covid-19 pandemic escalated the chains of negative effects on these group. As the current economic shrinkage heightens, the risk of prolonged unemployment among young workers is inevitable hence snowballing the socio-economic inequality and worsening quality of life. In other to alleviate the effect of the global economic shrinkage on young adults, this study has recommended useful regionally tailored policies. Young adults are the future hence there is a dare need to expand the labour market in ways that it will be favourable to young adults. The limited number of empirical studies from different regions and sub-region to give adequate insight into the exact situation of young adults regarding unemployment challenges during the pandemic was a major drawback of the study. Hence, it further narrowed the ability of the study to explore deeper into the economic effect of Covid-19 on young adult unemployment across global regions. Additionally, certain regions like the European Union and the Middle East and North Africa had limited data on young adult current experience during the pandemic. Information for this region was extracted from a general global economic impact of Covid-19. Hence, there is need to further conduct empirical focused study on these subject with respect to these areas highlighted.

Abstract

This paper explores the application of drones in the Malaysian healthcare supply chain during the COVID-19 pandemic and proposes strategies by identifying issues and challenges faced. A detailed literature review was conducted from a leading database to understand in detail the role of drones as a solution to the healthcare supply chain disruption during the COVID-19 pandemic. This study found several challenges such as limited technical capability, strict government regulation, need for a 5G network, high cost, and limited drone capabilities. Therefore, this study proposed strategies to mitigate these challenges which include investment in tertiary education, government legislation improvement, expedite 5G network adoption, collaboration with NGOs to reduce cost burden, and provide drones with multi-functionality. The findings of this study have significant implications and contributions to the body of knowledge relevant to drone technology and the healthcare supply chain. Specifically, the findings uncover challenges faced by the healthcare supply chain industry during the COVID-19 pandemic. Practically, the findings from this study may increase the understanding and awareness about the importance of drones and challenges among the key players (e.g. education, government, private sector, user, and manufacture). The study eneded with recommendations for future studies.

Keywords: Drones, Healthcare Supply Chain Management, COVID-19, Supply Chain Disruption, Sustainability

Introduction

The world is facing one of its toughest challenges in place of the COVID-19 pandemic. The global economy has been severely impacted. The current population has never experienced a pandemic of this magnitude, and recovery of the economy, for now, is uncertain. There are already existing gaps in the supply chain of raw materials and essential medications in which they were unprepared for due to destabilizing factors, pandemics included. The supply chain for healthcare has been severely affected, especially with regards to equipment such as personal protective equipment (PPE) in which there is an imbalance in supply and demand. Governments have set in place lockdowns and travel bans to curb the spread of the virus (Waiho et al., 2020). As expected, this has further disrupted the healthcare supply chain. Similar occurrences have been experienced during disasters such as flooding and earthquakes, in which there is difficulty in delivering medical supplies (Govind et al., 2020).

Cite this Article as: Muhammad Yazid SAHAK, Nikram SUBRAMANIAM, Siti Norida WAHAB, Ezutah Udoncy OLUGU, and Bolajoko Elizabeth OTEGBAYO"Scrum Solo: Application in Projects with a Strong Integration Component" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

A study from the Association for Professionals in Infection Control and Epidemiology, Inc, (APIC) had discovered that in the first few months of the 2009 H1N1 influenza pandemic, there was a 2 to a 3-year backlog of supply of N95 respirators and face masks for the infection preventionists (Rebmann, 2009). This is just one of the many studies that have proven that traditional methods are insufficient in combating natural disasters. There are many advances in technology that have been developed to assist, including the use of drones in the healthcare supply chain. It is important to ensure the accuracy of the material that is shared with all relevant stakeholders in the supply chain (Liu et al., 2018). The drone seems able to provide accurate information with an appropriate integration from one point to another within the supply chain (Floreano & Wood, 2015). It is not only suitable in the area of the healthcare supply chain. It is capable of being applied in every area including environmental monitoring, law enforcement, military applications, and many more (Marris, 2013). With the current pandemic situation, drones are capable of performing a wide range of activities including package delivery, inventory checking, production monitoring, simplifying the administration tasks, provide real-time information, same-day delivery as well as underwater operation (Nier at al., 2020; Olivares et al., 2015).

In the current situation, the drone application in the field of healthcare is relatively low due to some reason. A study by Graham (2016) identified few factors that may influence the drone application which include the organization, economic, political, and legislation. Additionally, relative advantage, perceived benefits, reliability, and perceived risk are other factors that may influence the drone application (Pappot & de Boer, 2015; Olivares & Cordova, 2015). In the Malaysian context, the drone has been used by the police and the military during the COVID-19 pandemic mainly to control public movement and to conduct aerial observation in ensuring the public are following the restrictions particularly in the park and public spaces. However, the issue of cybersecurity still in the grey area with the government still finding a way to ensure that privacy is protected (Bernama, 2020). Furthermore, the control of public movement, food delivery using a drone are also under trial phase in order to encourage the public to stay at home (Ling and Wahab, 2020). On the other hand, to improve the healthcare supply chain during the COVID-19, the Malaysia Ministry of Health is also looking into the methods to deliver medicines to the affected remote areas. Nevertheless, the usefulness of the exercise is still uncertain. Thus, the purpose of this study is to explore drone applications in the healthcare supply chain, its advantages, issues, challenges, and their impact on the healthcare supply chain. Since drone application in the healthcare supply chain is relatively a new concept in Malaysia, this study aims to propose strategies that enable to leverage it applicability particularly in the healthcare supply chain industry.

Drones in the Healthcare Supply Chain Overview

Healthcare has made numerous advances over the years. Technology has always been an avenue to augment the patient experience, treatment, and management. The integration of medical devices with IT is known as the Internet of Medical Things (IoMT). Drones, also known as Unmanned Aerial Vehicles (UAV) have been around for more than a hundred years. These vehicles without a pilot have been used by the military ever since World War I (Custers, 2016). Since then, it has gained popularity in many other fields, including agriculture, commercial, logistics, and even healthcare. The use of drones is for augmenting and increase the efficiency of healthcare.

While there are no official requirements for drones that are operating in healthcare settings, there are several recommendations based on generic drone technology that is being used in various humanitarian missions. A study by Tatham et al. (2017a) highlighted that a flight endurance of 8 - 12 hours which covers most of the daylight, could allow drones to operate with a much higher amount of time on task. The endurance is important to assist the answer in a remote and unreachable location, compared to situations where the location is nearer to the supplies. The feature of long flight hours is a high plus point in the drone industry and has always been the center focus of the manufacturer as an area to improve (Carlsson & Song, 2017). Additionally, the night-flying capability would be immensely useful especially in cases where a location might have daylight that is relatively short as this would allow transporting goods to occur during dark hours and the organization could also be benefited from data maximization due to longer flights. Hugely depending on the design of the drones, a night-flying feature would also require the use of infrared cameras that could, for example, help identify groups of people or individuals in an area based on their personal thermal signature or if there are the presence of campfires. The requirement for such endurance capacity as mentioned in the above points implies that the drones would need a more complex controlling system and must be able to maneuver beyond visual sight, and this requires the system to have a payload that can connect with satellite and advance network such as 5G for control purposes (Murray & Chu, 2015; Wahab & Khong, 2019). Alike, a camera with a function of infrared still and video to support the process of assessing needs whenever one arises. The extra function could also help in providing additional data for researchers. Thus, the ability to quickly and efficiently transmit the data generated from the camera and other sensors from the drone can be achieved. Undoubtedly, drones have been used in many countries to curb the COVID-19 spread. Some of the drones that are used for this purpose include multipurpose drones, thermal imaging drones, announcement drones, disinfectant drones, surveillance drones, and medical drones (Chamola, 2020).

India has developed its very own Corona Combat Drone (CCD), which is an agricultural drone that has been remodelled for sanitation (Ulmer & Thomas, 2018). This multipurpose drone is not only able to spray disinfectant but also able to do thermal imaging, carry COVID-19 test kits, make announcements on a speaker, and also has geofencing technology (Urban Air Mobility News, 2020). On the other hand, Malaysia has used drones for crowd surveillance and also to make announcements in three different languages of Malay, Chinese, and Tamil to inform the public to stay at home (Bullock, 2020). Additionally, a study on long-endurance remotely piloted aircraft systems (LE-RPAS) for the use of humanitarian response in areas affected by disasters such as earthquakes, floods, or cyclones has been implemented under the humanitarian logistics operations. There is difficulty in understanding the extent of the damage to buildings and the access routes available. This makes planning a movement for relief goods or other support extremely challenging. With the use of LE-PRAS, it will provide photographic information to the National Disaster Management Organisation (NDMO) (Tatham et al., 2017b).

Drones as a Solution for Healthcare Supply Chain

There are many uses for drones in the healthcare industry. One of the contemporary applications is as a solution to disruption of the healthcare supply chain during this COVID-19 pandemic. There are many areas in which drones have proven to improve the healthcare supply chain. Drone usage is very important and acts as a solution for the healthcare supply chain. A study by Tucker (2017) highlighted that drones are capable of delivering more effective healthcare services to patients from a distance. Drones are capable of transporting blood and other medical suppliers to patients and hospitals with less hassles. The two prominent company and institution who are actively studying the practicability of the drone application during the COVID-19 pandemic includes Zipline and DrOTS.

Zipline's medical delivery drones

Rwanda is a country in Africa with challenging terrain and poor infrastructure. A company known as Zipline has been using drones to supply blood products to over 25 hospitals and clinics across Rwanda every day. As shown in Figure 1, the technicians will store the blood in the cargo bay of the drone and run through checklists of preflight prep before the aircraft is launched. An electric catapult is used to launch the drone at a speed up to 100 kilometers per hour. These drones can make this delivery in a relatively short time. It is ideal for products that have a short shelf life and strict storage requirements. The drone cruises at an altitude of 120 meters, and they usually make around 20 to 30 trips a day (Ackerman, 2019).

Fig. 1: Drones for blood supply in Rwanda, Africa
Source (Ackerman, 2019)

Drones observed therapy system (DrOTS)

From 2016-2018, Stony Brook University (New York, USA) and the Pasteur Institute of Madagascar implemented a proof of concept (POC) for bi-directional drones to transport healthcare provisions known as Drones Observed Therapy System (DrOTS). The POC was in Malawi, Senegal, and Madagascar. The drones were able to carry sputum samples for TB & HIV, medications, blood, and injectable oxytocin for up to 120km journeys. Even though the POC used dummy samples, the POC was considered a success, and the respective countries are keen to adopt this technology. It was concluded that drones are worth future investments due to their compelling prospects (Knoblauch, 2019).

Research Objectives and Methodology

The purpose of this paper is to report on a detailed assessment of the use of drone technology in the healthcare supply chain and to develop effective mitigation strategies. Therefore, these research objectives are to analyse the issues and challenges of drone technology in the healthcare supply chain. Data collection methods include an extensive review of past literature. The literature gathered for initial data collection comes from various sources, such as JStor, Emerald, Reaxys, Scopus ScienceDirect, Online Library, and SpringerLink Journal, which fit or are linked to keywords such as Drones, Drones Technology, Healthcare, Supply Chain Disruption, COVID-19 Disruption. The review of literature generated 29 useful works of literature from journal articles, conference papers, master thesis, books, trade magazines, and newspapers. Other resources such as reliable news publications and blogs were taken to include views from industry leaders. This study was limited publications in English language. All the literature was then reviewed and categorized by inclusion or exclusion of Malaysia as the country being reviewed. All the information gathered was then used to develop the mitigation strategies in this study. The methodology that was adopted in this study is presented in Figure 2.

Fig. 2: Methodology used in this study

Issues and Challenges of Drones in the Healthcare Supply Chain

Despite many benefits drones can offer in response to health issues such as the COVID-19 pandemic, several constraints and challenges are inherent in drones implementation. The next section will further discuss the issues by dividing it into device-related and non-device-related challenges.

Device-related challenges

Vulnerability in drone operations

Exposure to hacking, such as GPS-jamming and radio control bypass has made drones an easy target and attractive prospect for hackers. Drones can be stolen, disabled, and used to carry out cyberterrorism and other illegal activities. Recently, several agencies including government-related have voiced concerns about the safety risks that drones pose (Rodday, 2016). The risks comprise system architecture and security vulnerability. In terms of system architecture, the 2.4Ghz radio frequency and telemetry (for further than 100m range) used in remote controlling drones could easily be hacked and controlled by other parties, making it very dangerous if the medical supplies failed to reach the necessary location or the supplies are of controlled pharmaceutical products. On the other hand, security vulnerability concerns on the system connectivity. Some drones have Wi-Fi connectivity, and this can pose a security threat to the devices and platforms that are connected to the network. Access points used in most drones are wired equivalent privacy (WEP) as encryption, and this technique can easily be cracked. The attacker can reach the drones' network and could control devices on the other end (Custers, 2016).

Drones technical limitations

Drones are currently facing some limitations in terms of battery life and loading capacity, which inhibit their ability to cover far and long distances and perform more than one delivery at a time. There is also concern about durability and justification for investment into the system. Most, if not all non-military drones are incapable of recognizing and avoiding other airborne objects such as other aircraft and birds (Wang & Sheu, 2019).

The need for 5G network technology

5G refers to the fifth generation of wireless communication technology that supports mobile networks through global connectivity. Among the benefits of 5G are low latency, high speed, increase in availability, wide range, and high reliability. Complementary technologies such as IoT and AI which benefited from the 5G network, could change the healthcare sector and affect many other industries that are related to it. The advancement in 5G technology, for example in China, has already proven to be beneficial in its response mechanism to the COVID-19 pandemic. The country was able to provide better assistance to the healthcare staff and frontlines with the help of a 5G network (Osman et al., 2020). In addition to that, the 5G network has been very helpful in setting up virus tracking, patient monitoring, data collection, and analysis (Govind et al., 2020).

With the use of smart wearables, drones, and mobile apps that improve the flexibility of the telemedicine market, 5G network technology is essential for the realization of such functionality. 4G networks are lacking in bandwidth and speed of data transfer, thus are unable to support high-quality, real-time long-range drone maneuvering. However, 4G LTE networks also obstruct the attachment of the Internet of Medical Things (IoMT) devices to cloud services, rendering them unreliable (ATT Business Editorial Team, 2020). 5G with its innovations such as ultra-low latency and high-speed data transfer would allow mobile networks in addressing these issues. However, as the 5G network is still in its infancy, and most countries don't have access to the technology, practitioners can only make use of the existing 4G network and bear with its limitation for now (see Figure 2).

Fig. 2: 5G epidemic monitoring platform

Source: Chamola (2020)

Lack of reliable weather data to help flight planning

One of the external factors that are crucial in drones' flight planning is the weather forecast. Weather plays important roles in determining the route, height, distance, weight, and schedule of drones' operations. Without reliable weather data, it is difficult and even dangerous, not to mention costly, to be operational. In bad weather, a drone could crash and hurt people or damage things on land, lost in flight, and effectively disrupt the supplies to vital healthcare centers (Sandvik, 2014).

Non-device-related challenges

Government regulation

In many countries, the incorporation of drones into the COVID-19 impact response system is bounded by the inconsistency of government regulatory policies (Chamola, 2020). As the pandemic shocked the world, many things are affected, and the government needs to prioritize life-affecting regulations before anything else. Thus, it is understandable that the regulations for drones are not being updated since COVID-19. However, certain policies are not clear even before the pandemic started. For example, the Federal Aviation Administration (FAA) in the US, requires commercial drones to go through the same safety and economic reviews, known as Part 135, as a 12-passenger private jet. Not only are both vehicles in a different class, but some of the requirements are also irrelevant to drones. Figure 3 details the differences between private jet and drone. In Malaysia, the Civil Aviation Authority of Malaysia (CAAM) is the national agency charged with the responsibility of managing aircraft-related matters. There are a few essential regulations required in order to operate a drone in Malaysia. One of the rules is the limitation on drone flights to daylight hours and requirements for commercial users to keep their aircraft within their visual sight (Osman et al., 2020). The limitation will hinder most drones' flight for supplies of healthcare products as the drop off locations would be further than visual distance.

Fig. 3: FAA requirements for commercial planes vs. drones

Source: Descant (2020)

Beyond Visible Line of Sight (BVLOS)

Although considerable advances in drone technology have been made recently, drone operations Beyond Visible Line of Sight (BVLOS) remain somewhat unsafe. While it's a known regulation, more importantly, it is why it is being ruled as such. There is a lack of evidence that BVLOS is as safe as manoeuvring drones within sight. Operational guidelines and technical assistance are increasingly needed to guarantee the security and safety of the operation of drones. From a practical perspective, most drones, especially non-commercial ones, are designed to be operated on a visual sightline basis (Marris, 2013). The controller must always have direct visuals of the drones and the surrounding area including the terrain and treelines in which it operates. This would mean there is a limit of 1.5 km radius between the operator and the drones, although the actual field of operating flight area can be extended by following the drones using a car or a boat while maintaining the rule of a maximum 1.5 km distance. However, some companies and organizations are lobbying the authorities for approval to undertake beyond visual line of sight where the drones pilot can rely on one or more remote observers to keep the unmanned aircraft always in sight. These observers then transmit any flight information to the controller via radio, thereby helping to maintain a safe separation from other aircraft (Tatham et al., 2017b).

Limited technical capability

From a supply chain management perspective, the drone's reliability is dependent on the availability of trained personnel who operates and maintains the drone and its system. From a more strategic perspective, in order to handle the drones efficiently and applying lean management strategy to the system, warehouses and distribution centers need to match supplies as demanded by customers (Pappot & de Boer, 2015). Given the current push-based approach to PPE campaigns with long lead times, this requires a shift in the supply chain strategy to ensure that local requirements can be met in real-time. Otherwise, this strategy will only lead to an inefficient distribution of inventories and, ultimately, defeat the propose of drones' usage in managing the supply chain in a pandemic (Comes, 2018).

Adaptability

The introduction of new logistic methods like drones will certainly require certain degrees of adaptability by the whole supply chain. A new system and requirements, either manual or automatic, needs to be created in order to adopt drones into the supply chain. Limitations of drones such as weight per trip, temperature control, and are new conditions that need to be considered in the new system (Ulmer & Thomas, 2018). There is also a concern for a new learning curve for existing workers in the supply chain, which will be a challenge, especially during a critical time where systems are required to run efficiently. The indicators for the healthcare supply chain that are using drones as their mode of logistics are like conventional logistic vehicles. However, the measurements are slightly different. Some of the indicators for the healthcare system performance include health facilities, patients reached, and health outcomes. Meanwhile, the indicators for supply chain management induces turn-around times, no of samples,

stock-outs, commodity or sample types, quantity, weight, volume/size, quality, no of successful deliveries made, and payload damage or loss (Olivares et al., 2015).

Cost

As noted by Mailey (2013), there is no standardized way of generating "cost/flight hour" or a similar metric. Nevertheless, Figure 5 shows drones' technical specifications and their cost to allow a better perspective on the feasibility of adopting a drone system. Evidently, the financial benefits of utilizing drones to serve healthcare supply chain needs can only be seen when the system runs at maximum capacity and the marginal cost of each flight would be reduced to a minimum. In order to reduce costs and increase efficiency, companies could outsource a drone service provider, or, a group of agencies within a regional interagency network could share the cost to develop their own system and use it alternately. A collaboration would help minimize risk and help to ensure a shared return for all the parties involved in their investments (Tatham et al., 2017a).

NAME Manufacturer	Global Hawk Northrop Grumman	ScanEagle Insitu	Lancaster Hawkeye PrecisionHawk	Phantom Vision 2+ DJI
PRIMARY USE	Military intelligence	Surveillance	Agriculture	Photography
SIZE	47.6 feet long by 130.9-foot wingspan	5.6 x 10.2 ft. wingspan	4 x 4 ft. wingspan	0.95 x 0.95 ft. quadcopter
WEIGHT	32,250 lb.	48.5 lb.	3 lb.	2.8 lb.
ENDURANCE	28 hours	24 hours	45 min	25 min
SPEED	357 mph	57 to 69 mph	25 mph	25 mph
OPERATING ALTITUDE	60,000 ft.	19,500 ft.	400 ft.	Less than 400 ft.

Drones Issues and its Impact on Healthcare Supply Chain

Challenges faced in onboarding drones as part of the healthcare supply chain would be crucial to be addressed as the dominos' effect could further cause disruption in the whole chain, especially the end-users. Some of the prominent challenges include supplier disruption. Having supply disruption would be counter-productive in adopting drones for healthcare supply chains. Supplies could be interrupted due to poor supplies flow, inefficient route planning, weather-caused rescheduling, drones' breakdown, and bottleneck from untrained personnel in adopting the new system (Liu et al., 2018). Furthermore, the patient backlog is another challenge faced by the industry. The end-users, like hospitals and clinics, would probably need less adoption of change with the use of drones in the healthcare supply chain but will be majorly affected if things do not go as planned. Medical personnel cannot perform efficiently if there is a bottleneck in the supply chain. Ineffective usage of drones to send specimens such as COVID-19 throat swabs to the central laboratory could potentially cause late diagnosis and eventually causing a higher spread of disease where it should be contained (Knoblauch et al., 2019). In addition, unavailability of drones to assist in supporting the delivery of healthcare supplies, logistic workers are required to have a higher frequency of close contact with high-risk groups like healthcare workers which might expose logistic workers to greater risk (Graham, 2016). Undoubtedly, the inefficiency of the supply chain cannot be achieved without a drone application. The routes planning, inventory, and order would need more real-time collaborations. While this allows for better efficiency, it could also cause more delays if there is even a part of the system that is not adopting and onboarding effectively. Wastage in terms of higher waiting time, over or under orders, and extra processing could reflect drones' adoption as just a fancy gimmick (Nier et al., 2020; Giones & Brem, 2017). However, the cost is always the main issue for the organization to adopt drone technology. Including drones as part of the healthcare supply chain is already going to cost a lot of money. Without effective and efficient adoption of it, there will be not only a higher monetary cost but also related costs such as higher mortality and morbidity of patients (Rajendran et

al., 2018). As highlighted by Tariq (2019), it is time for Malaysia to update the drone laws and provide more trainings to ensure the personnel are upto date in drone management.

Recommendations

There are certain aspects of the Malaysian healthcare supply chain that could benefit from the adoption of drones. There are certain rural areas, especially in places with no good access roads. This study found that drones could be used to complement the supply chain of these areas in tackling COVID-19 more efficiently. Firstly, a nationwide 5G network would be an ideal environment for the movement of drones around the country. According to Malaysia's former Prime Minister, the country will commercially launch 5G technology by the third quarter of 2020. If Malaysia can fast track that technology, it would greatly benefit the healthcare sector. For instance, Telekom Malaysia is developing Langkawi Island as the first 5G standalone network in Malaysia. The pilot project or proof of concept for our drone technology could be used in Langkawi Island to interlink the Langkawi Hospital and its surrounding clinics. Pilot projects are ideal in a smaller region or smaller sample size as there will be problems anticipated, and they can be rectified before nationwide implementation.

Furthermore, it is important to improve the legislation for drones that operate in healthcare services. Two policies that have heavily affected the drones' operations, particularly in healthcare services are daylight hours flight and beyond visible line of sight (VLOS). Currently, drones are only allowed to fly during daylight with visible sight, where medical supports are not bounded by time or location, and services are always required to be operational. Most importantly, to reach further from visible sight (~1.5km). While it is understood that this legislation is implemented for safety reasons, more research should be done to ensure that the limitations are not bounded by unempirical reasons. The potentials are huge for drones' adoption in the healthcare supply chain, especially in disrupted conventional healthcare supply chain events like COVID-19.

Meanwhile, the government should expedite the accreditation of certifications offered by educational institutions for commercial drone operation. While there are a few academics and institutions like Drone Academy Asia, Aviation Management College, Asia Drone and IoT technology that offer programs like Certified Drone Operation Proficient, Certified Drone Aerial Mapping And Surveying Proficient, Certified Drone Inspection Proficient, Certified Drone Maintenance And Repair Proficient, none of the courses are accredited by Malaysian Qualification Agency (MQA) while at the same time, are being accredited by international bodies. Accreditation is the rank or recognition of an MQA standard assessment. It also offers a framework for certain actors to accept the system for several reasons. For example, this accreditation status will be used by the Public Service Department (PSD) to recognize qualifications for public service employment. Academic bodies can use the accreditation of accredited graduates for registration as academic engineers.

On the other hand, the cost could probably be one of the biggest reasons that hinder organizations from considering drones in their supply chain line up. Thus, collaboration with NGOs and businesses to share the cost of drone usage in the healthcare supply chain is essential. Other than the new learning curve and creation of new SOPs and regulations in their existing system, the cost would only add up to more hesitations. Drones are very likely to change the landscape of the supply chain, including in the healthcare sector and investment made today will pay off in the future when the system stabilizes, and cost/benefit reduces as supplies sliding from conventional ways to drones. A small and medium organization should start collaborating and sharing the cost of implementation as part of their value supply chain. Operating drones involves multiple aspects such as pilots, maintenance, insurance, system development, and others not to mention the cost of owning the drones themselves. By sharing the cost or creative collaboration, more organizations can reap the benefits of integrating drones into their supply chain ecosystem.

In the current situation, there is a nationwide lack of PPE supply due to the increased usage and requirement in hospitals and clinics. There have been donations of PPE from NGO's that are being consolidated by organizations such as myPPEhub. Currently, the donated PPE is being manually transported to hospitals or clinics that are in dire need. A collaboration with myPPEhub in the distribution of PPE would make the supply more efficient. Drones could be deployed immediately after a PPE is collected and transported to facilities within a 100km radius. There are very strict guidelines according to the World Health Organization (WHO) on the collection, storage, packaging, and transport of COVID-19 swab specimens. These guidelines are in place to protect the specimens and the staff handling them. Specimens that can be delivered promptly to the laboratory can be stored and shipped at 2-8°C. When there is a tendency for the specimens to be a delay in reaching the laboratory, it is strongly recommended to use the viral transport medium. Whereas specimens may be frozen to - 20°C or ideally -70°C and shipped on dry ice if more time is required to reach the laboratory (WHO, 2020). Drones would be a much safer option in the transportation of specimens to laboratories. This could be proposed to the Ministry of Health or private clinics with a large sample size.

Conclusion

While the world is experiencing sudden and devastating changes from the COVID-19 pandemic, the emergence of various technologies, such as drones and 5G, are facilitating the impact mitigation effort. Keeping that as the foundation of this work, this study offered some of the latest insights into the COVID-19 pandemic and how the use of drones can help to minimize disruptions in the healthcare supply chain. This paper started with a general review of drones and their recent application in the healthcare and health supply chain. In order to relate to the impact of COVID-19, this study also dived into the functionality of drones in the previous pandemic crisis and the implementation challenges. This study identified drone technology interventions in the direction of COVID-19 impact management in the healthcare supply chain. From the intensive literature review and field observation, it is believed that the 5G network shall equip drones to offer higher versatility in functions and bigger areas of services. Regulations on drones are also encouraged to be revised based on the latest development in the industry. To ensure enough manpower in drone operation, education institutions should strive to get accreditation for their certifications. While it is noted that a few challenges are limiting the rapid adoption of drone technology, the immense potential that it holds in regard to supporting the healthcare supply chain cannot be overlooked. Government bodies and authorities should lead the collection and data assessment in local drones projects and invest more in drones research and development as the trend and adoption of this vehicle into the healthcare industry will only go one way up. Being among a few studies to investigate drone technology application in the Malaysian healthcare supply chain, the main limitation of this study is the extremely subjective nature of the findings. The emphasized issues, challenges, and mitigation strategies were based on literature search and current drone practice observation in the healthcare industry. Hence, future research should adopt a quantitative research approach. This would generate more more substantiated and significant outcomes. Furthermore, as the healthcare supply chain industry continuously advances, the proposition from this study particularly on the mitigation strategies should be considered as a guideline with emphasis on the continuous evolution of the industry in the future. Thus, future research should focus on empirical and structured studies. It is also suggested that future studies may engage focus groups to achieve more valuable insights towards the overall drone technology application in the healthcare industry particularly in Malaysia and other countries in general.

Abstract

The article examines the problem of integration of theatrical and museum techniques in the museum space, reveals the directions of staging in museums, gives examples of staging in the cultural and educational activities of museums.

Keywords: Museum, Staging, Theater in A Museum, Cultural and Educational Activities of A Museum.

Introduction

Staging is more often used in the practice of a modern museumwhich expands museum activities, emphasizes the readiness of museums to put new activities into practice and gain new experience. Staging in a museum is a kind of communication according to the laws of drama, when a certain interpretation of a museum object takes place in an exposition, museum program, event for visitors with the use of theater language and attributes (script, stage direction, roles, etc.). The issue of staging in a museum is studied by E.L. Krasnova, V.S. Maleev, A.L. Timofeeva, I.A. Shchepetkova and others.

The process of "staging in a museum" began in the 70s of the 20th century which was caused by a new communicative concept of museums. Today the process of staging occurs in a new format. According to V.S. Maleev (2018), there are two reasons for this – the need to preserve the intangible cultural heritage and the perception of the museum as a place not only for gaining knowledge, but also for leisure and getting new emotions and impressions. This can be achieved through staging, the use of the laws of drama.

I.A. Shchepetkova (2006) believes that staging in the museum has three directions:

1. Plot construction of the exposition, i.e. "staging of museum expositions (historical events, scientific discoveries, biographies of famous people, plots and heroes of mythology, etc.).
2. The use of sounds, music, tactile effects, game elements, etc. in the exhibition to enhance the influence on memory, perception, imagination, impression, to activate entertainment and create new opportunities for cognitive and entertaining work with visitors.
3. Presentation of museum and theatrical performances, art actions, immersive performances. They can be independent or part of another event (opening of an exhibition, anniversary of a poet or composer, City Day celebration, etc.).

According to M.V. Korotkova (2018), the use of staging in the museumrequires the fulfillment of a number of conditions: compliance with the main direction of the museum and the theme of the exposition; the use of the most striking, characteristic of the given era real exhibits in staging; organic integration of theatrical elements into the usual rhythm of life of the exposition, as well as the solution to personnel and financial problems, etc.

The purpose of our research was to study the experience of staging in the museum as part of its cultural and educational activities while working with visitors.

Results

The year of 2019 was declared the Year of Theater in Russia.As a result, a special attention was paid to this issue. The Theater Institute and the V. Potanin Charitable Foundation held the THEATRUM 2019 festival. One of the goals of the festival was to update and draw attention to stage practices in the museum. The festival program included such museum and theater projects as “UralmashGO!” (the Museum of the History of Ekaterinburg), “Uprising” (the Tomsk Regional Museum of Local History named after M.B. Shatilov and the Tomsk Regional Theater for Young Spectators), etc. So, the performance “UralmashGO” is based on the interview with workersfrom the largest plant in the Urals made by employees of the Museum of the History of Ekaterinburg. In the play, personal memories are intertwined with the history of the plant and the city.

A large project “Museum + Theater” is being implemented at the Anna Akhmatova Museum, where visitors can see small performances about the personality and work of Anna Akhmatova and other famous literary figures of the 20th century, as well as performances for the whole family based on the works of world children’s classics in whichnot only actors but also the audience take part. Bright puppets, shadow theater techniques, animation and light effects are used in staging. The performances of the project are laureates of numerous festivals. In addition, the museum has been hosting the Golden Chain theater festival since 2013. There is similar experience in many other literary museums where theater is a way to get closer to the writer and his characters.

The performance-excursion "Don Stefano" about the sculptor Stepan Erzia (Nefedov) (play by S. Senichev) is another example of successful cooperation of a museum with professional actors. The performance-excursion was presented by a group of young actors from the studio theater in the exhibition hall of the Mordovian Republican Museum of Fine Artsnamed after Erzia where the sculptures of the great master areexhibited. According to the creators of the project, this kind of performance will increase the audience’s interest in the artist and his works, as well as in the museum exhibitions.

Such public holidays as Christmas, Maslenitsa, Easter, Low Sunday, Trinitycan become a subject for staging in the museum. Museum visitors get acquainted with the holidays through the folk theater where traditions, rituals and things associated with them come to life. During the presentation, visitors get involved in the action, play, sing, craft, etc. For example, the Museum of the History of Yoshkar-Ola and the folk association “Tsarev Gorod” have been implementing the project of the children’s folklore studio “Teremok” for children over 1 year old for many years. It is based on a folk game as a unique means for communication with children. The program of classes also includes folk theater (folklore scenes, fairy tales). The same team have staged the play “It was in Petrovka”. The performance is based on folklore and ethnographic material.

Theatrical excursions have become more popular with the audience. At the Serpukhov Museum, employees conduct a theatrical excursion “Alive Pictures”, during which the heroes of the pictures give monologues, communicate with each other and with the audience. The “alive picture” based on the work by K.E. Makovsky “Down the aisle” can be a good example of it. It recreates the everyday life of boyars, introduces old-time folklore. “Alive pictures”are bright decoration of festive events and actions, such as Night at the Museum, Night of the Arts, etc. Moreover, depending on the theme of the event, various works of art are taken as the basis for staging. The second example from the practice of this museum is a walking city tour “Along Kaluzhskaya Street”. The excursion is conducted by several museum specialists, each of whom appears to the audience as a historical person who once lived in the city.

Theatrical excursions are held at the National Museum of the Republic of Mari El named after T. Evseev. On New Year and Christmas holidays, the excursion “Merry holiday Shorykyol” is conducted about the halls of the museum by fairy tale characters and accompanied by competitions, games, dances.“Traditional culture of the Mari people of the late XIX - early XX century”is a theatrical excursion with folk games, fortune telling, a master class in folk dances, etc. The museum program “Grandmother’s Chest” is also held with the participation of the actorsfrom the Mari National Drama Theater named after M. Shketan.

Museums also use shadow theater in the work with the audience that provides many opportunities for cultural, educational and recreational activities of the museum – interactivity, dynamics, entertainment, magic, immersion in the plot, perception of a museum object and immersion in history. Shadow theater is not widely used in the practice of museums and is more often targetedat a children’s audience as part of an excursion program or workshop in a museum, let us consider some examples.

An interactive tour “Shadow Theater” of the exposition “Theatrical life of Simbirsk-Ulyanovsk” for children in the Museum House-Studio of the Architect F.O. Livchak immerses the child in the magical world of theater, talks about the types of theater art and museum objects associated with it: ballet shoes, wigs, costumes, theater binoculars, posters and performance programs, portraits of actors and actresses. At the end of the excursion, children and adults take part in the theatrical shadow action, they make figures and decorations for the performance and move them according to the script of the play “Kolobok”.

The Museum of the Silver Age, a branch of the State Museum of the History of the Russian Literature named after V.I. Dahl, held a guided tour of the exhibition “Moomins: From Hat to Tip of Tail” based on the books by the

Finnish writer Tove Janssonas part of The Night of the Arts event. During the excursion, children from 5 to 9 years old and their parents visited a lighthouse on a desert island, measured the length of the Moomin's tail, guessed the heroes from the books, read their favorite books and then took partin a shadow theater. Figures of familiar heroes appeared on a white screen in the light of a lantern. Children took part in making the performance - they inventeda story, made figures of characters, brought them to life and showed the performance. The script was based on a story about Moomin and his friends.

During the research, we set an additional task – to develop a scheme for conducting a workshop for museum visitors, with the code name "Bright Shadows". The purpose of the workshop is not only to teach the technologies of shadow theater, but also to connect the storyline of the performance with the museum collection through the museum objects, pieces, museum environment. We believe that workshops and shadow theater can become the initial form of introducing shadow theater technologies into the practice of museums.

In conclusion, it is necessary to note that museums are introducing staging into their activities very successfully, striving to enhance the semantic and emotional impact on visitors, first of all, this concerns the cultural and educational activities of the museum. The museums hold independent theatrical performances, more often in cooperation with the theaters of the region, theatrical excursions and programs, puppet theater performances, shadow theater, folk holidays and events, museum classes and many other events which are popular with visitors, where staging acts as an element, component, tool, means. Thus, staging performs the functions of communication, education, upbringing. However, there are still issues related to the identification and description of successful experience, development of methodological foundations of staging in the museum space.

Exploring the Mediating Effects of Inspirational Motivation And Intellectual Stimulation on Creativity: A Case Study of Romanian Employees

Cristian – Liviu VELE

Technical University of Cluj Napoca,
North University Center in Baia Mare, Romania
Department of Economics
cristian.liviu.vele@gmail.com

Abstract

This article focuses on the implications that two dimensions of transformational leadership, more specifically inspirational motivation and intellectual stimulation, have on employee creativity in the context of the present global pandemic. These two variables were selected due to their direct influence in employee motivation and active implication in organizational long-term sustainability. We consider that the effects of the pandemic and the necessity to work from home in the case of a large number of employees have led to problems regarding adaptability and work efficiency, and for these reasons the study wishes to provide a better understanding of employee behavior and of what it takes to support individuals in terms of creativity and innovation. For this article, a quantitative research was conducted using a questionnaire based on the Multifactor Leadership Questionnaire (MLQ) which was applied to employees that work in companies located in the northern part of Romania. The answers of 60 respondents were analyzed and the findings led to the conclusion that inspirational motivation and intellectual motivation are strong influencers of employee creativity. At the same time we noticed that creativity is necessary in the majority of respondents and as a consequence they consider their work as productive for the organization.

Keywords: Transformational Leadership, Employee Creativity.

Introduction and literature Review

Creativity is seen as an ability to produce innovative solutions to organizational problems. Thus, creativity is a key factor in increasing organizational performance by using humans' cognitive abilities to solve problems. At the same time creativity is used as a basis for creating successful new business models based on innovation (Huang, Krasikova & Liu, 2016; Kark, Van Dijk, & Vashdi, 2018). There are different models and views regarding what it takes to support and lead creativity within organizations (Mumford, Scott, Gaddis, & Strange, 2002; Shalley & Gilson, 2004; Shalley, Zhou, & Oldham, 2004), one of the most used frameworks for supporting creative thoughts consist of eight core processing activities (Mumford *et al.,* 1991): problem definition, information gathering, concept selection, conceptual combination, idea generation, idea evaluation, implementation planning and monitoring. Given the fact that creativity is aimed at solving organizational problems in an innovative manner with the purpose of increasing performance we must ask ourselves how can organizations support employee creativity and increase the success off creative thinking and creative outcomes.

Studies have shown that transformational leadership can foster employee creativity (Amabile, 1988; Hughes et al., 2018; Koh, Lee, & Joshi, 2019), by motivating, inspiring and supporting employees in order to increase their participation in creative behavior. Transformational leadership can also be used to ensure the success of organizational change when adopting a climate designed at supporting innovation. Transformational leadership supports creativity and innovation by modeling the way in which people behave, by inspiring a shared vision and challenging the traditional processes of conducting different activities and by enabling others to take action in following their ideas. The main goal of transformational leadership is to build a vision for the future and to provide the appropriate model of behavior by setting high performance expectation and providing support for individuals in order to reach the expected performance and also by ensuring intellectual stimulation which is imperative in developing creativity (Avolio *et al.*, 1999; Gong et al., 2009; X. H. Wang, Kim, & Lee, 2016). In an organization in which transformational leadership is efficient the employees will put the needs of the organization before their personal needs (Gumusluoglu & Islev, 2009; Bass, 1996).

Cite this Article as: Cristian – Liviu VELE "Exploring the Mediating Effects of Inspirational Motivation and Intellectual Stimulation on Creativity: A Case Study of Romanian Employees" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Transformational leadership consists of four dimensions aimed at fostering employee creativity. These dimensions are (Avolio & Bass, 1985): idealized influence, individual consideration, inspirational motivation and intellectual stimulation. Through idealized influence a leader works on encouraging employees to invest their efforts in achieving the organization's mission. Individual consideration is focused on increasing the degree of communication between the leader and the employees, thus trying to best understand the individual needs of every employees. By using inspirational motivation a leader creates a shared vision for the organization and effectively communicates that vision to everyone in order to make sure that individuals invest their efforts, knowledge and abilities in reaching the vision. And finally, through intellectual stimulation a leader works on developing and encouraging critical thinking. As said before, creativity is aimed at finding novel innovative solutions to organizational problems. For this to happen within organizations leaders need to inspire individuals to think outside the box and to constantly stimulate them intellectually in order to ensure the development of innovative solutions.

The recent transformations that have occurred worldwide, during the present pandemic, have made creativity crucial for organizations, in order to grow and develop sustainable competitive advantages. Thus, factors that influence employee creativity such as in their motivation, personal control and uncertainty avoidance orientation (Shafi et al., 2020; Tse et al., 2018; Wang, 2020) need to be taken into consideration by leaders. At the same time, leaders need to be aware of the fact that having employees that are learning goal orientation is an important factor that influences creativity within the organization (Bakker *et. al*, 2020; Huang & Luthans, 2015). Learning goal orientated employees focus their efforts into constantly enhancing their own competencies and on developing new abilities and skills that can be put in the service of the organization in which they work. They tried to gain as much knowledge as they can and also share that knowledge with the intent of overcoming challenges and achieving their goals and those of the organization through creativity and innovation (Huang & Luthans, 2015).

Studies have shown that organizations which fail to develop a working environment based on creativity and innovation do not obtain high levels of productivity and sustainability due to the fact that these organizations are not able to adapt fast enough to changes in the business environment (Pitta, 2009). For this reason organizations need to promote an environment which positively influences both creativity and innovation (Cummings and Oldham, 1997; Oldham and Cummings, 1996; Krause (2004) , evidence suggesting that an organizational climate that supports creativity is an important contributor to individual and team creativity (Hunter et al. ,2007; Hsu and Fan, 2010; Gumusluoglu and Ilsev, 2009).

Therefore, the present study takes into consideration two of the dimensions of transformational leadership namely inspirational motivation and intellectual stimulation as influencers of employee creativity based on the fact that the present pandemic has forced organizations to adapt into allowing their employees to work from home and to give them an increase degree of freedom and responsibility.

Motivation is a crucial element in any model regarding human performance and a key factor for ensuring a business's long term development and sustainability (Pinder, 2014). Having a large percent of employees working from home has lead to new problems. For organizations the necessity of ensuring proper motivation has increased, in order to ensure active participation of employees in achieving organizational goals. In this context we consider inspirational motivation as being extremely important in ensuring superior level of motivation within the working force of an organization and also in creating an environment that encourages creativity and innovation.

At the same time we need to take into consideration the fact that creativity cannot be obtained in the lack of intellectual stimulation of those responsible for obtaining creative results and innovation. Through intellectual stimulation leaders encourage their followers to think in new ways and to develop their problem solving skills and the use of reasoning before taking a decision or an action. In addition, followers are encouraged not to accept the current situation and to question everything specially old assumptions, to reformulates problems and to unleash their imagination with the intent of finding new creative ways of doing things or solving problems (Bass, 1985; Hater & Bass, 1988; Kark & Van Dijk, 2003).

Methodology and Research

The present research focuses on the correlations between two dimensions of transformational leadership, namely *inspirational motivation* and *intellectual stimulation*, and employee creativity in the context of a pandemic situation that forced a large number of employees worldwide to work exclusively from home. The data was gathered using a multi-item scale questionnaire, based on the Multifactor Leadership Questionnaire (MLQ) (Avolio & Balls, 2005) and on the Kumar and Holman (1997) Creativity Styles Questionnaire. All items were measured on a five point Likert-type scale where (0) strongly disagree to (4) strongly agree.

The variables defined in our study are measured by three individual factors, using a number of three question for each factor regarding transformational leadership and four questions regarding creativity. The answers were loaded as a sum of responses into the variables, which were then processed using IBM SPSS 20. For the purpose of this research, we chose to use only the items regarding inspirational motivation and intellectual stimulation from the MLQ. A total of 60 valid questionnaires were gathered form the subjects that took part in our study. The participants in our study are working in companies located in the northern part of Romania, in fields such as sales, logistics, production or marketing, occupying both operational positions and also management positions.

In order to achieve the main objective of the research, namely a better understanding and explanation of the correlations between inspirational motivation and intellectual stimulation and employee creativity, a series of questions were asked to which we tried to provide with appropriate answers.

Q1: Does inspirational motivation has a positive influence on employee creativity?

Q2: Does intellectual stimulation has a positive influence on employee creativity?

To answer the above questions, first an analyze of the internal consistency of the scale used in the research questionnaire was performed, using a Cronbach's Alpha reliability test, and the results obtained let us to conclude that the internal consistency is good and we can proceed with analyzing the correlations between the defined variables within our study. As it can be seen below all the answers given in our study were taken into consideration.

Table 1: Cronbach Alpha coefficient

Findings

Of the participants in our study 75% are female and 25% are male with the majority of them being situated in the 20 to 30 years of age interval (56.7%). 30% of the participants have declared that the complexity of their work has increased during the time of the pandemic, while 56.7% have stated that the complexity of the work has remained the same, only 13.3% have declared that the complexity of their work has decreased as a result of the pandemic.
51.7% of the respondents have declared that they need to use their creativity on a daily basis (16.7% - frequently and 35% - fairly often), 33.3% of the respondents declared that they only need to use their creativity sometimes in their work, and only 3.3% of the respondents said that they never use creativity in their daily work.

The means of the two variable that were considered in our study as influencers of employee creativity have values below 9 while creativity has a mean value of almost 10. These values may lead us to the conclusion that inspiration motivation and intellectual stimulation may not influence creativity as much as we thought, further analysis needed to be conducted. Median values in inspirational motivation (9.00) intellectual stimulation (8.00) are relatively high meaning that the participants in our study are actively contributing to the formation of vision within the organization and share that vision to other members and at the same time try to convince others too think outside the box and stimulate them at an intellectual level. We can see that the median value of creativity is also relatively high (10.50), meaning that employees our creative in their daily work and need to use their creativity in solving different problems.

We can see some differences in the mode of the data set, the value that appears most often, in relation with the median values of the variables, which may suggest that there are some major differences in the answers that were provided in the research and furthermore, if we take into consideration also the values of the variances, especially in the case of creativity we can see that there are certain areas of expertise in which creativity is required and perhaps even a necessity while there are other fields in which creativity is not a requirement and individuals do not necessarily have to be creative.

(Source: own processing in SPSS)

As it can be seen above the value of the significance coefficient allows us to conclude that that the variables defined in our study have a positive influence on employee creativity and if you take into consideration the value of the Persons linear correlation coefficient we can see that inspirational motivation is a strong predictor of employee creativity (0.516) and also intellectual stimulation strongly influences employee creativity (0.514). Through inspirational motivation an environment characterized by high expectations within the organization is created, environment that has at its core a shared vision and every member of the organization is inspired to meet the high expectations set by that vision. It is extremely important for leaders and also for employees to clearly illustrate the future vision, to strengthen their commitment and encourage everyone to overcome any problem into achieving that vision.

The positive correlation between inspirational motivation and intellectual stimulation can also be noticed in the figures below, which show the link between the two independent variables and creativity, as the dependent variable of the study.

Intellectual stimulation comes and supports inspirational motivation by encouraging individuals to look at problems from different angles and the question traditional assumptions and traditional approaches to problem solving. By doing this, employees are somehow ignoring the traditional ways of doing things around the organization and focus on an innovative manner to identifying and implementing solutions to everyday problems.

Conclusion and Discussion

Creativity and innovation have become increasingly important especially in these times of global pandemic where organizations have been put into the situation in which their employees had to work from home. Even more, changes in the global business environment have led to new problems especially related to logistics production and sales problems that forced organizations to become more flexible and to adapt to these new changes. In this context, encouraging and supporting employee creativity has become paramount in assuring organizational survival and sustainable development.

We focused on this study exclusively on 2 dimensions of transformational leadership namely inspirational motivation and intellectual stimulation as predictors of employee creativity in the context of a global pandemic. We consider these two factors as extremely important in ensuring a high level of intrinsic motivation for individuals, which is necessary in order to keep them working towards meeting the organizational goals in times of great insecurity. At the same time intellectual stimulation plays a defining role in supporting employee adaptability to the new working context and in increasing the level of work productivity.

The respondents in our study work in companies located in the northern part of Romania and the statistical analysis of their responses revealed relatively high scores both in inspirational motivation and intellectual stimulation. Also, relatively strong correlations were obtained between these two independent variables and employee creativity, suggesting that organizations characterized by an environment in which a shared vision is promoted and individuals are intellectually stimulated also have the most creative employees.

The findings of this study provide a better understanding of the necessary actions needed to be taken by organizations in order to encourage and foster employee creativity, with the intent of obtaining superior performance and long term development. The fact that creativity is strongly influenced by inspirational motivation and intellectual stimulation provides organizations that have employees working from home with the necessary instruments for better motivate individuals and to actively implicate them in the overall organizational success.

Of course, the present research has certain limitations, due to the fact that it would be advisable to extend the range of the study and to include a higher statistical population. At the same time , it would be useful to extend the study on a longer period of time in order to better understand the effects of the global pandemic on the activity of the organizations and on the work of its members and to better identify what it takes to increase the degree of adaptability.

Abstract

We examine how the randomness of behavior and the flow of information between agents affect the formation of opinions. Our main research involves the process of opinion evolution, opinion clusters formation and studying the probability of sustaining opinion. The results show that opinion formation (clustering of opinion) is influenced by both flow of information between agents (interactions outside the closest neighbors) and randomness in adopting opinions.

Keywords: Opinion Dynamics, Social Modelling, Organization, Social Complex System, Agent-Based Model,

Introduction

Understanding what factors influence the formation of opinion in society is very important for many aspects of an organization's activities, including organizational behavior, organizational knowledge transfer, leadership and many more. The basis of the proposed approach in this paper is to look at the organization as a complex social system. This direction of research is more and more often seen as an important element of management science (Kowalska-Styczeń, 2018). To explain the specifications of social systems (including organization) such as self-organization, order, chaos, complexity, the evolution of mathematical theories must be extended (Ehsani et al., 2010). Such an extension of the theory is the usage of computer modeling, simulation, in particular agent-based modeling (Kowalska-Styczeń, 2020). As emphasized by Acemoglu and Ozdaglar (2011), we acquire our beliefs and opinions through various types of experiences, in particular through the process of 'social learning'. As part of this process, people communicate with other people, they obtain information and they update their beliefs and opinions. The communication takes place with a subgroup of society consisting of friends, colleagues and peers, co-workers and distant and close family members. Information obtained by a person from a particular partner on a social network is transferred to other members of that network. Depending on the communication (information flow) in the social network, this information transfer may have a smaller or larger reach, the information may amount to more or less people. It should also be noted that in the formation of opinions, we often deal with unpredictability, as well as with irrational processing of information (Sobkowicz, 2018; Stadelmann and Torgler, 2013).

The purpose of this article is to study the formation of clusters of opinions (i.e. groups of people with the same opinion). In a social network, individual opinions and interpersonal relationships always interact and evolve, leading to self-organization of clusters of opinions across the network (Zhang et al., 2013). Because it is very difficult to study social systems in terms of their complexity, researchers increasingly use computer simulations. Therefore, in this article, we propose simulations carried out for a model based on Latané (1981) theory of social impact, which takes into account both the different flow of information between community members and the randomness of their behavior (noise). The basic assumption of Latané's social impact theory is that people are members of a community and within that community they interact with each other. Social influence are all interactions between people (persuasion, joke, showing emotions, feelings, etc.). The theory of social influence is based on three principles: social power, psychosocial law, and multiplication or division.

Model Description

The computer model used here has been formally described in the work by Bańcerowski and Malarz (2019). The model was also tested by Kowalska-Styczeń and Malarz (2020) for two and three opinions available in the system and initially randomly distributed among agents. The formation of opinions in the community as a result of the flow of information and randomness of agents behavior was investigated, and several phases in the behavior of the system (community) due to these parameters were detected. In this paper, we focused on the relationship between the spatial distribution of opinions and the probability of sustaining opinion by agents in opinion clusters.
It should be noted that, the essence of social influence is not only exerting social influence, but also succumbing to it. In the used model, this fact was taken into account by introducing the following parameters: intensity of persuasion and intensity of support. These parameters determine the effectiveness of which an individual may interact with or influence other individuals by changing or confirming their opinions. These parameters are interpreted as follows:

- **intensity of persuasion**: the larger $0 \leq p_i \leq 1$ the agent is more convincing agents with other opinions from his neighborhood to accept his/her opinion,
- **intensity of support**: the larger $0 \leq s_i \leq 1$ the agent convinces more strongly with other agents from his neighborhood, so that they do not change their opinion if this opinion is identical with the opinion of agent i.

In the simulations presented in the next section, random values of p_i and s_i for each agent were assumed.
As in previous works, we take into account two parameters of the model: information flow in the community and random behavior (noise). The varied flow of information in the community was expressed in the model using the parameter α (this parameter talks about the influence of close and distant neighbors in the community). Small values (e.g. $\alpha = 1$ or 2) mean good communication between agents and good access to information (an exchange of information with a large number of agents in the network takes place). The larger values of α, the weaker the communication between the groups of agents (the exchange of information takes place only in the closest neighborhood, e.g. $\alpha = 6$).

The randomness of agents' behavior is expressed by the parameter T (social temperature). If T = 0, then a lack of randomness is observed, and the agent adopts an opinion that has the most influence on him/her. As T increases, more and more often opinions that do not have the greatest impact on agents are chosen.

To sum up, in the used computer model:

- The society is represented by agents occupying the nodes of the square lattice. Each network node corresponds to one person.
- Every agent i has one among K available opinions and, moreover, it is characterized by two parameters: intensity of persuasion (p_i) and intensity of support (s_i). We assume random values of these parameters for all agents.
- Each agent is influenced by all other agents. The strength of this influence decreases with increasing distance between them. Additionally, in order to reduce the impact of distant neighbors, the parameter α was introduced, which appears as a constant in the distance scaling function.
- The randomness of human behavior is reflected by T parameter, which characterize the entire system.

The simulations are carried out on square lattice of linear size L = 41 with open boundary conditions.

Results

Spatial distribution of opinions. Let us start presentation of the results by showing the spatial distribution of opinions for K = 2 (two possible opinion), for α = 2, 3, 6 (various levels of flow of information) and for T = 0, 1, 3, 5 (various levels of noise, i.e. various levels of randomness in the opinion adopting). As can be seen in Figure 1, both α and social temperature T have influence on opinion formation and polarization in the groups (self-organization of opinion clusters).

Fig. 1: Spatial distribution of opinions for K = 2 opinions for various α and various social temperatures (T) after t = 100 time steps of the system evolution (red and green mean different opinions)

For α = 2 (and α = 1) the consensus takes place (all agents accept one of two opinions), except of single cases for large T values. The higher α, the less interactions unit has outside the closest neighbors group, which leads to lower polarization of opinions (there are more and more clusters, i.e. groups of agents with the same opinions). In addition, small clusters are able to survive, although they are surrounded by large clusters of agents with different opinion. An analogous situation occurs when the T parameter is increased. With larger T , there is more heterogeneity in the areas where actors with opposite opinions occur and the division into clusters is less pronounced (less polarization of opinions in the groups). An increase of the social temperature T often results in the emergence of small clusters of agents with a minority of opinion. In general, the increase of T and causes that more clusters are formed, and the polarization of opinions in groups is weaker.

Fig. 2: Spatial distribution of probabilities of sustaining opinion for K = 2 opinions, social temperature T and for various values of after t = 100 time steps of the system evolution.

Probability of sustaining opinion. For Figure 1 discussed in the previous Section, corresponding heat-maps have been created (see Figure 2). Each agent is assigned to one point in the network with a certain color. This color depends on the probability that agent will sustain his/her opinion. The colors change from yellow (high probability of sustaining opinion) to black (low probability of sustaining opinion). We do not show heat-maps for T = 0, because the probability of sustaining the opinion has then only two values: either 0—the agent will change his/her opinions or 1—the agent will sustain his/her opinion. The smallest probability of sustaining the opinion occurs for agents on the outskirts of clusters—compare Figure 2 to Figure 1. In addition, this probability is higher in large clusters than in small ones. This likelihood also decreases with the increase of T (more and more darker colors in the agents' network). This probability is of course affected by T and α. The higher T , the less probability of sustaining the opinion (less yellow), which is especially visible for α = 6 in the Figure 2i and Figure 2l. The chances of sustaining the current opinion of agents also decrease with the rise of α (there is more and more darker color). To sum up, the greater the randomness of behavior and the smaller the flow of information (i.e. greater α), the less yellow color in the heat-maps is observed (a lower probability of sustaining opinion in the entire lattice of agents), which is particularly evident in Figure 2i (T = 3) and Figures 2k and 2l (T = 5).

Clustering of opinions. Analyzing the results in the previous Section, the clustering of opinions is influenced by both the level of randomness in agents' decisions (T) and the influence coming from close or distant neighbors (α). For clusters detection, the Hoshen and Kopelman (1976) algorithm has been applied. In Hoshen–Kopelman algorithm each agent is labelled in such way, that agent with the same opinions and in the same cluster have identical labels. The algorithm in this paper was used for a square lattice with von Neumann neighborhoods (with the nearest neighbors interactions).

In Table 1, the relative size S_{max}/L^2 of the largest cluster after t = 1000 simulations time steps for different values of T and for K = 2 has been shown. These results coincide with Figure 1. In all cases, for α = 1, the largest cluster fills the entire lattice in 100% (i.e. there is a consensus in opinion). It should be noted that this is a situation in which most agents in the lattice influence the opinion of the selected agent (the flow of information between agents is very good). For α = 2, the influence of other agents in the lattice is still greater than the influence of the closest neighborhood. The size of the maximum cluster then fluctuates around 100% of the network size (i.e. one large cluster with one opinion). In general, for any size of T , the size of the largest cluster of opinions decreases with the increase of α.

Table 1: The relative size of the largest cluster S_{max}/L^2 for L = 41.

T	α = 1	α = 2	α = 3	α = 6
0	100%	94%	54%	34,0%
1	100%	100%	83%	57%
2	100%	99%	92%	62%
3	100%	99%	92%	24%
4	100%	99%	90%	15%
5	100%	100%	85%	12%

In order to get a better look at the clustering of opinions, the average number of small and large clusters after thousand time steps for hundred simulations was also studied (see Figure 3). We assumed that small clusters contain no more than five agents sharing the same opinion (S ≤ 5). The randomness in accepting opinions (T) often results in the formation of small clusters of opposing opinions (as can be seen in the Figure 1). The number of clusters increases with an increase of α, i.e. the smaller the influence of all agents in the network on the selected agent, the more difficult is appearing the opinions clustering. In general, the number of clusters increases with T , but for α = 3 and α = 6 and for T = 1, the number of clusters is lower than for T = 0. First of all, the probability of a new cluster forming (with opposite opinion) inside another cluster is still very small. Secondly, the probability of changing opinions is greater at the clusters borders than inside the cluster. If the adjacent clusters have different sizes, then the probability of changing the agent's opinion in a smaller cluster is greater than in the larger one. This situation leads to the disappearance of small clusters, or in general to a reduction in number of clusters. We can see similar phenomena in terms of the number of small clusters (see Figure 3). The number of small clusters increases with T (of course, apart from low T values and for α > 1).

Fig. 4: Histogram of cluster sizes S for various values of temperature T and exponent α

Summary and Conclusions

In this article, we used a cellular automaton model in which the theories of Latané's social influence were implemented. We studied how the social temperature (randomness of human behavior) and the flow of information in society influenced the clustering of opinion. To achieve this goal, the spatial distribution of opinions, probability of sustaining opinion and the number of clusters were studied.

First, the spatial distribution of opinions after 100 steps of simulation was analyzed. The simulations showed how clusters of opinion are formed depending on the flow of information in the agents' network, as well as after considering the randomness in forming the opinion. Consensus (one large cluster) was possible for K = 2 (two opinions) for low values α (α = 1, 2), when agents formed their opinions also contacting more distant agents (that is, when the flow of information was good in the whole community).

Taking into the account the randomness in forming opinions in the case of consensus did not really matter.

Generally, the greater the α and T , the more clusters, i.e. groups of agents with the same opinions (less polarization of opinions in the groups). Of course, it should be noted that the appearance of noise in the system (T = 1) slightly orders the system in relation to the situation when T = 0 (lack of randomness). This is in accordance with other studies (Ren et al., 2007; Biondo et al., 2013; Shirado and Christakis, 2017; Kowalska-Styczeń and Malarz, 2020), in which a low noise level has brought order to the system. With the formation of opinion clusters, the probability of sustaining opinion is closely related. This probability is greater within the clusters than at their borders and it is larger in the larger clusters (Figure 2). This leads to the disappearance of small clusters, and thus to reduction of the number of clusters.

The formulation of opinions is also described by the number and size of clusters of opinion. The clustering of opinions is influenced by both the level of randomness in agents' decisions and the influence coming from neighbors. Generally, the size of the largest cluster of opinions decreases with the increase of α. This, of course, corresponds with the spatial distribution of opinions (see Figure 1). Furthermore, the number of clusters increases with α, i.e. the smaller the influence of all agents in the network on the selected agent, the more difficult it is for forming clusters of opinions. An interesting phenomenon occurs in the case of analysis of the impact of T (for T > 0). The probability of a new cluster forming (with different opinion) inside another cluster is then small and the probability of changing opinions is greater at the border between two clusters than inside them. Additionally, the

probability of changing the agent's opinion in a smaller cluster is greater than in the larger one, which leads to the disappearance of small clusters, or in general to a reduction in the number of clusters. In summary, the simulations showed that opinion formation and spread is influenced by both flow of information between agents (interactions outside the closest neighbors) and randomness (irrationality) in adopting opinions (what is shown in Table 2).

Table 2: The impact of both T and α on the formation and spread of opinions

Impact on	For T > 0	α
Spatial distribution of opinions	The greater the T, there are more and more clusters	The greater the α , there are more and more clusters
Probability of sustaining opinion	The higher T, the less probability of sustaining the opinion	The higher α, the chances of sustaining the current opinion of agents decrease
Clustering of opinions	The number of clusters increases with T	The number of clusters increases with α. The size of the largest cluster decreases with the increase of α
Summary	Generally randomness (irrationality) hinders polarization of opinions in groups	The better the flow of information in the community, the easier it is to form and spread opinions, also get a consensus

Better information flow, i.e. contacts with more agents in the network representing the community facilitates the formation of opinion and its spread. In the case of small values of α (when information flow is very good), the result of the simulation is a consensus, as in most sociophysical models of social dynamics (Castellano et al., 2009). For large values of α (when opinions are consulted only in the close neighborhood), the polarization of opinions is weak and there are many small groups of agents with the same opinion. In addition, the presence of many small clusters causes a lower probability of sustaining opinion for individual agents, i.e. they change their opinions more often.

As mentioned earlier, the better the flow of information in the community, the better the opinion spreads and the more often there is consensus and polarization of opinions. Also, Björkman et al. (2004) and Tsai (2002) emphasize that good communication and wide interaction channels favor the exchange of knowledge and information. In organization, good spread of opinions and information is particularly important in the case of organizational change, organizational culture and knowledge transfer. Managers should therefore ensure good information flow between members of the organization by creating both formal information flow channels and informal communication networks. Moreover, they should make sure that the number of members in the organization who act in a random and unpredictable manner is small, because the more randomness in the organizational behavior, the less chance of polarization of opinions and consensus appearing.

Abstract

For years, fraudsters have been using debit and credit card numbers that they have printed them on a blank plastic card so that they can use them in brick and mortar stores. For the past five years, banks had introduced Europay MasterCard and Visa (EMV) chip card technology, which made it possible for merchants to twitch demanding a PIN (here reference as personal identity number) for each transaction made. As frequency of transactions is increasing, number of fraudulent transactions is rapidly increasing. Hence the objective of this study to determine the effectiveness of logistic model tree (LMT) and gradient boosting decision tree (GBDT) to detect the amount of fraudulent transactions in South Africa (SA). A daily data for the period of 01 Mach 2020 to 10 July 2020, was obtained by, web-scrapping credit and debit card fraud from SA. The LMT and GBDT were constructed using training data on the 17 financial conditioning factors identified by the LogitBoost algorithm. We applied these models and validated them using receiver operating characteristics (ROC), and predictive accuracy (ACC). Overall, the two models exhibit reasonably a good performance; the LMT exhibits the highest predictive capability as compared to GBDT model. Our results indicated a success rate of 99.95% and a prediction rate of 99.9% when using the logistic model tree. This is a promising technique for online fraud susceptibility detection. The results of this study are useful for decision makers and SA financial sector for future use and planning in credit and debit prone areas.

Keywords: Classification, Detection Algorithms, Machine Learning, Multiple Anomalies.

Introduction

In recent years, fraud detection for online systems has become the most up-to-date topic. Efficient and complicated fraud detection systems must be owned by banking systems, electronic systems such as PayPal and fraud investigators among others in order to prevent fraud activities that change rapidly. The percentage of fraud loss order channel in online stores is currently at 74% and 49% in mobile channels. Grounded on these statistics, the moral is to govern incongruities across forms of fraud deeds that have endured transformation comparative to the past. A decent fraud detection system ought to be able to classify fraud transaction accurately and must make the detection possible in real time transactions. Fraud detection according to Seyedhossein andAshemi (2010) has two distinct groups namely (1) the anomaly detection and (2) misuse detection. Across different industries and organisation worldwide, financial fraud has been a huge concern because it brings large desolations to businesses. As indicated by Budhram (2012), the financial losses in South Africa because of credit cards fraud increased by 53% between 2010 and 2011. Furthermore, in these years; South African Banking Risk Intelligence Centre (SABRIC) had shown that two things have happened in the South African (SA) financial sector. (1) In the year 2011, a total loss of R403.15 million was recorded from the sector. This was an increase of R263.8 million from that of 2010. (2) High rate of card fraud perpetrated should thus be a major concern for establishment of accepting credit cards, the banking industry, and especially for individual users. Due to intensification and hastening of E-

Commerce, there has been an incredible use of debit and credit cards for online shopping which led to high volume of frauds related to both debit and credit cards. In the era of digitalisation, the need to identify both debit and credit card frauds is essential. Fraud detection involves monitoring and evaluation of the behaviour for innumerable users in order to detect or avoid unwanted behaviour. In order to categorise financial fraud detection effectively, various technologies, algorithms in detecting frauds must be understandable. Algorithms can differentiate transactions which are fraudulent and non-fraudulent. To effectively find fraud, they need to be passed to a dataset and knowledge of fraudulent transaction. They analyse the dataset and classify all transactions (Albshrawi and Lowell 2016). Fraud detection tools have been brought to scenic in order to address this problem and to provide reliable solutions to business. It is normally discovered through outlier detection process which in accordance with Jayakumar and Thomas (2013), it is enabled by data mining techniques, that are able to identify valuable information by revealing hidden trends, relationships and patterns found in a large database (Hassani et al. 2010).

Machine learning algorithms are employed to analyse all authorised transactions and report suspicious ones. These reports are investigated by professionals who contact the cardholders to confirm if the transaction was genuine or fraudulent. The investigators provide a feedback to the automated system which is used to train and update the algorithm to eventually improve the fraud detection performance over time. To our knowledge, this traditional way of detecting debit or credit card fraud is tedious and takes quite a time as some cards are stolen; lost or user threatened (i.e. the card holder is threatened to release card PIN). Hence this study contributes to the existing methods by building Google Flutter system and Chrome extension for android that flags" Fraud"/suspicious transaction that will help both banks and card holders about the knowledge of fraudulent transactions made. This is a new system that card holders will be able to install the Google Flutter application in their smart phones and have an opportunity to trace the whereabouts of their cards if stolen or lost and be able to stop the usage of the cards with the use of their cell phones. Even though detecting financial fraud is considered as a high priority for many organisations, recent literature lacks updated and comprehensive in-depth review that can help organisations with their decisions for selecting an appropriate data mining procedures. In the past, some scholars such as Pumsiriat and Liu (2018) and Ngai et al. (2013) have indicated that neural networks were introduced to detect credit card frauds. Therefore, in this study, our focus is based on deep learning which is a sub-field of machine learning (ML) to detect and classify the financial fraud in South Africa. Deep learning algorithms are used to extract knowledge about the processing of image or quantitative data. Furthermore, deep learning in neural networks has many algorithms for use in fraud detection, but in this paper, we selected the logistic model tree (LMT) and gradient boosting decision tree (GBDT) to detect whether a normal transaction of datasets qualified as a novel fraud. To accurately label the transactions as fraudulent and non-fraudulent, we build the Google Flutter platform for crowd-sourcing ratings instead of team labels. This lead us to supervised learning alone not unsupervised learning. See an example of the proposed Google Flutter in Figure 1. This will be build using the following link https://flutter.dev.

Figure 1: Flutter in Android Studio

Methods and Procedures

As already mentioned, the main goal of this study is to use deep learning algorithms to detect and classify financial fraud in South Africa., We use both the logistic model tree and gradient boosting decision tree classifiers to achieve this objective. As indicated by Tsangaratos and Ilia (2016), these classifiers are complicated regarding the developed models and the size of the training data that is to be used.[2]. These two features are somehow allied and the assortment of which make available an ideal recital for the established model Tsangaratos and Ilia (2016) and Costanzo et al. (2012).

Logistic Model Tree

The logistic model tree is a classification model, which combines decision tree learning methods and logistic regression (LR) Bui et al. (2016). Following Chen et al. (2017), we make use of Algorithm 1 in Appendix A to produce a LR model at every node in the tree, and the tree is pruned using a classification and regression tree (CART) algorithm of Breiman et al. (1984). The LMT uses cross-validation to find several LogitBoost iterations to prevent over-fitting of training data and use additive least-squares fits of the logistic regression for each $M_i$as follows

$$L_M(X) = \sum_{i=1}^{n} \beta_0 \beta_i X_i, \tag{1}$$

where β_i is the coefficient of the ith component of vector x, whereas n is the number of factors (Doetsch et al. 2009). Furthermore, just as in Chen et al. (2017)'s work, a linear logistic regression is estimated in order to compute posterior probabilities of leaf nodes in the LMT. According to Agresti (2018) and Stokes et al. (2012), the posteriors are calculated by

$$\mathrm{P}\ (\mathrm{M}\ |\mathrm{X}) = \frac{\exp(\mathrm{L_M}(\mathrm{X}))}{\sum_{\mathrm{M}\prime=1}^{\mathrm{D}} \exp(\mathrm{L_{M\prime}}(\mathrm{X}))}, \tag{2}$$

where D is the number of classes. For more readings on LogitBoost Algorithm, see for instance (Pham and Prakash (2019), Pourghasemi et al. (2018) and Kamarudin et al. (2017)) respectively. The LogitBoost algorithm is given in Algorithm 1.

Gradient Boosting Decision Tree

Boosting algorithms were originally introduced by machine learning community for classification problems. The main approach is to combine iteratively, several simple models; called 'weak learners', to obtain a 'strong learner' with improved prediction accuracy (Touzani et al. 2018). Boosting is an iterative algorithm that combines simple classification rules with 'mediocre' performance in terms of misclassification error rate to produce a highly accurate classification rule. Stochastic gradient boosting provides an enhancement which incorporates a random mechanism at each boosting step showing improvement in performance and speed while at the same time generating the ensemble Culp et al. (2016).

As declared by Son et al. (2015), gradient boosting algorithm utilises decision stumps or regression trees as weak classifiers. The weak learners measure the observed error in each node, and split the node using the following test function $k: \mathbb{R}^n \to \mathbb{R}$ with a threshold τ and return values η^{ι} and η^{r} respectively.In order to minimise the error after split, we identify the following triplet $(\eta^{\iota}, \eta^{r}, \tau)$and this make us to obtain an optimal split given by

$$\varepsilon(\tau) = \sum_{\mathrm{i:k(x_i)<\tau}} \omega_{\mathrm{i}}^{\mathrm{j}} \left(\mathrm{r}_{\mathrm{i}}^{\mathrm{j}} - \eta^{\iota}\right)^2 + \sum_{\mathrm{i:k(x_i)\geq\tau}} \omega_{\mathrm{i}}^{\mathrm{j}} \left(\mathrm{r}_{\mathrm{i}}^{\mathrm{j}} - \eta^{\mathrm{r}}\right)^2 \tag{3}$$

where ω_i^j and $r_i^j$are the weights and responses of $x_i$for the jth iteration. We, therefore, proceed by minimising the error in equation (3) so that we obtain an optimal tripled as (η^*, η^*, τ^*) over all possible $\tau's$at each node. Note

[2]Note that the complexity of these models is due to (1) the number of variables used to build the model. (2) The size of the training data which is more critical for the learning process.

that$\tau(\eta^{\iota}, \eta^{r})$ can be found simply by computing the weighted average of r_i^j's over training data that fall on the corresponding side of the split. The training procedure of gradient boosting decision tree is presented in Algorithm 2.[3]

$$\varepsilon_{t+1}\left(\tau_{(t+1,\rho)}\right) = \sum_{i=1}^{N_{\rho+1}} \omega_{t+1,i}\left(r^i - \eta_{t+1,\rho}\right)^2. \quad (4)$$

We firstly optimise $\eta_{t+1,\rho}$ because it assumed that $\tau_{(t+1,\rho)}$ is currently known and in an online learning,$\{(\omega_{t+1,i}, r_i)\}_{i=1,\cdots,N_\rho}$ is unavailable. For this reason, Touzani et al. (2018) declared that it is therefore impossible to minimise the error directly by adjusting $\tau_{t+1,\rho}$and also by computing the weighted average of r_i^j's as in the off-line learning. Consequently, Son et al. (2015) updated a weak classifier based on the new classifier as well as the limited information of the present classifier.

Representing the right-hand side of equation (3) by; $\Delta\eta$ we obtain

$$\varepsilon_{t+1}\left(\tau_{(t+1,\rho)}\right) = \sum_{i=1}^{N_{\rho+1}} \left\{\omega_{t+1,i}\left(r_i - \eta_{t,\rho}\right)^2 + \omega_{t+1,i}\left(-2\left(r_i - \eta_{t,\rho}\right)\Delta\eta + (\Delta\eta)^2\right)\right\} \quad (5)$$

which helped us to minimise the above quadratic function with respect to $\Delta\eta$ and obtain the solution in equation (6) as in Son et al. (2015)

$$\Delta\eta\left(\tau_{t+1,\rho}\right) = \begin{cases} \Delta\eta^{\iota}\left(\tau_{t+1,\rho}\right), & if K_\rho(x_i) < t + 1, \rho \\ \Delta\eta^{r}\left(\tau_{t+1,\rho}\right), & \text{otherwise} \end{cases} \quad (6)$$

where, $\Delta\eta^{\iota}\left(\tau_{t+1,\rho}\right) = \frac{\sum_{i:K_{\rho(x_i)\geq\tau_{t+1,\rho}}}^{N_{\rho+1}} \omega_{t+1,i} r_i}{\sum_{i:K_{\rho(x_i)\geq\tau_{t+1,\rho}}}^{N_{\rho+1}} \omega_{t+1,i,}} - \eta_{t,\rho}^{\iota}$

and

$\Delta\eta^{r}\left(\tau_{t+1,\rho}\right) = \frac{\sum_{i:K_{\rho(x_i)\geq\tau_{t+1,\rho}}}^{N_{\rho+1}} \omega_{t+1,i} r_i}{\sum_{i:K_{\rho(x_i)\geq\tau_{t+1,\rho}}}^{N_{\rho+1}} \omega_{t+1,i,}} - \eta_{t,\rho}^{r}.$

Employing recursive procedure to find η, Son et al. (2015) obtained these two equations

$$\Delta\eta^{\iota}\left(\tau_{t+1,\rho}\right) = \alpha\left(\omega_{t+1,i} N_\rho + 1 r N_{\rho+1} - \eta_{t,\rho}^{\iota}\right) \quad (7)$$

$$\Delta\eta^{r}\left(\tau_{t+1,\rho}\right) = \alpha\left(\omega_{t+1,i} N_\rho + 1 r N_{\rho+1} - \eta_{t,\rho}^{r}\right). \quad (8)$$

Here, αdenotes a learning rate. Intuitively, the return value $\eta$is updated with proportion to the amount of a difference between the weighted response of a new example and a previous return value. For readings on gradient boosting algorithm see for instance Touzani et al. (2018), Culp et al. (2016) and Son et al. (2015).

Model Assessment

The receiver operating characteristic (ROC) curve is a useful tool to assess performance of the proposed classifiers. The ROC curve is constructed using sensitivity as the Y-axis against 1-specificity as the X-axis with various cut-off thresholds Chen et al. (2017). The area under the ROC curve (AUC) represents the capability of a model to predict fraud. According to Bui et al. (2016), the value of 1 under AUC indicates that the estimated classifier is perfect otherwise; the value of 0 indicates a non-informative classifier. Khattak (2017) and Hussin et al. (2016) had emphasised that a correlation of predictive capacity and AUC could be quantified as follows: excellent (0.9-1), very good (0.8-0.9), good (0.7-0.8), average (0.6-0.7), and poor (0.5-0.6). In this study, the standard error of AUC values is used; and a smaller standard error indicates a better classifier.

Furthermore, the predictive accuracy (ACC) has also been widely used to assess the predictive capability of the models. The ACC is the proportion of fraud and non-fraud that the classifiers had correctly classified. In this study, ACC together with AUC are used to evaluate the performance of the two models. According to Ahmed (2018), Chen et al. (2017) and Pranckevicius and Marcinkevicius (2017) the prediction accuracy is computed by

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{FP} + \text{TN} + \text{FN}} \quad (9)$$

[3]$\nu$is a shrinkage factor to training data and to the classifier.

where TP (true positive) and TN (true negative) are the number of frauds that are correctly classified, and FP (false positive) and FN (false negative) are the numbers of fraud incorrectly classified Hussin et al. (2016). It is possible to obtain the AUC of a ROC curve using the following formula where $\Phi\odot$ denotes the cumulative standard normal distribution. The classification accuracy is calculated by actual labels that are equal to predicted label divided by total corpus size in test data.

$$\text{AUC} = \Phi\left(\frac{\alpha}{\sqrt{1+b^2}}\right) \tag{10}$$

Empirical Analysis

This section provides and discusses the empirical analysis of the data sets. We propose to use crowd-labelled, web-scraped credit and debit cards in South Africa to train a model to rate the 'reliability' of online transaction content. We therefore obtain a data set which is highly skewed, consisting of 592 frauds in a total of 376807 observations. This resulted in only 0.472% fraud cases. This skewed set is justified by low number of fraudulent transactions. Between the years 2018 and 2019, credit and debit card fraud has increased by 20.5% due to online transactions. As per the report of the SABRIC, the weak state of the country's economy has provided criminals with the impetus, and opportunity to commit financial crime. The group's data shows that digital banking incidents has increased by 20% in 2019, a number that is set to rise in the future, as criminals continue to use social engineering tactics to extract personal and confidential information from victims; and this enable them to transact on victims' accounts without authority. But, with cybercrime; a gross fraud loss on South African issued cards has increased by 20.5%. See for instance Figure 2.

Figure 2: Gross Fraud (Credit and Debit) Source: https://www.sabric.co.za

Preparation of Training and Validation Datasets

For confidentiality purpose with the obtained dataset, we perform a principal component analysis and we finally have 35 variables with 31 principal components. However, Mori et al. (2016) defined principal component analysis (PCA) as a commonly used descriptive multivariate method for handling quantitative data and can be extended to deal with mixed measurement level data. Table 1 present exploratory data analysis for both identified number fraudulent and valid transactions. The reported mean for fraudulent transaction indicates South African's are losing at around 122 Rands daily on made online transaction.

Table 1: Exploratory Data Analysis

	Total No	Mean	Std
Valid Transactions	376215	88.29	250.10
Fraud Transactions	592	122.21	256.68

Financial Conditioning Factors selection and Model Prediction

To begin our analysis, we first train a logistic model tree to establish a benchmark. We train this model with the ratio of 80%:20% training and test data. The assumption we made is that every transaction made is valid and 95% to 99% of the time our algorithm would be correct and cost the debit and credit cards holders in South Africa over 211.3 million Rands from the sample period of the study otherwise, the classifiers would not be useful. Using the LMT, we only obtain 17 principal components as important predictors of financial fraud in South Africa. Logistic regression model tree is used for classifying the probability of a class of fraudulent transaction or non-fraudulent transaction across both credit and debit cards. See Table 6. As Recommend by Bui et al. (2016), we removed all the conditioning factors with null predictive values.

Evaluation of the Classification Experiment

The values of the financial susceptibility index (FSI) have been calculated by the use of the LMT model. This model can cope with binary and multi-magnificence target variables, numeric and nominal attributes, and missing values (Chen et al. 2017). Using the training data, we were able to establish the LMT model. To lessen variability, we further use a cross-validation approach of ten-fold. This approach partitions training data into ten subsets and averages validation effects over ten rounds. The ten-fold cross-validation method was also used for the gradient boosting machine tree model in this study. The calculated FSI values were in the range of 0.01 to 0.988. The financial susceptibility map was reclassified into five classes inclusive of very low (0.001-0.09), low (0.10-0.30), moderate (0.31-0.49), high (0.50-0.64), and high (0.65-0.988) using the natural break method. Note that this same method has been proposed by Chen et al. (2017). In data mining and machine learning modelling, it is essential to assess and check the qualities of the ensuing models Moreover, Using a training data, Table 2 presents the results of the predictive accuracy (ACC) and AUC; while Figure 3, presents the sensitivity and specificity of the two models and Figure 4 and Figure 5 are the ROC curves of the models. The LMT model has the highest overall performance in terms of ACC and AUC, with values of 0.9995 and 0.9875, respectively. The GBDT model exhibited barely decreased ACC and AUC values than the LMT.

Table 2: Performance on Training Data

Parameters	LMT	GBDT
ACC	0.9995	0.9692
AUC	0.9875	0.9552

Figure 3: Sensitivity and Specificity Curves

The prediction capabilities of the two models were further evaluated using validation data, and results are shown in Table 3. LMT has good prediction capabilities with the highest ACC value of 0.999 and AUC value of 0.9885.

Table 3: Performance on Validation Data

Parameters	LMT	GBDT
ACC	0.9990	0.9892
AUC	0.9885	0.9776

Finally, to compare statistically significant differences between the two models, a pair-wise comparison was conducted using Wilcoxon signed-rank and model power test procedures on validation data. The former was used in the research that was carried by Chen et al. (2017) and Bui et al. (2016) while the latter was carried in the empirical analysis of Makatjane and Moroke (2016). The null hypothesis for this method is that there is no significant difference between the estimated fraud detection models at the 95% significance level. The z and p-values are used to evaluatesignificant differences between financial fraud detection models. Furthermore, the mean difference of the models was used to determine the actual power of the two models. When z values exceed criticalvalues of $(\pm 1{:}96)$ and p-values are smaller than the significant level (0:05), the null hypothesis willbe rejected and therefore the performances of these models are notably different. The results of the Wilcoxon signed rank and power tests are shown in Table 4. The LMT and GBDT models' performances are significantly different since$(\mathrm{p-value} = 0.0001, \mathrm{z\,value} = 6.53)$. In general performance, the LMT outperformed the GBDT as both the AUC and ACC are higher in the LMT hence we conclude that the LMT has accurately predicted the financial fraud in South Africa. This is also confirmed by the power test as the LMT has the actual power of92.41% giving LMT more prediction power of 1.43% than the GBDT.

Table 4: Pair-wise Comparison and Power Test

Wilcoxon Signed-Rank Test		Model Power Test		
Parameters	LMT vs GBDT	Model	Mean Difference	Actual Power
z-value	6.53	LMT	-0.0194	0.9241
p-value	0.0001	GBDT	0.07168	0.9098

Sensitivity and Detection Rate Analysis

Looking at the output in Table 5, we can see that we have the high accuracy of 99.9% as we expected. If we look at our confusion matrix in Table 7, we can see that, using our model, we only got 500 predictions wrong; this figure of 500 is made up of 353 false positive and 147 false negatives. Going from 259 wrong to 500 wrongs is quite an improvement on performance, but we must consider the importance of sensitivity and specificity when it comes to the real-world application which the results are reported in Table 5. Are the implications of a false negative significant than the implications of a false positive? Ultimately, there is no way lenders could function if they classified every transaction as fraud and investigated it thoroughly before deciding whether to approve it, the costs of doing that would be so high that it would not be feasible.

Table 5: Sensitivity Performance

Parameters	LMT
Accuracy	0.999
Sensitivity	0.9990
Specificity	0.8628
Prevalence	0.9967
Detection Rate	0.9936
Detection Prevalence	0.9959
Balanced Accuracy	0.9056

Discussion and Conclusion

Fraud detection is a complex issue that requires a substantial amount of planning before throwing machine learning algorithms at it. Nonetheless, it is also an application of data science and machine learning for the good, which makes sure that the customer's money is safe and not easily tampered with. However, mitigation financial hazard and management planning plays a critical role in financial society and economic world. The statistical input of this work lies in employing a logistic model tree as a benchmark to select the important predictors of the financial fraud in South Africa using the LogitBoost algorithm. We then further employed the gradient boosting decision tree to detect the gross financial fraud from online transaction made by the debit and credit cards of South Africans. There are few studies that aim to effectively detect financial fraud in South Africa to our knowledge, this is the first use of such algorithms to produce a map characterising fraudulent financial behaviour across financial sector in South Africa. Seventeen financial conditioning factors were extracted for the study including slope. To select these factors, we used the LMT method using LogitBoost algorithm, and all conditioning factors were used according based on assessing the results. Finally, model performances were evaluated and compared using ACC values, ROC curves, AUC values, Std. error, CI at 95%, and significance level. According to this case study, the two models exhibit reasonably good performances; the LMT model has the highest predictive capability compared with the GBDT model; with the success rate of 99.95% and a prediction rate of 99.9%. This is a promising technique for online fraud susceptibility detection. Finally, these study results may be useful for decision makers and South African financial sector for future use and planning in credit and debit prone areas. In the future, we recommend updating the established Google Flutter for android and build Chrome extension that flags "fraud or suspicious transaction" while purchasing goods and services online. While the flutter will help the card users to trace their lost or stolen cards and be able to stop any transaction immediately without going to the bank or card issuer. All these recommended procedures will also automatically notify the banks on the suspicious transactions and automatically train the system without confronting the card holder if the transaction was fraudulent or not. The main problem that we will encounter is when the card has been taken from the holder and is been threaten by the perpetrators. However, we ought to solve the problem by modifying how the ATM (reference here as automatic teller machine) on how they would request the PIN. Maybe, there should be some personal questions, or some OPT numbers to be sent to the card holders prior finalising the transaction. In the future, we recommend updating the established Google Flutter for android and build Chrome extension that flags "fraud or suspicious transaction" while purchasing goods and services online.

Emigration: Potentiating Factor of Social Tolerance in Romania

Andreea MURARU

PhD., The Bucharest University of Economic Studies, Bucharest, Romania
Email: andreea.muraru@ie.ase.ro

Abstract

In this article, I investigated whether higher social tolerance levels in Romania can also be attributed to emigration through its system of social remittances. In investigating this hypothesis, I used two waves of survey data from the World Value Survey for building a social tolerance index and analyzing it in relation to country specific questions on migration (specifically having or not friends or relatives who live abroad and the frequency of communicating with them). The results from multinomial logistic regressions show that there is an increased probability of having a higher tolerance level for persons who have friends or relatives abroad with whom they talk, the reverse being also valid – higher chances of being less tolerant for individuals who do not have friends or relatives who have emigrated. The impact of the communication frequency is not that clear cut, as high frequency communication does not seem to be significant in the multinomial logistic regression. However, average communication frequency has a direct impact on tolerance while rare communication increases the probability of lower tolerance levels. Association analysis confirms the results of the logistic regression.

Keywords: Migration, Social Tolerance, Multinomial Logistic Regression, Association Analysis.

Introduction and Literature Review

In the last two decades, Romania faced massive emigration flows. According to an OECD report (OECD, 2019), Romania has the 5th largest emigrant population in all OECD countries, registering an increase in emigration by more than 200 percent in the past 15 years, adding up to 3.4 million Romanians who reside abroad. According to the same OECD report, 75 percent in the decrease of Romania's population in the period 2000-2018 can be attributable to migration.

Migrants usually remain connected to their native countries through remittances, communication and life plans (Sandu, 2010). In the dedicated literature the flows from the Diasporas most referred to are financial remittances, which is not surprising as the sums at global level are notable: $689 billion USD in 2018 (according to World Bank data). But there are also other types of flows that come from migrants towards their home countries together with economic remittances: the social remittances. Peggy Levitt in 1998 defined the concept of social remittances as representing "ideas, behaviors, identities, and social capital that flow from receiving- to sending-country communities" (Levitt, 1998). The scholarship on social migration focuses either on the phenomenon in general (e.g Levitt, 2001, Levitt and Lamba-Nieves, 2011, Levitt and Merry, 2009, for Romania see for e.g. Anghel and Coșciug, 2017, Anghel, 2009, Horváth, 2009) or on different sides of it – political remittances (e.g. Chauvet and Mercier 2014), gender roles (Vlase, 2013), human rights and so on. There are also studies that show that there is a strong connection between economic and social remittances (for e.g., Vari-Lavoisier, 2016).

This study is subsumed to the literature on social remittances. The starting hypothesis is that migrants in recipient countries change or enrich their value system by the exposure to a different culture, language, learn about openness and alterity from the position of the foreigner and through their transnational connections transpose to a certain extent their enriched set of values on the aspirations of the staying population. Starting from a finding of White (2016), I would say that especially in the Eastern European former communist block, remittances in their social form, might also shape the way towards "normality" – a feature that for the former communist countries was only to be found in the foreign western countries –, in terms of values, tolerance and openness.

Even though the literature on the socioeconomic impact of migration in Romania is relatively abundant from an anthropological and sociological point of view (see for e.g. Anghel and Coșciug (2017), Horvat (2009), Anglet et al. (2016), Sandu (2010)), there is a very limited number of papers that use a quantitative approach to social remittances in Romania.

One quantitative study is that of Nikolova et al. (2015), in which the authors investigate if civic engagement of the staying population of Bulgaria and Romania is different whether they have or not relatives and friends living

Cite this Article as: Andreea MURARU "Emigration: Potentiating Factor of Social Tolerance in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

abroad. They use Gallup World Poll data and through regression analysis, logit and propensity score matching find that having family and friends abroad is positively associated with pro-social behavior (donating, volunteering, and helping strangers). Another study is that mentioned in Sandu (2010), who uses data from a survey on temporary migration taken in 2006 and also tests for the change in tolerance towards ethnic and religious minorities.

Nevertheless, the picture of Romanian migration changed drastically in the last decade and this study by using a different survey-based quantitative approach comes to enrich the picture on the social (tolerance) remittances in Romania. In this article, I investigated the importance of migration and preserving migration connection in promoting social tolerance in the staying population. As part of the democratic values, I consider that tolerance can also be one of the values transferred or enhanced through the system of social remittances. Nevertheless, there is a challenge in identifying this influence as cosmopolitanism and globalization also act as important factors that enhance the transmission of modern society values; therefore, I used two waves of survey to see whether the influence of migration changed in time. In addition, in the models I used, I tried to illustrate the impact of migration beyond that of specific demographic variables.

Furthermore, this study centers on social tolerance as an indicator built from the World Value Survey. Building social tolerance from this kind of data can also be found in Kirchner et al. (2011) and Dunn et al. (2009). In these two studies, the authors define tolerance as: "non-negative orientation toward groups outside of one's own" (Dunn et al. 2009) and "the willingness to tolerate or accept persons or certain groups as well as their underlying values and behavior by means of co-existence (even if they are completely different from one's own)" (Kirchner et al. 2011). Nevertheless, there are also studies who argue that this kind of approach, because of the way in which the questions in the survey are formulated, include prejudice in the definition of tolerance (Hjerm et al., 2019).

The paper is structured as follows: the next section describes the data and the methodological approach, section 3 presents the main findings and the last section concludes.

Data Sources and Methodology

The data sources for this article are the last two waves of the World Values Survey (WVS-7 which is still ongoing at world level, but which was completed in Romania in 2018, and WVS- 6, which was applied in Romania in 2012). For Romania, the Research Institute for Quality of Life organizes the survey and the Romanian Group for The Study of Social Values makes the results public on their website.

The main questionnaire of The World Value Survey includes a question, common for all countries, referring to social tolerance: "On this list are various groups of people. Could you please mention any that you would not like to have as neighbors?". The groups mentioned are: drug addicts, people of a different race, people who have AIDS, immigrants/foreign workers, homosexuals, people of different religion, heavy drinkers, unmarried couples living together, people who speak a different language. Following Kirchner et al. (2011) I have built the social tolerance index for Romania as an additive index on only 7 of the 9 categories as drug addicts and heavy drinkers are generally less tolerated groups and would have affected the results.

Besides this section of the WVS, I also used the country specific items referring to migration, specifically whether the respondent has relatives or friends living abroad ("Among the friends and relatives with whom you talk, are there persons who live or have lived abroad for at least one month?") and also the section referring to how frequently people communicate with their acquaintances from abroad ("How often do you get in contact with friends/relatives from that country? 1. Daily; 2. Weekly; 3. 2-3 times a month; 4. Monthly; 5. 2-3 times a month; 6. 1-2 times a year; 7. Even rarer). To my knowledge, the World Value Survey is a unique source for this kind of migration data for Romania.

For studying the influence of migration on tolerance levels, I used multinomial regression analysis and association analysis. The choice of these methods is justified not only by their suitability for categorical variables but also because the influence of migration connections on the tolerance level of the staying population might also be formulated as a classification or association problem, which can be effectively solved by applying these techniques.

For applying these methods, I had to recode both the social tolerance variable and the communication frequency variable. I have transformed them in 3-level variables for the ease of interpretation. For the social tolerance the three levels are:

(i) *low degree of tolerance*, people who had a maximum score of 2 from the total of 7 tolerance elements,

(ii) *medium tolerance* - a score between 3 and 5, and

(iii) *high tolerance* - individuals with a score of 6 and 7 on the social tolerance scale.

For some analyses, I also needed a binary form of the tolerance variable, therefore I have recoded it in *more likely to be more tolerant* (values 5, 6 and 7 form the social tolerance index), and *more likely to be less tolerant* (values 0,1,2,3 and 4 form the social tolerance index).

As concerns the communication frequency variable, the three levels that I have built are:

(i) *frequently* – for the persons who discussed at least 2-3 times per month;

(ii) *average* – for the persons who communicate on a monthly basis or at least once at 2-3 months, and

(iii) *rarely* – for individuals who only communicate once or twice a year or even less.

In the last category I also included the persons who did not have friends or relatives living abroad so as not to loose their impact on the low tolerance level.

Multinomial logistic regression is an extension of the binary logistic regression for a multiclass dependent variable. Given K classes of the Y variable, the multinomial logistic regression can be written as K-1 logits of the form:

$$\log\left(\frac{P(Y_i = 1|x_{i1}, x_{i2}, \dots, x_{im})}{P(Y_i = K|x_{i1}, x_{i2}, \dots, x_{im})}\right) = a_{10} + a_{11}x_{i1} + \cdots + a_{1m}x_{im} = a_1^{'}X_i$$

$$\log\left(\frac{P(Y_i = 2|x_{i1}, x_{i2}, \dots, x_{im})}{P(Y_i = K|x_{i1}, x_{i2}, \dots, x_{im})}\right) = a_{20} + a_{21}x_{i1} + \cdots + a_{2m}x_{im} = a_2^{'}X_i$$

…

$$\log\left(\frac{P(Y_i = i|x_{i1}, x_{i2}, \dots, x_{im})}{P(Y_i = K|x_{i1}, x_{i2}, \dots, x_{im})}\right) = a_{i0} + a_{i1}x_{i1} + \cdots + a_{im}x_{im} = a_i^{'}X_i$$

…

$$\log\left(\frac{P(Y_i = K-1|x_{i1}, x_{i2}, \dots, x_{im})}{P(Y_i = K|x_{i1}, x_{i2}, \dots, x_{im})}\right) = a_{20} + a_{21}x_{i1} + \cdots + a_{2m}x_{im} = a_{K-1}^{'}X_i$$

Coefficients a_{ij} can be interpreted as: an increase by one unit in x_{il}, keeping all other variables fixed leads to an increase in $\log\left(\frac{P(Y_i = i|x_{i1}, x_{i2}, \dots, x_{im})}{P(Y_i = K|x_{i1}, x_{i2}, \dots, x_{im})}\right)$ by a_{ij}. Probabilities can be derived by calculating the exponential. Coefficients are estimated through an extension of maximum-likelihood.

Association analysis is a data mining technique that identifies and validates associations between item sets with the goal of making predictions regarding the appearance of an event when another one happens (a rule of the type { X → Y }) . It is usually used in market basket analysis in recognizing items often bought together. In identifying associations, it uses the support measure (the number of transactions in which a set of items appears, or its frequency $S(\mathrm{X} \rightarrow \mathrm{Y}) = \frac{\sigma(X \cup Y)}{T}$, T=the total number of transactions), the confidence which is a ratio between the item set support and the support of the left-hand side item (its formula is $c(\mathrm{X} \rightarrow \mathrm{Y}) = \frac{\sigma(X \cup Y)}{\sigma(X)}$) and also the interest factor or the lift which calculates the ratio between the item set support and its support under the hypothesis of independence ($I(\mathrm{X} \rightarrow \mathrm{Y}) = \frac{S(\mathrm{X,Y})}{S(X)S(Y)}$). Values of the lift higher than 1 suggest a direct relation between categories, whereas a value lower than 1 suggests a reverse relation between them. When the interest factor equals 1, the items in the set are independent as the support for the set is equal to the product of the individual supports (Tan et al., 2019).

Results

The importance of variables for classification

In order to establish a ranking of variables in terms of their relevance in classifying a person as rather more tolerant than intolerant, I used decision trees, a tool highly versatile in classification analysis and perfectly fit for categorical and ordered variables.

In order to perform this analysis, I used the binary recoded social tolerance variable presented in the data section above (with value "yes" for tolerance index higher or equal to 5, out of the maximum 7, and value "no" for tolerance below or equal to 4) and then tested the importance of traditional demographic variables (education, age and gender) together with the migration variables in classifying individuals as rather more tolerant or rather more intolerant. Therefore, I estimated two models, one with the binary migration variable – having or not friends or relatives abroad – and one with the three-level communication frequency variable (built as specified in the data section).

As can be seen below, the importance of the gender variable was very low (Table 1 and Table 2), not being a very relevant variable in discriminating between the two classes of tolerance, therefore its inclusion in the multinomial logistic regression as explanatory variable would be unnecessary.

Table 1: Variable importance – model 1

Education	Age	Has friends/Relatives who emigrated	Gender
36.9	19.4	8.4	4.03

Table 2: Variable importance – model 2

Education	Age	Communication frequency	Gender
36.09	20.13	10	3.89

The decision tree for the second model can be seen in Fig. 1 below. In interpreting the tree, following the left branch means the *yes* answer to the category mentioned in the node, while the right is the *no* answer (e.g. if education is not primary, take right and reach the blue node corresponding to tolerance=yes, meaning more likely to be tolerant than intolerant; 78% of cases are in this node, with a probability of being assigned to this class of 0.76).

Fig.1: Decision tree

The most important variables among the selected demographic characteristics are, as expected, education and age, young and above average educated individuals being usually associated with a higher openness, tolerance and trust in democratic values.

Results form the multinomial logistic regression

The next step was to build a multinomial logistic regression model, in which the dependent variable was the three-level scale social tolerance index (*low degree of tolerance*, people with minimum score of 2 out of the 7 tolerance elements, *medium tolerance*, people with a score between 3 and 5, and *high tolerance* - individuals with a score of 6 and 7).

I estimated the multinomial logistic regression model on both waves of the survey 2012 and 2018 to compare results. As explanatory variables I used: education, age and alternatively the two variables for identifying the potential impact of migration (the binary variable showing whether the individual has or not a friend or relative living abroad and the three-level variable, quantifying the frequency of contact, built as shown in the data section).

Table 3: Results from multinomial logistic regression – model 1

2012	Intercept	Has friend/relatives emigrants=yes	Age	Education
Low tolerance	0.32	-0.35*	0.006	-0.14*
Medium tolerance	0.97*	-0.38*	-0.0009	-0.15*
2018				
Low tolerance	-1.15*	-0.48*	0.02*	-0.17*
Medium tolerance	-0.28	-0.17	0.08**	-0.08*

**=statistical significance at 0.05; **=statistical significance at 0.10*

The multinomial logit from the table above can be written as:

$$ln\left(\frac{P(tolerance = low)}{P(tolerance = high)}\right) = a_{10} + a_{11}(\text{Has friends/relatives emigrants} = \text{yes}\ ) + a_{12}\text{Age} + a_{13}\text{Education} + \varepsilon$$

$$ln\left(\frac{P(tolerance = medium)}{P(tolerance = high)}\right) a_{20} + a_{21}(\text{Has friends/relatives emigrants} = \text{yes}\ ) + a_{22}\text{Age} + a_{23}\text{Education} + \varepsilon$$

The coefficients show the contribution of the variables to the log-probabilities, or log-odds for having low tolerance vs. high tolerance.

Therefore, as can be seen from Table 3 above, in 2012, the coefficient $a_{11} = -0.35$ means that switching from the pivot category (the one not mentioned in the table) *has friends/relatives emigrants=no* to category *has friends/relatives emigrants=yes* (the category mentioned in the table) decreases the log-odds of having low tolerance versus high tolerance by 0.35 (increasing therefore the probability for the high tolerance group).

At the same time, when looking at the second logit, for the category *tolerance=medium*, the coefficient $a_{21} = -0.38$ shows that when switching from not having relatives or fiends living abroad to having, the log odds of being moderately tolerant vs. highly tolerant decreases by 0.38. The age coefficient isn't statistically significant, showing that an increase by one year in the age of the respondent doesn't necessarily modify its level of social tolerance. As age is significant in terms of classification, I would say the explanation for this is that the impact of age, at least for this survey year, might be seeable from the perspective of age groups (young vs. middle-aged vs. senior).

In 2018, there is a change in the magnitude of coefficients. The log-odds of having a low tolerance level vs. high tolerance when switching between the group of people who do not have friends or relatives who live abroad to the group that has, decreases to 0.48. Nevertheless, the log-odds of having medium tolerance vs. high tolerance when moving between the two categories of the binary migration variable becomes insignificant. Moreover, age becomes significant, showing maybe that the young generation in the six years between the two surveys, is more likely to be highly tolerant as a result of globalization and cosmopolitanism.

The education coefficient is at all times negative, showing that the higher the education level the most likely it is for the respondent to have higher tolerance (an increase by one in the education level, reduces the log-odds of belonging to a less tolerant group vs. the highest tolerant group).

The figures below graphically synthesize the results of the multinomial logistic regression in two instances: the impact of having or not friends and relatives living abroad relative to education (when holding age equal to its sample average) and relative to age (when holding education equal to its sample average).

As can be seen from Fig. 2, having friends or relatives who emigrated increases the probability of being highly tolerant by about 10 percentage points, while not having these kind of acquaintances increases the odds of being less tolerant (by about 5 percent in 2012, and decreasing from 5 to about 2.5 percent for the low tolerance class in 2018). Therefore, the direction of the impact is similar in both 2012 and 2018, but there are some differences regarding the level of probability associated to low and medium tolerance classes, which could show that during the 6 years between the two surveys there was a natural change towards higher tolerance.

2012	2018

Fig. 2: Impact of binary migration variable relative to education

Similar conclusion regarding the impact of having or not friends and relatives living abroad can be drawn from Fig 3 below. We can see from the graph that there is a higher likelihood of being highly tolerant for individuals who have acquaintances abroad and increased chances of being more intolerant if these connections with emigrants are absent. As in the graph before, there are also some differences between the two survey years, more pronounced on the age reference graph because, as it was seen from the analysis of the logit coefficients, age was not statistically significant in 2012.

2012	2018

Fig. 3: Impact of binary migration variable relative to age

The second model I investigated used the three-scale variable for communication frequency. The results of the model can be seen in Table 4 below.

Table 4: Results from multinomial logistic regression – model 2

2012	Intercept	Communication frequency =frequently	Communication frequency =rarely	Age	Education
Low	-0.17	0.10	0.5*	0.006	-0.15*
Medium	0.42	0.32	0.42*	0.00001	-0.15*

2018					
Low	-2.16*	0.64	0.87*	0.02*	-0.17*
Medium	-0.73*	0.43	0.26	0.08*	-0.08*

The logit models can be written as:

$$ln\left(\frac{P(tolerance = low)}{P(tolerance = high)}\right) = a_{10} + a_{11}(\text{communication frequency} = \text{frequent}) + a_{12}(\text{communication frequency} = \text{rarely}) + a_{14}\text{Age} + a_{14}\text{Education} + \varepsilon$$

$$ln\left(\frac{P(tolerance = medium)}{P(tolerance = high)}\right) = a_{10} + a_{11}(\text{communication frequency} = \text{frequent}) + a_{12}(\text{communication frequency} = \text{rarely}) + a_{14}\text{Age} + a_{14}\text{Education} + \varepsilon$$

Analyzing the coefficients in Table 4 above, we can see that the ones for *communication frequency=frequent* are not statistically significant in neither of the two years. But, the coefficients for *communication frequency=rarely* show that when passing from average contact frequency (the pivot category not mentioned in the table) to rare contact, there is an increase in the log-probability of having a low level of tolerance relative to high tolerance. The same is valid for the log-probability of belonging to the medium tolerance class relative to high when moving from average contact to rare contact. In 2018 this coefficient is no longer significant. Like in the previous specification frame, age is not statistically significant in 2012 and becomes significant in 2018, showing an increase in log-probability of belonging to the lesser tolerant groups relative to the high tolerance ones when age increases by one year, and education is significant at all times showing a direct connection between education and tolerance.

Graphically, we can see that the contact of average frequency with friends and relatives living abroad leads to an increase in the probability of being highly tolerant while a rare contact increases the odds of having a medium and low tolerance level. The influence of frequent contact in those graphs must be interpreted with caution, as the variable proved not to be statistically significant.

2012 | 2018

Fig. 4: Impact of *communication frequency* relative to education

The same conclusions can be drown from the figure below, which shows the impact of the frequency of contact with the friends and relatives who live abroad while holding education to its average level. As in the previous case, the average frequency contact increases the probability of belonging to the high tolerance group and decreases the odds for the medium and low tolerance groups.

2012 | 2018

Fig. 5: Impact of *communication frequency* relative to age

Results form Association analysis

For building association rules I used the social tolerance index in binary form (coded as *Yes* for more likely to be tolerant, and the value *No* for less likely to be tolerant, as described in the data section).

In investigating the association between having or not friends and relatives who live abroad and being more or less tolerant, I extracted all the 4 *yes-yes*, *yes-no*, *no-yes* and *no-no* rules. The analysis of the association rules offers similar results for both survey waves.

As can be seen from Table 5 below, the *yes-yes*, and *no-no* rules have a positive level for the lift, showing a direct association between the categories: individuals who have friends and relative living abroad usually are more tolerant (a confidence level of 0.72, showing that 72 percent of the persons who have emigrants as acquaintances have an above average tolerance level). In the no-no case, the confidence level is much lower but it is compensated by a much larger lift, showing a somewhat more important direct connection between the two. In the case of no-yes, yes-no rules, the lift is smaller than unit, showing that there is an important inverse connection between the categories.

Table 5: Association rules between binary migration variable and tolerance

Association rule	Support	Confidence	Lift
2012			
{Friends/relatives living abroad=Yes → Tolerance=Yes}	0.47	0.72	1.08
{Friends/relatives living abroad=Yes → Tolerance=No}	0.17	0.28	0.84
{Friends/relatives living abroad=No → Tolerance=No}	0.16	0.41	1.26
{Friends/relatives living abroad=No → Tolerance=Yes}	0.22	0.59	0.87
2018			
{Friends/relatives living abroad=Yes → Tolerance=Yes}	0.43	0.80	1.04
{Friends/relatives living abroad=Yes → Tolerance=No}	0.11	0.2	0.87
{Friends/relatives living abroad=No → Tolerance=No}	0.12	0.27	1.16
{Friends/relatives living abroad=No → Tolerance=Yes}	0.33	0.73	0.95

When looking at the association rules between the communication frequency and the binary tolerance index (Table 6 below), we can see that the rules between average communication frequency and *tolerance=yes* as well as between frequent communication and *tolerance=yes* have high confidence levels (above 0,7 in all cases) and lift values higher than one which confirms in almost all cases the positive relation between the two (with exception of

the lift very close to 1 in 2018 for the association rule {Frequency=frequently → Tolerance=Yes}, sign of independence). Also, the association between the rare frequency of communication and the below average level of tolerance is sustained by a 1,2/1,1 lift level in 2012/2018. As its confidence value was low, I also investigated the association rule between {Frequency=rarely → Tolerance=Yes }and as can be seen from the table below, even though its confidence level is high, the lift is below unit showing a reverse relation between the two.

Table 6: Association rules between communication frequency and tolerance

Association rule	Support	Confidence	Lift
2012			
{Frequency=rarely → Tolerance=No }	0.21	0.39	1.20
{Frequency=average → Tolerance=Yes}	0.12	0.76	1.12
{Frequency=frequently → Tolerance=Yes }	0.23	0.74	1.10
{ Frequency=rarely → Tolerance=Yes }	0.32	0.61	0.90
2018			
{Frequency=rarely → Tolerance=No }	0.14	0.26	1.11
{Frequency=average → Tolerance=Yes}	0.09	0.87	1.13
{Frequency=frequently → Tolerance=Yes }	0.25	0.78	1.02
{ Frequency=rarely → Tolerance=Yes }	0.43	0.74	0.97

Conclusions

In this study, I tried to investigate whether we can say that social tolerance in the staying population (the origin population of migrants) can be enhanced by the connections maintained between the people remaining in the country and the ones who have emigrated. In doing this, I used survey data form two waves of the World Value Survey for Romania and applied quantitative analysis techniques.

Even though migration is not one of the main determinants of tolerance, hypothesis that cannot even be taken into consideration, it still is a variable that, as the analyses showed, contributes to increasing the level of tolerance. The multinomial logistic regression illustrated that there is an important increase in the probability of being highly socially tolerant for persons who have friends and relatives who live or have lived abroad for at least one month and with whom they speak, and also that the lack of such connections leads to an increases the probability of being less tolerant, beyond the influence of education and age – important factors influencing tolerance.

The frequency of communication proves to be an important factor only when it comes to average vs. rare communication (average communication leading to higher chances of being highly tolerant), while the coefficient for frequently communicating in the multinomial logistic regression framework, did not prove to be significant. Results from the association analysis confirm the existence of a direct connection between migration and tolerance, persons who know and are in contact with emigrants being associated with a higher level of tolerance.

This study can be enhanced by adding supplementary variables regarding the recipient countries for the migrants, as it can influence their value system, and through a regional analysis on the social tolerance level for the staying population as well as.

mariusz.chmielewski@wat.edu.pl

Abstract

The paper introduces a novel system for pharmaceuticals companies or medical facilities that support or conduct clinical trials. The system consists of two applications, the CT (clinical trials) management portal accessible only to the supervisor of the trials and a mobile application concentrated on collecting data from the patient. The paper proposes a novel solution which allows to organize and accurately track the efficiency of clinical trials using sensor-based examinations, daily surveying, medicine intake reporting and user interaction tests. This set of activities makes the process of evaluation of the treatment easier and less prone to inaccuracies and subjectivity. The paper focuses on the usage of the system in clinical trials regarding the Parkinson's disease, testing new medicines and new approaches to the therapy. The paper presents synthetic view of requirements and conceptual and testing phase of a deployed IQPharma Clinical Trials Assistant system. The original findings concern correlating aspects (methods) of pharmaceutical therapy evaluation for Parkinson's Disease including: Patient subjective health state evaluation - using answers provided in the surveys, Detection of motor symptoms and evaluation of their intensity using signals of inertial and biomedical sensors – aggregated features of actigraphy and electromyography. Reflex and mental perception assessment using user interaction exercises to evaluate the reaction time, accuracy of movement and providing complemental assessment of patient.

Keywords: Parkinson's Disease, mobile system, clinical trials, patient state evaluation.

Introduction

Parkinson's disease is an uncurable brain disorder that touches mostly people over 50 years old (Gelb et al. (1999)). Due to its long-term character and constant progression it is essential to discover and test new therapies that will minimize the influence of symptoms in treated patients to allow them to live without unpleasant limitations. All of the newly proposed therapies and medications must undergo the process of clinical trials in order to verify the positive influence of that treatment and to discover potential side effects. The treatment is compared with results from previously used therapies and placebo. At the time of the trials it is essential to strictly follow the schedule of medicine intakes and to monitor the state of the patient as frequently as possible. Usually the patient reports the daily effects and his health condition at the end of the day what leads to many errors and inaccuracies. Furthermore most of the evaluation is carried out by the patient, what may lead to subjectivity of submitted results.

This paper presents a complete system created to supervise clinical trials, focusing mostly on trials regarding Parkinson's disease, minimizing the involvement of the doctor or the supervisor. The presented solution consists of a mobile application which is provided on a mobile device for every patient and a web application dedicated for clinical trials management. Through the web application the supervisor can schedule all medicine intakes as well as state evaluation activities such as completion of the questionnaire (e. g. the MDS-UPDRS), which can be completed individually by the patient, but also with the presence of the examiner to increase accuracy. To decrease the subjectivity of state evaluation a number of tests have been designed to access the current condition of the patient, onboard sensors and sensor bands such as Thalmic Labs MYO are used to measure the tremor and rigidity the patient is experiencing.

The described system can be used for any type of clinical trials, its goal is to support the treatment providing the doctor all the acquired and analysed patient data with the discussed system in order to make appropriate decisions that will lead to greater comfort of the participating patients (Friedman et al. (2015)). Depending on the defined questionaries, provided symptoms recognition device and defined activities, the system can accordingly be dedicated to support the treatment of various types of diseases with expected scope. Designed methods for state evaluation of the patient have been created based on observations, medical consultations and discovery of symptoms that can be measured using wearable devices.

Research Background

Parkinson's disease is the degeneration of brain structures of unknown cause. The essence of Parkinson's disease is the atrophy of dopaminergic cells in the brain, what causes symptoms such as motor slowing down, muscle stiffness, resting tremor, gait and posture disorders, it usually as an asymmetric onset mentioned by Gelb et al. (1999). The definition of PD is also formulated as: a progressive disease of the extrapyramidal system consisting of the disappearance of substantia nigra cells producing dopamine and the presence of Lewy bodies on histopathological examination as mentioned by Poewe et al. (2017). It is a spontaneous, slowly progressive degenerative disease of the central nervous system.

Parkinson's disease is progressive, which means that the treatment needs to be adjusted over time to maintain the efficiency. In the first period, which lasts about 5 years, the response to dopamine treatment is very good. As the disease progresses the damage spreads to other areas of the brain and it becomes more difficult the keep the dopamine at the sufficient level. To make matters worse, after taking the medication, the symptoms do not go away quickly (patients sometimes think that it is the medication that harms them, because they have taken the pill and for 0.5-1 hours nothing improves). As the doses get larger the chance of the dopamine level exceeding the expected also increase. This may lead to additional movement disorders such as dyskinesias.

Levodopa is the main drug used in the pharmacotherapy of PD. It is an amino acid that can pass from blood to the brain and be converted into dopamine in the brain. Levodopa is rapidly degraded in the peripheral tissues before it reaches the brain; on the other hand, it is not possible to administer higher doses of the drug as this causes increased side effects what has been mentioned by Contin et al. (2010). The solution is to give a combined administration of the peripheral enzyme dopa-decarboxylase inhibitor levodopa, for example carbidopa or benserazide. The main complications of the use of levodopa are the so-called on-off syndromes characterized by the occurrence of significant hypokinesis when the drug concentration in the blood decreases, interspersed with hyperkinesis (involuntary movements) at the top of the dose (Direnfeld et al. (1978)). Another complication is the occurrence of mental disorders when using high doses of the drug.

To monitor the progression and evaluate the severity of the disease several rating scales have been proposed by Goetz et al. (2008). One of the most commonly used is a revision of UPDRS known as MDS-UPDRS. It is based on a completion of a questionnaire. The survey consists of four parts: Part I - Exceptional aspects of everyday activities skills), Part II - Movement aspects of everyday activities, Part III - Movement symptoms and Part IV – movement complications. The survey is designed to be completed by the patient as well as the examiner. Parts IA, III and IV are to be completed by the examiner in the presence of the patient (they provide instructions for the examiner and the patient) and sections IB and II can be completed individually by the patient. All of the parts require the severity evaluation of certain symptoms in the scale of 0 – Normal to 4 – Severe. These evaluations make up 56 scores of the survey, there are also 5 yes/no type questions. The survey is designed to be completed within 30 minutes and based on the provided answers the total score is calculated.

Architecture and technology stack

The system is built up of two application, the mobile application - IQPharma Clinical Trials Assistance and the web application – IQPharma Clinical Trials Server. They communicate and exchange data through the secure HTTP protocol (the REST API served by the web application).

The mobile application is developed for the mobile devices that use Android 4.4 or higher in Java 1.8. For data exchange with the web application the device must provide an Internet connection. To use external sensor platforms the device should support a specified communication standard such as Bluetooth or USB, depending on the device. The mobile application is the only access point to the system available to the patient participating in the trials. It include 9 main modules:

- Sensor examination module responsible for performing the patient state examinations using built in and external sensors connect via USB or Bluetooth,

- Questionnaire module, which manages the completion of the survey by the patient and the question flow,
- Communication module in charge of the communication with the web application, it manages sending patient data - completed examinations, surveys, exercises and other events from the application, it also gets data from the server such as clinical trials schedules, updates, information from the supervisor,
- Notification module organizing the push notifications and alerts sent from the application to inform the user about the need to complete a certain activity, it also consumes the push notifications received from Google Firebase Messaging,
- User interaction module which coordinates the interaction-based exercises the patient is obliged to complete during the trials for state evaluation,
- Medicine intake module, managing the reminders about necessary intakes of medicine,
- Administration module, available for the supervisor to specify settings and permissions for clinical trials and the application,
- Analysis and statistics module providing the basic analysis view based on registered signals, surveys and other patient activities as well as statistics regarding the patient's involvement in the trials,
- Settings module allowing the patient to define person related setting and update his profile.

The application uses Realm database to store local data and received schedules from the server. All of the activities do not require constant Internet connection, they are saved in the local database and once the Internet connection is established, they are persisted to the global database for the information and analysis performed by the clinical trials supervisor using the management portal.

The IQPharma CTA Trials Management Portal is an application built of two parts: frontend SPA (Single Page Application) built with Angular framework and the backend in Java developed using Spring Boot framework. The management portal is accessible only to medical supervisors to oversee the clinical trials. The application uses a PostgreSQL database and static files for storing sensor signals, the Google Firebase Messaging is used to instantly send notifications to the mobile app about changes in the schedule and other crucial messages. The application consists of the following modules:

- Schedule management module which allows for definition of new schedules for medicine intakes, surveys, exercises and other activities to be performed by the user. The created schedules can be modified using the module other activities can also be defined.
- Communication module responsible for the communication with mobile apps through Google Firebase Messaging,
- Analysis and statistics module which presents advanced analysis of the clinical trials and the results for every participating patient,
- Patient data module allowing to access and modify patient data,
- Messaging module organizing the communication between the patients and assigned supervisor,
- Data access module providing an interface to access and to modify data in the database and static files.

The relations between modules and communication between applications is presented on Fig. **1**.

Fig. 1: The architecture of IQPharma CTA system presenting two subsystem - IQPharma-CTA and IQPharma-CTS

Clinical trials assistance and tool composition

The assistance in clinical trials is provided by the system on multiply levels. First of all, it supports fast communication between the patient and the supervisor, allowing the patient to report any noticed problems instantly. The supervisor can assign a medicine intake schedule for every patient, at each intake time the patient is notified through the mobile device. It is also possible to schedule other events for the patient such as survey completion, which allows to keep track of the current condition. To keep track of the intensity of motor symptoms of the disease, sensor-based examinations and interaction tests have been defined, these enable the objective evaluation of the symptoms ignoring the subjective impression of the patient. The activities scheduled for the patient are time-constrained, they all must be completed at specified time and the patient is reminded of them by notifications shown on Fig 2.

Fig 2: The view of notifications generated by the application (left), the history of completed activities (middle) and the daily schedule of activities (right).

Medicine Intake Tracking

Building the schedule of medicine intakes requires to provide the dose size and specific times at which the intake should take place or the number of intakes during the day and the time of the first and last dose (the other dosages

will be planned during the day with equal time intervals). Provided this information the schedule is built and sent to mobile devices of the desired patient group. Once the medical trials start, every time the user is obliged to take the medication, he will be notified with a push notification and if the appropriate permission are provided also a remainder is displayed on the whole screen and an alert sound is played until the user performs one of the desired actions: confirms that the medicine has been taken, delays the reminder by 5 minutes or dismisses it, the remainder has been presented on Fig 3. In case of dismission or no reaction within 10 minutes the supervisor is instantly informed in order to apply adequate measures. The times of the reminder and the actual intake are sent to the web application for further analysis.

Daily questionnaires for well-being and symptoms evaluation

The system has an extensive support for questionnaires. It supports multiply answering formats: Yes/No, single choice, multiply choice, number and text answers. All of the questions should be defined through the management portal where they can be assigned to created clinical trials or specific patients. Just like in case of medicine intake the time of the survey can be defined in two ways. At the time of survey, a reminder is displayed which allows the user to complete it immediately or to delay it by 5 minutes. The number of questions and their order might change depending on the provided answers, the question flow is defined by the supervisor. The user can move between questions and return to a completed survey in order to correct the answers. Depending on the configuration the application may record the signals from selected sensors at the time of answering the questions. It might provide information about the state of the patient without his awareness.

For Parkinson's disease two different surveys have been implemented: short survey consisting of questions regarding the current state of the patient and the dyskinesis and the MDS-UPDRS survey which has proven to give a good evaluation of the disease progression collecting the data regarding the last week. The MDS-UPDRS survey has been implemented in two modes one of them requires the presence of the examiner, who answers the questions based on the responses of the patient and a version to be completed just by the patient (example questions are provided on Fig 4. and Fig 5). Every completed survey is sent to the management portal where the supervisor can view the overall score, the answers and sensor signal analysis, if the data is collected.

Fig 3. Medicine intake reminder in IQPharma-CTA

Fig 4. Question 1.7 from the MDS-UPDRS survey displayed in IQPharma-CTA

Fig 5. Question 2.1 from the MDS-UPDRS survey displayed in IQPharma-CTA

Sensor Examinations

In order to objectively evaluate the state of patients, especially their motor symptoms, a set of sensors built into the mobile device have been selected to register the signal (LeMoyne et al. (2014)). If the user is equipped with an external sensor device with Bluetooth connectivity, such as MYO armband, it can be used to register the signals too. The sensors selected for motor symptoms of Parkinson's disease include: accelerometer, gyroscope, magnetometer and electromyograph (Rigas et al. (2012)). Each of the signal component presented in Table 1 plus the calculated magnitude are collected at a constant frequency, saved and sent to the server for analysis.

Table 1: The sensors available on different platforms with their signal components and sampling frequencies

	Accelerometer (50 Hz)	Gyroscope (50 Hz)	Magnetometer (50 Hz)	Electromyograph (200 Hz)
Mobile device	3 channels - X,Y,Z	3 channels - X,Y,Z	3 channels - X,Y,Z	n/a
MYO arm band	3 channels - X,Y,Z	3 channels - X,Y,Z	n/a	8 channels - E1, E2, E3, E4, E5, E6, E7, E8

The examination using the sensors is performed at times specified by the supervisor through the management portal. The supervisor can specify the duration of the examination, used sensors and also the limb used for the examination. At the specified time the patient is notified and asked to complete the examination. Once the examination is complete, the sensor signals undergo processing using low-pass and high-pass filters in order to remove the noise and gravity (accelerometer signal) components. The filtered signal is then used to calculate time and frequency domain parameters that give an overview of the signal characteristics. The list of used parameters is described by Gutowski et al. (2020). The signal analysis results can be viewed in the management portal as well as in the mobile application in administrator view what is presented on Fig. **6**. and Fig. **7**.

Fig. 6: Sensor signal visualisation in the management portal for electromyograph and accelerometer

Fig. 7: Sensor signal analysis visible in the administrator mode of the mobile application for accelerometer

Evaluation of motor skills and reflexes using user interaction tests

The user interaction test is designed to measure the reflex, reaction time of the patient and their mental condition, it corresponds directly to the third part of the MDS-UPDRS survey. Every time the patient agrees to taking the test, he is provided with a set of six exercises to complete. The first two exercises focus on gaining as many points as possible, the third and fourth need to be completed in minimum time, the last two exercises measure the precision of movement. Throughout the whole test, the remaining time, number of points and mean reaction time are displayed.

The first exercise requires the patient to perform as many clicks as possible within the restricted area in 30 seconds. For every click the number of points is increased and timespan between clicks is registered. The second exercise is presented on Fig 8., the screen is split into 25 squares and every time an area is highlighted the patient must click it as quickly as possible. After each correct click another square is highlighted (within 250 ms) until the end of time. To complete the third and fourth exercise the user must click on the squares too, but each of the squares has a number displayed in the middle, the goal is to click them in ascending order. In exercise 3 all of the correctly picked squares are highlighted, in the fourth exercise only the last correctly clicked is, it is more difficult to find the next number. For every attempt with exercise 5 a drawing with a path is displayed, Fig **9**. presents an example. The user must follow the path while touching the screen. The distance for every crucial point is calculated between the original and the path drawn by the patient. The last exercise focuses on analysing the handwriting, the patient must write 6 words (3 consisting of 3 letters and 3 consisting of 4 letters) using block lettering on the screen, what is presented on Fig 10. The writing is then recognized and based on the number of recognized letters the score is calculated.

Fig 8. Second exercise with a highlighted square.

Fig 9. Fifth exercise presenting the pattern path (blue) along with the path drawn by the user (red).

Fig 10. Sixth exercise presenting the recognition of handwritten words.

The total number of points is calculated with the following equation:

$$P = \left(\frac{220 - p_{e1}}{n_{e1}} + \frac{75 - p_{e2}}{n_{e2}} + \frac{t_{e3} - 15}{n_{e3}} - \frac{t_{e4} - 20}{n_{e4}} + \frac{\sum_{i=0}^{n_{e5}} d_i}{6n_{e5}} + \frac{21 - p_{e6}}{n_{e6}}\right) \cdot 100 \qquad (1)$$

Where n_{e1}, n_{e2}, n_{e3}, n_{e4}, n_{e6} are the normalization factors with the following default values: $n_{e1} = 1320$, $n_{e2} = 450$, $n_{e3} = 450$, $n_{e4} = 420$, $n_{e6} = 126$.

Table 2: The definition of symbols used in the equation and the ranges of their values

Symbol	Definition	Value range
P	total number of points	[0,100]
p_{e1}	number of performed click (collected points) during the first exercise	[0,250]
p_{e2}	number of correctly clicked squares (collected points) during the second exercise	[0,75]
t_{e3}	time in seconds required to sort the squares with maximum time of 90 seconds (third exercise)	[0,75]
t_{e4}	time in seconds required to sort the squares with maximum time of 90 seconds (fourth exercise)	[0,70]
d_i	normalized value of distance between the i-th crucial point in the pattern path and the i-th crucial point in the pattern drawn by the patient (fifth exercise)	[0,1]
n_{e5}	number of crucial points for the path (fifth exercise)	[1,20]
p_{e6}	number of letters correctly recognized in the words written by the patient (sixth exercise)	[0,21]

Each of the values presented in Table 2 has an assigned value range, if the value acquired from the exercise exceeds the maximum value, it is rounded to the maximum value. The higher the total number of points (P) the more severe the motor symptoms are for the patient. The provided scale does not allow to diagnose the patient with Parkinson's disease, users without any disorders might still receive a significant score. The goal of the exercises is to evaluate the current condition of the patient in reference to other patients and his previous condition to keep track of the progression of the disease and to verify medication effects. Example score values received by a healthy patient are presented below, they provide the total score of 19.1:

$p_{e1} = 197$, $p_{e2} = 56$, $t_{e3} = 37$, $t_{e4} = 41$, $\sum_{i=0}^{n_{e5}} d_i = 1.8$, $n_{e5} = 12$, $p_{e6} = 20$.

Tool Application Methodology

The process of tool application starts at the management portal where the supervisor defines the clinical trials providing the basic information including the name, aim, description, assigned supervisors, doctors, start and end date. The next two steps include assigning patients to the trials, and definition of activities that the patients will be required to perform to allow evaluation of their state. Assigning patients to the clinical trials can be performed in marked groups not visible to the patients (e.g. patients taking levodopa and patients taking placebo). They are two ways of assigning the patient to the trials: If the patient already has an account he just needs to be signed up for the trials, otherwise an account must be created either through the mobile application by the patient or through the management portal by the administrator.

The supervisor can create custom sensor measurements selecting the sensors, their sampling frequency (not higher than the maximum supported by the sensor), parameters that will be calculated based on the signal, the duration of every examination. A user guide for every examination type can also be defined. As described before, a custom survey can be defined with a formulae to calculate the points, exercises for the users and also medicine intake reminders. The created schedule is time-constrained, every activity is assigned to indicated time and every activity completion, delay or dismissal is saved and known to the supervisor. The schedule defined at the level of clinical trials can be overridden at the level of chosen group or patient. Once the schedules and the patients are assigned, the system awaits for the starting time of the trials, then the supervisors and the patients receive a reminder. During the trials the patients are requested to complete specific activities and report their state at defined times, the supervisor is informed about the progress of the trials and at any time of the trials can view the data that has already been collected and conduct analysis.

CTA supported clinical trials evaluation tests

In order to evaluate the capability of supporting clinical trials by the system several tests have been conducted. The first test was to check the approachability and the speed of survey completion in reference to the traditional manual approach presented on Fig. **11**. The test proved the completion of survey using the application was faster and simpler, however the limited area on the screen made it impossible to view all the instructions and answers at once using a font visible for older people with presbyopia, what is not the case when using the printed copy. The completion of the survey in conventional form requires the presence of the patient and the supervisor at the same time whereas the application allows for individual questionnaire completion by the patient and the supervisor, providing the possibility of more frequent surveying.

Another test included the detection of tremor in Parkinson's disease using the internal sensors as well as MYO Armband in reference to the Leap Motion controller which uses infrared cameras to track the movement of palms shown on Fig. **12**. The Leap Motion controller has proven to provide more precise values regarding the tremor than sensors in the mobile device and in the armband, unfortunately the controller was prone to losing the detected position of hands, in case of intensive tremor, this was not the case for the armband and mobile device. The parameter values registered with the mobile device were more representative than the ones from the armband, the reason for this is the fact that the palm experiences a higher amplitude tremor than forearms, where the band was placed.

Fig. 11: Manual completion of the MDS-UPDRS survey by the supervisor

Fig. 12: Sensor based examination using Leap Motion controller as an alternative tremor recognition sensor

Conclusions

Providing objective methods for clinical trials is a crucial and demanding task that needs to be conducted in order to achieve objective assessment of pharmaceutical treatment tailored to the needs of the patient. The management over the trials is time and resource consuming it also requires taking additional precautions to make sure the results are objective and accurate. The tool provides a solution for continuous monitoring of trials and objective evaluation of patient's condition during composed clinically sound treatment. IQPharma CTA is based on time-constrained activities performed by the patient, at the time and frequency planned and requested by the trials' supervisor. The application keeps track of any medical events, occurring inconveniences supplemented with possible patient's actions delays while monitoring the trials progress. Constructed application is dedicated for effective, remote, autonomous monitoring neurological disorders and in particular Parkinson's disease providing methods of symptom intensity evaluation. The novelty of the tool comes from the composition of surveying supplemented by biomedical monitoring as well as human interaction testing, providing new means of identifying tremor, bradykinesias, rigidness and other movement related symptoms of neurological disorders. The discussed solution has been tested against traditional surveying method of state evaluation and has proven to require less time for configuration, remote management and execution of CTs as well as to provide more frequent and accurate state evaluation but most of all delivering quantitative algorithms for symptoms intensity evaluation therefore ON/OFF state recognition. This directly leads to higher reliability and accuracy of medical trials evaluation and in the end better quality of the process.

Acknowledgment

This work was partially financed by EU funded grant PBU 01-087 IQ-Pharma Clinical Trials Assistant, that concentrates on biomedical sensor data acquisition and processing medical surveys in relation to recorded biomedical sensor data in order to evaluate the effectiveness of pharmaceutical treatment.

Abstract

The goal of the paper is to critically assess the current solutions in the field of disclosure of components of comprehensive income in financial statements and to develop a proposal for the structure of the statement of comprehensive income that will improve its usefulness.
Based on the literature studies and the results of previous empirical research on comprehensive income reporting, the authors of the paper formulated the following thesis: The principles of disclosing comprehensive income in accordance with the law do not provide optimal information about the financial effects of the entity's operations.
The paper is structured as follows. Section 1 presents the outline the concepts of comprehensive income reporting. In Section 2 we describe our idea of disclosure of comprehensive income. Section 3 includes our empirical research and application of a new concept of the statement of comprehensive income in practice. The last section contains final comments on the use of the new concept of the statement of CI in assessing the company's profitability. Our proposal will contribute to the increased transparency of the statement of comprehensive income and will help the users of financial statements in proper understanding of the significance of comprehensive income and other comprehensive income. The proposed structure of the statement of comprehensive income is also intended to assist users in interpreting the ratios calculated on its basis.

Keywords: Comprehensive Income, Net Income

Introduction

Profit (or loss) is one of the most important economic categories used to assess the financial position of an entity and its management. The rules for its presentation in the financial statements are set out in accounting standards which have been subject to quite large changes in recent years. Since 2009, the companies listed on regulated markets in the European Union have been required to present total comprehensive income (CI) and its components in the comprehensive income statement prepared under International Financial Reporting Standards (IFRS). It is the result of a joint agreement between the International Accounting Standards Board (IASB) and Financial Accounting Standards Board (FASB) to take into account the information needs of investors and other capital 'providers'. This statement is also the result of adopting a new concept of presenting information on the overall result - comprehensive income, not only profit and loss.

This solution has good points, but there are also negative effects, particularly concerned with difficult interpretation of dates about the other comprehensive income in respect of profitability.

The goal of the paper is to:

- critically assess the current solutions in the field of disclosure of components of comprehensive income in financial statements,
- develop a proposal for the structure of the statement of comprehensive income that will improve its usefulness.

The paper has been based on literature review, analysis and interpretation of International Accounting Standard 1 (IAS 1), and a review of financial statements. We used the financial statements of a selected company listed on the Warsaw Stock Exchange prepared for 2019 according to IFRS. We applied the method of content analysis, synthesis and deductive inference.

Cite this Article as: Marzena REMLEIN and Małgorzata RÓWIŃSKA-KRÁĽ " The Statement of Comprehensive Income – A New Disclosure Concept" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The paper is structured as follows. Section 1 presents the outline the concepts of comprehensive income reporting. In Section 2 we describe our idea of disclosure of comprehensive income. Section 3 includes our empirical research and application of a new concept of the statement of comprehensive income in practice. The last section contains final comments on the use of the new concept of the statement of CI in assessing the company's profitability.

Outline of the concepts of comprehensive income reporting

The concept of comprehensive income (CI) involves the necessity to include in the financial result of the entity also events that were previously recognized in equity. This results directly from the definition of comprehensive income in IAS 1, according to which total comprehensive income is the change in equity during a period resulting from transactions and other events, other than those changes resulting from transactions with owners in their capacity as owners (IAS 1.7). According to IFRS total comprehensive income is a new measure for assessing an entity's performance in the reporting period. It includes components such as:

- profit and loss as the entity's financial result calculated in the traditional profit and loss account,
- other comprehensive income so far disclosed in equity.

The comprehensive income formula is as following:

$$CI = I_n + OCI_n$$

CI – comprehensive income,
I_n - net income (profit/loss),
OCI_n - other comprehensive income.

Other comprehensive income includes income and expense that other IFRS specifically exclude from profit and loss account. The financial result established in the profit and loss account and its structure indicate the profitability realized in a given period. Other comprehensive income provides information on potential profits or losses which the unit will realize in subsequent periods and which have already caused changes in the revaluation reserve for the current period. For this reason, when evaluating the financial condition of an economic entity, it is necessary to take into consideration also the increase in equity capital understood as the „global" result of the entity.

The issue of reporting of comprehensive income is still the subject of many discussions, studies and researches by both Polish and foreign scientists (eg. Szychta, 2010, s. 117-141; Walińska, 2009, s.335 - 348; Gierusz, Gawrońska, 2012, s. 29-46; Mechelli , Cimini, 2014; Poniatowska, Rówińska, 2018; Dehning & Ratliff 2004; Chambers et al., 2007;
As far as the benefits resulting from applying the concept of comprehensive income are concerned, it is the most frequently indicated that it provides a better insight into the ability of an entity to generate profits in the future (Kanagaretman et al., 2009); it constitutes a better evaluation of the value creation process and helps to forecast a company's ability to generate cash and its equivalents (Marchini & D'Este, 2015); it also minimizes the negative effects in connection with the phenomenon of active shaping of profits by managements resulting from transferring expenses (Chambers et al., 2007).

According to the concept of comprehensive income, the effects of the balance sheet valuation shape the effect of the entity's activity. However, there is a doubt as to whether disclosing them in the financial statements, they can be added to the result of real transactions?

Based on the literature studies and the results of previous empirical research on comprehensive income reporting, the authors of the paper formulated the following thesis: The principles of disclosing comprehensive income in accordance with the law do not provide optimal information about the financial effects of the entity's operations.
It is not our intention to discuss the advisability of disclosing comprehensive income. We can find some papers about it (Mironiuca, Huiana 2016, s.498; Du, Stevens, McEnroe, 2015; Gazzola, Amelio, 2014; Pascan, 2014; Luty, 2010; Szychta, 2011; Hodgson Russell, 2014; Kuzior, Rówińska, 2017). We would like to show that by presenting the structure of comprehensive income in a different way, stakeholders in financial statements get more useful information.

IAS 1 requires that all the items of income and expense be recognized in a period, i.e. the items comprising CI, be presented either:

- in a single statement of CI (hereinafter referred to as combined statement of CI), or
- in two statements: a statement displaying components of profit or loss (separate income statement) and a second statement beginning with profit or loss and displaying components of OCI (statement of CI) - hereinafter referred to as separate statement of CI.

According to IAS 1, an entity is free to choose the way of presenting costs and information on other comprehensive income. As a minimum, the statement of comprehensive income shall include line items that present the following amounts for the period (IAS 1. 82):

- revenue;
- finance costs;
- share of the profit or loss of associates and joint ventures accounted for using the equity method;
- tax expense;
- a single amount comprising the total of:
  - the post-tax profit or loss of discontinued operations and
  - the post-tax gain or loss recognized on the measurement to fair value less costs to sell or on the disposal of the assets or disposal group(s) constituting the discontinued operation;
- profit or loss;
- each component of other comprehensive income classified by nature;
- share of the other comprehensive income of associates and joint ventures accounted for using the equity method; and
- total comprehensive income.

New disclosure concept of comprehensive income

There should be noted that the total income is shaped by:

- the effects of completed transactions,
- effects of the valuation made as at the balance sheet date.

The methods and ways of valuation result from the accounting policy and the profit management policy adopted by the entity. The financial consequences of the performed balance sheet valuation only mean the potential profits or losses (revenues, costs) identified (but not yet realized) at the balance sheet date. We can call them virtual profits or losses because we don't know if and in what amount they will appear in the future. We call the effects of balance sheet valuation as unrealized profits or losses.

Our suggestion is to look at comprehensive income as the sum of the results of realized trades and unrealized profits or losses:

$$CI = ICT_n + IUT_n$$

ICT_n is the net income on completed transactions (realized profits or losses), IUT_n is the net income on unrealized transactions (unrealized profits or losses).

$$IUT_n = IUT_{nP/L} + IUT_{nE}$$

$IUT_{nP/L}$ are the effects of the valuation through profit or loss, IUT_{nE} are the effects of the valuation through equity.

$$CI = ICT_n + IUT_{nP/L} + IUT_{nE}$$

Comprehensive income is determined by the net values (after income tax). Profit or loss on completed transactions is the gross profit (or loss) less current income tax. While unrealized profits and losses are adjusted for deferred income tax.

$$CI = GP_{bT} \times (1 - TR_c) + (IUT_{P/L} + IUT_E) \times (1 - TR_d)$$

GP_{bT} is the gross profit (before income tax), $IUT_{P/L}$ are the effects of the valuation through profit or loss (gross value), IUT_E are the effects of the valuation through equity (gross value), TR_c is the current income tax rate, TR_d is the deferred income tax rate.

Following the presented formulas, we propose a change in the structure of the statement of comprehensive income:

A. Net profit (or loss) on completed transactions

Revenue (completed)
- Costs (completed)

- Tax expense

B. Net profit on unrealized transactions

Unrealized profits and losses through profit or loss
+ Unrealized profits and losses through equity
– Deferred income tax

Comprehensive income (A+B)

The consequence of the new disclosure concept of comprehensive income should be a change in the way of disclosing the financial results in the statement of financial position. We can notice some inconsistency in disclosures in the financial statements:

- the statement of comprehensive income discloses comprehensive income (net), including the net profit (or loss) and other comprehensive income (net),
- the statement of financial position (as part of equity) discloses net profit (or loss), while other comprehensive income is often disclosed as retained earnings.

Therefore, we propose to change the way of disclosing equity and liabilities in the statement of financial position to the following:

1. Equity including net profit (or loss) on completed transactions.
2. The effects of the valuation through:
    a. profit or loss,
    b. equity.
3. Liabilities[1].

The use of the proposed structure of the statement of comprehensive income and statement of financial position provides more clear and unambiguous information for stakeholders. It clearly shows the coherence of these two elements of the financial statement.

Research and Discussion

We examine the statement of comprehensive income of Mercator Medical S.A. covers the year 2019. The goal of the empirical research is to present the differences in the scope of disclosure of reporting information published by the Mercator Medical S.A. (in accordance with IAS 1) and our proposal. Thus, we will indicate the scope of their use by stakeholders.

Table 1 presents the elements shaping the comprehensive income of the examined company.

Tab. 1 : The structure of the statement of comprehensive income of the Mercator Medical S.A.

Specification	**Value (PLN thousand)**
Sales revenue of products and services	3 147
Sales revenue of goods and materials	271 237
Other operating revenue	1 303
Operating revenue	**275 687**
Operating costs	(40 937)
Value of sold goods and materials	(234 390)

[1] The statement of financial position is not the subject of this paper. More on the proposed structure of equity and liabilities in: Remlein M., Rówińska-Král' M. (2020), *Nowa perspektywa bilansu. Wartość poznawcza i analityczna – studium przypadku*, w: Zeszyty Teoretyczne Rachunkowości, nr 108 (164), pp. 151-166.

Other operating costs	(1 465)
Operating costs	**(276 792)**
Operating profit (or loss)	**(1 105)**
Financial revenur	7 776
Financial costs	(7 387)
Profit (or loss) before taxes	**(716)**
Current income tax	(1 039)
Deferred income tax	(98)
Net profit (or loss)	**(1 853)**
Other comprehensive income	(46)
Comprehensive income	**(1 899)**

Source: Mercator Medical S.A.

First of all, we used the content analysis of the notes to identify revenues and costs which are the effects of the valuation made as at the balance sheet date and which are unrealized profit or loss. Table 2 presents the results of our analysis.

Tab 2 : Financial effects of the valuation disclosed in the statement of comprehensive income of the Mercator Medical S.A.

Occurrences	Item of the statement of comprehensive income	Value (PLN thousand)
Reversal of the write-down of receivables	Other operating revenue	11
Reversal of inventories write-down	Other operating revenue	37
Write-down of receivables	Other operating costs	(88)
Inventories write-off	Other operating costs	(75)
Updating investment value	Financial costs	(3 650)
Valuation of financial instruments	Financial costs	(318)
Unrealized profits and losses through profit or loss		**(4 083)**
Exchange differences	Other comprehensive income	(46)
Unrealized profits and losses through equity		**(46)**

Source: authors' own elaboration on based Mercator Medical S.A.

The next step, we entered the above information to the form of the statement of comprehensive income we proposed (tab.3).

Tab. 3 : New concept of the statement of comprehensive income

Specification	Value (PLN thousand)
A. Net profit (or loss) on completed transactions	**2 328**
Sales revenue of products, goods and materials	274 384
Other revenues of completed transactions	9 031*
Costs of sold products, goods and materials	**(275 327)**
Other costs of completed transactions	(4 721)*
Current income tax	**(1 039)**

B. Net profit (or loss) on unrealized transactions	**(4 227)**
Unrealized profits and losses through profit or loss	**(4 083)**
Unrealized profits and losses through equity	(46)
Deferred income tax	(98)
Comprehensive income (A+B)	**(1 899)**

Source: authors' own elaboration on based Mercator Medical S.A.

The new concept of the statement of comprehensive income presents net profit on completed transactions. There is a positive situation for the company. In the statement of comprehensive income report according to IAS 1, the company had an operating loss. The final negative comprehensive income of the Mercator Medical S.A. is a consequence of the negative adjustments made in connection with the balance sheet valuation.

Usefulness of the new concept of the statement of CI in assessing the company's profitability

The separation of comprehensive income into completed and unrealized transactions is of great importance for investors as they can assess the real situation of the company. The use of the proposed structure of the statement of CI also makes it possible to enrich the financial analysis with indicators that do not appear in the "traditional" scope of the analysis, and provide relevant information for the stakeholders. We propose the following ratios to realistically assess the company's financial situation:

- share of unrealized profit (or loss) in comprehensive income (**IUT_n / CI**),
- share of realized profit (or loss) in comprehensive income (**ICT_n / CI**),
- share of unrealized profit (or loss) in equity (**IUT_n / E**),
- share of realized profit (or loss) in equity (**ICT_n / E**),
- ratio of unrealized profit (or loss) (**IUT_n / L**),
- ratio of realized profit (or loss) (**ICT_n / L**),
- share of realized profit (or loss) in unrealized profit (or loss) (**ICT_n / IUT_n**).

The first two ratios allow to assess the actual, real value of the income achieved in a period. Share of unrealized profit (or loss) in comprehensive income shows the portion of income for a period that may or may not become future income. The next two ratios show the relation of profit or loss (realized and unrealized) in relation to equity. The good financial standing of the company is evidenced by the high share of realized profit in equity. In the next step we relate realized and unrealized profit (or loss) to liabilities. In our opinion the most important is the last one "share of realized profit (or loss) in unrealized profit (or loss)" which should be as high as possible.

The presented ratios provide additional information for the stakeholders, which in our opinion is extremely important information. They indicate the role and significance of the realized profit (or loss) and present also the influence of the applied principles of balance sheet valuation on the value of comprehensive income and equity.

The above-mentioned possibilities offered by the proposed concept of the structure of the statement of comprehensive income make it more useful and clear for each group of stakeholders. It also allows for a more detailed approach to profitability research (assets, equity, sales).

The concept of comprehensive income contained in IFRS and the possibility of "controlling" the financial result (through balance sheet valuation) introduced chaos to the profitability analysis. We ask questions:

1) should the benchmark in assessing profitability be comprehensive income or (traditionally) net profit (or loss)?
2) And if the net profit (or loss), do the results of the balance sheet valuation (depending on the adopted accounting policy) describe company's profitability?

In our opinion, for the purposes of profitability analysis, information about profit (or loss) on completed transactions should be used. It is especially important when, using profitability ratios, we want to compare the financial situation of various entities using different balance sheet valuation models.

Analysing the statement of comprehensive income of Mercator Medical S.A. we can see that the examined company has net loss and negative value of comprehensive income (Table 1). Seemingly, it indicates the company's deficit. Using the proposed structure of the statement of comprehensive income (Table 3), we clearly find out a net profit on completed transactions, which proves the company's profitability. A loss on unrealized transactions should not be viewed negatively. It may indicate the application of the earnings management policy (accounting policy) which uses to a large extent the prudence principle. The loss on unrealized transactions, shown in the financial statements, is only a "virtual" loss, not yet incurred, which will not necessarily be incurred in the future. In our opinion information about the profit or loss on unrealized transactions should not be considered when assessing the Company's profitability.

Conclusions

There is no conceptual basis for when an item should be included in other comprehensive income and when in profit and loss account. Vast majority of companies presents profit and loss account and other comprehensive income as separate statements. The reason is that other comprehensive income is still mostly ignored by investors and other users outside accounting and financial reporting. Companies are afraid that presenting profit or loss and other comprehensive income in one report would make a net profit a subtotal in arriving at the total comprehensive income.

It should be noted that the great freedom afforded by IAS 1 and the lack of a uniform template for the statement of comprehensive income encourage the search for ready-made solutions. It is visible that this document is prepared according to the templates published by recognized audit and consulting companies. We notice this gap and undertake to fill it with a proposal for a new concept of comprehensive income report. The most important is the separate disclosure of completed transactions (realized profits or losses) and unrealized transactions (unrealized profits or losses).

This division is of great importance for investors as they can assess the real situation of the company. Thus, our concept is relevant to both accounting theory and economic practice.

We hope our proposal will contribute to the increased transparency of the statement of comprehensive income and will help the users of financial statements in proper understanding of the significance of comprehensive income and other comprehensive income. The proposed structure of the statement of comprehensive income is also intended to assist users in interpreting the ratios calculated on its basis. The proposed structure of the statement of comprehensive income is also intended to assist users in interpreting the ratios calculated on its basis. Those issues will be the subject of authors' future empirical research.

Abstract

Ce papier a pour but de résoudre le problème de prélèvement et de collectes de tubes sanguins et/ou urinaires des personnes malades à domicile via un staff médical (infirmier/aide-soignant) depuis le laboratoire d'une façon optimale. Pour assurer une bonne gestion, plusieurs contraintes doivent être prises en compte à savoir : horaires du staff, préférences des patients, la durée maximale de retard d'un prélèvement sanguin… Ce problème s'intègre sous le problème de tournée de véhicule avec fenêtre de temps, préférence et priorité selon les cas urgents. Nous avons proposé tous d'abord une formulation mathématique du problème considérées en utilisant les méthodes de programmation linéaires variables à nombres entiers (MILP) ainsi que différents méta-heuristiques. Pour les résultats, nous avons appliqués une instance réelle d'un laboratoire au Maroc (Témara) nommée Laboratoire **BioGuich** afin de sélectionner la méthode donnant les résultats les plus optimales.

Mot clés : Méta-heuristiques, Problème de tournée de véhicules, Allocation et Planification, Soins à domicile.

Introduction

Depuis une vingtaine d'année, la population du Maroc a grimpé d'une dizaine de millions de personnes selon le recensement de 2014 estimant une hausse considérable du taux du vieillissement impliquant une hausse de nombres de malades de maladies chroniques nécessitants des traitement et des prélèvements périodiques afin d'assurer le suivi médicale adéquat. Cela à changer la philosophie de faire les choses incitant les structures médicales (hôpitaux, laboratoires…) à diversifier leurs services et ainsi à se déplacer d'eux-mêmes afin d'assurer les soins et prélèvements nécessaires pour les patients.

Cet article traite plus spécifiquement le problème d'acheminement et de routage des véhicules et des équipes de soins à domicile où les prélèvements sont faits durant un intervalle de temps bien précis et chaque type de prélèvements doit être effectués par un soignant qualifié.

Etat de l'art

Dans le cadre des services de prélèvements médicale à domiciles, l'enjeu de la logistique touchent plusieurs points à savoir le problème d'allocation et de planification ainsi que le problème de ramassage et de livraison.

Dans le travail de Fahle (2001), Begur et al (1997) et Akjiratikarl et al (2007), les auteurs ont considérés la planification et l'acheminement des soignants (infirmiers(ères)) à domicile et ont développés un système d'aide à la décision spatiale. Pour cela, une heuristique a été réalisée pour construire des routes pour chaque infirmier(ère) en se limitant à la contrainte d'indisponibilité du personnels et aide soignants. Un autre aspect du problème a été introduit par Rousseau et al (2013) qui a proposé une variante du problème Dial-a-Ride où une équipe de soignant est envoyés au parallèle au malade afin de réaliser un service requis avant le service principale (soins/prélèvements sanguins…) tel que le lavage complet du malade, changement d'habit, mesure de tension artérielle, prises de

pilules…Cela nécessite une coordination entre les différents acteurs (soignants, infirmiers(ères)…) pour réaliser ces services d'une façon optimale. Ce même auteur a souligné sur l'importance des contraintes de synchronisations qui permettent de mettre le trait sur l'aspect prioritaires des visites.

Liu et al (2013) ont abordé un problème d'ordonnancement des véhicules rencontré dans la logistique des soins à domicile. Il s'agit de fournir aux patients des dispositifs médicaux de la pharmacie et des médicaments de l'entreprise de soins à domicile, de livrer des médicaments spéciaux d'un hôpital aux patients et de collecter des échantillons biologiques et des médicaments non utilisés et des dispositifs médicaux pour les patients. Le problème peut être vu comme un problème particulier d'acheminement des véhicules avec des livraisons simultanées, de ramassage et de fenêtre de temps, avec quatre types d'exigences: livraison depuis le dépôt vers le patient, livraison depuis un hôpital vers le patient, ramassage depuis l'emplacement du patient vers le dépôt et ramassage depuis l'emplacement d'un patient vers un laboratoire médical. Dans le cas où le patient a besoin de médicaments fournis par l'hôpital, le véhicule doit d'abord visiter ce dernier. Deux modèles de programmation mixtes ont été proposés avec un algorithme génétique (GA) et une méthode de recherche taboue (TS). L'algorithme génétique est basé sur un chromosome de permutation, une procédure de division et d'une recherche locale. Les attributs d'attribution de routes pour les patients constituent l'élément de base de la méthode de recherche taboue. Ces approches sont testées sur des cas de test à partir de benchmarks VRPTW existants.

Présentation Du Problème

Le problème traité sous cet article entre dans le cas du problème de tournée de véhicules avec les contraintes de fenêtres de temps, synchronisation et priorité.

Supposons V l'ensemble de services demandés et V1 le sous-ensemble des demandes à horaires fixes et V2 le sous-ensemble des demandes à horaires variables. Chaque demande i est caractérisée par une location (domicile du patient) et une plage horaire [ai, bi] où chaque soignant (travailleur) est contraint de prélever et/ou collecter l'échantillon (tube sanguins/urinaires…).

Soit ei l'estimation du temps d'exécution requis pour la collecte d'échantillons. Au cas où un service requis a été réalisé par une entité externe, un cout ci considéré. Pour des tests spécifiques où il est impérative de prélever/collecter un échantillon, sa durée ne doit pas dépasser une durée maximale entre la collecte et la réalisation du test au sein du laboratoire et est affilié un variable Dmaxi, quoi que ce soit le test devient inutile. En générale, quand les prélèvements sont réalisés, il est nécessaire que les tubes arrivent dans un délai ne dépassant pas 90 minutes au laboratoire, quant à la collecte, ils sont assurées par des véhicules gérés par le laboratoire lui-même qui roulent en continus afin de ramasser les tubes à travers le champs géographique où le laboratoire réalise ses services. Ces échantillons critiques sont estimés à 30% des tests globales réalisés par le laboratoire en question, c'est pour cela que le laboratoire à déléguer cette tâche à une équipe spécialement conçus pour cela et qui se déplace que pour ce genre de cas. Le laboratoire en question a plusieurs points de collecte qui ont été mis en disposition où les infirmier(ères) après avoir réalisés un prélèvement peuvent déposer leur échantillonnages pour se libérer à d'autres patients attendant de recevoir un service similaire soit de prélèvements ou de collectes et qui aura pour but de gagner du temps afin de minimiser le cout de déplacement(aller/retour) du laboratoire vers les domiciles des patients et vice-versa.

Pour généraliser et simplifier le problème, nous avons considérés un planning de travail journalier.

Dans cet article, le but principale est de trouver un ensemble de routes possibles pour acheminer les tubes sanguins/urinaires depuis le laboratoire ver les domiciles des patients (demandeurs de services) et vice-versa d'une façon optimale. Pour cela, on va suivre un plan comme suit :

- Proposer une formulation mathématique du problème considéré.
- Utiliser un solveur linéaire CPLEX afin de trouver un résultat exact du problème.
- Appliquer 2 algorithmes méta-heuristiques afin de trouver une solution approchée du problème.
- Appliquer ces techniques sur une instance réelle de laboratoire BioGuich pour un intervalle maximale d'une journée de travail.
- Comparer les différents résultats obtenus par les techniques appliquées.

Formulation Mathématiques

Plusieurs formulations mathématiques ont été proposées afin de modaliser ce type de problème. Dans cette section, on présentera une formulation connue pour sa simplicité qui a été introduit au début par Fisher et Jaikumar (1981). Notre modèle est défini par un graphe orientée $G = (V, E)$ où $V = N \cup D \cup C$ où N est l'ensemble des demandes de

prélèvement, D représente le point de départ et le point d'arrivé de chaque infirmière et finalement C dénote la combinaison laboratoire/point de collecte chacune spécifié par son temps de collecte en concordance avec son planning de transport. Le nœud 0 représente le laboratoire et chaque nœud $i \in V\{0\}$ représente un patient qui a besoin d'être prélever. Chaque arcs $(i,j) \epsilon E$ possede un poids d_{ij} qui représente la durée de déplacement des véhicules du laboratoire au domicile du patient. Le durée requis pour charger un point de collecte en entier est notée $partd_i$. Un ensemble M des infirmières est disponible pour asservir toutes les demandes. Les infirmières sont dénotées par l'index k tel quek $\in$ M, et sont caractérisées par un planning de travail (STa_k pour l'heure de début et End_k pour la fin), un point de départ H_k généralement le laboratoire et un point final B_k soit un point de collecte ou le laboratoire. On introduit aussi le paramètre SV qui représente un nombre réel et un indicateur LT_i pour chaque demande i qui prend la valeur booléenne 1 si le test est critique et 0 sinon. Dans le cas du laboratoire dont l'étude est concernée, le laboratoire ne possède qu'un seul point de collecte. Ce modèle nécessites des variables de décisions binaires n^2K soit x_{ijk} et des variables nK soit y_{ik} tel que :

$$\boldsymbol{Min}\ \left(\sum_{i\in N_1} C_i\left(1-\sum_{k\in M}\ \sum_{j\in V/i\neq j} x_{jik}\right)+\left(\sum_{k\in M}\ \sum_{i\in V}\ \sum_{j\in V/i\neq j} d_{ij}.x_{ijk}\right)\right) \quad \textbf{(1)}$$

Subject to:

$$\forall i \in N : \sum_{k\in M}\ \sum_{j\in V/i\neq j} x_{jik} = \sum_{j\in V/i\neq j} x_{ijk} \quad \textbf{(2)}$$

$$\forall i \in V/D\ , \forall k \in M: \sum_{j\in V/i\neq j} x_{jik} = \sum_{j\in V/i\neq j} x_{ijk} \quad \textbf{(3)}$$

$$\forall k,k' \in M\ /\ k \neq k' : \sum_{i\in V/i\neq B_k} x_{iB_k k} = 1\ ;\ \sum_{i\in V/i\neq B_{k'}} x_{iB_{k'}k} = 0 \quad \textbf{(4)}$$

$$\forall k,k' \in M\ /\ k \neq k' : \sum_{i\in V/i\neq H_k} x_{H_k ik} = 1\ ;\ \sum_{i\in V/i\neq H_{k'}} x_{H_{k'}ik} = 0 \quad \textbf{(5)}$$

$$\forall k \in M : \sum_{i\in C} x_{H_k ik} = 0 \quad \textbf{(6)}$$

$$\forall i \in N, \forall k \in M\backslash b_i : \sum_{j\in V/i\neq j} x_{\mathrm{ijk}} = 0 \quad \textbf{(7)}$$

$$t_i + e_i + d_{ij} \leq t_j + \mathrm{SV}.(1-\sum_{k\epsilon M} x_{\mathrm{ijk}}) \quad \textbf{(8)}$$

$$\forall i \in N, \forall j \in C, \forall k \in M \quad t_i + e_i + d_{ij} \leq t_{jk} + \mathrm{SV}.(1-x_{\mathrm{ijk}}) \quad \textbf{(9)}$$

$$\forall i \in C, \forall j \in N, \forall k \in M,\ \ t_{ik} + td_i + d_{ij} \leq t_j + \mathrm{SV}.(1-x_{\mathrm{ijk}}) \quad \textbf{(10)}$$

$$\forall i \in N, \forall k \in M, \qquad x_{\mathrm{H_k}ik}.(ST a_{\mathrm{k}} + d_{\mathrm{H_k}i}) \leq t_i \quad \textbf{(11)}$$

$$\forall i \in N, \forall k \in M,$$

$$t_i + e_i + d_{i\mathrm{B_k}} \leq End_k + Ret_k + \mathrm{SV}.(1 - x_{\mathrm{ijk}}) \quad \textbf{(12)}$$

$$\forall i \in C, \forall k \in M, \quad t_{ik} + td_i + d_{i\mathrm{B_k}} \leq End_k + Ret_k + \mathrm{SV}.(1 - x_{\mathrm{ijk}}) \quad \textbf{(13)}$$

$$\forall k \in M, \qquad Ret_k \leq Max_{Ret_k} \quad \textbf{(14)}$$

$$\forall i \in N: a_i.\sum_{k\in M} \sum_{j\in V/i\neq j} x_{jik} \leq t_i \leq b_i + Lateness_i \quad \textbf{(15)}$$

$$\forall i \in N: t_i \leq \left(b_i + Max_{Lateness_i}\right).\sum_{k\in M} \sum_{j\in V/i\neq j} x_{jik} \quad \textbf{(16)}$$

$$\forall i \in N/LT_i = 1, \forall j \in C, \forall k \in M, \quad PT_j.drp_{ijk} - t_i \leq DMax_i \quad \textbf{(17)}$$

$$\forall i \in N/LT_i = 1, \forall j \in C, \forall k \in M, \quad t_{jk} \leq PT_j + SV(1 - drp_{ijk}) \quad \textbf{(18)}$$

$$\forall i, j \in V, \forall k \in M, \quad \mathrm{x}_{ijk} \in \left\{\begin{matrix} 1, si\ \mathrm{l'}infirmièrek\ traverse\ du\ noeud\ i\ au\ noeud\ j \\ 0\ sinon \end{matrix}\right\} \quad \textbf{(19)}$$

$\forall i \in N = \mathrm{N_1} \cup \mathrm{N_2}: \mathrm{t}_i$: *Heure d'arrivée au domicile du patient* **(20)**

$\forall i \in C, \forall k \in M: \mathrm{t}_{ik}$ *: Heure d'arrivée de l'infirmière k au point de collecte avec temps de collecte égale à* PT_j **(21)**

$$\forall i \in N/LT_i = 1, \forall j \in C, \forall k \in M: drp_{ijk} \in \left\{\begin{matrix} 1, si\ \mathrm{l'}infirmière\ est\ transportée\ au\ laboratoire \\ 0, sinon \end{matrix}\right\} \quad \textbf{(22)}$$

$\forall k \in M$:Ret_k *: Retard de l'infirmière k(Travail supplémentaires)* **(23)**

$\forall i \in N$:$Lateness_i$: *Retard de la demande i* **(24)**

La fonction objective(1) est de minimiser les retards tout en respectant les fenêtres de temps des patients et le planning horaires des infirmières charger de prélever et de collecter les tubes sanguins/urinaires ainsi que de minimiser la somme totales des distances parcourues. La contrainte(2) indique que chaque nœud ne peut être visité qu'une et une seule fois. La contrainte(3) assure la continuité des routes. Les contraintes(4), (5) et (6) sont mises en place pour définir les points de départ et arrivée de chacune des routes. La contrainte (7) spécifie les possibles préférences et exigences de certaines infirmières pour un patient. Les contraintes(8), (9) et (10) représentent la durée d'un voyage entre deux points. Le planning de travail est assuré par les contraintes(11), (12) et (13) tandis que les contraintes(14) et (15) définissent les fenêtres de temps de chaque demande établie par un patient. La contrainte(16) est spécialement élaborée afin de permettre les retards à condition qu'ils soient délimités. Pour finir, les contraintes(17) et (18) servent à démontrer que la durée écoulée entre la collecte d'un test critique et l'instant où il est testé dans le laboratoire ne doit pas dépasser une limite de tempsDMax_i. Les contraintes(19), (20), (21), (22), (23) et (24) définissent la nature des variables de décision.

Approche de résolution

Notre approche s'appuie sur la décomposition du problème en un problème de routage journalier. Dans un premier lieu, on va déterminer les routes pour chaque infirmière pour une journée de travail. Au début, on a considéré le planning pour une période vaste allant d'une semaine jusqu'à un moins, mais après une reconsidération et large réflexion on a trouvé que cette idée et non attractive et que ça complique le problème de planification vue le nombre de contraintes à considérer est grand. Pour remédier à cela, on a trouvé que la meilleure solution est de planifier les visites des infirmières en concordance avec les demandes des patients jour par jour et en faisant cela, on réussira à réaliser un équilibrage de charge.

Les expériences dont nous avons réalisées en utilisant le solveur linéaires CPLEX ont démontré une limitation et que nous ne pouvant arriver à des bon résultats que pour de petites instances. Le fait que le problème étudié dans ce papier sera appliqué sur une instance réelle et donc un cas pratique, les demandes ne feront qu'augmenter et pour cela que nous sommes dans l'obligation de trouver une autre approche qui satisfera les demandes des patients pour ainsi mieux gérer les déplacements des infirmières au patients concernés, ce qui nous amènent à trouver une approche plus persistante et plus adéquate tel que les méthodes approchées à savoir dans note cas les méta-heuristiques dont nous utiliserons deux méthodes ; l'algorithme de recherche taboue et l'algorithme de recherche à voisinage variable. Afin d'utiliser et d'appliquer ces deux algorithmes, nous devons tous d'abord définir la notion d'opérateurs de voisinage qui sont la base d'utilisation et sans ces opérateurs on sera dans l'incapacité de développer une solution à partir de ces deux méta-heuristiques.

Opérateurs de voisinages

Les algorithmes de recherche taboue et de recherche à voisinage variable sont basés sur deux types d'opérateurs de voisinages. Le premier type est l'opérateur d'insertion qui possède trois mouvement possible: - Une demande dont elle appartient déjà à une route peut être insérer dans une autre route, une demande sous-traité par une entité externe peut être insérer dans une route et finalement une demande appartenant à une route peut être enlevée d'une route et ajouter à l'ensemble des demandes sous sous-traitance.

Le deuxième type d'opérateur de voisinage est l'opérateur de permutation. Cet opérateur possède deux types de mouvement. Une demande appartenant à l'ensemble des demandes sous-traitées peut être échangé avec une demande appartenant à une route, le deuxième mouvement est qu'une demande appartenant au préalable à une route peut être échangées avec une autre demande appartenant à la même route ou à une différente route.

Algorithmes

Solutions Initiales

La première étape à considérer avant l'utilisation de chacune des deux méthodes introduit est de générées une première solution couramment appelé solution initiale. Cette solution est construites par insérer les demandes des patients dans les routes une par une au sein de la meilleur position possible, en prenant compte de leur priorité. Dans notre cas, la priorité est accordée aux demandes à horaires fixes en considérant les tailles des fenêtres de temps par ordre décroissant pour chaque visite d'un patient, tandis que les demandes à horaires variables, ils sont traitées par les nombres des jours restants jusqu'à la fin de leur fenêtre de temps spécifié. Si une demande n'est pas insérer, l'ensemble de ces demandes seront placées dans une liste des demandes reportées. Pour les demandes critiques, un point de collecte est inséré.

L'algorithme de Recherche Taboue

Cet algorithme suit une structure classique : à partir d'une solution initiale, l'algorithme se déplace de la solution courante à une autre solution on explorant le voisinage tout en évitant ceux qui sont actuellement taboues jusqu'à rencontrer la condition d'arrêt. Dans ce cas, on a opté d'utiliser le type d'opérateur d'insertion. L'algorithme en question utilise une liste taboue des demandes récemment déplacer. La condition d'arrêt utilisé dans ce cas est le nombre max d'itérations correspondant à la taille de la liste taboue.

L'algorithme de Recherche à voisinage variables :

VNS

Début
- $Sol_{mei} \longleftarrow$ Génération de solution initiale
- k $\longleftarrow$ 1
- Tant qu'un nombre prédéfini d'itération sans amélioration :
  - Répéter
    - S' $\longleftarrow$ Secouer en utilisant l'operateur kth et commencer depuis Sol_{mei}
    - S'' $\longleftarrow$ VNS^2 en commençant par S'
    - Si f(S'') < f (Sol_{mei}) alors
      - $Sol_{mei} \longleftarrow$ S''
      - k $\longleftarrow$ 1
    - Sinon
      - k $\longleftarrow$ k+1

Résultats Numériques :

Le laboratoire dont on va appliquer les algorithmes et méthodes décrits en dessus nous a fournis des instances réelles d'une semaine de travail à savoir une semaine de travail commencent le lundi et finis le vendredi dont la plage horaire de travail pour chaque jours d'étale de 8h00 à 18h00. Pour la généralisation du problème étudié, les temps de repos du personnel n'a pas été pris en compte et peut être l'objet d'un prochain travail comme perspective. On a générés deux groupes d'instances, le premier groupe est un ensemble relativement petit et simple composé de 10, 15 et 20 demandes, avec respectivement 6, 9 et 12 demandes à horaires fixes. Le nombre d'infirmières allouées pour ces demandes est généralement de 1 ou 2, et pas de point de collecte pour ce groupe d'instance (Pas de test critique). Cette petite instance est pratiquement ficelé pour la méthode exacte (MILP) afin d'obtenir une solution optimale pour pouvoir la comparer avec les résultats obtenues par les algorithmes heuristiques. Le deuxième groupes d'instances est obtenues par le laboratoire BioGuich pour des demandes réelles en cours d'une semaine de travail, le nombre de demande pour chaque journée varies généralement de 150 jusqu'à 200 dans la majorité des cas avec respectivement des demandes à horaires fixes de 90 jusqu'à 120. Nous avons optés à appliquer nos algorithmes pour les nombres de demandes de 150, 175 et 200 avec respectivement des demandes à horaires fixes de 90, 105 et 120. Pour les tests critiques, le pourcentage est environ de 20% (5 points de collectes) qui sera asservie et dépendra de la distance depuis le laboratoire, si le domicile du patient dont le prélèvement est considéré critique et jugé comme loin, l'infirmière dépose le test au point de collecte qui se charge de livrer le test au laboratoire dans un délai ne dépassant pas 90 minutes maximum, sinon l'infirmière elle-même se charge de déposer le test au laboratoire.

Les tests des méthodes étudiées dans ce papier ont été réalisées sur une machine 2.4 GHz Intel Core (TM) i7-5500 CPU avec 8GB de RAM, fonctionnant sous Windows 10 Home. Les codes ont été programmés en CPLEX Studio version 12.10 pour la formulation mathématique, et Python 3.8 pour les algorithmes heuristiques.

Table 1 : Résultats pour les petites instances

Instances			MILP	Heuristiques	
Patient	**Infirmière**	**Point de Collecte**	**% Optimale**	**Recherche Taboue (%)**	**Recherche à Voisinage Variables (%)**
10	1	0	100	100	80
15	1	0	100	80	60
15	2	0	100	60	40
20	1	0	100	70	50
20	2	0	100	20	30
10	1	1	100	80	90
15	1	1	50	90	70
15	2	1	20	80	20
20	1	1	0	90	90
20	2	1	0	100	100

Afin de mieux comprendre la Table I, chaque ligne représente un ensemble de 10 instances. Les trois premières colonnes représentent la taille de chaque instance et est composée du nombre de patients, le nombre d'infirmières et le point de collecte. La colonne MILP représente le pourcentage d'instances où le solveur linéaire CPLEX a trouvé une solution optimale. La durée maximale d'exécution a été limitée à une heure maximum. Dans le cas où CPLEX n'a pas trouvé de solution optimale, on utilise la meilleure solution trouvée après une heure d'exécution pour la comparer avec les résultats des algorithmes heuristiques. Les deux colonnes restantes indique la proportion d'instances où chaque algorithme à trouver une solution meilleur que celle trouvé par le solveur linéaires CPLEX. Comme il est clair, le solveur linéaires trouvent toujours des résultats optimales que celle des heuristiques à condition où le point de collecte n'est pas utilisé, mais lorsqu'un point de collecte entre en vigueur, les heuristiques arrivent à converger vers une solution meilleur que celle du solveur linéaire. Malgré la puissance des algorithmes heuristiques par rapport au solveur linéaire, cela ne prouvent pas que ces derniers ont pu trouver des solutions optimales.

En ce qui concerne la rapidité des algorithmes proposées, il est évident que l'algorithme de recherche taboué est clairement rapide que les autres, malgré cela la qualité des solutions produites par ce dernier sont inférieures.

Après avoir conduit plusieurs tests sur des petites instances, il a été déduit que les paramètres des valeurs stratégiques des algorithmes heuristiques sont comme suit : la taille de la liste taboue est fixée à 65% du total des nombres de demandes, et le nombre d'itération sans amélioration tout en respectant les meilleurs solutions a été fixé à 1000. Pour l'algorithme de recherche à voisinage variable, le nombre d'itérations maximales a été fixé à 500. Ces valeurs ont été choisies afin de pouvoir obtenir des résultats pour des instances réelles du problème étudiées dans un temps raisonnables.

Table II. Résultats

Instances			Recherche Taboue		Recherche à voisinage variable	
Patient	**Infirmière**	**Point de collectes**	**% du meilleur**	**CPU(ms)**	**% du meilleur**	**CPU(ms)**
150	10	5	0	1105	60	59562
150	15	5	40	2560	20	71056
150	20	5	70	3050	10	75487
175	10	5	0	1080	50	68154
175	15	5	0	1700	40	66213
175	20	5	50	4520	30	94054
200	10	5	0	2065	20	78456
200	15	5	20	2310	60	112289
200	20	5	30	7200	20	125394

La Table II montre les résultats obtenus par le groupe d'instances numéro 2, d'une semaine de travail dans le laboratoire BioGuich. Chaque ligne représente un ensemble de 10 instances. Les trois premières colonnes indiquent le nombre de patients, le nombre d'infirmières et le nombre de point de collecte. La colonne 4 et 6 démontre le pourcentage totale des instances pour lesquelles on trouve des solutions efficaces ce qui peut nous donner une idée sur quelle méthodes a donné les meilleurs résultats. Les colonnes 5 et 7 indiquent le temps d'exécution de chaque solution pour les deux algorithmes qui précisent que l'algorithme de recherche à voisinage variables est plus rapide que l'algorithme de recherche taboue tandis que pour la qualité des résultats obtenus, l'algorithme de recherche taboue donne des résultats meilleur que l'algorithme de recherche à voisinage variables.

Table III. Données du laboratoire d'une semaine de travail

	Lundi	**Mardi**	**Mercredi**	**Jeudi**	**Vendredi**
Nombres de demandes	164	145	158	128	106
Nombres de demandes à horaires fixes	128	85	108	94	72
Nombres de demandes critiques	36	24	30	26	18
Nombres d'infirmières	8	8	8	8	8

La Table III propose des détails sur une semaine de travail (Fin Septembre 2020) dans le laboratoire BioGuich avec un totale de 801 demandes exécutées par 8 infirmières au cours de la semaine.

Table IV : Résultat Recherche Taboue

Instances			**Recherche Taboue**			
Patient	**Infirmière**	**Point de collectes**	**Nombres de demandes sous-traitées**	**Nombres de demandes reportées**	**Total des retards**	**Distance totale parcourue**
150	10	5	8	49.3	308.5	1,389.4
150	15	5	4.2	5.8	208.4	2,178.9
150	20	5	2.9	1.2	23.5	1,487.6
175	10	5	18.5	61.6	352.8	1,356.2
175	15	5	3.2	23.8	315.4	2,487.9
175	20	5	4	2.9	81.6	2,154.3
200	10	5	28.4	74.1	295.7	1,348.4
200	15	5	5.2	42.6	367.1	2,259.1
200	20	5	3.5	6.2	236.9	2,478

Les Tables IV et V mettent en évidence les valeurs Objectives de chaque critère des algorithmes heuristiques étudiées dans ce papier.

Table V : Résultat Recherche à Voisinage Variable

Instances			**Recherche à Voisinage Variable**			
Patient	**Infirmière**	**Point de collectes**	**Nombres de demandes sous-traitées**	**Nombres de demandes reportées**	**Total des retards**	**Distance totale parcourue**
150	10	5	6.4	44.3	306.6	1,176.5
150	15	5	3.2	6.2	216.2	2,126.4
150	20	5	2.9	1.5	26.4	1,619.1
175	10	5	15.3	57.8	364.1	1,247.6
175	15	5	2.5	20.7	302.3	2,392.3
175	20	5	2.8	3.1	85.9	2,276
200	10	5	22.7	72.6	312.2	1,218.8
200	15	5	5.1	38.4	371	2,142.7
200	20	5	3.4	6.9	208.5	2,431.2

Conclusion et perspectives

Dans ce papier, nous avons étudiés un cas spécifique du problème de tournée de véhicules pour les prélèvements et la collecte d'échantillon sanguins/urinaires dans la ville de Témara situé au Maroc. Dans le cadre de cette études, le laboratoire BioGuich pour les analyses médicales depuis le début du confinement en mars 2020 due au COVID-19 au Maroc a ajouté le service de se déplacer vers les patients à leur domicile afin d'effectuer les prélèvements et collecte requis pour limiter les déplacements des patients. Pour cela, il s'est avérer nécessaires pour le laboratoire de mettre au point un système de logistique visant à optimiser les ressources pour une bonne gestion de ce service. Le fruit obtenues par cette études est le développement de deux méta-heuristiques pour optimiser et planifier du mieux possible les déplacements des infirmières afin d'asservir les demandes des patients qui ne cessent d'augmenter jour en jour. Cette études a pu faire gagner au laboratoire un temps considérable ainsi d'augmenter la traçabilité des échantillons collectés ce qui améliore la qualité des tests réalisés. Pour de futur travaux, il est nécessaires d'ajouter les contraintes humaines telle que les pauses des infirmières, instaurer un système de pénalité pour les tests en retard, affiner les routes disponibles afin de minimiser de plus en plus la durée des trajets.

Abstract

The educational research is effectively benefitting from the statistical techniques such as multiple regression which is a multivariate technique used to determine the correlation that may exist between a dependent variable and a combination of multiple predictor variables. This paper presents a multiple linear regression model to analyze the students' final grades in four mathematics courses and their correlation with the response variable, the CGPA. The outcome shows that students' performance in mathematics courses may affect their overall performance in a university degree program. Finally, the study recommends that universities and faculty are required to work hard towards adopting effective teaching methodologies for improving students' performance in mathematics.

Keywords*:* Multiple regression, CGPA, R-Square,

Introduction

Mathematics and Basic Science are an integral part of any engineering degree program. Mathematical technique models and reasoning are integral to most areas of engineering and the discipline depends on mathematics for many of its fundamental underpinnings [ACM (IEEE) CE2016]. Science provides us about the laws of the natural world and Mathematics helps us to establish relationships among different components [1]. Mathematics is used in Physics comprehensively, in graphics structurally and in engineering practically. Mathematical courses play a key role in the understanding and applications of engineering program. Enhancing student's academic enactment via Mathematical courses is one of the prime services for the academic community of higher education. Mathematical courses can develop intellectual maturity. Engineers are using Mathematics as a tool for solving numerous boundary value problems and optimization problems. According to the information by United States National Research Council (1989), simple skills of Mathematics and geometry are essential for almost all occupations. Tobias (1978) emphasized the importance of basic high school mathematics knowledge in the examinations required for recruitment in the public and private sectors.

Mathematics provides a language for working with ideas relevant to computer engineering, specific tools for analysis and verification, and a theoretical framework for understanding important ideas [ACM (IEEE) CE2016]. Mathematics and science courses considered as creating an overall style or ethos for a specific computer engineering degree program. [ACM (IEEE) CE2016]

The article presents a multiple linear regression model to analyses the student's final grade (CGPA) based on his/her grade in four Mathematical courses namely Calculus I, Calculus II, Linear algebra and Differential equations, in Engineering degree program. In the first level of Calculus, students are getting knowledge about limits, continuity, derivative and integration with application. In second level of Calculus, concept of Improper integral, functions of several variables, Multiple Integral, Polar curves, Sequence and Series has given to the students. In the course Linear Algebra students are learning Matrices and Determinant with applications, Eigenvalues and Eigen vectors, Analytic functions etc. The calculus and differential equations are required to support engineering material as communications theory, signals and systems, and analog electronics. The analysis of continuous functions is fundamental to all engineering programs [ACM IEEE CE2016]. Linear algebra is required for solving networks of equations describing voltage/current relationships in basic circuits and is used in engineering application areas such as computer graphics and robotics [ACM IEEE CE2016].

In this paper multiple regression analysis has been used as a technique to visualize the influence of Mathematical courses to the final grade of an engineering student. Multiple Regression is a set of techniques used to analyze the relationship between two or more independent variables and a dependent variable. Multiple linear regression is

defined as a multivariate technique for determining the correlation between a response variable Y and some combination of two or more predictor variables, X , [Montgomery and Peck (1982)], [Draper and Smith (1998)], [Tamhane and Dunlop (2000)], and [McClave and Sincich (2006)]. It can be used to analyze data from causal-comparative, correlational, or experimental research.

Multiple linear regression is one of the most widely used statistical techniques in educational research. It is regarded as the "Mother of All Statistical Techniques." Many colleges and universities develop regression models for predicting the GPA of incoming freshmen. The predicted GPA can then be used to make admission decisions. In addition, many researchers have studied the use of multiple linear regression in the field of educational research. The use of multiple linear regression has been studied by Shepard (1979) to determine the predictive validity of the California Entry Level Test (ELT). In [Draper and Smith (1998)], the use of multiple linear regression is illustrated in a prediction study of the candidate's aggregate performance in the G. C. E. examination.

A multiple linear regression model based on a number of independent (or predictor) variables X, X_1,.., X_k can be obtained by the method of least squares, and is given by the equation

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k + \varepsilon,$$

where Y = response variable, X =predictor variables, β_k = the population regression coefficients, and ε = a random error, Mendenhall, et al (1993), Draper and Smith (1998). Multiple linear regression allows for the simultaneous use of several independent (or predictor) variables, X, to explain the variation in the response variable Y. The fitted equation is given by

$$\hat{Y} = \hat{\beta}_0 + \hat{\beta}_1 X_1 + \hat{\beta}_2 X_2 + \ldots + \hat{\beta}_k X_k$$

where $\hat{Y}$ = predicted or fitted value and $\hat{\beta}$ = estimates of the population regression coefficients. The sum of squares of deviations (residuals) of the observed value of Y from its predicted or fitted value is given by

Multiple standard error of estimate measures the error in the predicted value of the dependent variable.

$$SE = \sqrt{\frac{\sum(Y-\hat{Y})^2}{n-(k+1)}}$$

Where:

Y is the observation.
$\hat{Y}$ is the value estimated from the regression equation.
n is the number of observations in the sample.
k is the number of independent variables.
SE is the standard error of estimate.

Methodology

In this resourceful experimental study, we observed the inference of Mathematical courses over the CGPA of a student in an engineering degree program. In this study marks obtained by 36 students' in four different mathematical courses and their CGPA has been analyzed via multiple regression method. Table 1 displays the marks obtained by 36 students in 4 Mathematical courses along with their CGPA.

Table 1: Marks and CGPA of students

N	$(X_1)^a$	$(X_2)^b$	$(X_3)^c$	$(X_4)^d$	CGPA (Y)

[d]: Differential Equations

The objective of this study was to develop an appropriate multiple linear regression model to relate the student's CGPA (considered as the dependent or response variable Y) to the student's scores in four Mathematical courses (considered as the independent or predictor variables X). It examined how well the scores in mathematical courses could be used to predict the student's GPA.

This study investigated the feasibility of the use of the four constraints namely X_1, X_2, X_3 and X_4 for 36 undergraduate students enrolled in engineering degree program in 4 mathematical courses. The multiple regression method is used to analyze the result. The following model was developed to find the expected CGPA.

$$\text{CGPA} = \left.\begin{array}{c} 0.033721493 + \\ (0.011278972 * X_1) + \\ (-0.004118305 * X_2) + \\ (0.022707756 * X_3) + \\ (0.010690464 * X_4) \end{array}\right\} \quad (1)$$

Table 2 shows the Regression statistics obtained from the data and Table 3 shows the standard error (SE) and regression coefficients.

Table 2: Regression Statistics

Regression Statistics	
Multiple R	0.913386647
R Square	0.834275167
Adjusted R Square	0.812891317
Standard Error	0.227941938
Observations	36

Table 3: Statistical Data

	Coefficients	*SE*	*t Stat*	*p*
X_1	0.01127897	0.00622	1.8148	0.079
X_2	-0.0041183	0.00882	-0.467	0.644
X_3	0.02270776	0.0083	2.7346	0.01
X_4	0.01069046	0.00715	1.4948	0.145

Table 4: Analysis of Variance

	df	*SS*	*MS*	*F*	*p*
Regression	4	8.108	2.027	39.014	1.1E-11
Residual	31	1.611	0.052		
Total	35	9.719			

Interpretation of the Results

a) From the Analysis of Variance table, we observe that the p-value is very small 1.1E-11. This implies that that the model estimated by the regression procedure is significant at an α -level of 0.05. Thus at least one of the regression coefficients is different from zero.

b) The p-values for the estimated coefficients of X_1 and X_3 are respectively 0.079 and 0.01, indicating that they are significantly related to Y. The p-value for X_2 is 0.644, indicating that it is probably not related to Y and the p-value for X_4 is 0.0145 indicating that it is less related to Y at an α -level of 0.05.

c) The R^2 value in the regression output indicates that only 83.4 % of the total variation of the Y values about their mean can be explained by the predictor variables used in the model. The adjusted R^2 value indicates that 81.3% of the total variation of the Y values about their mean can be explained 1 2 by the *k* predictor variables used in the model., As the values of R^2 and adjusted R^2 are not very different, it shows that at least one of the predictor variables contributes information for the prediction of Y.

d) The variance about the regression σ^2 of the dependent variables for any given set of the independent variables is estimated by the residual mean square (s^2) which is equal to ss(residual) divided by appropriate number of degrees of freedom. For our problem, we have, $s^2 = 0.051968$ and $s = 0.22796$
Since the 's' value is very small, it indicates thar the prediction is meticulous.

Figure 1

Figure 1 shows the regression plot of CGPA verses predicted CGPA. R value for this plot is 0.905387 which indicates the CGPA and Predicted CGPA are strongly related. R^2 value in this plot is 0.8197 which shows that the regression predictions fit the decisively.

Figure 2

Figure 2 shows the Normal probability plot. From the plot, we observe that there exists an approximately linear pattern. This indicates the consistency of the data with a normal distribution.

Figure 3

Figure 3 provides the predicted CGPA residual plot.

A residual plot **is** a graph that shows the residuals on the vertical axis and the independent variable on the horizontal axis. If the points in a residual plot are randomly dispersed around the horizontal axis, a linear regression model is appropriate for the data; otherwise, a non-linear model is more suitable [2]. This plot shows random pattern which is good fit for linear model

Conclusion

From the above analysis, it appears that our multiple regression model for predicting the student's CGPA is useful and adequate. The s value in the given study is very small which implies that at least one of the predictor variables contributes to the prediction of CGPA.

Extracting Knowledge from an Image: An Example of VAD Stroke Volume Calculation

Krzysztof MURAWSKI

Cybernetics Faculty, Military University of Technology, Warsaw, Poland
krzysztof.murawski@wat.edu.pl

Abstract

The paper presents the method of calculation of the blood stroke volume of Ventricular Assist Device (VAD). The method was developed for a pneumatic extracorporeal myocardial support pump, which was equipped with a miniature camera during the research. The aim of the publication is to show the method of "extraction of knowledge" from a 2D image showing the view from above of a multilayer flaccid diaphragm. The knowledge is being "extracted" during image processing and analysis, as well as during 3D modeling of the diaphragm shape. The result of the calculation is a three-dimensional view of the diaphragm and the value of the VAD stroke volume. The developed technique calculates the three-dimensional shape of the diaphragm and the blood stroke volume on the basis of only one image. This enables the stroke volume to be measured at any diaphragm position and at any time, and the frequency of the results is not less than 30 Hz. Basically it depends only on the time of image acquisition of a camera used. Experiments, during which the developed method was tested, have shown that image processing and analysis allows to "extract knowledge", from which it is possible to obtain a hitherto unknown stroke volume with an average measurement error not exceeding ±2 ml.

Keywords: Knowledge Acquisition, Stroke Volume, Image Processing.

Introduction

The problem of determining the shape of diaphragm assembly (multilayer flaccid diaphragm), Fig. 1, of the pneumatic extracorporeal Ventricular Assist Device (VAD), Fig. 2, was noticed by the author due to the research conducted by the Optoelectronics Department of the Silesian University of Technology within the "*Polish Artificial Heart*" program: Czak et al (2013), Gibinski et al (2011), Konieczny et al (2011), Kustosz et al (2013), Konieczny et al (2012), Opilski et al (2011), Konieczny et al (2013), Sobotnicki et al (2013), Pustelny et al (2013). After the completion of the program, the author conducted his own research works at the Military University of Technology, within which he attempted to calculate the blood stroke volume, using image processing and analysis. The result is a visual method of distance measurement Murawski (2014), Murawski (2015), Murawski et al (2016), which was used in the method of calculation of the shape of a multilayer flaccid diaphragm of the pneumatic extracorporeal Ventricular Assist Device, Murawski et al (2015), Murawski and Sulej (2018), Murawski et al (2018), Sulej, W. and Grad and Murawski (2017), Sulej and Murawski (2017), Sulej and Murawski (2018), Murawski et al (2018), Sulej et al (2017), Sulej and Murawski (2017), Sulej and Murawski (2018), Sulej et al (2018) and in the method of calculation of the stroke volume (*SV*), Murawski et al (2016), Sulej and Murawski (2017), Murawski et al (2018), Sulej et al (2018), Grad et al (2016), Grad et al (2017), Grad et al (2018) presented in Murawski et al (2015). The method included in Murawski et al (2015) is the subject of the patent application No. P.414104 of 09.22.2015 and is entitled: "The system and the method of calculation of a shape of the diaphragm assembly of a pneumatic extracorporeal Ventricular Assist Device." It has been implemented by the author and embedded in an embedded computer system. The software has unique features of the distance measurement proprietary method presented in detail in Murawski (2014), Murawski (2015), Murawski et al (2016). These features include: 1) measuring the distance to the object on the basis of one photo only; 2) simultaneous multi-point measurement of the distances to all objects in the camera's field of view; 3) measuring the distances to an object outside the focus range of the camera objective; 4) measurement of the distance by a fixed camera equipped with an objective with a fixed focus, unchanged during the measurement. The method of calculation of the stroke volume has been tested by the author under laboratory conditions Murawski (2014), Murawski (2015), Murawski et al

(2016) and Murawski et al (2018). The measuring stand consists of the following elements:

1) the model of the pneumatic extracorporeal Ventricular Assist Device (VAD), Fig. 2;
2) the shadowless illuminator using the phenomenon of electroluminescence, Fig. 3a;
3) the peristaltic pump, Fig. 9;
4) the microprocessor controller of peristaltic pump, Fig. 9;
5) a computer system made by using the IBM PC platform;
6) the Ximea MQ013RG-E2 industrial camera with the camera objective, Fig. 4;
7) hydraulic system, Fig. 9.

The shape of the flaccid membrane and the stroke volume of the pneumatic extracorporeal VAD were calculated at a frequency of 30 Hz (without visualization) and at a frequency of 15 Hz with the diaphragm's software graphic visualization enabled.

Measurement of a momentary stroke volume

The subject of this presentation is a method using image analysis and processing to calculate the stroke volume of the VAD, Fig. 2. The method requires the use of a non-moving camera equipped with a standard non-stereoscopic objective with a fixed aperture and focus, unchanged during measurement. The camera, Fig. 4, is placed above the diaphragm assembly, whose main element is a multilayer flaccid diaphragm shown in Fig. 1 and Fig. 2a. The camera enables simultaneous observation of the entire membrane surface, Fig. 3b and Fig. 5. Diaphragm shape calculation is based on the analysis of the view of the diaphragm e.g. of the view shown in Fig. 5a or Fig. 5c. When we know the current view of the diaphragm, e.g. Fig. 5c, and have the image of a flat diaphragm stored in the memory of the reference system, Fig. 5b, the method enables us to determine the shape of the diaphragm represented in 3D space Grad et al (2017) and to determine the blood stroke volume Sulej et al (2017).

Diaphragm shape calculation technique (Murawski, Pustelny and Murawska (2015))

The shape of the flaccid diaphragm is determined in three phases. The first phase (configuration of the video measurement system) consists in: a) setting the sensitivity of the camera; b) setting the operating parameters of the illuminator Murawski et al (2018), Fig. 3a, which illuminates the flaccid membrane with passive measurement markers, Fig. 2a; c) setting the aperture and the focus for the central marker located in the center of the diaphragm, in the resting position, halfway between the extreme positions of the diaphragm deflection, Fig. 4a; d) segmentation of the membrane image Murawski at al (2015) and calculation of z_0 area of the central marker, Fig. 4a; e) calculating the outline of the membrane; e) transformation of the membrane outline into M of virtual markers $\{(x_m, y_m, z_0)\}$ where m = 1…M, x_m - coordinate x of the center of gravity of the virtual marker, y_m - coordinate y of the center of gravity of the virtual marker, z_0 - area of the central marker. The first phase is carried out only once, before the surface shape of the flaccid membrane is calculated. The second phase consists in: a) taking a picture of the membrane, e.g. Fig. 5a, Fig. 8; b) carrying out segmentation of the picture, e.g. Fig. 6, Fig. 7a; c) calculating the position N of the measurement markers and calculating their centers of gravity $\{(x_i, y_i)\}$ and determining for them the area of the marker z_i where i = 1…N. The results of the second phase are the positions of measurement markers

Fig. 8: Examples of diaphragm shapes calculated by the discussed technique

Fig. 9: Diagram of the measurement system (a), the system view (b)

$\{(x_i, y_i, z_i)\}$, where i = 1…N, determined in 3D space. The third phase consists in: a) creating, with the step k, a regular two-dimensional grid of K^2 points and placing M virtual markers on the created grid $\{(x_m, y_m, z_0)\}$, where m = 1…M, according to their positions resulting from the designated outline of the membrane; b) placing N measurement markers on the created grid $\{(x_i, y_i, z_i)\}$, where i=1…N; c) calculating areas for z_j where j = 1…$K^2 - (M + N)$ points of the grid, by using interpolation in three-dimensional space, e.g. Cubic type. The result of the calculations are nodal points of the desired shape of the diaphragm, whose example view is shown in Fig. 7b. Other calculated membrane shapes are shown in Fig. 8. The presented method of calculating the shape of the diaphragm of a VAD has many advantages. It has been confirmed that the determination of the shape of the diaphragm can be done at the rate of the incoming camera images, e.g. 30 images per second. Thus, it is possible for the system controlling the pump supporting the heart muscle to react quickly to changes in the pump's operating conditions. The method also allows to determine the shape of the diaphragm in pneumatic pumps where opaque materials have been used, mainly to minimize the risk of clotting. The advantage of the described method is also the use of only passive markers, as shown in Fig. 8.

Measurement System

The correctness of the technique presented in item "*Diaphragm shape calculation technique*" is shown in the system shown in Fig. 9. In the study, the model of the VAD, as shown in Fig. 2b, was used. The only difference is in the material, of which the blood ventricle was made. The model used in the study has had the printed blood ventricle. Currently, for technological reasons, only blood ventricles cast in glass-epoxy resin or polyurethane are used in the research. The cast ventricle variant eliminates the problems caused by insufficiently tight of the 3D print layers. The laboratory system shown in Fig. 9 consists of elements conventionally marked *A* to *H* and of the pump *P*. The element marked *C* is a 500 ml Dreschl washer. During start-up, it is used to flood the measuring system,

Figure 10. The sketch of a pump supporting the work of the heart (a) and the model of the heart assist pump.

Fig. 11: Example of markers' distribution on diaphragm surface (a), diaphragm views (b) and (c)

including the pump *P* under test, with liquid, e.g. water or glycerin solution. The 250 ml Dreschl *H* flush absorbs excess liquid from the system. Pump *B* is started with valves *A* and *E* open and valve *F* closed. Under these conditions, the shaft of peristaltic pump *B*, turning counterclockwise ("+"→"-"), draws in liquid from washer *C* and, through open valve *E*, discharges the gas pushed out by the liquid from the blood ventricle of pump *P* into washer *H*. The appearance of liquid in washer *H* means that the hydraulic system is vented off completely. Thus, the blood ventricle of the tested VAD *P* is fully filled with liquid, which results in pushing the membrane assembly upwards. Next, pump *B* continues operation with valve *E* closed and valve *F* open. The flowing liquid then vents the connection of pump *P* to the burette *G*. After the measurement system is completely vented, the pump is switched off and valve *A* is closed. Under these conditions, burette *G* enables precise measurement of the volume of the liquid pushed/sucked from/to the blood ventricle of pump *P*. It thus shows the actual value of the stroke volume. The stroke volume value read during the verification of the developed method is considered as a reference value. A 100 ml burette was installed in the system. It enables to measure the stroke volume with an accuracy of ±0.5 ml.

The figure also shows the intake manifold of the operating gas Fig. 10a-9 and the camera position, Fig. 10a-5. In the system shown in Fig. 9a, the pneumatic ventricle was left unconnected. In the study, the shape of the diaphragm was changed by a peristaltic pump *B*, which operated with valves *A* and *E* closed and valve *F* open. As the peristaltic pump shaft rotated clockwise, pump *B* drew liquid from the measurement burette *G* and pressed it into the VAD, which results in an upward movement of the diaphragm. When shaft of the pump *B* rotates counterclockwise, the pump *B* sucks in (takes away) the liquid from the blood ventricle of the pump *P* and the diaphragm moves downwards. The liquid being sucked in is directed through the open valve *F* to the inside of the measurement burette *G*. This enables the reading of the stroke volume values and thus the evaluation of the performance of the developed method for calculating the stroke volume, by using image analysis and processing.

3D reconstruction of the diaphragm shape - example

Let us assume that during the experiment a photograph of the membrane, Fig. 11b, was taken, on which markers were placed according to the pattern presented in Fig. 11a. For her, in the configuration shown in Fig. 4a, a photograph of the central marker was taken and the marker's surface was calculated. Let the surface area of the central marker be z_0 = 780 px. In the same system, the outline of the membrane, which consisted of 1501 points, was calculated. These points have been transformed into M = 1501 of virtual markers. Virtual markers are saved in the format $\{(x_m, y_m, z_0)\}$ where m = 1…1501. The obtained values of x^T_m and y^T_m were as follows:

```

The value z_0 of all virtual markers was calculated on the basis of the central marker area calculated during calibration. In this example, the area was 780 px. On the analyzed picture of the diaphragm, $N = 45$ measurement markers with coordinates $\{(x_i, y_i, z_i)\}$ where i = 1…45, were identified. These values were:

x^T_i = [86,96,103,115,125,151,158,166,176,188,197,204,219,229,237,246,258,270,276,294,

Fig. 14: Pump cross-section: during full filling with blood (a), at full stroke (discharge) (b)

According to the method shown in item "*Diaphragm shape calculation technique*", a two-dimensional point grid was created. The resolution of the grid in the X and Y axes is assumed to be $K = 30$ points, whose coordinates in the X and Y axes are evenly distributed between the maximum and minimum values of the interpolated variables. The determined values of grid steps were $k_x = (\max(x^T_m) - \min(x^T_m))/(K\text{-}1)$, $k_y = (\max(y^T_m) - \min(y^T_m))/(K\text{-}1)$. The result is the grid with a size

a) b)

Fig. 15: Diaphragm shape calculated: when the pump is fully flooded (a), when fully pushed out (full stroke) (b)

of $K^2 = 900$ points. Scaled coordinates of measurement and virtual markers have been inserted into the point grid. For the created grid of the markers, Z-axis values were determined by using "Cubic" interpolation in 3D space. The result of the calculation, Fig. 12a, represents the desired diaphragm shape. The position of virtual markers and measurement markers on the 2D plane after scaling to the grid size is shown in Fig. 12b. The calculations were also checked for other measurement data. Let's assume that we determined, during another measurement, the position of $N = 15$ markers with coordinates $\{(x_i, y_i, z_i)\}$ where i = 1…15, such that:

```
xTi = [288,457,302,152,584,488,325,160,55,495,350,94,197,360,240]
yTi = [582,480,474,444,350,334,318,286,276,189,153,156,141,53,53]
zTi = [798,1412,2106,1519,798,2006,3006,1969,798,1427,2294,798,1545,959,798]
```

By repeating the calculations for the new input data, the shape of the diaphragm shown in Fig. 13 was obtained.

Measurement of stroke volume

The stroke volume of the pump is proposed to be calculated on the basis of the determined shape of the flaccid diaphragm separating the pneumatic ventricle from the blood ventricle. The difficulty to determine the stroke volume of a ventricular assist device equipped with a flaccid membrane, Fig. 1a, lies in the fact that there are only two diaphragm states that are well defined mathematically. The first state occurs when the pump is fully filled with blood (liquid), Fig. 14a. Then the flaccid membrane is pushed upwards and the volume of blood accumulated in the pump is much greater than 70 ml. The second state, well defined mathematically, occurs during a full blood pump stroke (about 70 ml for an adult). In this case, the flaccid membrane is fully pushed towards the blood ventricle, Fig. 14b. Between the indicated two membrane positions there is an infinite number of its states (shapes), which must be calculated and which have no known mathematical description. For this reason, the techniques presented in sections (*Diaphragm shape calculation technique*) and (*3D reconstruction of the diaphragm shape - example*) were used to calculate the stroke volume. The proposed method can be used in two implementations: a) measurement of the stroke volume of the VAD, implemented in the virtual world; b) measurement of the stroke volume of the VAD, implemented in the real world; Measurement of the stroke volume of the VAD, implemented in the virtual world, requires a one

a) b)

Fig. 16. Measurement of the stroke volume in the virtual world: the calculated shape of the diaphragm (a), the idea of calculating the stroke volume (b)

Fig. 17. Chart of measurement results of the stroke volume obtained in two measurement cycles, Sulej (2018)

times sensor calibration. Calibration consists in determining the grid of points (matrix) describing the shape of the flaccid membrane for its two extreme positions, Fig. 15a and Fig. 15b. Then, when we know the sum of the distances calculated between the corresponding grid points, and the projected pump stroke volume determined by the two extreme positions of the diaphragm, we can calculate the measurement constant for the stroke volume φ. The determination of a constant φ completes the calibration phase. Measurement of the stroke volume of the pump implemented in the virtual world consists in: calculation of the grid describing the shape of the diaphragm, e.g. shown in Fig. 16a; calculation of, shown in Fig. 16b, the sum of distances D between the corresponding points of the grid of the diaphragms: observed one, Fig. 16a, and convex one, Fig. 16b, obtained during maximum pushing the diaphragm into the pneumatic ventricle. The desired stroke volume is then determined from the formula $V = V_{MAX}-D\varphi$. However, the measurement method shown may be relatively easily disturbed by the expansion of the diaphragm, which may be due to natural aging/wear of the material. As an alternative to the above, the measurement is carried out in the real world. This measurement also requires a single sensor calibration. During calibration, the values of the parameters necessary for the correction of errors in the image resulting from the influence of optical distortion are calculated (the angle of view of the camera objective is about 130°). The calculation of the parameters' values completes the calibration phase. The measurement of the stroke volume carried out in the real world consists in determining the points of the grid describing the shape of the observed diaphragm, whose coordinates are specified in [mm] and calculating the stroke volume V of the pump as a result of numerical integration. These calculations can be performed by using, for example, the Simpson method or using the definition of the Riemann marked integral. This variant of calculating the stroke volume has been studied in depth under item Sulej (2018). It was confirmed there that the volume of liquid in the pump model used, contained between the upper and lower diaphragm positions is approximately 70 ml. Due to numerical integration the calculated volume was 69.9988 ml. Elimination of optical distortion has also significantly improved the shape of the obtained grids Sulej et al (2017). The most characteristic ones of them are shown in Fig. 18. The improved shape calculation of the diaphragms has had a positive impact on the accuracy of the calculation of the stroke volume. The graph showing two complete cycles of pump operation, during which the stroke volume was calculated and measured at the same time is shown in Fig. 17. For the results obtained there, the following error values were calculated: average relative error (≈1.5%), average absolute error (<1.83 ml), max. absolute error (<5 ml), Sulej (2018).

Fig. 18: Visualization of the grids calculated for the diaphragms: convex (a), flat (b) and concave (c), Sulej (2018).

Conclusion

The publication presents in a comprehensive and compact way the method of calculating the stroke volume of the pulse, extracorporeal and pneumatic Ventricular Assist Device. The measurement of the stroke volume was possible due to the knowledge gained during the processing and analysis of images and during the interpolation of the determined nodal point positions of the diaphragm. The conducted research works proved the validity of the stroke volume measurement theory developed by the author and included in Murawski, Pustelny and Murawska (2015). This statement is also confirmed by the graph shown in Fig. 17, discussed in detail in the work Sulej (2018). The measurement results are very encouraging. The average absolute error was ultimately below 1.83 ml and the average relative error did not exceed 1.5 %. These values are small and fully acceptable, also by the medical community. More information about the presented solution can be found in the literature pointed out in the References.

Abstract

We apply modified K-means and decision trees classification methods to classify projects in two ways: according to industry, organization size, project duration and project management type, in order to find out which risks are most common for each class, and additionally according to risk types identified in the risk identification process, in order to determine which risk types indicate that the customer expectations with respect to project outcome may turn out to be substantially different at the end of the project than they were at its beginning. Results of a questionnaire with 350 respondents are used for calculations. The conclusions may improve the project management process: they will help to prioritize risk classes and to decide when to put more weight on project scope and requirements management.

Keywords: Clustering, Classification Trees, Risk, Requirements Management, Project Management.

Introduction

It is common knowledge that risk is an inherent part of projects and that its proper management consumes huge amounts or resources, but omission of spending these resources may result in project total or partial failure. It has also been known for years (Mirai, 2020) that in many cases we deal with customers who do not really know or do not really realize what they actually expect and are not aware of their ignorance. Obviously, each project manager should be able to identify which risks they should put emphasis on in each given situation and when the customer needs special attention with respect to project requirements management.

The objective of the research is thus twofold:

- O1: to analyze the dependencies between company type, project management type and project type dominant in the company on one hand and risks that may appear in their projects on the other hand;
- O2: to analyze the dependencies between risks identified in the project risk identification process on one hand and the magnitude of differences between the customer expectations expressed at the beginning and those articulated at the end on the other hand.

The goal of both analyses is to provide indications with respect to project management. The first analysis will results in advice as to how to prioritize risk in the project risk management process for a given project in a given organization. The second one will lead to the identification of situations when special emphasis should be put on project requirements management and communication with the customer and end users of the project product.

The research was conducted in the following steps: data collection, data cleaning and transformation, data labeling, data classification.

The research methods that were used are: questionnaire (used in data collection), in-depth analysis (manual process that was used for data labeling), a modified version of K-means classification method and decision tree classification algorithms. We also used very fundamental statistics methods.

Literature Review

In this article we use a set of risk categories, into which we classify the risks that were listed in the respondents' answers. To have a representative risk classification, we conducted a literature analysis. The following search terms (for article titles) were used: {"software project risk", "construction project risk", "project management risk"} AND {"classification", "types", "typology", "checklist", "register", "identification", "factors", "dimensions"}. The analysis is summarized in Table 1.

Table 1: Project risks typology

PROJECTS IN GENERAL	
(Khallaf et al., 2018)	Operational, Political, Financial (macro), Technology, Contracts, Financing (market), Business cultural differences, Market potential, Contracts and legal issues, Resources, Design, Quality, Financing (project), Construction and cultural issues, Other.
(Zhang et al, 2018)	Organizational environment, Client, Complexity, Contract, Execution, Vendor.
(Yu et al 2017)	(Top 15) Legal, Cooperation, Tariff, Financing, Political, Technology, Corruption, Administrative procedures, Currency, Demand and revenue, Credit, Worker, Construction, Operation, Force majeure.
(Sanchez-Cazorla et al., 2016)	Design, Operation and maintenance, Demand, Market, Social profitability, Construction, Labor, Environmental, Financial, Economic, Legal and/or political, Contractual, Impact on local groups, Reputational, Force majeure.
(Asan et al., 2014)	Operational, Business and market, Engineering and design, Organizational, Financial and economic, Procurement and contractual, Political and legal, Environmental, Social and safety.
(Gandhi et al., 2012)	Schedule, Technical, Financial, Vendor, Culture, Reputation, Intellectual property, Flexibility, Compliance, Quality.
(Hillson, 2003)	Corporate, Customer and stakeholder, Natural environment, Cultural, Economic, Requirements, Performance, Application.
(Marcinek, 2001)	Macroeconomic, Industry, Regional, Technical, Marketing, Financial, Management.
CONSTRUCTION PROJECTS	
(Baba, 2019)	Economic, Land acquisition, Design, Financial, Construction, Force majeure.
(Chatterjee et al., 2018)	Political instability, Economic, Social, Technological, Work quality, Time and cost, Resource, Documents and information, stakeholder`s.
(Sohrabinejad, Rahimi, 2015)	Enviromental and social, Legal factors, Economic factors, Political, Design, Execution, Project management, Planning and scheduling, Human resources, Res. and Equipment, Partners.
(Valipour et al., 2015)	Financial, Legal, Political, Market, Operation, Organization and coordination, Force majeure.
(Burcar et al., 2013)	Legal, Political, Economic, Social, Nature, Management, Technical, Human factor, Procurement, Contractual.
(Rezakhani, 2012)	External, Operational, Project-Management, Engineering, Financial.
SOFTWARE PROJECTS	
(Hoodat, 2009)	Requirement, Cost, Scheduling, Quality, Business.
(Wallace et al., 2004)	Team, Organizational environment, Requirements, Planning and control risk, User risk, Complexity.
(Ropponen and Lyytinen, 2000)	Scheduling and timing, System functionality, Subcontracting, Requirement management, resource usage and performance, personnel management.

Based on the literature analysis, we decided to use eight classes of risks for the purpose of further analysis: random events (force majeur), market risks, law risks, technical risks, people risks, financial risks, time risks, quality risks.

The query "risk" AND "project" AND "type", whose objective was to identify literature items referring to the dependencies between project or organization or project management type on one hand and project risk types on the other (Objective O1), led only to one relevant output (Perrenoud et al., 2014) which treats the impact of project type

on risk timing and frequency in construction projects. The query "risk" AND "project" AND {"requirement" OR "customer"), whose objective was to identify literature items referring to the dependencies between risks identified in the risk identification stage and the problems with customer expectations or requirements (Objective O2), returned no relevant results.

Method

Data collection

The dataset was collected by means of a questionnaire (21 closed questions and two open questions in five sections). Data from 350 different Polish companies were gathered in January 2020, using the CATI method. It describes the companies in a few dimensions, i.e.: company industry (a simplified form of NACE categories (Eurostat, 2008)), company size (micro – less than 10 employees, small – between 10 and 49, medium – between 50 and 249, big – over 250), project management type which dominates in the organization (traditional, Agile, mixed), predominant project duration and project risks which are usually identified. The respondents (project managers) were also asked to provide information on the last project they managed, among other on the differences between the customer expectations expressed at the beginning of the project and those expressed at the end. They were supposed to use the Likert scale: 1 – almost none differences, 2 – very small, 3 – small, 4 – middle, 5 – big, 6 – very big, 7 – fundamental differences.

Selected statistical information about the sample and the answers given is presented in Table 2 and Table 3.

Table 2: Frequencies of individual risk types

risk	random	market	law	technical	people	financial	time	quality	none
frequency	20%	30%	9%	10%	23%	34%	24%	16%	2%

Table 3: Dominant risk categories in selected company types

Group of respondents	Dominating risk categories
construction companies	financial (35%), market (30%)
IT companies	financial (30%), time (30%)
Agile management dominant	technical (36%), people (36%), finance (36%), quality (36%)
traditional management dominant	market (40%), finance (37%)

On top of that in 20% of cases it was indicated that the differences between initial and final customer expectation were small, medium, big, very or fundamental, thus not negligible.

Data Cleaning and Transformation

The data cleaning process is a very important part of data analysis. Many articles show that a good quality of data has a great influence on the results quality (Gudivada et al., 2017). The data cleaning process was performed in a few steps. Firstly, we excluded the companies that did not give any risk information or any information on the differences in the customer expectations at the beginning and at the end. This reduced our dataset to 253 companies. In the second step we analyzed the company types represented among the respondents and decided to analyze only two most frequently represented company industries and ignore the rest. The most frequently represented industries were Civil engineering (referred to as "construction" in the following) and IT&Communication (abbreviated as "IT" in the following). This step reduced our dataset to 185 companies. In the last step we decided to exclude four more companies for answer quality reasons. The final dataset was composed of 181 companies in total for the K-means classification (objective O1) and 177 for decision tree classification (objective O2).

In the step of data transformation, we distinguished two subsets of questionnaire questions: one set that was related to company basic characteristics and the second related to the last project managed by the respondents. When building basic characteristics, we considered only those data attributes which were easy to be transformed into numerical values. Thus we selected four company attributes: industry, company size, average project duration, predominant project management type. The further data transformation process was evident. The only less trivial transformation was extracting the information about the project management predominant in the organization and was based on selecting the management type with the highest weight assigned by the respondent.

Data Labeling

The initial dataset had the answers about risks written in free text, which made it difficult for quantitative data analysis. For this purpose, we decided to use manual labeling that allowed us to assign risk classes to each of the answers. For labeling we asked the opinion of two independent experts, which allowed us to eliminate mistakes. In case of the answers for which the opinion of both experts did not match, we used a further in-depth discussion about how to classify the risks. Based on the literature presented in Table 1 we distinguished eight risk classes: random events (like weather conditions or various accidents), market risks (risk that are connected with changing market conditions and market competition), law risks (connected to official and legal procedures that influence the company's business), technical risks (connected with quick technology change or technology problems), risks referring to people (connected with human relations, human conflicts, job change, etc.), financial risks (connected with costs), time risks (connected with time estimations and exceeding the tasks execution time), quality risks (connected with product quality or guarantee issues or customer requirements expectations in general).

K-means based data clustering (Objective O1)

Our final dataset for objective O1 included 181 companies and was represented by the following attributes: industry, company size, average project duration, project management type, risk attributes (eight binary attributes with eight types of risks assigned). We decided to cluster non-risks attributes using the K-means method, which is a classical clustering approach (Likas et al, 2011), but we used a modified quality measure adjusted to the needs of multiple class classification. For the purpose of K-means clustering we used the implementation and normalization techniques described in (McCaffrey, 2013). The implementation was adjusted in the normalization part, so that also the data attributes for which the standard deviation equals 0 are correctly handled and does not produce any division by zero cases. There are several advantages and disadvantages of using K-means clustering (Likas et al, 2011). One of the most discussed drawbacks of the method is that the number of clusters (parameter *K)* is not given and it needs to be selected experimentally. Thus we analyzed different cluster numbers, from four to twelve, and observed the risk distributions. We selected the cluster number for which the risk distribution maximized the quality measure. As a quality measure we selected the average percentage of records covered with most representative risk combinations. This quality measure shows how well the risk subsets match the clusters (which were obtained on the basis of the four company attributes described above). We assumed that a combination should be counted as a matching one even if more risks (than listed in the combination) appear. This allows to achieve a higher value of records that match, which suits the case of small datasets. This also means that shorter combinations will have higher scores and it reflects the hierarchy of the most common risk combinations that are expected to appear – starting from the shorter ones and ending with the longer. What is more, because the dataset is small, we considered only the two-level hierarchies, i.e. combinations of length one or two.

There are several methods that can be used to measure the quality of clustering. The methods are usually based on pair counting (Pfitzner et al., 2009). The problem in the case that is described in this article is that we should expect clusterings to have multiple classes of risks. That is why we also use pair counting, but we select only those classes whose match measure exceeds a given threshold *T*. This approach is a modification of the Dice asymmetric index (Pfitzner et al., 2009). The modification is summarized in formulae (1) and (2), which define the clustering quality measure $Q(S)$ (*S* is a given clustering, symbol |*X*| denotes the cardinality of set *X*).

$$Q(S) = \frac{1}{N}\sum_{i=1}^{N}\sum_{k=1}^{2}\frac{1}{|R(T,k,i)|}\sum_{C\in R(T,k,i)} M\big(C,S(i)\big) \qquad (1)$$

where *N* is the number of clusters in the clustering *S*, $S(i)$ is the *i*-th cluster in the clustering, $R(T,k,i)$ stands for the set of possible *k* elements risk combinations *C* whose risk match measure $M\big(C,S(i)\big)$ (defined in (2)) exceeds threshold *T*.

$$M\big(C,S(i)\big) = \left|E\big(C,S(i)\big)\right| \Big/ |S(i)| \qquad (2)$$

where $E\big(C,S(i)\big)$ stands for the set of all entries in $S(i)$ with combination *C*. An entry counts also if it contains additional risks than the elements of *C*.

Decision trees-based classification (Objective O2)

The final dataset for objective O2 was composed of 177 companies, where both the information on risk classes identified in the organizations and on the differences between the customer expectations in the beginning and in the end of the recently managed project were available. We used classification decision trees based algorithm CRT (Classification and Regression Tee) (Rokach and Maimon, 2008), (Larouse, 2005).

Results

First we present the results regarding objective O1. The risk threshold value *T* for the match measure (2) was arbitrary set to 0.3. This means that we analyzed only the risks combinations that were represented in the given cluster in more than 30% of possible occurrences. In other words, we analyzed the risks that should appear in at least 30% of the companies from a given cluster. Based on different possible clusterings, we first identified the clustering with the highest quality measure. After selecting the best cluster, we tried to analyze in more depth the given clustering and risks. In Table 4 we present the results for different number of clusters.

Table 4: K-means clustering quality results

Clusters count	3	4	5	6	7	8	9	10	11	12
Quality	0.39	0.40	0.41	0.43	0.32	0.30	0.36	0.30	0.41	0.35

The highest results quality was obtained for 6 clusters. The detailed results for 6-class clustering with respect to the most common risk types are shown in Table 5.

Table 5: Best K(=6) for K-means clustering – detailed results

No.	Cluster centroid (industry, size, project duration, management type)	Most common risks (match)
1	civil engineering, small, years, unknown-traditional	market (0.43)
2	any, small-middle, quarter-half of year, mixed	time (0.47)
3	civil engineering, middle, unknown, unknown-traditional	random events (0.44)
4	civil engineering, micro-small, quarter-half of year, unknown-traditional	financial (0.34)
5	any, micro-small, days-months, unknown-traditional	financial (0.34)
6	IT, micro-small, days-months, agile-mixed	financial (0.67), market & financial (0.50)

The words “unknown” in Table 4 mean that in the respective organizations both project management types are used, pairs of answers connected with a hyphen represent the case when two answers were present in the data cluster. Expressions similar to “days-months” refer to the best unit(s) in which average project duration in the corresponding company should be counted (according to the respondent). Let us now analyze the results for objective O2 (Table 6).

Table 6: Probabilities of having the given level of differences between customer expectations for companies which declared the given risk type

Cust. exp.	All projects	Risk								
		random	market	law	technical	people	financial	time	quality	none
almost none	0.51	0.66	0.56	0.60	0.65	0.44	0.55	0.36	0.31	0.50
very small	0.29	0.26	0.25	0.20	0.18	0.32	0.27	0.45	0.35	0.00
at least small	0.20	0.08	0.19	0.20	0.17	0.24	0.18	0.19	0.34	0.50

For example, the probability of having at least small differences among the initial and final customer expectations for all the projects is equal to 0.20, and for projects where risk of “people” type is identified - to 0.24.

The tree classification algorithms were used to identify homogenous classes, defined by individual risk types, with respect to the differences in the customer expectations. They generated nine homogenous classes, out of which two correspond to cases in which the probability of having small, medium, big, very big or fundamental differences between the customer expectations at the beginning and at the end of the project are over 35% :

- included market and people risk, excluded time and quality risk: 37% of probability of having at least small differences in the customer expectations;
- included quality risk, time risk excluded: 35% of probability of having at least small differences in the customer expectations.

Discussion and Conclusions

With respect to objective O1, which was to analyze the dependencies between company and their project (management) types and project risks, we state that we did not obtain any clusters centered around Agile, which may show that Agile approach was not popular for the companies that were analyzed. In fact, we had only 11 company datasets (among 181) classified as Agile. We also did not obtain any clusters centered around company size "big", probably for the same reason: there were only 14 such entries.

The results of the clustering show that for micro and small organizations (clusters 4, 5, 6 in Table 5) the most common risk type are financial risks. This shows that the risk of exceeding project budget is very dangerous for small companies and should be handled with special care. In case of micro (or small) IT companies this kind of risk was identified in 67% of the cases, which seems to be a significant result.

For civil engineering companies that are of middle size (cluster 3, Table 5) the riskiest are random events (force majeur). This classification includes the risk of bad weather or human accidents or human sickness.

For small civil engineering companies (cluster 1, Table 5) the risks that are most likely are market conditions, which include risks connected with market competition or the risks that are generated by the subcontractors who do not fulfil their commitments.

For both civil engineering and IT companies that realize projects with duration under half a year (cluster 2, Table 4) the most common risk type that was identified is time risk (almost half of the cases).

As far as objective O2 is concerned, it was found out the identification of people and market risk with the exclusion of time and quality risk or the identification of quality risk with the exclusion of time risk may indicate a high probability (over 35%) of having significant differences between the customer expectations expressed at the beginning of the project and those expressed in the end. Also, it was proven that in about 20% of projects, independently of the risk identified, those differences are at least small. This means a high probability of customer dissatisfaction, which may be equivalent to project failure and/or missed new project opportunities.

The conclusions presented above are important for the risk management process. We identified priority risks for different company types (described by industry, company size, project duration and project management type). This prioritization helps to determine in each case if a given risk group is worth further analysis. In particular, the prioritization can be used in designing risk response strategies (PMI, 2017), based on company type, and indicates which risks should be treated more carefully in the risk management process. Also, we pointed out situations when the identification of some risks may be equivalent to a high probability of the occurrence of a risk event which in many cases may be crucial for project success: the ultimate lack of customer satisfaction. In such cases special attention has to be paid to requirements management and communication with the customer.

As part of the future research we plan to narrow the investigation to the selected companies type that was most often represented in our data (i.e: civil engineering companies) and try to collect more data. We also plan to check the different quality measures on the data collected and compare the results, as well as to re-apply tree classification algorithms to the extended data and examine more profoundly the influence of risk identified in projects on the fundamental problem of achieving ultimate customer satisfaction.

Abstract

The theme "Quality management system and models as a tool for small and medium enterprieses development and competitiveness increase" is determined by the basic concepts included in the topic - small and medium enterprises (hereinafter referred to as "SMEs"); competitiveness and quality management system (hereinafter referred to as "QMS"). Small and medium-sized enterprises are interested in producing products in which potential buyers can see the qualitative features they need to meet their needs. Thus, the merchant, the quality requirements and competitiveness of the product produced by him coalesce into one system whose function is closely related to the goal of the product buyer to more fully meet their needs. Today, the European Economic System employs more than 23 million small and medium-sized enterprises, which produce goods and services worth more than 4 billion Euros. These companies employ over 90 million economically active people from different European countries (Eurostat, 2018). Object and object of the research: the following object of the research is determined: competitiveness of small and medium enterprises and the subject of this research: improvement of the competitiveness of small and medium enterprises by applying the conformity requirements defined by the quality management system.
The purpose and tasks of the research: to reveal the positive effects of the implementation of the quality management system on increasing the competitiveness of small and medium enterprises, as well as to identify the most important barriers to the restructuring of production in accordance with the requirements of the quality management system for small and medium enterprises in the local economy.
The following main tasks are identified for achieving the goal:

- explain the most important concepts of the work theme;
- create a model for interconversion and interaction between customers' quality requirements and production conformity requirements.

Research Hypothesis: elements of the quality management system applied to increase the competitiveness of SMEs can lead to a competitive advantage in the market.
Research methodology and methods: the study uses analysis and synthesis methods, deductions and induction methods as well as logical approach methods. However, appropriate quantitative methods are used to process the data obtained.

Result of the research: in the course of the research a model is developed and recommendations for implementation of the quality management system in enterprises are worked out.

Keywords: small and medium-sized enterprises, competitiveness, quality management system, management, competition, national economy

Introduction

In today's world, with the rapid expansion of SMEs in the EU and in other parts of the world, their competitiveness and economic significance are consistently increasing. At present, the proportion of SMEs in the EU has reached 99.8% of the total number of enterprises, and in the different sectors of the national economy (hereinafter "TS"),

they account for not more than 68% of all economically active population, producing over 42% of GDP in these enterprises (Eurostat, 2018).) Large Chinese exports account for 60% of SMEs, while Thailand 46%. In many countries of the world, in practice, it has been demonstrated that micro and small enterprises are more capable of responding more flexibly to economic crises and other external threats (OECD, 2017). In the practice of small and medium-sized enterprises, it has been shown that companies in this group compete successfully with large companies in several performance indicators. Convincingly, the following scientific research findings about the positive effects of SME activity in different parts of the world are highlighted:

- In individual sectors of the economy, the global competitiveness of SMEs is 2-3 times higher than the competitiveness of large enterprises in local and foreign markets (OECD, 2018);
- SMEs are more competitive than large companies in creating new products and offering additional jobs (Sargeant, 2011);
- Thanks to the successful implementation of SME development policy in Japan, over several decades, unemployment rates in the country are close to the natural rate of unemployment and are several times lower compared to the unemployment rate in the USA and the EU (Meti, 2017);
- The results of SME Performance Surveys in Japan show that 10% of industrial small businesses have higher productivity compared to large companies, while in service industries this figure is up to 30%;
- Small and medium-sized enterprises are generally more satisfied with work and working conditions than large companies, mainly due to their higher standing and trust from employers (Kok, J. et al. 2011);

The above-mentioned research findings on the global prevalence of SMEs, their impact on the country's economic development and the competitiveness of SMEs in different markets clearly demonstrate the need to focus on small and medium-sized enterprise development problems and solutions. Competition and competitiveness are the main categories of market economy that have undergone dramatic changes with the transformation of the market economy itself. Therefore, the concept of "competitiveness" is given a great deal of attention in various academic and other types of publications. Famous scientists P. Krugman, M.Porters, P.Samulens, M.Spens, J.Stiglicks, J.Tirol and many others have devoted much attention to the study of competition and competitiveness, the revelation of their content.

The results of the study indicate that quality is a much broader concept than competitiveness. This concept is widely used on a daily basis in each of the economic groups - households, enterprises, state and local government institutions, as well as in public organizations, but possibly with different content. In practice, it has proven that everyone knows what quality is, but only a few can explain it. The content of the concept of quality is widely discussed in the academic environment, starting with the beginning of the XX century. Well-known researchers in the field of quality are such as J. Juran (1989), E. Deming (Deming, 2000), R. Dorfman and P. Sheaterer (Dorfman, Steiner, 1954), Lefler (1982), G. Kanji and M. Ascher (1996), G.Knovless (Knowles, 2011), who have focused on studying the quality of different products in relation to customer quality requirements, their constant changes in the goods and services market.

Transform customer quality requirements into compliance requirements

Taking into account the wide range of studies on quality and the lessons from their critical evaluation, Quality is defined as "quality" - a set of characteristics defined by the entity that is used to assess the suitability of a particular tangible or intangible item to meet his or her needs. This concept can be shortened in the following form: quality - a set of characteristics defined by the entity. In the work, the term "quality" is related to the concept of "relevance", which in essence is inextricably linked in any field of human activity. Conformity concept work explains the following: compliance - a set of characteristics defined by an individual, a company or another organization, used to measure the usefulness of the product and / or service processes and / or the value of the value of the product produced. Abridged Explanation of Conformity A set of features defined by the entity or organization.

Small and medium-sized enterprises, which have taken a decision to increase the competitiveness by using the potential competitiveness advantages included in the Quality Management Standard, it is important to understand how the transformation of quality requirements into conformity requirements occurs. The model developed in the framework of the study on the requirements for the transformation of quality requirements into compliance requirements is included in Figure 1.

Abbreviations used in the picture: ***D*** *- Dimension;* ***QR*** *- quality requirement;* ***F*** *– feedback*

Fig. 1: Transformation of customer qualification requirements into compliance requirements and model of production of the corresponding product

Source: authors own study

The model shows that one product meets several quality requirements, the content of which is determined by the buyers, creating a set of qualitative requirements ΣCnDn, which consists of a social, technical, economic and management dimension. The picture shows that the war for the client and each of these dimensions has several qualitative features, for example: - C1D1QR1 - the first quality of the first dimension of the first customer I, etc. Thus, SMEs get an idea of customer quality requirements.

At this point, the decisive moment in the development of competitiveness begins - from the customer's quality requirements identified in the market research, it is necessary to select the requirements to be included in the product being produced, which are referred to as qualitative features of the work and their time remains unchanged. The model shows that the quality requirements identified in the market research reach the manager of the company, which decides on the quality requirements to be set in the product, the production of which comes as compliance requirements. In order for SMEs to maintain their competitiveness in the target market or to increase it, it is important for him to include in his product the most qualitative requirements that are most relevant to the customer, but increasing these quality features makes the product manufactured more expensive and more expensive for the buyer.

Abbreviations used in the picture: ***F*** *– feedback*

Fig. 2: Manufacturing Compliance System Model for Better Execution of Customers' Requirements and Increased Competitiveness

Source: authors own study

To obtain a more complete picture of the production of appropriate products for increasing the competitiveness of SMEs, a production conformity system model is presented in Figure 2, which adds elements of the production conformity model of Figure 1 and reveals their relevance to the product market and customer satisfaction requirements.

The model shows that the signs of conformity of the identified manufactured product come to the company in the green field. The economic resources that meet and define the requirements of SMEs come into production and start the process of their coupling, or the second important stage in the production of the corresponding product. Using elements included in the production conformity system, the validation of the result of the work performed is carried out throughout the production process in order to verify the appropriateness of the presence at each stage of production and at each workplace.

The product produced comes into the warehouse of the company and the last job of creating the corresponding product starts. The feedback generated within the production conformity system is one of the key elements in creating the positive effect of producing a product that creates the necessary prerequisites for all production process units to operate in accordance with the defined characteristics of the product's compliance. As soon as the product goes through the SME gate and goes to the market, it transforms the corresponding product produced by the company into a quality product from the buyer.

Significant Elements of The Quality Management System and Their Relevance to Increasing the Competitiveness of The Company

The introduction of quality management systems (hereinafter referred to as QMS) is a strategic decision, which requires good knowledge and understanding of the key elements of the QMS and their interconnectedness in the implementation and successful implementation. The most significant of these elements is the company itself, which has a production conformity system. This system model is shown in Figure 2 and follows a brief explanation of system operation. It is important for managers to be aware that the production conformity system is oriented towards the market and the dominant client. This means that the production conformity system must consistently meet customer changing quality requirements. Many researchers have pointed out that the internal environment of the business, the dominant threats and opportunities, is the most significant aspect of business formation and development. The next element of the QMS is management, its quantitative and qualitative composition. Exactly the management determines the goals and objectives of the activity, mission and vision, in which the most important place is allocated to the client and his quality requirements. These issues are continually being widely discussed in the academic environment, where the opponents express bold ideas about various issues of raising the effectiveness of corporate governance (Maxwell, 2013; Mezzei, 2006). In these and many other scientific studies a large attention is paid to the issues of compliance of the managers themselves, the dimensions of their competence level and competency. It is important for drivers to know the driver's compliance law, which specifies the need for compliance of the characteristics of the management entity with the characteristics of the control object, the objectives and tasks of its operation.

The next QMS element - the employed staff - is closely linked to management. The employees of the company are the most significant of the resources at their disposal, which is the largest opportunity and, in some cases, the greatest threat to the company's pursuit of the goal. R. Tricker is one of the many scholars who have turned to the staff of the company. He has come to the conclusion that the greatest benefit of the involvement of employees is the human feeling of being responsible for their performance (Triker, 2014). L. Dale and G.Ouens-Brogers, in turn, have shown a scientific interest in staff compliance issues and their training as a sufficiently effective means of maintaining the required compliance level (Triker, 2017). It is important to recognize that the relevance of the staff begins at the moment when interviews with potential employees take place. In this respect, not only formal signs of compliance are important, but also the possible synergy effect and the desired positive synergy effect for the company.

The fourth element of the QMS is the processes. Despite the fact that each of us is a witness to many processes and has managed to engage in a number of processes during the day, in practice, it can be verified that many managers are struggling to create processes, their mutual commitment and the disclosure of interactions. In essence, this is the first sign of discrepancy, but not always with such a conclusion is enough to solve the problem. To a large extent this is due to the inadequacy of the concept of "process" in the QMS - as any action requiring resources and not in accordance with observations in practice, where the process emerges as a set of targeted, interoperable and complementary activities with its own goal. But the requirement of resource requirements included in the Standard is an unnecessary and unnecessary interruption, because nothing happens without resources. But it is important for the company to provide each of the production conformity system processes with the necessary, interoperable and complementary resources whose quantitative and qualitative composition is determined by the product being produced. D. Besterfield, and other scientists, devoted a great deal of research to the production conformity system. In these scientific studies, managers and process researchers can get useful insights on the process set-up efficiency. This means that it is impossible and not necessary for an enterprise to create efficient processes - this is an integral part of every process. But there must be sufficiently efficient processes that form a unified process system that fits organically into the production conformity system. These processes will work with the effectiveness that a manager of the company has created with his management decisions, the content and relevance of which in all cases determines managerial knowledge and understanding of the management object.

Systemic thinking and production conformity system is the fifth key element of QMS. Its significance relates to the production conformity system and as a system incorporating the manufacturing conformity subsystem. Despite the fact that many scholars have devoted their work to research into various socio-economic systems and their constituent elements, systemic thinking for many managers seems to be something new and unusual, often too complicated. It is important to note that in this context lies one of the most important aspects of enhancing competitiveness - the manager must be able to think systematically and well-positioned in the company as a special and unique socio-economic, technical and management system. Systemic thinking is closely linked to compliance in general and the production conformity system in particular. An unwritten rule for each driver is to establish a system of adequately functioning production compliance that is able to continuously offer products that meet customer quality requirements and continually follow these changes. The inefficiently functioning production conformity system at best increases the cost of production and reduces the company's profitability, but in the worst case, the product's compliance with the much higher negative consequences for competitiveness increase.

The systemic approach is closely related to the next element of QMS - the continuous improvement of the product produced. In essence, product placement is one of the processes that is closely related to the customer's quality requirements. The issue has been given a great deal of attention by the founders of the quality management system, Demings, Juran and others. It's important for management to know what should be improved and in which direction they should go. Although the answer to these questions is not complicated, it is more difficult to decide on making improvements and providing them with the resources that are difficult for many companies to overcome barriers. In practice, it has been observed that there is a passive and active phase in the development of the product as well as in the production processes. In the passive phase, minor improvements are made, which is sufficient for the company not to lose the achieved level of production efficiency and / or to reduce the sale of products manufactured at a reasonable price to the merchant. In this phase, management decisions about product and / or product development are taken primarily based on customer complaints and novelty elements in alternative products.

On the other hand, in the active phase, radical and rapid improvement measures of the product and production system are being implemented, aimed at switching to the production of a new product that could more fully meet customer quality requirements.

The last element of the QMS included in the work is mutually beneficial cooperation partnerships. In an effort to build this QMS and manufacturing compliance element, it's important for managers to be aware of what are the key partners and have mutually beneficial relationships. Ready-to-use, and in all cases, useful answers to these questions is not a question of experience and intuition. But the manager should understand that his company is isolated from others - potential co-operation partners are not able and will not be able to produce products that will meet the customer's quality requirements. The above theoretical aspects of QMS, production conformity systems and customer quality requirements are used for continuation of theoretical and applied research in relation to the compliance of manufactured products with customer quality requirements and the continuous improvement of the product produced.

Conclusion

The European Economic System employs more than 23 million small and medium-sized enterprises, or 99.8% of the total number of companies, with a value of over 4 billion Euro, employing more than 90 million economically active population, making SMEs the most significant aspect of socio-economic development. SMEs operating in different countries of the world have shown a relatively high level of competitiveness and have surpassed the performance of large companies in certain sectors of the economy. SMEs are more flexible in responding to changes in the goods and services market, they are overwhelming in creating new jobs, therefore, in many countries of the world, much attention is being paid to the competitiveness of SMEs

Drivers and / or owners should take into system that any recommendations made in the external environment do not give rise to production conformity systems and the production of quality products, and can’t give a positive result until the manager and / or owner himself / herself is aware of the uniqueness of its business, its competitive advantages and disadvantages by taking internal and / threats and opportunities prevailing in the external environment

It is important for the SMEs managers to take into account the fact that its operation is based on several elements of the quality management system, the most important of which are the management and personnel of the company, their interdependence; the internal environment of the company and the threats and opportunities prevailing therein; business processes, their interdependence and complementarity; systemic thinking in management decision making; feedback and their effective operation; mutually beneficial cooperation partners.

Within the framework of the study, a model is developed that reveals the transformation of quality requirements into compliance requirements, demonstrating that in one product several quality requirements are matched, the content of which is determined by the purchasers, creating a set of qualitative requirements.

The customer quality requirements identified in the market research are used to select the requirements for the product to be manufactured, or the fixed quality features that remain unchanged for some time. The model shows that the SMEs manager decides on the quality requirements to be recorded in the product to be manufactured, which are presented as conformance requirements.

To enable SMEs to maintain its competitiveness in the target market or increase it, it is important for him to include in his product the most qualitative requirements that are most relevant to the customer, but increasing these quality characteristics makes the product manufactured more expensive and more difficult for the buyer.

The developed production conformity system model complements the quality requirements transformation model, revealing how the production of the appropriate product and the monitoring of compliance requirements in all production processes lead to the product being transformed into the quality product required by the buyer when it

comes to the market.

Abstract

The paper presents relevant figures and a general macroeconomic picture of an emerging economy like Romania as well as the main aspects that determine and influence the employment decision of graduates, with emphasis on the engineering in foreign languages, especially the German language, as well as the roles of the actors in the talent management process. Informed persons take their decisions rationally, fully aware of the situation and their options. Bachelor and master graduates face the challenge to understand the local, regional, and global economic situation as good as possible, identify the opportunities, make the best choice for their career, and find the path in their specialization to the best suitable job consistent to their talents and to a work-life balance. Based on data acquisition about the graduates of the German stream of the Faculty of Engineering in Foreign Languages, the paper enumerates some examples of job titles they hold.

Keywords: engineering in foreign languages, higher education, employment, talent management, Romania, emerging economy

Towards the Knowledge-Based Economy

The present paper exemplifies how talent management and recruitment of persons with academic degree, especially the graduates who studied industrial engineering in German language is covered in Romania, the more so as it is a niche study program, being the only one in the country, with this specialization. Compared to the past, the awareness is higher for the graduates, because of the new type of profile companies are seeking for, with a high demand of specialization and soft skills.

Towards the knowledge-based economy, the simple human resources develop to human capital, i.e. to the value of the workers´ knowledge and the added value they provide through knowledge. Therefore, managing people turned into a high demanding activity, an integrative endeavor of universities, employers, and recruiters, accompanying the various stages of the employee life cycle, optimizing the human capital, and transforming it into talent management. This is a mutual adaptation of the human to the new situations arising with the digitalization and the new technology, which gets ubiquitous.

A responsible data gathering about the alumni, allowed the faculty to follow their employment rate and their career path quite after graduating.

Economic situation – way to Industry 4.0 and knowledge-based economy

The trend in the knowledge-based economy, where the developed countries belong, is based on intellectual capital and on one of its subsets, the human capital as the main business asset. The emerging economies, as Romania was reclassified by FTSE Russell (1) are defined as economies, that have experienced economic growth that is much higher than that of high-income countries for an extended time range, as stated in the book by Tsunekawa and Todo (2019), which move away from the traditional economies that have relied on exports of raw materials and agriculture, through innovation and technological dynamism in a fast economic catch-up, as partners of the developed countries,

as in the book Globalization and the Emerging State: Past Advance and Future Challenges by Tsunekawa, cited by Medel D. (2019) in his essay on emerging markets. Beside the higher investability, the emerging economies build sustainable value chains as parts of the global value chains. Domestic industries in both industrialized and developing countries have become intertwined through complex business networks created through foreign direct investment and global information and finance sourcing, occupying specialized niches within global value chains, according to Gereffi and Sturgeon (2013) in Global value chains and industrial policy: The role of emerging economies, cited by Gereffi (2015) in the Working Paper.

The process of startup and SME-development goes parallel with the privatization of the key sectors of economies and needs qualified and specialized workforce and skilled labor with high economic value. There is a paradigm shift, a new way of identifying value and capitalizing the intangible assets of companies. Contrary to the fears of Keynes (1930), who warned in his essay about "technological unemployment", a change of the nature of work is perceived, with systemic transformations, which increasingly require a specialized workforce. Beside the fast digitization of companies, the digitalization takes over and provides new opportunities and business models, according to the Gartner glossary, in a strong human-computer interaction. The perceiving and understanding of the human-computer interaction (HCI) have evolved since this concept has been coined in the 1970s. The HCI is like an "arms race" between human and Artificial Intelligence (AI), machine learning, big data, 3D and 4D printers, 5G, Virtual Reality, Blockchain, Augmented Reality and the Internet of Things (IoT), only that the main result must be the co-existence between technology and society and assure that it remains human-centered. As Schwab considered in the book The Fourth Industrial Revolution (2016), "technology is not an exogenous force over which we have no control".

Human values need an adaptation in relation to the computing innovation and possibly will become more critical as researchers come up with ever more ingenious and potentially intrusive ways of sensing, monitoring, collecting, and sharing digital information, as anticipated in the book Being Human. Human-Computer Interaction in the Year 2020, edited by Harper, Rodden, Rogers and Sellen (2008). This is the only path for companies to resist on the market, develop and make profit.

Adaptability is demanded from employers or employees, as individuals, from the companies, as organizations and from the digital technology, in a process of Digital Darwinism, which was defined as "an era where technology and society are evolving faster than businesses can naturally adapt" as Schwartz (1999) stated in his book about Digital Darwinism and where businesses must keep up with a high demand for technology, information systems, and responsiveness (to data, communication, and customers´/stakeholders´ expectations).

At this moment, there are two types of signals coming from the market, proving the same trend. The market-listed companies show a rather reluctant conjunctural behavior as Weisenhaus (2020) states in his article, with the pandemic effects already priced in, according to dts New York (2020), and the stock exchanges are recovering, inching up with higher investments predominantly on technology titles. On the other hand, in the EU, one in 10 SMEs in Europe could be expected to file for bankruptcy within the next six months, according to Dimson, Mladenov, Sharma, and Tadjeddine (2020), in their article COVID-19 and European small and medium-size enterprises: How they are weathering the storm.

A recent report of the World Economic Forum (2020) about the Future of Jobs, predicts by 2025 a disruption of about 85 million jobs and that 97 million new jobs may emerge "that are more adapted to the new division of labor between humans, machines and algorithms", whereas 40% of the workforce will be able to re-skill.

1. 2 Romania, Balkan country. Some figures

With a population of 19.52 million inhabitants, the workforce distribution on the economic sectors is as follows: 47.55% services, 30% industry and 22.45% agriculture. Approximately 3.4 million Romanians live abroad. The EU-accession was in 2007, together with Bulgaria, when the second wave of Eastern Extension took place.

There are financial problems in the educational system, e.g. schools and high-schools are underfinanced and there are still some disparities between the development of the urban and rural areas, although the rural and poor areas have improved over the last two decades, at least in economic terms (in 2018, the five poorest areas – rural areas in Romania – had 18.3% to 25.4% of the average GDP per capita in the EU). In the time 2000-2018, Romania achieved an 80% increase of relative improvements in the urban area (with a real income convergence), compared to the EU-average, but the disparities between urban and rural areas persist (equipment and facilities, internet connection, the number of teachers), as presented in the study of Eurostat (2018), Methodological manual on territorial typologies.

Romania has a mean download speed of 61.08 Mbps and is ranked no. 26 worldwide. An index showing a high digitalization potential is that of the private households with internet access (83% in 2019) as a statistic of Eurostat

(2018) showed. A further Eurostat (2019) statistic states that round 23% of the enterprises have ERP solutions, compared to about 37% in the EU-27.
According to an annual report (2019) of the National Bank of Romania, the foreign investments in Romania decreased with 68%, from 4,364 bn Euro, in the first eight months of 2019, to 1,395 bn Euro in the first eight months of 2020. Traditionally, the main investors are Germany, Italy and Netherlands.

Positioning Romania in the economic picture

Between brain drain, start-ups and getting employed in a big company, there is a force field that gives the great potential of the economy, despite the inherent difficulties. After presenting some figures and options on the labor market, some opportunities are detailed, and some conclusions are drawn.

Labor Market – domestic and foreign – temptation to go working abroad, skilled migration

Romania has been admitted for 13 years in the EU, during this time a broad reform and adaptation to the European higher education area has taken place, which includes the fact that curricula are adjusted to the needs of the EU labor market and graduates get interdisciplinary technical, economic and management skills, in the pursuit of a high employability and a quality employment.

According to a report of the National Statistics Institute, the Labour Force in Romania. Employment and Unemployment (2019), the highest level of employment rate for working age persons was registered among graduates of superior level of education (89.2%). As the level of education decreases, the employment rate also decreases.

Complementary, according to Eurostat Regional Yearbook (2020), edited by the European Union, about 38% of the Romanian specialists worked in science and technology, with the highest number in Bucharest (50.8% of the labor force) in 2018. This is only one of the figures that demonstrate the monocentric pattern of development in Romania, with a concentrated activity in and around the capital.

Romania recorded very low old-age dependency ratios (which is positive aspect) and the commuter zones surrounding Bucharest were relatively small, accounting for less than 15 % of the total population in their functional urban areas. The figures show the tendency of concentration of big and small companies in the capital and in the important cities, with effects on the renting prices and the household burden for living several years during academic studies and after graduation. The highest activity rate (90.6%) was registered for persons aged 15-64 years with higher education level (university of short and long term, including master's, doctoral, postdoctoral and postgraduate).

Table 1: share of students in tertiary education institutions in Romania (academic year 2019-2020)

Tertiary Institution	Percentage
Business, administration, law	24.1%
Engineering, construction, manufacturing	20.4%
Health and welfare	13.9%
Social sciences, journalism, and information	9.0%
Arts and humanities	8.9%
ICT	7.2%
Agriculture, forestry, fisheries, veterinary sciences	4.5%
Natural sciences, mathematics, statistics	4.4%
Services	4.1%
Education	3.5%

The share of students in tertiary education institutions in Romania in the academic year 2019-2020, by field of study shows that the “engineering, manufacturing and construction” branch is among the highest in demand, on the second place with 20.4% (among the highest share in EU), after “business, administration and law”.

The student-academic staff ratio in tertiary education is 19.4 (number of students per member of academic staff), compared to the EU-28 average of 15.4, according to a Eurostat (2017) statistic regarding the tertiary education, which is a rather good number.

The skilled migration drove Romania to the top countries with the highest international migration rates worldwide: 7.3% p.a., second placed after Syria, as in the International Migration Report 2015: Highlights. In a report for the

World Bank by Dospinescu and Russo (2018), figures show that between 1990 – 2017, Romania registered the highest rise in the migration stock among all EU states: 287%, producing a loss of human capital represented by highly skilled workforce, with negative impact on the key sectors of the economy (health, informational technology, civil constructions, education, and physics) and capitalization of investments in the educational system by the destination countries, but on the other hand with positive effects like high remittances to countries of origin and decrease of unemployment rate.

The EU-integration brought a significant change in the Romanian migrant profile: "the mobility for labor of professionals in the context of the economic-financial crisis seems to set up the foundations of the skilled and highly-skilled personnel migration for labor", as stated by Iacob (2018), in the Romanian Journal of Communication and Public Relations.

As in a statistic of Eurostat (2019), research shows that in 2019, Romania had the lowest share (25.8%) of people aged 30-34 with tertiary education in the European Union.

The motives invoked by the migrated workforce are categorized as follows:

- economic factors: economic instability, unsatisfying salary level in Romania, lack of work position corresponding to the professional skills in Romania, infrastructure
- socio-political factors: political and legislative instability, corruption, status of the education system, status of the sanitary system, reunification with family already established abroad, social pressure, Romanian lifestyle
- organizational factors: limited number of career opportunities, leadership at the workplace in Romania, the interaction with co-workers in Romania

The Path to Entrepreneurship

A statistic from Eurostat (2020) regarding Structural Business Statistics. Business Demography Statistics shows that in 2018, in Romania, 135,532 new businesses were registered, while 80,181 deregistered, cited by Păunescu and Molnar (2020) in the article Country's Entrepreneurial Environment Predictors for Starting a New Venture—Evidence for Romania, while in 2020, statistics from the Romanian National Trade Register Office present a decrease of the average number of incorporations of natural and legal persons, in 2020, compared with 2019, with about -27.76%, depending on the 41 counties, the least decrease was in Bucharest and Ilfov county (-2%) and the highest in Arges county (-44.5%). The branches with the most SME incorporations are: Professional scientific and technical activities, trade and repair centers, construction, Information Technology and Communications.

As in the statistics of the National Trade Register regarding the student registrations in 2020, among the companies founded by students, from 19,880, only 9,196 are still functioning, the other were closed after a period of 3 years.

Financing Innovative Start-ups with potential

According to the Global Innovation Index (2020), the current crisis influenced the innovation at a time of flourishing. In 2018, research and development (R&D) spending grew by 5.2%, after recovering from the financial crisis of 2008-2009. Venture capital (VC) and the use of intellectual property (IP) were at an all-time high and policies provide a strong fostering of innovation, including in developing countries, in a promising trend.
Basically, figures show that:

- the pandemic has not changed the potential for breakthrough technologies and innovation
- top companies and R&D spenders will continue their respective activities of R&D, IP, and innovation for competitivity
- top R&D firms in the information technology sector, will push to digitalization and foster innovation
- pharmaceuticals and biotechnology sector will experience R&D growth because of the new focus on health R&D
- transport will migrate to "clean energy"
- innovation catalysis in traditional sectors (tourism, education, retail) but also on organizational level

This innovative potential requires government support as well as collaborative models and continued private sector investment in innovation.

On global level, the crisis has modified the financing scheme of VC deals that had started before the pandemic. Rather than financing novel, small, and diverse start-ups, venture capitalists began focusing on so-called "mega-deals",

boosting a number of large firms rather than giving money to a broader base of start-ups. Less early-stage VCs, by R&D-intensive start-ups with longer-term research interests in fields such as life sciences, and by ventures outside of the top VC hotspots. Current VC investments are concentrated in a few hot spots in the world (Israel, Hong Kong, Luxembourg, the USA, the UK), and only a few in emerging economies (China, India, Singapore), mainly towards health, online education, big data, e-commerce, and robotics.

According to Romania Insider (2019), Romanian venture capital fund GapMinder launches new selection round for startups and the article of Purice, Polish entrepreneurs launch in Romania Mill Games, the first accelerator to invest in independent gaming studios, main VC funds in Romania are: Catalyst (the first private equity fund designed for Romania), GapMinder (targeting IT Software and Services start-ups in Romania and Central Eastern Europe), Mill Game (Polish investment accelerator for game developers), Early Game Ventures (an early-stage venture capital firm in Romania investing in startups that create new industries in Europe's emerging markets), ROCA X (investment fund focused on early-stage tech startups), Cleverage Venture Capital, Founders Bridge, SeedBlink (crowdfunding platform) (medical service providers selling preventive medical packages to firms), Gradient Ventures, Techstars Ventures, Next Capital (for telemedicine), Sparking Capital (for circular economy, waste recycling).

Furthermore, there are some Business angels and private investors for tech start-ups like job recruitment platform through gamification, park-sharing application, software robots to provide companies with a faster way to automate processes etc.

Eliciting the fact that consumers spend more and more time online, some innovations in e-commerce are: omnichannel retail and industrial services (e.g. in real-estate), a marketplace for software applications.

The article of Cristea on Business Review (2020) states that foreign investments continued in Romania despite pandemic: expanding the production operations, greenfield investment, IT investment (mobile and embedded devices, software), R&D investment, a regional hub investment, scaling up investment.

Although there are first steps of financing tech start-ups by VC and business angels, the percentage is still small. Despite the high interest for entrepreneurial education and the wide range of courses and trainings about how to start a business, the step into entrepreneurship is strongly connected to the personal decision of young persons to take risks and responsibilities and choose the entrepreneurial pathway instead of the status of an employee of a big company or look for a job abroad.

Slower innovativeness on local level

Most of the Central and Eastern European countries have a moderate degree of innovativeness, Romania is an exception, being classified as a modest innovator, positioned below the EU-average, shows the report European Innovation Scoreboard (2019).

One essential cause of the slower innovativeness is the fact that some of the companies perceive barriers to digitalization. Some of them are:

- falsely perceived high cost
- difficulty in integrating a new software
- wrong mindset of not perceiving the time pressure and missing the opportunities
- lack of digital skills
- resistance to change.

Yet, the internet is a major driver for economic growth and over time more and more companies are coming to this conclusion. Big challenges occurred in the educational system. Higher education as a driving force is continuously adapting to this process.

Higher Education and the digitalization

Due to the pandemic, the academic field is exposed to a fast change of the teaching-learning process, which migrated from presence courses to online learning.

Universities are in charge with harmonizing the profiles of the graduates the labor market require, with the digitalization process and the job offer mutations (new job names, new job descriptions and requirements), meaning that the applicants´ profiles are changing towards digital literacy. That means that the future of university is more than ever entangled with the business field.

Talent Management

Talent management is expected to shift towards digitalization, as well as current psychological counseling.

The ideal situation is when every person finds a job according to their skills and talents, there is a motivational saying about this perfect matching, if you do the things you like, you will never need to work.

The upcoming trend has been lately to make more and more interviews online, saving time, costs and providing environment sustainability, so the pandemic acted as a catalyzer.

There are three categories of students: Those who just want to graduate, those who are outstanding in the theoretical part, they get good marks but have no experience, and those who are not focused on marks, but on internships or voluntary activities.

At present, some companies restrain their activity and cut the costs, because of the pandemic and are not in the situation to pay for the career reorientation of the employees, but the need for skilled workforce remains.

The selection can be made on two levels: the recruiters, as vendors, try to select persons according to their declared skills and competencies in the CV, but the company representative is interested in every detail which reveals the real level of competency and takes the final decision in “hiring and firing”. The importance of the managers is tremendous because they employ the candidates, although they not always know better who is fit for a certain job. In this case, recruiters and employers are allies in the recruitment process.

On the other side, the graduates, as candidates have the essential role of understanding their environment, gathering relevant information, make a rational choice and be able to highlight the strengths and convince the employer of their qualification.

In the sustainability circle, there is one more important actor: the university. The expectation of the recruiters towards universities is to enrich the curricula and adapt them for the new market challenges. Only a self-regulating circuit allows the divergent university curricula to be permanently adjusted and thus be corrected and adapted to the labor market requests.

The permanent strive of the higher education is to continuously modernize the curricula and keep it balanced and fill the gap between the CV and the effective competence.

The digitalization is a tremendous activator of rearranging the existing values and creating new dimensions, which induce a collaboration among the three parties, assisted and supported by the university and provides accuracy in solving the crisis and sustainability of the process.

The Innovative Perspective of the Recruitment Companies

Generally, the main challenge of the recruitment companies is matching the best applicant with a certain job offer. Therefore, assessments need accuracy, to satisfy both the objective and subjective expectations of the employers. According to a study conducted in 2016 by LinkedIn Talent Solutions (2019) that surveyed 1,297 hiring managers in 6 most important job markets in the world, the "potential means slightly different things to different companies".

Equally important is the personalized approach to the questions asked in the interview, for revealing the true potential of a candidate and highlighting it. It is not so relevant and conclusive to apply a set of closed and classic questions that restrict their true personality and sometimes push candidates to come up with pre-prepared answers. The most important qualities for a candidate are his soft skills. According to the study, there are six very important skills, namely Adaptability, Culture add, Collaboration, Leadership, Growth potential and Prioritization. These soft skills are closely followed by some key questions, which are not so predictable by candidates. The answers to these questions are not categorized as "good" or "bad", but as important for creating the candidate's profile as a whole. These answers follow the candidate's thinking and behavior in certain unexpected or unforeseen situations.

Traditionally, companies resort to recruitment companies and rely on them for hiring and training of the employees. Either a company has its own department, which supervises the career plan of each employee, or makes outsourcing to a specialized recruitment company, in case of SMEs. The innovation in human resources implies the entire interaction between organizations and its people and includes methods for talent assessment and management, as well as new innovative metrics to emphasize the important aspects of talent seeking, employment and management.

The pandemic forced the large-scale shift to remote working, creating a marketplace for remote or hybrid work. The report Labour Force in Romania. Employment and Unemployment (2019) evidenced by both strong demand from jobseekers (2) as well as an increasing demand from employers for jobs that are based remotely (3). These circumstances forced new concepts for doing business and continue the working activities. Among the new concepts there are variable staffing models, like a blended team. That implies high adaptability and flexibility and a mindset for unexpected tasks and uncertainty. That makes teamwork crucial for the successful solving of the tasks. Notions like core team (4) or team alignment get a new weighting. Just as it is very important to take soft skills into account in digital recruitment, it is just as important to test the candidate according to the theories of personality types and thus gather and facilitate analysis of information about teams or specific groups of people, based on the result of interactions in terms of preferences, interests, reactions, values, motivations, and skills. This characterization can very effectively determine a candidate's personality and adaptability and his inclusion in a core team.

The recruitment has three perspectives: of the employer, of the recruiter and of the job seekers; each one´s needs are important. The employer demands graduates with solid knowledge and some practical experience, at reasonable costs. The recruiter (which is a vendor) is the intermediating part (first has to understand exactly the needs of the employer, then seeks suitable candidates) and the candidate (searches for the best workplace, with reasonable pay and perks).
As consultants from recruiting companies state, the tendency is that students and graduates usually don´t ask for specialized counseling and a career development plan, sometimes not even when this action is financed through a project and the candidate would get consultancy for free. Instead, it is usual to rather ask friends or relatives for advice.

The advantages of a specialized coaching for finding the most adequate job are undeniable. The assessment elicits general essential features of the person, for a higher awareness on the job seeking, or specific features of the person towards a specific job profile and an assessment based on psychological aptitude tests reduces the seeking area to the most adequate jobs according to the strengths of the person.

If the competencies and skills lack from the candidate´s profile, training and re-skill are recommended. Sometimes qualified and specialized workforce is hard to find, so the burden of additional training falls on the employer.

The Role of the University as an Agent for Talent Management

In the Talent Management Handbook, Second Edition: Creating a Sustainable Competitive Advantage by Selecting, Developing, and Promoting the Best People, Berger and Berger (2010) conclude that Universities assist companies in their objectives related to talent management: to discover and promote new talent, to train, inspire and coach future leaders, to retain and reward the best people and thus implement a culture of organizational excellence. Universities have the first chance to identify, acquire and promote new talents, while building up new competencies on their way to graduation. Additionally, in the book Strengths-Based Recruitment and Development: A Practical Guide to Transforming Talent Management Strategy for Business Results, Bibb (2016) finds that “afterwards companies should find which of these talents are naturally fit for the jobs they need, as this approach promises more success compared to only find the people who can do the job”.

With an international experience of almost 30 years, the Faculty for Engineering in Foreign Languages has excellent connections to many of the companies with foreign investors, supporting companies in finding proper workforce for their open positions in engineering and management.

Instrumental Skills and the Market Value of a Graduate

A decisive task of the university teachers is to focus on core competencies, abilities, aptitudes, and instrumental skills beside the economic and technic skills, essential to be induced to the students, for getting them well equipped for the future. Instrumental skills are mainly instrumental values, which optimize the problem-solving capacity, keeping the balance at the workplace (calm, happiness, contentment, patience, active listening, leader vs. manager).

The Market Value of a graduate is illustrated in the rapidity of finding a job after applying and fitting perfect to the job according to the person´s qualification and specialization and to the total satisfaction of the employer. The whole process should lead to the win-win situation where both parts are content with their choice.

By understanding its role, universities contribute to a better adaptation to the workforce (5) sustainability through its specific instruments.

A Higher Responsibility within the Experiential Learning Cycle

The Experiential Learning Cycle undergoes a transformation to a quality Learning Cycle which includes the selection of the best suitable information from the flood and redundance of the information. In the author´s opinion, a rigorous selection of the courses the person enrolls in occurs, and thus Kolb´s model gets a new stage (see Fig 1), when students actively decide and choose the most adequate courses which bring them the most significant information and help them get the skills and competencies they need for employment. This is a feature we induce in our faculty by all the curricula, teaching the students who to learn, through giving them the choice and offering them the instruments to make rational decisions in what they need for their specialization, but they also like to learn, according to their preferences and talents. The active selection provides optimal information, and the student is at the right place and chooses the optimal combination of disciplines, so he/she will never have the impression that information is redundant or irrelevant.

Fig. 1: The Revised Model of the Experiential Learning Cycle (own representation)

A student that internalizes this learning methodology activates a high degree of selectivity and optimizes the learning process. Online courses require and induce a higher responsibility to the students, they get aware of the essential aspects that they need for a job that fits to their profile and build a career. On one side, the student learns to make rational options, on the other side, the faculty tries to permanently improve and optimize the curricula.

The entire perspective of the economic climate is eclectic and demanding for the young graduates and creates an interplay between the temptation to work abroad, start-up a business or get employed.

An example for the involvement of the German Stream from the Faculty of Engineering in Foreign Languages in the Talent Management

The German stream of the Faculty of Engineering in Foreign Languages is not so numerous, so it might be considered a niche. The interest of the German companies is high because the faculty it is a pool of German speaking graduates. The Job offers are generally sent to us, teachers, as one of the important recruitment channels for the companies. On the shortest way, teachers forward these job requests to the students or even to the graduates, over the Alumni Network.

Center for Counseling and Career Orientation

The University Politehnica of Bucharest (UPB) takes the agent function for talent management very serious, through its Center for Counseling and Career Orientation, students may get counseling and workshops on various topics, from writing a CV, time management, identification of the personal values, to sessions about discovering entrepreneurial skills.

A survey among the students and graduates of the German Stream at the Faculty of Engineering in Foreign Languages (N=56 after sampling) showed that 26.9% knew about the activities of the center and got information about:

- jobs in Romania (80.8%)
- jobs abroad (57.7%)
- study opportunities abroad (30.8%)
- study continuation opportunities (34.6%)
- techniques of job hunting (65.4%)
- self-awareness (53.8%)
- career planning strategies (73.1%)

Only 3.8% were counseled by a HR company, 57.5% got counseling within an EU-project and only 3.8% got counseling within specialized courses (Social Competencies, Personal Competencies). A first conclusion is that there is improvement potential in the communication among the center and the students, for a targeted information.

Initiatives on Faculty level

Many initiatives support the students and graduates in job seeking and in practical trainings:

- simulation of a job interview with representatives from companies or the Romanian-German Chamber of Commerce and Industry (AHK Romania)
- participation at POLIFEST (the annual career expo of UPB, which presents the educational offer, the industry-university partnerships and offers study taster days for high-school students)
- specialized courses and seminars on topics like: Leadership, Business communication, Social competencies
- stressing out entrepreneurial skills through gamification and within the Entrepreneurial Hub
- assisting the student organization of the German stream for preparing talent management events
- collaboration with recruitment companies and pointing out their role in the career planning of the students

The yearly survey carried out by the UPB highlights the fact that the graduates of the German stream record a 100% employability after their bachelor´s degree, some of them work part-time even during studies. This sheds a light on the employability profile of the graduates. The fact that our graduates have a very high employment rate demonstrates that their market value is high as well.

Analyzing the responses to the surveys made every 5 years (0-5-15 years) by our faculty, some of the job titles our graduates hold, are: Head of Sales Operations, Senior Buyer, Managing Director, Marketing Director, Technology Consultant, Credit and Risk Manager, Product Manager, Cost Manager, Salesforce Technology Analyst, International Key Account Manager, Brand Manager, International Purchasing Director. Few of them (three graduates, meaning 1%) are freelancers or founded their own small company in the last 5 years.

In the last decade, opportunities for studying abroad increased very much, thus students could gain a lot of management and technical experience on international level and practice the language among German speaking natives.

Conclusions

As an emerging economy, Romania has a great potential for foreign investments and the development of the innovative SME sector, and a rather good digital infrastructure, in terms of internet speed and ERP solutions. Nevertheless, there is a high demand for sustainable investments, to absorb the well qualified workforce. On one side, the attraction of the jobs abroad is high, on the other side, there are good opportunities for graduates to get employed in an innovative company or to start-up a business in an innovative field.

The paper presents some facts and figures about Romania, regarding the status of the higher education graduates and their perspectives to develop a career in the country and as a case study, the perspectives of a niche: the German speaking graduates with industrial engineering specialization.

The Faculty of Engineering in Foreign Languages understands its role of an education agent, which actively helps intermediating graduates for best fitting jobs, according to their knowledge, skills and aptitudes, through optimized curricula, continuous improvement and through the networks and university-company partnerships, which give graduates the opportunity to find their career path.

Our faculty is very active in keeping up the contact to its graduates in a network which means knowing about each other and providing information about practical stages or jobs for the students. Through its international experience and the know-how, curricula on technical and managerial knowledge, with a strong entrepreneurial focus is permanently adapted and kept up to date to the requirements of the labor market.

The actual research focused on the extent on which the information provided on university level reaches the students from our faculties. The figures show that there is space for improvement in communication and that the direct connection between the faculty and the companies, assure a good information flow, regarding the job opportunities for students and graduates.

Although on macroeconomic level, the tendency is to export workforce in other countries, when the performance characteristics and the qualifications meet the labor market needs, then the labor market value is high (100% employability), and our graduates find adequate jobs in Romania or (to a lesser extent, because of the economic risks) get financed for innovative start-ups and develop their career (as an alternative to the IT-branch, which definitely is a success story).

Acknowledgment

Authors are thankful for the thoughtful comments and valuable suggestions of Mr. Marius Neagu, psychologist and learning and development consultant at APT- evolution, which increased the quality of this article.

This paper was funded by UPB, through the project „Engineer in Europe" Nr. 457/GP/06.08.2020.

Endnotes

(1) Starting from September 2020, Romania was reclassified by FTSE Russell (the trading name of FTSE, wholly owned subsidiary of London Stock Exchange Group (LSEG) and is a unit of the Information Services Division) from Frontier to Secondary Emerging market status within the market benchmark and will be included in the FTSE Global Equity Index Series (GEIS) from March 2021). This is a step forward for the foreign direct investments from the point of view of investability and stock-exchange presence.
(2) Jobseekers searching for roles on the LinkedIn platform using built-in remote job filters, normalized against changes to all job searches.
(3) The share of job postings, which use number of keywords (i.e. 'remote work', 'work from home', home office') in 10 different languages, as well as built-in remote job filters.
(4) The theory of psychological type introduced by Carl G. Jung in 1920. This theory outlines a characterization of the person in depending on the types later developed in the form of a correspondence table with 16 personality types by Isabel Briggs Myers in 1940 based on the initial study.
(5) Workforce refers both to employment and self-employment.

Forecasting Time Series: Trend Function with Wavelet

Monika HADAS-DYDUCH

University of Economics in Katowice, Department of Statistical and Mathematical Methods in Economics,
40-287 Katowice, ul. 1 Maja 50, Poland
Email: monika.dyduch@uekat.pl

Abstract

The aim of this article is to present the author's combination of the creeping trend method with wavelet analysis. The purpose of merging the above-mentioned methods are short-term prediction of time series - several elements, even though as a rule wavelets are used for series consisting of at least several dozen observations. The applied creeping trend method has been modified in several essential stages. The proposed model is mainly used to predict macroeconomic indicators.

Keywords: wavelets, macroeconomic indicators, prediction, creeping trend.

Introduction

Forecasting is a technique that uses historical data as inputs to make informed estimates that are predictive in determining the direction of future trends. Businesses utilize forecasting to determine how to allocate their budgets or plan for anticipated expenses for an upcoming period of time. This is typically based on the projected demand for the goods and services offered.

In the other words, forecasting is a technique of predicting the future based on the results of previous data. It involves a detailed analysis of past and present trends or events to predict future events. It uses statistical tools and techniques. Therefore, it is also called as Statistical analysis. In other words, we can say that forecasting act as a planning tool that helps enterprises to get ready for the uncertainty that can occur in the future. Forecasting actually begins with management's experience and knowledge sharing. To obtain the most numerous advantage from forecasts, organizations must know the finer details of the different types of forecasting methods, understand what an appropriate forecasting method type can and cannot do, and know what forecast type is best suited to a specific need. Lets list down some major benefits of Forecasting:

- Better utilization of resources
- Formulating business plans
- Enhance the quality of management
- Helps in establishing a new business model
- Helps in taking best managerial decisions

Accurate forecasting is essential for every manufacturer, retailer, the distributor in the industries. The critical benefits are –

- Increased customer satisfaction.
- Efficient optimization of inventory.
- Better planning to reduce stock out and to overstock.
- Efficient Production Scheduling.
- Reduce the safety stock requirement.
- Lowering the cost of near expiry products.
- Improvement in pricing and promotion management.

The appropriate forecasting methods depend largely on what data are available. If there are no data available, or if the data available are not relevant to the forecasts, then qualitative forecasting methods must be used. These

Cite this Article as: Monika HADAS-DYDUCH" Forecasting Time Series: Trend Function with Wavelet" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

methods are not purely guesswork—there are well-developed structured approaches to obtaining good forecasts without using historical data. Quantitative forecasting can be applied when two conditions are satisfied: numerical information about the past is available; it is reasonable to assume that some aspects of the past patterns will continue into the future.

Prediction can be performed with various methods and models. These can be mechanical methods based on series analysis, trend models, econometric models of cause and effect, analog methods, methods based on artificial neural networks, wavelets, etc. The article uses wavelet and two adaptive models to predict time series, i.e. the creeping trend method and the method of exponential smoothing. However, the key role in the proposed proprietary model is played by wavelets.

The aim of the article is to present the author's combination of the creeping trend method with the wavelet analysis based on the Daubechies wavelet, the structure of which is a direct one because it does not require a thorough knowledge of the wavelet theory. It allows you to easily calculate the approximate values of the scaling function and the wavelet. This construction begins with certain numerical values that follow directly from the general theory.

The proposed model can be applied to various social and economic problems (see: Hadaś-Dyduch, Koutsky, Meluzinova, Balcerzak and Pietrzak, 2019; Hadaś-Dyduch, Balcerzak, Pietrzak 2016) . Each problem has its own importance (see for example: Balcerzak, 2015, 2016, 2017, 2020; Balcerzak & Pietrzak, 2017; Cheba & Szopik-Depczyńska, 2017; Dmytrów & Bieszk-Stolorz, 2019; Simionescu et al., 2017; Gavurova et al., 2017; Hadaś-Dyduch et al., 2017; Hadaś-Dyduch, 2018a, b, 2019a, b)

Wavelets

A wavelet is a waveform of effectively limited duration that has an average value of zero and nonzero norm. Many signals and images of interest exhibit piecewise smooth behavior punctuated by transients. Speech signals are characterized by short bursts encoding consonants followed by steady-state oscillations indicative of vowels. Natural images have edges. Financial time series exhibit transient behavior, which characterize rapid upturns and downturns in economic conditions. Unlike the Fourier basis, wavelet bases are adept at sparsely representing piecewise regular signals and images, which include transient behavior.

Wavelets as the Fourier transform decomposes a signal into a family of complex sinusoids, the wavelet transform decomposes a signal into a family of wavelets. Unlike sinusoids, which are symmetric, smooth, and regular, wavelets can be either symmetric or asymmetric, sharp or smooth, regular or irregular.

For different types of signals, you can select different types of wavelets that best match the features of the signal you want to analyze. Therefore, you can perform wavelet signal processing and generate reliable results about the underlying information of a signal.

The family of wavelets contains the dilated and translated versions of a prototype function. Traditionally, the prototype function is called a mother wavelet. The scale and shift of wavelets determine how the mother wavelet dilates and translates along the time or space axis. A scale factor greater than one corresponds to a dilation of the mother wavelet along the horizontal axis, and a positive shift corresponds to a translation to the right of the scaled wavelet along the horizontal axis. The following figure shows the db02 mother wavelet and the associated dilated and translated wavelets with different scale factors and shift values.

The Daubechies wavelet was applied to the research in the article, the basic properties of which were widely described in (Hadaś-Dyduch 2015, 2015c, 2016a,2019d, 2019e). The Daubechies wavelets, based on the work of Ingrid Daubechies, are a family of orthogonal wavelets defining a discrete wavelet transform and characterized by a maximal number of vanishing moments for some given support. With each wavelet type of this class, there is a scaling function (called the father wavelet) which generates an orthogonal multiresolution analysis.

Fig. 1: Daubechies wavelet

For Daubechies scaling functions, the connection coefficients contained in the matrix (Beylkin 1992, Ziółko 2000):

$$F = \begin{pmatrix} 0 & 2 & 0 & 2 & 0 & 2 & 0 & \cdots \\ & 0 & 2 & 0 & 2 & 0 & 2 & \cdots \\ & & 0 & 2 & 0 & 2 & 0 & \cdots \\ & & & 0 & 2 & 0 & 2 & \cdots \\ & & & & 0 & 2 & 0 & \cdots \\ & & & & & 0 & 2 & \cdots \\ & & & & & & 0 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix}$$

meet the rule:

$$f_{m,n}^{j} = 2^{-2j} \int_{-\infty}^{\infty} \varphi\left(2^{-j} x - m\right) \frac{d\varphi\left(2^{-j} x - n\right)}{dx} dx = 2^{-j} f_{m-n}$$

where:

$$f_n = \begin{cases} 0 & gdy \quad n = 0 \text{ lub } n \geq 2M - 1 \\ \int_0^{\infty} \varphi(x-n) \frac{d\varphi}{dx} dx & gdy \quad 1 \leq n \leq 2M - 2 \end{cases}$$

$$\varphi_{m,n}(x) = 2^{\frac{m}{2}} \varphi\left(2^m x - n\right), m \in Z,\ n \in \aleph,$$

$$\aleph = \left\{ n \in Z : \sup p\varphi_{m,n} \cap (0,1) \neq \varnothing \right\}.$$

$$f_{-n} = -f_n.$$

Algorithm

Proposed algorithm for prediction of time series with the use of wavelet Daubechies is a proprietary algorithm, later referred to as the M-2 model. The proprietary model is intended for prediction based on a one-dimensional time series. It is intended for short-term prediction. We introduce a time series into the model at the input, which is a one-dimensional, n-element series:

$$y_1,\ y_2,\ y_3,\ \ldots,\ y_n,$$

Then we follow the diagram shown in Fig. 2, as well as in Fig. 3 and Fig. 4.

Fig. 2: Graf – one of the step of algorithm

Fig. 3: Graf – one of the step of algorithm

Fig. 4: Graf – one of the step of algorithm

Algorithm Application

This part of the work presents the implementation of the M-2 model. The purpose of implementation is to predict macroeconomic indicators of the euro area countries. A detailed description of the implementation of the M-2 model is presented for the number of unemployed people in the euro area. Data on the number of unemployed in the euro area used to implement the M-2 model were taken from the Eurostat database. For clarity, the description of the implementation is presented in several key steps.

Series

As mentioned above, the implementation of the M-2 model was carried out for the time series presenting unemployment in euro area countries (series). The series included in the study covers the period 1997-2014 ((EA11-2000, EA12-2006, EA13-2007, EA15-2008, EA16-2010, EA17-2013, EA18-2014, EA19), annual average, 1000 people). However, the model was implemented for 2003-2019 data. 2019 was left as the test year.

Sub-series

A subjectively smoothing constant equal to 4 was adopted in the study. Thus, the series representing unemployment is divided into four-element sub-series. We get the following 14 sub-series:

SUB SERIES 1:

$$y_1,\ y_2,\ y_3,\ y_4$$

SUB SERIES 2:

$$y_2,\ y_3,\ y_4,\ y_5$$

SUB SERIES 3:

$$y_3,\ y_4,\ y_5,\ y_6$$

……

SUB SERIES 13:

$$y_{13},\ y_{14},\ y_{15},\ y_{16}$$

SUB SERIES 14:

$$y_{14},\ y_{15},\ y_{16},\ y_{17}$$

Extension of the sub-series

We can extend the obtained sub-ranks by various methods. The article adopts two trivial methods that give the worst results in the wavelet transform, i.e. the method by adding zeros and the symmetric method. The extension matrices in both methods for the analyzed example are as follows:

$$R_{M_1} = \begin{pmatrix} 0 & 0 & 0 & 0 & 14122 & 13503 & 12428 & 11262 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 13503 & 12428 & 11262 & 11004 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 12428 & 11262 & 11004 & 11706 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 11262 & 11004 & 11706 & 12604 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 11004 & 11706 & 12604 & 13084 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 11706 & 12604 & 13084 & 13179 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 12604 & 13084 & 13179 & 12336 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 13084 & 13179 & 12336 & 11238 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 13179 & 12336 & 11238 & 11482 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 12336 & 11238 & 11482 & 14736 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 11238 & 11482 & 14736 & 15565 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 11482 & 14736 & 15565 & 15776 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 14736 & 15565 & 15776 & 17835 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 15565 & 15776 & 17935 & 18928 & 0 & 0 & 0 & 0 \end{pmatrix}$$

$$R_{M2} = \begin{pmatrix} 11262 & 12428 & 13503 & 14122 & 14122 & 13503 & 12428 & 11262 & 11262 & \ddots \\ 11004 & 11262 & 12428 & 13503 & 13503 & 12428 & 11262 & 11004 & 11004 & \ddots \\ 11706 & 11004 & 11262 & 12428 & 12428 & 11262 & 11004 & 11706 & 11706 & \ddots \\ 12604 & 11706 & 11004 & 11262 & 11262 & 11004 & 11706 & 12604 & 12604 & \ddots \\ 13084 & 12604 & 11706 & 11004 & 11004 & 11706 & 12604 & 13084 & 13084 & \ddots \\ 13179 & 13084 & 12604 & 11706 & 11706 & 12604 & 13084 & 13179 & 13179 & \ddots \\ 12336 & 13179 & 13084 & 12604 & 12604 & 13084 & 13179 & 12336 & 12336 & \ddots \\ 11238 & 12336 & 13179 & 13084 & 13084 & 13179 & 12336 & 11238 & 11238 & \ddots \\ 11482 & 11238 & 12336 & 13179 & 13179 & 12336 & 11238 & 11482 & 11482 & \ddots \\ 14736 & 11482 & 11238 & 12336 & 12336 & 11238 & 11482 & 14736 & 14736 & \ddots \\ 15565 & 14736 & 11482 & 11238 & 11238 & 11482 & 14736 & 15565 & 15565 & \ddots \\ 15776 & 15565 & 14736 & 11482 & 11482 & 14736 & 15565 & 15776 & 15776 & \ddots \\ 17835 & 15776 & 15565 & 14736 & 14736 & 15565 & 15776 & 17835 & 17835 & \ddots \\ 18928 & 17935 & 15776 & 15565 & 15565 & 15776 & 17935 & 18928 & 18928 & \ddots \end{pmatrix}$$

Wavelet Coefficients

Following the algorithm of the wavelet transform for the Daubechies wavelet, we determine for each sub-series the wavelet coefficients (for the first resolution level), i.e. the coefficients:

$$a_0^{(n-1)}, a_1^{(n-1)}, a_2^{(n-1)}, a_3^{(n-1)}, c_0^{(n-1)}, c_1^{(n-1)}, c_2^{(n-1)}, c_3^{(n-1)}$$

For example, for the first sub-series from the calculation we get the following coefficients:

- extanding sub-series with method 1:

$$a_0^{(n-1)} = 14787{,}72 \qquad a_1^{(n-1)} = 10947{,}66$$
$$a_2^{(n-1)} = 1026{,}21 \qquad a_3^{(n-1)} = 14787{,}72$$
$$c_0^{(n-1)} = 5790{,}82 \qquad c_1^{(n-1)} = -1407{,}75$$
$$c_2^{(n-1)} = 3829{,}86 \qquad c_3^{(n-1)} = 5790{,}8212$$

- extanding sub-series with method 2:

$$a_0^{(n-1)} = 13142{,}89 \qquad a_1^{(n-1)} = 10947{,}66$$
$$a_2^{(n-1)} = 12989{,}17 \qquad a_3^{(n-1)} = 12142{,}89$$
$$c_0^{(n-1)} = -347{,}77 \qquad c_1^{(n-1)} = -163{,}35$$
$$c_2^{(n-1)} = 624{,}40 \qquad c_3^{(n-1)} = -347{,}77$$

Segmental Model

For the first level of wavelet resolution, we obtain 14 segment models. For each model, we determine the function values:

$$\tilde{f}(r) = \sum_{k=0}^{2^n-1} a_k^{(n-1)} \cdot \varphi([r/2]-k) + \sum_{k=0}^{2^n-1} c_k^{(n-1)} \cdot \psi([r/2-1]-k)$$

For $\mathrm{r} = 0, 1, 2, 3, 4$ (where ψ - wavelet Daubechies).

Model

Theoretical value:

$$\hat{y}_1,\ \hat{y}_2,\ \hat{y}_3,\ \ldots,\ \hat{y}_t\ \ \hat{y}_{t+1}$$

we need to calculate

$$m_2,\ m_3,\ \ m_4,\ \ldots, m_t$$

Basing on :

$$m_t = \alpha \cdot \hat{y}_t + (1-\alpha) \cdot y_{t-1},$$
$$t = 2,3,\ldots,n,n+1 \quad \alpha \in \langle 0,1 \rangle$$

Forecast and Forecast Error

Based on the formula (1) and the estimated value, we forecast the number of unemployed euro area countries for the next period. The obtained values do not match one hundred percent with the real value, they are burdened with some errors, which are listed in the table. From the two methods of sample extension proposed in the M-2 model during the wavelet transform, Method 1 gives more accurate prediction results.

Table 1: Errors in predicting the number of unemployed people in the euro area depending on the method of sub-series extension

Method	Error		
	AE	**PE**	**APE**
Method 1	46,3393	-0,2512%	0,2512%
Method 2	118,6669	-0,6433%	0,6433%

Source: Own

Summary

The article presents a combination of the creeping trend method with wavelet analysis and forecasting using the exponential smoothing method. The obtained results of the presented prediction method are relatively low compared to the results obtained with other adaptive methods. For example, the APE error for alpha minimizing the error of expired forecasts in the classical method of exponential smoothing is 8.5267%, while in the classical method of the crawling trend with the prediction method of harmonic weights it is 8.3336%.

The proposed in this article model can be applied to various social and economic problems. Each problem has its own importance. One of the increasing trends in the world for at least a quarter of a century is the progressing socio-economic diversification and cracking the world into two separate blocks - the world of poverty and the world of wealth (see: Cheba, 2015; Hadaś-Dyduch, 2015a, b, 2016, 2016b,c, 2017, 2019c, 2020; Pietrzak & Ziemkiewicz, 2018b, 2019). The social structure is changing (see: Horáková, 2015; Jankiewicz, 2018a, 2018b, 2018c, Jankiewicz & Pietrzak, 2020).

The distances between individual market segments and those remaining outside this market are growing. The benefits of economic growth are not evenly distributed. The richest are quickly escaping and at the same time the area of relative poverty of both the unemployed and some of the employed is growing, even in the conditions of favorable macroeconomic indicators and good economic condition of companies (see Balcerzak, 2015, 2016, 2017, 2020; Balcerzak & Pietrzak 2017; Goryakin & Yevgeniy, 2015; Potrafke, 2015; Kuc, 2017a, 2017b; Pietrzak et al., 2017b; Kuc-Czarnecka et al., 2020; Potrafke, 2015; Sánchez-López, Aceytuno, & De Paz-Bañez, 2019)

Abstract

The article is devoted to the research of processes for commercializing innovations taking into account interests coordination for the subjects of an innovation cycle. The purpose of the research is to characterize the current problems of the market for intellectual products, within which the commercialization of innovations is carried out. Based on the analysis of official statistical information, trends in the development of the Russian innovation market were identified. It is noted that the demand in the domestic market for intellectual property resulting from private businesses is relatively low. It is revealed that the activity of the private sector for investing in the innovation sphere is inferior to the state. The article suggests systematic marketing research of consumers ' requests for innovative products, the formation of a new mechanism for synchronizing financing at the stages of the innovation cycle, expanding the practice of concluding license agreements, developing innovation infrastructure, stimulating investment in science and training innovative personnel.

Keywords: Innovation, Innovation Activity, Innovation Management, Intellectual Resource.

Introduction

To characterize the modern economy, the definition of "knowledge economy" is often used, which emphasizes the importance of intellectual resources as a decisive factor in the efficiency of economic activity. In the knowledge economy, the process of labour-intensive production, based on the mass use of physical labour, takes a back seat. Traditional enterprises, which differ in their traditional capital structure and production organization, are being replaced by new intellectual organizations. The added value of the products in such organizations increases due to the use of knowledge and creative approaches, and the efficiency of production is evaluated by intellectual potential and innovation activity.

Innovation processes that commercialize innovations in specific production structures become a significant argument for structural transformations in the economy (Mashegov, P.N., 2004). The end result of novelties is innovation. In fact, innovation is a useful effect of accumulating intellectual capital, the result of the development, creation and distribution of new types of products and technologies in the production sector. The process of commercializing innovations involves the implementation of new knowledge in a specific product, technology, organizational and methodological approaches. This is the creation of a specific use value and the implementation of a value assessment

for the results of intellectual activity.

The fundamental essence of the concept forthe commercialization of innovations is to obtain an economic effect from the implementation of scientific and technological development. A simplified scheme for commercializing innovations looks like this: an interested customer or consumer invests in research and development or buys ready-made results of intellectual activity, and long-awaited funding comes to science. At the same time, successful commercialization of innovations requires a balance of interests among all stakeholders in the market of intellectual products, including developers, investors and end users. This study is devoted to the problem of matching the interests among the subjects of the innovation cycle in the process of commercializing innovations.

Literature Review

Research in the field of creating and commercializing the results of intellectual activity is of considerable interest to both domestic and foreign scientists. The relevance of the problems to form an effective system for mutually beneficial commercialization of intellectual property is due not only to the theoretical interest in the laws of development of innovation processes, but also to the practical significance of building effective models for commercializing innovations based on achieving a balance of interests among direct developers, investors, consumers and the state.

Such scientists as F. Khaek, J. Schumpeter, P. Drucker, A. Hosking, M. Peters, P. Senge, K. Vesper, etc. are interested in the problems of innovation management.

Questions of creation and commercialization of intellectual property objects are reflected in the research of I. A. Bliznets, V. A. Bobryshev, G. V. Bromberg, Yu.I. Vorobyov, A. A. Dynkin, R. Kelly, N. M. Korshunov, A. N. Kozyrev, A.D. Korchagin, K. B. Leontiev, V. A. Logachev, V. N. Lopatin, V. L. Makarov, S. V. Morozov, A. P. Sergeev, S. V. Usoltseva, M. Yu. Chelyshev and others etc.

Theoretical and methodological aspects to form an effective algorithm for commercialization of innovations were studied in the works of A. Brett, M.A. Pivovarova, Peter F. Boer, M. Porter, E.A. Kozlovskaya, Yu.V. Radionova, and others. However, the development of models for the commercialization of innovations based on the coordination of the interests between the seller and buyer of intellectual property objects in terms of paying the cost remains a very relevant area for further research.

To find out the best ways to improve the efficiency of commercializing innovations, it is necessary to create scientifically based methods for analyzing the market potential of innovations, forecasting demand and assessing risks at the early stages and in the process of conducting research.

Research Problem

Historical and modern experience of the society development shows that the need for science, scientific achievements, their usefulness, including for individuals, is constantly increasing, that is, the need for knowledge, spiritual and intellectual goods and values should be attributed to unsaturated. At the same time, it should be noted that the demand for innovation results from the industrial and social sectors lags behind the capabilities of the scientific and technical potential. To some extent, this can be explained by the fact that certain economic laws and regularities can be interpreted quite specifically in relation to the products of intellectual activity.

Among the essential features of science and its products, as a specific product resulting from the use of intellectual capital, the following items can be distinguished: uncertainty of costs, terms and results of research and development, "non-digestibility", "non-alienability", non-consumability in consumption, unpredictability and non-obviousness of scientific discoveries and inventions, non-linearity of the world around us. Features of the use value for scientific work are that they do not "wear out"in the process of consumption or "wear out" in a specific way. When transferring this product, it remains with the transmitting (selling) it. Once created, it either does not require new costs to be reused, or they are significantly lower than the cost of creating it. The main characteristics of the use value (cost) of an intellectual product in science at any stage are novelty, originality,uniqueness, as well as timeliness, potential or real profitability (Volkova, T.I., 2004).

The innovation process consists of obtaining and commercializing inventions, new technologies, products, and solutions in the field of production organization. The promotion of an innovative project from one stage to another requires mandatory feedback between the intermediate results of R &d and the market, because it is possible to implement a scientific result or technology only when it is able to strengthen someone's competitive advantage, to bring or to increase profits. Successful development of the innovation process requires multi-stage decision-making

and a variety of connections.

The result of commercializing innovations is the transformation of intellectual property products into a specific product that is sold on the innovation market in order to generate income (Kovazhenkov, M.A. and Bgantseva, Ya.V., 2009). Under the process of commercialization, innovations receive a market assessment of their use value (depending on the quality and novelty of the intellectual product), and their cost is specified (including the basis of evaluating the resources involved in the development and replication of the innovative product).

The process of commercializing innovations is actually determined by the duration of the stages in the innovation process itself, since at the stage of creating an innovation and its industrial development, two factors acquire a special influence: the risk level of investment losses and the level of investment costs. This is due to the fact that the return from scientific and technical activities can only be predicted taking into account the possible risks and the results obtained may not be commercialized. The risk level of investment losses decreases as positive results of scientific, technical, technological and commercial results related to a specific innovative project are obtained.

The following indicators can serve as criteria for selecting an innovative idea that involves subsequent commercialization:

- probability of technical success;
- patent purity;
- availability of scientific and technical prerequisites for transformation into a business idea;
- scientific and technical potential;
- the market potential of products created on the basis of innovation, the capacity of the future sales market;
- estimated production costs and sales price;
- availability and nature of competition;
- features of allocation channels;
- financial and economic indicators of investment efficiency.

The current state of the innovation market in the Russian Federation allows us to evaluate different indicators of innovative development (table 1).

Table 1: Target indicators of innovative development in the Russian Federation (Official website of the State statistics Committee, 2020)

Indicator name	Measureunit	2017	2018	2019
Share of organizations that implement technological innovations in the total number of organizations	percent	20.8	19.8	21.6
Domestic research and development expenditures, as a percentage of gross domestic product	percent	1.11	1.0	1.03
Internal research and development costs by funding source:	percent			
budgetary funds		63.8	64.3	64.4
extra budgetary funds		36.2	35.7	35.6
The share of costs for technological innovations in the total production costs of goods shipped, works performed, and services provided by industrial production organizations	percent	1.7	1.5	1.6
Share of innovative goods, works, and services in the total volume of goods shipped, works performed, and services provided by industrial production organizations	percent	6.7	6.0	6.1
Share of innovative goods (works, services) new to the world market in the total volume of goods shipped, works performed, and services provided by industrial production organizations	percent	0.2	0.2	0.3

Indicator name	Measureunit	2017	2018	2019
Share of innovative goods, works, and services in the total volume of exports of goods, works, and services of industrial production organizations	percent	7.1	6.6	5.2
Balance of export-import for technologies	mln. USA$	-2124,0	-1659,3	-1316,7

Analysis of the data presented in the table allows us to conclude that the domestic innovation market is quite stable. According to comparative estimates of specialists at the Higher School of Economics, who compared the indicators of innovative development of Russia and the EU countries, our country is in the top ten in terms of the intensity to spend on technological innovations. At the same time, it should be recognized that a significant share of the above costs falls on the modernization of the production apparatus (32.6%) (HSE University, 2020). A positive aspect is the reduction of the negative gap in the balance between export and import of technologies. However, Russian investors are not yet ready psychologically and financially to invest in innovative development. The structure of internal research and development expenditures is dominated by budget funds, which indicates an insufficient level of funding from private investors.

Market realities are such that the volume of effective demand is relatively limited, in other words, limiting (this is primarily relevant for the domestic market of the country), so a change in the paradigm of economic relations in the "science – production – consumption" cycle is necessary. And this process is gradually unfolding in Russia.

The stability of the innovation system, the ability to maintain its parameters under conditions of disturbing external influence is achieved with absolute efficiency of communication between the subjects of innovation-direct developers of intellectual products, investors, consumers and the state.

If we take into account that the appearance of the final product of innovation in the sphere of consumption involves the relationship of ten or several hundredseconomic entities, we can imagine the scale of their interaction and the number of economic ties that permeate the economic system.

Rational interweaving of economic relations leads to mutual consistency of the entire system of general, private and individual proportions of production and economic interests, i.e. the balance of the economic system. The alignment of interests is always relative and implies the possibility of deviations from the balance. Specific features of the innovation market create certain problems to coordinate the interests of innovation sector entities.

First, the specifics and transfer of ownership rights to intellectual products have a direct impact on pricing in the process of commercializing innovations. Transactions are mostly private, individual in nature, and there is a possibility of selling the same product and (or) its rights to several persons. The development level of modern information technologies makes it possible for unauthorized replication and use of intellectual property products.

Stratification of property rights, legal and normative regulation of relations between stakeholders significantly increases the protection of copyright. Regulation of transactions on the transfer of ownership, disposal and use of intellectual property objects reduces the number of conflicts and contradictions in the commercialization of innovations.

Second, the innovation market has pronounced features of an imperfect competition market. This is a market for differentiated products with low product interchangeability where a relatively small number of sellers and buyers interact. The asymmetry of the information field also contributes to the reduction of competitiveness. Imperfect information about prices, demand and competitiveness of an intellectual product negatively affects the balance of interests for innovation market participants.

Third, the innovation market is highly influenced by non-market factors implementing these products. These include the influence of subjective factors on price formation, the growth of transaction costs (the costs of specification and protection of property rights, the costs of opportunistic behavior), institutional and financial conditions that differ from the traditional market and are determined by state policy.

The main problems of commercializing innovations in Russia include:

– shortcomings in the tax legislation that is not focused on stimulating the innovative activity of enterprises and the cooperation of all participants in the innovation cycle;
– underdeveloped infrastructure of the innovation market;
– low efficiency of the state scientific and technical policy aimed at preserving, rather than expanding the

reproduction of the country's scientific and technical potential;

– underdevelopment of the small business system and state mechanisms that encourage support for the advanced development of such structures in intellectual production;

– lack of training in innovative professions, both from a quantitative and qualitative point of view;

– capitalization of science mainly at the level of individuals;

– the gap between science and education and, as a result, scientific results are not capitalized in the field of education, and young specialists are not involved in scientific research;

– the risk to degenerate domestic science resulting from external leakage of the best scientific personnel;

– low efficiency of innovation activity, which is due to the underdevelopment of existing institutions, rules, laws regulating economic relations in the innovation sphere;

– low efficiency of the system to protect intellectual property rights, poorly developed law enforcement practice protecting the legal rights forthe owners of industrial property;

– the long-term nature of the necessary research work in the short-term state policy and at the same time the demand for innovation from companies is mostly situational in the absence of long term systemic demand for innovation;

– the impact of supply on demand in the field of innovation at this stage is very weak, which is due to the technological backwardness of most companies, and the "operational gap" between the number of inventions created and the number of inventions actually implemented on a commercial basis in Russian companies is growing.

To find out the best ways to improve the efficiency of commercializing innovations, it is necessary to create scientifically based methods for analyzing the market potential of innovations, forecasting demand and assessing risks at the early stages and in the process of conducting research.

The modern innovation strategy is formed in accordance with the requirements of the new stage in post-industrial society development. The fourth industrial revolution, based on the priority in the development of digital technologies, dictates the need to choose areas of innovation in such spheres as development and implementation of end-to-end technologies thus ensuring the "digitalization" of economic processes. Key areas of support for digital initiatives were identified within the framework of the national program "Digital economy of the Russian Federation" adopted in 2017. These areas are presented as roadmaps to implement new technologies in business processes. Among the most significant are the following: artificial intelligence technologies, robotics, big data and IoT technologies, virtual and augmented reality technologies, and digital innovations in the field of production technologies (Komkov, N.I., Eroshkin, S.Yu. and Kravchenko M.V., 2005).

The implementation of the national program has its aim not only to overcome the delay of the Russian economy behind the technological leaders, including Singapore, Finland, Sweden, Norway, the United States of America, the Netherlands, Switzerland, Great Britain, Luxembourg and Japan, but also to create its own competitive technologies that correspond to the new technological order.

Accomplishment of digital innovations involves mixed financing of projects, since the introduction of digital technologies meets the interests of both the state and the business environment. The financial plan for state support of domestic developments in the field of end-to-end digital technologies involves the use of such tools as the grants allocation, subsidizing the interest rate on the loan, and direct financing of the activities by innovative leaders. Innovative programs are implemented with the help of the Ministry of Communications and Digital Development, the Ministry of Industry and Trade, as well as organizations such as the Russian Venture Company, the SKOLKOVO Foundation, the Innovation Promotion Fund, the Russian Information Technology Development Fund, and others.

The choice of priorities for innovative development also determines the construction of a modern algorithm to commercialize innovations. In our opinion, it is possible to achieve a relative alignment of the interests between subjects involved in the creation and implementation for technological products only if we change the model of economic relations in the "science-production-consumption" cycle. The relationship between these objects of the innovation process is often presented as a sequential (or parallel-sequential) linear relationship between its main links (the so-called "technological push" model). It considers research and development as the source and the only driving force. As a rule, an investor is actively involved in the commercialization process of an innovation at the stage of its introduction to the market. The consumer receives the finished product and adapts it while using it. It is obvious that such a model may have limited application in modern market conditions.

The new economic conditions are more consistent with the nature of communication, focused on the consumption and the consumer. The consumer forms a request for an innovative product, he/she is ready to accept and implement new ideas and technologies. It is at the stage of analyzing a consumer request when an association between an investor and a developer arises. The process of co-financing is carried out in the form of research grants, creation of spin-off companies or strategic alliances.

This structural and logical model implies close cooperation within the agreement relations, including the division of responsibility and risk between science, production and consumption. Creating an intelligent product in the form of new ideas and scientific concepts at the research stage involves timely adjustment for the characteristics of the intelligent product, taking into account consumer requests (Pivovarova, M.A., 2004)

Thus, according to E. A. Kozlovskaya and Yu. V. Rodionova, the developers and consumers' integration in the process of production and development of an innovative product provides a significant economic effect and accelerates the process of introducing this product to the market (Kozlovskaya, E.A. and Rodionova, Yu.V., 2014).

This approach reduces the risk of entrepreneurs ' investments bringing the product to the stage of commercial use, and reduces the cost of consumers to finish and adapt the intellectual product to its needs and requirements. In addition, the consumer will have sufficient information, which creates obstacles for an unscrupulous seller (selling an outdated product, inflating its price, etc.). Close structural and functional interaction will reduce the risk of shadow relations associated, among other things, with the institution of mediation, which is widespread in the intellectual sphere, including the sphere of science (Pivovarova, M.A., 2004).

The principle of state regulation at all stages of the intellectual product movement has a consistent impact on all processes of production and reproduction for an intellectual product. The inclusion of state power and management structures in the model provides legal protection for the developer and the manufacturer, the necessary support of the parties, and external conditions for the normal flow of the innovation process as a whole.

Of course, at the stage of fundamental research, ideas about the production (commercial) consumption of an intellectual product are usually general in nature. It is obvious that it is advisable to emphasize state support on this particular area of research. The implementation of state programs aimed at the development of domestic science can be carried out through co-financing and management, creation of a developed infrastructure for innovation, its scientific-based economic and legal support, compliance with certain proportions in the science – production cycle, etc.

Discussion and Results

Achieving a relative alignment of the interests among the subjects involved in the innovations creation is possible, first of all, by changing the model of economic relations in the cycle "science-production – consumption". Therefore, the concept of effective organization for the innovation processis of great importance. This includes a full cycle of creating innovative developments from the birth of a scientific concept to the creation of high-tech products and its further use to meet the needs of society and the state.

When making decisions about investments in research and determining their economic feasibility, it is necessary to use various methodological approaches to economic calculations that take into account the expected economic, technical, production and other types of effect, the profitability of innovation, and so on.

There is no doubt that to ensure the interdependence and interaction of the subjects in the innovation cycle, systematic marketing research is necessary, including identifying and taking into account consumer requests, evaluating the commercial potential of innovative products and products produced on their basis, the potential market, stimulating demand and promoting products from the manufacturer to the consumer, etc. There is also a need for a new mechanism for connecting science, investors, production, and consumers, which contributes to the commercial potential of innovations.

In recent decades, Russia has lagged behind the economies of developed countries in many areas. This state of affairs is largely due to both external and internal reasons. External reasons are the lack of demand for innovations and new technologies, the lack of state support for science and innovation, and the low attractiveness of science for young people. Internal reasons for the decline in the attractiveness of science are a decrease in the number of researchers, the amount of funding, which is manifested by a decrease in its effectiveness, a smaller number of patents, new technologies being created, and publications in leading journals (Komkov, N.I., Eroshkin, S.Yu. and Kravchenko M.V., 2005).

The problem of implementing research results remains significant for the Russian economy. It is necessary to create a new mechanism for making coordinated decisions, fully synchronizing funding from justification to development of innovative projects and development of their results in the future. The development of such a mechanism based on the strengthening of horizontal relationships between the subjects of the innovation cycle contributes to the coordination of their interests in the process of commercializing innovations.

Today, the country's leadership clearly understands that radical changes in the structure of ownership, production and employment are needed. The need to transit to an innovative economy, long understood and implemented on a large scale by developed countries, is gradually being recognized in Russia, both at the state level and at the level of private business.

The next direction of increasing the efficiency of commercialization is the possibility of attracting advanced foreign production and organizational and management technologies. Without this, it is impossible not only to effectively commercialize innovative developments that correspond to the era of the "knowledge economy" and the intellectualization of production, but also to solve such problems as updating the material and technical base, organizing new high-tech industries, and introducing modern management and marketing methods.

It is necessary to expand the practice of concluding license agreements that can actually save foreign exchange costs and allow the seller to get know-how assistance in improving the licensed product, as well as its commercialization and implementation in foreign markets.

To ensure the large-scale flow of innovation processes in Russia, a well-developed innovation infrastructure is necessary. Also, professionally trained specialists in the field of innovation and technology transfer are needed, since the volume of capital investments in successful enterprises into intangible assets that form the knowledge base is often equal to or even higher than investments in physical equipment (Pivovarova, M.A., 2004). In the modern world economy, under the conditions of high competition in the industrial sphere, it is the efficiency of mastering and improving the mechanisms for commercialization of research and development results that ensures the stability of the innovation process by attracting investors who are always at the emergence of new promising economic sectors.

All the above-mentioned processes should be accompanied by serious investments in science, because it opens up new directions of social-economic and technical-technological development of society. Since R &d often has a long time lag and a degree of risk, and scientists and businessmen sometimes do not get on well, the state should take such a responsibility as being a long-term strategic investor.

Overcoming the scientific and technological gap, switching to an innovative development path, and increasing the efficiency of innovation commercialization requires developing a long-term strategy for Russia's participation in the formation of the global economic, scientific and technological space. This strategy should become an integral part of the national socio-economic development strategy. This provides for the rational use of promising areas of Russia's international specialization, taking into account its competitive advantages. Such a strategy would allow Russian companies to get initial guidelines for forming business plans designed mainly for the future to enter foreign markets, acquire foreign assets, and develop cooperation with partners from other countries.

Only the transition to an innovative development scenario, targeting the widespread use of intellectual capital products, and improving the efficiency of innovation commercialization that meets the interests of all participants in the innovation process, opens the way to modernizing the Russian economy, increasing the pace and efficiency of its development based on the intensive use of domestic intellectual potential and the development of advanced technologies.

In conclusion, ii should be said that the effective functioning of the economic system requires the interaction of all its agents. Investors, manufacturers, scientists, the population and public authorities, despite the difference in motivation, should have a common understanding and a goal – "Development is for the sake of the country's future, not for short–term personal gain". In this connection, it is impossible not to recall the well-known thesis of J. Grata "innovation is, first of all, a state of mind". Unfortunately, as the history of world development shows, it takes tens or even hundreds of years to form a unified public consciousness.

Abstract

Smart devices and systems are increasingly getting into our lives and our homes. As technology advanced, and more and more devices got "smart", or "smarter", the number, complexity and impact of their addressed threats increased proportionally. As smart devices have reduced capabilities and performances, compared to classic ICT equipment, reduced attack surface and increased cybersecurity level may be expected. Still, the reality differs and, at present time, smart devices and systems bring new threats and increase the risks for ICT infrastructures. Due to their nature, errors, attacks, hacking on smart devices and systems have physical consequences, impacting safety and security of humans and their properties, safety and security of communities, and even nations.

Keywords: Smart Device, Smart System, Cybersecurity, Risk Assessment.

Introduction

While the first prototype of the first known automated house, ECHO IV, became operational in April 1966 as Computer History Museum (2016) published in a curatorial insight, the idea was not new, being prospected by inventors from the industrial revolution when, at the beginning of the previous century, electric home appliances were first introduced to market. As those were not smart devices, 60 more years were necessary to evolve into ECHO IV to control rooms temperature and start and stop some home appliances. In the next 20 years ECHO IV was followed by many other attempts to automate house processes and activities, from the 1969's Honeywell Kitchen Computer as Computer History Museum published (2016), to the more complex systems of the 1990's designed to help elders handle common tasks. Despite the fact that a major progress was made with the invention of micro-controllers and miniaturization, the "smart" revolution took the giant leap in the last 20 years, following the market development in computers, networking, multimedia and, of course, smart mobile terminals. Still, some areas like cybersecurity for smart devices and systems fell behind the market, and advance slower.

A smart home system refers to a system containing appliances, devices and software applications that work together to automatically or manually control the installed appliances from a local data network or Internet (remotely), using a mobile application or device. Securing complex technological environments, containing ICT and IoT technologies is currently a challenging task for professionals, and an almost impossible one for common consumers, as we are also showing in the present paper.

Considerations on Smart Devices Security

All "smart" equipment, device or system is based on 3 main pillars: computing power, programmable capabilities, and inter-connectivity (networking). Combined, they provide a sufficiently large attack surface for any person with some hacking knowledge, proper tools and an interest in getting into someone else data, or privacy.

As part of the larger technological revolution of IoT, smart devices continuously increase their presence in our day to day lives, starting from industrial automation, environmental sensors, or automated public services, to building management, home automation, or support to elders, persons with disabilities or ill people. Smart devices are basically specialised devices performing one or few simple and clear tasks, and contain a processing unit, memory unit, are programmable in certain aspects, and are capable to communicate with other devices using standardised data exchange protocols. Smart devices are products with reduced processing and networking capabilities built,

usually, for long term usage in various conditions and environments, with low to nonexistent change rate. Considering these, one might think smart devices provide a smaller attack surface for cybersecurity incidents. In comparison computers, tablets, or smartphones are general usage computing equipment used for lots and lots of tasks and activities, with tens of thousands of running application, services and processes, lots of input/output ports, tens of data exchange protocols, and dozens of programming languages used to create software applications. General use computing equipment provide a very large attack surface and are more prone to vulnerabilities, threats and cybersecurity incidents. Still, general use computing equipment, namely computers, servers, tablets, or smartphones use several protection means to prevent cybersecurity exposure and vulnerabilities exploiting, without relevant impact on performance, storage, or user experience. In smart devices, instead, there is a number of several cumulative factors contributing to increased risks, such as:

a) Outdating technologies, due to fast technological advancements;
b) Reduced performance due to constraints like smaller dimensions, low energy consumption, etc;
c) Smaller memory space, due to low cost and low energy constraints;
d) Limited protection means, due to reduced performance, reduced resources, and low energy constraints;
e) Permanent exposure into the network or Internet, due to the nature and purpose of the device;
f) Low to nonexistent update rate due to cost constraints, and fast technological advancements, etc.

Generally speaking, smart devices face a number of physical threats, several human related risks, and a large number of logical threats. The physical threats are mainly related to theft, physical destruction, and damage due to environmental conditions. Theft related risks may be mitigated making smart devices difficult for physical access using hard enclosures, concealed installations, and controlled or monitored environments. We should emphasise the fact that installation of sensors in remote, not monitored, or not guarded areas, may expose them to theft risks or as well may protect them, depending on every particular situation – parking sensors in a locality, versus environmental sensors in a forest.

When analyzing threats related to human users or operators, we should mostly consider those leading to loss of personal or sensitive information, especially consisting of images or sounds from the inside of buildings, or of people, data regarding presence inside the building, schedules, habits, etc. Misusing smart devices may result in leaks of such information to the Internet, with unpredictable consequences. Such incidents might be caused, as example, by accidental touches of an intelligent remote control pad leading to streams of multimedia data published on the Internet. Weak credentials to authenticate to the system, or to WiFi are, as well, important risks related to human use.

Logical threats, or cybersecurity risks, are much more difficult to predict, prevent, identify, and mitigate. In less than 10 years, cybersecurity transformed from an important ICT aspect, into a critical one, following the market explosion of mobile technologies, cloud computing, social media, or IoT, all summing up to previously known security aspects of classical computing. To fight cybersecurity risks, governments around the globe use a responsible approach on cybersecurity in their national legislation and institutions, with deeper focus on critical infrastructures, critical data, and service continuity for the society. As we exemplified in a previous paper, Ion M., Carutasu G. (2020), in the last 10 years the European Union had one of the most concentrated approach by issuing and renewing dozens of regulatory acts on subjects related to cybersecurity, critical infrastructures and IoT in general enforced at both, community and Member States' national levels, by establishing responsible institutional relationships at community level, and by strongly supporting market development in cybersecurity and critical systems.

An important aspect of smart devices and systems is that despite the fact that they use different technologies and different protocols for technological and historical reasons, in the end they can be regarded as following an architecture very similar to ICT, structured to the ISO/OSI model (physical, data link, network, transport, session, presentation and application layers) as published by the International Standardisation Organisation (1984), as well as its common TCP/IP implementation (physical, data link, network, transport and application layers). This situation may lead to similarities in attack patterns between the two (IoT and ICT), still considering the particularities related to specific technologies that were used, and the purpose of the device. As examples, consider a network of TCP/IP environmental sensors connected to the Internet to transmit pollution data in a busy city, or a network of LoraWAN public parking sensors, or Bluetooth bracelets taking the pulse and blood pressure of elders or chronic disease people. They mark some technological differences (analog or digital signal, gateway or cloud, communication protocols, etc) and some similarities (processing, storage, and transmission of data, standardised and common data protocols and architecture, Internet usage, etc), and they all behave similar, having the same usage cycle: they collect data, eventually they store some data, transmit data to a central system or cloud infrastructure over a standardised protocol, eventually receive some commands, process data, and perform some other tasks, such as alert

people in case of life threatening situations (pulse variations, blood pressure drops, etc). Smart devices are, usually, meant to function continuously, as long as they are powered, in recurrent usage cycles, as described above:

- Data collection stage: handles the collection of physical parameters from the environment or a target system in analogic or digital form. Transformation from analogic to digital is possible to occure at this stage, as sensors may be analogic or digital, and processing systems are commonly digital.
- Data storage stage: handles collected data storage on the device, considering the storage size available. As smart devices face constraints related to storage size, keeping data on device is only on temporary basis. Some data transformation may occur at this stage, considering the standardised formats implemented through programming.
- Data transmission stage: deals with the transmission of collected or stored data to a central processing system, or a cloud computing infrastructure, using standardised data transmission protocols. Data transformation occur in this stage, in order to encapsulate data in the proper data units according to the used transmission protocol.
- Data processing stage: is handled by a central processing system, an ICT system with specialised software applications, depending on the destination of the entire system. Data processing may be performed automatically, or based on human interaction.
- Commands stage: deals with commands received from the central processing system, and meant to determine some actions to be performed at logical level (inside the smart device), or at the physical layer (on the environment, or the target system). This stage is not always present (ex: passive sensors), and requires already programmed data processing at device level, in order to perform the commanded tasks.

This entire usage cycle is repeated over and over again in a repeated feedback loop, until the smart device is damaged, losses its electric power, or receives a stop command. The usage cycle stages of a smart device correspond to one or more layers in the classical computing OSI architecture making it easier to switch from classic computing systems hacking, to IoT hacking. Moreover, increased usage of TCP/IP, WiFi, and other general data communication protocols increases the exposure of smart devices to cybersecurity risks.

The above cycle is based, as may easily be seen, on a structural approach of a smart system. While some authors focus on similar, structural approaches regarding IoT architectures – Hu F. (2016) –, we tend to consider the ISO/OSI model quickly becoming more suitable, due to the increasing technological similarities between ICS and IoT retaining, still, the particularities related to IoT devices' usage purposes. This means, as already mentioned, that cybersecurity incidents may replicate reasonably easy, and in large aspects from the ICT world to the IoT one. Because IoT is, by its nature, connected with the physical world, consequences of cybersecurity incidents will have a more complex result and threatening impact on actual safety and security of people and society than ICT cybersecurity incidents. In this prospect, we observe that merging ICT and IoT technologies removes barriers, increases the complexity of cybersecurity incidents, and makes them dangerous in both physical and virtual worlds.

At present time defence means for complex cybersecurity incidents involving ICT infrastructures and smart devices or systems are difficult to access, or even understand for common users, and organisations. Regarding consumer level IoT systems, they are almost nonexistent. As result, despite a reduced exposed attack surface, smart devices may be vulnerable on their entire usage cycle, and a mitigation policy should address it entirely in order to ensure a safe usage, considering all their limitations, as already mentioned. In this perspective, we may conclude that, generally speaking, smart devices have a significantly lower level of cybersecurity compared to computers, smartphones, or tablets. Still, there are several ways one can take to increase the security of smart devices and, in particular, smart home devices, and that includes measures like:

a) Use strong credentials in all systems;
b) Keep smart devices in isolated network segments;
c) Use updated routers and firewalls;
d) Keep smart devices out of the Internet, unless necessary;
e) Update the firmware/software to latest stable version;
f) Replace old, not updated smart technologies, etc.

A particular category of technological threats has been brought in the recent years by artificial intelligence. As AI technologies develop, they are increasingly introduced, integrated into smart systems, and improved continuously with real life data collected, in purpose or error, without users' consent and sent over the Internet, as several cybersecurity and personal data breaches showed in the last years, such as: Alexa's 2018 privacy breach incident – Zhou Y. (2018), Amazon's 2018 personal data breach incident – Murnane K. (2018) –, Google Assistant's 2019 privacy breach – Barbaschow A. (2019) –, etc (the enumeration is not exhaustive, but only an exemplification).

Thus, despite the continuous development, reaching new heights in specialised domains, with regard to privacy and interaction with human environment improvements are still necessary – AI is still far from discerning between things to listen and process, and things private, or perilous to human safety or even human life. An appropriate approach that needs to be further investigated in the following years must focus on bringing the subject open on the table and promote building smart systems with "ethics by design" principles in mind, as evidentiated by Stefan R., Carutasu G. (2020).

Smart home systems – technological integration risks and mitigation

A smart home system represent a sum of IoT and ICT hardware and software technologies, with the purpose to manage and automate processes, tasks, and activities inside the house, in order to improve life conditions of the inhabitants. Smart systems are used, practically, in all areas of our present lives: in residential, professional, and critical infrastructure environments. We carry and use every day smart devices, parts of smart systems, being smartphones, smart watches, smart bracelets, smart sensors, smart actuators, smart tags, smart cars, remote controls, smart apps, etc. Considering the buildings application, the IoT components of smart systems fall into 2 structural categories, and comprise mainly in sensoring and actuating devices, as follows:

a) Building related: environmental sensors (light, temperature, humidity are the most common), safety sensors (electrical energy, gas, water, fire), as well as actuators elements such as: environmental actuators (windows, aerators, air conditioning, lights, etc), access actuators (gates, doors, windows), etc.
b) Inhabitants related: presence sensors, health related sensors (pulse and blood pressure are the most common), emergency button, etc.

From an ICT perspective, a smart building system (residential or professional application) falls into one of the 3 following variants:

a) An independent system: data processing is performed on devices, the system has limited functionalities manageable at device level;
b) With local ICT infrastructure: the central processing system is present on location and is, probably, directly connected to the IoT component; access to Internet may be required for mobile management applications;
c) On cloud computing infrastructure: the central processing system is running in cloud; Internet access is required; smart devices may connect directly to the system in cloud, or using a central gateway.

As smart systems used in home or professional building applications contain a large number of IoT and ICT technologies, each with its own vulnerabilities and threats, it is important to manage them as a whole, taking into account all their components and characteristics. Considering the diversity and fast development in technology, and also the continuously increasing merging between ICT and IoT technologies, cybersecurity in smart systems is a real challenge for everyone, especially for common users of smart building systems, in home or professional applications. A common user of smart technologies usually doesn't possess the necessary knowledge to properly secure them and trustfully relies heavily on the protection the device or system provides by itself. An older smart system usually rises much more cybersecurity challenges to its owner, compared to a new system. Even older components included in newer smart systems, will rise more cybersecurity concerns, from this perspective. A good example of mixed threat and complex attack based on merging technologies is the 2018 hacking of a fish tank to steal data from a casino – Wei W. (2018) –, clearly showing the impact of a not secured IoT device on secured ICT systems.

Considering the increasingly interconnection of different devices, the fast development in IoT and cybersecurity industries, and the fact that the people manifest a high latency towards money spending on technology adoption or technology update, smart systems face an increasing number of cybersecurity threats on all technological layers of their IoT and ICT components. Also, an important aspect caused by the same increased interconnection between technologies we daily use – computers, smartphones, smart TVs, smart watches, smart home devices, e-mail, file server, cloud storage, online payment, telework, etc –, is the fact that a cybersecurity breach may provoke much more damage than, maybe, previously estimated. Losses or modification of data, publication of personal data on the Internet, multimedia streaming, exfiltration of credentials, patterns and behaviors of inhabitants, modifications in smart home systems, malware installation, are all possible consequences of cybersecurity incidents involving ICT and IoT infrastructures in residential or professional environments.

To try to diminish the kind of above mentioned threats and risks, tasks related to cybersecurity would be better handled by technology providers and professionals in this area, capable to evaluate risks, take relevant corrective

actions and implement prevention measures. From this point of view, cloud based solutions will become the most secure for common users, as many technological activities are handled by technologies provider (hardware maintenance, software maintenance, networking, ICT cybersecurity, etc), even if human error may still appear. As well, IoT smart devices and systems may connect to specialised update services and automatically updating their software to eliminate vulnerabilities and limit risks. Cybersecurity devices to protect local smart environments (e.g. building environments for home or professional use) are still to penetrate the markets.

Still, every user of smart systems implemented in residential and professional environments can take few measures to increase the protection of informational and automated systems, such as:

a) Use strong credentials
b) Apply producers' recommended measures
c) Have data network segmented and use firewall technology
d) Keep important, and personal data away from IoT
e) Keep data private, especially credentials
f) Use anti-malware technologies
g) Update and upgrade technologies to their latest stable variants, and patches
h) Apply best practices, preferably issued by professionals
i) Periodically evaluate systems security, preferably by professionals
j) Apply professionals' recommended measures
k) Contact professionals on each hacking suspicions, etc.

Cybersecurity Risk Assessment for Smart Systems

The first step in cybersecurity of smart systems, especially in residential environments, is acknowledging and understanding the threat, and the risk. This may be hard for some consumers, as technology gets more and more complex and difficult to understand.

The second step is risk assessment, a realistic as possible evaluation of what might happen, and the possible consequences. Smart systems are complex systems that integrate multiple technologies: electric, electronic, data communication, and information technology, with particularities specific to each domain. Considering the diversity of purposes, technologies, and implementations, as well as the merging between ICT and IoT, it is difficult to asses risks from all perspective without in-depth knowledge in all or most of these areas.

A cybersecurity risk assessment framework represents a set of rules, standards, and activities performed in order to evaluate the risk level of computing infrastructures. It represents the foundation of all future measures regarding cybersecurity, and it is important to identify and apply a properly tailored risk assessment framework to the computing infrastructure, its purpose, and implementation. As well, cybersecurity risk assessment frameworks may target quantitative or qualitative aspects in different proportions, or both, in order to fit various purposes and applications. As a result, taking also into consideration the large variety of technologies, increased level of integration and multidisciplinarity of smart systems, development of several risk assessment frameworks and methodologies, each tailored to specific applications, became necessary. Currently, several organisations proposed some risk assessment frameworks to help evaluate the cybersecurity of smart systems, such as NIST (National Institute of Standards and Technologyh – NIST Cybersecurity for IoT Program), IoT Security Foundation (IoT Security compliance framework, by IoT Security Foundation (2020)), ISO/IEC (International Organisation for Standardisation / International Electrotechnical Commission), Intel (Threat Agent Risk Assessment methodology), etc. Considering all above, there is no general framework that can be applied as is to all smart systems in residential, professional, or critical infrastructures, and therefore, professionals will need to develop skills considering these criteria, and specialise on sectorial applications instead of generic ones. Due to constraints given by the available space, the paper will only analyse the 2 approaches we consider the most representative for the IoT cybersecurity market: the NIST program, and the ISO/IEC standardisation framework.

In their effort to support cybersecurity in IoT, NIST developed a Cybersecurity for IoT Program to support the "development and application of standards, guidelines, and related tools to improve the cybersecurity of connected devices and the environments in which they are deployed. By collaborating with stakeholders across government, industry, international bodies, and academia, the program aims to cultivate trust and foster an environment that enables innovation on a global scale.", NIST (2016). The Program takes into consideration the multidisciplinarity of smart systems and uses previously developments, building upon them, including IoT devices, data communication protocols for IT and IoT, hardware and software infrastructure, cloud computing, data management, IT

cybersecurity. NIST's Program has a wide profile, concentrating more on qualitative and disaster management aspects of cybersecurity of IoT systems.

ISO/IEC approach focuses, instead, on standardisation and common methodology to asses risk, being complementary, in this aspect, to NIST Cybersecurity for IoT Program. ISO concentrates on voluntary conformity to published standards elaborated by large open communities of experts. The general framework of ISO/IEC for cybersecurity is represented by the ISO/IEC 27000 serie containing dozens of standards on the application of cybersecurity in organisations, as well as other relevant standards. Among them ISO/IEC 27030 – Guidelines for security and privacy in IoT, still in continuous development, concentrates explicitly on cybersecurity of IoT systems, while the rest have a more general approach to cybersecurity, targeting IT systems, data communication, incident management, privacy, etc. Other ISO/IEC standards outside the 270000 series targeting security on IoT platforms, are: ISO/IEC 20924 – IoT definition and vocabulary, ISO/IEC 29161 – Unique identification for IoT, ISO/IEC 30141 – IoT Reference architecture, ISO/IEC 30147 – Methodology for Trustworthiness of IoT system/service, or ISO/IEC 30149 – IoT Trustworthiness framework. ISO/IEC standardisation approach of technologies and methodologies is complementary with any other risk assessment framework. Standardisation and mutual recognition, interoperability of concepts, technologies, methodologies are critical for general progress, market development, and intelligent use of resources, but need enforcement of compliance in critical aspects, or critical areas (e.g. critical infrastructures, important data protection, etc). Still, ISO/IEC standardisation approach is compliant and complementary to all other approaches concentrating on the actual evaluation process of cybersecurity. Other organisations involved in the process of standardisation with impact in cybersecurity area for IoT are ITU (International Telecommunication Union) and IEEE (Institute for Electrical and Electronics Engineers).

It is important to mention that other organisations and companies are deeply involved in IoT security and offer support in risk assessments through standards, guidance, best practices, tools and frameworks for evaluation or autoevaluation of risk exposure. As already mentioned, a integrative approach is necessary to cover all relevant aspects, the multidisciplinarity of IoT and the large diversity of technologies, and applications.

Conclusions

IoT technologies will accelerate their development and market penetration. IoT already becomes common presence in our lives, without us even really noticing. Due to cost constraints, users will continue to adopt technologies with a perceptible latency. As complexity and interconnection increases, cybersecurity become more difficult to be applied by normal users. As well, with technological accelerated progress common users cannot keep up with all the information will need to be remembered, all the tasks will need to be performed for a safe and secure IoT environment. Choosing between standards, frameworks, methodologies and tools to evaluate risk in own IoT environments is, already, overcoming to normal users, and will get increasingly difficult. Therefore, cybersecurity will need to evolve into automated processes and tools, performing more and more without human intervention. Where still needed, professionals should to be involved in resolving more complex cybersecurity incidents. Cost constraints, on the other hand, may lead to important raising in cybersecurity incidents caused by, on involving IoT devices and systems. Considering all these, IoT cybersecurity need to be addressed in simpler ways for the customer, keeping technological activities at technological level while maintaining the optimum performance in resolving incidents and keeping users, their data and their systems safe and secure.

Abstract

This article analyzes the impact of entrepreneurial behavior and attitudes on the economic growth of 21 European countries. The objective is through a set of entrepreneurship indicators collected by the Global Entrepreneurship Monitor (GEM) that measure entrepreneurial behaviors and attitudes such as Perceived Opportunities, Perceived Capabilities, Total Early-Stage, Entrepreneurial Activity, Established Business Ownership, Entrepreneurial Employee Activity and Innovation, assess the impact of these indicators of entrepreneurial activity on the economic growth of these countries. The empirical study uses a data panel covering 21 European countries and a period from 2001 to 2019. A statistical analysis of the dependent and independent variables, a correlation analysis, and a multiple linear regression model was estimated. The results suggest that entrepreneurial activity driven by opportunity, innovation, stable business owners and the involvement of employees in promoting entrepreneurial activity has a positive impact on Gross Domestic Product per capita and, as such, stimulates countries' economic growth. Europeans considered in this sample. However, entrepreneurial activity at an early stage and the skills and knowledge to start a new business have a negative impact on the economic growth of these countries. This study complements the existing literature that analyzes the impact of entrepreneurship on economic growth, but using a sample of European countries (there are few empirical studies with this purpose on European countries), and it is innovative since it uses the indicators for the first time. classified as entrepreneurial behaviors and attitudes collected by GEM to assess their impact on countries' economic growth.

Keywords: Entrepreneurial Behavior, Entrepreneurial Attitude, Entrepreneurship, Economic Growth.

Introduction

In recent years, the role of entrepreneurship as a driver of economic growth in countries and regions has been emphasized, arousing the growing interest of several authors. The first difficulties that are imposed on the study of entrepreneurship are to define the concepts of entrepreneurship and the entrepreneur and to find a reliable, robust, comprehensive and comparable measure of the entrepreneurial activity of the countries (Pittaway, 2005; Wennekers et al., 2005).

Taking into account the definitions of entrepreneurship and entrepreneur that bring together the greatest theoretical consensus among the authors, we can define entrepreneurship as an activity of innovating through a process of creative destruction (Schumpeter, 1911), the discovery of information that allows the detection of business opportunities (Kirzner, 1973) in environments of uncertainty and risk (Knight, 1921). Thus, in general terms, we can define entrepreneurship as the intention and / or action to create value through new businesses, products and / or methods and the entrepreneur the individual who develops the entrepreneurial activity, bearing risks, uncertainties and business opportunities.
If capturing the dimension of entrepreneurship and entrepreneurship in a single definition is difficult, it is even more challenging to find a measure, in empirical terms, of entrepreneurship that is robust and efficient and that allows countries to be compared in terms of entrepreneurial activity since, there are numerous definitions of

Cite this Article as: Sofia GOMES, Pedro FERREIRA and Tiago TRANCOSO"The Impact of Entrepreneurial Behavior And Attitudes In Economic Growth of European Countries" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

entrepreneurship, several international databases that collect different measures and dimensions of entrepreneurial activity, making comparison difficult.

Over time, several empirical studies have been carried out that demonstrate that entrepreneurship has an impact on the economic growth of countries (Ács, 2006; Ács & Naudé, 2011; Amorós, Fernández, & Tapia, 2012; Audretsch, 2007; Baumol & Strom, 2007; Carlsson et al., 2009; Hessels & Van Stel, 2011; Kourilsky et al, 2007; Minniti & Lévesque, 2010; Olaison & Meier Sørensen, 2014; Stam & Van Stel, 2011; Van Praag & Versloot, 2007; Van Stel et al., 2005; Wennekers and Thurik, 1999). However, there is no consensus among authors on the results of this impact, which may vary according to the macroeconomic condition of the countries (usually expressed by the Gross Domestic Product per capita) and the variables used to measure entrepreneurial activity. In this context, our study aims to measure the impact of entrepreneurial activity measured through entrepreneurial behavior and attitudes variables collected by GEM on the economic growth of 21 European countries (Belgium, Croatia, Denmark Finland, France, Hungary, Germany, Greece, Ireland, Italy, Latvia, Netherlands, Norway, Poland, Portugal, Russia, Slovenia, Spain, Sweden, Switzerland and the United Kingdom), from 2001 to 2019, with European countries being selected according to data availability.

This article contributes to the study of the impact of entrepreneurship on the economic growth of countries in two ways: (1) there are few studies that use a sample of European countries (Stoica & Roman, 2020) and (2) they are, for the first time, measures of entrepreneurial behavior and attitudes were used as measures of entrepreneurship to assess their impact on the economic growth of the European countries considered.

This article is organized as follows: in section II there is a brief review of the literature on the relationship between entrepreneurship and economic growth; in section III, data, variables and methodology used are presented; in section IV the results of the statistical and econometric analyzes performed are presented and the results are discussed and in the final section, the conclusions and recommendations for future studies.

Literature Review on Entrepreneurship and Economic Growth

Over time, entrepreneurship has been measured in quantitative terms, through the self-employment rate (Carree & Thurik, 2008; Mojica, Gebremedhin & Schaeffer, 2009; Carree et al., 2002) or by the percentage of own businesses (except for the agricultural sector) as a function of the total labor force (Audrestch & Fritsch, 2002; Carree et al., 2007; Parker & Robson, 2003; Li et al., 2009; Nzaku & Bukenya, 2005; Deller, 2007) and the number of new companies created, the latter measure being widely used by several authors as the main measure of entrepreneurial activity (Ács & Szerb, 2010; Audrestch & Fritsch, 2002; Fritsch & Muller, 2002; Baptista, Escárcia & Madruga, 2004; Fritsch, 2004; Carree & Thurik, 2008; Gries & Naudé, 2010; Hartog, Parker, Van Stel & Thurik, 2010; Bosma, Stam & Schutjens, 2006; Bosma, Erik & Schutjens, 2006; Callejon & Segarra , 1999; Ács & Armington, 2004; Audretsch & Fritsch, 2002; Hessels & Van Stel, 2011; Mariet Ocasio & Mariet Occasion, 2016).

However, several criticisms have arisen since, reducing entrepreneurial activity to the creation of new companies does not include, for example, innovation, the identified opportunity, entrepreneurial capacities, motivations and motivational appetite to undertake, being limited only to results of the entrepreneurial activity and not to the causes that motivated the action to undertake. This measure of entrepreneurship has proved to be very reductive (Baliamoune-Lutz, 2015) because for entrepreneurial activity it is not mandatory to have to create a new company since, entrepreneurship can occur within existing companies (without the need for new companies are created) as a result of a new idea or business opportunity.

According to Wong et al. (2005), the use of a quantitative measure of entrepreneurship such as the rate of creation of new companies results from the difficulty of obtaining better measures that can be tested econometrically to assess the impact of entrepreneurship on economic growth, which in turn is measured, for example, through the Gross Domestic Product per capita (GDP per capita).

In order to overcome the limitations of business creation as a quantitative measure of entrepreneurship and its impact on economic growth, GEM measured business creation through four indicators widely used by several authors (Ács & Szerb, 2010; Van Stel, Carree & Thurik, 2005; Wong et al., 2005; Stam et al., 2007; Martin & Picazo, 2008; Wennekers et al, 2005; Ács, 2006; Amoros, 2007; Koellinger & Thurik, 2009; Thurik, 2009; Audrestsch & Thurik, 2001; Audrestsch, 2007; Naudé, 2008):

(i) *Total Entrepreneurial Activity (TEA) Index* - Percentage of people involved in the creation of a new business or ownership / management of an existing youth business up to 3.5 years in relation to the adult population (18-64 years), that is, have been paying wages, salaries and other payments for more than 3 months, but for less than 3.5 years (includes self-employed or self-employed workers).

(ii) *Nascent Entrepreneurial Activity Index* - Percentage of people involved in creating a business in relation to the adult population (18-64 years old) up to 3 months, that is, people actively involved in starting a business as owners or co-owners (this business does not yet pay salaries, wages and other payments).

(iii) *Young Firm Entrepreneurial Activity Index* - Percentage of people involved in the ownership / management of a new business that has existed for more than 3 months, but less than 3.5 years in relation to the adult population (18-64 years), that is, the ownership and management of a business that have been paying salaries, wages and other payments for more than 3 months and less than 3.5 years.

(iv) *Established Businesses Activity Index* - Percentage of people involved in the ownership / management of an existing business for more than 3.5 years in relation to the adult population (18-64 years) who pay salaries, wages and other payments.

Even though there is consensus among the authors that entrepreneurship has an impact on the economic growth of countries (Ács, 2006; Ács & Naudé, 2011; Amorós, Fernández, & Tapia, 2012; Audretsch, 2007; Baumol & Strom, 2007; Carlsson et al. , 2009; Hessels & Van Stel, 2011; Doran et al. (2018); Walstad, & Thomas, 2007; Minniti and Lévesque, 2010; Olaison & Meier Sørensen, 2014; Stam & Van Stel, 2011; Van Praag and Versloot, 2007; Van Stel et al., 2005; Wennekers and Thurik, 1999), although the effect is not consensual. This impact depends on the growth stage of the economy under analysis (Bosma et al., 2009; Ferreira et al., 2017; Gries & Naudé, 2010; Sternberg & Wennekers, 2005; Wennekers et al., 2005), the same measures being possible entrepreneurs have different economic results, whether they are developed or developing countries (Sternberg & Wennekers, 2005; Valliere & Peterson, 2009).

In general, entrepreneurship can drive economic growth in countries by diversifying the offer of products and / or services, increasing competition (opening up to new markets and increasing efficiency) with positive externalities for families, of knowledge spillowers , job creation, increased innovation and productivity, increased company efficiency, stimulating creative destruction, with the replacement of less competitive and innovative companies, among others (Audretsch & Keilbach, 2004; Ács, 2006; Van Praag & Versloot, 2007; Van Stel et al., 2005; Wong et al., 2005; Fritsch, 2008).

However, the results are not consensual: studies have concluded that entrepreneurial activity has a positive and greater impact in developed countries than in developing countries (Stam, et al, 2011; Van Stel et al., 2005) but for other authors, entrepreneurship does not have a significant impact in high-income countries but has a positive impact in poorer countries (Stam, et al, 2011; Sternberg & Wennekers, 2005; Van Stel et al., 2005).

Thus, considering that entrepreneurship affects countries' economic growth in different ways depending on their stage of development, several authors have analyzed this relationship by distinguishing developed economies from developing economies (Bosma et al., 2009; Ferreira et al., 2017; Gries & Naudé, 2010; Sternberg & Wennekers, 2005; Wennekers et al., 2005; Avnimelech, Zelekha, & Sharabi, 2014; Hashi & Krasniqi, 2011; Marcotte, 2014; Van Stel et al., 2005; Wong et al., 2005), instead of using a single country data panel, regardless of their stage of development.

Although these studies make the connection between entrepreneurship and economic growth, some authors (Audretsch, 2007 and Audretsch & Keilbach, 2004) pointed out omissions in the neoclassical model of economic growth that was based on the factors of production - the connection of labor and capital to product, including, with a positive impact, the concept of entrepreneurial capital in economic growth models. Entrepreneurial capital included the number of start-ups per capita, initial activity in an information and communication technology company, that is, entrepreneurial capital encompassed all factors that facilitated the start of new businesses and positively influenced the economic environment. Other authors, such as Ács & Vargas (2005), have empirically tested the impact of Research and Development and human capital and concluded that they have a positive impact on economic growth; also Hessels & Van Stel (2011) showed that companies with export guidance have a positive impact on entrepreneurship and are an additional contribution to economic growth.

But even with the use of more quantitative measures, they are still not enough to measure the impact of entrepreneurship on economic growth, with GEM recognizing this limitation (Bosma, 2013), and revising its model. In this review, the concept of entrepreneurship was reformulated, having introduced three essential components (Bosma et al., 2009), which the GEM also started to collect:

- Attitudes / behaviors related to general attitudes and behaviors towards entrepreneurship in a country or group of countries;

- Activities that contemplates the creation of new initiatives and not the reducing vision of creation of new companies and,

- Entrepreneurial aspirations related to business innovation, growth and prosperity.

The three components can affect the economic impact of entrepreneurial activities, and introduced important changes in the concept of entrepreneurship, and, according to Ács & Szerb (2010), entrepreneurship came to be defined as a dynamic, multifaceted interaction of attitudes, activities and aspirations, allowing a new approach to the study of the impact of entrepreneurship on the economic growth of countries.

Galindo and Méndez (2014) explored the link between entrepreneurship, economic growth and innovation and concluded that there is a positive relationship between these three factors, since entrepreneurship and innovative activities contribute to the increase of the economic product and this, in turn , promotes entrepreneurial initiatives and entrepreneurship. Bosma et al. (2018) concluded through an empirical analysis that the quality of the institutional environment, such as financial stability, the size of government and the perceived skills for creating a new business, stimulates entrepreneurship and, as such, economic growth. Some authors (Marfatia, 2014; Marfatia, 2015; Hüning, 2017; Hüning, 2019) concluded that the levels of risk and uncertainty about the countries' economy, that is, a country's monetary policy influences the motivation of entrepreneurs, with consequences at the product level in macroeconomic terms. A more recent study by Doran et al. (2018) showed that entrepreneurial attitudes have a positive and significant effect on GDP per capita in developed countries, while entrepreneurial activity has a negative impact in low and middle income countries. Bohlmann et al. (2017) concluded through an empirical study that the perception of opportunities by entrepreneurs is positively related to entrepreneurial activity because individuals who perceive opportunities define more challenging goals and, ultimately, apply higher standards to assess the achievement of your goals.

In this way, increasing opportunity recognition, in turn, can increase entrepreneurial behavior and, as such, economic growth. On the other hand, the impact of entrepreneurs' perceived opportunities on entrepreneurship is not consensual since entrepreneurial capacity does not only include cognitive skills on how to start a new business, but requires the ability to recognize and explore opportunities, persistence to overcome potential obstacles and leadership skills in contexts of uncertainty. In this way, entrepreneurs' perceived opportunities are negatively with age due to certain age-related cognitive and physical declines (younger adults may be biased towards their own perceived skills and abilities for entrepreneurship) but positively related to entrepreneurial activity since the perceptions of capabilities by entrepreneurs are the basis for achieving the defined objective (Bohlmann et al., 2017; Ackerman et al., 2002).

The studies analyzed indicate that, in general, there is a positive effect of entrepreneurial activity on economic growth, but the extent of this impact is not consensual depending on the measures used to capture entrepreneurial activity. On the other hand, most studies use quantitative measures of entrepreneurial activity, especially the creation of new businesses, not incorporating the review of the concept of entrepreneurship carried out by GEM that covers entrepreneurial attitudes, behaviors and aspirations. In this way, our study complements the existing literature on entrepreneurship and economic growth, adding a new perspective that measures entrepreneurial activity through the attitudes and behaviors of entrepreneurs using a sample of European countries (according to the review carried out, there are few studies using samples with European countries), the ultimate objective being to assess the impact of entrepreneurs 'attitudes and behaviors on countries' economic growth.

Data and Methods

For the analysis of the impact of entrepreneurial attitudes and behaviors on the countries' economic growth, we consider a sample of 21 European countries (Belgium, Croatia, Denmark Finland, France, Hungary, Germany, Greece, Ireland, Italy, Latvia, Netherlands, Norway, Poland , Portugal, Russia, Slovenia, Spain, Sweden, Switzerland and the United Kingdom). These countries were chosen according to the availability of data in GEM, which is one of the most important databases of entrepreneurship.

For each country, measures of economic growth and entrepreneurial attitudes and behavior were considered. In this way, the dependent variable is the Gross Domestic Product per capita (GDP per capita) collected in the World Bank's World Development Indicators as a measure of the countries economic growth and the independent variables are the entrepreneurial attitudes and behaviors collected in the GEM. GEM data are collected from the adult population, for a sample of at least 2,000 respondents per country, and the basic research questions are the same for each participating country, which ensures comparable measures and allows relevant analyzes to be carried out between countries. Thus, the independent entrepreneurship variables used and their definitions are specified in table 1:

Table 1: Independent variables

ENTREPRENEURIAL BEHAVIOUR AND ATTITUDES INDICATOR (Abbreviation)	DEFINITION BY GEM
Perceived opportunities (PO)	Percentage of 18-64 population who see good opportunities to start a firm in the area where they live
Perceived capabilities (PC)	Percentage of 18-64 population who believe they have the required skills and knowledge to start a business
Total early-stage Entrepreneurial Activity (TEA)	Percentage of 18-64 population who are either a nascent entrepreneur or owner-manager of a new business
Established Business Ownership (EBO)	Percentage of 18-64 population who are currently an owner-manager of an established business, i.e., owning and managing a running business that has paid salaries, wages, or any other payments to the owners for more than 42 months
Entrepreneurial Employee Activity (EEA)	Rate of involvement of employees in entrepreneurial activities, such as developing or launching new goods or services, or setting up a new business unit, a new establishment or subsidiary
Innovation (INOV)	Percentage of those involved in TEA who indicate that their product or service is new to at least some customers and that few/no businesses offer the same product

Source: Own elaboration based on GEM definitions

The main objective of our study is to assess the impact of entrepreneurial attitudes and behaviors on economic growth measured through the GDP per capita of 21 European countries, previously mentioned, for the period from 2001 to 2019. The main hypotheses are:

- Hypothesis 1 (H1): The entrepreneurial activity measured by TEA, EBO and EEA have a positive impact on economic growth, as they are indicators of the level of entrepreneurial activity.

- Hypothesis 2 (H2): High levels of perception of capacities and opportunities (PO and PC) by entrepreneurs are positively related to countries' per capita GDP.

- Hypotheses 3 (H3): Countries with higher levels of innovation (INOV) will have higher rates of economic growth.

These hypotheses were tested using a multiple linear regression model, by the method of ordinary least squares (OLS) using a dynamic data panel since the sample collected has transversal and temporal data. As the sample considered in this econometric analysis is a dynamic observation panel, there may be some temporal correlations between the variables, and dynamic panel data estimation techniques should be used. In this way, we start from the basic model of dynamic panel data specified as follows:

$y_{it} = \eta_i + \alpha y_{i,t-1} + x_{it}'\beta + v_{it}$, being that, $v_{it} \sim iidN(0,\sigma_v^2)$

In these models, the problems are concentrated on the question of accidental parameters when fixed effects are omitted and on issues of simultaneity and endogeneity when the nature of these effects is random. Anderson and Hsiao (1981) suggested including the first differences in the dynamic model to overcome these problems:

$$\Delta y_{it} = \delta \Delta y_{i,t-1} + \Delta x_{it}'\beta + \Delta\varepsilon_{it}$$

where: *i* represents the country and *t* is the time; $\Delta \ln Y_{it}$: first differentiated logarithm of GDP per capita; $\Delta \ln X_{it}$: first logarithm of the dependent variables shown in table 1; εit: the error term. Thus, all the variables used (dependent and independent) were used in the model estimated in logarithm.

The collected sample was subject to a descriptive statistical analysis, a correlation analysis and, finally, the estimation of the regression model.

Results and Discussion

Table 2 shows the descriptive statistics for the variables (dependent and independent). The number of observations is 115 observations during the period from 2001 to 2019. In terms of GDP per capita, the maximum value $ 97,019.18, recorded by Norway in 2014 and the minimum value is $ 8,704.9 recorded by Russia in 2002 Regarding the independent variables related to entrepreneurial attitudes and behaviors, the maximum and minimum values recorded vary between countries (for example: TEA has a minimum value of 3.65% in 2011 in Slovenia and a maximum value of 14.16% in 2016 in Latvia; the PO has a maximum rate of 81.56% in Sweden in 2018 and a minimum rate of 10.87% in 2011 in Greece; the PC has a maximum rate of 60.22% in 2016 in Poland and a minimum rate of 27.46% in 2018 in Russia), thus suggesting that the independent variables have different impacts on the countries' economic growth, having been confirmed that there are no lagged effects.

Table 2: Descriptive statistics

	GDP_PC	TEA	EBO	EEA	PC	PO	INOV

Note: in the estimated model, all the variables used were logorithimized as suggested by Anderson and Hsiao, 1981 for this type of models. Source: authors own calculations.

Table 3 presents a correlation test between the variables, showing the existence of multicollinearity between the variables, since the test reveals a high correlation between some independent variables such as ASD and CP, which reveal a very positive correlation (0,52, $\rho = 0$) and EEA with INOV (0.42, $\rho = 0$) and with PO (0.59, $\rho = 0$). There are also some independent variables present a significant negative correlation, such as EBO and INOV (-0.15, $\rho = 0$).

Table 3: Correlation matrix of dependent and independent variables

The model is statistically significant according to the F statistics data. The adjusted R squared value is greater than 70%, that is, more than 70% of the variation of economic growth in the European countries in the sample measured by GDP per capita is explained by the independent variables of entrepreneurship.

The TEA that corresponds to the percentage of the population aged 18 to 64 who is a nascent entrepreneur or owner-manager of a new business has a negative impact on the economic growth of the countries, which can be explained by the fact that the countries are not divided by their stage of development economic - developed and developing countries and, corroborating, the conclusions of several authors in which TEA can have different economic results (Bosma et al., 2009 and 2012; Ferreira et al., 2017; Gries & Naudé, 2010; Sternberg & Wennekers, 2005; Wennekers et al., 2005; (Sternberg & Wennekers, 2005; Valliere & Peterson, 2009). The EBO that measures the percentage of the 18- to 64-year-old population who is currently the managing owner of an established company, that is, it owns and manages a functioning company that has paid salaries, wages or any other payments to owners for more than 42 months, has a positive impact on economic growth, explaining 49% of the variations. s in the GDP per capita of the European countries considered. The EEA as measured by the rate of employee involvement in business activities, such as the development or launch of new goods or services, or the creation of a new business unit, a new establishment or subsidiary also has a positive impact on economic growth, explaining 26 % of changes in GDP per capita of the European countries considered. The impacts of EBO and EEA on economic growth are also not consensual among authors, and may have different impacts depending on the level of economic development in countries (Bosma et al., 2009 and 2012), based on the premise that the greater the number owners of their own business and the more involved employees are in the entrepreneurial activities of companies, the higher the rate of business activity and, as such, the greater the economic growth.

Thus, hypothesis 1 is confirmed with respect to the variables EBO and EEA that have a positive impact on economic growth, since they are indicators of the level of entrepreneurial activity. With regard to the negative impact of TEA on GDP per capita, it is proved once again that its impact on countries' economic growth depends on their stage of development.

The PO measured by the percentage of the population aged 18 to 64 who sees good opportunities to open a business in the area of residence, has a positive impact on economic growth, that is, 43% of the changes in GDP per capita are explained by this variable, as found by Bohlmann et (2017) in his empirical study.

CP measured by the percentage of the population aged 18 to 64 who believes they have the skills and knowledge necessary to start a business, has a negative impact on GDP per capita. This result, according to studies by Bohlmann et al., 2017 and Ackerman et al., 2002, may result from the fact that the population included in the sample is older, that is, older adults have cognitive and physical declines related to age in as such, less perceived opportunities, having a negative impact on entrepreneurial activity and, consequently, on economic growth.
Hypothesis 2 that high levels of OP and CP are positively related to countries' per capita GDP is only partially confirmed. There would have to be greater discrimination of the sample separating the population from the countries considered by age.

INOV measured by the percentage of those involved in TEA who indicate that their product or service is new to at least some customers and that few / no companies offer the same product, has a positive impact on GDP per capita

and explains 63% of variations in the economic growth of the countries considered, as argued by several authors (Audretsch & Keilbach, 2004; Ács, 2006; Van Praag & Versloot, 2007; Van Stel et al., 2005; Wong et al., 2005; Fritsch, 2008; Galindo and Méndez, 2014). Thus, hypothesis 3 is confirmed that countries with higher levels of innovation will have higher rates of economic growth.

Thus, in the European countries considered, the level of economic growth depends on the level of entrepreneurial activity measured by the variables TEA, EBO and EEA, the capabilities of entrepreneurs (PO and PC) and the degree of innovation in the country (INOV), being mostly your positive impact.

Conclusions

Starting from the relationship already studied, in empirical terms, by various authors, between entrepreneurship and economic growth, we elaborated a new model in which the entrepreneurship variables are attitudes and behaviors of entrepreneurs collected by GEM. We conclude, for a group of 21 European countries that, in general terms, there is a positive impact of entrepreneurial attitudes and behaviors on the countries' economic growth, as measured by GDP per capita.

For this group of countries, entrepreneurial activity as measured by the entrepreneurial activity of stable business owners (EBO), that is, existing for more than 42 months and by the involvement of employees in promoting entrepreneurial activity (EEA) positively influence economic growth. However, entrepreneurial activity measured through early-stage entrepreneurial activity (ASE) in the group of countries considered has a negative impact on economic growth, since differences in the countries' stage of development have not been considered (classification of countries into countries developed and developing according to the value of GDP per capita).

The entrepreneurial activity captured by the ability to perceive that there is a good opportunity (PO) to start a new business in the area of residence has a positive and expressive impact on economic growth. However, the perception of entrepreneurs who have the skills and knowledge to start a new business (PC) has a negative impact on economic growth, which can be explained by the fact that the age of entrepreneurs has a negative effect on PC. On the other hand, this variable is negatively related to the fear of failure of entrepreneurs. Finally, entrepreneurial activity is positively influenced by innovation (INOV) existing in entrepreneurial activity at an early stage and, as such, has a positive impact on economic growth.

In general, this study suggests that entrepreneurship driven by opportunity, innovation, stable business owners and the involvement of employees in promoting entrepreneurial activity are key factors in stimulating the economic growth of European countries considered in this sample.

In terms of limitations, this study uses a relatively small sample (21 European countries and a maximum time period of 2001-2019), as a result of the availability of data. In future studies, we will try to use a larger sample of countries, divide countries by their stage of development (developed and developing countries) and include new variables that capture the attitudes and behaviors of entrepreneurs such as, for example, the intention entrepreneurship, the motivation index of entrepreneurs, fear of failure and entrepreneurship as a good career choice, measuring its impact on countries economic growth.

Abstract

Among the different categories of challenges that modern managers are faced with, one should consider the dangers that effective and efficient knowledge management must tackle. The critical meaning of knowledge is underscored in both the practice and theory of organizational management. In recent years, an increasing interest in the issue of stupidity in the context of organizational management has been observed. The purpose of the research is to present a diagnosis of the practical application of knowledge management systems, stupidity management and employee suggestion schemes. The initial research conducted permits to draw the conclusion that organizational stupidity management is a valid and important issue since it constitutes an integral element of knowledge management and employee suggestion schemes.

Keywords: Knowledge Management, Stupidity Management, Kaizen Management, Suggestion Schemes.

Introduction

Knowledge management has become one of the fundamental directions of research on how the competitive advantage of a business is shaped (Lee and Choi, 2003), on the sources of productivity and on the micro foundations of the broadly defined organizational success. It is often said in management literature that broadly understood organizational knowledge is an essential area of management research. One of the charges raised against the concept of knowledge management is the assumption that the members of an organization are oriented onto activities aimed at the acquisition, transfer, allocation and reallocation of knowledge, or the sharing of redundant knowledge (Davenport, et al., 1998).

When considering the imperfections of the knowledge management concept Alvesson and Spicer (2016) note that 'quick feet and hands combined with a friendly smile matter more for the economy than the intellect of a relatively small group of elite knowledge workers' (Alvesson and Spicer, 2016, pp. 6-7). These scholars have coined the notion of functional stupidity defined as 'organizationally-supported lack of reflexivity, substantive reasoning, and justification. It entails a refusal to use intellectual resources outside a narrow and 'safe' terrain. It can provide a sense of certainty that allows organizations to function smoothly' (Alvesson and Spicer, 2012, p. 1196).

Organizational stupidity management is a relatively new notion and not yet comprehensively studied in the area of management and quality studies. For this reason, the authors decided to conduct initial empirical research to determine whether the problem of organizational stupidity is raised in economic practice.

Based on the direction for research on stupidity in the context of the knowledge management pyramid proposed by Chwiłkowska-Kubala, Krasiński and Janiszewski (2020), the paper presents the results of initial research on the

Cite this Article as: Anna CHWIŁKOWSKA-KUBALA, Jan M. JANISZEWSKI and Marek KRASIŃSKI "Knowledge Management and Stupidity Management as New Competences of a Manager in the 21st Century - A Research Perspective" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

significance of knowledge management systems, stupidity management and employee suggestion schemes in economic practice.

The fundamental objective of the empirical research was to evaluate the legitimacy of research on stupidity management. The main purpose of the research was operationalized to three detailed research questions:

1) To what degree do contemporary organizations apply knowledge management, stupidity management and employee suggestion schemes?
2) What is the importance of knowledge management, stupidity management and employee suggestion scheme metrics in contemporary organizations?
3) How is organizational stupidity manifested in contemporary organizations?

Theoretical background

Knowledge Management

Knowledge management may be analysed from many different perspectives, namely human resources management, strategic management, IT systems management or with the adoption of an approach integrating many management functions. Table 1 shows selected definitions demonstrating the different approaches to knowledge management and research perspectives. From an interdisciplinary perspective, knowledge management can be defined as: 'effective learning processes associated with exploration, exploitation and sharing of human knowledge (tacit and explicit) that use appropriate technology and cultural environments to enhance an organization's intellectual capital and performance' (Jashapara, 2011).

Table 1: Selected knowledge management definitions

Authors	Definition
Dhar, et. al. (1997)	'Effective knowledge management systems allow people to learn from past decisions, both good and bad, and to apply the lessons learned to complex choices and future decisions.'
Tiwana (2001)	'Knowledge management is not knowledge engineering. Knowledge engineering has been a vital part of computer science but is barely even related to knowledge management. Knowledge management is a business problem and falls in the domain of information systems and management, not in computer science. Knowledge management needs to meld information systems and people in ways that knowledge engineering has never been able to.'
Davenport, et al. (1998)	'Knowledge management draws from existing resources that your organisation may already have in place – good information systems management, organizational change management, and human resources management practices.'
Swan, et al. (1999)	'… any process or practice of creating, acquiring, capturing, sharing, and using knowledge, wherever it resides, to enhance learning and performance in organizations.'
Skyrme (1999)	'The explicit and systematic management of vital knowledge and its associated processes of creating, gathering, organising, diffusion, use and exploitation, in pursuit of organisational objectives.'
Mertins, et al. (2000)	'… all methods, instruments and tools that in a holistic approach contribute to the promotion of core knowledge processes.'
uit Beijerse (2000)	'The achievement of the organization's goals by making the factor knowledge productive.'
Newell, et al. (2009)	'… improving the ways in which firms facing highly turbulent environments can mobilise their knowledge base (or leverage their knowledge 'assets') in order to ensure continuous innovation.'
Bergeron (2003)	'Knowledge Management (KM) is a deliberate, systematic business optimization strategy that selects, distils, stores, organizes, packages, and communicates information essential to the business of a company in a manner that improves employee performance and corporate competitiveness.'

The definitions presented in Table 1 by Bergeron and Dhar refer in part to the issue of continuous improvement of processes and the culture of learning via solving problems. These definitions are essential with respect to organizational stupidity and the kaizen system that will be discussed further on in the paper.

When referring to knowledge management one must discuss the issue of knowledge sharing. Knowledge sharing is of paramount importance and it is a characteristic of organizations that ground their operations on the premise of continuous improvement of their processes. Table 2 shows the most crucial impediments that organizations are faced with while sharing knowledge. Knowledge management systems in organizations ought to focus on removing these impediments, while 'knowledge managers' must be aware of their existence and should not deny them.

Table 2: Sharing Knowledge: Reasons and Impediments

Enablers	Impediments
High levels of trust	Fear and suspicion
Rewards for sharing	Unintentionally rewarded for hoarding
Team-based collaborative work	Individual effort without recognition and reward
Aligned mission, vision and values, and strategy	Individual accountability and reward
Joint team-wide accountability and rewards	Functional focus
Group accountability and rewards	Employee-owner interest conflicts.
Process focus	Lack of alignment
Focus on customer satisfaction	Not-invented-here syndrome
Open to outside ideas	Too busy to share
Eye on competition	Internal competition
Collaborative and cross-functional work	Incompatible IT
Need to share	Compartmentalization of functional groups
Localized decision making	Centralized top-down decision making

Source: Tiwana (2000, p. 80).

Among the greatest obstacles that the implementation of a knowledge management policy within a business is faced with is selling ideas to senior management and to end users. Knowledge management is often an expensive proposition as it does not only entail the expense of the technology infrastructure used to enable but also the expense in implementing corporate culture changes and revitalizing employee reward structures. Incorrect planning of a knowledge management strategy will not always produce immediate visible results, which could give rise to scepticism among upper management that controls the budget (Tiwana, 2000). The impediments listed in Table 2 related to knowledge sharing contribute to the development of stupidity in organizations, which will be discussed further on.

DIKW Hierarchy

DIKW is data (D), information (D), knowledge (K), wisdom (W): a four-layer hierarchy, where each layer adds certain attributes over and above the previous one (Fig. 1). Data is the most basic level; Information adds context; Knowledge adds how to use it; Wisdom adds when and why to use it. Despite being at the top of the DIKW hierarchy, wisdom is a neglected concept in knowledge management (Jifa, 2013; Rowley, 2007).

Fig 1. DIKW Hierarchy (Knowledge Management Pyramid)
Source: Rowley (2006, p. 164)

Data

All organizations need data, and some industries are heavily dependent on it. Data in contemporary organizations is usually stored in various technology systems where it is entered into by different departments e.g. finance, accounting, and marketing.

Information

Peter Drucker said that information is 'data endowed with relevance and purpose' which, of course, suggests that data by itself has little relevance or purpose. (Davenport, et al., 1998) Information is 'systematised data' (Meadows, 2001). Information shapes data and affects the vision of reality. Ackoff (1989) finds that although more and more information is being made available to managers this does not necessarily translate into better functioning of an organization. This would be possible in the event of no conflict between managers. Unfortunately, managerial conflicts in organizations tend to be more frequent than conflicts between competing businesses.

Knowledge

Knowledge and knowledge management are lofty concepts – debated by academics and managers and even doubted by some analysts – that only a few businesses have mastered.

In a practical sense, knowledge could be considered as 'actionable information'. 'Actionable information' allows us to make better decisions and provide an effective input to dialogue and creativity in organizations. Knowledge allows us to act more effectively than information or data and equips us with a greater ability to predict future outcomes (Tiwana, 2000).

Knowledge is the key resource in intelligent decision-making, forecasting, design, planning, diagnosis, analysis, evaluation, and intuitive judgment. Knowledge formed in and shared between individual and collective minds is not the product of databases but it evolves with experience, successes, failures, and learning over time. Tiwana's golden rule concludes: 'People first, then technology'. Davenport and Prusak's definition of knowledge highlights the characteristics that make knowledge valuable and those – often the same ones – that make it difficult to manage well: 'Knowledge is a fluid mix of framed experience, values, contextual information, expert insight and grounded intuition that provides an environment and framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms.' (Davenport, et al., 1998).

Wisdom

As arises from Figure 1 wisdom is at the top of the hierarchy. Wisdom is the ability to adopt reasonable and correct actions. All humans absorb information in the same way, yet they are not all equally apt at transforming the information they learn into knowledge, nor in putting the knowledge into use. In a class taught by the same

teachers, some students will score better than others in exams despite having been provided with exactly the same amount and the same quality of knowledge. This may result from facts such as motivation or experience, but there obviously also exist personal differences in learning ability (Meadows, 2001).

Wisdom includes (Jifa, 2013):

- understanding knowledge related to self;
- enlightening others as to knowledge;
- applying knowledge concerning with when, where to use;
- creating and inventing knowledge means obtaining new knowledge.

Employee suggestion system

Management of knowledge must encompass and improve business processes. Without a way of capturing and integrating past knowledge, any development process can quickly dissolve into chaos. Given this, it is crucial that organizations are managed in compliance with the kaizen concept via constant improvement through small changes and innovations.

The Japanese view of management this boils down to one precept: maintain and improve standards. Kaizen is a Japanese term and was initially used and spread by Masaaki Imai. Imai (2012) acknowledges that in the context of kaizen, management has two major functions: maintenance and improvement. Maintenance refers to activities directed toward maintaining current managerial, technological, and operating standards and upholding standards through discipline and training. It is very important for managers that everybody can follow standard operating procedures. Improvement refers to activities directed toward elevating current standards.

Kaizen is process-oriented, processes must be improved before results, as opposed to result-orientation where outcomes are all that counts. (Berger 1997.)

Improvements are initiated by individuals and most commonly organized in some form of a suggestion scheme. A suggestion scheme can be described as a formalized mechanism which encourages employees to contribute constructive ideas for improving processes in organization. Implemented ideas are rewarded by a monetary award or some other form of recognition usually proportionate to the benefits generated. (Milner, et. Al) 1995.

Organizational stupidity management

It may be concluded from an analysis of source literature that the discussion of knowledge and broadly defined organizational competence is dominated by categories proposed by scholars such as incompetence (Argyris and Business, 1986), organizational incompetence, or stupidity (Ott and Shafritz, 1994). In the context of stupidity, one notion worth noting is myopia of learning coined by Cohen and Levinthal (Levinthal and March, 1993) which is manifested in economic practice as having no holistic approach, focusing on current activities without considering the importance of the long-term perspective and underestimating the significance of potential failures.

M. Alvesson and A. Spicer (Alvesson and Spicer, 2017) state that we can encounter numerous instances of stupidity in economic practice. They have introduced the notion of functional stupidity defined as ‘organizationally-supported lack of reflexivity, substantive reasoning, and justification. It entails a refusal to use intellectual resources outside a narrow and ‘safe’ terrain. It can provide a sense of certainty that allows organizations to function smoothly’ (Alvesson and Spicer, 2012, p. 1196).

Ott and Shafritz (1994) point out that stupidity may be studied as per three different approaches: epistemological, socio-cultural and moral. At the epistemological level stupidity is failure to gather and use information. This may be exemplified by a situation where the information policy of a given organization forces decision-makers to make bad decisions. Ott and Shafritz (1994) found that even a good manager overwhelmed with an excessive amount of data that he or she is required to process will be unable to make the right decisions at the right time. From the socio-cultural and moral perspectives, as Ott and Shrafitz (1994) note, people are likely to do stupid things out of the need to adhere to rules applicable in a given society (or organization). Moreover, these researchers found that stupid conduct may also be the result of a drive to maintain good relations. What is more, Ott and Shafritz suggest that stupidity may actually be reinforced and promoted by culture, including organizational culture.

Alvesson and Einola (Alvesson and Einola, 2018) listed three aspects of functional stupidity:

- lack of reflectiveness manifested by taking one's assumptions as a given;
- not asking why one does something (justification);
- not considering the consequences or wider meaning of one's actions (lack of substantive reasoning).

Researchers have found that the members of an organization when taking various actions display a tendency to comply with organizational routine, procedures or guidelines. This results on one hand from the fact that they take certain principles as a given and on the other, from their passivity in asking questions and reflecting over the legitimacy of the actions they take (Alvesson and Einola, 2018).

According to Alvesson and Spicer (2017), there exist a number of ways for managers to encourage functional stupidity the purpose of which is to discourage employees from asking questions and reflecting on the tasks assigned or to curb such reflection. Among these methodologies Alvesson and Spicer name authority, seduction, naturalisation and opportunism.

Authority consists in taking advantage of the respect for a manager and the conviction that a manager 'knows best' and that it is up to the manager to determine the ways in which assignments must be completed. The authority technique is applied primarily in highly hierarchical structures oriented onto maximizing the efficiency of work assignments. Ott and Shafritz (1994) reached similar conclusions that hierarchical structures support the consolidation of stupidity.

The next three techniques of enhancing stupidity according to Alvesson and Spicer (2017) are similar to the socio-cultural and moral aspects of the perception of stupidity put forth by Ott and Shafritz (1994). Seduction refers to the 'charming' of subordinates by a manager through his or her impressive speeches, eloquence or great appearance. Managers who use the seduction technique are able to convey amazing visions and convince subordinates that their ideas are visionary and worth implementing. In line with the naturalisation methodology, the members of an organization are made to believe that a given solution is always implemented in the given company or is a successful industry standard. Arguments regarding alleged lack of alternative solutions is another component of naturalisation. According to Alvesson and Spicer, opportunism is a methodology often practiced in businesses rendering professional services. Opportunism is reinforced by a system of incentives and benefits that the persons completing an assigned task may expect to obtain. One manifestation of opportunism is doing tasks that produce measurable benefits without questioning their significance even if they are considered stupid by a consultant.

Functional stupidity may bring benefits from the perspective of an organization. It reinforces the feeling of certainty that one is doing the right thing and making the right decisions (Falkheimer et al., 2016). At the same time, it can contribute to reinforcing negative patterns of thinking both from the perspective of the individual and the entire organization.

As found by Alvesson and Einola (2018), the functional stupidity concept coined by Alvesson and Spicer (2012, 2017) is not tantamount to pure stupidity or a low intelligence quotient. To be considered functionally stupid, one needs to be intelligent and competent within a given area (via following the rules of a certain job, mastering recipes for success, being likely to take a subordinate position, etc.) (Alvesson and Einola, 2018). In reference to the concept put forth by Alvesson and Spicer (2012), Falkheimer et al. (2016) suggest that managers have a tendency to focus on linear decision models. The scholars found that this tendency may be paired with an orientation onto controlling processes and a strive at interpreting phenomena in the surroundings. This, in turn, makes stupidity management easier.

Table 3 presents a comparison of the differences in the various approaches: the concept of a knowledge-based organization and the concept of functional stupidity. The individual pairs of characteristics are not opposites per se but extreme attitudes/behaviour models.

Table 3: Knowledge-based organization vs functional stupidity

In line with the concept of a knowledge-based organization:	Concept of functional stupidity assumes that:
Employees are encouraged to delve into problems	It is easier to make decisions when people do not ask too many questions
Growth in productivity and efficiency owing to delving into problems	Reflecting and posing questions shorten the time to execute ongoing assignments
Creating new knowledge based on experience; concentration on shaping learning skills	Concentration on following the assumed career path by attaining set goals
Organizational culture strengthening openness to experiments and sharing experience, 'culture of different opinions'; readiness to accept mistakes	Caring about a good image within a group hinders willingness to propose non-standard solutions or comments regarding the set goals
Orientation onto the long-term perspective from the point of view of the resource base	Concentration on the short-term perspective – completion of assignments

Source: (Chwiłkowska-Kubala et al., 2020, p. 139).

Methods

The study was conducted using the CAWI (Computer-Assisted Web Interview) methodology in a targeted sample of graduates of post-graduate studies in Lean Management, Six Sigma and Management for Engineers. The assumption of the research was that a targeted sample would allow us to guarantee the right level of subject-matter knowledge of respondents since the syllabuses of these post-graduate courses covered issues related to knowledge management, continuous improvement, innovations, etc. The questionnaire research was conducted with the use of the Google Formular tool. Analysis of collected data was conducted based on descriptive statistics.

We received 44 replies in our initial study. Most respondents represented organizations operating on the market for over 16 years (56.8%), another 22.7% of replies came from businesses with 11 to 15 years of presence on the market, and 11.4% of replies came from those present on the market for 6 to 10 years, while the smallest percentage of replies i.e. 9.1% came from businesses with a market presence of 1 to 5 years. Bearing in mind the fact that 52.3% of replies were provided by representatives of large organizations (over 250 employees) it should be assumed that procedures and management processes are formalised in the organizations studied. All respondents hold managerial positions in their respective organizations.

The first part of the questionnaire pertained to the identification of whether knowledge management systems, stupidity management systems and employee suggestion schemes exist in the organizations studied and if so, whether any metrics are used to manage the systems.

Results and Discussion

The distribution of answers is shown in Table 4. Based on an analysis of the results obtained we can reach the conclusion than none of the three management systems exists in more than 50% of the organizations studied. The most common is the employee suggestion scheme management system (45.5%), which is only an introduction or a component of the knowledge management system (40.9%). In the times of knowledge-based society and knowledge-based economy these results are hardly optimistic. The situation is even worse when it comes to management of such systems since only half of employee suggestion schemes are measured and as regards knowledge management systems, only 44.4% of them are. Bearing in mind the well-known saying by Peter Drucker 'you can't manage what you can't measure' we are faced with the question what the knowledge management systems and employee suggestion schemes are used for in over half of the companies we studied.

Table 4: Management systems in organizations studied

Existence of a management system:	Knowledge		Stupidity		Employee suggestions	
	Yes	40.9%	Yes	6.8%	Yes	45.5%
	No	59.1%	No	93.2%	No	54.5%
Measurement of a management system:	Knowledge		Stupidity		Employee suggestions	
	Yes	44.4%	Yes	66.7%	Yes	50.0%
	No	55.6%	No	33.3%	No	50.0%

Source: Own materials based on the results of the empirical study conducted.

The research conducted was also aimed at providing the authors with answers to the question whether the issue of stupidity management is worth taking up in the future. In the light of the assumptions of the stupidity concept discussed earlier on in the paper, we have found that the issue is significant from the theoretical perspective. In practice, however, only 6.8% of the organizations studied declared that a stupidity management system is in place at their workplace but – interestingly – in 2/3 cases the system is actually measured. This may mean that the problem is still relatively new and as such not popular, but those businesses that made attempts to implement it have also decided to apply metrics to measure the system.

The second part of the questionnaire was aimed at answering the question whether there exist manifestations of organizational stupidity in the organizations studied. Since there are no stupidity management systems in place, perhaps no such manifestations have been observed in the first place? The results of this part of the study are shown in Table 5.

Table 5: Manifestations of stupidity and knowledge in the organizations studied

Please specify which statement best describes the reality in your organization											
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	
Employees are encouraged to delve into problems	11%	5%	18%	9%	7%	14%	9%	11%	11%	5%	It is easier to make decisions when people do not ask too many questions
Growth in productivity and efficiency owing to delving into problems	11%	7%	9%	16%	11%	11%	11%	14%	7%	2%	Reflecting and posing questions shorten the time to execute ongoing assignments
Creating new knowledge based on experience; concentration on shaping learning skills	9%	7%	11%	16%	14%	16%	16%	5%	2%	5%	Concentration on following the assumed career path by attaining set goals
Organizational culture strengthening openness to experiments and sharing experience, 'culture of different opinions'; readiness to accept mistakes	11%	7%	11%	7%	11%	11%	16%	14%	2%	9%	Caring about a good image within a group hinders willingness to propose non-standard solutions or comments regarding the set goals
Orientation onto the long-term perspective from the point of view of the resource base	11%	5%	16%	2%	11%	0%	7%	23%	5%	20%	Concentration on the short-term perspective – completion of assignments

Source: Own materials based on the results of the empirical study conducted.

The attitudes and organizational behaviour presented in the left-had side of the table are characteristic of organizations oriented onto knowledge management, while the right-hand side shows manifestations of

organizational stupidity. Respondents were asked to mark the statement that best exemplifies the situation at their workplace and a 10-point scale was adopted. The distribution of answers to the first pair of statements demonstrates that – if we treat them as bipolar opposites – there is a perfect equilibrium – each received 50% of all answers. However, there are considerably more (11% for answer 1) cases where knowledge management issues prevailed over stupidity-related issues (5% for answer 10). The second and third pairs of statements demonstrate a slight advantage of knowledge management (55% to 45% in the second pair and 57% to 43% in the third pair), while the two last pairs tend to incline towards manifestations of stupidity (52% to 48% in the fourth pair and 55% to 45% in the fifth pair). The analysis of overall results but also detailed results for the individual values in the table allows for the finding that manifestations of organizational stupidity are common in the organizations studied. Therefore, we should pay more attention to this problem so that not only knowledge but also stupidity could be effectively managed.

The third part of the questionnaire featured questions the purpose of which was to formulate a diagnosis of the manifestations of organizational stupidity and knowledge management and employee suggestion schemes with regard to the individual levels of the knowledge management hierarchy discussed earlier on in this article.

Out of the total of organizations studied, 34.1% of them are not undertaking any actions aimed at ensuring the right quality of data supplied to them. It is a standard procedure to assure data quality at 31.8% of the organizations and 34.1% of them sometimes do it. At the same time, only 45.5% of the organizations studied do not allow their employees to use data obtained randomly. This means that in the organizations studied the existence of organizational stupidity has solid foundations and it could be transmitted onto the higher levels of the DIKW hierarchy. A decision-making process grounded on unverified data may lead to reaching wrong decisions, which could be detrimental to the entire business.

Unfortunately, at a higher level of the knowledge management hierarchy the issue of quality assurance – in this case of information – looks even worse. There are no information quality assurance systems in place in 70.5% of the organizations studied, and 52.3% of employees are not trained or instructed on the correct use and generation of information in any way. Such training is available to all employees in just 29.5% of businesses studied and in 18.2% of organizations only selected persons undergo such training. It arises from these results that at the level of information, in the organizations studied there exist even more manifestations of organizational stupidity than was the case at the level of data.

The next level of the knowledge management hierarchy studied was knowledge itself. Only 52.3% respondents said that there exist knowledge bases or banks in their businesses and similarly, just over one half (54.5%) of organizations studied hold meetings during which employees are given the opportunity to share their knowledge about the projects they are working on. The fact that knowledge is not codified and is predominantly hidden, the weak foundations of knowledge management and the high chances for spreading organizational stupidity at the base of the knowledge management hierarchy translate into a situation where decisions in organizations are made in considerable number of cases without a substantive justification, as claimed by 61.4% respondents. Only 22.7% of respondents demonstrated a converse opinion, while 15.9% could not provide any answer to this question.

The initial research conducted allows for the conclusion that the problem of organizational stupidity management, as an integral component of knowledge management and employee suggestion scheme management, is valid and significant. There is a widespread debate on the issue of knowledge management, a lot is being written on the topic and many trainings are being organized in this field of study. However, little attention is paid to a specific threat that this approach must tackle. Organizational stupidity exists. It may often be covert but it still exists. It might be worth introducing a formal stupidity management system so as to minimise its impact on the added value generated in organizations, while in advanced stupidity management systems one could also try to generate some added value of stupidity itself.

Future Research Perspectives

The results of the research allow for the conclusion that the issue of stupidity deserves the attention of researchers. In our opinion, it would be worthwhile to conduct research on a larger sample where the criteria could include the size of the organization or the sector of the economy a given organization operates in to identify correlations between sectors, company size and stupidity and knowledge.

Among the directions for future research on the topic are studies on conditions favourable to the emergence of organizational stupidity, as well as research on the impact of stupidity on the productivity of contemporary organizations.

Abstract

The principal features of contemporary reality are fluency and rationality in the use of modern digital technologies. It is essential that children and young people develop the digital competences of the future. This article discusses the trends in future labour markets and the characteristics of digital competences. The aim of the article is to verify areas and factors influencing the development of digital competence in the context of future labour market requirements. The student's contemporary environment should be examined to answer the research question: are modern students provided with suitable conditions for acquiring basic and advanced digital competences? This examination will allow the identification of the components of the future digital competence indicator. Therefore, on the basis of research conducted among experts, the authors have proposed factors affecting the components of the future digital competence indicator, which may be proposed in the context of assessing the level of competence of students prepared for the future labour market. The following research methods were adopted during the research process: critical analysis of literature, heuristic method, selected quantitative methods, analysis of digital competence level.
The authors conducted primary research among: experts in digital competences and among primary school students (children and youth).

Keywords: Digital Competence, Education, Information and Communication Technologies

Introduction

The key features of contemporary reality are fluency and rationality in the use of modern digital technologies. It is essential that children and young people develop digital competences of the future.

It is expected that the most crucial competences will include fluency and rationality in exploiting the potential offered by information and communication technologies while recognising and consciously avoiding emerging risks. It is essential in this respect to develop, among other things, digital competences, the possession of which has been recognised as a prerequisite for functioning in a digitised environment and achieving success in life (2018/C 189/01) (2018/C 189/01).

The aim of the article is to verify areas and factors influencing the development of digital competence in the context of the future labour market requirements.

The student's contemporary environment should be examined to answer the research question: are modern students provided with suitable conditions for acquiring basic and advanced digital competences? The aim of this examination is to identify the components of the future digital competence indicator. Therefore, on the basis of research conducted among experts, the authors have proposed factors affecting the indicator of future digital competences, which may be proposed in the context of assessing students who are being prepared for the future labour market.

Cite this Article as: Agnieszka BUDZIEWICZ-GUŹLECKA and Anna DRAB-KUROWSKA "Analysis of Factors Influencing the Level of Digital Competence of Children and Youth in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The following research methods were used during the research process:

- critical analysis of the literature;
- the heuristic method;
- the selected quantitative methods;
- analysis of the level of digital competence.

The authors conducted primary research among: experts in digital competences and among primary school students (children and youth).

Trends in future labour markets

The primary megatrends (Jeliński, 2016, Vukanović, 2018), which will emerge as a result of technological progress and ubiquitous transmission of information, include:

- industry 4.0 – the fourth industrial revolution is the term used to describe the technologies and rules of economic organisations operation (Ustundag, Cevikcan, 2017) which systemically use:
  - (a) cyber-physical systems and modelling;
  - (b) Internet of things and services;
  - (c) cloud computing capabilities;
  - (d) Internet of Everything;
- economics of sharing (Budziewicz-Guźlecka, 2017);
- artificial intelligence, automation and robotics.

All these trends will affect future employees (currently still students). Typically social megatrends, i.e. the lifestyle resulting from the interpenetration of the real world with the digital world, will also be instrumental.

In the face of the dynamically developing service sector, demographic trends will render it necessary to make the current, traditional forms of employment more flexible, allowing for more teleworking, more informal, self-organising project teams, making greater use of the knowledge of freelancers. They will also result in a more extensive use of robotisation, machine learning and automation of repetitive business processes, thus releasing valuable human resources that will creatively undertake new activities to foster sustainable development and social inclusion that guarantee an improved quality of life.

Changes in the principles of work organisation might include:

1. The concept of working time will cease to exist over the years – the concept of daily or annual work, as well as the concept of the workplace itself, will undergo a significant transformation. Communication technologies offer the ability to make working time more flexible – the convenience of not having to meet rigid schedules cannot be overestimated. Discussions conducted in certain countries about work and family responsibilities are a sign of a trend that is emerging and difficult to stop (A. Mas-Colell).
2. The role of self-employment will increase concurrently with the transformation of traditional businesses, which will blur the differences between traditional employment contracts and service contracts. In the future, on the one hand, there will primarily be civil servants (employed in the traditional form under a contract of employment), and on the other hand, independent employees who will form a dense network of contacts.
3. The work will become more interesting as repetitive, routine duties will be automated. However, despite the possibility of shortening the working day resulting from the ever cheaper automation, this situation will not prevail. At the same time, the motivation to get promoted or achieve success will still be very strong, prompting efforts and spending time at work.

As Drab-Kurowska claims, digitisation of the economy, and in particular the development of the on-demand economy will cause changes in the labour market and is forcing and will force new forms of employment. Due to digitisation, the work will be much less related to time and place and more to independence, autonomy which entails monitoring of results.

It should be stressed that Revolution 4.0 is changing the nature of present work. Some of the current professions will be replaced by new specialisations. However, as with any innovation, this is inevitable. Technical and technological progress initially leads to lower demand for labour, however subsequently causes the creation of new jobs. Companies should be aware that they need to react quickly to market changes and adapt to the needs of new customers. As Budziewicz-Guźlecka claims, this results in the search for employees who have digital competences

in addition to the ability to function in a very rapidly changing environment. In particular, the tasks of low and medium-skilled workers performing repetitive and uncomplicated activities are likely to be automated.

On the other hand, e-competence (digital skills and competences) (Redecker, 2017, Vuorikari at, 2016), entrepreneurship, change management skills and creativity will be most sought-after by employers.

The characteristics of digital competence as the foundation of the future labour market

Digital competence should be understood as a set of skills, knowledge and attitudes that enable effective use of digital technologies. Digital competence is defined as a set of information literacy skills which includes the ability to retrieve information, to understand it, and to assess its reliability and usefulness, as well as digital competence which includes the ability to use computers and other electronic devices, to use the Internet and to run applications and software of all kinds, and to create digital content. Additionally, digital competence involves the ability to use the opportunities offered by digital media creatively, to communicate and to develop relationships through electronic media, using the Internet safely. Digital competence is a broad set of skills (Stopar, Bartol, 2019, Periáñez-Cañadillas, 2019, De Vito, 2017) which determine the efficient and deliberate use of new technologies (Budziewicz-Guźlecka, Drab-Kurowska, 2009) and active participation in society.

Digital competence consists of skills, attitudes and knowledge necessary to understand and be able to use the main functions of ICT. Computer skills include skills that are related to the following activities on telecommunication devices: proper operation of the equipment, i.e. basic computer functionality, i.e. using a mouse, keyboard or touch screen, connecting a monitor, using a printer; using software, i.e. skills that allow the use of programs such as text, graphics editors etc.; using applications, i.e. effective use of specialised software.

Information literacy, on the other hand, is the ability to use information and communication technologies to find, evaluate, create and communicate information, requiring cognitive and technical competence (American Library). The scope of information literacy should include the skills that allow us to (Jasiewicz, Filiciak , Mierzecka, et al):

- determine the type and scope of the searched information;
- find and secure effective access to a variety of information sources;
- analyse and critically evaluate information and verify the metadata;
- integrate information found with one's knowledge and value system;
- use the information in a manner conducive to the achievement of a specific objective;
- understand the social, economic and legal aspects of access to and use of information.

Information literacy is a prerequisite for being an active citizen of the information society, who will meet the requirements of the future labour market.

Functional competence, on the other hand, is the combination of IT and information competence with different areas of life. According to the "Framework Directory of Digital Skills", 8 key areas are defined for functional competences. They include:

- work and professional development;
- relations with relatives;
- pursuit of interests;
- health;
- finances;
- religion and spiritual needs;
- day-to-day activities;
- civic engagement.

To sum up, functional competence (Lloyd) is based on digital competences and information literacy which allow taking specific actions and achieving goals using digital technologies. Digital competence is the basis for information literacy which enables the development of functional competence.

Digital competence responds to the challenges related to greater communication opportunities, easier access to information and progress in technology. The challenges of the future will be related to the development of artificial intelligence, 5G, big data, virtual reality, such as augmented reality.

Broadly defined digital competences additionally include so-called computational thinking (Swanson, Anton, Bain, et al.) which is the ability to find solutions to complex, open problems, generally using digital technologies and data analysis.

These relationships are presented in Figure 1.

Fig. 1: Relationships between competencies

Source: own work

Functioning in the digital reality requires the development of computational thinking skills that enable us to solve problems in different fields. Digital competence is a certain kind of compilation that is not only based on a combination of awareness, knowledge and skills, but also on attitudes and behaviours.

Analysis of factors influencing the structure of the future digital competence indicator

For the purpose of this study, it is necessary to identify factors influencing the future digital competence indicator in the context of ongoing processes of development of information transmission techniques and technologies and the requirements of future labour markets. The identification of this indicator requires a broad analysis of the competences of current students who will enter the labour market in a few years.

The starting point is the use of multidimensional benchmarking to identify the factors influencing the future digital competence indicator among students. It should be stressed that the selection of diagnostic features in the multidimensional benchmarking method is crucial. Out of many variables, it is necessary to select those that have the greatest impact on the analysed phenomenon and provide key information. This is a fundamental problem of a substantive as well as statistical nature. In principle, the selection of the features should not be subjective, but based on a specific procedure. The procedure is as follows: – determining the initial set of features (variables) on the basis of substantive criteria, – conducting formal and statistical analysis on the set, – selecting the optimal set of explanatory variables on the basis of results. The application of formal and statistical criteria allows the elimination of those variables which do not meet the required criteria. However, this does not mean that the others must be included in the study. From the received set, an optimal set, meeting specific criteria, should be selected.
The components affecting the indicator include:

- infrastructure area;
- area of basic competence;
- area of advanced competence.

This indicator may be illustrated as follows:

$$\mathbf{I_{fdc} = (0{,}3*i_1+0{,}2*i_2+0{,}3*i_3+0{,}2*i_4) + (0{,}25*p_1 +0{,}25*p_2+0{,}25*p_3+0{,}25*p_4) + (0{,}4* z_1+0{,}3*z_2+0{,}3*z_3)}$$

Source: own work

To determine the weight of the individual indicators, this study uses expert evaluation[1]. The adopted method involved the collection of experts' evaluations which allowed the determination of the significance of individual

[1] The study involved a team of 65 specialists in the field of digital competences and education of children and youth. These included teachers, university representatives and employers. The experts have knowledge and experience in the subject matter of the study.

indicators that affect the future digital competence indicator, i.e. I_{fdc} – and confirmed the validity of the adopted criteria.

Table 1 demonstrates the variables (diagnostic features) that are included in the components of the future digital competence indicator – in the area of infrastructure.

Table 1: Variables (diagnostic features) included future digital competence indicator I_{fdc} – in the area of infrastructure.

No.		Variable name	Assigned weight	Scoring criterion (0.1)

The study uses an element of the Delphi method, i.e. expert evaluation. The method adopted in the conducted study involved the collection of experts' evaluations which allowed the determination of factors affecting the digital competences of the future.

These variables allow the determination of the level of future digital competences, depending on the needs and purpose of research. This indicator may be used for research in the following frames of reference:

- spatial (regional differentiation);
- demographic (age of respondents);
- educational (different levels of education, school profiles).

The indicator will provide a recommendation for decision-makers at various levels which will allow the development of instruments to improve the digital competences of the future for children and youth.

ICT-enabled infrastructure for children and youth in schools

The starting point for acquiring digital competences in schools is the application of modern technologies using the Internet (Herout, 2016). However, many schools in Poland currently lack an adequate number of computers and a fixed broadband connection.

This problem has been identified and, as a result, the National Education Network Programme (*OSE – Ogólnopolska Sieć Edukacyjna*) is currently being implemented in Poland. Its main objectives are to provide all schools with safe, fast and, above all, free internet. The aim of OSE is to:

- create an infrastructure to enable schools to connect to the broadband Internet;
- equalise educational opportunities for students, especially from small schools;
- develop students' digital competences;
- assist in the development of education using on-line resources.

OSE aims to provide common and equal access to very fast, safe and free Internet for schools to enable a civilisational change in the manner students are educated, by supporting analogue education with digital education. As regards the development of digital competences, it is particularly crucial that the Internet provided by OSE is fully safe, both for the school and its students. In order to use the potential of the OSE programme, it is necessary to integrate its existing network infrastructure with the programme network (https://www.szkolawchmurze.pl/ose/). The main benefits of the integration of the school network with the OSE network include: cost reduction – network integration will allow the resignation from fees for the services of existing Internet provides, guarantee of safety of students using the Internet throughout the school, stable and efficient school computer network, monitoring the condition of devices in the school network around the clock using dedicated software, maintenance of the entire solution.

OSE provides a unique opportunity to make a qualitative change aimed at creating a digital learning environment at school, shared by students and teachers (Gudmundsdottir, Hatlevik, 2018).

School equipment is important in developing students' digital competences, however, it is not crucial and should not be a starting point and a reason to take interest in this issue. The mere development of technology at school, without a specific teaching strategy, will not lead to any changes. A smartly designed digital classroom does not have to be based on a perfectly equipped computer lab. Not every teacher who will be provided with modern technological solutions will be able to use them effectively (Pettersson, 2018, Napal Fraile, Peñalva-Vélez, Mendióroz Lacambra, 2018, Instefjord, Munthe, 2017). Conversely, a teacher with passion, eager to discover new methods of working with a student, may perfectly cope with the equipment deficiency. Unfortunately, Polish education is usually focused on the passive acquisition and reproduction of knowledge. The models that activate students, requiring them to be more creative and to seek solutions to problems on their own are considerably more effective. For students, however, the principal aspect is how the Internet is used in their everyday classes.

Infrastructure plays the primary role, and it is followed by its skilful use. The results of research related to infrastructure in schools and its use by teachers will be presented in another study.

Digital competence in education process – basic area

Digital awareness, understood as the actual intellectual state that has been obtained based on the level of knowledge, understanding and reasonable valuation of information that takes place in the surrounding world. This ability involves acquiring, analysing and managing information as well as using technology. In addition, when analysing the concept of digital competence awareness, it is necessary to recognise how important it is for an individual (student) to be aware of the need for “digital” knowledge. However, it is only the ability to analyse the

information obtained and to apply it to specific situations in everyday life that enables potentially optimal and generally the most complete participation of an individual in society and the future labour market.

The student's digital awareness is developed by the environment, i.e. teachers, parents and institutions.

Parents with digital awareness should become mentors for their children and encourage wise use of on-line resources. Parents often do not know how to protect their children responsibly from possible dangers. This is confirmed by the results of the research (the research was conducted among parents of children attending primary schools) conducted by the authors (Budziewicz-Guźlecka, Drab-Kurowska, 2018).

To a considerable extent, the responsibility for digital competence lies with teachers and principals who had attended traditional schools and are often unwilling to treat the Internet as a potential educational environment and who more often than not lack the necessary teaching and digital competence to use ICT effectively as a teaching aid and content resource. A school should be the primary place for students to acquire digital competences.

From an institutional point of view, the introduction of practical methods of developing digital competences must not be limited to modifying the core curriculum or issuing top-down recommendations, but requires significant professional support for teachers and reorganisation of the operation of the Polish school.

Digital competence or network security skills should be tested in practice. They should be verified practically through computer tests as a part of which the student would be required to demonstrate a given skill.

Students with extraordinary digital skills should have an opportunity to broaden these skills through the support in the development of advanced digital competence.

To analyse the use of the Internet by students, the authors conducted a study. The study was carried out among 252 students[2] aged 7-14 who attend primary schools. For the purpose of this article, the main conclusions of the study will be presented. Teenagers use the network on their own since the age of seven. The following correlation may be observed: the younger the generation, the earlier this contact occurs. This is due to the dynamic development of information transmission technology and its prevalence and availability. The time spent on-line is increasing due to the general availability of smartphones. The Internet provides teenagers mainly with entertainment, but also with access to culture (music, films, etc.).

Nearly 40% of students expressed the opinion that school education does not prepare them for life in a world based on modern technologies.

The vast majority of the respondents (81%) do not have the opportunity to create educational resources on their own during classes. Only 20% of the students had such an opportunity. Most often during classes students had the opportunity to create multimedia presentations on their own. More than 7% of the respondents had the opportunity to do so, and this was the highest percentage score in terms of the type of multimedia resources created during classes. During classes, students more frequently use ready-made multimedia aids rather than prepare them independently. If there is an opportunity to create educational resources on one's own, these usually include simple reference materials, increasing the attractiveness of the message rather than its effectiveness and involvement of other participants. Graphic materials, digital texts and multimedia materials come second (about 4% of responses). E-books, digital textbooks and mobile applications were the least frequently created (2% of students indicated this possibility).

The study reveals that students are aware of the risks they may face on-line. For example, after the students were made aware of what Internet violence is, it proved that only half of the respondents (51%) have not directly experienced Internet violence. Most often, teenagers were the victims of name-calling, ridicule and humiliation. Nearly one in three affected students does not take any action, does not even inform relatives or other people who could provide support in this situation.

Most families do not introduce rules to limit time spent on-line or select the content available to teenagers. This entails the risk of strong smartphone addiction which, when accompanied by increasing Internet usage, may forecast the escalation of the problem. Children and youth may be protected against Internet threats through access restriction rather than other safeguards. It should be concluded that parents lack knowledge about safeguards and thus need to increase their digital awareness.

[2] Students participating in the study took part in the project: "Young e-leader" POWER 2014 – 2020, III. Higher education for economy and development. The study was conducted from November 2019 to February 2020.

Younger students of primary schools were much more likely to admit that parents, regardless of their declaration, check what they actually do on-line, as well as set time limits for its use, i.e. they establish rules restricting access to selected types of content.

Digital competence in education process – advanced area

Advanced digital competences foster creativity, entrepreneurship and innovation; they help build social, intellectual and economic capital. Moreover, it should be stressed that the development of digital competences serves to reduce social disparities and the lack of these competences gives rise to new forms of social exclusion.

In social and economic activities various technologies and information systems are used. They range from simple information systems (information portals) through complex management information systems (for businesses, banks, offices, etc.) which automatically carry out complex calculation procedures, to the development of artificial intelligence. The indicated examples of systems and their scope of application are characterised by different functional capabilities which depend on the type of system and its area of operation. As a result of these transformations, a common tendency is becoming increasingly clear, which is defined by experts as the virtualisation of social life.

Appropriate competences of students who will enter the labour market are a necessary condition for the development of institutions, companies and organisations; allowing the increase of effectiveness of operation, create new forms of cooperation, involvement and communication or use of digital technologies fostering the economic potential of a country. According to Budziewicz-Guźlecka and Drab-Kurowska (2012, 2017), digital competences are necessary for the development of e-government services and intelligent cities. Moreover, digital competence opens up new vistas for meeting life's needs – it enables fuller personal development as well as active participation in social and cultural life.

The advanced competencies include mainly data set analysis, construction of software robots and use of artificial intelligence mechanisms. The results of the study related to advanced competences will be presented by the authors in another article.

Conclusions

The mechanism of raising digital awareness involves the realisation of the objective, which is to increase the effectiveness of actions taken to enhance digital education. Effectiveness is interpreted as the compliance of the decision made with the educational goal (at basic or advanced level).

Modern technologies are and will be a permanent element of the modern network society. Great digital competences will allow children and youth to navigate successfully through the future labour market. It is necessary to verify whether the modern user is prepared to exploit the potential of the digital economy. To measure digital competence, the presented digital competence indicator may be applied. The indicator enables the calculation of the competence level in different aspects (spatial, educational, age, etc.).

The future digital competence indicator proposed by the authors will render the measurement of the level of digital competences more realistic and will allow better identification of different factors which need to be developed in order to increase the level of digital competences of children and youth.

Abstract

Pollution or environmental degradation due to agriculture is a major problem in Nigeria. This threatens the capacity for future agricultural production to meet the rising world population expected to grow to almost 10 billion by 2050 (UNDESA, 2019). This paper explores empowerment of female Nigerian farmers as a strategy for drastic reduction in pollution or environmental degradation. Agriculture creates employment opportunities to 70% -75% of the Nigerian working population and contributes about 20.9% of Nigeria's total gross domestic product. Globally, agricultural practices degrade and pollute the environment and threaten its capacity for future agricultural production. Meanwhile, everyday, women who provide most agricultural labour under the broad sector use, manage or conserve natural resources when carrying out their roles as consumers or educators. In addition, their production and consumption patterns tend to be more resource-efficient and they make more sustainable decisions for their households and businesses (OECD, 2007). Women also have smaller ecological footprint than men. However, this has not translated to reduced pollution or environmental degradation due to agriculture. This paper using a desk review method discusses the key role women play in ensuring environmental performance of farms and various ways they can be empowered to do more. This paper concludes with recommendations.

Keywords*:* Environmental Performance, Female Farmers, Women Empowerment, Sustainable Development Goals

Introduction

In the past half-century, agricultural intensification was achieved through increased use of land, fertilizers, pesticides, irrigation water and agricultural machinery without considering the impact of business activities on the environment. Lampridi, Sørensen, & Bochtis (2019) mentioned that environmental impact of agriculture is

devastating; clearing of half of the global forest, erosion of biodiversity and air pollution by greenhouse gases released during burning.

This is contrary to sustainable development which encourages continuous use of resources to improve the quality of life of citizens without depriving future generation from meeting their needs (Gberevbie, Joshua, Excellence - Oluye, & Oyeyemi, 2017). Therefore, things must change in order to meet the growing demand for agricultural produce fueled by the rising world population which is expected to grow to almost 10 billion by 2050 (UNDESA, 2019). As a consequence of these developments, countries are moving towards environmentally friendly or sustainable agriculture using innovative systems that protect and enhance the natural resource base, while increasing productivity.

Finding ways to promote environmental performance needs to focus on women in the agriculture sector. This is because women play a key role in global and Sub Saharan Africa's agricultural production. Logeswari & Thiruchenduran (2016); Njobe & Kaaria (2015) confirm that women are the backbone of the sector because they represent 52% of the total population in the sector and are responsible for approximately 50% of the agricultural labour on farms in Sub-Saharan Africa. Njobe & Kaaria (2015) also confirmed that women produce 60% to 80% of the Africa's food.

Women also use, manage or conserve natural resources when carrying out their roles as consumers or educators. OECD (2007) also confirmed that the female production and consumption patterns tend to be more resource-efficient and they make more sustainable decisions for their households and businesses. Sachs, Barbercheck, Braiser, Kiernan, & Terman, (2016) also stated that women care more about environmental problems than men. However, a research study by Njobe & Kaaria (2015) revealed that African and Nigerian women remain an untapped opportunity in agriculture and environmental performance. Women's level and quality of participation does not meet the sustainable socio-economic development benefits. Women involved in agriculture either as workers, farmers, processors, livestock owners or entrepreneurs consistently experience limited access to productive resources, compared to their male counterparts.

Similarly, despite representing more than half of Africa's population women only contribute 39% of Africa's GDP. Oedl-Wieser (2020) opined it is due to the peculiarity of the agricultural sector which is gendered. The major players(women) are not the ones that determine how to run the farm. That is not all. A research study by Abdulai & Hazell (1995) cited in Nwachukwu (2016) stated that the incorrect use of modern inputs like fertilizer, pesticides, irrigation water often result in destruction of beneficial species because of water logging, chemical contamination of water, and pesticide poisoning. All these deteriorate land, reduce yields and productivity (Nwachukwu, 2016). Which are among the greatest agricultural problems Africa is facing.

Women who want to promote environmentally friendly farming need access to land, suitable technologies, environmental education, and training. The ability of female farmers to deliver is affected by empowerment. According to FAO, the underperformance of agriculture in developing countries is attributable to women's limited access to productive resources and inability to take advantage of opportunities in the sector. Limited access in this regard, is experienced more by women than their male counterparts, demonstrating a clear "gender gap".

According to AfDB, (2015) women empowerment and eradication of gender inequality can lead to Africa's development because it has the potential of increasing productivity of about one billion inhabitants. Women empowerment and gender equality are also imperative to achieving the 2030 Agenda for Sustainable Development. It is also a channel for achieving other goals like promoting full and productive employment and decent work for all, ending poverty, food security, reducing inequalities. This implies that women empowerment and environmental performance are synonymous; one cannot promote environmental performance without starting with women empowerment.

In this paper, we bring to the fore the areas female farmers can be empowerment particularly in relation to environmental performance. The paper is structured as follows: section 1 consists of introduction, objectives, and methodology. While review of literatures covering the concept of women empowerment and environmental performance, theoretical underpinning of the paper can be found in section 2.Conclusion and recommendations are contained in section 3.

Objectives of the Paper

The major objective of this paper is to propose a model of enhancing environmental performance through empowerment of female farmers.

In achieving this objective, the following research questions, which reflect areas of concern in this paper, will be answered.

1. What is women empowerment?
2. What is environmental performance?
3. What are the factors affecting environmental performance of female farmers?
4. In what ways can be environmental performance of female farmers be enhanced?

Methodology

This paper uses a desk review approach. Desk research involves gathering of data from available materials like the press, statistical, empirical, and analytical reports, internet, and academic journal. After that, the materials are cross referenced and collated (Juneja, 2018). It is useful and usually carried out at the beginning of a study to get necessary information which can be used as a standard during the study (Pitan 2016).

Existing conceptual and empirical literatures on women empowerment, sustainable development, environmental performance, and agriculture globally and in Nigeria was reviewed.

Literature Review

Women Empowerment

Women's empowerment is a socio-political concept made up of psychological, cognitive, economic and political dimensions (Logeswari & Thiruchenduran, 2016). According to Moses, (2009) women empowerment entails giving women power to function at their utmost capacity. Women empowerment also refers to the way women get the ability to make strategic life choices in areas they were formerly denied this choice (Kabeer, 1999). He stressed that resources, agency, and achievements dictate the ability to make individual choices.

Resources here mean human, material, social expectations and allocations while agency is the ability to determine one's goals, take steps towards achieving these goals, and choose their strategic life outcomes. Achievements can be in different forms like better welfare, having equal number of women and men in political positions.

O'Neil, Domingo, & Valters, 2014 mentioned that empowerment can be economic, psychological, social, and political. While Moses (2009) state that empowerment can be channeled towards education, finance, training, decision making power, and economic status of women to promote their active participation in development process.

Countries have developed several strategies to empower women. They have reviewed laws on status of women and encouraged women to participate in politics and the cash economy, improved women's access to education. For example, in 2000, the Federal Government of Nigeria started introduced the national policy on women. This was expected to help increase the percentage of women in the legislature and executive to 35 percent. Also, the Nigerian Government established the National Women Development Centre under the Federal Ministry of Women Affairs (WomenAid Collective, 2008). A look into women's role in agricultural production shows that their productivity and environmental performance can be enhanced through empowerment. Some of the forms of empowerment are

a. Environmental Education and Training:

Education is very important in promoting farmers adoption of environmentally sustainable farming techniques. It helps them identify and abandon harmful practices. Zahra (2018) opines that farmers can only change their mindset and practice environment-friendly agriculture when they have knowledge about sustainable farming.

However, women cannot practice sustainable farming due to lack of environmental education. There are low numbers of women compared to men in informal training. According to the Nigerian National Bureau of Statistics and World Bank (2019), from the age of 20, literacy rates for males are considerably higher than those of females, particularly in the 65 and over age group, where 61.8 percent of males report being literate, while for females that number is only 27.5 percent. This is due to some social and cultural factors that see modern education or informal

training of women as waste of time and resources because females end up as mere housewives. This is responsible for the increased rates of teenage pregnancies in secondary school and early marriage of girls.

Also, most training programmes are not designed with gender in mind. Many a times women are time constrained and cannot attend because they lack money to pay for this training. Access to quality education and the acquisition of knowledge on environmental sustenance could reduce environmental degradation and create opportunities for women.

In addition, Swanson (2008) revealed that women have not received enough attention from extension workers considering the key role they play in agriculture. Hamisu, Ardo, Makinta, Garba & Musa (2017) stated that this extension workers act as technician, agents of change, consultant. They also assist farmers to identify and find suitable solution to their problems. They also serve as middleman between agricultural research institutions and farmer. Lack of access to all these services hinders their performance. Also, some agricultural agents are men with a mindset that there are things women can do or not do. According to Anunobi & Anunobi (2018) ; Nigerian National Bureau of Statistics and World Bank (2019) this makes women miss extension services like training, advisory services and information to enhance their sustainable agricultural practices in the farm.

The contribution of female farmers to environmental performance is affected because knowledge of new and better agricultural practices, changing climate allows them to make good decisions, like adopting sustainable agricultural machinery and other adaptative measures (Anunobi & Anunobi, 2018, Solomon and Edet, 2018).

b. Decision Making Power:

Women represent almost half of humanity but their contribution to leadership and management is much less. Female participation and representation in decision-making processes that pertains to them and their families' environmental well-being are often restricted. According to Moses (2009) only a small number of women hold leadership positions and have equally contribution like men in decision making. It is not different environmentally.

Women are missing in key decision-making forums that decide how economic and financial resources and opportunities are assigned (UN, 2009). This also means women's knowledge about the environment and agriculture is mostly not acknowledged by agricultural development agencies and other personnel. Whereas, it may be this knowledge that will birth methods of achieving agricultural practices that are environmentally friendly and preserve natural resources.

According to Sachs et. al. (1997) women care more about environmental problems than men and women have been assisting in finding solutions to these problems. However, women are excluded from or have low representation in groups established to encourage better management of natural resources, due to discriminatory rules and social norms. Women are not also involved in development and planning of environmental policies and programs meant for them. These have often made the programs counterproductive, because they fail to meet purpose of increasing women's control over natural resources (Green & Thropp, 1998).

c. Access to Land

Access to land is the right to use or control land and its resources. Women's ownership and control of land means women will determine what is planted and how it is planted, how the proceeds from the farm are used (Agri, Kennedy, Bonmwa, & Acha, 2018). Presently, access to land is limited as less than 13 percent of agricultural landowners are women (UN Women, 2018). Also, numerous Nigeria women are marginalized regarding ownership and access to land (Ajala, 2017; George, Olokoyo, Osabuohien, Efobi & Beecroft, 2015). Land is still largely consolidated in male hands.

Tiondi (2000) asserts that access to land, property and water in agriculture determines how people handle natural resources. The existing common ownership of land is also a challenge because each user maximize their own self-interest, not minding the impact of their actions on other users.

Environmental performance

Environmental performance focuses on the commitment of organizations to preserving and protecting their natural environment like maintaining air, water, soil quality (Gallego-Álvarez, Vicente-Galindo, Galindo-Villardón, & Rodríguez-Rosa, 2014). Environmental performance also refers to the impact of business activities and products on the natural environment, like the amount of resource they consume, quantity of waste generated, and emissions (Epstein, 1996) cited in (Gallego-Álvarez et.al. 2014). Environmental performance finds its root in sustainable agriculture which looks for ways of meeting the objectives of a healthy environment, economic profitability, and social and economic equity. These three pillars are informally referred to as people, planet and profits.

A report by FAO (2018) stated that wrong application and poor management of fertilizers for agricultural use can alert the quality of the environment. Similarly, in most countries, the way water is taken from rivers and underground beds is beyond the environmentally sustainable level leaving a negative impact on rivers and underground beds. They also confirmed that pesticides are important inputs for plants and animals in modern agriculture, but if not well managed they can cause harm to people's health or to the environment.

Titilola (2008) mentioned other factors leading to resource deterioration as clearing of land for agriculture or other economic purposes, collection of word for cooking without planting trees, unsustainable housing and feeding of animals, the time land is left uncultivated is now shorter. All this are fueled by the high demand for agricultural products.

Theoretical Framework

The theoretical framework of this paper is predicated on the Social Inclusion Theory propounded by Weber. According to the World Bank "it is the process of improving the terms for individuals and groups who are disadvantaged to take part in society, by increasing their access to resources, opportunities, ensuring their voice is heard and respect for rights". Social Inclusion Theory is relevant to this study because it explains the importance of women as social agents that must be empowered for environmental performance.

Proposed Model: Figure1 show the relationship between environmental education, access to land, decision making power as empowerment female farmers need to promote environmental performance

Fig. 1: Female Farmers Empowerment and Environmental Performance

Fig. 2: Relationship between Women Empowerment and Environmental Performance

If female farmers are empowered, they will engage in more environmentally friendly activities and practices which increase their environmental performance. When empowerment of female farmers increases, their environmental performance increases and vice versa.

Conclusion and Recommendations

For women farmers to fully contribute to environmental performance, they need access to and control over productive resources. They also must be better educated on environmental issues and the implication of their activities on the environment. Better education can also increase women's level of participation in decision making at all levels of government and the farm. Training must be planned and carried out with women in mind. Greater efforts must be made to increase the number of female extension worker. This can be done by encouraging or giving scholarship to females taking STEM courses. Generally, it will go a long way in achieving SDG 4 – quality education.

Women as key players must be actively involved in making decisions on the farm, at the state, local or national level. Design and implementation of sustainable development programmes should be done with the mind that most participants are women. More importantly, their suggestions or contributions on policies about the environment, conservation, and degradation, should be acknowledged and considered. To achieve this and the SDG 5 - gender equality, the participation and representation of women in politics especially in the legislature is required.

Better land reforms and financial empowerment like credit that women can use to acquire land will go a long way in increasing their access to land. Reduced and less costly legal requirement for land processing for women can also increase access to land. This enhances achievement of SDG 16 which aims to promote of peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable, and inclusive institutions at all levels.

Also, infrastructures need to be provided as lack of infrastructures puts pressure on the earth, for example collection of firewood and smoke from burning has negative environmental and health impact. Provision of infrastructure will also help in providing modern access to energy - SDG 7 and safe and clean water -SDG 6.

Management Through Individualisation. How Can Artificial Intelligence Help Us Manage Effectively and Increase Employees' Efficiency?

Ewa JOCHHEIM

Czestochowa University of Technology (Poland) Faculty of Management, Czestochowa, Poland
ewa@aiaconcept.com

Abstract

The objective of the article is to present management through individualisation, which supports effective attainment of business objectives. The created tool supports people who analyse internal needs of employees and teams, as well as helps translate this knowledge into effective management. The tool combines knowledge from various fields such as artificial intelligence (AI), management psychology and psychology of needs. The application is scientifically founded. It analyses employees' needs and gives managers tips on how to manage individuals and teams. Consequently, it helps organisations to quickly and effectively attain their business objectives by applying an individual approach and new information techniques.

Keywords: Needs Analysis, Management Through Individualisation, Artificial Intelligence.

Introduction

Management through individualisation is a novel approach to managing employees and employee teams. A literature overview gives an insight into research on an individual attitude towards employees, but there are no articles answering the question of how to actually apply an individual approach and our knowledge about it.

There are few studies on the benefits of individualised management. Some researchers believe, however, that motivation to work is to a large extent a reflection of individual differences in character traits, such as scrupulousness (e.g. Barrick and Mount, 1991). The individualisation process was researched in many contexts, such as an active formation of one's professional career (Beck, 1992). The approach applied so far which considers money to be the best motivator (Taylor, 1996) has been criticised by researchers who stress the role of other factors in the motivational process, such as the attitude to work, type of work and team work. Maslow (1963) described in his theory five basic needs, and additional needs of some people. The role of individual needs in shaping behaviours can also be found in the Two Factor Theory of motivation by Herzberg (1968, 2003), in which internal factors, so called motivators, increase satisfaction from work, which boosts employees' productivity. That is why organisations which want to be effective in the attainment of business objectives should be designed in a way which helps satisfy individual, internal desires of employees. J. W. Atkinson (1974b) also paid attention to the fact that individual traits can have an impact on motivation to work, and some of them are genetical (Skinner, 1988). These and many other ideas (Malinowski, 1958; Maslow, 1963; Obuchowski, 1983) have been reflected in the theory developed by S. Reiss (2012), which underlines special role of an individualised approach to the employee, helping increase effectiveness and improve management. The theories presented above show that individual needs are the basis for human behaviour and motivate to perform certain activities. Therefore, getting to know the needs and their in-depth analysis should be the starting point for creating tools for effective employees' management.

The gist of management through individualisation

If an organisation cannot rise to its challenges, looking for the source of the problem should start at the management level. In one study, 359 managers were asked why organisations do not achieve their objectives and various reasons for failure were named (Longenecker, Simonetti & Sharkey, 1999). Managers from 30 different companies were asked to assess the impact of 25 factors on their ability to achieve expected results. The main reasons for failure were internal competition, lack of cooperation between employees and between the manager and employees. Another problem was ineffective communication between managers and lower level employees, as well as contradictory objectives. But the factors that prevent them from achieving their business objectives show not only mistakes committed by managers, but also lack of company's support for the management staff (Toor & Ogunlana, 2009). On top of that, individual differences between employees have a significant impact on the effectiveness of

Cite this Article as: Ewa JOCHHEIM" Management Through Individualisation. How Can Artificial Intelligence Help Us Manage Effectively and Increase Employees' Efficiency?" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

both individuals and objectives achieved by teams. Cognitive, emotional and social individual differences between employees have an impact on group processes and the functioning of the team as a whole. What is more, individual differences influence the way in which people behave in various situations and have a significant impact on their behaviour (Robertson & Callinan, 1998; Larsson, 1989). In studies applying the Big Five model (Costa & McCrae, 1992; McCrae & Costa, 1990) as well as the results of two metanalyses (Barrick & Mount, 1991; Tett, Jackson, & Rothstein, 1991), it was found that typical traits of a given individual have an impact on their results at work.

Given the above conclusions, the problems that organisations are not dealing with stem not only from underestimating the importance of individual differences and needs in terms of the results of individuals and teams, but also from lack of support for the management staff. The tool that we have been developing takes into account these factors and uses them to support managers in managing individual employees and teams. According to the Gallup report, 52% of employees in the USA are not engaged, which means that they are not emotionally engaged in their work, they do not invest in it enough energy and passion, which, consequently, leads to simply fulfilling orders (Gallup, 2020). Management through individualisation aims to engage employees more, which will generate more positive emotions and translate into more effective and creative work (Harter, Schmidt & Keyes, 2003).

Researching Needs – Contemporary Measurement Methods

Social sciences focus on defining and finding a perfect method of measuring a given phenomenon. Psychometric tools that are available on the market are very often expensive and difficult to interpret. Plus, tools in social sciences have recently been often undermined. There are no transparent and reliable methods which would allow to collect the necessary content, interpret it quickly and draw conclusions (Flake & Fried, 2019). Barry and co-workers (2014) have shown in their research that 40-93 % of measurement methods used in studies published in scientific magazines did not have the accuracy of their tool confirmed. And Weidmann and co-workers (2017) have proved that out of 365 measurement methods, 69% were used without reference to any earlier studies or did not describe the scale validation process. The tool described here is a remedy to the above problems and the figure 1 below shows how the prepared tool called AIA works. The AIA application is easy to interpret, highly accurate and reliable. During the design process, a set of questions and needs were defined. During the validation and tests, the number of needs was reduced to 32. The mobile application conducts online studies, and artificial intelligence prepares an individual a profile of a given person. AI establishes the profile on the basis of answers, taking into account all parameters fed into the application. AI looks for correlations in the calculations. The application hones the model all the time, by feeding itself with new studies and downloaded data after the following confirmation/negation from the user.

Fig 1. Description of the AIA system based on artificial intelligence Source: Own work.

Methodology and tool description

The starting point for the tool (AIA) is an analysis of individual needs of the employee. Based on research on needs, the number of needs was established at 32.

Table 1 shows the name of the need and describes typical personality traits of a person who has a high (80% in comparison to the whole population) intensity of the need.

Table 1. 32 Individual needs studied by AIA

	Need	Personality traits typical of the need
1	Influence exertion	Strong will, efficiency, ambition, power
2	Fulfilling tasks	Fulfilling tasks, acting for others, people-oriented
3	Autonomy in action	Independence, pride, individuality
4	Team work	Dependence, humbleness, building bonds, closeness, relations
5	Intellectuality	Thinking, searching for truth, insightful approach
6	Practical actions	Practicality, resourcefulness, creation, acquiring experience
7	Sensitivity to criticism	Low self-esteem, acceptance, recognition, approval
8	Confidence	High self-esteem, assertiveness, emotional strength
9	Structure and organisation	Process orientation, method, routine, punctuality, perfection
10	Openness to changes	Flexibility and creativity in action, spontaneity
11	Collecting	Collecting objects, gathering, ownership
12	Generousness	Magnanimousness, tendency to lose things, sharing
13	Responsibility	Sticking to principles, rightness, honesty, diligence
14	Opportunism	Goals orientation, calculation, self-interested
15	Social engagement	Humanitarianism, altruism, idealism
16	Social pragmatism	Realism, self-orientation, apolitical
17	Sociability	Extravert, openness to others, many contacts
18	Privacy	Introvert, reserve in contact with others
19	Taking care for your family	Bringing up and taking care of children, self-sacrifice, homebody, family oriented
20	Partnership in family	Independence of children and family
21	Prestige	Social position, importance, elitism, status, hierarchy
22	Modesty	Egalitarianism, equality, naturality, restraint
23	Competition	Comparing oneself, competition, rebelliousness, inclination to compete
24	Harmony	Compromises, arbitrariness
25	Sensuality	Romanticism, aestheticism, beauty
26	Ascetism	Practicality, utilitarianism, reserve, simplicity
27	Enjoy taste	Gourmet, food enthusiast
28	Quenching hunger	Eating as survival need
29	Movement and physical activity	Physical activity, energetic
30	Physical restraint	Sedentary, comfortable life style
31	Security	Stability, predictability, conservative position, unwillingness to changes
32	Courage	Risk, insecurity, spontaneity, adventure

Source: own work

Each person has all the above mentioned needs, but to a varying extent. First, to define the intensity on the scale from 0% to 100%, you fill in an AIA questionnaire.

Next, once the value of the need has been established, AI develops tips for the manager. The app gives hints what actions should be taken towards the employee to improve their effectiveness. The supervisor simply follows the tips from the system and gives feedback whether the recommended tip was useful or not. Thanks to the system of active cooperation between the manager and the application, the AIA application learns on an ongoing basis from the human and their tips become more and more accurate. The system is based on AI and deep learning.

Up until now, managers not only had to observe employees to analyse their individual needs, but also draw conclusions with regard to how to manage them and the whole team. Developing an individual management strategy was not only tiring and time-consuming, but also prone to many potential errors.

An analysis of individual needs conducted by the AIA system is a starting point for creating a tool, the functioning of which boils down to three basic steps:

1. Analysis of individual needs of the manager, employee and team.
2. Analysis with development tips that the manager should apply to improve effectiveness of the employee/team.
3. Feedback from the manager, on the basis of which the system learns how to effectively analyse needs and create a development strategy, it hones the algorithm and develops tips for effective management.

The AIA application gives ready-made tips for the manager in a virtual talk on how to work with the employee. It helps answer the following questions:

- What individual objectives should be set for the employee?
- How to individually communicate with the employee?
- What individual work conditions should be provided for the employee?
- How to individually show recognition to the employee?

The tool is a universal one, which means that the needs analysis can be conducted in many contexts, not only in management through individualisation, but also for example in professional sports, checking the compatibility of needs in relations or studying the probability of committing a crime. The questionnaire should be filled in the same way, the only differences are in the report that is generated and tips from the system. The interdisciplinary character of the method was of crucial importance in the process of effective development of the application: AI achievements are combined with those from social sciences on the reasons for human behaviour.

Research problems that may arise in the future will most likely be related to the analysis of the application's effectiveness. The application uses artificial intelligence together with a deep learning system - the needs analysis and recommendation system, is a constantly learning and changing system. When analyzing the effectiveness, determinants will be analyzed, the value of which loses validity over time. This means that they could have been replaced with other, more accurate values defined by artificial intelligence, which makes those analyzed in the research obsolete. Another research challenge will be to clearly define the effectiveness of the application presented here. As it examines the individual needs of a person and prepares individual recommendations, the increase in the effectiveness of a manager, employee or team will also be very individual and difficult to clearly define. An additional question is whether the list of needs proposed here is complete? In the future, it makes sense to verify it and adapt it to the changing working and living conditions and environment, and to human life on the Internet.

Conclusions

AIA will help managers by improving employees' efficiency and effective attainment of business objectives. From the very beginning of the application development, it is tested on an ongoing basis by managers managing teams. Their task is to check the functionality of the application as well as assess the usefulness of the tips that are provided to them. In addition, from autumn 2020, the tool is tested by managers and sales teams, which will allow to determine whether the sales effectiveness of sellers has been increased thanks to the use of the tool. The priority is not only to support managers in effective and precise management through individualisation, but increasing engagement and motivation, and hence effectiveness of employees. The tool can become a binder between the manager and the employee and will use specific tips to develop the strategy for successful management of both the individual and the whole team.

Conceptualization of Intuitive Planning in Commercial Services

Elzbieta SKAPSKA

Bialystok University of Technology, Bialystok, Poland
e.skapska@pb.edu.pl

Abstract

Contemporary conditions on a service market require dynamic planning to create new quality and value in products and services. The use of an *intuitive planning* concept may prove to be an effective tool. The aim of the study was to fill a gap in research on the subject of services in a theoretical way as well as in a reviewing and cognitive framework. In order to reach the goal, creative and empirical research has been performed in which the most important role is played by intuitive reasoning that is supported by rational reasoning. For the purposes of the article, several distinct components of the process of providing market services were analyzed and conceptualized on the basis of perception and intuition that are at the heart of this sort of planning. The following research questions were formulated: can *intuitive planning* be applied to service-oriented business activity and does its introduction make sense in the process of service provision? Are there visible differences in production planning and service provision processes? The result of scientific deliberations constitutes a set of recommendations for service providers with regard to planning service-oriented activities in economic practice in the context of their profitability and aptitude for bringing prosperity. Based on the trial of 247 students, the results have shown that the most indications are assigned to the 'forecast of the optimal achievement of a goal' and the fewest – 'taking risks, but with the chance of significant rewards'.

Keywords: planning, intuition, rationality, commercial services, service provision process.

Introduction

One of the most significant characteristics of today's market economy is a growing significance of commercial (market) services associated with an access to a wide range of the ICT sector which has brought new opportunities to educate consumers, facilitate access to the market, support decision-making processes and engage consumers in the service provision process. A change in consumer behavior resulting from the application of digital technologies requires service providers to re-design their market relations. Apart from "hard" components of the purchase-sale process on the market, in terms of consumer-salesman relations, also its "soft" business-related elements gain in significance. This is associated with the need to complement traditional planning (based on measurable factors) with planning based on perception and intuition, i.e. intuitive planning.

Paweł Harasim (2009) is considered the Polish promoter of intuitive/sensual planning. Intuitive planning is a relatively new notion, poorly propagated and rarely undertaken by authors. It constitutes – as has been mentioned – a part of complementary planning with regard to traditional planning and additionally entails other elements, e.g.: the human factor, working atmosphere, interpersonal relations, personality types of employees. Despite the fact that researchers have noticed an economic value of "soft" elements of planning, they take on this issue rather unwillingly, which may result from the immeasurability feature of factors that accompany this process, particularly in case of the service provision process.

D. Kahneman puts an emphasis on intuition in business activity. In his view, it suffices that such activity is characterized by logical consistency, not necessarily reason (Kahneman, 2002). Cognition takes place through a sequence of logical experiences, a total of insights and a reception of stimuli through two types of personality: analytical and intuitive.

Hence, necessary cognitive structures in the process of planning may be divided into: a) the ones connected with imagination; understood as expectations and needs that are engaged by subconscious; b) structures associated with intelligence which corrects experiences that are recorded in imagination. Intuition is a general ability to adapt to new conditions and perform new tasks by means of various models of intuitive, rational, irrational and emotional thinking. The thinking that is, to varying degree, dependant on the context. With regard to new value of enterprises with their results and benefits, an immensely significant role is ascribed to intellectual capital, intuition and cognitive processes

so that the information included in memory could reflect the semantic, episodic and context connections (Salvi et al., 2020; Popov et al., 2020). Information processing, that occurs in the nerve system, consists in the reception of information from the environment, storing and transforming it, and finally, introducing it, again, into the environment in a form of reaction, i.e. behavior (In psychology there is the law of effect that associates the experience of satisfaction with particular behavior in a given situation. If the experience repeats in the future the probability of repeating this specific behavior increases - Thorndike, 1898). A relation with a client is one of the key indicators of service provider's profitability, e.g. banks. The attention that is drawn to effective initiative in communication with a client results in obtaining the knowledge on various strategic decisions which are, or will be, realized and contribute to the understanding of developmental directions. In the literature, there is a confirmation of a positive relation between communication in practice and a level of satisfaction (Parajuli, 2020). Orientation towards entrepreneurship in services constitutes the grounds for internationalization and innovation. At the same time, it makes contribution to the creation of entrepreneurship culture (Vuorio et al., 2020). In services, it is crucial to evince trust in an individual as well as the trust at the level of a whole organization. Organizational trust has a direct connection with a broad range of organizational variables which affect success and effectiveness while achieving goals (Sado et al., 2020).

Idea of intuitive planning

In general terms, planning refers to the management function and is based on the analysis of figures, forecasts or other measurable factors, and thus enables the planning of effective and preventive measures. Intuitive planning is used especially in operational planning, and more specifically in short-term planning (up to three months), i.e. in the case of a supply chain it will concern production and purchase planning at a factory level (Harasim, 2009). The use of perception and intuition in planning allows the entrepreneur to predict the emergence of crisis situations by gaining a holistic view of the planning process, also in service businesses. It is noteworthy that the application of traditional and intuitive planning to business activities requires the fulfillment of appropriate conditions (Table 1).

Table 1: Conditions necessary to use intuitive planning in enterprise (Source: own elaboration based on: (Harasim, 2009)).

Conditions	Traditional planning	Intuitive planning
intellectual potential		+
knowledge of organization/company		+
knowledge of people (behavior, personality, interpersonal relations)		+
knowledge of environment (surroundings)	+	+
reliable data and information	+	+
knowledge	+	+
knowledge of planning processes and methods	+	+
experience	+	+

As mentioned above, the main components of sensual intuitive planning are: the human factor, working atmosphere, interpersonal relations, personality types of employees. The research (Skąpska, 2020) confirms situations, in which these factors concern the exploration of perception and intuition for planning pro-development activities in the company. The survey shows that the most frequent and at the same time most desirable feature of relations between co-workers is relationship based on cooperation. Such an answer was provided by 40% of respondents. This relationship refers to a situation where the manager respects a subordinate and values their opinion. Among significant, but not the most important relations, respondents indicated a relation motivating to change (46.4% of responses) as well as a relation based on tolerance (34.4%) and friendliness (45.6%). The achieved result can be explained by the fact that employees are willing to innovate, but need encouragement, and a friendly attitude to another person promotes efficiency and effectiveness achieved in an organization's team. In this regard, respondents also pay attention to respect for differences in character, views and appearance. Still, they attach the least importance to the compassion and motivating-for-effort relation as well as a claim-type relation, which can be a manifestation of the fact that, in the workplace, employees are disciplined and want to focus on their tasks.

Entrepreneurs/employers are obliged to ensure adequate working conditions, i.e. those based on ethical, moral and human rights principles, but this is not always the case. Depending on the preferred forms of respect, employees' personalities can be divided into two groups. The first of these is represented by a philosopher, a friend, an expert and a seeker. These are persons who value most contact and information flow. This means that soft values are an expression of meeting their higher-level needs, i.e. self-development, respect and recognition. The second group is composed of: a star, a builder, a creator and a free spirit, who, more than soft components, rely on hard motivation,

e.g. in the form of publicity, higher wages, better working conditions or enriched workplace equipment (Skąpska, 2020).

Any theories need to be confirmed in economic practice or, in other words, facts need to be described. On the basis of observations and literature review, it is possible to compare opportunities and threats that are associated with the implementation of intuitive planning into an organization (Table 2).

Table 2: Opportunities and threats of application of intuitive planning concept by enterprise (Source: own elaboration based on: (Harasim, 2009)).

Opportunities	Threats
allows for preventive activity	entails a high risk
helps to predict "black scenarios"	*requires a great emotional effort from the management to be put into the production or service provision process, which may result in a lack of focus on the task
comprehensive analysis that takes into account many more factors than traditional planning	**causes increased labor costs, e.g. salaries (prizes, motivation systems, training)
fosters a holistic view of the crisis situation and enables to find a solution	***increases the transfer of *know-how* (outflow of employees involved into the project/mission of the company)

; **; * - author's elements of the table.*

In considering two versions of planning: traditional and intuitive, it is noteworthy to draw attention to differences in the components of their potential (Figure 1).

Figure 1: Elements of traditional and intuitive planning potential
(Source: own elaboration).

In traditional planning, the most important are those factors that relate to the establishment/order, and intuitive planning – those relating to spontaneity/marketing. Reason and order constitute planes for repeated activities, for established norms. Feeling/reception, reactions to stimuli (perception) and premonition (intuition), on the other hand, are rooted in natural order, unforced instructions, but require management of emotions.

The basis for a service provider's perception, in a positive and negative sense, is the quality of services and expectations of these services. Additionally, perceptual behavior of the recipient of services is related both to knowledge contained in books, media, images, sound, magnetic and optical discs, and hidden knowledge created by skills, experiences and reflections (Skąpska, 2019).

Commercial services as the subject of planning

Planning forms a part of management which, in turn, means a process that involves social responsibility for economic and effective planning and regulates the company's activities in pursuit of specific objectives (Junega, 2018). Similarly to controlling, it should be considered as a tool to improve management functions of an enterprise (Akhmetshin et al., 2019). Lack of an internal control system in a company leads not only to inappropriate management of human resources and other business processes, but also increases the likelihood of negative

consequences for the company, such as: loss of important commercial information, allocation of market share to competitors, increased risk of fraud (Rahim et al., 2017; more about risk, see: Jibril et al., 2019).

Key decisions made by a service provider and a recipient are different, therefore the service provider decides on a service by looking for answers to the questions: what, in what quantities, for whom. The recipient of the service, in turn, decides about a self-service rather than a service and answers the questions: what, in what quantities, for how much, from whom. In pursuit of their different goals, it becomes desirable to find a way to reach a compromise. The service provider is primarily interested in economic (hard) management, which refers to traditional planning. However, due to his pro-consumer attitude they have to take into account (soft) management, which can undoubtedly refer to intuitive planning. Economic management, or economization, is connected with the commercial approach of an entrepreneur to conducting business, e.g. with making profit and strengthening the market position. Hence, the commercialization of activity means that it is based on market principles. The market forces the division of services into commercial and non-commercial ones and their assumption of respective characteristics (Table 3).

Table 3: Features of commercial and non-commercial services
(Source: own elaboration)

Commercial services	Non-Commercial services
are of a market/private nature	are of a state/public nature
tradable	intended for general social use
paid	unpaid
material and non-material	mostly non-material
their launch must be profitable (related to generating revenue, profit)	their introduction to the public sector must serve the general public (accessible to all)
provided by private sector operators	provided by private and non-profit sector operators

Economic management should be considered in relation to the place of service provision, i.e. 'economization in services', and management – to its object, i.e. to services, hence: 'service management'. Apart from the criterion of remuneration, according to which services are divided into commercial and non-commercial ones, another division of services deserves to be mentioned in the market context. M. Katouzjan (1970) made a distinction between old (not requiring high qualifications, whose importance decreases with economic growth) and new services. With regard to such a manner of division, 'freeing up services' within the framework of transforming the system of a centrally controlled economy to a market economy system (commercial service) was considered a breakthrough moment as it became a condition for the new functioning of service providers (Table 4).

Table 4: Examples of commercial traditional and modern services
Source: (Skąpska, 2019)

Traditional services	Modern services
Housekeeping (cleaning, ironing and cooking services)	Digital services (teleconferences, intranet systems)
Intermediate services (street sales)	Modern business services (consulting, database handling, marketing)
Repair services (shoemaking, tailoring)	Business services (tax consultancy, controlling, asset management, development and implementation of promotional programs, property protection)
Commercial services (sale of low-tech items)	High-tech services (information technology services, biotechnology, licenses and patents)
Professional services (market research, traditional photography services)	Electronic banking services
Repair of motor vehicles and household appliances	Tele-medicine
Wholesale and retail trade	Information-based services (web portal services)
Hotels and restaurants	Consumer services (travel)
Transport	Services related to industry (legal, accounting, banking, financial, insurance, logistic services)
Storage and communication services	Directory services combined with self-service (databases in operating systems and applications, e.g. Red Hat, Fedora, IBM Tivoli)

When considering services in the light of new economic and market trends, services of a contemporary nature i.e. consumer, business, highly informative and self-service, seem to be particularly interesting (Skąpska, 2019).

With regard to the above mentioned concept, the idea of planning in services is based not so much on expectations as on desires, especially that the process of service provision is not easy to plan in the traditional way due to the negligible possibility of recreating each of its stages. Any potential consumer can make planning more difficult by having a different idea of the service. The specificity of this activity consists in adapting existing services to the needs of specific users and launching innovative activity, which is a manifestation of innovative business (Skąpska, 2019). In the area of services a great stress is put on a service provider because of their ability to play different roles (owner, manager, agent, client, innovator, contractor) in the course of their economic activity. An entity performing work gives meaning to the service-oriented activity by means of using awareness to stimulate growth at every level of 'advancement', i.e. maturity of activities. A service provider is an entity running a business activity of a service nature which results in services focused both on people and facilities, falling in the 'market' category. Categories of services, together their changing characteristics, will be determined according to the stage (the above mentioned level). It should be remembered, however, that social processes are not only dominated by reason, which still remains an asset, but also extra-national motives and interests. Rationalization of the social process means seeking to control forces opposing reason and solving conflicting interests of individuals and social groups in order to protect humanity from extinction (Bochenek, 1999). Everyone is responsible for the fate of the entire humankind, regardless of their functions, profession, etc. (Hall, 1990).

In order to be able to design the desired course of the process of providing travel services, planning should be based on key elements. Management teams are forced to start with three projects: firstly, they should map the travels of their clients. An important idea is to map these travels and obtain answers to the questions: what happens in the presence of the client and what has to happen behind the scenes to ensure this 'on stage' impression. Secondly, they should assess themselves (and their competitors) with regard to basic elements of customer experience and technical excellence. Thirdly, they should identify critical interactions with customers. These distinctive moments that determine an organization's identity and strategy are of great significance to customers (Leavy, 2017).

Intuitive planning of services in the market context

The market is an important platform for creating relations and a place of social bonds. In the liberal thought, trade is analyzed as a means of serving rational individuals. By signaling prices and volumes of trade, it provides information that allows each social actor to freely adjust his or her behavior ensuring self-regulation of the economy and society (Bremond, 2007, p. 107). On every market, including services, there is a phenomenon of satisfying needs and raising awareness of them. Their satisfaction, as T. Veblen (2008) stresses, does not result from rational choice, but is conditioned by already existing social institutions and infrastructure. Institutionalism indicates that economics is a psychological science when it refers to the behavior of people in the economization process.

J. B. Say claimed that producing means creating usefulness. Production, in turn, means readiness to provide services. Provision is division and exchange, and consumption is an intake associated with satisfying needs (Say, 1967). Thus, the use value of goods consists of a number of distinct useful characteristics which may be present in goods at different intensity. These features are usually easily understood by the recipient (Table 5).

Table 5: Useful features of goods and services – differences (Source: own elaboration based on: (Ładoński, 1994)).

Goods	Services*
product functionality	high quality
operational reliability	imagined outcome of an activity
durability	satisfaction with consumption
efficiency	adequacy to expectations
life span	willingness to re-consume
reparability	possibility of co-creation
modernity	complexity, i.e. additional services
safe use of the product	trust, belief in the expected effect

** author's elements of the table concerning useful features of services*

An important principle for the survival and development of a company on the market is an imperative of being competitive in striving for balance between organizational culture and service design. 'Great culture' manifests itself in the ability of managers/planners to work in a relationship with customers and staff and meet the expectations of both groups. This is particularly important in a service organization. A person planning a service process should decide whether traditional planning is sufficient to achieve the desired effect, or whether the process should be extended by adding new stages, i.e. implement intuitive planning (Figure 2). The length of the process certainly depends on the characteristics of services.

The following features constitute the specificity of services and their distinctness with regard to material goods: a) intangibility – the service as a product for sale is dominated by intangible elements: the service cannot be touched, felt, tasted in the same way as tangible goods; b) indivisibility – refers to the simultaneity of the service provided by the service provider and its consumption by the customer, i.e. to the inseparability of the person providing the service with the product, the customer's participation as a co-creator of the service, and the role that can be played by the other customers in this process, (c) diversity – means the difficulty of maintaining homogeneous quality standards and the difference in the level of concluded transactions and provided services; (d) impermanence – by rule services may not be stored and maintained, so it is not possible to produce them in stock to, for example, sell them at the time of increased demand.

Figure 2: Planning stages in services

(Source: own elaboration).

In a deliberate selection of activities, a market participant has the opportunity to assess which activities lead to better and which to worse results. In the provision of services, what counts are the structural components of the person's type of character and trust as a relationship value. This gives the reasoning of individuals certain specificity. In services, the components of the provision process are factors that hinder repeatability, such as emotions, dominance of the human factor together with its level of maturity, professional experience, personality, qualifications, etc. People's economic behavior depends on their subjective perception of reality, knowledge and standards. The set of rules of behavior of individuals and organizations reduces uncertainty, ensures regularity of behavior/activities. When, as a result of the provision process, the service meets or exceeds the expectations of the recipient, the cycle can be repeated to some extent, i.e. a new process can be planned. Planning initiates the reproduction process and a new cycle of the service provision process after the first cycle has been completed and there occurs a desire to resume it (Figure 3).

Figure 3: Stages of resuming the planning process in services

(Source: own elaboration).

In a more developed form of organization of the economization process, also in the service sector, the market emerges as a network of economic institutions, the division of labor and knowledge, and the problem of benefits resulting from the use of individual skills, qualifications as well as knowledge, place and time (Hayek, 1945). Appropriate application of the logic of thinking translates into rational activity, allowing to reduce losses in human resources. In this respect, service providers can take advantage of the opportunities offered by an economic order that fosters greater rationality. It is not perceived as a form of specific directives, but as an ethos, not as a logical category, but as a psycho-sociological one. A service provider solves problems based on intuition, imagination, insight and emotions. Taking into account the influence of these factors on economic choices, it is possible to divide planning paths into two parts (Figure 4): a path leading to benefits and a path that brings costs, expenses, but not always losses. In the long run, costs (capital expenditure) can be transferred into benefits.

Figure 4: Effects of selecting the planning path

(Source: own elaboration).

Planning results in projections of the decision consequences which include costs or benefits. In services, one of the prediction methods entails basing the thinking and acting on intuition, imagining the process as well as acting on the perception of individual activities that may lead to positive acceptance of the effect of the process, i.e. service consumption.

Intuitive planning and rationality vision in economic management

Planning assumes the ability to imagine things. In service relations and in a process of service provision, intuition, or in other words, creative imagination rests on a unique set of abilities of a person as well as on favorable opportunities and means that enable intellectual potential to show (Garden, 2008). The set includes:

- verbal-linguistic intelligence (highly developed verbal skills and sensitivity to meaning and word rhythms);
- logical-mathematical intelligence (ability to think about concepts and abstract ideas as well as to differentiate logical and numerical patterns);
- spatial-visual intelligence (ability to associate and remember things graphically as well as to visualize abstract concepts);
- kinesthetic intelligence (ability to control the movement of the body and to operate certain objects);
- musical intelligence (ability to appreciate the rhythm);
- interpersonal intelligence (ability to properly detect and properly respond to other people's moods, motivations and desires);
- intrapersonal intelligence (ability to be aware of internal feelings and to conform to them as well as one's values, beliefs and thought processes);
- naturalistic intelligence (ability to recognize and categorize plants, animals and other objects in nature);
- existential intelligence (sensitivity and ability to search for answers to deep questions with regard to human existence – What is the sense of life? How did we get here?).

Using the perception and intuition for thinking about actions, i.e. planning, consists in a basis for a reasonable production process, especially the process of service provision. The perception, in this context, should be understood as an interpretative processes. The intuition, however, based on intelligence, constitutes the ability to predict. The points of view on how to administer and manage rationally derive from the image of the world, the image of a human and from the origin of performing the science [Stacewicz, 2003]. A new paradigm of rationality is connected with the name of H. A. Simon (1955). New quality in economics has been introduced by researchers of the institutional economics. According to them, a human is a being who seeks for satisfaction and not the optimum. Rational behavior of people is formed by the structure of a task and calculating capabilities of a human. They must formulate judgments based on strongly filtrated data. The rationality in respect to services was first defined by E. Skąpska [2019]. According to her 'rationality is a trait of a reasoned economic action with regard to logical cohesion and human mind. Such action in services may hardly be replaced by artificial mind (e.g. computer)'. Simultaneously, the ability to predict events requires an additional skill of proper perception of reality which is connected with the following notions [Gardenfors, 2006]:

1) internal world – it is necessary for a skill of instant planning;
2) definitions of various emotions – at this level, an individual is capable of observing and understanding that someone is, for instance, suffering. It is sympathy. Even though one understands someone else's emotions, it does not mean they know what somebody believes in or desires;
3) focalization – it is being able to understand what someone focuses on or pays attention to. This skill does not assume the existence of any concept of an internal world;
4) intention – it is the ability to, above all, understand that there might be a specific purpose behind someone else's particular behavior. This form of everyday reasoning is especially interesting;
5) mind – the skill behind the concept of mind has been previously defined as possessing symbols or concepts on the subject of what individuals believe in or desire;
6) self-insight – at this level one needs symbols and concept of their internal world. The example may be their own beliefs or desires. To be more precise, it means the ability to meditate on them. A special case constitutes the ability to pre-plan, which assumes that one is capable of defining their needs.

The above 1 – 6 levels form a series of layers in the cognitive development of humans and lead to self-awareness.

Construction of the problem

Each attempt to create a concept of rationality poses, by definition, an attempt to improve the functioning of an individual enterprise. It needs to be stressed that, if its postulations are not in accordance with the reality, there is a danger of creating an utopia. Rational actions are a basis of economic activities and they become rational, thus correct, if they are congruent with the rule of economy, which has been present in the literature since the half of the 18th century. Acting (administering or managing) is considered to be rational when an entity that realizes a preferable goal chooses, based on their knowledge, the most effective means.

Ignoring the validity of aims and morality of means undermines the sense of rationality and reason. Although business activity is generally rational, there is no sole rationality. Objectivistic rationality, subjectivism rationality and rationality of actions are not identical to rationality of thinking. One should accept the fact that there are always more rational projects, plans and economic actions.

Methods

247 students of economics from Polish economic universities (Warsaw, Wrocław, Kraków, Poznań and Katowice) and 111 entrepreneurs (exhibitors at international fairs in Polish cities) took part in the study conducted by the author. In the first case, a questionnaire was used, which was distributed to students. And in the second one, a direct interview was conducted.

Results

Intuitive planning usually refers to irrationality and a quick decision. Rational thinking is opposed to emotional activity, a lack of analysis, complete information and thoughtful phases of operation. These issues were resolved during the research (Figure 5. and Figure 6).

Figure 5: Importance of rationality in opinion of economic students
(Source: own elaboration based on authors research).

The largest number of responses, as much as 68.4%, concerned the understanding of rationality of the entrepreneur as a forecast of the optimal achievement of the goal. The fewest votes were given to the approach of taking risk, but with a chance for significant benefits. This is only 6% of indications (Table 6).

Table 6: Entrepreneur rationality
(Source: own elaboration based on authors research).

No.	Respondent answers	Indication proportion
1	taking risks, but with chance of significant rewards	6%
2	security, certainty, complete information	47%
3	ability to reduce costs	8%
4	forecast of optimal achievement of goal	68%
5	maximum effects and minimum expenditure	25%
6	minimization of inputs, minimization of waste	22%

The most indications were assigned to the 'forecast of the optimal achievement of the goal' (68%), and the fewest – 'taking risks, but with the chance of significant rewards' (6%). Such proportion might mean that rationality is perceived as a trait associated with effectiveness that is led to by a proper plan based on a vision of achieving benefits.

Other goals by the service entrepreneurs included: experience, amenities, technology, optimization, reduction of costs, increase of earnings, a plan, a strategy for actions. On the other hand, the production entrepreneurs valued high quality of production.

Conclusions

Based on the undertaken considerations, it appears that traditional planning without emotional involvement and knowledge of economic psychology, or emotional or social intelligence, may be considered incomplete. However, complementing this form of planning with intuitive planning involves additional risks and costs which may turn out to be both a successful and unsuccessful investment. Planning with a positive effect can give an entrepreneur a holistic view of an organization, where people are the greatest capital. Then, the culture of the organization, based on open discussions that foster innovation and increase work efficiency, will be associated with the profit. The possibility of obtaining many benefits, for both service sellers and service buyers and resulting from the implementation of intuitive planning into services, allows to conclude that there is a need for further, this time empirical, research on the subject.

The traditional planning, under rational thinking and acting in order to achieve a goal, is based on an analysis, numbers, risk and cost estimation, minimization of risk. The risk, within the reason, is controlled. Everything is precisely calculated – each step investigated. This element of the process may prove itself in the production process, but in the service provision it is not entirely predictable. One cannot repeat many stages in the next activity cycle of a service provider and a service receiver. The process itself, obviously, needs to be deliberate and thought over. However, the process of service provision is affected by emotional state, real time prediction and instant decisions that are made based on participant's experiences and promises. Therefore, those specific features of services make it necessary to complement the traditional planning with the emotion-based planning, i.e. intuitive planning which is sensitive to individuals participating in the service provision process.

In the context of use value of services, i.e. consumer's satisfaction of needs, one needs to pay a particular attention to meeting service personnel's expectations, their desires and ideas with regard to services.

Rationality is Service Provider's Trait

Elzbieta SKAPSKA

Bialystok University of Technology, Bialystok, Poland
e.skapska@pb.edu.pl

Abstract

Specificity of services requires separate, special treatment as they face the issue associated with rationality. It significantly connects with various factors which are often ascribed only to people. Those factors regard relations and interactions. They constitute a part of organizational potential, but they do not shape any substantive or financial matters. The aim of the article is to explain the notion of rationality and form an attempt to ascribe it to a service provider. Achieving the assigned goal is based on the results of survey research and interviews. Those results concern a cardinal conclusion that rationality, in economic sense and with regard to services, is about conscious acting that brings benefits and, in comparison with production, is far more attached to human reason and market-environment relations. This means that rationality should be a trait of an every economic entity. However, as for a trait of a service provider, it might be understood as a unique skill that a person uses in order to repeat a successful and effective process of service provision based on employer's involvement in accurate (in accordance with expectations) satisfaction of service consumer needs.

Keywords: Services, Business Activity, Rationality

Introduction

Rationality regards a human in the context of economic management and the evolution of conditions for their activity. The traditional perception of rationality is evolving. The source of this process is rationality in the classic view. New alternative views are emerging all the time, which testifies to the need for adjusting to the current progressive changes. Service may only be provided by a human equipped with competence, qualifications, experience, personality, i.e. human capital. Accepting this fundamental assumption leads to a conclusion that human labor is a basic generative factor in services. J. B. Say (1967) claimed that productivity meant creating usefulness, and the production constitutes readiness to provide services.

In the 60s, there was a turnaround towards the belief in human's rationality. Contemporary psychologists believe that humans, in their everyday lives, apply the rule of deduction that does not diverge from the rules of logic or statistics and they perceive the world in a way that hardly differs from the scientific perspective (Szewczak, 2013, p.73). At this point, one may summon up rationality in a macro scale, which was taken by O. Lange with a measurable goal, i.e. the increase of national income. Thus, if we relate the EU countries, we may talk about rationality that refers to common goals instead of universal rationality. It is worth stressing that the basis and the reason for the economic activity is composed of, firstly, unlimited human needs and desires, and secondly, resources that are necessary to satisfy them. However, the later ones are limited at a given place and time. This requires making economic decisions. Global communication generates the same or very similar needs for all the people, but only some of them may satisfy their desires.

The concept of economic rationality was enriched by J. Bentham, who was a representative of utilitarianism in the 17th century. He introduced the model of a calculating unit/individual which originated from the principle of utility. According to him, each person calculates the utility that comes from the actions. Even insane or mentally ill people constantly calculate their actions. 'The principle of utility uses the rule that either approves of or rebukes any activity that expands or reduces one's happiness associated with their desired goals – even if it is only a tendency to do so. Friedman (1953), in connection to the theory of the rational choice, claimed that it had been invented as a mathematical simplification that enabled creation of a set of results which reflect analytical power. People, even though they possess neither formal tools nor cognitive resources in order to calculate the optimum, behave like bicycle riders – they keep the balance in spite of being unaware of equations behind the dynamics of movement. Simon (1978) notices that exercising the rationality requires an effort, but its consequences are pervasive, especially with respect to an organization or an institution. Baumol (1979), however, discovered a different point of view as for a satisfactory criterion that guides economic entities. Simon's criterion covered the establishing the first decision which passes the acceptance test. The different point of view on maximization concerns the comparison of all the

available alternatives. In the second half of the 20th century, it was concluded that human behavior systematically diverged from the assumptions of the rational choice theory depending on various circumstances, for instance, making a decision under different risk factors (Tversky and Kahneman, 1979).

Subsequent generations of researchers, inspired by Simon's works, introduced new models into the notion of limited rationality, for example, the reductionistic interpretation was dominating among neoclassical economists (Gigerenzer, 2004, p. 389-409). According to this interpretation, the limited rationality is nothing close to the subversive theory. It may be easily utilized for modeling full optimal procedures with regard to costs, time capital, financial resources, resource limitations (Arrow, 2004, p. 47-55). In turn, Ariely (2009) draws attention to the departures from the traditional theory of a rational choice which are characteristic of people. These are automatic and intuitive errors rather than controlled and analytical ones like aversion to a loss, control illusion or an error in a group.

One of the first attempts to explain rationality in the context of services was made by E. Skąpska (2019) who defined the rationality of economic management in services as a feature of deliberate economic activity that is grounded on logical coherence and human mind – the mind that may be replaced by artificial mind to only a limited extent. The deliberations that are included in E. Skąpska's book have become prerogatives for further research on the subject of rationality in services and some of them are presented in this article.

Rationality Essence

Rationality is a polysemic notion which is difficult to fathom. However, each and every attempt to explore the issue seems to be necessary as it is a key term in the economics. The activity of an entity that takes up economic challenges might be regarded with respect to the assumed definition of rational economic activity. A rational entity chooses an action which is the most beneficial with regard to the profit loss balance. Therefore, it leads to the state of the utmost utility for the unit or an individual. In reality, there are many types of departures from the rational calculation, but at least some of them, to some extent, might be controlled by an entity that makes the decision. This approach by D. Kahneman and A. Tversky (1973) is considered to be a turning point. In the period of behaviorism domination (the 50s of 20th c.), it was mostly emphasized that emotions affected the perception processes and logical deduction in a disruptive manner (e.g. attribution errors), which, obviously, denied the rationality of an individual or a unit.

Comparing the characteristic of a service enterprise and a production enterprise shows certain differences which are significant while determining the rationality of actions. One may use specific criteria to discern the distinction. Considering the subject of activity, in a service enterprise it is service, and in a production unit there is a material product. As for the activity goals, there is service provision in a service enterprise, which requires consideration for individual expectations and client's character. And, there is a serial production in accordance with the type of a consumer and their previously determined needs. The result of service provider's activity is individual services, and producer's – mass products. Challenges that are associated with the rationality and a service provider consequently regard the definition of a service product for the sake of service provision and the verification of knowledge in real life as well as full information on a client (Rogoziński, 2000, p. 35). Service receivers, before making a decision, possess knowledge about service providers and their offered products/services. During the selection, receivers gain information from the Internet, discuss the subject with their friends and have conversations or conduct negotiations. Therefore, current service providers are forced to maintain communication channels in order to keep coherence as for expectations and synergy (Mortimer & Pressey, 2013, p.55). However, one should highlight the fact that consumers, who represent various cultures, pay attention to different factors while assessing services, and thus they see their quality in various manners. People from the eastern Asia have strong bonds with other people from their group and they stress keeping the harmony among the people they identify with. On the other hand, people from the western countries make decisions on their purchases regardless of the norms and expectations of other people (Lin et al., 2013, p. 500-510).

Service provider as entity of economic activity

A service provider is an entity that runs business activity with regard to services as well as a person who provides service. Services may be divided in an economic sense into the following categories: a) trade services (transportation, foreign travel, mail and telecommunication, finance, construction, IT industry, advisory, exhibitions, fairs); b) non-trade services (copyrights, medical services, maintenance of non-governmental enterprises); c) governmental services (maintenance of representative agencies, intergovernmental organizations).

Personality of an individual has, among others, two interplaying components: wisdom and intelligence. In that sense, wisdom builds strategic grounds which support human's behavior, and intelligence regulates efficiency of thought processes.

Thus, rationality is a trait of conscious human activity which plays various roles, including the economic role. It constitutes an ability that is available to everyone in all situations. It consists in proper demeanor which an expression of economic reason (Bochenek, 1999). Rationality is also entity's knowledge, their access to information and the ability to process it (Kotarbiński, 1973, p. 306).

This may also relate to demand for reaching greatest benefits at the lowest costs which is an expression of the so-called principle of rational economic management (i.e. an assumption about maximizing character of human activity). The rule might be considered as, firstly, a principle of the biggest effect at a given level of effort which brings a maximal level of the aim realization and, secondly, a principle of minimal expenditure when a given goal is realized at minimal effort. (Milewski, 1998). However, proper understanding of rationality, according to J. Stecewicz, meets contemporary requirements and it needs consulting extra-economic dimensions of managing: ecology, philosophy, psychology.

Rationality in services requires a significant amount of effort from a decision maker. They must take into account psycho-social factors that cover cultural diversity, religion, social capital or trust. Egoism and reluctance to knowledge do not favor rationality. Any labor that cooperates with creation of utility (value), such as doctor's work, lawyer's or scientist's work, is productive work. Those people produce intangible goods. Each of entities that participate in the creation of social relations must use tools and systems which provide them with the current access to information from various fields of activity, incl. sales, organization, finance. Rules (traditions) assist a person in understanding the character of the rational world view. Any defined parameters, functions, principles are temporary and transitional. A rule may help to make a decision because majority of people accept it as reliable and based on an interpersonal agreement (Nozick, 1993, p. 80). B. Spinoza and G. W. F. Hegel see coupling between rational activity, morality and the values within them. Thanks to rationality one may achieve, according to the authors, higher values. Hence, the rationality itself becomes a value. It plays a role of an ethical pattern for human activity and it paves the way to rich knowledge and a better world (Bochenek, 1999, p.60).

An economic approach does not approve of the existence of irrational decisions. However, it does not enable clear predictions as for human behavior patterns. It only has the ability to explain already made decisions *ex post* which is based, most frequently, on a far ambiguous and very flexible category of 'psychological costs'. Consequently, in an economic reality, there are various types of human attitudes and behavior patterns (Stacewicz, 1991, p.92): instinctive patterns which originate from a biological character; rational (sane) patterns that come from the intellect; emotional patterns connected with positive and negative moods.

Moreover, the author also finds principles that describe the potential of human behavior: 1. Pleasure principle – one's own satisfaction without weighing someone else's opinions; 2. Reality principle – optimizing one's own benefits with regard to limitations, incl. simultaneous activity of other people; 3. Development principle – unselfish provision of help to others or renouncement of one's own benefits to the favor of others. Concepts of rationality in economic activity are associated with the vision of a human as an economically managing entity. Those include (Stacewicz, 1991, p.90-91):

A. 'Economic human' concept – it connects with economic rationality in the most traditional sense, i.e. microeconomic rationality which is success oriented rationality in terms of finance. An economic human is reduced in their economic activity to narrow economic motives of egoistic features;
B. 'Social human' concept – leads to rationality that has political features. It may, depending on conditions, take a shape of macroeconomic rationality that focuses on the increase of development pace or techno-economic rationality that maximizes productivity of creative factors. A social human is an idealized, hypothetical entity that is driven by a collective interest.
C. 'Multidimensional human' concept – leads to administrative rationality that focuses on the quality of life that is humanistic rationality. A complete, 'multidimensional' human acts based on different economic and social motives. The evolutionary view on business activity is the one that sees a gradual transition from cunning activities to reasonable activities and finally to wise activities.

Mindful conduction of service activity in practice and the economic theory include two standpoints. The microeconomic standpoint (researched in this article) comes down to establishing human's traits in economic activity, i.e. human nature, especially answering the questions about motives and the rationality of their behavior, which enables the author to determine the rules for functioning of economic entities. In the macroeconomic standpoint, however, it is analyzed how the administration/managing works in the scale of societies (countries), that

is in a national economy (Bartkowiak, 2013, p.11). In this respect, researchers pay attention to specialization and division. The issue of production, as economists claim, is solved. It seems that economics faces the problem of the division in the field of services. Few economists notice the significance of extra-mathematical elements of economic managing which are particularly specific to services. Therefore, there is a poorly recognized problem of a new approach towards the rationality of this type of management.

Methodology

Proprietary research on the subject of rationality by service providers has been divided into 2 stages. First of all, the online surveys reached 100 Polish managers of service companies. Diversified service activity regards rational collection of resources, disposal, i.e. reducing the loss and maximizing the effects.

The structure of the service companies included the following types:

- 28% educational companies (professional training, courses).
- 14% construction companies (incl. design offices).
- 13% trade (incl. bookstores).
- 10% advertising (advertising in private media, incl. reporting photography).
- 10% consulting (tax advisory, accounting, judicial assessment).
- 9% medical (specialist private offices, incl. stomatology).
- 8% information and IT (incl. logistics).
- 3% financial (loans, insurances).
- 2% service.
- 1% production.
- 1% tourist (customer service center).
- 1% trade-extractive company.

The following research stage regarded the in-depth interview. The questions were directed at exhibitors at an international job fair in Polish cities: Warsaw, Wrocław, Szczecin, Poznań. The responding companies included various activities (production and services) and the interview took on a form of a questionnaire. The research sample amounted to 80% of all the exhibitors and it constituted, in this case, N=109 observations, incl. 17 production companies and 92 service providers. The original sample had been N=110 observations, but a company that conducted business, both in the production and in the services, was removed. One of the other companies changed the category from 'business advisory' into 'business advisory/services'.

Results

In order to distinguish the relationships that were statistically important among the researched variables, the chi-square test of independence was performed. The assumed confidence level was 0.95. As a measure of relationship's strength, V- Cramer measure was adopted. The following data presents only statistically significant relations.

Table 1: Enterprise profile against management method (in %)
(Source: own elaboration based on research).

Enterprise profile	Management method (democratic style, transactional style etc.)				
	1	2	3	4	5
educational	0.0	13.0	34.8	30.4	21.7
consulting	0.0	22.2	44.4	33.3	0.0
construction	0.0	14.3	50.0	28.6	7.1
advertising	22.2	22.2	11.1	44.4	0.0
information and IT	14.3	0.0	14.3	57.1	14.3
other	57.1	14.3	14.3	14.3	0.0
trade	33.3	16.7	25.0	8.3	16.7
financial	33.3	0.0	33.3	33.3	0.0
medical	12.5	0.0	12.5	12.5	62.5

A relationship between the enterprise profile and the management method was observed - Question 1. from Part I: '*What factors do you take into account while assessing the effectiveness of service provision?*'. The V-Cramer measure valued at 0.379 indicates an average relationship between the variables. The analysis of results in Table 2. indicates that the method of management had greater significance for educational companies, consulting, construction, advertising and information/IT companies than for trade, financial, medical and other companies.

Table 2: Enterprise profile against staff competence and skills (Source: own elaboration).

Enterprise profile	High competence and skills of staff				
	1	2	3	4	5
educational	0.0%	0.0%	0.0%	3.6%	96.4%
consulting	0.0%	0.0%	0.0%	11.1%	88.9%
construction	0.0%	0.0%	21.4%	21.4%	57.1%
advertising	0.0%	11.1%	0.0%	33.3%	55.6%
information and IT	0.0%	0.0%	0.0%	12.5%	87.5%
other	0.0%	0.0%	0.0%	25.0%	75.0%
trade	0.0%	0.0%	0.0%	16.7%	83.3%
financial	0.0%	0.0%	0.0%	0.0%	100.0%
medical	0.0%	0.0%	0.0%	0.0%	100.0%

The variable of *Activity profile* affected significantly the two factors from Question 2, Part 1: '*Which factors, according to you, have positive influence on the effectiveness of service provision?*'. This variable affected the evaluation of the next factor: *High competence and skills of staff* (V-Cramer 0.36) and *Client-oriented staff* (V-Cramer 0.35). The *High competence and skills of staff* factor has the biggest influence on the effectiveness of the provided services primarily for medical companies, financial companies, trade companies, information/IT companies, as well as for educational and consulting companies. Its significance is lesser for construction and also, which is surprising, for advertising companies (Table 3.).

Table 3: Enterprise profile against client-oriented staff (Source: own elaboration).

Enterprise profile	Client-oriented staff (with proper personality, empathy)				
	1	2	3	4	5
educational	0.0%	3.7%	7.4%	14.8%	74.1%
consulting	0.0%	11.1%	33.3%	55.6%	0.0%
construction	0.0%	14.3%	35.7%	14.3%	35.7%
advertising	0.0%	0.0%	33.3%	33.3%	33.3%
information and IT	0.0%	0.0%	12.5%	25.0%	62.5%
other	0.0%	0.0%	37.5%	12.5%	50.0%
trade	0.0%	0.0%	8.3%	16.7%	75.0%
financial	0.0%	0.0%	0.0%	66.7%	33.3%
medical	0.0%	0.0%	0.0%	22.2%	77.8%

The variable of *Client-oriented staff* has the greatest influence on the effectiveness of provided services primarily for medical companies, financial and trade companies – grades 4 and 5. However, if one goes up the table, it may be noticed, that the significance of this factor is decreasing. Thus, it is the least important to construction companies as well as consulting (see Table 4.).

Table 4: Enterprise profile against knowledge sharing (Source: own elaboration).

Enterprise profile	Knowledge sharing				
	1	2	3	4	5
educational	0.0%	0.0%	0.0%	14.8%	85.2%
consulting	0.0%	0.0%	0.0%	66.7%	33.3%
construction	0.0%	0.0%	21.4%	42.9%	35.7%
advertising	0.0%	0.0%	44.4%	33.3%	22.2%
information and IT	0.0%	0.0%	25.0%	37.5%	37.5%
other	0.0%	0.0%	50.0%	25.0%	25.0%
trade	0.0%	0.0%	50.0%	8.3%	41.7%
financial	0.0%	0.0%	0.0%	66.7%	33.3%
medical	0.0%	0.0%	0.0%	33.3%	66.7%

A statistically significant relation was also detected between the question from the metric about *Activity profile*, and Question 4 from Part II of the survey: *What staff competences contribute to the development of the services you provide?*'. That relationship regarded two factors from this question: *Knowledge sharing* (V-Cramer measure 0.47) and *Staff engagement* (V-Cramer measure 0.44).

Table 5: Enterprise profile against staff engagement (Source: own elaboration based on research).

Enterprise profile	Staff engagement				
	1	2	3	4	5
educational	0.0%	0.0%	0.0%	3.7%	96.3%
consulting	0.0%	0.0%	0.0%	33.3%	66.7%
construction	0.0%	0.0%	0.0%	28.6%	71.4%
advertising	0.0%	0.0%	0.0%	33.3%	66.7%
information and IT	0.0%	0.0%	0.0%	25.0%	75.0%
other	0.0%	0.0%	25.0%	50.0%	25.0%
trade	0.0%	0.0%	0.0%	8.3%	91.7%
financial	0.0%	0.0%	0.0%	0.0%	100.0%
medical	0.0%	0.0%	0.0%	22.2%	77.8%

The most important measure of rationality in business activity was the one that indicated the ratio of regular clients to the number of commissions (Table 6). It means that it is the value that should guide the service provider who act rationally and they are obliged to maintain bonds with a client in order to obtain their loyalty.

Table 6: Indicators for activity rationality depending on effect advantage over expenditure (Source: own elaboration based on research).

Detailed list	Effect advantage over expenditure [%]				
	No $n = 47$	Yes $n = 62$	Avg. profile $N = 109$	$\chi^2(1)$	p
material consumption costs/daily takings	19.1	11.3	14.7	1.32	0.251
no. of provided services/time (day, month, year)	40.4	53.2	47.7	1.76	0.185
no. of clients/physical effort plus material consumption	21.3	25.8	23.9	0.30	0.583
service sales volume/ no. of clients daily	34	29	31.2	0.31	0.576
no. of pieces of advice /number of receivers	6.4	16.1	11.9	2.42	0.120
sales volume/daily takings	14.9	8.1	11.0	1.27	0.259
regular client number/commissions	29.8*	51.6*	42.2	5.22	0.022
other measure	23.4	17.7	20.2	0.53	0.466

It was also worth noticing that there was correlation between the assessment of effect advantage over expenditure and the assessment of the measure for the number of regular clients/commissions. The companies with the advantage of the effects over expenditure more often pointed out the significance of this measure with regard to the rationality of this activity.

The next step consisted in performing the analysis of correlation between the type of business (production vs. services) and the assessment of the effect advantage over expenditure (Table 7.). In order to do that, the chi-square test of independence was performed. Because the result of the test was statistically insignificant [$\chi^2(1) = 1.54$; $p = 0.119$], one should write that the variables had not been correlated.

Table 7: Effect to expenditure ratio depending on business type (Source: own elaboration based on research).

Effect advantage over expenditure	Production	Services	Total
no	5 (29.4%)	42 (45.7%)	47 (43.1%)
yes	12 (70.6%)	50 (54.3%)	62 (56.9%)
total	17 (100%)	92 (100%)	109 (100%)

The further stage included the analysis of correlations between the type of business and the assessment of the net profit to revenue ratio (Table 8.). The statistically insignificant test result of the chi-square [$\chi^2(2) = 0.02$; $p = 0.990$] made one conclude there were no correlations between the variables.

Table 8: Net profit to sales revenue ratio depending on business type (Source: own elaboration based on research).

Net profit to revenue ratio	Production	Services	Total
high profitability	10 (58.8%)	53 (57.6%)	63 (57.8%)
low / below expectations	1 (5.9%)	5 (5.4%)	6 (5.5%)
meets expectations	6 (35.3%)	34 (37.0%)	40 (36.7%)
total	17 (100%)	92 (100%)	109 (100%)

The last stage of analysis used the chi-square test to examine the correlation between the assessment of the net profit to sales revenue ratio and the assessment of the effect advantage over expenditure (Table 9). The test result was not statistically significant [$\chi^2(2) = 4.47$; $p = 0.107$] which means there were no enough grounds to confirm the statement that the variables had been correlated.

Table 9: Net profit to revenue ratio depending on effect assessment (Source: own elaboration based on research).

Net profit to revenue ratio	Effect advantage over expenditure		
	No	Yes	Total
high profitability	27 (57.4%)	36 (58.1%)	63 (57.8%)
low / below expectations	5 (10.6%)	1 (1.6%)	6 (5.5%)
according to expectations	15 (31.9%)	25 (40.3%)	40 (36.7%)
total	47 (100%)	62 (100%)	109 (100%)

Therefore, we may say that the enterprises were concordant as for the profitability and reasonableness of their business activity.

Seeing the research results that concern the rationality, one should observe the differences in economic activities, both, in production and in services. Despite the fact that the respondents were dominated by the representatives of service enterprises (84.5%), the ability to choose more than one answer enabled the researchers to make comparisons with regard the respondents' answers (Figure 1.).

Figure 1: Understanding rationality of economic activity by service and production enterprise representatives (in %) (Source: own elaboration based on research).

The answers concerning the definition of rationality in economic management differed depending on the presented types of business activity. The service representatives accepted that it might be defined as something more than only the ability to use the opportunity to lower costs. Almost 50% of respondents agreed with that statement. Other aspects of rationality included the ability to achieve assigned goals (not only financial ones) and to adjust to the needs of both parties based on complete documented information, sense of security and minimalization of risk (only controlled risk is possible). In trade, rationality means attitude towards the enhancement of further stages, i.e. rationalization (e.g. material segregation, systems for managing goods, minimizing wastage). In activity connected

with customer service, rationality is about conducting a thorough interview with a client and getting to know their expectations, and then taking such actions so that the both parties are fully satisfied by the transaction. Being rational is also doing profitable activities with respect to the value and the mission of the company, which also requires recognition of its possibilities and resources. In construction, it is an ability to establish proportions between the performance and the number of work hours; the price and the investments in real assets (machines, fixed assets).

Entrepreneurs relate the rationality of actions to a certain situation (Figure 2.) where there is room for safety and complete information, including the ability to reduce costs and take risk, but with the prospect to gain considerable benefits. Some of the researched people saw the rationality differently. According to them, rational activity is the one that brings a person to intended effects. It is also taking the most profitable actions with regard to the value, culture and the company's mission along with the possibilities and company resources. Moreover, rationality is logical and it is mainly about performing tasks which lead to the realization of goals, fulfillment of company entrusted commissions, most frequently in accordance with the needs of a client, and the benefits.

Figure 2: Perception of rationality term by entrepreneurs (in %)
(Source: own elaboration based on research).

In confrontation, the theory distinguishes rationality, effectiveness, efficiency, but in the practice people often equate them with one another.

Rational activity is, according to entrepreneurs, justified acts that are not taken without a need and in accordance with a project. They are planned, but with a possibility to modify them in case it is necessary. They are conscious and have a distinct division of responsibilities. Those responsibilities are defined according to particular standards and norms. What is more, rational actions are verifiable, based on facts and experience, i.e. their consequences are known. Rationality is also maintaining the balance and taking measured actions ('Look before you leap'). It is a hierarchy of tasks and using tools that enhance one's assessment (many representatives stressed this). It is 'fast, cheap and with no mistakes'. Rational activity is prospective and developmental activity that conforms to market's trends (nonpersonal). It is not always economical or accurate (proportional to duties directed at achieving a goal). Some opinions claim its aim is 'to quickly achieve your aim, but adequately to the situation and possibilities'. It takes care of a balanced progress through recycling, voluntary service and an internal audit to verify cleanliness. The respondents highlighted that rational actions must make sense, i.e. bring effects and added value. Thus, they should be coordinated, controlled and directed so that they allow optimal realization of the goal. Finally, they must be in accordance with the laws, agreements and they should seek the balance and the lack of impulsivity.

The entrepreneurs most frequently present rationality of actions by using the following indicators (Figure 3.):

- number of provided services/time (day, month, quarter, year) – 23.43%;
- number of regular clients/commissions – 20.73%;
- sales volume/number of clients– 15.32%;
- number of clients/physical effort plus material consumption – 11.72%;
- material consumption cost/daily takings – 7.21%;
- number of pieces of advice/number of clients – 5.86%.

Non-statistical measures (mentioned in some cases) turned out to be the following items: sales volume/number of employees; production volume/ realization time; margin/sales volume; expenditures/commissions (contract volume); commission value/number of working days; staff input/results; friends' recommendation/number of commissions; project/result expressed in financial means as well as yearly revenue/income.

The rationality of a producer/service provider has an impact on the following factors (Figure 3.) in the descending order: knowledge resources, labor resources, real capital and financial capital (27.34%), work organization and working conditions (19.05%), the management method (partner, autocratic) (18.79%), intellect (mental abilities) (16.71%) and 8.94% of the researched people mentioned time (work hours). 'Natural conditions (raw materials, weather)' factor received the same percentage of the answers. 0.26% of the researched group answered 'other'.

Figure 3: Activity rationality factors for producer/service provider (in %) (Source: own elaboration based on research).

The data clearly shows that classic production factors (work, capital), but fortified with proper resource of knowledge, have the greatest influence on service provider's rationality.

Conclusion

The discussion about rationality leads to a main conclusion that the most rational activity in services is the one that may be repeated. It means that a service provider needs some necessary guidelines and instructions which will let them create a proper framework, rules for specific behavior as well as suitable and proper to the character of the service expression of flexibility. One should also mind the fact that the kind of business activity (i.e. production and service enterprises) does not differentiate significantly the concept of rationality – the answers in production and service companies were very similar. Needs of the service market are much more customized and realized on a client's commission compared with the production. Therefore, the condition for correct (rational) proceeding of a service provider is information that constitutes the basis for the whole process of service provision, from inspiration (the idea) to a final effect – a final product. It is often the thing that cannot be counted (intuition, context, emotions and spirituality), which is significant for the service provision process. This provision (a service economic management process), definitely and more frequently, sees the victory of intuition over the reason. A service provider, depending on the kind of provision, engages a service receiver into the process of provision which makes them (the receiver) partially play the role of the provider. According to practitioners of economic life, the rationality of a service provider is expressed in specific proportions. Essentially, it concerns a number of provided services in relation to a given time – daily, monthly, yearly (23.43%) and a number of regular clients with respect to the commission rate (20.73% of the answers).

Abstract

The classical models for construction of investment portfolio do not take into account fundamental values of companies in which one invests. In our approach we extend the portfolio choice by adding this dimension to the classical criteria of profitability and risk. It is assumed that an investor selects stocks according to their attractiveness, measured by some fundamental values of companies. In this approach portfolios are assessed according to three criteria: their profitability, risk (measured by variance of returns) and their fundamental value (measured by some indicators of financial standing of companies). In this article we consider earnings to price ratio as the measure of the fundamental value of a company. In the paper we consider an algorithm for constructing portfolios with fundamental criterion based on analytical solutions for appropriate optimization problems. In the optimization problem we consider minimizing variance with constrains on expected return and attractiveness of investment, measured with some indicators of fundamental values of companies in a portfolio. We also present empirical examples of calculating effective portfolios of stocks listed on the Warsaw Stock Exchange.

Keywords: Portfolio Analysis, Fundamental Value, Multicriterial Choice, Fundamental Analysis.

Introduction

Classical methods for selecting portfolio of investments, developed by Markowitz (1952, 1959) and Sharpe (1963), take into account only market performance of companies measured by their returns. In the classical model potential portfolios of investment are evaluated according to two criteria: profitability and risk. The first criterion is measured with expected rate of return and the second one with variance or standard deviation of return. In other words, this approach takes into account only the information that are reflected in the market prices of companies. One does not consider any other criteria, which can give some additional information about the future prospects of the company or its financial and competitive situation.

However in the recent years there was a growing interest in the methods of portfolio analysis in which one considers alternative ways of constructing portfolio. The article of Kolm, Tütüncü and Fabozzi (2014) contains a survey of major developments in portfolio theory since the beginning of its existence, and the book of Doumpos and Zopounidis (2014) lay the attention on multicritera methods used in this field. Most of innovations depends on using some criteria of risk other than variance or standard deviation of returns, as for example semivariance or conditional value at risk (CVaR). The article of Fabozzi, Focardi and Jonas (2007) presents the variety of risk measures that are currently used in practice of portfolio investments. In some other approaches some characteristics of distributions of returns are assets are used as additional criteria for evaluating portfolio performance. Examples of such characteristics can be skewness or kurtosis. Such extended portfolio analysis is presented in (Briec, Kerstens and Jokund, 2007) or (Rodríguez, Luque and González, 2011).

There are several research in which one considers criteria that are not based on assets' returns. There is a branch of the literature which takes into account ethical, social or environmental criteria in portfolio construction. The so-called socially responsible investments approach was described for example in (Steuer, Qi and Hirschberger 2007). The articles (Ballestero et al. 2012) and (Bilbao-Terol et al. 2013) are another examples of this approach.

Lo, Petrov and Wierzbicki (2003) considered liquidity of stocks as an additional criterion in the portfolio construction process. There are only a few papers which considers also fundamental values of companies. Xidonas, Mavrotas and Psarras (2010) considered the amount of dividends paid by companies. Jacobs and Levy (2013) in their paper take into account the risk associated with leverage. The utility function of an investor includes the costs of margin calls, which can force borrowers to liquidate securities at adverse prices due to illiquidity, losses exceeding the capital invested, and the possibility of bankruptcy.

Tarczyński (2002) applied a synthetically developed measurement to evaluate the economic and financial standing of a company and used this measure as an additional criterion for evaluation possible portfolios. He called this measure the taxonomic measure of attractiveness of investment (TMAI). The portfolio constructed with the use of this measure was called fundamental portfolio. In recent years this model was modified for example by substituting variance as a measure of risk by semi-variance (Rutkowska-Ziarko and Garsztka 2014). In (Rutkowska-Ziarko 2013) the Mahalanobis distance was used to determine the TMAI, due to a possible correlation between diagnostic financial variables.

In this paper we propose an approach in which one uses price-earnings ratio as a measure of fundamental value of companies in a portfolio. We present a simple algorithm for constructing a fundamental portfolio with price-earnings fraction as an additional criterion for evaluating portfolios. The algorithm is based on analytical solutions of optimization problems. In the empirical part we verify this method computing fundamental portfolios of the stocks traded on the Warsaw Stock Exchange. The article is organized as follows. After this introduction, in the section 2 we present our proposition of extending classical portfolio theory for additional, fundamental criterion. Section 3 provides analytical solutions to the problems connected with computing fundamental portfolios and algorithm for constructing such portfolios. Section 4 contains empirical examples from the Warsaw Stock Exchange and section 5 concludes.

Portfolio problem with criterion on price-earnings ratio

In the article we use a generalization of classical Markowitz model of portfolio optimization, see (Markowitz 1952) and (Markowitz 1959). We consider an investor who tries to determine optimal composition of his portfolio. Assume that there are n risky assets with random rates of returns $R_1, \ldots, R_n$. Let μ_i be an expected return of asset i: $\mu_i = E[R_i]$. By cov_{ij} we denote covariance between the asset i and j, $cov_{ij} = \mathrm{cov}(R_i, R_j)$. By x_i we denote the proportion of wealth invested in the asset i. As in the classical Markowitz model an investor evaluates a portfolio according to criteria of expected rate of return and risk. The expected return equals

$$\mu_P = \sum_{i=1}^{n} x_i \mu_i \tag{1}$$

and the risk is measured by the variance of return from portfolio, which equals

$$\sigma_P^2 = \sum_{i=1}^{n} \sum_{j=1}^{n} x_i x_j cov_{ij} \ . \tag{2}$$

The expected return and variance of return of portfolio's components are estimated on the basis of historical returns of the shares of companies. The problem of portfolio selection thus relies entirely on the past market data. In our approach we combine this classical approach to estimating future market performance with the fundamental analysis. It augments Markowitz model with a third criterion which describe financial and economic standing of companies which shares are in a portfolio.

Market multiples are financial indicators that compere given accounting values per share with the market price of this share. Loughran and Wellman (2011) analysed a broad sample of not financial firms from NYSE, AMEX, NASDAQ. They found that companies with low levels of market multiples appeared to have higher stock returns than companies with high levels of market multiples.

Price to earnings ratio (P/E) is one of the most popular market multiples Price to earnings ratio (P/E) relates earnings per one ordinary share to its market price:

$$\mathrm{P/E} = \frac{market\ price\ of\ a\ share}{net\ profit\ per\ share}.$$

It is considered that the P/E ratio can give valuable information about the future profitability of investments. The research on the pricing anomalies connected with the price to earnings ratio dates back to the work of Breen (1968). He considered US companies from S&P 500 in the period 1953-1966. He discovered that portfolios of companies with the lowest P/E ratio were more profitable for investors. This phenomenon was called earnings effects. Similar results were obtained for NYSE by Basu (1977, 1983).

Price to earnings ratio anomaly is still the topic of interest in the field of finance. Chaya and Nigam (2015) analysed 500 the most liquid companies listed on Bombay Stock Exchange (BSE). They found that it is possible to get abnormal returns on capital markets for investing in companies with low value of price to earnings ratio. They termed this phenomenon as value premium. The term value premium relates to others market multiples as well. Troung (2009) discovered that low P/E stocks outperform high P/E stocks in New Zealand. Ikoku, Hosseini and Okany (2010) examined the information value of price-earnings (P/E) ratios in the Nigerian stock exchange prediction of stock prices.

Since the of P/E has a role in predicting future stock prices, this ratio can be used in the portfolio selection problem. Richie (1992) proposed the strategy of buying stocks of companies with low value of P/E ratio, e.g. out of three or four first deciles. This strategy however ignores the risk analysis and portfolio diversification. In our work we combined the fundamental strategy based on the P/E ratio with risk analysis in the context of Markowitz portfolio theory. Instead of price to earnings ratio the reciprocal of this ratio was used in the portfolio chose model. We used earnings to price ratio (EP), calculated as in equation below:

$$\mathrm{EP} = \frac{net\ profit\ per\ share}{market\ price\ of\ a\ share}.$$

We used E/P ratio in multicriteria portfolio selection problem. We assume that it is beneficial for investors to buy the stocks of companies with a high level of net income per share compared to its market price. The EP as an additive measure. It can be shown that the ratio of earnings of all companies in a portfolio (proportional to number of shares in the portfolio) divided by the value of the portfolio is a weighted average of earnings to price ratios of all companies in this portfolio. In other words earnings to profit ratio of any portfolio (EP_P) is given by

$$EP_P = \sum_{i=1}^{n} x_i EP_i, \tag{3}$$

where $EP_1, \ldots, EP_n$ are earnings to profit ratios of single companies.

With the introduction of EP_P we have three criteria for assessing an investment: profitability, risk and fundamental value. The formulas for calculating these criteria are given in Eqs. 1-2 and Eq. 7. One of the methods for obtaining a portfolio which is efficient with respect to all three criteria is to solve a problem of minimizing variance of a portfolio with constrains on the two other criteria. This leads to the following optimization problem:

$$minimize \sum_{i=1}^{n} \sum_{j=1}^{n} x_i x_j cov_{ij} \tag{4}$$

with respect to

$$\sum_{i=1}^{n} x_i \mu_i \geq \gamma \tag{5}$$

and

$$\sum_{i=1}^{n} x_i EP_i \geq EP_\gamma, \tag{6}$$

where γ is the target rate of return and EP_γ is the fundamental value of portfolio required by the investor. Of course, there is an additional condition that $\sum_{i=1}^{n} x_i = 1$.

The analytical solution of the portfolio problem

Let Σ be a covariance matrix of returns, i.e.

$$\Sigma = \begin{bmatrix} cov_{11} & \cdots & cov_{1n} \\ \vdots & \ddots & \vdots \\ cov_{1n} & \cdots & cov_{nn} \end{bmatrix}.$$

Define the following vectors: $\mu = (\mu_1, \ldots, \mu_n)^T$, $z = (EP_1, \ldots, EP_n)^T$ and let e be a column vector of length n: $e = (1, \ldots, 1)^T$. Using the vector notation, the optimization problem (4)-(6) can be formulated as follows:

$$minimize\ \frac{1}{2} x^T \Sigma x \tag{7}$$

with respect to

$$x^T e = 1, \tag{8}$$

$$x^T \mu \geq \gamma \tag{9}$$

and

$$x^T z \geq EP_\gamma. \tag{10}$$

The Kuhn-Tucker conditions for the problem (7)-(9) are as follows

$$\Sigma x = \lambda_1 e + \lambda_2 \mu + \lambda_3 z, \tag{11}$$

where $\lambda_2, \lambda_3 \geq 0$, with the complementary conditions

$$\lambda_2 (x^T \mu - \gamma) = 0, \tag{12}$$

$$\lambda_3 \left(x^T z - EP_\gamma\right) = 0. \tag{13}$$

Assuming that covariance matrix is nondegenerate (as it is in practical usages), it follows from eqn. (11) that the solution has the following form:

$$x = \lambda_1 \Sigma^{-1} e + \lambda_2 \Sigma^{-1} \mu + \lambda_3 \Sigma^{-1} z. \tag{14}$$

We have to consider several cases. To simplify the notation, we define the following symbols. Let

$$g_{11} = e^T v^1, g_{12} = e^T v^2, g_{13} = e^T v^3, g_{22} = \mu^T v^2, \tag{15}$$
$$g_{23} = \mu^T v^3, g_{33} = z^T v^3,$$

Where

$$v^1 = \Sigma^{-1} e, \quad v^2 = \Sigma^{-1} \mu, \quad v^3 = \Sigma^{-1} z. \tag{16}$$

Firstly, assume that $\lambda_2 = \lambda_3 = 0$. From complimentary condition (12) and (13) it turns out that only condition (8) must be satisfy as equality. Putting the solution (11) with $\lambda_2 = \lambda_3 = 0$ into (8) we obtain the solution

$$\tilde{x}^1 = \frac{1}{g_{11}} \Sigma^{-1} e. \tag{17}$$

The minimal variance in this case equals

$$\sigma_1^2 = \frac{1}{g_{11}^2}. \tag{18}$$

In the case when $\lambda_2 > 0, \lambda_3 = 0$, in the optimal solution condition (8) is fulfilled and condition (9) holds as an equation, which gives a system of equations

$$\lambda_1 g_{11} + \lambda_2 g_{12} = 1, \tag{19}$$

$$\lambda_1 g_{12} + \lambda_2 g_{22} = \gamma. \tag{20}$$

After some manipulations one can write the solution of this system as

$$\tilde{x}^{12} = (1 - \alpha_{12})\, \tilde{x}^1 + \alpha_{12} \frac{v^2}{g_{12}}, \tag{21}$$

where

$$\alpha_{12} = \frac{g_{12}(\gamma g_{11} - g_{12})}{g_{11} g_{22} - g_{12}^2}. \tag{22}$$

The variance of the portfolio in this solution equals $\sigma_{12}^2 = \sigma_1^2 + \Delta\sigma_{12}^2$, where

$$\Delta\sigma_{12}^2 = \frac{(\gamma g_{11} - g_{12})^2}{g_{11}}. \tag{23}$$

The case $\lambda_2 = 0, \lambda_3 > 0$, is analogic to the last one. The optimal solution satisfies conditions (8) and (10) as equations. The solution can be expressed as

$$\tilde{x}^{13} = (1 - \alpha_{13})\, \tilde{x}^1 + \alpha_{13} \frac{v^3}{g_{13}}, \tag{24}$$

where

$$\alpha_{13} = \frac{g_{13}(EP_\gamma g_{11} - g_{13})}{g_{11} g_{33} - g_{13}^2}. \tag{25}$$

The growth of variance when switching from $\tilde{x}^1$ to $\tilde{x}^{13}$ equals

$$\Delta\sigma_{13}^2 = \frac{\left(EP_\gamma g_{11} - g_{13}\right)^2}{g_{11}}. \tag{26}$$

In the last remaining case is when $\lambda_2 > 0, \lambda_3 > 0$. In this case all conditions (8)-(10) must be fulfilled as equalities, which brings us to the following system of equations

$$\lambda G = a, \tag{27}$$

where λ is the vector of multipliers $\lambda = (\lambda_1, \lambda_2, \lambda_3)^T$, $a = \left(1, \gamma, EP_\gamma\right)^T$ and the matrix G is

$$G = \begin{bmatrix} g_{11} & g_{12} & g_{13} \\ g_{12} & g_{22} & g_{23} \\ g_{13} & g_{23} & g_{33} \end{bmatrix}.$$

The optimal solution to the problem (4)-(7) with all conditions fulfilled as equation can be thus formulated as follows:

$$\tilde{x}^{123} = \lambda_1 v^1 + \lambda_2 v^2 + \lambda_3 v^3, \tag{28}$$

where $\lambda = G^{-1}a$.

These derivations lead to the following algorithm for finding the optimal solution of the problem (4)-(6):

1. Compute the vector $\tilde{x}^1$ and check if it fulfills the conditions (5) and (6). If so, it is the optimal solution.
2. Otherwise, calculate $\Delta\sigma_{12}^2$ and $\Delta\sigma_{13}^2$. Choose the smaller value: let it be $\Delta\sigma_{1k}^2$.

Compute the vector $\tilde{x}^{1k}$ and check if it fulfills the conditions (5) and (6). If so, it is the optimal solution. Otherwise the optimal solution is the vector $\tilde{x}^{123}$.

Empirical results

In the empirical part we analyze 20 largest and most liquid companies quoted on the Warsaw Stock Exchange. The sample includes all companies form WIG20. The computations are based on quarterly returns calculated on daily closing prices in the period starting from the beginning of 2014 and ending at 5 March 2019. Returns are computed as relative increases of prices according to the formula:

$$r_{it} = \frac{P_{it+s} - P_{it}}{P_{it}} \cdot 100\% ,$$

where r_{it} is the rate of return on security i at time t, s is the length of investment horizon (in our case one quarter) expressed in days and P_{it} is the quoted price of security i at time t.

Financial indicators for each company were calculated based on annual financial reports for 2018. For each company in the sample we computed earnings to price ratio. Mean return and standard deviations were calculated based on time series of returns. Table 1 contains information concerning profitability, risk and price to earnings ratio for all companies.

Table 1: Profitability, risk, price-earnings ratios (P/E) and earning-price ratios (EP)

Source: own calculations

During the period under research, there were only two companies with negative earnings: EUR and OPL. For companies with positive earnings the P/E ratio was the lowest for TPE. At the same time, this was a company with the highest risk and its expected return was negative. The lowest standard deviation was for the ACP and the P/E ratio for this company was positive and quite low. The EP ratio of companies was negatively correlated with the mean returns (correlation coefficient -0.254) and there was no correlation between standard deviation of return and EP ratio (correlation coefficient 0.033). There was also no correlation between mean return and risk measured with variance (correlation coefficient -0.035).

The problem of portfolio choice in this situation can be considered as a trade-off between risk and two other criteria. We seek for a portfolio which minimizes risk. However low-risk portfolios tend to have lower expected return. On the other hand, if we assume higher requirements on mean return of a portfolio, the solution will have lower EP. Figure 1 depicts the efficient frontier for the three-criteria portfolio choice. Each point on the graph represents a solution for the problem (4)-(6) for different combination of required mean return and required level of EP.

Fig. 1: Effective frontier for the portfolio problem with three criteria

To analyze the impact of fundamental values of companies in which one is willing to invest on the trade-off between profitability and risk, we determined the shape of efficient frontiers for various values of the required EP ratio. We calculated, using algorithm proposed in section 3, effective portfolios for EP_γ at the levels of 0.06, 0.18 and 0.27. The results are depicted at Figure 2. As one can see, the higher levels of required earnings-price ratio moves the effective frontier upwards. For low levels of required EP ratio, as the required profitability of expected return grows, the restriction connected with EP ratio (given by eqn. 6) is less important and for the highest levels of expected rate of return it is not binding. This phenomenon is expressed on the figure by the convergence of effective frontiers on the right side of the plot. However, when required EP ratio is high enough, the restriction on EP becomes binding for any value of expected return, which moves classical efficient frontier much upwards. This shift of efficient frontier illustrates the trade-off between assessment of a portfolio measures by market measures and its fundamental value.

Fig. 2: Effective frontiers for different values of earnings-price ratio

Conclusions

In the paper we propose an algorithm for constructing a portfolio of assets for which three criteria are considered: profitability (measured with expected return), risk (measured with variance of returns) and a fundamental value of companies in the portfolio (measured with price to earnings ratio). The algorithm for finding effective portfolios with respect to all three criteria is based on the analytical solutions of the suitable optimization problem. We have shown that the algorithm is effective and allows one to construct efficient portfolios with minimal computational effort.

The proposed algorithm allows us to determine the effective frontier (i.e. the tradeoff between profitability and risk) for several level of requirements concerning fundamental values of companies which stocks are in the portfolio. The results from empirical research for the major companies traded on the Warsaw Stock Exchange reveals that if an investor requires high expected return from his portfolio, then the constrain on fundamental value is not binding.

Abstract

Uncertainty, fast change, volatility, market competition and technology advancement are the keywords of the last decade. This paper highlights the main elements of a doctoral research regarding the relationship between organizational innovation processes and the agile methodology. Organizations are faced with continuous change and are challenged to adapt innovatively to evolving requirements in order to survive in the market. As digitalization completely changed the performance scenarios of organizations, by introducing Internet of Things (IoT) technologies, big data and cyber security concepts, simply aligning with the technology usage may not be enough; the transition to organizational innovation requires a cultural change, focused on employees and customers, emphasizing the need for flexibility and agility. It is the employees themselves who can have the most impact on process acceleration and management facilitation, as they are involved directly in the process delivery. Hence, organizations are trying nowadays to build agile innovation based on processes, by linking the terms agility and innovation. The aim of this study is to develop a framework for future studies on the relationship between agile methodology, agile innovation, organizational innovation processes and digitalization. Based on a total of 100 publications, including recognized publishers and data sets at European level, in this study we strive to provide a holistic overview on past accomplishments and future agreements on the terms above.

Keywords: Agile Innovation, Business Agility, Organizational Innovation, Digitalization

Introduction

It is widely accepted that organizations face new challenges in the current context, marked by the fourth industrial revolution (Industry 4.0), which leads to the digitalization of industries by focusing on smart technical solutions, increasingly relying on the Internet of Things (IoT) technologies, automatization and optimization of processes to improve productivity and profits (Parida et al., 2019). Forced to quickly adapt to the increasingly rapid environment changes, the principles of agility seem to be the answer for organizations, in order to develop innovation opportunities. However, as Parida et al. (2019) observed in their study, simply using technological applications is not enough: the organization's business models, and the methodologies used must align with the standards of innovation. By using IoT, business processes become agile and connected. In their research, Akhtar et al. (2018) highlighted that a better competitive advantage can be obtained by organizations by combining the IoTs and dynamic data and information processing capabilities. The main reason is that in this way agility is deeply implemented in their processes, at its turn a consequence of the IT infrastructure development. Based on Vodafone's 2019 IoT Barometer, 34% of worldwide businesses are now using IoT in daily operations, up from 29% in 2018, with 95% of IoT adopters already observing measurable benefits; 81% of IoT adopters say their reliance on IoT has grown, and 76% of adopters say IoT is mission-critical to them; 58% are using analytics platforms to get more insights from their IoT data to improve decision making (Forbes, 2019). Also, on the Vodafone IoT Barometer (Forbes, 2019), where they investigated eight fields of activity (finance, retail, automotive, healthcare, transport, energy, manufacturing or all of it), it was depicted a comparison between the main benefits considered to be brought by IoT enterprises. The adopters are seeing a wide range of benefits, based on Forbes (2019), such as: reduced operating costs (53%), better collection of accurate data/insights (48%), improved employee productivity (47%), increased existing revenue streams (42%), reduced fixed costs (41%), improved asset utilisation or uptime (41%), enhances customer experience/loyalty (39%), improved brand

TRIFAN and Dorin MAIER "Study on Agile Digital Transformation in Relation to Organizational Innovation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

differentiation (37%), streamlined compliance with regulation (35%), reduced waste (35%) and created new revenue streams (33%).

Despite these statistics, based on Akhtar et al. (2018), the correlations between IoT, dynamic data and information processing capabilities (DDIPCs) and operational agility are still at an infancy state. An enterprise which has embedded operational agility means that it can provide quick responses, cost-efficiency and adapted actions. Also, it supposes assistance in improving operational changes and flexibility in daily actions (Langer and Alting, 2000).

Quick reaction to changes in the business environment supported by a balance between the need for stability and the adequate level of flexibility represents the agility of the organization (Ciric et al., 2019).

However, in the Lean methodology, the Value is defined as the critical factor of success in implementing agility in daily processes. It is often considered that an activity that does not add Value for the company or for the customer is a waste (Poppendieck, 2011). Value is often interpreted in a traditional way, as profit generation. But, as described by Khurum et al. in 2013, it is a much more complex concept: besides the Customer Value and the Financial Value, there are also some internal Value Aspects (Value degradation of assets and legacy within the development company). However, the definition of Value within the organization will always suggest the maximization of it for a given investment (Alahyari et al., 2017). In order to do this, it is mandatory to understand the exact meaning of 'Value' for each organization and thus derive what strategy should be applied in order to achieve Value creation. Even though numerous articles were published about how organizations may create Value, they are focused only on aspects such as quality (de Azevedo Santos et al., 2011; Conboy, 2009), simplicity (Conboy, 2009), economy (Conboy, 2009) and frequent releases (Hoda et al., 2011; Petersen and Wohlin, 2010).

Also, by mixing the Lean Six Sigma methodology with innovation management, the focus is on the principles of quality management, which helps in the analysis of the innovation impact on organizations' processes (Ifrim et al., 2020). In the current international environment, where globalization affects most market segments and consumer expectations, an organization which includes in its processes strategic agility will be better equipped to compete in the continuously changing market. Multiple definitions were developed in recent years for the concept of strategic agility: Weber & Tarba (2014) defined it as 'the ability to remain flexible in facing new developments and to develop innovative ways to create value', while Junni et al. (2015) suggests that indeed, an organization must be able to 'renew itself and stay flexible without sacrificing efficiency'. Thus, as observed by Shams et al., 2020 in their study, strategic agility enables organizations to stay flexible and create value with a set of activities, such as: variations in specific processes, power of diversity, dedication of resources which are able to maintain the level of flexibility.

It is important to understand that adopting an agile development doesn't imply the existence of perfectly defined and validated requirements, as specified by Shim and Lee (2019) in their study. An agile development emphasizes the idea that an organization is not perfectly resisting change but embracing it. As Ghezzi & Cavallo (2020) mentioned in their study, (based on Beck et al.' Agile Manifesto Principles, http://agilemanifesto.org/principles.html, accessed in 18th October 2020), one of the main agile principles is 'Delivering the highest value to customer quickly'. Meeting customers' expectations is the centre of a successfully developed organization.

In 2015, Campanelli & Parreiras observed in their study that there is a similarity between the Lean methodology and Agile methodology, related to the main values in both: individuals and interaction, working software, customer collaboration and responding to change.

Research Methodology

This study in the result of an early PHD research on agile methodology, digitalization and innovation. Whereas the research is in an early stage, by analysing an extensive review of 100 data sets of existing academic literature from recognized publishers, we managed to obtain a broad view on the subject of interest. In this light, this paper aims to establish how an agile approach of an organization may have an influence on the organization innovation processes and the relationship between them.

Theoretical Framework

A Literature Review of the Agile Approach

Taking into consideration the complexity and the continuous changes brought about by innovation, the business world is required to quickly adapt their strategies. The Agile methodologies, such as Scrum, Kanban or Extreme

Programming have as main focus to provide an adapted process model to develop products, in order to achieve users' needs and customer expectations (Schon et al., 2017).

In a research study by Teich and Faddoul (2013), using an agile approach means emphasize with continuous process improvement, the purpose being to minimise waste while maximise customer value. Though, it is important to understand the difference between a traditional approach of management and the agile approach. By traditional management, in the speciality literature, the term "waterfall" is often encountered. Basically, this means clarifying the objectives, developing a structured plan, establishing various timelines and deliverables and it can take several years, as observed by McMakin and Hefferman in their study (2020). By introducing the agile approach, the projects are divided into "sprints" and it comes with a rapid delivery of different evolutions that can be tested in collaboration with the developer and the customer. In terms of failure, agility means failing fast, but at a small scale. Based on recent studies, different authors consider that organizations which are adopting agile as methodology should embrace its both parts: technical aspect and social aspect (Danese et al.,2018; Shah and Ward, 2007).

In their research, Takeuchi et. al (1986) declared that a subsequent phased approach for product development does not provide enough flexibility. After this statement, other process models have been developed: RUP - Rational Unified Process (Kruchten, P.,1998; Kruchten, P., 2004), Scrum (Schwaber, K., 1997; Schwaber, K., 2004), XP - Extreme Programming (Beck, K., 2000), Kanban or Feature-Driven Development (Palmer, S.R. et al., 2001). Later in 2001, many leaders of these streams managed to create together the Manifesto for Agile Software Development, with all values and principles included (Beck et al., 2001). In the Agile Manifesto we can find four main values (Schon et al., 2017):

- individuals and intercommunication instead of processes and tools;
- leaving documentation and procedures behind and introducing working software;
- renunciation of contract negotiation and using customer collaboration;
- avoid following a plan and instead adapt and respond in a positive way to change.

Fig. 2: Outcomes vs. human needs in agile approach

Source: elaborated by the authors, based on the research of Schon et al. (2017)

As we can observe in Figure 2, since the creation of Agile approach, software development focuses more on value-driven process models, instead of plan-driven ones. In the plan driven domains, people tend to negotiate the price, the project plans, etc., contrary to people in value-driven domains, that focus on experiences and employees' values. In the end, the agile methodology has as centre point the human being.

Traditional Collaboration versus Agile Approach

There are multiple key-parts in the projects and organizations based on agile methodology (Hoeren & Pinelli, 2018): developers are always connected to the business teams, they are working in sprints (small development units delivered in order to be tested), they have a product owner (customer's voice) and a scrum master.

Adopting the Agile methodology means accepting the fact that in every step taken the progress cannot be predicted and many changes and risks from the client or from other process parts may interfere in developing different models or products. The logic of agility offers a flexible approach, followed by a learning from failure.

To offer a better view on traditional approach and the approach proposed by agile methodology, in Table 1 we will examine it in contrast.

Table 1: Traditional approach vs. Agile approach

Traditional approach (Waterfall model)	**Agile approach (Scrum-method)**
Long delivery and development cycles	Sprint method – small delivery and development units
Constant delivery of software solutions	Constant delivery of small and independent software parts
Long-term phases: design, programming, tests	Short-term sprints
Very procedural and fixed flow chart	Flexible workflow
Old and traditional roles: client and contractor	New roles: product owner, business analyst, development team, agile master
The client predefines the targets	Constant interaction and continuous adjustment
The progress is determined related to targets	The progress measuring units must be determined first

Source: adjusted by the authors, based on the research of Hoeren & Pinelli, 2018

Working in sprints helps organizations to better prioritize the tasks in the product backlog. If the deadline agreed for one sprint is not respected, the unfinished developments must be reassessed and reprioritized. Historically, organizations have continuously tried to improve the speed and efficiency of processes and information, as well as for materials used in service delivery chain, in order to face the dynamic business environments (Khoghlahn & Ardabili, 2016); hence, they were unable to achieve constant performance. But the agile approach is dynamic due to the fact that the client is in continuous communication with the development team, which at it's turn is open to changes in areas that can be identified, no matter the moment.

The Relationship Between Organizational Innovation Processes and Agile methodology

The need for agility and innovation is most often encountered in Multinational Enterprises (MNEs), as they operate in different host countries (Shams et al., 2020). The performance is based on the ability of the organization to adapt to all the cultural specificities and to develop associated dynamic capabilities (Junni et al., 2015). One of the crucial factors that are influencing the performance improvement, the functional communication and geographical boundaries is represented by the information technologies (IT). Based on recent research, big data analytics and analogous capabilities improve decision-making processes, and by adding knowledge management skills it leads to the association with performance (Rialti et al., 2019; Ferraris et al., 2019). In his research, Maier, D. (2018) observed that there are multiple types of innovation: innovation of technology flow, of the manufacturing processes and the less need of knowledge. Numerous studies were elaborated on the connexion between information technology capability of an organization and agility. In 2011, Lu and Ramamurthy (2011) confirmed in their research that information technology improves organizational agility, by offering both market capitalizing opportunities and increased operational agility. Later in 2014, Chen et al. (2014) proved in their study that an IT-based capability has a positive impact, due to its flexibility and quickly reactive operations and processes.

Digitalization and Digital Technologies: between opportunity and challenge

Trying to define the terms ‘digitalization’ and ‘digital technologies’ is still a challenge for researchers. Hess (2016) in his article considers that the automation of daily tasks with the aid of information technology describes the meaning of digital transformation. Clearly, nowadays, the digital transformations are visible in multiple sectors: political decision-making, supply chain and the general public daily lives. Social media, IoT, Big Data and Cloud are the main factors of influence in processes, services and business models, by connecting machines, people and things and encouraging new ways of collaboration (Legner et al., 2017). Taking the example of Uber, that leads taxi-drivers to protest over the world or AirBnb, which managed to compete with the hotel industry and transformed almost every home into an accommodation, we observe the platform-based business model and the multi-sided marketplace

business model (Fogoros et. al, 2020). Though, digital transformation represents a global phenomenon with influence on worldwide organization business processes (Grab et al., 2019). Moreover, the usage of IT gradually evolved: if in the past, IT started to be used for automation of internal business processes, nowadays it's more and more present in everyday external products and services: smart houses, smart and electric cars and cloud-connected toys for our children (Legner et al., 2017). The progress made by companies in all these areas, brought on by digital transformation, is also starting to incorporate much-needed sustainability principles as well (Dumitrescu and Buzatu, 2020). For an organization, from the point of view of Legner et al. (2017), there are three key fields of action for digitalization which can be observed in Figure 3.

Fig. 3. Key fields of action for organizations' digitalization

Source: elaborated by the authors, based on the research of Legner et al. (2017)

Based on the research of Marquardt et al. (2018), the main obstacles aligned with the digitalization in business processes are the following: the lack of IT skills of employees, lack of specialists' availability, the legal concerns in terms of security and the difficulties in the conversion of existing IT systems and processes.

Research Contribution

The aim of this study is to propose a research agenda to advance academic discussion on how an agile approach can provide opportunities for an organization, having as main focus the innovation of processes. As the literature review shows, there are some key factors supporting in enabling organizational innovation processes, such as: information technology, the agile approach, monitoring upcoming technologies, adapting the business models, embracing the change introduced by digitization, providing the necessary resources capable to manage technology, etc. Adopting an agile approach having as main goal the digitalization of an organization represents indeed an opportunity for growth. Hence, there are multiple challenges that must be handled by organizations in the current business context.

Current state of innovation in Europe

The European Innovation Scoreboard (EIS) tool used to measure innovation results is developed by the European Commission. This tool provides a comparative analysis of innovation state in EU countries, displaying 2019 data. It is important to specify that in the context of the Covid-19 health crisis and its consequences, the data may not be less relevant for the short-term, current context.

Following the score for 27 separate indicators, such as innovation activities in organizations, investment in research and innovation, human resources and employment elements, there are four categories of performance groups (European Commission, 2020): innovation leaders, strong innovators, moderate innovators and modest innovators (Bulgaria and Romania are below 50% of the EU average). Based on the scoreboard provided by the European Commission (2020), we noted the following countries for any category of performance group:

- modest innovators: Romania and Bulgaria;
- moderate innovators: Croatia, Poland, Latvia, Hungary, Slovakia, Greece, Lithuania, Italy, Malta, Czechia, Slovenia, Spain, Cyprus;
- strong innovators: Portugal, Estonia, France, Ireland, Austria, Germany, Belgium;
- innovation leaders: Luxembourg, Netherlands, Denmark, Finland, Sweden.

Some countries performed exceptionally well on certain individual dimensions: Luxembourg has attractive research systems and researchers are very well connected at international level, Portugal and Finland have high shares of SMEs with innovative products and processes, Austria has a high versatile innovation capability, Sweden invests in human resources and Denmark is known for its innovation-friendly environment.

Challenges introduced by the Agile Innovation

Continuous performance, framework conditions, investments, innovation activities and good ideas are the building blocks for achieving an innovative culture within an organization. However, due to the advancement of technology, organizations must be able to provide a quick response through new projects, developing new products and services, etc., to stay competitive. This is the moment where agility must interfere, by introducing the idea of value added to all processes, by freeing resources and integrating them in the innovation process (Guell, F., retrieved on: https://www.fguell.com/en/agile-innovation/). The fusion between innovation and agility leads to the agile innovation concept, which supposes flexibility, reactivity and responsiveness.

In Table 2 we extracted some of the most encountered challenges faced by organizations with regards to the traditional approach and where the agile approach contributes with new and useful insights.

Table 2: Summary of challenges of traditional and agile approach

No.	Source of research	Researchers' opinion	Authors' opinion
		Challenges of the traditional approach	**Agility Innovation approach**
1.	Bjarnason et al., 2011	Communication issues	Continuous interaction with the customer, the business analyst, the developer and the teams. Recurrent meetings are taking place in order to erase communication gaps.
2.	Bjarnason et al., 2011	Over scoping	There is a list of evolutions sent to the developers which is constantly updated and prioritized depending on the customer's requirements. In this way, repeated allocation in projects is rarely encountered.
3.	Carlson & Matuzic, 2010	Evolutions prioritisation	The client's voice is always listened: the evolutions list is always reprioritised, and less important requirements are put on hold. Before fully developing an evolution, the customers receive blueprints to be tested and validated before passing to the production environment.
4.	Bjarnason et al., 2011	Long procedures and documentation requirements	The agile methodology supposes working with user stories and with product backlogs, which are precise, and which avoid large and useless procedures.
5.	Guell, F., 2020	Financial resources	The contract is negotiated each year, when the cost and potential value of projects is established.

Source: Authors' own research.

In Figure 5 we elaborated the Agile Project Management Methodology framework, often used in organizations for its short development cycles of a product or service.

Fig. 5: Agile Project Management Methodology framework

Source: elaborated by the authors, based on the research of Reddy, S. (2019). Retrieved on: https://medium.com/@sudarhtc/agile-project-management-methodology-manifesto-frameworks-and-process-f4c332ddb779, accessed 24 October 2020

As in every project, there are as well some risks involved while using the agile approach, such as: the scope creep, the timeline issues and the budget issues. If an organization decides to use Agile as methodology, it must pay attention to properly defining the scope from the beginning, with all the features included (requirements specifications, acceptance criteria, actual and future evolutions). Also, based on the number of resources available, the deadlines should be well established, compared to the amount of effort required. Last, but not least, regarding the financial aspects, there are some factors to take into consideration, such as quality and value. Exceeding agreed budgets may show overcharging on the customer's side or overlooking items that should have been specified from the beginning.

Conclusion

The authors of this paper attempted to develop a framework for future studies on the relationship between agile methodology, agile innovation, organizational innovation processes and digitalization.

As the digital transformations are now part of both business processes and everyday life, it is important to adapt to technology-induced changes in order to stay competitive.

Regarding our analysis, we first elaborated a solid literature review on the following concepts: the agile approach, the differences between the traditional and agile approaches, the relationship between organizational innovation processes and agile methodology and finally we analysed the digital technologies in terms of opportunities and challenges.

We also considered crucial to observe the current state of innovation in European countries, based on several indicators. Moreover, analysing the challenges introduced by innovation and agility represents a base for future studies.

There are still many parts in the agile approach usage by organizations to be improved, starting with the financial aspects, the relationship between departments, the culture of organization and so on. Nevertheless, it is the individual who remains the centre of all the automation, standardisation and digitalization of business processes. The companies should first focus on preparing their employees with the aid of a solid knowledge base for the digitalization of their current jobs and after that, offering them the chance to be part of the automation process.

Analysis of Investment Plans Supporting Industry 4.0 Among Small and Medium-Sized Enterprises in Poland

Alina RYDZEWSKA

Silesian University of Technology, Faculty of Organization and Management
Poland, (email: Alina.Rydzewska@polsl.pl)

Abstract

The aim of this study is to analyse investment plans supporting Industry 4.0 among small and medium-sized enterprises in the industrial sector in Poland.
The research carried out allowed to conclude that the majority of enterprises do not have specific plans for investments supporting Industry 4.0. However, in the case of responses that were definite, the largest part was "probably yes". Considering the investment plans of enterprises from the point of view of the size criterion, micro enterprises (turnover up to or equal to EUR 2 million) constitute a group characterised by less definite investment plans. Taking into account the duration of operation (number of years), the statistical analysis did not indicate a group of enterprises that differs from the others. In turn, the results of the analysis concerning the investment plans of enterprises from various provinces are not clear. The initial analysis showed the following provinces: Pomeranian, Podlaskie, Łódź, Greater Poland, of which companies generally declared plans to increase investment outlays. However, the statistical analysis did not show any differences. The PKD (Polish Classification of Business Activities) section, in which most respondents intend to make investments related to Industry 4.0 is the production of finished metal products.

Keywords: Industry 4.0, investment plans, small and medium-sized enterprises, statistical analysis

Introduction

Each era brings new challenges that create opportunities and threats. An entity that wants to develop must adapt to new conditions and then anticipate changes, so that it can act on them in advance. The success of business entities largely depends on innovation and the ability to implement new solutions that respond to new environmental conditions.

The contemporary challenges facing enterprises are changes related to Industry 4.0. After the third industrial revolution, which was associated with the automation of individual processes, the fourth one came. The essence of the fourth revolution is connecting the virtual world with the real one by combining organisation and work systems, as well as creating networks and integrating people with digitally controlled machines, that extensively use the Internet and information technology (Bauernhansl et al., 2014). According to K. Schwab, the scope of this revolution is more extensive than the previous one, and its most important stimulants are: universal and global access to the Internet, significant reduction of data storage costs, device mobility, intelligent sensors, renewable energy sources and artificial intelligence (Schwab, 2016). Hence, the observed changes are not assessed as a revolution, but as a stage of evolution of existing solutions (Alcácer et al., 2016).

In view of the presented conditions of operation, enterprises can take advantage of the opportunities offered by Industry 4.0. The measurable effects of the changes introduced in connection with the fourth revolution are higher revenues and a jump in efficiency (Kiel et al.. 2017, Götz, 2018). It should be noted, that the possibilities of the modern environment are not only limited to large, strong economic entities. Industry 4.0 is also an opportunity for smaller business entities, that are able to flexibly adapt to the needs of their customers. Moreover, conditions of the Polish economy, such as: short logistic paths to Western Europe, membership in the European Union, large internal market and access to production staff, provide opportunities for the development of economic entities operating in it.

In this study, the aim was to verify investment plans for Industry 4.0 among small and medium-sized enterprises in the industrial sector in Poland.

Therefore, the following research questions were formulated:

1) Are small and medium-sized enterprises in Poland planning to increase investments in Industry 4.0 solutions within 5 years?
2) Do the investment plans related to Industry 4.0 differ in the groups of small and medium-sized enterprises, according to their:

a) size,
b) duration of operation,
c) location,
d) PKD sector.
The following research methods were used for the study: histogram and analysis of structure indices, as well as statistical analysis of the significance of differences – Kruskal-Wallis ANOVA tests and post-hoc tests. In order to carry out the presented analyses, this study uses a part of a comprehensive research on Industry 4.0 among small and medium-sized enterprises in the industrial sector in Poland. The research was carried out in the form of a questionnaire and was conducted in the first quarter of 2020

Investments supporting Industry 4.0 and related benefits

An economic entity wishing to develop must make investments. Investments are understood as financial outlays [...] which are to bring benefits in the future (Mayo, 2019). These outlays may be related to the increase and/or reorganisation of tangible, human, financial or intangible resources. Companies that do not invest strategically lose their position in the market. According to P. F. Drücker, "a minimal amount of growth may simply be necessary for survival. And you always need it when the market grows or when the structure of the industry changes [...] if the market grows, you need to grow with it – dropping to the margin means disappearing" (Drücker, 1995).

Enterprises operating in the conditions created by Industry 4.0, therefore, also take actions that should translate into higher economic results in the future (Müller, 2019). These activities cover three main areas: tangible, organisational and procedural, as well as personnel. The tangible (physical) area is related to investments in advanced robots, software, Internet connections, data security systems, data collection and production monitoring equipment, as well as remote production control and communication (*Information and Communications Technology* – ICT). The organisational and process area refers to activities aimed at creating a virtual organisation, cyber-physical solutions, along with decentralisation and personalisation of production, development of the architecture of remote production control processes, along with pre-sale and after-sales activities. However, the personnel area includes activities related to the regrouping of job positions, flexible organisation of work, task systems, training allowing employees to acquire new competences and ways of functioning in the virtual world (Kujawińska et al., 2016).

As a result of the investments carried out, enterprises undergo a thorough digital transformation. They reconstruct individual functions of the internal (vertical) value chain and – with the participation of external partners – the horizontal value chain (Khan, Turkowski, 2016). By taking advantage of the opportunities offered by data analytics and new technologies (including intelligent sensors, communication devices), companies expand their offer by introducing innovative services and products tailored to the needs of customers. Using mobile connectivity for data transmission, they connect devices with each other via the Internet of Things (IoT) (Kagermann, 2013). Thanks to the automation of production and the dissemination of robots, they outsource the implementation of production tasks to machines that are able to run production systems independently, without human participation. They also create new business model solutions to optimise customer relationships and offer comprehensive solutions within the digital ecosystem. The implementation of the presented elements has a different scope and pace. It depends, among others, on the specifics of the industry, the financial resources necessary to carry out investments, the attitude of managers to the challenges of Industry 4.0, access to new employees related to the implementation of projects in connection with the fourth revolution, the attitude of employees to changes in their qualifications.

Research carried out by PWC shows that companies, on a global scale, plan to increase investment outlays related to Industry 4.0 solutions by 2 percentage points within 5 years, which will translate into expenditures of over PLN 100 billion per year. These entities are convinced that, thanks to these activities, they will achieve a jump in efficiency improvement and reduce costs. 27% of the surveyed companies, that are the leaders in changes, expect an increase in revenues and a reduction in operating costs by approximately 30% within 5 years. Among the surveyed enterprises, that have not yet undergone the fourth industrial revolution, such results were expected by 10% of the

respondents. The average drop in operating costs expected by economic operators is 3.6% annually, which varies for individual economic sectors (e.g. the metallurgical industry, as well as transport and logistics forecast a cost reduction of 3.2%, and the paper industry 1%) (Błasiak et al., 2017).

Investing in digital transformation is costly. However, despite the need to incur additional costs, enterprises implementing Industry 4.0 solutions are convinced that the revenues generated will significantly exceed the costs incurred, and the period of return on investment will be quite short. 83% of respondents believe they will get a return on their investment in a maximum of five years. They also point out that the key success factor is not technology, but people who can use it effectively (Veile et al., 2019, Horváth, Szabó, 2019). However, the largest beneficiary of the investments carried out will be the customer who, in the era of digitisation, turns into a digital customer with new, specific requirements for the enterprise (Szwajca, 2019).

Research Methodology

In this elaboration, in order to verify investment plans for Industry 4.0 among small- and medium-sized enterprises, a fragment of a comprehensive study was used. This study was commissioned by the Faculty of Organization and Management, Silesian University of Technology. The contractor was a professional research company. The subject of the study was the issue of Industry 4.0 among small- and medium-sized enterprises in Poland.

The research was conducted among enterprises from the industrial sector, included in section C of the Polish Classification of Activities (PKD), and covered 23 PKD divisions of industrial processing. The choice of production enterprises was based on the fact, that Industry 4.0 solutions are primarily used in production processes (Mariani et al., 2019).

For the research, a questionnaire was used, which concerned enterprises employing from 10 to 249 people, whose annual turnover did not exceed EUR 50 million, or whose balance sheet total did not exceed EUR 43 million. The survey was conducted using an anonymous questionnaire. The link to the questionnaire was sent to the participating enterprises via e-mail. The respondents were top managers, as they have the most extensive information about the enterprise.

The research was carried out from December 2019 to April 2020. The scope covered 900 enterprises, 613 of which responded to the questionnaire. The selection of enterprises for the sample was random. In order to confirm the statistical representativeness of the sample, power analyses were performed. Both the power analysis for the entire group of enterprises (one mean, t-test) and for groups (multiple means, one-way ANOVA) were equal to 1.0 or close to one (0.9986 for groups, based on the duration of functioning).

The survey questions analysed in this study were closed questions, and the Likert scale was used for answers (1 – No, 2 – Probably not, 3 – Hard to say, 4 – Probably yes, 5 – Yes).

The following research methodology was adopted in the study:

1) Are small and medium-sized enterprises in Poland planning to increase investments in Industry 4.0 solutions within 5 years?
In order to answer the presented research question, a histogram with a fitted normal curve was used, as well as the analysis of absolute values and structure indices.

2) Do the investment plans related to Industry 4.0 differ in particular groups of small and medium-sized enterprises?
To verify the presented research question, tests of significance of differences were used, namely the Kruskal-Wallis ANOVA test and post hoc tests. These tests are valid for more than 2 samples for the ordinal dependent variable. It should be noted that the system of survey responses is ordinal (Likert scale).
In order to conduct the tests, we formulated the following statistical hypotheses (null)

$H_{0\ (1)}$ In the group of enterprises, according to the size, there are no differences in the investment plans of enterprises from the SME sector

The division of enterprises into four groups was based on the turnover: the smallest (micro) entities – up to EUR 2 million, small – from EUR 2 million to EUR 10 million, medium – from EUR 10 million to EUR 50 million, and large – over EUR 50 million. This criterion was considered important, because – among the studies conducted so far – the availability of financial resources was mentioned as a limitation to investing in Industry 4.0 solutions (Ates

et al., 2013).Therefore, it can be concluded that the smaller the enterprise, the lower the financial resources, and so the limited investment plans (Rydzewska, 2019).

H0 (2) In the group of enterprises, according to the length of operation, there are no differences in the investment plans of enterprises from the SME sector

According to the criterion of the length of operation of the enterprise, five groups of enterprises were distinguished: the youngest entities operating up to 5 years (formation), (early) growth from 6 to 10 years, late growth from 11 to 15 years, mature 16-20 years and stabilised – over 20 years (Dodge and Robbins, 1992). From the theoretical point of view, investment activities are most often undertaken by enterprises in the period of (early and late) growth phases. These entities, after the first years of activities related to staying on the market, focus on rapid growth and development. As part of early maturity, they focus on systematic development, while in the late growth phase – on permanent changes related to the expansion of their resource potential.

H0 (3) In the group of enterprises, according to the location (province), there are no differences in the investment plans of enterprises from the SME sector

The criterion of location, i.e. the province, in which the enterprise operates, was considered important. Provinces in Poland are characterised by a different degree of industrialisation. There is a division into regions of western Poland, where the degree of industrialisation (calculated as Manufacturing Value Added per capita) is high; regions: Lower Silesia, Greater Poland, Silesian, Lubusz (over EUR 2,500 million per capita, as the national average); Central Poland regions: Pomeranian, Łódź, Masovian, Opole, Kuyavian-Pomeranian (at the level of the national average of about EUR 2,500 million per capita), and eastern regions: Subcarpathian, Lesser Poland, Warmian-Masurian, Holy Cross, Podlaskie, Lublin – with the exception of West Pomeranian (less than EUR 2,500 million per capita) (Bukowski, M. et al., 2017). Therefore, it can be concluded that, in western regions, the surveyed enterprises will be more willing to invest in Industry 4.0 than in other regions, especially eastern Poland.

H0 (4) In the group of enterprises, according to the sector (PKD division, section C) there are no differences in the investment plans of enterprises from the SME sector

The last criterion was the sector, namely the PKD division of section C, Industrial processing. Within this classification, 23 activities have been distinguished. The theoretical basis and the research carried out allow to conclude that the scope and type of investments related to Industry 4.0 is determined by the specificity of the activity, including technology. Therefore, it is possible to distinguish sectors that will show wider investment plans, e.g. the electronics industry (according to PWC research, companies in the sector in question plan to invest at the level of 7% of total expenditure) and at a lower level (according to PWC, companies from the paper and metallurgical sectors will invest the least) (Błasiak et al., 2017).

Findings

Considering the results of the research conducted among all enterprises, when asked about plans to increase investments related to Industry 4.0 within the next 5 years, the presented histogram (Figure 1) shows that the largest part of respondents (31%) answered “Hard to say” (number 3 on the Likert scale). Also, the analysis of the fitted normal distribution indicates that most responses fell within the range of answer number 3. However, the second group of responses, in terms of numbers, is answer number 4 in the Likert scale. “Probably yes” was indicated by 27% of the surveyed enterprises. Definite “Yes” and “No” answers were given by comparable size groups, which constituted 16% of the respondents. The smallest group of enterprises (11%) indicated the answer 2 – “Probably not”

Fig. 1: Histogram with numbers and structure of responses based on the Likert scale

To sum up, the largest part of the surveyed enterprises, when asked about their plans to increase investments in Industry 4.0 solutions in the next 5 years, answered "Hard to say". However, among companies with specific investment plans, they were mostly positive ("Probably yes").

Initially considering the investment plans for Industry 4.0 among enterprises of various sizes (measured by the turnover), on the basis of the box and whisker plot analysis (Figure 2), it can be noticed, that the enterprise group that differs from the others is the group of micro enterprises (with a turnover lower or equal to EUR 2 million). The median of responses for these companies is number 3 ("Hard to say"), while the median of responses by enterprises of other sizes is number 4 ("Probably yes").

Fig. 2: A box and whisker plot concerning investment plans in Industry 4.0 solutions for groups according to the size (annual turnover)

The presented initial conclusions were statistically confirmed. The performed test concerning the significance of differences – the Kruskal-Wallis test ($p = 0$) indicated, with the adopted significance level ($\alpha = 0.05$), the rejection of the verified null hypothesis (Appendix 1). This means that there is at least one group among enterprises, which differs from others according to their size. In turn, further post-hoc tests (Appendix 2) show that significant differences exist between the group of micro-enterprises (with a turnover of less than EUR 2 million) and small (with a turnover of EUR 2 to 10 million) and medium (with a turnover of EUR 10 to 50 million) enterprise groups.

These results are consistent with the theoretical assumptions that smaller enterprises have lower resource potential and, therefore, their investment plans may be limited (Sommer, 2015). Hence, micro-companies, with a turnover of up to or equal to EUR 2 million, mainly indicated responses in which they were not determined whether they want to increase expenditure on investments in Industry 4.0.

Initially analysing the responses of enterprises from the SME sector regarding investment plans supporting Industry 4.0, on the basis of box and whisker plot (Figure 3), the group is not visible according to the length of its operation, which differs from the others. The median response of all groups (operating: 0 to 5 years, 5 to 10 years, 11 to 15 years, 15 to 20 years and over 20 years) is the same, and it is number 3 on the Likert scale, namely "Hard to say".

The initial conclusions are confirmed by the statistical analysis of the significance of the differences. The results of the Kruskal-Wallis test ($p = 0.2961$), with the adopted significance level ($\alpha = 0.05$), indicate no grounds for rejecting the verified null hypothesis (Appendix 3). This means that, within the studied groups of enterprises, there is not a single statistically different group.

Fig. 3: A box and whisker plot concerning investment plans in Industry 4.0 solutions for groups according to the length of operation (number of years)

Thus, the statistical research is not in line with the theoretical assumptions. Theoretical considerations suggest that enterprises in the early and late growth phase (operating from 6 to 10 years and from 11 to 15 years) are most willing to undertake investment activities. However, this is not confirmed by Polish enterprises in relation to investments in Industry 4.0.

Fig. 4: A box and whisker plot concerning investment plans in Industry 4.0 solutions for groups according to location (province)

However, when conducting statistical research, the results of the Kruskal-Wallis test ($p = 0.1619$) with the adopted significance level ($\alpha = 0.05$) indicate that there are no grounds for rejecting the verified null hypothesis (Appendix 4). Therefore, within the groups of enterprises from individual provinces, there is not a single statistically different group.

The presented research contradicts theoretical considerations, which indicated that, in the regions of western Poland (with a higher degree of industrialisation), they would be willing to invest to a greater degree than enterprises from eastern Poland (with a lower degree of industrialisation). The results of the analysis of differences indicate no statistically significant differences between the investment plans related to Industry of 4.0 enterprises from individual provinces. However, the box and whisker plot analysis shows that there are groups of enterprises whose median response is 4 ("Probably yes"). They showed a higher tendency to invest in Industry 4.0. However, these are companies from the provinces of central Poland and the Podlaskie province (eastern Poland). However, enterprises from western Poland (West Pomerania province) indicated responses between "Hard to say" and "Probably not".

Empirical research may, therefore, lead to initial conclusions that the solutions of Industry 4.0 and, therefore, also investments, are not related to the level of industrialisation of the environment. Industry 4.0 relies on the extensive use of the Internet and information technology, which is independent of location.

Fig. 5. A box and whisker plot for investment plans in Industry 4.0 solutions for groups according to the sector (section C, Industrial processing)

On the other hand, initially considering the responses to investment plans supporting Industry 4.0 among enterprises of particular PKD divisions (under section C, Industrial processing), on the basis of the box and whisker plot analysis (Figure 5), it can be noticed that groups of enterprises differ from the others. Median responses of 4 on the Likert scale ("Probably yes") occur in the case of divisions 27 (manufacture of electrical equipment), division 25 (manufacture of finished metal products – excluding machinery and equipment), division 28 (manufacture of machinery and equipment), division 24 (manufacture of metal), division 23 (manufacture from other non-metallic mineral products), division 29 (manufacture of motor vehicles). However, divisions 13 (manufacture of textiles) and 15 (manufacture of leather and related products) have a median response of 2 ("Probably not"). The remaining divisions have a median response of 3 ("Hard to say").

However, the statistical analysis of the significance of the differences – the Kruskal-Wallis test ($p = 0.003$), with the adopted significance level ($\alpha = 0.05$), indicates the rejection of the verified null hypothesis (Appendix 6). This means that there is at least one sector that differs statistically from the others, due to the responses to investment plans in Industry 4.0 solutions. Post-hoc analysis (Appendix 7) gives grounds for the conclusion that the statistically significant sector is division 25 (manufacture of finished metal products – excluding machinery and equipment) with respect to divisions 32 (other manufacturing) and 33 (repair, maintenance and installation of machinery and equipment). The other sectors do not show statistically significant differences.

The presented research is consistent with the theoretical assumptions that the sectors may differ in their investment plans supporting Industry 4.0. On the basis of the initial box and whisker plot analysis, divisions characterised by a higher investment initiative were distinguished (mainly these are: production of electrical appliances, machinery and equipment, metal products, motor vehicles). However, statistical analysis indicated sector 25 (production of finished metal products – excluding machinery and equipment) that differed statistically in terms of responses to investments in Industry 4.0 solutions.

Summary

In this study, the aim was to verify investment plans for Industry 4.0 among small and medium-sized enterprises in the industrial sector in Poland. Therefore:

1) the structure of responses regarding investment plans of enterprises in general was analysed,
2) an analysis of differences was performed, in order to identify groups of enterprises differing in investment plans according to their: size, length of operation, location and PKD sector.

The conducted research and their analysis allowed to identify initial investment plans under Industry 4.0 within the next 5 years among small and medium-sized enterprises operating in Poland. And so, the greatest number of respondents indicated the answer "Hard to say" (number 3 on the Likert scale). However, in the case of responses that were definite, the largest part was answer number 4 on the Likert scale ("Probably yes").
Considering the results of the responses of enterprises of various sizes, the statistical analysis indicated micro enterprises (turnover up to EUR 2 million) as a group of enterprises characterised by less definite plans to invest in Industry 4.0 solutions. These results are consistent with the theoretical considerations that the smaller enterprises, due to the lower financial resources, are characterised by more limited investment plans.

When analysing the results of research on enterprises according to the length of their operation, the statistical research did not indicate a group of enterprises that differed from the others. These results are not in line with the theoretical assumptions, according to which companies in the period of (early and late) growth invest the most. A possible explanation of these results is that these companies have already made investment steps towards solutions to the fourth revolution and their plans for the next 5 years are not comparable to those of the other groups.

Considering the results of research on enterprise investment plans related to Industry 4.0 according to location, they are not conclusive. The results of the test of significance of difference indicate no statistically significant differences between the plans of enterprises from individual provinces. However, the box and whisker plot analysis shows that there are groups of enterprises with a higher tendency to invest in Industry 4.0. However, these are mainly companies from the provinces of central Poland. Thus, the investment plans of the small and medium-sized sector in Poland do not correspond to the level of industrialisation of the regions, which may be associated with the fact that some solutions of the fourth revolution (such as computerisation and digitisation) are independent of location. Therefore, they may constitute an opportunity for the development of companies from less industrialised provinces.

The last criterion used to study investment plans of enterprises related to Industry 4.0 within groups is the type of activity (PKD division under section C, Industrial processing). The results of statistical surveys indicated the following sectors: production of finished metal products, production of electrical appliances, machinery and equipment, metal products, motor vehicles, which enterprises generally declared to increase their investment outlays within 5 years. However, the PKD divisions, within which enterprises did not generally declare their willingness to invest in Industry 4.0, were: manufacture of textiles and manufacture of leather and related products. Thus, enterprises operating within individual economic divisions and sectors show investment plans at various levels. Development intentions related to the fourth revolution are determined by the specificity of the activity.

The presented studies need to be continued. Their further conduct should take into account the verification of individual investment intentions under Industry 4.0 and the benefits associated with them in terms of economic results (increase in revenues, reduction of costs, increase in efficiency).

Appendix 8: Divisions of sector C, Industrial processing

Division 10 – Manufacture of Food Products
Division 11 – Manufacture of Beverages
Division 12 – Manufacture of Tobacco Products
Division 13 – Manufacture of Textiles
Division 14 – Manufacture of Clothing
Division 15 – Manufacture of Leather and Related Products
Division 16 – Manufacture of Wood and Products of Wood and Cork, Except Furniture; Manufacture of Articles of Straw and Plaiting Materials
Division 17 – Manufacture of Paper and Paper Products
Division 18 – Printing and Reproduction of Recorded Media
Division 19 – Manufacture and Processing of Coke and Refined Petroleum Products
Division 20 – Manufacture of Chemicals and Chemical Products
Division 21 – Manufacture of Basic Pharmaceutical Products and Medicines, as well as Pharmaceutical Preparations
Division 22 – Manufacture of Rubber and Plastic Products
Division 23 – Manufacture of Other Non-metallic Mineral Products
Division 24 – Manufacture of Metals
Division 25 – Manufacture of Fabricated Metal Products, Except Machinery and Equipment
Division 26 – Manufacture of Computer, Electronic and Optical Products
Division 27 – Manufacture of Electrical Equipment
Division 28 – Manufacture of Machinery and Equipment, n.e.c.
Division 29 – Manufacture of Motor Vehicles, Trailers and Semi-Trailers, Except Motorcycles
Division 30 – Manufacture of Other Transport Equipment
Division 31 – Manufacture of Furniture
Division 32 – Other Manufacturing
Division 33 – Repair, Maintenance and Installation of Machinery and Equipment

Cybersecurity of Children and Youth in Poland

Piotr ŁADNY

University of Szczecin, Szczecin, Poland
piotr.ladny@usz.edu.pl

Abstract

The development of the Internet and modern technologies irreversibly changes the modern world and affects the functioning of almost all spheres of life. Cyberspace is becoming a natural environment for functioning for many people, especially for representatives of the young generation. The growing activity in the use of information and communication technologies, however, creates a number of new threats to which children and young people are particularly exposed.

The purpose of the article is to attempt to define the most important dangers associated with the use of the Internet by minors and to critically analyse solutions and proposals aimed at raising the level of cybersecurity in Poland by limiting access to pornographic material.

Based on the collected data on threats related to the access of minors to dangerous content, in particular pornographic materials and actions taken to limit their accessibility, the basic elements on which the IT security model of children and adolescents should be based have been indicated.

The research method adopted by the author is secondary research, based on analysis of the literature, research results and legal regulations regarding cybersecurity.

Keywords: cybersecurity, children, Internet, Poland

Introduction

Growing range, popularity and possibilities caused that the Internet revolutionized not only ways of communication but had a huge impact on almost all aspects of functioning of the modern world. By creating new opportunities and influencing the acceleration of innovative processes, the Internet becomes a catalyst for positive social and economic changes, which increases the quality of life. However, it is also an environment in which various unfavourable or dangerous phenomena appear and develop.

The growing number of incidents and new threats that appear in the digital space from year to year, with the simultaneous increase in social and economic costs associated with the liquidation of their effects, make the problem of cybersecurity a challenge for companies, institutions, individual users of the Internet and for state authorities and international organizations. The result is more and more intense activities including developing modern hardware and programming solutions in the area of IT security, creating recommendations and guidelines for companies and organizations, developing new strategies and legal regulations, establishing agencies at national and international level responsible for the protection of electronic communications networks as well as creating educational programmes aimed at preventing, effective response and reduction of the effects of attacks and incidents in cyberspace.

Creating conditions for safe and hygienic use of the network and its resources by minors is becoming particularly important area related to cyber security. Children and adolescents are very active and engaged users of information and communication technologies, but due to the lack of knowledge, experience and assertiveness, and the natural curiosity of the world, they do not have sufficient defines mechanisms, which is why they are much more exposed to the risks associated with the use of adults than adults' networks, its resources and capabilities and thus require special protection.

Internet activity of Polish children and youth in the light of research

Research on the use of digital technologies by children and young people in Poland indicates that, like in other countries, the Internet is for the young generation a natural growth environment and a place for the implementation

Cite this Article as: Piotr ŁADNY" Cybersecurity of Children and Youth in Poland" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of a growing number of activities, and a smartphone, tablet, smartwatch or computer connected to the network are everyday tools.

The „Nastolatki wobec Internetu 3.0" [Teenagers towards the Internet 3.0] report, prepared by NASK in 2017, shows that almost all young people use the Internet and the percentage of people declaring that they do not use the network is only 0.7% (Kamieniecki, Bochenek, Tanaś, Wrońska, Lange , Fila, Loba, Konopczyński, 2017, p. 7). Young people most often use the Internet at home (80%), at school (39.2%), at friends (32.4%) or in public places where Wi-Fi is available (29.7%) while indicating that they treat and perceive modern communication technologies as an integral part of their home, school and community everyday life.

Research conducted by the CBOS Public Opinion Research Centre (Skierka, 2018, pp. 1-3) shows that 87% of young people between 6 and 19 years old use Internet resources, and in the last fifteen years this percentage has increased by as much as 29%. From the declarations of guardians, it can be concluded that the majority of children and young people using the Internet are in the 13-15 age group (94%), slightly less (91%) - in the age group from 16 to 19 years old, and the youngest group from 6 up to 12 years old, they constitute 86%, which means that also primary school students from primary schools eagerly use the network.

Research indicates that as internet is becoming more widespread, the age of internet initiation is decreasing, and internet use is increasing. The data collected by NASK shows that the average age of internet initiation among teenagers in 2017 was 9 years and 7 months (median = 10 years), while the data presented in the next edition of the report (Bochenek, Lange, 2019, p. 6) indicate that teens use the net on their own from the age of seven. It is emphasized that the younger the generation, the earlier the contact with digital technologies.
Analysing the changes taking place in many researchers (Orange Polska, 2016; Eurostat Statistics Explained, 2017; Lange, Bochenek, Wrońska, 2018), it is believed that during the last few years the age has shifted when children start their adventure with the network from an average age of 9-10 to 6-7, and less.

Using the web has become a natural element of behaviour for teenagers. Thanks to mobile technology, young people have permanent access to the Internet, which affects, among others, an increase in the average number of hours spent online. From 2017 (i.e. for 2 years), this value has increased by as much as 32 minutes and is now 4 hours and 12 minutes. Compared to research conducted in 2010, the time spent every day on the Internet increased by as much as 30% (EU Kids Online 2020, p. 22).

The research results confirm that the Internet has permanently entered the everyday life of Polish teenagers. Nearly 96% of respondents declared using the network every day. Occasional use of the Internet ("several times a week" or "several times a month") was declared by less than 4% of respondents. Almost every teenager in Poland is online every day, regardless of age, type of school or gender.

Along with the increase in the use of IT technologies, however, the risk of children and young people being exposed to various threats related directly or indirectly to the use of the Internet and digital services increases.

Characteristics of cyber threats to children and teenagers

Cybersecurity is a heterogeneous, complex area covering many aspects (including technical, legal, organizational, social, psychological), and due to the evolution of existing threats and the emergence of new, quite difficult to be characterized and systematized. This also applies to threats and methods of protecting children and teenagers using information and communication technologies. The threats among minors that may be found in cyberspace (Aftab, 2003, p. 84), e.g.

- Access to information that is inappropriate for them (pornography, hatred, intolerance, bigotry, violence, fraud, gambling, false information, manipulated or exaggerated information);
- Access to dangerous information (instructions on how to obtain and use services and dangerous goods - chemical and explosive materials, poisons, drugs and weapons);
- The possibility of child grooming or disturbance by other network users, including minors (vulgar or offensive comments, threats, blackmail, distribution of malware or hacking into network devices and services);
- The possibility of phishing private information (via phishing, forms, competitions) by traders using unfair marketing techniques;
- The risk of fraud and disclosure of confidential financial information (payment card numbers, passwords, pins), such as credit card numbers, pin numbers and passwords) during online purchases;
- The risk of contact with cyber-attackers and, consequently, meetings in the real world.

The issue of threats resulting from uncontrolled use of the Internet can also be referred to the basic spheres of human functioning by indicating (Biała, 2006, p. 105), among others:

- Physical hazards: eyes strain, stain fatigue, which stays in the same, bad for the body position for a long time, headache, wrist pain, fatigue;
- Psychological threats, consisting of addiction to the network to such an extent that a young person gains confidence and security only in front of a computer, and in relation to relatives gains a growing stranger and distance;
- Moral threats: they result from using these sites, which are an incentive for early sexual intercourse, performing sex, and easy access to pornography;
- Social threats: anonymity can be a source of using profanity and the use of psychological techniques that threaten proper social communication;
- Intellectual threats: a lack of distance to the propagated content reduces criticism and creative thinking in a child who recognizes that information obtained from the Internet as true.

One of the most common hazard classifications in the literature on the subject in relation to children and teenagers is the division into 3 basic groups, whose sources are:

- Exposure to content present and available on the Internet, and inappropriate to the child's level of development (emotional, social, intellectual) and to the system of values adopted in a given culture;
- Behaviours of other Internet users, e.g. hate, grooming, phishing, malicious software;
- Internet user's own behaviour, e.g. publishing his or her data and photos, contacts with people he or she met on the Internet, internet abuse, downloading and sharing copyrighted content, gambling.

Although the typology presented is one of the most frequently indicated and used in scientific research (Pyżalski, 2012; Włodarczyk, 2013), it seems that it does not cover threats that have appeared in recent years, which result from technological development and the dissemination of technology cloud computing, the use of algorithms that use machine learning and artificial intelligence, the Internet of things, and wearables.

The examples of recent years indicate that online threats to which children and young people are exposed may have their source in factors other than those listed in the above classification and relate not only to content, contacts and behaviour but also to the technologies themselves used by children or their guardians. Although it is assumed that information technologies should be treated as neutral and they do not pose a threat by themselves, errors or neglect of equipment manufacturers or developers creating programs and applications may, in practice, cause that certain solutions or products using information technologies may be dangerous for users . One of such areas are solutions related to the collection and processing of large data sets, which in the absence of appropriate rules for acquisition and analysis or in the event of leaks may violate the privacy of the data subjects. An example could be interactive toys designed for the youngest (e.g. Cayla Doll or i-Que robot) that were highlighted in the 2017 Joint Research Centre (JRC) developed and published by the European Commission on the order of the European Commission on online toys (Chaudron et al., 2017, pp. 8-9). The report emphasized that toys connected to the Internet, having built-in microphones and speakers, and using speech recognition technology and learning algorithms for interactive communication "give the child new and important opportunities for play and learning and provide him or her with educational support, but at the same time carry a risk to children's safety, may violate their right to privacy and a sense of trust (...) ".

Webcams used for remote supervision of small children (electronic nannies) have become another example of the risks associated with the growing popularity of IOTs. Due to security holes in the software of these devices or as a result of users leaving default passwords, such devices may allow unauthorized persons to access photos and video recordings as well as personal data of users. Information about such events has appeared in the media many times and in relation to various manufacturers (Sekurak 2018). A similar risk is associated with the use of network devices (routers, access points), which due to software vulnerabilities, lack of support from manufacturers or failure to install updates by users may be a weak point in the security of the home network and all connected devices (computers, televisions, game consoles, monitoring cameras, digital assistants).

An area of potential threats is also the increase in popularity of wearable electronics (wearables) in the form of smartwatches, sports bands or locators used for remote supervision of children. As in the case of IOT, these devices often do not have adequate security mechanisms, which means that their users are exposed to the acquisition of confidential data on activity, location or even remote eavesdropping. In 2019, it was revealed that one of the manufacturers of smartwatches intended for children did not implement sufficient security on servers collecting data from watches, which made it possible to obtain remote access to virtually any user account (over 5,000) and location information, related telephone number with watch, photos, call recordings. The published information (Morgenstern, 2019) showed that a large number of devices to which remote access was possible was in Poland.

The examples cited above cannot be attributed to any of the three groups mentioned earlier, and with the development of new technologies, it can be expected that the risks associated with the lack of adequate security or the negligence of manufacturers will be a growing cybersecurity problem. For this reason, it seems reasonable to indicate the 4th area that can be defined as a technological environment related to the security of service and application equipment.

The appearance of the phenomenon of sharenting on the network, which determines the behaviour of parents or guardians consisting in displaying the image of children and reporting their lives on the Internet, mainly in social media, has created a new area of digital threats. The word sharenting arose from the combination of two English words: share and parenting. To emphasize the different degree of potential harmfulness of such activities, sharenting differs from oversharenting, which means extreme activity of parents in this area, and troll parenting, which means sharing content that compromises children or shows difficult moments for them. Research conducted in 2010 by AVG Technologies covering 2,200 mothers of children under 2 years of age from the USA, selected EU countries, Australia, New Zealand and Japan showed that 81% of children under 2 years of age have a digital profile or trace in the form of a photo left on the Internet by their parents (in the US this percentage was the highest, i.e. 92%, and the average for EU countries participating in the survey is 73%). Research conducted among Polish parents of children aged 0-18 (Nogała, 2019) shows that up to 3 million Polish children already have their photos online, and the percentage of parents who publish them is about 40%. Posting photos, videos, embarrassing information or location data cannot only expose your child to jeering and ridicule but also create potentially dangerous situations related to the use of photos by paedophile-prone people and expose them to the risk of unwanted contacts in the real world (e.g. at school or place of residence). Dangerous behaviour of parents towards children may result from low digital competences and the related lack of awareness of potential threats, but may also be undertaken for commercial purposes, and may be based on the desire to monetize the image of the child or family.

Although it should be assumed that the intention of the vast majority of parents is not to expose children to any risk, such behaviours can be described as the next, fifth group of threats, defining it as the activity of parents and guardians towards children.

Quantitative research conducted on representative samples shows, among the various threats that young people may encounter on the Internet, that one of the most common is contact with dangerous content. According to the results of the latest edition of the EU Kids Online study (Pyżalski, Zdrodowska, Tomczyk, 2019, p. 82), only 28% of Polish 9-17-year-olds declared that they had no contact with dangerous content. As many as 43% had to deal with violent images, and 37% with content showing how to commit suicide. Every third Polish teenager encountered hate speech during the year preceding the test. In turn, the research carried out by Dajemy Dzieciom Siłę foundation shows that on average 43% of children aged 11-17 have contact with pornography on the Internet (Makaruk, Włodarczyk, Michalski, 2017, p. 10).

Pornographic materials are easily and widely available on the Internet and the lack of any warnings causes that contact with such materials may occur not only as a result of intentional action but also unintentionally, as a result of clicking on a random advertisement or a link sent in email spam.

Research on the impact of viewing pornographic material by children and teenagers indicates a number of negative effects that pornography may have on emotional, personality and social development. It is noted (Behun, Owens, 2019) that pornographic content can shape unrealistic expectations of sex life and false relationship patterns, and viewing them can be a source of complexes regarding appearance or physical characteristics. The relationship between compulsive viewing of pornography and the occurrence of mental problems and less satisfaction with life is also emphasized, and that girls who have contact with the sexualizing material presented in the media are more likely to experience depression.

In the light of the data indicating the growing scale of threats to which children and young people using the Internet are exposed, the need to introduce systemic solutions aimed at increasing the level of cybersecurity of children and young people is increasingly pointed out.

One of the more frequently indicated problems that should be solved is the elimination or limitation of children and young people's access to dangerous content, including pornographic material.

The possibilities to limit access to pornographic content

Although the discussion about the possibility of restricting access to pornography has been conducted for a long time, in practice in no country, except for those where the Internet is subject to strict state control (e.g. China or Turkey), it has not been possible to introduce effective mechanisms to protect children and young people against such content.

The first and only European country where work began to solve this problem was Great Britain, where in 2013 actions were taken to limit the availability of pornography on the Internet. The introduced solutions were initially based on self-regulatory activities under which the largest Internet providers serving a total of about 90% of customers used filters blocking access to websites classified as containing pornographic content, gambling or extremist materials. Unfortunately, the implemented solutions have not only blocked pages containing undesirable content but also many others that have been incorrectly classified (e.g. pages about sex education and even politicians' websites). As a result of the reported problems, Internet providers have introduced the option to opt out of blocking assuming that filters will be applied to all people who do not want to opt out. After two years, the British office controlling and supervising the media and telecommunications market (Ofcom) conducted research, which showed that only a few to a dozen or so percent of customers use filters imposed on the Internet supplied by means of wired technologies. Due to the low effectiveness of the actions taken, an agreement was concluded under which the same self-regulation mechanisms were used by cellular operators. The actions taken did not, however, lead to the solution of the problem because, as it turned out, the effectiveness of the filters used was not 100% (additionally other sites were blocked than assumed) and the mechanism itself proved to be easy to be circumvented.

Because self-regulation and blockades used by network providers proved to be ineffective, work began in 2016 to introduce a legal requirement to verify the age of Internet users who want to access pornographic content. Adopted in 2017, the Digital Economy Act, 2017 contained provisions that obliged adult content providers to verify the age of users to confirm their age of majority. The Act did not specify the mechanisms on which this verification was to be based, indicating only that they were to be effective. A regulator, which was the organization dealing with the awarding of age marks to films distributed in Great Britain (British Board of Film Classification), was appointed to verify the effectiveness of these mechanisms. The Act also introduced financial penalties imposed on content providers who, when directing messages in the territory of Great Britain, will not use age verification tools and the option of blocking access to a website whose provider will not comply with the introduced provisions, and also gave the regulator the opportunity to apply to payment organizations (Visa , MasterCard, PayPal) with a request to block payments for access to sites that distribute pornographic content without using age verification tools. The initially adopted provisions had to come into effect in 2018, however, concerns about the security and confidentiality of data collected for the needs of the age verification system and votes indicating the possibility of violations of the privacy of persons using such a system caused that after further postponements, in October 2019 it was announced that age verification provisions will not be introduced.

Due to the importance of the problem of strengthening the protection of minors against access to pornographic content on the Internet, the European Union has decided to take legal action. As a result, on November 14, 2018, the European Parliament adopted a new directive (2018/1808), amending the so-called the Audiovisual Media Services Directive, which as one of the assumptions adopted the extension of the protection of minors against harmful content. The European Commission has obliged Member States to ensure that, under their responsibility, providers of video-sharing platforms apply - preferably through co-regulation - appropriate measures to protect minors from harmful content.

The directive states that "Member States shall take appropriate measures to ensure that audiovisual media services provided by media service providers under their jurisdiction, which may harm the physical, mental or moral development of minors, are only made available in such a way as to that underage circumstances may not be listened to or viewed by minors. These measures may include selection of broadcasting hours, age verification tools or other technical solutions." At the same time, it was pointed out that the most harmful content, such as unreasonable violence and pornography, should be subjected to the strictest remedies.

In the context of the introduced regulations, it should be noted that the regulations do not specify definitely what measures are to be applied by the member states in order to limit access to harmful content. Although an age verification mechanism was indicated, unspecified "other technical solutions" were also allowed. In addition, the regulations apply only to entities that are based in one of the member states. Poland - like other EU member states - is required to implement the directive in its legal order by 19 September 2020.

It seems that reports indicating the growing problem of the availability of pornography on the Internet, and the legislative initiative of the European Commission may have inspired the authors of the Polish draft regulation restricting access to pornographic content (STS, 2019), which was presented in December 2019 by Twoja Sprawa association.

As indicated in Article 1 of the draft, its purpose is to define the obligations of "entities providing qualified pornographic content on the Internet and other entities providing electronic services, entities providing payment services and telecommunication undertakings, in order to protect minors against access to such content."

According to the presented proposal, the basic mechanism used to protect minors is to be age verification - "The entity providing qualified pornographic content is required to use effective tools to verify the age of the recipient in order to prevent minors from accessing such content." The National Broadcasting Council is to be responsible for implementing the provisions of the Act, which, together with the co-regulator appointed (it is assumed that this body will operate as a foundation), will monitor compliance with the obligation to verify age and block access to websites offering pornographic content.

The project also envisages the creation of a register of Internet domains and accounts through which pornographic materials are distributed without the use of effective age verification tools. Information about the providers of content entered in the register is to be provided to telecommunications operators and payment service providers in order to block access to their websites and block any payments for access to content covered by the Act.

Despite the lack of detailed information on what the most important element of the proposed regulations should look like in practice, i.e. the age verification mechanism, and thus its effectiveness, the level of security of collected data and the cost of implementation, the Ministry of Family, Labour and Social Policy together with the Prime Minister of the Polish government announced that the presented draft will become the basis for legislative works, which are to begin in the first half of 2020.

It should be emphasized that, apart from the doubts indicated above regarding the mechanism of age verification that would be used, the project included other questionable entries, such as the statement that "Tools to verify the age of the recipient are considered effective, even if it is possible to circumvent them by minors, if this requires the use of extraordinary measures and actions by such minors that cannot be expected from the average recipient."- which provokes the question whether installing a browser plug-in or an alternative browser using block bypass mechanisms can be considered extraordinary measures and actions? Another questionable provision of the project is to regulate only some of the entities (those for which sharing pornographic content is part of the basic sphere of activity) excluding those services and services on which pornographic materials are e.g. exchanged between users (Instagram, TikTok, Twitter or Reddit) or shared among other harmless content (e.g. Google or Youtube), however, also easily accessible.

Another doubt raises the statutory provisions not only of providers of pornographic content but also of all providers of telecommunications and payment services. The regulations also apply to content providers operating outside of Poland. It is hard to imagine a willingness to cooperate with such suppliers and voluntarily adapting to Polish regulations, when, for example, one of the largest pornographic content providers, Pornhub announced the creation of its website in the anonymous TOR network, which enables, among others, bypassing locks and guaranteeing access from any network. The difficulty in forcing creators of adult websites is also indicated by the fact that, despite the provisions of the Penal Code (Article 202 § 1) in Poland, which penalizes the public presentation of pornographic content, or adopted in June 2014 on the basis of self-regulation by Employers The Internet Industry "Code of Good Practice on the Detailed Rules for the Protection of Minors in Audiovisual Media Services on Demand" (IAB, 2014), none of the pornographic services located on Polish servers or registered by a Polish company or organization has used effective safeguards verifying the age of users (KRRiT , 2015).

The project also lacks information indicating what mechanism should be used to block those sites whose owners do not meet the obligations imposed on them. This means that, as in the case of age verification, it is impossible to assess what costs will be necessary to create it, and because the blockades are to be implemented by telecommunications operators, what costs will be borne by these entities. The authors do not indicate exactly how to block websites that will be entered in the domain register, but the record indicating "removal from telecommunication systems of telecommunications entrepreneurs, used to change domain names to IP addresses" suggests one of the simplest solutions involving the use of operators' DNS servers. However, this solution is very easy to be bypassed, because it only requires changing the operator's DNS server address to a non-operator address in the device configuration (computer, smartphone).

In the light of British experience, the biggest weaknesses and obstacles to successful implementation are the above-mentioned doubts regarding the age verification mechanism that would guarantee that access to pornographic content is obtained only for adults.

An important problem that has not yet been solved anywhere is the creation of such an age verification system that will be reliable and at the same time ensure anonymity and privacy for the verified persons. This condition is not met by systems used in some countries based on payment cards or using e.g. electronic identities because they combine information about the use of websites offering specific pornographic content with a specific person. It should be noted that there is a serious contradiction here because, on the one hand, such a system cannot be anonymous as confirmation of age must occur for a specific person and, on the other hand, it cannot combine information about a specific person

with information about which services it uses because it could lead to the disclosure of information, e.g. unusual sexual preferences of such a person.

The statements of the representatives of the Ministry of Digitization (Słomski, 2020) appearing in the media, which is involved in the work on the project, show that one of the ways can be cooperation with the creators of browsers and embedding mechanisms of age verification and blocking access for those who will not be positively verified. However, such an idea seems completely unreal considering the number of web browsers available on the market (there are over 200 in the Google Play store only), the fact that none of the largest browsers is being developed in Poland.

Obstacles to the implementation of the proposed solutions, particularly with regard to blocking certain content and websites, are the doubts raised as to the legality of such solutions under European law. It is pointed out that imposing a legal general obligation to filter and block pornographic content on telecommunications providers could be considered incompatible with Article 15 of the Electronic Commerce Directive (Directive 2000/31/EC). The Court of Justice of the European Union also stated this in its judgment of November 24, 2011 in case C-70/10 Scarlet v SABAM11. The Court has ruled that EU law does not allow an internet provider to be ordered to implement a system to filter all electronic connections transmitted through its services, applicable to all its customers, at its sole expense and without a time limit.

The above reservations indicate that the bill prepared by Twoja Sprawa Association and approved by the government administration indicates a real problem, however, its general nature, lack of relevant information, lack of market realism, records indicating ignorance of technical problems and even doubts as to compliance with EU regulations cannot be in its present shape, considered to be a regulation that has real chances for implementation and effective prevention of addressed threats.

Summary

Despite the prevailing consensus on the harmfulness of the phenomenon and the broad public support for the fight against the scourge of pornography among minors, there are currently no countries that have systemic and effective solutions in the field of limiting access to pornography for minors (while maintaining the principles of open Internet). The lack of solutions that could be indicated as exemplary and the failure of the 5-year attempt to build such a system in Great Britain indicate that the solution to this problem is extremely complicated and multidimensional. Certainly it is not possible to introduce effective solutions based solely on technological solutions, because their level of advancement and rapid development gives the possibility of identifying and blocking dangerous content (e.g. using artificial intelligence algorithms) but at the same time enables the creation of simple and easily accessible tools for bypassing blockades and restrictions effectively.

It should be emphasized that the introduction of specific technical solutions must be preceded by an analysis of their capabilities and effectiveness, which will indicate at what level (end devices, local/home/school networks, internet service providers or content providers) their application will be the most effective and rational. There are currently no such analyses. The implementation of solutions that will allow any restrictions on access to dangerous content (including pornography) on the Internet must also be preceded by a discussion and a decision whether the principles and regulatory framework in this area should be defined in hard law (at national or EU level), in the form of or co-regulation, or probably European Commission guidelines encouraging member states to take specific actions would be sufficient?

It also seems that the construction of a cybersecurity system for children and teenagers cannot be limited to selected problems (dangerous content or digital violence) but should take into account a wide spectrum of threats.

Abstract

The study defines the conceptual foundations of the migration crime risks, it also identifies the development trends of the phenomenon under study. The paper assesses the migration crime risks in the context of the crisis caused by the coronavirus pandemic COVID-19. The stated research is relevant and timely since there is a need to ensure an effective migration policy that is subject to the effects of the pandemic crisis. The purpose of this study is a theoretical insight of a new concept of "migration crime risks" as a necessary prerequisite for a prognostic study that identifies the development trends of the phenomenon under study in relation to the external factors. Based on the results of the study, the authors define the concepts of "migration crime" and "migration crime risks"; the factors affecting the development of migration crime are identified and the most probable risks of migration crime are predicted in atypical conditions of a pandemic crisis.

Keywords: Migration Crime, Illegal Migration, Criminality Of Migration Processes, Migration Policy, Pandemic Crisis, Migration Regime.

Introduction.

The year 2020 will become a world history as a year of critical rethinking of global problems caused by geopolitical, economic and environmental crises in the unique conditions of pandemic coronavirus infection COVID-19, announced on the 11th of March, 2020 by the World Health Organization. The pandemic has complicated the already controversial migration situation on a global scale.

The experts agree that the coronavirus will worsen the impending global economic crisis. The signs of a recession can be observed now. There is a sharp decline in commodity circulation and capital flows globally. The exchange of labor resources was interrupted due to the complete or partial international border closure. Because of the measures taken to counter the spread of coronavirus infection, many migrants were stranded in the host country and are in a formally involuntary violation of the migration regime's regulations. The prospects for their return to their homeland are not clear. Due to the development of unemployment, access to the labor market is significantly limited. There is an acute threat of new flows of refugees from economically depressed states to centers of attraction for migration. Provoking social tension, these factors have got the criminogenic potential. So, there is a need for a prognostic assessment of the migration crime risks through the prism of "social reflexivity". W. Beck (2000) defines it as risk reduction and prevention of negative consequences.

The results of such an assessment can serve as a basis for optimizing migration policy at the state and interstate levels, aimed at minimizing the risks of migration crime.

Methods

The starting point of this research is the theoretical development of a conceptual framework for the migration crime risks. This new perspective direction of scientific research allows us to predict the development of the studied phenomenon through the prism of the external influence on it. The use of the general scientific cognition methods that is: legal and dogmatic, comparative, analysis and synthesis allowed us to formulate the concept of migration

crime and identify the relationship of this phenomenon with illegal migration, which is one of the main factors in the formation of migration crime risks.

The dialectical method made it possible to predict the development of migration crime in relation to the external factors caused or amplified by the pandemic crisis.

The main methods of obtaining criminologically significant information about the determinants of migration crime that affect the formation of its risks are statistical, comparative, sociological methods, observation, expert assessment and questionnaire survey. The survey involved 280 people living in the cities of Moscow and Kursk, three categories: indigenous residents (citizens of the Russian Federation), foreign citizens, and law enforcement officers.

The theoretical and prognostic components of the present study complement each other and form the basis for the formation of a methodology for the preventive impact on migration crime in order to minimize its risks in general and in situations of crisis in particular.

Results and Discussion

Based on the results of the research, the author formulated the definition of migration crime, which means a socially dangerous illegal phenomenon of social reality, which includes three groups of crimes: 1) committed by foreign citizens (stateless persons); 2) in relation to the specified category of persons; 3) against the migration regime (entry procedure, stay (residence) of foreign citizens and stateless persons).

Migration crime risks are understood as qualitative and quantitative characteristics of destructive manifestations of migration processes that affect the criminogenic well-being of the population. They create the social tension and increase the level of conflict between citizens of the host state and migrants. In the context of the pandemic crisis, their negative impact will gradually increase. In the medium term, this will lead to an increase in real migration crime.

One of the main factors in the formation of migration crime risks is illegal migration. The relationship of these comparable, but quite independent phenomena is more significant than is commonly believed. Awareness of the importance of illegal migration in determining migration crime affects the rethinking of the public danger of this type of crime and should be taken into account when optimizing migration policy, as well as national security strategies.

During the pandemic crisis, formally forced violation of the migration regime of socially unprotected illegal migrants will inevitably provoke an increase in migration crime. If the restrictions that create obstacles to legal migration are strengthened, then after removing the barriers caused by the need to prevent the spread of COVID-19, illegal migration and the scale of human smuggling will increase.

The specific features of the pandemic crisis allowed us to identify the most likely risks of migration crime. These include an increased violent and mercenary crime and ethnic clashes, the criminalization of economic relations involving migrants and corruption in the migration sphere, and the smuggling and exploitation of migrants.

Discussion

To date, we have accumulated an extensive experience in studying various aspects of migration. The problem of counteracting migratory crime is among them. There are lots of disputes around it regarding its definition, essence, and correlation with related concepts.

In the scientific literature two main points of view have been formed regarding the content of the concept of "migration crime". Supporters of a narrow approach, such as Sobolnikov (2011), interpret it as a set of crimes committed by migrants (foreign citizens and stateless persons). Adherents of a broader approach, such as Lopashenko (2017) and Markova, Koshelev and Sukhodonlov (2018), in addition to this component, include in the scope of definition a set of crimes where migrants are victims.

Criminal violations of the entry and stay of foreign nationals and stateless persons in the territory of the host State, which constitute special rules for the management of migration processes, are also a component of the content of migration crime. These offences are not fully covered by any of the above categories. They do not have a victim; they can be committed by any person with the consent and (or) in the interests of migrants.

The concept of "risks of migration crime" has relatively recently been introduced into a scientific circulation by sociologists. The risks of migration crime, as stated by Yudina and Bormotova (2019) are "a measure of possible

danger caused by migration processes that directly affect the stability and criminogenic well-being of people living in a certain territory". The main risks of migration crime include an increase in interethnic conflicts, terrorism, extremism, cross-border crime, an increase in drug use of society, corruption, criminalization of economic relations, general social tension, etc.

In doctrinal sources, such as Kovalenko, Shuraeva and Zhukov (2018), Sychenkova (2009) and Borishpolets (2007), the term "migration risks" is often used to characterize the category under consideration. It seems that in volume it is broader than the risks of migration crime. Unlike the concept of the migration crime risks, it does not always have a negative meaning.

Migration as a phenomenon creates risks and is simultaneously caused by them, regardless of whether it is legal or illegal, at all stages of the migration cycle and at all levels: domestic, community, regional, national and global. Migration, as Williams and Baláž (2012) conclude, is also a reference source concerned a risk or uncertainty that affects behavior choices.

The term "risks of criminality of migration processes", as Lopashenko (2017) notes, is as close as possible to understanding the risks of migration crime. To characterize the category in question, it is preferable to use "migration crime risks" for two reasons. First, the attention of the observer is focused on the negative social phenomenon. Migration unlike migration crime is a complex phenomenon that combines positive and negative principles. Migration is a natural process based on the inalienable human right to freedom of movement. This right is enshrined in international acts, in particular: the Universal Declaration of Human Rights of 10 December 1948, International Covenant on Civil and Political Rights of 16 December 1996 et al. It is guaranteed by all democratic states. Secondly, the risks of migratory crime include criminal components directly related to the crimes, and not only those that generate them.

With regard to the risks of migration crime, the measure of possible danger refers to the qualitative and quantitative characteristics of the destructive manifestations of migration processes.

The assessment of these parameters is significantly complicated in view of the fact that the real migration crime has the features of uncertainty, unpredictability and the absence of, as named by Sobolnikov (2011), "conditions for its sufficient criminal diagnosis" and it is characterized by a high level of latency. This specificity is due to the fact that the attributive sign of real migration crime is illegal in form and uncontrolled in content migration, which is almost impossible to count. The importance of illegal migration in determining migration crime has not been fully studied. This explains the contradictory assessment of the impact of migration on the crime rate in host countries, in particular European countries and the USA, as stated by Ousey and Kubrin (2018), Crocitti (2014), Nunziata (2015). The scientific literature, such as Ousey and Kubrin (2018), notes that the existing counting methods do not take into account unobserved factors that significantly influence the correlation between migration and crime. The main one is illegal migration. However, the studies such as Nunziata (2015), have pointed out that the level of migration crime decreases if migration is properly controlled.

In the Russian Federation, the evaluation method of migration crime does not also take into account the relationship of this phenomenon with illegal migration. In the absence of profile statistics with a high migration susceptibility migration crime is extremely low (Russia takes the fourth place after the USA, Germany and Saudi Arabia in terms of the number of international migrants with an indicator of 11.6 million people, as noted by United Nations (2019); about the same number of illegal migrants stay in its territory every year according to reports by Markova, Koshelev and Sukhodolov (2018).

In the total share of recorded crime, the number of crimes committed by a foreign contingent is approximately 2%; only 3 per cent of those convicted persons are foreign nationals and stateless persons.

Fig. 1. Number of crimes committed by foreign nationals and stateless persons

The underestimation of the importance of illegal migration when determining migration crime is confirmed by the official data: by a comparison of the number of crimes committed by foreign citizens and stateless persons (Fig. 1) and the number of detected foreign citizens and stateless persons who have committed crimes (Fig.2).

Fig.2. Number of foreign nationals and stateless persons identified as having committed crimes

The comparison of these data groups is almost identical. Meanwhile, hidden from observation, highly latent migration crime, determined by the illegal status of the subjects of crimes or victims, is the most dangerous because of its lack of visibility and scale.

In the meantime, hidden from surveillance highly latent migration crime, determined by the illegal situation of the perpetrators or victims, poses the greatest danger in view of its non-obviousness and dimension.

Among the factors that determine migration crime 18% of respondents mentioned illegal migration. It is the third most popular response, after ineffective migration policy (27%) and corruption in the migration sphere (25%).

Low official indicators of criminal activity of migrants in 2020 (Fig.1 and Fig.2) are explained not only by the unregistered part of migration crime due to the illegal status of foreign citizens (stateless persons), but also by the fact that the burden on law enforcement agencies has increased in the context of the pandemic crisis. They were reoriented to provide restrictive measures to prevent the spread of coronavirus infection and deliberately did not take measures to detect and suppress offenses in order to prevent the potential spread of COVID-19 in detention facilities and special

institutions for foreign citizens who are waiting for a forcible return to their homeland. This trend has been observed by Phillips (2020) in many countries.

Therefore, the official data and skeptic characterizations by Varshaver (2020), in reference to the growth of migration crime, more likely are concerned with the short-term development of this phenomenon. They do not take into consideration the specific features of the pandemic crisis that the economists do, that is: the market conditions have sharply worsened, a pandemic has layered on it, a sharp drop in oil prices, international sanctions and border closures with the suspension of economic activity. The shadow sector of the economy is expected to grow, where the competitive advantage of foreign workers will be lower social demands compared to the indigenous population.

Among the respondents surveyed, 76% are predicting an increase in migration crime after the removal of the restrictive measures to counter coronavirus infection. The main risks of migration crime in the context of the pandemic were identified by respondents as an increase in violent and mercenary crime (31%), ethnic clashes (18%), criminalization of economic relations involving migrants (18%), corruption (17%), and terrorist attacks (10%).

The experts suppose that the reasons for the increase in migration crime are the more difficult situation of migrants compared to the indigenous population: the loss of work without any guarantees, the inability to go home due to the closed borders, the lack of money, housing rent, overcrowded accommodation without the opportunity to isolate increases the risk of COVID-19 infection, difficulty in accessing medical care.

82% of respondents answered in the affirmative when answering the question: "Will the tightening migration policy after the abolition of restrictive measures to counter the spread of coronavirus infection lead to an increase in migration crime?". 62% of respondents attributed the smuggling and exploitation of migrants to the possible risks of increasing restrictions on the migration regime.

An important component of the pandemic crisis is the social anxiety of the population caused by the already observed negative socio-economic consequences caused by the pandemic crisis. In the medium term, it is expected that xenophobia increases as a reaction to the illegal behavior of migrants, and as a result, there will be a crime wave committed against them.

It is no coincidence that in the first recession year of 2013, the number of crimes committed by migrants increased by 10%, with a slight crime wave committed against them. In 2014 there has been a sharp increase in the number of assaults by 30%, where migrants became crime victims (see Fig. 1, 2, 3).

Fig. 3. Registered crimes against foreign citizens and stateless persons

Conclusion

Given the uncertainty of the pandemic crisis, it is difficult to make accurate assessment of the trends in migration crime and its risks. But it is already possible to predict an increase in migration crime with a high degree of probability. Taking into account the specifics of the pandemic crisis in the medium term, it is expected that officially recorded indicators of migration crime will increase in size exceeding the corresponding indicators of the last crisis of 2013-2014: at the beginning there will be a crime wave committed by migrants (over 10% in 2020), then after some time it will be against them (more than 30% in 2021).

The main factor affecting the increase in the risks of migration crime is illegal migration, the scale of which will increase if the migration policy is tightened and additional restrictions are imposed on the migration regime.

The most likely risks contributing to the growth of migration crime will be an increase in inter-ethnic conflicts and general social tension, a growth of the violent and mercenary crimes, a criminalization of economic relations involving migrants and an increased corruption in the migration sphere. The risk of terrorist attacks will remain.

Abstract

In this article, the authors focus on the disclosure of the concept of fraud in the insurance sector in domestic legal science and abroad. The article highlights the practical aspects of the criminal activities of a fraudulent insurer based on international experience in the insurance industry. The authors consider various forms of such fraud, both by policyholders and by insurers. Analysis of foreign experience in combating insurance fraud allows, on their basis, to formulate recommendations for the regulation of the Russian insurance market in order to counter insurance fraud. The authors cite statistical data from international organizations whose activities are aimed at countering the negative phenomenon under consideration, which allow us to summarize that such an appeal for experience to foreign countries is useful and expedient for Russian society. The authors came to the conclusion that due to the urgency of the problem of criminalizing fraud in the insurance industry, which in Russia is given a less significant place at the legislative level than in foreign countries, an important direction in the activities of the domestic legislator is the appeal to international experience in the fight against insurance fraud. This can provide an excellent basis for improving insurance fraud legislation.

Introduction

The relevance of the chosen research topic is determined by the conducted research on the state of crime in the economic sphere at the global level. Thus, according to the data obtained by the international network of companies PwC (PricewaterhouseCoopers), the issue of the criminal situation in the field of payments, finance and insurance at the global level remains very relevant and is characterized by further criminalization of economic relations. And, according to Craig (2018), statistical indicators indicate an increase in the number of crimes in the economic sphere.

It is important to note that one of the significant economic indicators is the prevalence of fraud. This negative phenomenon firmly occupies one of the leading places in the system of financial crimes. Their disclosure is directly related to a number of difficulties, which necessitates a high level of legal qualifications.

We will pay more detailed attention in the article to fraud in the insurance industry, due to the fact that today the problem of insurance fraud remains the most urgent and widespread in the insurance industry.

The epidemiological situation with the spread of COVID-19, which led to a crisis in the economy, as a result of which, according to experts, a sharp rise in insurance fraud should be expected, also gives topicality to the study. According to the chairman of the committee for combating insurance fraud of the All-Russian Union of Insurers Sergei Ivanovich

Cite this Article as: Valery NOVICHKOV, Andrey BAYBARIN, Alexander GREBENKOV, Elena SHATANKOVA and Natalia PETRISHCHEVA " Insurance Fraud as An International Problem: A Comparative Legal Analysis of Russian And Foreign Legislation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Efremov, on the basis of the existing Russian practice of the crisis years, it can be concluded that there is a stable growth of fraud by 5-10% in "difficult times for Russia." Metelitsa (2015) cites as an example the period of the crisis of the Russian economy from 1998 to 2008.

A similar point of view is shared by Farhutdinova and Suslyakova (2020), who claim that the pandemic will result in an increase in insurance rates for our state for all policyholders, since they will include additional risks from fraudsters.

Methods

In this study, a specific scientific methodology is applied using such general scientific methods as analysis and synthesis, which allowed the authors to compare and contrast different approaches to the subject of study, as well as to consider its individual elements, which together gives the result of the most effective study of the topic under consideration.

Particular scientific methods were also used: comparative legal and formal legal. They allowed, through their toolkit, to analyze domestic and foreign legislative regulation of such a crime as insurance fraud.

The methodological basis of the research is also made up of the provisions of dialectics, taken in unity with general and particular scientific methods, which made it possible to study the problem under consideration in an indissoluble unity with other legal phenomena.

As sources, the authors used the regulatory legal acts of Russia, as well as of a number of foreign countries, along with the scientific works of such authors as T.A. Filippova, N.V. Bykova, D. Kruger, Kelly E. Riddle and a number of other authors who have authority in this area.

Results and Discussion

The development of insurance fraud is closely related to the development of the insurance itself and the insurance market as a whole, as well as to the spread and differentiation of various types of insurance. These include car insurance, including compulsory motor third party liability insurance (OSAGO), health insurance, life insurance, etc.

In the global industry, most of the crimes in the economic sphere are precisely in insurance fraud. According to Bykova (2009), statistical data indicate the largest percentage of such frauds in this area. In particular, fraud is most prevalent in health insurance, and the largest losses from fraud are in auto insurance. Undoubtedly, for a particular state, these indicators may fluctuate depending on the national characteristics of the development of the insurance market, which have a significant impact on the level of fraud. As a rule, in economically developed countries, financial, insurance and credit crimes are developed no worse, which is confirmed by Avakyan (2011) citing specific practical cases and statistical data from their practice.

For example, American family insurers lose about $ 1000 each year due to fraud, while British ones lose about £ 700. Note also the fact that according to the National Bureau of Insurance Crimes in the United States, insurance fraud is the second most common economic crime in the United States.

In Holland, fraudsters are paid about $ 0.5 billion. According to experts, Canadian society loses about $ 1.5 billion annually from this phenomenon. It is believed by Europol (2020) that about a third of each dollar of premium goes towards insurance claims initiated by fraudsters.

The German state is characterized by losses due to insurance fraud in the amount of almost 10% of the total payments. However, as some experts note, in reality the figures are significantly higher than in official sources. At the same time, in Germany, as well as in other European countries, the predominant direction in fraudulent activities is car insurance. In most cases, according to Nets Group (2019), fraudsters manage to gain about 500 €.

In France, losses caused by illegal acts of insurers are estimated at about $ 3 billion. Some statistical indicators indicate that only the share of solved crimes in terms of fraud is already 10% of the paid insurance compensation. However, despite this, the prevailing opinion by Europol (2020) is that it is France that is the leader in Europe in terms of the effectiveness of organizing the fight against insurance crime.

In general, the European Insurance Committee estimates losses due to this kind of crime in Europe at almost 10 billion €, which is 2% of all insurance premiums in the European Union, and at least 10% of all payments were received by fraudsters, as stated by European Commission (2020).

Considering the situation in the Russian state, we note that just 10-15 years ago, citizens did not suspect about such a “rock of society” as insurance fraud, but now, according to Bykova (2009), it has become so large-scale that it has a negative impact on all participants in the insurance industry without exception. Thus, according to the statistical data of the Federal Insurance Supervision Service, as provided by Bank of Russia (2020), every year Russian citizens-insurers lose up to 15 billion rubles due to illegal acts of both clients and employees of insurance companies.

At the same time, similar to the experience of foreign countries, almost 70% of all cases of insurance fraud are in the field of auto insurance. According to Bank of Russia (2020), each car owner paid on average about 0.5 million rubles for payments to scammers. Some large companies claim that payments to fraudsters account for up to 10% of auto insurance premiums.

According to the Russian Union of Auto Insurers, payments of insurers in court in 2018 increased by 1.5 times. According to the estimates of the Committee of the All-Russian Union of Insurers for Combating Insurance Fraud, the statistics of disclosure balances at a fairly low level - about 10%. In general, the damage from fraud in OSAGO RSA is estimated by TASS (2018) at almost 60 billion rubles annually, a third of which are losses due to illegal actions of intermediaries, almost 20% from fraud by the insurers themselves, 25% from the distribution of fake OSAGO policies and about 20% due to transport management without CTP policy.

Let's move on to consider the very essence of such a phenomenon as insurance fraud. Until recently, when this concept was not introduced by the legislator, the prevailing point of view, as stated by Mitrohin (1995), was that insurance fraud was understood as a form of unlawful behavior of individual subjects of an insurance contract, the purpose of which was illegal and gratuitous recourse of insurance compensation payments through deception, or abuse of confidence, or making a smaller insurance premium, or hiding important information when concluding an insurance contract, as well as refusal of the insurer to pay insurance compensation without legal grounds. Roughly speaking, this interpretation also meant that all types of illegal actions in the field of insurance can be attributed to the objective side of insurance fraud, regardless of their subjects, the presence of a criminal structure, etc.

However, this point of view was later criticized by Zhilkina (2005), referring to the fact that not all of the named legal facts contain elements of the crime of fraud, focusing on the fact that if we integrate into one concept acts both committed against the insurer and those committed by the insurer or a person, posing as his representative, this will lead to unfoundedness both from a legal and economic point of view. In addition, such an association does not emphasize the differences between fraud as criminal offenses from, for example, violations of civil (insurance) legislation.

That is why, up to a certain point, an intermediate position has arisen in the Russian literature, according to which insurance fraud is understood as all fraud related to insurance. That is, in this case, crimes committed by fictitious insurance organizations (branches, representative offices), insurance intermediaries that have no legal rights, etc. are also taken into account by Larichev and Galaguza (1999).

In connection with such an ambiguous legal practice in relation to a unified approach to determining the legal essence of insurance fraud, Sharapova (2018) notes that there is a need to reform the Russian criminal legislation. Undoubtedly, an important step in this direction was the Federal Law of November 29, 2012 No. 207-FZ "On Amendments to the Criminal Code of the Russian Federation and Certain Legislative Acts of the Russian Federation". This novel supplemented the Criminal Law of the Russian Federation with six articles at once, providing for liability for special types of fraud, including in the field of insurance. From now on, a precise definition of the term under study was given at the legislative level. So, fraud in the field of insurance means theft of someone else's property through deception regarding the occurrence of an insured event, or the amount of insurance compensation that is payable in accordance with the law or contract to the policyholder or another person.

Obviously, for a more detailed study of the concept of "insurance fraud", one should refer to the experience of foreign countries, where the indicated criminal act is not as "young" as in Russian society, as a result of which foreign experience has considerable experience in determining its legal essence, qualifications, methods identifying and dealing with it.

So, Kryuger (2018) interprets the concept under study as follows: this is a deliberate crime committed by the insured (beneficiary), the purpose of which is unfair enrichment at the expense of the insurer by deceiving the insurance company, distorting information about the insurance object, as well as taking actions aimed at the occurrence of an insured event or increasing insurance compensation.

If we analyze the above definitions, we can identify the difference between their interpretations: in foreign experience, giving an interpretation of fraudulent actions, only one subject is mentioned - the insured (beneficiary), while in the

Russian interpretation there is an alternative to subjects: from the side of the insured (beneficiary), so and by the insurer. In our opinion, the domestic understanding of insurance fraud is closer to reality, since we cannot completely exclude the possibility of an insurer's dishonest behavior.

Let's move on to the very issue of comparative legal analysis of qualifications in Russian and foreign legislation. Let's start with an examination of the domestic corpus delicti.

So, under the crime under Art. 159.5 of the Criminal Code of the Russian Federation "Fraud in the field of insurance", which is included in section 8 of the Criminal Code of the Russian Federation "Crimes in the field of economy", means all crimes that infringe on property relations and economic rights of citizens, legal entities, municipal and state formations.

According to Sharapova (2018), the objective side of insurance fraud includes a number of characteristics and features, thanks to which we can correctly qualify this act. These include, firstly, the very content of the crime, which consists in the theft of someone else's property (in particular, money), i.e., gratuitous seizure, illegal movement and circulation in their favor or in favor of other persons. In this case, the act can be expressed both in an active form (action - for example, staging a car theft, deliberate communication of information that does not correspond to reality, etc.), and in passive (inaction - for example, failure to provide assistance to the insured person, etc.).

Second, it is worth mentioning the ways in which insurance fraud is committed. Such can be, for example, deception - the communication of deliberately false information or even the omission of true facts. At the same time, deception is a mandatory sign of fraud and can be expressed in various forms, for example, oral, written, etc.

Thirdly, the fact that the subject of the crime violates the norm of the criminal law, speaks of the unlawfulness of his act.

Fourth, the presence of a socially dangerous result (consequences). These include, in most cases, causing property damage to the insurance company, its owners, participants, or other customers, whose money supply goes to illegal payments to fraudsters.

And the last sign of a crime, fraud in the insurance industry is its causal relationship between the act and the socially dangerous consequences that have occurred. In this case, a prerequisite is the real possibility of causing property damage and its occurrence as a result of a criminal act.

We will pay special attention to the subjective characteristics of the composition of insurance fraud. So, as stated by Prometov (2008), most often the subjective side is expressed in the form of direct intent, due to the fact that a person realizes the social danger of his actions (inaction) and foresees the possibility or inevitability of the onset of socially dangerous consequences, and also wants their occurrence. However, in the science of criminal law, it is allowed to commit fraud in the field of insurance with indirect intent with complicity, i.e., the person realizes the social danger of his actions (inaction), foresees the possibility of the onset of criminal consequences, but does not want them to occur, as he is indifferent to them.

In contrast to this point of view, some legal scholars argue that insurance fraud is always committed with direct intent, due to the fact that in order to achieve the desired result, the fraudster in relation to the victim commits many active actions that require intellectual and analytical activity from him. Thus, according to Sharapova (2018), for a successful outcome of the case, a fraudster must develop a certain action plan in order to achieve the desired result. In this case, the fraudster remembers the selfish purpose for which he commits fraud.

It should be borne in mind that often the criminal orientation and social danger of insurance fraud do not seem to the fraudsters to be something significant and illegal. For example, as stated by Kuznecov (2016), a survey was conducted among insurers in Germany and America, according to which about 93% of them do not see anything criminal in getting a little more from the insurance company than they should.

So, we smoothly moved on to consider the experience of criminalization of insurance fraud by foreign countries. First of all, we note that only in a number of foreign countries this type of crime is determined by the usual norms of criminal law, which provides for liability for fraud in general. That is, there is a single, "maternal" norm for fraud in different spheres of human life. Until recently, as we found out, Russia was one of such countries. However, since 2012, according to Filippova (2012), Russia, like most foreign countries (for example, Sweden, Austria, Germany, Bulgaria, Poland, etc.), includes fraudulent actions related to insurance in the criminal legislation as an independent, separate corpus delicti.

For example, Austrian criminal law (§151) includes insurance fraud under offenses against other people's property. The objective part of this act includes a number of alternative acts, such as destroying, damaging or hiding insurance items; as well as causing or attempting to cause harm to oneself or to third parties in order to thereby generate property benefits directly or indirectly related to insurance. The sanction for such an act provides for imprisonment up to six months or a fine.

Dutch Criminal Law (327bis) as the subject of a crime brings a person who, through a “clever trick”, misleads the insurer with regard to data related to the insurance contract, thus forcing him to agree to conditions that are not legal and lawful. The punishment in this case is imprisonment for no more than one year or a fine.

In the Polish Criminal Code (Art. 298), the main object of insurance fraud is the country's economic turnover. And the legislator refers to the objective side only those actions, the purpose of which is the unfair acquisition of insurance compensation due to a premeditated incident that is the basis for obtaining monetary compensation. The sanction of the article provides for punishment in the form of imprisonment for a term of 3 months to 5 years.

In the United States, the problems of criminalizing insurance fraud are given a significant place at the legislative level, due to the fact that insurance is mandatory in many areas of every American's life. Thus, 47 states (representing 94% of the total number of states) qualify this act as a crime, while 37 states qualify insurance fraud as “felony”, which means the most serious of criminal acts.

At the federal level, there is the National Insurance Crime Bureau, which is responsible for detecting and investigating insurance fraud. And in 42 states - there is a specialized Bureau for combating insurance fraud ("insurance fraud bureaus"), which operate under the State Insurance Department. And the anti-fraud units in the states of South Carolina, Nevada and Pennsylvania, according to Bykova (2009), are generally part of the department of General Attorney (that is, they are real "law enforcement" agencies).

In addition, 26 states have separate criminal laws that govern certain types of insurance fraud. Most often this applies to the field of auto insurance, medical, as well as insurance of employees against accidents and a number of other types.

It is important to note that the main US criminal law - the Model Criminal Code - sets out the main points related to the qualification of insurance fraud in several sections. So, in Chapter 2, space is allocated for the interpretation of this type of crime, according to which it is understood as an intentional act committed by any person, which is aimed at depriving third parties of profits. At the same time, fraud is recognized as a deception by an insurance company, reporting false data when concluding an insurance contract, when submitting an application for insurance compensation, etc. As we can see, this definition includes a variety of the objective side of the fraudster. And Chapter 4 of the Model Law already provides for the differentiation of the sanctions applied to the violator. The criterion for choosing a particular punishment, as stated by Riddle (2013), is the nature and severity of the act committed.

Given the law enforcement and legislative features of the American federal state, it is natural that the definitions and sanctions of insurance fraud vary from state to state, due to the fact that they may have their own definition, which will differ from the interpretation of the US Model Law. As, for example, it was with the legislation of the state of Arizona. So Arizona Fraud Statutes of April 29, 1997. In §20-463, it defines that insurance fraud is a felony of rank 6, which indicates a high level of public danger, as a result of which the legislator provides for punishment of up to 10 years in prison, as well as a fine of up to $ 150 thousand.

As we can see from the above analysis, foreign states are characterized by a fairly strict system of sanctions, which provides not only significant amounts of fines, but even deprivation for more than 10 years (Criminal Code of the PRC). Fraud cases are carefully monitored, widely publicized and, for the most part, severely suppressed. This situation is explained by Bykova (2009) by the fact that foreign legislators subject all aspects of insurance to a thorough criminal law and criminal procedure.

In order to “keep up”, Russia, as already noted, to effectively combat insurance fraud, clearly differentiated the criminal sphere of fraud at the legislative level, thereby consolidating the concept of “insurance fraud” in the law, as well as providing specific types of punishment for it. It should be noted that domestic repressive measures are not inferior in severity to foreign sanctions. So, the minimum punishment for this crime is to pay a fine of up to 120 thousand rubles or in the amount of the convict's salary or other income for a period of up to one year, while the maximum provides for imprisonment up to 10 years with a fine of up to 1 million rubles or in the amount of wages or other income for a period of up to 3 years (or without it) or with restriction of freedom for up to 2 years (or without it), which indicates the cumulative nature of the sanction.

We will also pay attention to the issues of regulating the legal framework for the bodies involved in the fight against fraud in the insurance industry. Thus, the activities of the above American bodies (the National Bureau of Insurance Fraud, the specialized Bureau of Insurance Fraud, the State Insurance Department, the anti-fraud units in some states, etc.) are mainly regulated by special state laws. For example, Florida is governed by §1880 Fraud bureau, Utah is §31 Fraud bureau, etc. However, many of these laws are based on the Model Fraud Bureau Act, which is considered the governing law for all states. It defines the competence of the authorities, fixes their legal status, describes the procedure for conducting an investigation and a number of other legal aspects.

The Canadian state is characterized by the activities of a special committee at the Insurance Bureau of Canada (IBC). It performs the function of detecting and disclosing insurance fraud cases, while actively working with the Canadian police to investigate insurance fraud. At the same time, their police even have a special "Anti-Fraud Protocol", which defines the content of insurance fraud, declares the main provisions for its disclosure and prevention. Assistance to the Insurance Bureau of Canada and insurance organizations in the performance of these functions is provided by a variety of separate investigation bureaus that deal only with insurance issues, having a special license for this.

France is also not inferior in the organization of law enforcement measures to combat and counter insurance fraud. Thus, the investigation of such acts is carried out by external organizations, which are mostly composed of police officers. After the investigation procedure, all cases are sent to court. At the same time, the insurance company does not pay insurance compensation in the pre-trial period. An interesting fact is that all insurance companies in France, without exception, keep a special record of persons who have committed crimes in the field of insurance, so as not to “make mistakes” again. In addition, according to Sitnikova (2010), on the basis of these reports, they develop methods for specialists on the occurrence and further regulation of insurance losses due to fraud, as well as on the procedure for checking cases for fraud.

As we have already noted, the problem of combating fraud abroad is one of the most urgent, which is determined both by the scale of development of the insurance itself, and the degree of organization of the fight against this type of crime. At the same time, as stated by Filippova (2012), this negative phenomenon is being fought both in the companies themselves and at the state and global levels.

Thus, the main mechanisms that make up the system of collective security against fraud in this area, in international practice, include the consolidation of efforts of all insurance companies in the fight against fraud, as well as their interaction with law enforcement agencies of the state apparatus; protection of corporate capital from fraud by fraudsters; as well as strict observance of all recommendations and rules of conduct that are provided by the legislator to prevent cases of fraud.

It is important to note that international experience can become the basis for the formation of the foundations for combating fraud in the Russian insurance sector, since the world community, according to statistics and experts' opinions, has very effective mechanisms in its arsenal. For example, the international community has long begun to take measures to combat insurance fraud. An important step in countering this negative phenomenon was the formation in 2006 of the Insurance Fraud Bureau (IFB). This non-profit organization was founded in the insurance industry precisely with the aim of detecting and combating organized fraud.

According to her data for May 2018, international insurance organizations, by joint efforts, focusing on combating fraud, managed to reduce the number of claims related to this crime by the industry by almost a third compared to 2015. And also this kind of consolidation led to a drop in the volume of fraud in Europe to almost £ 1.5 million, according to Association of British Insurers (2020).

In addition, the Bureau of Insurance Fraud, based on data that was sent anonymously via the hotline, she developed a strategy for 2015-2019, which consisted in an in-depth study of fraudulent schemes in all types of insurance, as stated in The Insurance Fraud Bureau (2020).

Let us also note some states that, with the global goal of the global fight against insurance fraud, have reformed their legislative framework to restructure the consciousness of economic entities in the insurance market and increase attention to insurance crimes, as mentioned in Petuhova (2018). For example, in the UK, the following legislative change initiatives have been proposed relatively recently. Firstly, the consolidation at the legislative level of the foundations of the anti-fraud mechanism, including in the field of insurance. Secondly, the use of accounting systems, which was mentioned earlier, with information about former fraudulent clients with a special penalty coefficient. Thirdly, the introduction of an additional term for insurance companies to verify customer information (based on the same accounting systems). Fourth, a limited number of warning messages about fraudulent attempts. Fifth, as stated by Voronin (2017), the establishment of a number of specific grounds for refusals to provide insurance services due to the identification of N-th number of fraud attempts.

In general, the result of the fight against insurance fraud in the UK was reflected in the increased attention of business entities to this problem, which led to an increase in investments in the Insurance Fraud Bureau, which led to an expansion of the controlled and supervised scope of activities, as well as to the restructuring of the target group.

It will also note the fact that holding various scientific and practical conferences, forums and round tables will also be useful for application in Russian practice. For example, 3 years ago, Austria hosted the II international conference on combating fraud, which was attended by representatives of major Russian insurance companies and organizations. At this conference, the methods and measures to combat unscrupulous insurers were discussed, which, undoubtedly, can serve as a support for the development of further long-term policies to combat insurance fraud in the Russian insurers market. Thus, such measures of international exchange of experience will most favorably influence the activities to combat insurance fraud.

Let us emphasize that as the Russian insurance market develops into the practice of domestic companies, it is advisable to gradually introduce some of the methods of combating fraud used abroad. Not all of them can be automatically adapted to Russian soil, regardless of national characteristics. For example, the publicity of fraud, which is typical for a number of European countries, i.e., the disclosure of disclosed facts of fraud and punishment of criminals) in Russia will have, according to Sitnikova (2010), two types of consequences.

On the one hand, a positive effect, since the educational effect will work (i.e., citizens see that a crime is solved, and criminals are punished). However, on the other hand, in Russia, such information may, on the contrary, serve as a prerequisite for some persons to commit an illegal act, since they, knowing little about insurance, thus learn from information channels about such opportunities for illegal enrichment at the expense of insurers or insurance companies. As a result, when using this toolkit (if necessary), it is important to be careful about its use by means of partial "dosage" of information, without a detailed description of the model of the crime, focusing on the exposure and application of sanctions to the offender.

Conclusion

Summing up the comparative legal analysis of fraud in the field of insurance on the example of Russia and a number of foreign countries, we came to the conclusion that this problem remains one of the most urgent and widespread for the world community today. Foreign interpretation of the term insurance fraud is in many ways similar to the Russian concept enshrined in the Criminal Law. The only significant difference is the person performing the objective side. In our opinion, as noted, Russian terminology is more accurate and consistent with reality.

Let us emphasize that over the past decade, Russia has made great strides in regulating the institution of insurance fraud. Most recently, the Russians did not know anything about such a problem, and now the legislator has singled out an independent article 159.5 of the Criminal Code of the Russian Federation, which fixes the structure of this crime, reveals its content and features.

Based on the study, we also found out that the system of sanctions providing for liability for “insurance fraud” is almost equally strict both in foreign countries and in the domestic criminal system. However, in some countries, for example, the USA and Canada, the problems of criminalizing insurance fraud are still given a more significant place at the legislative level than in Russia.

In addition, as we have already noted, the problem of combating fraud abroad is one of the most urgent, which is determined both by the scale of development of the insurance itself and the degree of organization of the fight against this type of crime. In this area, international experience can serve as a foundation for improving legislation on insurance fraud.

Summarizing the above, without a doubt, it can be argued that the Russian legislator has already taken the first step towards effectively combating the studied negative phenomenon - he has formed at the federal level a unified approach to the concept of insurance fraud by introducing it into the Criminal Law, differentiating at the same time the sanctions for committing these crimes. The next important step, in our opinion, should be the introduction of international experience of the collective security system in insurance. This can be expressed in the form of the consolidation of efforts of all insurance companies in the fight against fraud, the creation of associations of various insurance companies with the support of the central bank, the legislative empowerment of security officers of insurance companies with special powers, the creation of special bodies to investigate and conduct operational-search measures in cases of insurance fraud, etc.

Thus, the use of international experience in the fight against insurance fraud can become really effective and useful in Russian practice, therefore, the domestic legislator must necessarily turn to the world community for valuable experience in combating fraudsters in insurance and other sectors of the financial market

Abstract

The article is devoted to the study of the quantitative and qualitative characteristics of computer crime in the Russian Federation, which, together with a detailed analysis of the criminological parameters of a cybercriminal's personality, made it possible to substantiate the main trends that have formed over the past 5 years in this area. Particular attention is focused on the analysis of statistical indicators presented by the Judicial Department at the Supreme Court of the Russian Federation for the period 2015-2019, which made it possible to draw up a typical criminological portrait of the personality of a Russian computer criminal.

Keywords: computer crime, cybercrime, criminological characterization, information and communication technologies, typology, computer offender.

Introduction

The widespread use of information systems in various areas of the life of society, along with the intensive improvement of the means and methods of using information and telecommunications technologies for illegal purposes, creates new threats to the security of Russia. This complicates not only the structure of computer crime, but also increases the professional skills of those who encroach on information technologies.

Confirmation of this trend in the field of computer crime are the indicators reflected in the statistical compendium of the Prosecutor General's Office of the Russian Federation, which indicate that in January-December 2019: law enforcement agencies of the Russian Federation registered 294,409 crimes committed using information and telecommunications technologies or in the field of computer information. A study of the dynamics of this type of crime allows us to state its twenty-sixtieth growth over the past seven years (in 2013, 11 thousand cybercrimes were recorded).

In addition, possessing a high level of latency, computer crime is of particular interest in the context of the study of its structure and dynamics, and in particular the personality of a cybercrime with specific knowledge in the field of computer technology. At the same time, the establishment of criminal law, socio-demographic, moral and psychological signs, as well as his «professional skills» becomes important when conducting a structural analysis of the identity of a computer offender.

Methods

General and special scientific methods, traditional for theoretical and applied legal research, were used, such as formal-legal, system-structural, content analysis of various publications, comparative legal method.

Results and Discussion

Crime, existing in virtual space or using the achievements and opportunities of information and communication technologies, is a new, poorly studied negative cyber-social phenomenon for Russian society. Thus, in the context of the dichotomy of digital renewal of the criminal legal sphere, a new type of crime has formed - computer crime, which should be understood as a set of crimes that encroach on information and communication infrastructure.

Computer crime as a hyperlatent and super-changing social and negative phenomenon leads to the emergence of new categories of criminals, the identification of whose personal characteristics contributes to actively countering crimes committed using information and communication technologies. In this regard, modern studies of Russian and foreign scientists are devoted to the analysis and classification of computer criminals on various grounds (for example, on social status, sex age, motives, etc.), while focusing on the typology of persons who commit crimes in the field of computer information.

In the most simplified form, the typology of computer criminals is given by A.E. Pobegailo (2018), who identifies only three types of the corresponding category of persons:

1) persons who are characterized by a combination of professionalism in the field of computer technology and programming with elements of a kind of fanaticism and ingenuity ("ideological" criminals);

2) persons who suffer from various mental illnesses that make communication difficult in the real world and force them to focus on a virtual world in which it is easier to communicate and assert themselves;

3) professional computer criminals.

The typology presented by the author is generalizing in nature, as it reflects the most extensive groups of computer criminals.

Of particular interest within the stated topic of graduation qualification work is the typology of professional computer criminals.

Thus, E.T. Khaliullina (2018), senior researcher at the Research Institute of the University of the Prosecutor's Office of the Russian Federation, identifies the following types of professional computer criminals:

- Hackers who have a high level of computer technology knowledge and spend a lot of time at the computer in search of computer system vulnerabilities;

- hacktivist. This term is used to refer to the new phenomenon of social protest, which is a kind of synthesis of social activity, aimed at protesting against something, and hacking;

- cybercriminals. Unlike hackers themselves, such persons gain access to data in ways that are not directly related to the hacking of protection systems, but through deception, abuse of trust or official authority;

- persons engaged in industrial espionage;

- cyberterrorists - persons who use the Internet as a tool for real harm.

In turn, T. M. Lopatina (2007) believes that "the development of computer technologies contributes to new trends in the development of the computer underground. There is a peculiar evolution of hackers, more dangerous varieties of them appear:

- information brokers - order the theft of information to professional hackers, and then resell it to commercial competitors or other interested persons;

- metahackers - parasitize the activities of professional hackers, tracking their work and remaining unnoticed, and then use the results for their own purposes;

- darksiders - reject the principles of classical hacking, putting commercial profit and enrichment at the head of their activities ".

Professor A.L. Osipenko (2004), depending on the available programming skills and the means used in committing a criminal attack, identifies the following groups of hackers:

- «script kiddies» - a large group of novice hackers, consisting of people who are poorly versed in the basics of programming and use ready-made software to carry out attacks, often not even understanding the principles of their action;

- The main group of hackers, consisting of persons with good programming skills, capable of creating their own hacking software, better understanding the fundamentals of the functioning of computing systems attacked, and including a number of subgroups: «crackers» - entities specializing in destroying the security of networks or computer systems in order to illegally use their resources; "phreakers"

- Persons entering telephone networks and other secure telecommunication systems;

- «coders» - individuals who hack software and distribute stolen material free of charge through specialized sites;

- hackers of the «old guard» (oldguard hackers) - persons with high professional training in the absence of direct criminal intentions. Such persons with some superiority relate to the requirements of the law, believing that they are allowed almost everything in the networks [6].

If A.L. Osipenko considers «crackers» as a subgroup of hackers, then M.E. Flenov (2012) distinguishes between "hackers" and "crackers" as creators and destroyers, and believes that the «crackers» include:

- «virus descriptors - persons who use their knowledge to develop a destructive program;

- vandals - persons seeking to destroy the system, delete all files or disrupt the server;

- computer/server hackers - persons who commit "burglary" for the purpose of profit, often fulfilling someone's orders to obtain information.

- program hackers - individuals who remove protection from the software and provide it for universal use. Such people cause damage to software firms and the state.

At the same time, as I.P. Rodivilin (2017) notes, «the circle of persons who commit crimes in the field of computer information is not limited only to" hackers, "in connection with which the term" information thieves "should be applied to these persons, since their goal is to steal an important resource in the modern world – information». Such an interpretation makes it possible to refer to computer criminals any person who, due to either certain or independent circumstances, influences information. Therefore, the introduction of the term in question seems inappropriate.

Let us turn to the position of foreign scientists considering typologies of computer criminals. So, for example, the Canadian psychologist M.K. Rogers (2002), identified groups of computer criminals depending on the level of their technical readiness: beginners, cyber punks, their own - employees of victim organizations, encoders, hackers of the old guard, professional criminals, cyberterrorists. The typology presented fully correlates with the position of the foreign legislator regarding the regulation of liability for criminal attacks committed using information and communication technologies.

The constant improvement of information and communication technologies has a direct impact on the transformation of not only computer crime, but also the personality of a cybercrime in modern Russia. The corresponding changes are reflected in the criminological characteristic of the computer offender, which, along with existing typologies, allows you to form a holistic idea of persons who commit crimes in the field of computer information.

Criminologically significant information about the identity of a computer offender in Russia was obtained as a result of a study of statistical indicators published on the official website of the Judicial Department at the Supreme Court of the Russian Federation, for 2015-2019.

Consider the socio-demographic signs of a cybercrime - gender, age, citizenship, place of residence, level of education, social status.

Among computer criminals, men predominate, accounting for 92.4 per cent of the total number of convicts in the period under review (847 out of 917). Accordingly, the proportion of female convicts is 7.6% (70 of 917), of which 5.7% (4 of 70) committed a criminal assault while pregnant, and 2.9% (2 of 70) had children under the age of 3.

According to the above data, the proportion of persons between the ages of 18 and 24 is 34.4 per cent of the total number of convicted persons; from 25 to 29 years old - 26.8%, from 30 to 49 years old - 34.2%, from 50 years and older - 3.1%.

When considering the age limits of convicted computer criminals, close attention should be paid to the criminal activities of minors. For this purpose, reference is made to the statistical data reflected in the report of the Judicial Department of the Supreme Court of the Russian Federation on convicted persons who have committed crimes under the age of minor.

The number of minors convicted of crimes in the field of computer information for 2015-2019. is 14 people (1.5% of the total number of convicts under c.28 of the Criminal Code of the Russian Federation). At the same time, in 2017, the maximum number of convicted persons aged 14 to 17 years is 6 people, of which 2 are sentenced to imprisonment for a term of one to two years, 1 is from three to five years.

The availability of data on convicted minors in statistical indicators indicates that, as stated by Rudik and Toporov (2016), «at the age of 14, a person has sufficient skills and technical capabilities to carry out illegal activities, as well as that computer crimes committed by minors are a new feature of modern crime, which requires new forms and methods of counteracting». One solution to this negative situation is to lower the age of criminal responsibility for certain types of computer crimes. In this regard, attention should be drawn to article 12 of the Criminal Code of the Republic of Belarus, which provides for a lower age limit for criminal liability for theft through the use of computer equipment of 14 years.

Continuing the analysis of the socio-demographic features of a cybercrime, we turn to the question of the citizenship of convicted persons: for example, more than 98% of all persons convicted of crimes under chapter 28 of the Criminal Code of the Russian Federation are citizens of the Russian Federation; about 1.7% are citizens of the CIS states; 0.3% - citizens of other states. At the same time, the proportion of stateless persons in relation to the total number of convicts is zero.

About 93.5 per cent of convicts are permanent residents of the area, i.e. they have permanent residence; 6.5% are residents of a different area. The proportion of homeless persons and refugees and internally displaced persons is zero.

As noted earlier, the basic criterion for identifying various typologies of computer criminals is the level of their technical and organizational skills in working with information and communication technologies, which directly or indirectly depends on the level of education of such persons. therefore, such a criterion is of paramount importance in compiling a criminological portrait of a modern criminal.

Most computer criminals had higher education - 35.3% of the total number of convicts; secondary vocational education - 31.5 per cent; secondary general education - 25.8 per cent; basic general, primary or no education - 7.3%.

After analyzing the socio-demographic characteristics of convicts, we draw up an intermediate criminological portrait of a modern Russian cybercrime: this is a man aged 18 to 49 years, a citizen of the Russian Federation who has a permanent place of residence, as well as higher or secondary vocational education, who is socially able-bodied person without a permanent source of income or a worker.

Consider the criminal evidence of a computer offender - the place where the crime was committed, the presence/absence of complicity, unsubstantiated or outstanding convictions at the time of trial, etc.

About 61.8 per cent of persons committed a computer crime in the administrative centres of the constituent entities of the Russian Federation, 4.8 per cent in rural areas, respectively, 33.4 per cent in another territory within the Russian Federation.

In complicity in the group, 98 convicts committed criminal attacks in the field of computer information, which is 10.7% of their total number, of which 31.6% were members of an organized group.

Conclusion

Having analyzed the criminal legal characteristics of the convicts, we highlight the following features of the computer offender: in the past, he had no criminal record and was not prosecuted; prefers to commit criminal acts alone in the administrative centers of the constituent entities of the Russian Federation.

In addition to the analysis of the socio-demographic and criminal-legal characteristics of the cybercrime, we highlight the main trends that have developed over the past 5 years in the area under consideration.

Firstly, in 2019 there was a decrease in the number of convicted persons according to the composition of criminal attacks provided for in chapter 28 of the Criminal Code of the Russian Federation, by about 30% (in 2015 - 235, in 2019 - 165). The resulting trend is mainly due to the sign of the virtuality of computer crime, since, providing anonymity and physical distance from the immediate victim, virtual space acts as a significant advantage and at the same time a powerful determinant of the commission of criminal assault, and, as a result, the level of latency of the group of crimes in question increases significantly. At the same time, the lack of tactical and methodological recommendations for the investigation and disclosure of criminal attacks in the field of computer information significantly complicates the collection of information relevant to the criminal case.

Secondly, there is a qualitative change in the composition of convicts: the proportion of women prosecuted for computer crimes increased by 10%, respectively, the proportion of male convicts decreased by a similar indicator.

Thirdly, if previously computer criminals were characterized by the presence of secondary vocational education (in 2015 - 37.4%, in 2019 - 29.1%), now higher education is considered as a priority level of education (in 2015 - 29.8%, in 2019 - 37.6%). At approximately the same level, the proportion of convicted cybercriminals with secondary general education remains.

Fourthly, the proportion of criminal attacks committed in the group has increased - over the past 5 years, this figure has increased from 6.0% to 21.2%, of which in an organized group - decreased from 50% to 40%.

Considering the data obtained, it can be concluded that the typical criminological portrait of the personality of a Russian computer offender is currently as follows: this is a man aged 18 to 49 years, a citizen of the Russian Federation who has a permanent residence, as well as a higher or secondary vocational education, who is socially able-bodied person without a permanent source of income or a worker. In the past, he had no criminal record and was not prosecuted. He prefers to commit criminal acts alone in the administrative centers of the constituent entities of the Russian Federation.

Abstract

Russia and China face the problem of international terrorism and ethnic separatism; various manifestations of violence cover different regions in both countries, but geographically are tied to the main centers of instability: the North Caucasus region in Russia and Xinjiang in China. Both countries have considerable experience of counterterrorism cooperation at the global and regional levels. However, bilateral cooperation is becoming one of the main conditions for an effective fight against terrorism. Analysing the features of the North Caucasus region and Xinjiang, the authors study the main prerequisites for the relevance of Russia-China interaction on countering international terrorism, distinguishing such factors as a common border between two countries, foreign trade relations, geopolitical position of the states, analogous problems in terms of countering international terrorist organizations and Islamic extremist groups, as well as experience in countering political terrorism and separatism. Thus, the development of national counterterrorism policy requires a multifactorial analysis and multi-directional state control over key factors and their dynamics, and the bilateral Russia-China counterterrorism cooperation must rely on geographical proximity and common interests, serving a stable platform for further interaction in fighting terrorism at the regional level.

Keywords: Terrorism, Separatism, Counterterrorism, Bilateral Cooperation, Russia, China.

Introduction

International terrorism as a destructive phenomenon is spread on all continents and in all regions of the world. In Russia, the majority of terrorist attacks took place in the 1990s and the first half of the 2000s, China for the first time faced this problem in the early 2010s. The North Caucasus in Russia and the Xinjiang Uyghur Autonomous Region of China, the regions with intertwined cultures, customs, and confessions, are the places most affecting by terrorism and separatism in both countries. The acts of manifestations of international terrorism have general patterns and features caused by many factors. The additional motives of terrorist threat in these regions are their geopolitical and geo-economic position and the intention of some actors in the world economy and politics to use the factor of instability caused by relevant activities for achieving their interests. In this regard, it is of interest to study the prerequisites that determine the relevance of bilateral counterterrorism cooperation between Russia and China.

Research Material and Methods

The purpose of the study is to analyse the prerequisites of bilateral Russia-China cooperation in terms of countering terrorism.

Cite this Article as: Irina V. MINAKOVA, Tatyana N. BUKREEVA, Anastasia V. POPOVA and Dmitry N. NECHAEV "Prerequisites of Russia-China Bilateral Counterterrorism Cooperation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The research works of the following Chinese and Russian scholars cover the issues of Russia-China security cooperation: E Lizhi (2016), Jin Huixin (2011), and Vasiliev L.V. (2014). The features of the terrorism in the North Caucasus are studied in the papers of Shitova N.A. and Chihichin V.V. (2014), Yaroshenko G.V. (2016), Baranov A.V. (2017), and Ivanov S.M. (2019). Scientific works of Buyarov D.V. (2015), Clarke, M. (2018), and Wang Zhengxun (2014) are devoted to socio-economic and ethnopolitical prerequisites for the manifestation of international terrorism in China.
During the research process, there were used the following research methods for studying complex social objects: analysis, synthesis, comparison, analogy.

Research Results

Today terrorism has assumed the global character and become one of the major global threats to the national security of most countries. The internationalization of terrorism, an extensive network of international terrorist organizations, and the mobility of terrorist forces require from the world community a collective approach and regular interaction in countering terrorism. International cooperation has already become one of the effective forms of interaction between states in responding to terrorism.

The main prerequisites for the relevance of Russia-China interaction on countering international terrorism are

- bordering countries and foreign trade relations
- geopolitical position of the states
- similar problems in terms of countering international terrorist organizations and Islamic extremist groups
- experience in countering political terrorism and separatism.

In China, Xinjiang and Tibet are the main hotbeds of instability, where ethnic separatism embraced terrorist tactics have got widespread.

In Russia, the North Caucasus is a region with complicated political, social and economic situation. Counter-terrorism and homeland security are the main directions of national policy in this region. Terrorist attacks have been committed in the North Caucasus for over 25 years (Baranov, 2017). It should be noted that the Russian legal system focuses attention only on two macro-regions; it emphasizes their special position, the North Caucasus and the Far East. Moreover, the North Caucasian region of Russia is marked by a significant number of violent incidents caused by terrorist organizations, most of which have international roots.

The same situation happens in Xinjiang. According to the Chinese authorities, today there are several separatist groups in Xinjiang associated with the global Islamic terrorist network actively helping to fuel conflicts in China. It is known that many Uyghur are fighting in Syria on the side of terrorist groups (Minakova, Bukreeva, Golovin, and Bykovskaya, 2019).

In the North Caucasus, terrorism has strong connection with the geopolitical and geo-economic position of the region. The territory of the region has become an area of interests (national, economic, etc.) of such actors in world politics and economy as the United States, Turkey, China, and Iran. The North Caucasus is also included in the Virtual Caliphate (a quasi-state supposed to be created by certain terrorist movements). According to a popular, widespread 'the Three Seas Initiative', the South Caucasus (closely connected with the North Caucasian region of Russia) is a part of a wider region, which stretches forth the Mediterranean Sea inclusively (moreover, this increases the importance of the geopolitical and geo-economic position of the South Caucasus) (Ivanov, 2019).

In China, the Uyghur problem escalated after the collapse of the Soviet Union, when the Central Asian republics gained independence, it arouse the envy of the Uyghur minority population in Xinjiang: newly formed countries with a kindred Turkic culture turned out to be right next door to them. In those years, Afghanistan and Central Asia were tormented by Islamic extremists, and the Chinese Muslim population also conceived the idea of an armed religious struggle. The utopian dream of creating an independent state (East Turkestan or Uyghuristan) began to gain particular popularity due to the fact that economic development of Xinjiang was far behind Eastern China. The radical Islamists, as in Afghanistan, ideologically cultivated the illiterate population (Shanin, 2020).

The actors in world politics can confront each other using different means, even involving terrorist and separatist organizations. This moment is facilitated by the geographical location of the regions, some of which are border areas; it makes the state borders of China and Russia 'relatively transparent'.

In addition, the process of countering manifestations of international terrorism in the North Caucasus and Xinjiang is complicated by significant imbalances in the socio-economic development of the regions.

Yaroshenko (2016) identifies the main economic reasons conducive to the spread of terrorist ideology among different groups of the population, they are social and economic crises, decline in production, unemployment, deterioration of economic prospects for a significant part of the population.

According to Rosstat data (2018), personal consumption expenditures per capita in many territorial entities of the North Caucasian Federal District is significantly lower than the all-Russian value (Russia – 26,780 rubles, Ingushetia – 9360 rubles, Karachay-Cherkess Republic – 11,121 rubles). Undoubtedly, the revealed imbalances are not final and require additional research, which is carried out by some scientists. Shitova and Chihichin (2014) note the significant intraregional differences in the socio-economic development of the territorial entities of the North Caucasian Federal District (the situation will be different in urban and rural areas, in cities and towns, in suburban and peripheral villages).
A similar situation is observed in Xinjiang (see fig. 1). According to the rank, Xinjiang with an average personal consumption expenditure of 7,591 RMB is in 23rd place, the autonomous region is not only behind the developed eastern provinces of China (Zhejiang – 15,029 RMB, Guangdong – 13,113 RMB, Jiansu – 12,215 RMB, Fujian – 12,038 RMB, etc.), but also behind other autonomous regions (Inner Mongolia – 8,798 RMB, and Ningxia – 7,857 RMB).

Fig. 1: Rank of Chinese provinces and municipalities in terms of per capita personal consumption expenditures for the first half of 2020, RMB (Chen, 2020)

Both regions, the North Caucasus in Russia and Xinjiang in China, are developing regions, where multiconfessional and multiethnic component often leads to political and armed conflicts, used by international terrorist organizations for achieving their goals (directly or indirectly giving them a religious, political or ethnic overtones, and often camouflaging high priority economic goals).

As a result, the memories about settled conflicts are often passed down through several generations, and some conflicts become simmering or hidden. Ultimately, in case of relaxation of the political, economic and military influence of the central government in the region, terrorist and separatist movements intend to use these historical controversial situations.

Similar problems and prerequisites for manifestations of terrorism in Russia and China make international cooperation a necessary condition to ensure the national security of the countries. The priority area of bilateral cooperation between China and Russia is to conduct regular military exercises, which serve as a demonstration of a well-functioning mechanism of joint interaction and advanced level of professional performance in responding to terrorist threats. Counterterrorism exercises are held within the framework of the SCO events with the participation of all member countries of the organization, and separately between the armed forces of Russia and China.

The first large-scale international counterterrorism exercises 'Coopertion-2003' were held in August 2003 within the SCO in the territory of Kazakhstan and China (Xinjiang Uyghur Autonomous Region) with the participation of 5 member states of the organization, including China and Russia.

Since 2005, the bilateral Russian-Chinese military exercises 'Peace Mission' have been held annually. In 2012, Russia and China began to conduct the Maritime Interaction maneuvers. For the years of the existence of this naval interaction, bilateral exercises were staged in the Seas of Japan and Okhotsk (Russia) and in waters of the Yellow Sea, the East and South China Seas (China). In 2015, for the first time the naval exercises were conducted in 2 stages: the first stage took place in the Mediterranean Sea, the second one – in Primorye (Russia). In September 2019, the forces of the eight SCO member states conducted military exercise 'Center-2019'. This multilateral exercise demonstrated the readiness of Russia and the Central Asian states to protect national interests. Strengthening the military interaction became an important component of the objectives of the exercises (Bukreeva, 2020). The international counterterrorism exercises of the SCO member states 'Peace Mission-2020', originally scheduled for August 2020, have been postponed to 2021 due to the global spread of the coronavirus.

Conclusion

The spread of international terrorism and separatism in the North Caucasus (Russia) and Xinjiang (China) is determined by both general prerequisites (similar or suitable for certain regions of the world) and regional features, including a large number of particular factors. The development of counterterrorism policy, strategy or plan requires a multifactorial analysis and multi-directional state control over key factors and their dynamics. Developing bilateral counterterrorism cooperation, Russia and China must rely on such factors as geographical proximity and common interests, serving a stable platform for further interaction in fighting terrorism at the regional level.

Abstract

Recently, a lot of attention has been paid to the necessity to increase the quality of pre-gradual teacher training programmes at universities in Slovakia and to adapt their content to the current needs and requirements of students, the society and the labour market. DTI University in Dubnica nad Váhom, Slovakia, has implemented a new project focusing on the application of video microteaching as an innovation in teacher trainees' compulsory teaching practice, which can be realized both in the classroom and online. The purpose of the proposed paper is to draw attention to the benefits of video microteaching from the point of view of increasing the quality of teacher training and from the aspect of the organization of teaching practice which is getting more and more difficult. In the paper, the authors briefly introduce the above project under realization and point out the innovation in the content, as well as in the functional and conceptual focus of teacher trainees' compulsory teaching practice. Based on recently gained experiences and available research in this field, it can be stated that video microteaching appears to be a suitable, effective and attractive alternative to traditional classroom based observations and provides opportunities for recording and analysing lessons conducted by teacher trainees as well. Microteaching is also interesting from the aspect of the current pandemic, which highlighted the necessity to promote university education in the virtual environment.

Keywords: Video Microteaching, Teacher Trainees, Teaching Practice, Innovation.

Introduction

As it is generally accepted, in the context of education, teachers, their competencies (Gabrhelová, 2018), personality traits (Bilčík and Krištofiaková, 2019), and their preparedness for performing their job have an important role to play. Teacher training is focused on preparing future teachers (in our case vocational school teachers) for dealing with demanding tasks and requirements placed on them in the modern society and the needs of the labour market. Well-prepared teachers are able to respond to the needs of students and become important factors in the process of their students' personality development, throughout which their individuality, diversity, special needs, disabilities, but also talents must be taken into account.

Unfortunately, current experiences show that large groups of teacher trainees are unlikely to work as teachers in the future (Čepelová, 2019), which can represent a serious issue for the educational system. It is a clear signal that some measures must be taken and the attractiveness of the teaching profession must be increased. One of the possible pathways leading to increasing the teacher trainees' interest in becoming a vocational school teacher is providing them with positive teaching practice experiences, which have the potential to become a source of motivation for educating youth in schools. It is undeniable that positive experiences during pre-gradual studies increase teacher candidates' willingness to teach in the future despite the mental demands of this profession and teachers' low financial remuneration.

The current situation in the field of ensuring pre-service teachers' compulsory teaching practice in Slovakia

In the context of teacher trainees' compulsory teaching practice, two trends can be observed. One is related to the focus of teaching practice and the other one to the conditions of its realization.

Recently, it has come to certain changes as for the content and focus of teacher trainees' teaching practice in Slovakia. While in the past, it was focused on practicing certain pedagogical tasks (Spilková, 2003; Hlásna et al., 2005); recently, self-reflection, as well as creating a link between theory and practice are more accentuated (Geršicová, 2008; Geršicová and Tóthová, 2008; Geršicová and Adamík-Šimegová, 2012; Bizová et al., 2016). It can be considered a positive shift but, unfortunately, some barriers to the realization of teacher trainees' teaching practice in vocational schools have occurred both on the side of schools and on the side of teacher trainees.

Some universities providing teacher training have signed contracts with schools where teacher trainees can carry out their teaching practice but it must be pointed out that finding a school open to cooperation is more and more difficult. Although these schools welcome teacher trainees, their teachers are not able to devote them as much time as expected because of several reasons:

- There is a lack of well-qualified and experienced teachers willing to take part in the realization of teacher trainees' teaching practice.
- Teachers are not sufficiently financially motivated as, in their contract, the maximum amount of working hours is specified.
- Teachers' busy timetables and other duties do not allow them to spend enough time with teacher trainees.
- The management of teacher trainees' teaching practice is demanding.
- There is a lack of a clear guidance regarding the realization of teacher trainees' teaching practice in schools.

There is still a large group of teacher trainees who want to or must find a school where they can undergo their compulsory teaching practice by themselves. In many cases, it shows to be a demanding task and teacher trainees must deal with several problems, including teachers' unwillingness to work with teacher trainees, locality of available schools, problems with distance and costs (commuting), time, and their inability to synchronize their other duties with the realization of teaching practice.

The issues of teaching practice have been dealt with by a number of experts in Slovakia (e.g. Spilková, 2003; Geršicová and Gubricová, 2014; Danek, 2019) in two contexts: the teaching practice of teacher trainees and of practicing teachers. The theoretical and application level of teacher trainees' teaching practice has currently been dealt with by e.g. Matúšová, Prusáková, and Slaboňová (2018), who focused on vocational didactic modules in teaching practice, while Sirotová (2018) paid attention to student portfolios and their role during a university student's – a future teacher's – teaching practice. Lobotková (2018) described teaching practice as a motivation factor for teachers-to-be; and also other authors – e.g. Sirotová and Michvocíková (2019); Michvocíková (2019); Severini, Kostrub, and Yuzyk (2019); Danek (2019) – dealt with the issues of teacher trainees' teaching practice. In their work, Kancír and Madziková (2018) focused on teaching practice from the point of view of the development of practicing teachers' key competencies and introducing innovative trends in field didactics; and Szíjjártóová and Kramáreková (2019) consider it a tool for increasing the quality of teachers' education. From the aspect of the presented topic, an important finding is that virtual platforms are not much used in the context of teacher trainees' teaching practice in Slovakia (Geršicová and Gubricová, 2014).

Microteaching

Microteaching is a teaching method applied in teacher training, a part of which is formed by video records of teaching (lessons and teaching units) with the aim to gain a constructive feedback from another student, a mentor, a teacher, or a group of students about things that worked well and opportunities for improvement in the field of didactic skills. Microteaching as such is nothing new, in the mid-60s, this didactic method was introduced by D. W. Allen at Stanford University and, subsequently, it found its application in all forms of teacher training. Watching a video record of teaching and getting feedback from practicing teachers and students, provides a teacher (or teacher trainees during their teaching practice) with a good picture of the lesson and enables carrying out a detailed analysis of intentionally selected lessons, teaching units, their sequences, but also vocational school students' vocational training and so, to optimize teacher trainees' experiences with the realization of the educational process (Barnová and Krásna, 2019c). Moreover, the results of a survey on microteaching (Hattie's survey within the Visible Learning project) – showed that microteaching ranked 6th among the most effective didactic methods contributing to the improvement of students' skills (Waack, n.d.).

Video microteaching in teacher trainees' teaching practice

With introducing video microteaching into teacher training, innovation stands on two pillars – using media and transformation (changing from student to teacher).

Application of digital technologies in modern schools is a must nowadays (Barnová and Krásna, 2018a,b,c; Barnová and Krásna, 2019a,b,c; Krásna and Barnová, 2018a,b; Krásna and Barnová, 2019, Rybičková and Hasajová, 2007) and, undoubtedly, videos help create a link between university courses focusing on the didactic and methodical aspects of vocational school and practical training teachers' pre-gradual training (Pasternáková and Lajčin, 2012) with the everyday practice in vocational schools. The basic requirement when creating videos with the aim to innovate the concept of university courses, is focusing on the didactic and methodic aspects and ensuring compliance with the national curriculum policy, as well as the everyday educational practice in vocational schools.

In the process of transformation of a student into a teacher, video records of teaching units with experienced teachers of vocational subjects and with experienced teachers of practical training, as well as records of their own teaching practice can serve as a motivation factor and also provide students with opportunities for self-reflection and self-evaluation.

The advantages of introducing video microteaching as one of the alternative forms of teacher trainees' teaching practice are as follows:

- Video records can help university students understand how they can create a link between the theoretical knowledge gained during their studies and the reality of educational practice in schools.
- In vocational schools where teaching practice is carried out, practicing teachers are given the opportunity to build professional relationships with their future colleagues.
- Teachers taking part in teacher trainees' teaching practice are "forced" to keep pace with up-to-date knowledge from field didactics.
- Teachers get useful feedback from external students currently employed as teachers of practical training in other schools, which they can use for their own development and they are also provided with an opportunity to exchange experiences.

From the aspect of increasing the quality of teaching practice, implementation of microteaching brings several benefits. If compared to traditional classroom observations, video records or their selected sequences can be viewed and analysed several times by several individuals from various places and at any time. When microteaching is used, special attention can be paid to every detail, every step, word, and the procedures applied by the teacher in the context of achieving the teaching unit's goals. The essence of microteaching lies in discussing the procedures, methods, and the organization of teaching. Video records of lessons conducted by teacher trainees and their detailed analysis form an important part of their teaching practice, too, as they enable them to reveal their weaknesses, to evaluate the efficiency of the selected procedures, to suggest suitable methods, and, also space for role plays is created. Another proof of the efficiency of microteaching is that in the process of analysis, student assessment, pedagogical diagnostics, the teacher's non-verbal communication, the changing atmosphere during the lesson, etc. can be focused on.

Project on introducing video microteaching as a part of teacher training programme

In accordance with its mission, the aim of DTI University in Dubnica nad Váhom, Slovakia – being a private educational institution – is to permanently increase the quality of services provided to its students, to implement modern, effective and innovative forms and methods of education, and to make its study programmes more accessible to everyone. Therefore, the University's intention is to provide its students with alternatives in the form of distance learning opportunities. In this context, DTI University has decided to realize a project focusing on the implementation of video microteaching into teacher trainees' compulsory teaching practice. The project is focused on the innovation of classroom observations by students in the Bachelor's and Master's study programmes in the field of Teaching vocational subjects and practical training by means of the application of video records, (self)reflection and portfolios. It is targeted on the development of DTI University students' professional, practical and application skills, which are needed in the process analysing videos recorded in the classroom – especially during vocational subject lessons, but also during practical training in vocational schools. The outputs of the project can be used as a source of help for mentors during teaching practice and the creators of the University's concept of teaching practice, where classroom observations form a part of teaching practice.

At the stage of project preparation, an analysis of university students' needs and their experiences with classroom observations during their teaching practice was realized. The findings were compared with the findings of the analysis carried out at the Faculty Education of Trnava University (Bizová, Geršicová et al., 2015), where also video records

of lessons were applied. The results show that using video records for the purposes of classroom observations can be considered a suitable, innovative, attractive, rational, and effective solution for teacher trainees, including DTI University students.

Based on the results of the analysis of classroom observations within students' teaching practice, the following objectives of the project were formulated:

- To work out a concept of basic thematic units for university courses, which require reflection on teaching situations in order to create a link between theoretical knowledge and the educational practice;
- To create the content of the set of lessons, teaching units, and educational situations corresponding with the educational goals, explain how it can be used for the development of students' critical thinking, (self)reflection, and make video records in collaboration with selected vocational schools.
- To process the video records for the purposes of instructional courses and make them available online.
- To design methodical materials with video records of lessons, teaching units, and educational situations for instructional courses and to make them available online.
- To work out a portfolio containing the results of future teachers' and practicing teachers' (self)reflection activities as one of the possible approaches to the innovation of students' teaching practice.

Creating a series and a database of video records representing typical teaching situations modelling problem aspects of teaching can significantly help in the organization and realization of teacher trainees' teaching practice and increase the quality of their reflective ability for analysing lessons and pedagogical situations. By means of video records, university students' analytic and divergent thinking processes can be developed. They can analyse the basic methods, forms and principles of teaching, the content of the lesson, problem situations and suggest possible solutions. Video records also contribute to the development of students' (self)reflective thinking (Schön, 1987) and, by means of them, a link between theoretical knowledge and the educational reality is created.

The outputs of the project under realization will contain the following:

- a set of lessons, teaching units, and educational situations representing the educational goals and developing students' (self)reflective thinking,
- video records of lessons, teaching units, and educational situations in collaboration with vocational school teachers,
- video records processed for the purposes of instructional courses,
- methodical materials for basic instructional courses,
- framework of criteria for self-evaluation as a means of quality of education.

Video records have the potential to increase interactivity in pre-gradual teacher training, as well as its accessibility due to the flexibility and effectiveness of their application and the fact that they enable highly personalized, individualized and own-paced learning based on the needs of every student.

Video microteaching in the context of school closures

One of the mail goals of DTI University is to make education provided at this institution more flexible, individualized, personalized, accessible and affordable to its current and potential students. Implementation of video microteaching helps the University achieve this goal as recorded lessons or pedagogical situation can be well analysed online, where there are no restrictions as for teacher trainees' location or time.

The benefits of microteaching for both students and universities could be clearly observed when it came to massive school closures during the COVID-19 pandemics in spring 2020, when teacher trainees neither had opportunities to observe lessons nor to teach in classrooms. In that situation, video records and their analysis represented the only way of completing the compulsory course of teaching practice. The results of this unexpected and unintended experiment showed that under specific circumstances, video microteaching has the potential to replace teaching practice in schools to a certain extent.

Conclusion

Video microteaching – despite its undeniable benefits – is not frequently used for the purposes of teacher training in Slovakia. DTI University in Dubnica nad Váhom – as a reaction to the changing needs and requirements of teacher trainees, schools, the Slovak educational system and the whole society – has made the decision to realize a project within which video microteaching is applied for the purposes of teacher trainees' teaching practice. Taking into account the current trends in education and the rapid development of digital technologies, introduction of innovations

is a must. It not only increases the quality of pre-gradual teacher training but highly individualized and personalized forms of learning increase the teacher trainees' motivation to continuously develop their skills and to opt for the teaching profession in the future. It must be also noted that sufficiently developed didactic competencies during teacher trainees' teaching practice can be a source of teacher trainees confidence in the direct educational practice. For the above reasons, it can be assumed that the project under realization has the potential to broaden knowledge in the presented field and provides an opportunity for the implementation of its outputs into pre-gradual teacher training programmes.

Abstract

The aim of the research study is to compare traders in the level of coping strategies from the viewpoint of type of education (humanistic and economic university education) and age of traders (traders younger than 40,99 years and traders older than 41 years). Research sample consisted of 143 participants aged from 18 to 65 years (average age was 35.235 with standard deviation of 2.432). Czech version of the German Stress coping style questionnaire SVF 78 (Janke, Erdmann 2003, Janke & Erdmann, 2002) was used for measuring coping strategies. T- test for two independent samples did not find statistically significant differences between traders with humanistic university education and traders with economic university education. The comparison of means of differences found statistically significant differences in the level of substitutional satisfaction (p=0.025). Statistically significant differences were found in the level of guilt rejection in the context of age.

Keywords: coping, coping strategies, business, trader

Introduction

The research study deals with the issue of coping strategies from the viewpoint of education and age of traders. Coping is defined as „constantly changing cognitive and behavioral effort to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person“ (Lazarus, Folkman 1984 p .141)

Coping and coping strategies

Coping is defined by Křivohlavý (1994) as an effort to minimize, tolerate, manage or reduce unusually hign, buredsome or strenuous requirements of the internal or external environment, as well as various conflicts between the given requirements. Lazarus and Folkman (1984) and Compas et al. (2001) definitions of coping highlight the role of coping as a process of responding to stress. Further, both definitions emphasize coping as a controlled, effortful process; that is, responses that require conscious, purposeful, and intentional thoughts and behaviors (Compas et al., 2017). Lazarus distinguished between two general types of coping. The first, termed problem-focused coping, is defined as problem solving or doing something to alter the source of the stress. The second, termed emotion-focused coping, is aimed at reducing or managing the emotional distress that is associated with the situation. These responses are different from each other, and they may have very different implications for a person's success in coping (Carver, Weintraub, Scheier, 1989).

Bartuňková (2010) divides coping techniques into active and passive. Active coping techniques include sublimation, aggression, compensation, identification and behavioral attention. Passive techniques include

reggresion, denial, isolation, escape to solitude, secpae to illness or daliy dreaming. The choice of individual coping strategies depends on several factors, and as Scheier and Carver (1985) point out, positive coping strategies can have consequences for how traders cope with work stress that is a part of their daily functioning (Lazarus, Kanner, Folkman, 1980; Reker, Wong, 1985). Theoretical postulates provide us with a basis for the formulation of hypotheses and subsequently for interpretation of research findings.

Research Methodology

The main goal of the research study is to compare traders in the level of coping strategies from the viewpoint of type of education (humanistic and economic university education) and age of traders (traders younger than 40,99 years and traders older than 41 years).

We assume the existence of statistically significant differences between traders with humanistic university education and traders with economic university education in the level of coping strategies.

We assume the existence of statistically significant differences between traders younger than 40,99 years and traders older than 41 years in the level of coping strategies.

We assume the existence of statistically significant differences between employees with humanistic university education and economic university education in the level of coping strategies in the context age.

Research Sample

Research sample consisted of 143 participants aged from 18 to 65 years (average age was 35.235 with standard deviation of 2.432). Research sample consisted of traders younger than 40,99 years (75 participants) and traders older than 40,99 years (68 participants). The proportionality of genders was uneven- the sample contained 86 women and 57 men. The research sample consisted of traders with humanistic university education (47 respondents) and traders with economic university education (53 respondents). 43 respondents disposed with technical and science university education employees with secondary education (84 participants) and employees with university education (56 participants). The research instrument administered in print form to traders working in private sector in Prešov and Košice County during March 2019. Employees completed questionnaire during work break. It took approximately 20 minutes to complete the questionnaire.

Research Methods

Czech version of the German Stress coping style questionnaire SVF 78 (Janke, Erdmann 2003) used for measuring coping strategies. Stress coping style questionnaire contains 78 statements about dealing with stress and using coping strategies. The respondent evaluates each item using a 5-points Likert scale, ranging from “Not at all” to “Very likely”. The 78 items are divided into 13 subscales, each represent a particular way of reacting to a stressful event: Underestimation, Guilt rejection, Tilt, Substitutional satisfaction, Control of situation, Control of reaction, Positive self-instruction, Need for social support, Active avoidance, Flight tendency, Rumination, Resignation, Self-blaming. Internal reliabilities for the 13 subscales range from $\alpha = 0.77 - 0.94$

Research Results

The comparison of differences in the level of coping styles in the context of type of education and age of traders were assessed by using statistical method t-test for two independent samples and processed in statistical program IBM SPSS 20.00 Statistics. Table 1 shows comparison of means in the level of coping styles in the context of type of education.

Table 1: Comparison of statistically significant differences in the level of coping style of traders in the context of type of education

	Type of university education	n	Mean	Standard deviation	t	Degree of freedom	p
Self-blaming	Humanistic	47	3.184	0.751	-1.162	98	0.248
	Economic	53	3.010	0.751			
Resignation	Humanistic	47	3.445	0.685	-0.849	98	0.398
	Economic	53	3.330	0.686

The comparison of means is not statistically significant. T- test for two independent samples did not find statistically significant differences between traders with humanistic university education and traders with economic university education. Table 2 shows comparison of means in the level of coping styles in the context of age of traders.

Table 2: Comparison of statistically significant differences in the level of coping style of traders in the context of type of age

	Age	n	Mean	Standard deviation	t	Degree of freedom	p
Self-blaming	Under 40.99	75	3.033	0.841	-1.287	141	0.200
	More than 41	68	3.203	0.729			
Resignation	Under 40.99	75	3.330	0.707	-0.735	141	0.464
	More than 41	68	3.417	0.721			
Rumination	Under 40.99	75	2.680	0.905	-0.195	141	0.845
	More than 41	68	2.708	0.820			
Active avoidance	Under 40.99	75	2.246	0.727	0.710	141	0.479
	More than 41	68	2.159	0.743

	More than 41	68	2.880	0.623			

Source: (own proceeding)

The comparison of means of differences is statistically significant in two cases. Statistically significant were found in the level of substitutional satisfaction (p=0.025). Traders older than 41 years dispose with higher level of substitutional satisfaction than traders younger than 40.99 years. Statistically significant differences were found in the level of guilt rejection in the context of age. Traders younger than 40.99 years dispose with higher level of guilt rejection than traders older than 41 years. T- test for two independent samples did not find statistically significant differences in other coping strategies.

Discussion and Conclusion

Research found statistically significant differences in the level of substitutional satisfaction. Traders older than 41 years dispose with higher level of substitutional satisfaction than traders younger than 40.99 years. Previous research by Aldwin (1991) showed that older adults are less likely to perceive stressful episodes as controllable, they should also be less likely to use instrumental action and more likely to use palliative or avoidant coping strategies. Substitutional satisfaction is considered as avoidant coping strategy and our findings that older traders dispose with higher level of subsitutional satisfaction are consisted with previous research by Aldwin (1991). Frankovský and Ištvániková (2008) poit out the fact that managers and traders get into problematic situations on a daily basis and in solving they need to mobilize all their forces, sometimes with less success in managing them and there are also cases where they fail in these situations and in this case, they choose negative ways of coping.

Statistically significant differences were found in the level of guilt rejection in the context of age. Traders younger than 40.99 years dispose with higher level of guilt rejection than traders older than 41 years. T- test for two independent samples did not find statistically significant differences in other coping strategies. For example, the Vaillant (1977) study mentioned earlier found that middle-aged men in the Grant study used fewer neurotic and immature defense mechanisms and more mature strategies, in contrast with their youthful selves (Aldwin, 1991). Our findings are in line with previous research by Vaillant (1977), because guilt rejection is consider as a less mature coping strategy.

Limitation of research study is occasional selection of participants and the research sample is not representative. The research results can be considered as the preliminary findings. Coping strategies are a prerequisite for coping with work- related stress placed on traders in their work. The research confirmed statistically significant differences in the level of two coping strategies in the context of age.

Acknowledgment

The research project presented in this article is supported by grant project 1/0807/19 – VEGA (Research on the determinants of trading behavior and marketing effects in the area of neuromarketing and the relation to neuro-linguistic programming).

Abstract

Not only functionality and price, but also the overall design (material and method of packaging) affect the customer and his experience with the product as a whole. The application of the principles of neuromarketing can provide an excellent insight about the final design of products and its emotional effects on the customer. The motive for buying products may also be that the product evokes a certain idea of consumer prestige, is associated with a certain symbol with which the consumer wants to identify. The result of neuromarketing is effective marketing communication, set according to real brain reactions and optimization of the product itself as a whole. If we buy a product, we are interested as a whole - brand, material, packaging, price, location, promotion. The product as a whole evokes emotions in us. The aim of the paper is a theoretical summary of product policy and neuromarketing, as well as identifying differences in the perception of quality and selected forms of promotion, which significantly affect the shopping behavior of Slovak consumers.

Keywords: Product Policy, Neuromarketing, Consumer, Business Behavior.

Introduction

Marketing is an important tool for achieving business goals. It takes place in market economy conditions, where market demand and supply meet. Many companies, large and small, began to realize the need and importance of marketing and therefore decided to adapt their business philosophy to marketing, respectively. gradually change your corporate philosophy to marketing. It is characteristic of the current rapid pace of market development that companies are waging a competitive struggle in which they are fighting for customers. There are currently a number of definitions, wordings and versions of the term marketing. One common feature for all these definitions is the customer and the satisfaction of his needs (Rajan, 2005).

Neuromarketing is a combination of neuroscience, psychology, and economics, involving the practical application of neuroscientific knowledge and techniques (often derived from consumer neuroscience) to obtain company-specific marketing information (Hubert and Kenning, 2008; Camerer and Yoon, 2015; Shaw and Bagozzi, 2017; Nuñez-Gomez et al., 2020), and to measure the impact of commercial communication (Madan, 2010; Mañas-Viniegra et al., 2020). Neuromarketing helps researchers to overcome the limitations encountered in studying decision-making processes when consumers respond to brands. It also helps us to understand the processes that inform perceptions of advertising (Baron et al., 2017).

Literature Review

Blythe and Zimmerman (2005) define a product as an offer of a company that satisfies the needs of customers. Customers look for benefits when buying and are willing to say goodbye to valuable things, including money and their time, in exchange for gaining these satisfaction. This includes the basic product and benefits, the value that the customer actually buys, and product attributes that include the brand name, design, country of origin, price and packaging as well as support services such as delivery, installation and warranty.

Cite this Article as: Tatiana Tatiana PETHÖ, Róbert ŠTEFKO and Jaroslava GBUROVÁ "Neuromarketing And Product Policy from The Perspective of the Slovak Consumer" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The product is evaluated from two sides, from the point of view of the buyer, where it is such a performance or object that is able to satisfy one wish or one need. The other side is the manufacturer and what it can offer on the market. These are usually services, goods or solvable problems (Štefko et al., 2012; Nastišin, 2018). The product in its unaltered form cannot be successfully offered on the market indefinitely. The reason is the constantly changing marketing environment of each company (changes in customer requirements, changing possibilities of the company, the arrival of new competitors, the emergence of new technologies, etc.). Take timely measures in the area of product policy (eg. the need to improve existing products, withdraw products from sale, development of new products, etc.), but also in the area of other tools of the marketing mix allows the company to monitor the product life cycle (Srpová et al., 2010 ; Wijonarko et al., 2019).

According to Machkovej (2015) the mark can take various forms and can be represented graphically, verbally or spatially. A mark is a complex symbol that can be expressed by different symbols at different levels of meaning. The brand identifies the manufacturer of the products and brings a number of benefits not only to the consumer but also to the owner of the brand. The value created for the customer is enhanced by the style and design of the product. Design is an important marketing element and represents a broader concept than style. The style is more related to the appearance of the product and the design has a much deeper core, which relates to the very basic function of the product. The design of the product helps to the functionality, usability and operation of the product, as well as its appearance. It can give the manufacturer a strong competitive advantage in the target market and is considered a good marketing tool for building a brand, as it helps consumers to distinguish often similar products. Only a very small number of managers can distinguish between design and value (Kotler et al., 2007).

The packaging is an important part of the implementation phase of the marketing algorithm and should reflect the ideas of the manufacturer and is a visual and physical proof of the product. The significance of packaging lies in the fact that it transmits a message about its own product, brand, in which category it is included, addresses a typical customer or promotes the benefits of the product (content). The public and consumers should be made aware of the product, its uses and benefits. Businesses are aware of the power of good packaging in creating instant knowledge of the brand and business to consumers. High-quality and correctly innovated packaging brings a competitive advantage. On the other hand, improperly designed packaging reduces the company's sales and worries consumers. For this reason, it follows that poor communication through packaging leads to bankruptcy (Šalgovičová, 2001).

Through neuromarketing research, we can obtain information on two areas: polarity and activation. Emotional polarity indicates both positive and negative fluctuations from zero, ie the extent to which the respondent likes the shot or not. The activation curve indicates the ability of the stimulus to arouse a stronger, less variable emotion, ie interest in the product. Thus, the research agency thus obtains information on the extent to which the spot can influence purchasing decisions. The course of neuro curves must be examined and compared with the results of in-depth interviews and focus mainly on those areas where different data are measured (Tahal et al., 2017).

Neuromarketing is a combination of Neuroscience, Psychology and Economics (Madan, 2010). Despite being an emerging field that appeared in 2002, it has rapidly gained credibility in recent years (Morin, 2011). Neuromarketing has expanded its scope beyond measuring the effectiveness of brand advertising campaigns and the psychology of consumer behaviour (Lee et al., 2007; Plassmann et al., 2012). Hence, some authors consider that the most appropriate term is Neurocommunication (Cuesta-Cambra et al., 2017; Manas-Viniegra, Nunez-Gomez, Tur-Vines, 2020).

The main advantage of neuromarketing is the ability to test the impact of communication on an individual's emotions. Unlike other methods, depending on the extent to which and what respondents are willing to reveal about themselves, neuromarketing measures the actual survival of a given activity by individuals at the moment of contact with the stimulus tested. As already mentioned, neuromarketing is used in combination with interview, and it is with this traditional method of market research that it is most effective. This is also because it can elucidate many reasons for behavior (Tahal et al., 2017). Among the announced disadvantages of neuromarketing is the fact that it is inappropriate and problematic to apply in the preparatory phase of research, where the emotional response is much lower. Neuromarketing research is very expensive. This is due to the technological equipment needed for this research, but also to the prices of the services of neuromarketing agencies. According to Bennett (2011), it is first necessary to determine the price of neuromarketing research in order for a firm to consider whether such research is worthwhile. The costs are usually very high and therefore only large companies can afford this research. It is important to compare what results we get from this research and what we can get from alternative forms of research. The biggest negative of the use of neuromarketing is the weak regulation in the field of ethics. The magnetic resonance method allows you to monitor the activity of the whole brain without the possibility of privacy. A lie detector is easier to deceive than modern imaging devices. This means that one has no right to any privacy, one cannot hide any thoughts. Of course, research is always attended by volunteers who are fully aware of the risk associated with the experiment (Fronková, 2016).

Methods and Methodology

The aim of the research was to identify differences in the perception of quality and selected forms of promotion, which significantly affect the shopping behavior of Slovak consumers. The object of the research was consumers living in the region of eastern Slovakia. The selection of the survey sample was carried out by random selection in the form of a questionnaire. The obtained primary data were subsequently processed in the statistical program Statistica.

To determine the goal of the research, we set the following hypotheses:

H_1: We assume that there are statistically significant differences in the perception of satisfaction with the quality of purchased products in the Slovak Republic depending on the gender of the surveyed respondents.

H_2: We assume that there are statistically significant differences in the impact of selected forms of product promotion on consumer shopping behavior depending on the gender of the surveyed respondents.

Survey Results

The research sample consisted of a total of 166 respondents. Based on the processed results, we can state that the largest share in the research has respondents aged 18 to 30 years, 77 (46.39%), followed by respondents aged 41 to 50 years in the number of 35 (21.08%), from 31 to 40 years with the number of 29 (17.47%) and from 51 years and above 25 (15.06%).

As far as completed education is concerned, of the respondents, most respondents have completed tertiary education I. level 58 with a share of 34.94%, secondary education with a high school diploma of 52 and a share of 31.33%, higher education II. and III. degree 30 with a share of 18.07%, secondary school without a GCSE 22 with a share of 13.25% and basic education 4 with a share of 2.41%. The research involved 89 interviewed women and 77 interviewed men. Women formed a larger group with a share of 53.61% and men 46.39%.

In the questionnaire, we asked the respondents how they search and buy products on the market. Respondents could choose from 4 closed answers or from the opportunity to express their own opinion. Out of 166 respondents, up to 97 (58.43%) respondents search for and buy products of this company in the retail chain, 39 (23.5%) in retail, over the Internet 20 (12.05%), from the known 10 (6.02%) and none of the respondents used the other option.

Price is one of the psychological factors that influences the shopping behavior and shopping decisions of consumers, so the next question we wanted to find out whether the respondents prefer quality over price. Respondents chose from a five-point Likert scale, from the option definitely yes - 5, rather yes - 4, I don't know - 3, rather no - 2 and definitely no - 1. Within the above question, up to 63 (37.95%) respondents marked the answer earlier not. This means that when buying products, respondents watch their prices rather than quality. Of the 166 respondents, 47 (28.32%) respondents, on the other hand, prefer quality over price. Answers were definitely not marked by 24 (14.46%) respondents, definitely by yes 18 (10.84%) and I do not know the answer by 14 (8.43%) respondents.

The aim of our research hypothesis H_1 was to determine whether there are statistically significant differences in the perception of satisfaction with the quality of purchased products in the Slovak Republic depending on the gender of the surveyed respondents. The results are processed in the tables below.

Table 1: Contingency table - gender of respondents versus quality of services

			Are you satisfied with the quality of the products provided?					Total
Likert scale			5	4	3	2	1	
Gender of respondents	Man 1	n	25	37	9	5	1	77
		%	15,06 %	22,29 %	5,42 %	3,01 %	0,6 %	46,39 %
	Woman 2	n	18	50	13	8	0	89
		%	10,84 %	30,12 %	7,83 %	4,82 %	0 %	53,61 %

Total	n	43	87	22	13	1	166
	%	25,90 %	52,41 %	13,25 %	7,83 %	0,6 %	100 %

Source: Own elaboration

Based on the results processed in Table 1, the answers of the respondents (men and women) to the question related to satisfaction with the two services provided are given. Respondents had the opportunity to choose from a five-point Likert scale, from the options definitely yes - 5, rather yes - 4, I do not know - 3, rather no - 2 and definitely no - 1. Number of important groups of women number 89 and men 77. Possibility to decide yes chose 25 men and 18 women, rather yes 37 men and 50 women, I do not know 9 men and 13 women, rather not 5 men and 8 women and the last option definitely marked only 1 man.

Table 2 : Chi-square test - gender of respondents versus quality of services

Likert scale			**5**	**4**	**3**	**2**	**1**	**Total**
Gender of respondents	**Man**		19,94578	40,35542	10,20482	6,03012	0,463855	77
	Woman		23,05422	46,64458	11,79518	6,96988	0,536145	89
Total			43,00000	87,00000	22,00000	13,00000	1,000000	166

Table 3: Summary table: Expected numbers

Pearson's chi-quadrant	4,65852
Sv	4
P	0, 324163

Source: Own elaboration

The value of the probability captured by Table 3 is p = 0.324163. The level of significance at which we verified the hypothesis, t. j. α = 0.05 is less than the probability value, so the relationship found is not statistically significant. We reject Hypothesis 1 and we can state that there are no statistically significant differences in the perception of satisfaction with the quality of purchased products in the Slovak Republic depending on the gender of the surveyed respondents.

The main task of marketing and marketing communication is to know the customer, reveal his needs and wishes, communicate with him and important for the company itself is feedback. The aim of the company is to offer its consumers the greatest possible value. With a suitable marketing strategy, the company builds its competitive position in the market. An organization that currently wants to succeed in the market must monitor and evaluate competition, adapt its product or service offering to market changes, and be able to reach a large number of users.

Promotion is one of the tools that influences consumers' shopping behavior and shopping decisions. For this reason, in the second research hypothesis H_2, we focused on finding out whether there are statistically significant differences in the impact of selected forms of product promotion on consumer shopping behavior depending on the gender of respondents. Respondents could choose one of the options in the questionnaire, which were selected forms of promotion, namely: 1 - Sales promotion, 2 - Advertising, 3 - Personal sales, 4 - Internet, 5 - Social networks, 6 - Direct marketing, 7 - New trends in marketing communication. We used Pearson's Chi-square test of independence for verification.

Table 4: Contingency table - gender of respondents versus choice of form of promotion

			Which of the following forms of promotion do you consider to be the most effective?							Total
Selected forms of promotion			**1**	**2**	**3**	**4**	**5**	**6**	**7**	
Gender of respondents	**Man 1**	N	23	13	12	11	3	10	5	77
		%	13,86%	7,83%	7,23%	6,63%	1,8%	6,02%	3,01%	46,39%
	Woman 2	N	38	13	12	7	4	8	7	89
		%	22,89%	7,83%	7,23%	4,22%	2,4%	4,82%	4,22%	53,61 %
Total		N	61	26	24	18	7	18	12	166
		%	36,75 %	15,66%	14,46%	10,84%	4,22%	10,84%	7,23%	100 %

Source: Own elaboration

In Table 4, we capture how men and women answered the question asked. Respondents chose from 7 options offered. The larger group consisted of women 89 and men 77. Of the 166 respondents 61 (36.75%) of respondents, the answer was sales support, 23 men and 38 women. The same number of women and men 26 and the Internet 12. marked answer was social networks with a share of 4.22%

Table 5: Chi-square test - gender of respondents versus choice of form of promotion

Selected forms of promotion		**1**	**2**	**3**	**4**	**5**	**6**	**7**	**Total**
Gender of responden	**Man**	28,295	12,060	11,132	8,349	3,246	8,349	5,566	77
	Woman	32,704	13,939	12,867	9,650	3,753	9,650	6,433	89
Total		61,000	26,000	24,000	18,000	7,000	18,00	12,00	166

Source: Own elaboration

Table 6: Summary table: Expected numbers

Pearson's chi-quadrant	0,43151
Sv	6
P	0,618492

Source: Own elaboration

The value of the probability captured by Table 6 is p = 0.618492. The level of significance at which we verified the hypothesis, t. j. $\alpha = 0.05$ is less than the probability value, so the relationship found is not statistically significant. We reject the hypothesis and can conclude that there are no statistically significant differences in the impact of selected forms of product promotion on consumer shopping behavior depending on the gender of the respondents.

Conclusion

Every day, companies are fighting for the favor of customers, and therefore in order for a company to function, it must use all possible ways to gain a competitive advantage. The basic element of business is the product and it is no longer enough just to produce and wait for who to buy the product, but it is necessary to know which products suit the customer. The product strategy is important in terms of long-term, comprehensive and effective operation in the global and global market. Product policy is part of the marketing mix and its task is to analyze, plan, implement and control product decisions. There is a very diverse competitive environment in the market in which products are lost

and indistinguishable. The organization's priority is to create and find its place in the market and gain the favor of consumers. The result of a good product strategy is customer satisfaction as well as organization.

Neuromarketing can confirm, reconfigure, or improve the conventional theories of marketing theory. The classical methodology of market research that we are already familiar with is incomplete because it can only probe the consumer's consciousness, but not his subconscious. Some might say that such studies are also made in the forms of classic marketing, but the tools used in neuromarketing are brain scanners that use magnetic resonance imaging. All this is done in order to determine the exact reactions of the potential consumers (Gurgu, Gurgu, Tonis, 2020).

Neuromarketing combines marketing, neurology, psychology or sociology. Marketing is basically anything that helps to get a product / service to the attention of customers, remember it / it and ultimately sell it. Neuromarketing incorporates knowledge from human behavior research into this process - which products / services and why customers perceive them more attractive than others.

The article was prepared within the framework of the State Assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 1.13.20 F "Conceptual basics for ensuring the economic security of the Russian Federation in the context of digitalization: outlines of spatial transformations").

Abstract

The current stage of development of society is characterized by an increasing role in the field of information. Currently, technical means allow for the collection and processing of significant amounts of socially significant data necessary for the effective functioning of state mechanisms, the flow of public processes, and the implementation of human rights. Increasing the vulnerability of people's private lives and creating threats to illicit trafficking in personal data is facilitated by the intensive development of automated technologies in the field of information processing and transmission, their introduction into all social spheres of society. Proper legal regulation of this process should maintain a balance of interests of participants in information turnover and to some extent compensate for the increase in the effectiveness of modern technologies used in cross-border transfer of personal data.

For both Russian and foreign legislation and legal doctrine, the task of legal protection of personal information becomes particularly relevant in the context of active development of open information systems that significantly simplify the leakage and other forms of illegal use of personal data.

In this article, we consider the legislation on personal data of the member States of the Eurasian economic Union in terms of personal data security during cross-border transmission in the integrated information system of the EAEU. Problems related to the comprehensive state approach of the EAEU member States in the field of protection of the rights of personal data subjects are identified.

Keywords: personal data, EAEU, cross-border transmission, integrated information system, cryptographic security of information

Introduction

In the legislation on personal data (hereinafter PD) of Russia and the Republic of Armenia, the categories "personal data" are similar and represent any information or information related directly or indirectly to a specific or identifiable individual. The legislation on personal data of the Republic of Kazakhstan and the Kyrgyz Republic

Cite this Article as: Natalia E. DERKACH, Olga I. SOLODUKHINA , Svetlana A. STARYKH, Alexey N. BOROZDIN and Mariia A. GOLOLOBOVA "The Security of Personal Data during Cross-Border Transmission in the Integrated Information System of the EAEU in the Context of the Digitalization of the Economy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

additionally includes in the concept of "personal data" information and information about the subject of personal data recorded on a tangible medium (paper, electronic or other). In the Republic of Belarus, there is no basic law on personal data, but a draft law "on personal data" has been developed, which treats "personal data" by analogy with the legislation on personal data of Russia and the Republic of Armenia.

PD is information of limited distribution (confidential information) and is not subject to transmittal and distribution to third parties without the consent of the PD subject, except in cases established by the legislation of the EAEU member States, as well as when the PD subject independently or personally considered it necessary to place the PD In the public space.

It should be noted that among other types of confidential information, PD Is the most sensitive, since it directly affects the rights and freedoms of a person and citizen and includes many identification features: direct and indirect, which can be used to determine the subject of PD. In this connection, the measures to ensure the security of PD differ in their content and composition from the measures taken to ensure the security of other types of confidential information, although there are similar points.

The measures taken to ensure the security of PD may differ significantly in different countries, depending on the category of PD, the established levels of security of PD information systems, the adopted standards for information security and, in general, on the state approach to protecting this type of processed information.

The purpose of the study is to analyze the legislation on personal data of the member States of the Eurasian economic Union in terms of personal data security during cross-border transmission in the integrated information system of the EAEU.

The object of the research is the system of public relations in the field of personal data. The subject of the research is the norms of domestic and international law regulating the use and protection of personal data in cross-border transmission in the integrated information system of the EAEU.

Material and Methods

The validity of the proposed provisions, conclusions and recommendations is confirmed by the choice of the subject and object of research, the completeness of use and critical analysis of literary sources, and the application of a systematic approach to research. The main scientific provisions set forth in the work correspond to the set goal and objectives of the research. The reliability of the results obtained is ensured by:

- using modern scientific research methodology;
- using a set of methods of scientific knowledge: comparative and system analysis, synthesis;
- using reliable information (analytical data and reviews, monographic research materials, periodicals, Internet resources) and adequate methods of its processing (methods of comparative analysis, induction and deduction);
– justification of theoretical conclusions, using a variety of bibliographic databases.

Results and Discussion

PD security is a state of personal data security characterized by the ability of users, technical means and information technologies to ensure the confidentiality, integrity and availability of PD when processing Them in PD information systems [14].

Cross-border transfer of PD means the transfer or provision of personal data to other States. Cross-border transfer of personal Data in electronic form between the EAEU member States is carried out through the integrated information system of the Eurasian economic Union (hereinafter-the EEU IIS).

The EEU is an organizational set of geographically distributed state information resources and information systems of authorized bodies, information resources and information systems of the Eurasian economic Commission (hereinafter referred to as the Commission, the EEC), United by national segments of the member States and the integration segment of the Commission [2]. National segment of the member state, integration segment of the Commission - information systems that provide information interaction of information systems of authorized bodies and information systems of the Commission within the framework of the information system [2].

Within the framework of the EAEU, the IIS is intended to solve the following tasks: interstate exchange of data and electronic documents, creation and maintenance of a unified system of normative and reference information,

creation of common information resources, creation and operation of a common infrastructure for documenting information in electronic form, etc.

The IIS is a continuation of the integrated information system for foreign and mutual trade, which was established in accordance with the Agreement Of the governments of the Customs Union member States "on the creation, operation and development of the integrated information system for foreign and mutual trade of the Customs Union" on September 21, 2010 and was implemented in 2011-2014.

In the case of cross-border interaction between the customs authorities of the EAEU member States in the implementation of common processes, information is exchanged, including personal data of individuals: last name, first name, patronymic, information about the identity document of an individual, a unique identifier of an individual, and others [3]. In addition, the competent authorities of the EAEU member States exchange information in the field of labor migration and social security.

In accordance with article 361 Of the Customs Code of the EAEU, customs authorities have the right to collect information about persons engaged in foreign economic activities related to the movement of goods across the customs border of the Union, or other activities in relation to goods under customs control, including information about individuals: personal data (surname, first name, patronymic), date and place of birth, gender, address of residence, details of an identity document, including the personal (individual identification) number of an individual (if available), taxpayer identification (registration, registration) number (if available)) and the frequency of movement of goods by these persons across the customs border of the Union. At the same time, information is collected by customs authorities when performing customs operations and by receiving it from other state bodies of the member States [1].

On December 19, 2005, Russia ratified the Council of Europe Convention on the protection of individuals in the automated processing of personal data of January 28, 1981 (hereinafter referred to as the 1981 Convention), assuming obligations to comply with the domestic legislation of this Convention. On July 27, 2006, Russia adopted Federal Act No. 152-FA "on personal data". Articles 12 of this law define the following:

- item 1- " cross-Border transfer of PD On the territory of foreign States that are parties to the 1981 Convention, as well as other foreign States that provide adequate protection of the rights of PD subjects, is carried out in accordance with this Federal law…»;
- item 2- " the Authorized body for the protection of the rights of PD subjects approves the list of foreign States that are not parties to the 1981 Convention and provide adequate protection of the rights of PD subjects. A state that is not a party to the 1981 Convention may be included in the list of foreign States that provide adequate protection of the rights of PD subjects, provided that the provisions of the 1981 Convention comply with the legal norms in force in the relevant state and the security measures applied for PD»;
- item 3- " cross-Border transfer of PD on the territory of foreign States that do not provide adequate protection of the rights of PD subjects may be carried out in the following cases:... provided for by international treaties of the Russian Federation... " [9].

The 1981 Convention was ratified by two EEU member countries-Russia and the Republic of Armenia. In accordance with the order of Roskomnadzor dated 15.03.2013 N 274 (ed.from 15.06.2017) "on approval of the list of foreign States that are not parties to the Council of Europe Convention on the protection of individuals with automated processing of personal data and ensuring adequate protection of the rights of personal data subjects", the Republic of Kazakhstan provides adequate protection of the rights of PD subjects. Thus, the EEU member States-the Republic of Belarus and the Kyrgyz Republic, in the opinion of the Russian side, cannot properly ensure the security of PD during their cross-border transfer. However, if the cross-border transfer of PD is provided for by international treaties of the Russian Federation, it is possible.

The current legislation of the Russian Federation does not provide for criteria that determine the adequacy of protection of the rights of PD subjects on the territory of a foreign state [18].

In the Republic of Armenia, the procedure and conditions for processing personal data are Regulated by the Law of the Republic of Armenia No. LR-49 "on personal data protection" dated June 13, 2015. Article 27 of this law provides for the transfer of personal data to other States. Article 27, paragraph 2, States: "Personal data may be transferred to another state without the permission of the authorized body, if this state provides a satisfactory level of personal data protection. A satisfactory level of personal data protection is considered to be provided if: 1) personal data is transferred in accordance with international agreements; 2) personal data is transferred to a country included in the list officially published by the authorized body." Paragraph 6 of article 27 States: "personal data held

by state bodies may be transferred to the authorities of foreign States only within the framework of interstate agreements, and to non-state bodies – in accordance with the norms of this article" [10].

The provisions of the provisions of the articles on cross-border transfer of PD in the national legislation of the Republic of Armenia and Russia are similar, which is due to the intention of these countries to comply with the principles of the 1981 Convention.
In the Kyrgyz Republic, the legal regulation of working with PD is carried out in accordance with The law of the Kyrgyz Republic dated April 14, 2008 No. 58 (ed.from 20 07.2017) "On personal information". Cross-border transfer of PD is provided for in article 25. According to paragraph 1 of this article: "The cross-border transfer of personal data the holder (owner) of the array of personal data under the jurisdiction of the Kyrgyz Republic, transmitting the data comes from an international agreement between the parties under which the receiving party ensures an adequate level of protection of the rights and freedoms of subjects of personal data and the protection of personal data established in the Kyrgyz Republic" [11].

In the Republic of Kazakhstan, public relations in the field of personal Data are regulated by the Law of the Republic of Kazakhstan dated may 21, 2013 N 94-V (ed. from 28.12.2017) "on personal data and their protection". Article 16 of this law provides for cross-border transfer of PD. In particular, it is determined that the cross-border transfer of PD to the territory of foreign States is carried out only if these States ensure the protection of PD, otherwise it can be carried out in cases stipulated by international treaties ratified by the Republic of Kazakhstan [12].

In the Republic of Belarus, the cross-border transfer of personal Data is defined in the law "on personal data". Paragraph 1 of article 10 of the bill provides for the following: "cross-border transfer of PD is prohibited if an appropriate level of protection is not provided in another state, except in cases when: collection, processing, distribution, provision of PD is carried out within the framework of an international Treaty of the Republic of Belarus" [13].

Conclusions

As a result of the analysis of the national legislation on personal Data of the EAEU member States, the following conclusions are formulated:

1. ensuring the safety of personal Data during their processing is achieved through a set of measures: legal, organizational and technical. The application of these measures is the responsibility of the operator for personal data processing. These measures depend on the information security regulations and technical standards adopted within States.
2. the Security of cross-border transfer of PD is characterized by a greater degree of technical aspect of their protection, in particular the use of cryptographic means of information protection. These tools are used to neutralize those threats to the security of PD That can be closed using such tools. So, using encryption of information containing PD, the requirements for ensuring their confidentiality and integrity are met. Threats associated with unauthorized access to information are minimal.
Article 19, paragraph 2, of The law no. LR-49"on personal data" of the Republic of Armenia explicitly States: "When processing personal data, the operator is obliged to use encryption tools to ensure the protection of information systems containing personal data ...", while there is no direct rule in the legislation of the Republic of Kazakhstan and the Republic of Belarus. In Russia and the Kyrgyz Republic, the use of cryptographic information security tools depends on the established requirements for the protection of personal Data, the implementation of which ensures the levels of personal Data security established by the Government of the Russian Federation and the government of the Kyrgyz Republic. Thus, there is no unified approach to the organization of ensuring the security of PD transmission using cryptographic means of protecting information containing PD in the EAEU member States.

In the EAEU member States, cryptographic protection is based on the development of their own cryptographic algorithms taken as a basis as national standards.

Thus, in accordance with the decision of the Council of the Eurasian economic Commission of 18.09.2014 N 73 "on the Concept of using services and legally binding electronic documents in interstate information interaction" – "member States use national standards for cryptographic algorithms for creating and verifying EDS. The methods used by the state authorities of the member States to implement cryptographic algorithms are incompatible with each other, which is due to different approaches to ensuring information security." These provisions are currently relevant.

The decision of the Council of the Eurasian economic Commission of 18.09.2014 N 73 says: "If, in accordance with the legislation or the relevant agreement of the member States, it is required to ensure the confidentiality of the document, the information contained in the electronic document can be encrypted (converted using cryptographic information protection tools). The procedure for using cryptographic information security tools in such cases is established by international agreements within the Union." This provision implies that confidential information does not have to be encrypted, it can be encrypted, which contradicts the very essence of the concept of confidentiality of information, that is, restrictions on its access.

3. it is clear from the national legislation of the EAEU member States that PD is confidential information and currently PD is transferred to the AIS between countries for customs purposes. However, as for the international agreements of the EAEU member States on the cross-border transfer of PD And their protection within the framework of joint integration, which would define all agreed and unified necessary measures for the safe processing of PD with a sufficient level of security, they are absent.

In the law of the EAEU, there is an international agreement that declares General requirements for the protection of restricted access information, including cryptographic protection of information circulating in the components of the information system. Thus, information protection in the EAEU is carried out in accordance with the terms of reference for the creation of the EEU IC, approved by Decision No. 137 of the Board of the Eurasian economic Commission "on approval of the terms of reference for the creation of an integrated information system of the Eurasian economic Union" (hereinafter the Terms of reference). The terms of Reference indicate that information protection in the information security system should be provided in accordance with the requirements for the creation, development and functioning of a cross-border space of trust, developed by the Commission in cooperation with authorized bodies and approved by it.In addition, protection against unauthorized access to information in the information security system must be provided in accordance with the requirements of the terms of Reference and taking into account the provisions of technical, technological, methodological and organizational documents, approved by the Commission for the purpose of ensuring the unification of applied organizational and technical solutions in the creation, operation and development of an integrated system and maintaining an appropriate level of information security.

In addition, international agreements have been signed that provide for the use of international recommendations and standards taken as a basis for the exchange of electronic documents in cross-border interaction. This is the" X. 509 Standard "- the ITU-T X. 509 standard " Information technology. Open systems interconnection. Reference: public key and attribute certificate Structures"; "XAdES Standard" - XML AdvancedElectronicSignature standard that describes the extended format of an electronic digital signature (e-signature) in XML format; "XMLDSig standard" - a standard for syntax and processing of an electronic digital signature (e-signature) in XML format, as well as the applied public key infrastructure (PublicKeyInfrastructure) in accordance with the recommendations of X. 509 PublicKeyInfrastructure. In this case, the agreed cryptographic standards of the EDS and the agreed cryptographic standards of the hashing function, approved by the Commission, should be used [5].

Taking into account that the national legislation of the EAEU member States should use cryptographic information protection tools and cryptographic algorithms implemented by them to encrypt and create electronic signatures of their own domestic development, therefore, cryptographic standards in the EAEU should be unified within the framework of international agreements. But, as stated in The decision of the Council of the Eurasian economic Commission of 18.09.2014 N 73 "on the Concept of using services and legally binding electronic documents in interstate information interaction» – "The use of unified cryptographic means of EDS in cross-border electronic data exchange between public authorities of the member States is currently impossible, since in accordance with the regulatory framework of the member States, only cryptographic means certified according to national standards are allowed to be used in the member States." Therefore, the problem of creating unified cryptographic means of protecting information in information interaction in the EAEU is relevant, and the use of cryptographic means of protecting information from manufacturers of countries outside the EAEU increases national security risks.

The Protocol on amendments to the European Convention of 1981 (hereinafter referred to as the Protocol) was signed in Strasbourg on October 10, 2018. Russia, along with 19 member States of the Council of Europe, supported the updated version of the Treaty. The changes relate to obligations to strengthen control over the circulation of PD, processing of "special" types of data, such as biometrics or genetic data, as well as regulation of cross-border exchange and international cooperation [19].

The new version of the 1981 Convention provides for uniform rules for refusal in the cross-border transfer of PD, if the state is obliged to comply with the agreed protection rules established by a regional international organization [20]. The question arises: how is it possible to cross-border transfer of PD within the framework of information interaction in the EAEU on the basis of international agreements drawn up between the EAEU member States,

while the new rules of the 1981 Convention require countries that have joined the updated Convention to comply with the norms established by it? The answer is not long in coming, the EAEU member States that are not parties to the 1981 Convention will need to sign and ratify the new rules of the 1981 Convention. Moreover, to bring their legislation in the field of protection of personal Data in line with the norms of the updated Convention.

Taking into account that the entry into force of the modernized Convention of 1981 is expected within five years, it is advisable for this period to develop common requirements and measures for ensuring the security of Pdnp for cross-border transmission within the framework of information interaction in the information system.

4.in the EAEU member States, in General, a small role is assigned to the protection of the rights of PD subjects, in particular in the cross-border transfer of PD to the AIS. This is due to a number of identified reasons. This is the "lag" of national legislation from generally recognized international norms of law in the field of respect for human rights and fundamental freedoms. The lack of a unified developed policy for the safe processing of PD circulating in the AIS and the relegation of this problem to the level of national legislation. Lack of common criteria that determine the adequacy of protection of the rights of PD subjects on the territory of States that are not members of the EEU. So, in the European Union these criteria are established and reflected in Regulations N 2016/679 European Parliament and of the Council of the European Union "On the protection of individuals when processing personal data and free circulation of such data, and repealing Directive 95/46/EC (General Regulation on the protection of personal data)" (Adopted in Brussels on 27.04.2016). At the same time, none of the EAEU member States meets the criteria for assessing the adequacy of the country and is not considered, from the point of view of the European Union legislation on PD, as a country that provides an adequate level of protection of PD, despite the fact that Russia and the Republic of Armenia have ratified the 1981 Convention. All this causes certain difficulties in the free exchange of personal data And their protection both within the framework of close integration processes of the EEU, and in interaction with the countries of the European Union for one reason or another.

The article was prepared within the framework of the State Assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 1.13.20 F "Conceptual basics for ensuring the economic security of the Russian Federation in the context of digitalization: outlines of spatial transformations").

Abstract

In modern realities the development of economy and socio-economic, information and technical systems depends on full-scale formation of digital environment and infrastructure (industry). The structured model of digital economy positively influences both the activity of economic entities and the mechanism of functioning of its constituent elements: it allows attracting instruments of investment from outside, to develop and modernize electronic commerce and platforms, taking into account application of new software and digital products.
The article analyzes the comparison of the essence of crypt currency and digital money. The classification of digital money and payment systems is considered. The correlation of the terms and e-money, their similarity and difference, as well as their main features are studied, problem aspects and perspective directions of development are revealed.

Keywords: Digital Money, Virtual Currency, Crypt Currency, Bitcoin, Blockchain, Payment System.

Introduction

In the current state of innovative economy development, a range of new requirements and standards for telecommunications, computing hardware and software products, automated information systems are naturally emerging.

Considering the process of formation and development of this sphere in the Russian Federation, it should be noted that the main requirements and recommendations are based on the legal framework.

In particular, the legal support of the digital economy in the Russian Federation is introduced by the Russian Government Decree of 02.03.2019 № 234 "On the system of management of the national program "Digital Economy of the Russian Federation" (including "Regulations on the system of management of the national program "Digital Economy of the Russian Federation") [15].

Studying international trends in the development of economies and economic processes, virtual currency (also known as digital money) has acquired a special role in the integrated world economy [9, 11].
For example, the essence of large-scale effect from the creation and introduction of digital currencies and monetary instruments is studied by many specialists and scientists in various fields: economic, social, legal, macroeconomic, political [10].

References Review

Methodological approaches to assessing the quality of financial statements are based on the works of Benish M., Deshow P., Richardson S. A., Sloan R. and others. Criticism of the results obtained by foreign researchers is formed by using the heritage and modern developments of members of the Russian statistical school: D. Zhuravsky, V. Glinsky, I. Eliseeva, N. Kablukova, V. Nemchinova, V. S. Suslova, A. Chuprova, and Yanson U.E.

Explanations of the financial market functioning mechanism were offered by the following authors: Black F., Fama E. F. and others. The study of the evolutionary component of economic development is present in the works of Lo A., Nelson R., Niederhoffer W., Winter S. J. Among the few publications that focus on the study of the instability of the financial system in the context of information flows are the works of Vercelli A., Minsk H. R., Sordi S.

Methodology of Research

The methodological basis of the research is determined by the following fundamental methods and principles: analysis, synthesis, analogy, abstraction, descriptive, mathematical and mathematical-statistical methods.

Practical significance and implementation results, results of expert studies

Having performed a comprehensive analysis of digital money, the following classification of currencies (instruments) was identified, which can be divided into three components:

1. Traditional funds (paper money, bank and commercial deposits, securities).
2. Electronic funds (bank and credit cards, Internet money system; various payment systems - Yandex.Money, Pay Pal, Apple Pay, Google Pay, Samsung Pay, Web Money; smart cards (electronic wallet).
3. Digital means (digital money, cryptocurrency) [5].

Having studied the main provisions and regulations of the European Directive on the development and use of electronic money, it should be noted that electronic money is an electronic (including magnetic) stored monetary value, represented by the requirement to the issuer, which is issued when the issuer receives money to make payments and is accepted as a means of payment by institutions other than the issuer of electronic money. That is, the various payment systems presented above allow to carry out transactions, commercial and other operations with a greater degree of efficiency and optimality, which in turn has a favorable impact on the information and economic processes of the involved parties. These operations include:

- Paying for goods and services on the Internet regardless of the country and location;
- Making money transfers to debit and credit cards;
- Conducting and completing e-currency purchases and exchange transactions through stand-alone devices and secure communication channels;
- Applying settlement accounts using e-mail, a technological software product or a device.

Almost the entire flow of transactions with electronic money is made with a special electronic wallet, which is a unique identifier consisting of a set of structured elements (numbers and letters). You can open one or more electronic wallets on the official website of the payment system, having previously registered on this platform.

Virtual (digital) money is a type of unregulated digital money, which is issued and, most commonly, regulated and controlled by its developers, accepted and used among members of a certain virtual community, in some cases, created with the initiative of a state market segment [6].

Electronic and digital money are based on a single principle of non-material payment methods, but at the same time have a number of essential features that distinguish their individual characteristics. The main difference between digital money is that it is not directly connected with the state currency system, but is created directly through software systems and electronic platforms that are not elements of a single network. In turn, traditional money to be

converted into electronic format must be deposited in cash equivalents. These criteria and basic requirements are met by cryptocurrencies.

Cryptocurrency is a digital currency based on cryptographic encryption and protection methods. This type of currency is created virtually and contains information and data encrypted by mathematical methods, protected from possibility of forgery and copying. Known and frequently used cryptographic currencies are: Bitcoin, BitcoinCard, Ethereum, Dash and Ripple. The active cryptovalut is formed on the basis of the Bitcoin technology - it is a centralized database, which consists of information blocks and contains records on the crediting, transfer and withdrawal of funds, that is, all transactions [3].

An important aspect is the fact that the implementation of this chain is based on the impossibility of changing these records of information blocks, which can only be supplemented. Each transaction is protected by an electronic signature of the user, who performs operations with digital monetary instruments. Comparison and analysis of cryptocurrency and electronic money is presented in Table 1.

Table 1: Relationships between the characteristics of digital monetary instruments

Characteristic	Cryptocurrency	Digital Money
Cost of a constituent element	Confidence in the payment system, optimal ratio of supply and demand	Reasonable equivalent to the quantity of fiduciary money, converted into an electronic form
Emission method	Forging, Mining, (rally), ICO (Initial coin offering) based on mathematical model of system generation	Predominantly electronic depending on the value of fiduciary money in the current period
Availability	Access to the Internet and digital sites	Access to various elements of the Internet, electronic devices, client bases and communication systems
Customer Identification	Ability to use digital units anonymously	Identification by performed operations, taking into account the database, registration and protection of servers
Connection to inflation	Not exposed to inflation, not available at this period	There is a direct correlation
Regulation	- are legalized and taxed, have integrational value (Japan, USA, Canada, Germany, etc.) - restricted circulation of cryptocurrency for banks, allowed for individuals (China) - prohibited (Bangladesh, Bolivia, Vietnam)	The process of regulation in the corresponding country is carried out by the Central Bank of the state
Security, risks (on the example of the Russian Federation)	- threat of viral attacks - data password loss - virtual theft - lack of full legal regulation in this sphere	- inflation - threat of theft, fraud, illegal operations - Longer term of money transfer
Issuer	Decentralized	Centralized

Based on the data from Table 1, it can be concluded that digital money and cryptocurrency have priority values in themselves, depending on the individual characteristics of each. The choice of application of one of them is based

on the bases of functioning of a specific system of operations and commercial transactions, depending on the form and methods of financial and cash flows. However, in the modern reality, cryptocurrencies have a number of significant advantages, which is confirmed by the society, since the use of this digital money instrument has gained considerable popularity and profitability in recent years [12, 14]. Hence, the following privileged categories can be distinguished:

- transaction speed;
- minimum commissions for transactions;
- security of financial flows;
- convenience of storage and accumulation;
- possibility of complete confidentiality;
- long-term actualization.

It should be noted that the cryptocurrency is not widespread in everyday life as a means of payment. However, according to estimates of leading scientists and specialists of the world, if the current dynamics of the use and creation of digital currencies will be preserved, by 2030 the number of users of block wallets will reach the level of 200 million, and in the future the cryptocurrency will replace cash at all [1].

In order to reach a new consumer level and achieve the desired maximum, it is necessary to solve the main problem aspects within the application of cryptocurrency, namely:

1) The cost of the leading cryptocurrencies used for settlement operations should be stable. It is necessary to carry out their legal transition to a legitimate status, based on the established legal and regulatory framework in this area.
2) Implementation of the process of cryptocurrency integration by the leading companies in the field of payments. Through mobile devices and applications (ApplePay, GooglePay), among Visa and Mastercard card providers, retailers Amazon and Ozon.
3) The financial system must be prepared and configured for power outages and cyberattacks, as well as the availability of modern scientific, technical, software, computer and computing facilities [6].

Conclusions

Cryptocurrencies require legal recognition and a unified system of control and regulation. With the advent of regulation, it will be necessary to abandon the principles that were originally embedded in the technology of the Blockchains. That is why it is of primary importance to find the point of balance between freedom and control, so that investors will be willing to invest in a promising project to create a Unified Automated System of Digital Cash.

Discussion of Results

The development of the modern global economy is an obvious consequence of the progress of the digital market and turnover [7,8].

Moreover, users are waiting for substantial guarantees to ensure the protection of digital operations against viruses, hacking, confidentiality of informational and financial flows and personal data. A full interconnection between the public sector and private, commercial entities will allow developing an optimal mechanism to create a Unified system of digital money application, which will entail a new turn in economic development in the current state of digitalization and globalization in general. In Russia, this issue has been sufficiently studied, which made it possible to form and apply an integral concept aimed at the development of the electronic money market within the framework of the national program "Digital Economy of the Russian Federation".

The article was prepared within the framework of the State Assignment of the Ministry of Science and Higher Education of the Russian Federation (topic No. 1.13.20 F "Conceptual basics for ensuring the economic security of the Russian Federation in the context of digitalization: outlines of spatial transformations").

Abstract

The paper proposes an algorithm for selecting priority investment facilities on the basis of a competitiveness assessment technique through the effects of investees on micro-, mini -, meso - and macro-levels. Levels of competitiveness are considered. Theoretical formulas for the measurement of competitiveness are proposed.

Keywords: competition, competitiveness, competitiveness assessment techniques.

Introduction

The Russian government is actively seeking the ways of overcoming the country's economic crisis. Achieving this goal is fraught with many difficulties, including the problems of creating a competitive environment. Competition policy is still at an early stage of development and has no support based on the understanding of the importance of competition. Many economic executives associate competition with poorly organized transition to open international trade or with destructive competition based on negative (and sometimes adverse) forms and manifestations. Within this framework, there mainly appear such theoretical ideas as the formation of a competitive economy by supporting the strongest economic sectors and groups of enterprises.

Material and Methods

When describing the problems of analysis and assessment of competitiveness, Professor N. A. Faminskiy notes a few specific features. The multivariance of factors and conditions of competitiveness, the relativity of this category leads to the complexity of its definition [1]. Professor P. S. Zavyalov notes [2] that "there is no single and universal concept of competitiveness", therefore, it is necessary to study and apply a set of methods of quantitative analysis and evaluation of competitiveness taking into account its properties of "multulayerness". The main factors that determine the possibility of multiple interpretations of this concept are the various initial positions of economists regarding the fact what should we see as a manufacturer: only individual enterprise, a separate industry or the whole economy.

Depending on the object of competition all the variety of competitive relations arising in the economic sphere, can be divided into four levels: micro (the competitiveness of products (goods, services)); mini (the competitiveness of enterprises), meso- (industry competitiveness) and macro level (the competitiveness of the region (country)).

Cite this Article as: Natalia E. DERKACH, Olga I. SOLODUKHINA , Svetlana A. STARYKH and Daniel I. RASPOPIN "The Mechanism of Selecting Priority Investment Facilities on the Basis of Integral Indicators of Competitiveness" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In this case, the problem of competitiveness evaluation can be represented in the form of a pyramid (Fig. 1) in which each subsequent level is based on the lower one. In addition, it has its own elements, characteristics and serves as the basis for the higher level.

Fig. 1: Competitiveness pyramid

At the base of the pyramid is competitiveness, which is determined by the following elements:
• price competitiveness of products – the ratio of the price level with the prices of similar products of main competitors; the effectiveness of price differentiation system depending on the supply-and-demand situation and the policies of competitors; the attractiveness of discounts for consumers;
• quality of products – technical and functional characteristics of the product (functionality, reliability, safety, ease of use; food, energy, physiological value, harmlessness, storageability, etc.),status of products;
• competitiveness of marketing, advertising and maintenance systems.

The next level of competitiveness of a business entity – enterprises - can be represented as a total of two sets:
- many parameters characterizing a business entity on mini level. For example, the efficiency of company production, financial position of a company, the efficiency of marketing and market promotion of goods, etc.;
- a variety of competitive goods and services provided by a business entity. In other words, each competitive item of goods of a business entity becomes a structural element of its competitiveness, i.e. its competitive advantage[6].
In a formalized form, the index of competitiveness of commodity producers can be represented as follows:

$$КС_{т/произ.i} = F(x_i) + КС_{тов.i}\,,\ i = \overline{1,I} \qquad (1)$$

где $F(x_i)$ – the economic parameters characterizing a business entity (*i*) at the micro level; $КС_{тов.i}$ - the index of goods competitiveness provided by a business entity (*i*).
At the meso-level there can be surveyed the competitiveness of industries, business combinations and the association of various enterprises (holdings, etc.). The competitiveness of a business entity at the meso-level can be defined in the form of the following two sets:
- many parameters characterizing the state of meso-entity (industry). They can be the following ones: the level of integration, specialization and cooperation in industry, the level of unification
and standardization of industry products, etc.;
- many competitive mini-entities (enterprises and organizations), as well as a subset of competitive goods and services of meso-entity.
In a formalized manner and by analogy with the micro level, the competitiveness of meso-entities is represented as:

$$КС_{мезосуб.s} = F(y_s) + КС_{т/произ.i_s} \qquad (2)$$

where $F(y_s)$ – the economic parameters characterizing a business entity at the meso-level, $КС_{т/произ.i}$ - the index of competitiveness of mini-entities *(i)* (commodity producers, companies, etc.) determined by a certain meso-entity *(s)*.
The next level of competitiveness – macro level. It analyses the competitiveness of national economic systems, institutional systems of countries, regions, etc. The components of macro-entities' competitiveness are divided by analogy with mini and meso-levels into the parameters which characterize a macro-level, such as climatic and geographical conditions, level of education of the population etc., and the competitiveness of those meso and mini-entities, which in turn, form the structure of a macro-entity.

Regarding the competitiveness of countries, Adrianov V. [3] says that "the synthetic index which combines the competitiveness of goods, commodity producers, industries, and describes the country's position in the global market, is the country competitiveness. In general terms it can be defined as the capacity of a country under the conditions of free fair competition to produce goods and services that meet the requirements of the world market and improve welfare of the people of this country and its citizens.

The components of macro-entity's competitiveness are divided into the following two sets and two subsets:

- a variety of parameters and factors characterizing the state of a macro-entity;
- a set of competitive meso-entities, and, in its turn, the subsets of competitive mini - and micro-entities.

Similarly, in a formalized manner the competitiveness of macro-entities is represented as follows:

$$КС_{макросуб.n} = F(h_n) + КС_{мезосуб.sn},\ n = \overline{1,N},\ s_n = \overline{1,S_n} \quad (3)$$

where $F(h_n)$ – the economic parameters characterizing a business entity at the macro level, $КС_{мезосуб.sn}$ - the indicator of competitiveness of meso-entitities (industries) *(s)* determined by macro-entity (*n)*.

Business entities, whether they are enterprises, industries, or countries, are the active elements of the economic system, and the objects of commodity level, as such, are passive elements. Moreover, in our opinion the goods and services as the final product of any entity determine the need for a separate analysis and estimation of competitiveness of business facilities and entities. Therefore the structure of competitiveness of business facilities and entities can be represented as a set of economic activities parameters of a macro-entity, including meso - and micro-entities, as well as many of objects of commodity level as a consequence of end result of micro- meso - and macro-entities' activity.

Based on the aforesaid, formally the competitiveness of a macro-entity can be represented in the form of an integrated index of competitiveness [4]:

$$КС_{макросуб.n} = F(П_{nsi}) + КС_{микро.n},\ n = \overline{1,N},\ s = \overline{1,S},\ i = \overline{1,I}, \quad (4)$$

where N – the number of macro-entities; S – the number of meso-entities of a macro-entity *(n)*; I – the number of micro-entities of a meso-entity *(s)*; $КС_{макросуб.n}$ - the integrated index of competitiveness of a macro-entity *(n)*; $F(П_{nsi})$ - a great number of economic parameters of micro-entities *(i)* and meso-entities *(s)* of a macro-entity *(n)*; $КС_{микро.n}$ - the integrated index of competitiveness of all goods and services provided by a macro-entity *(n)*.

Results and Discussion

Thus, the assessment of entities' competitiveness of each level should be based on the structural decomposition of objects and entities of competitiveness. It must not be a formal addition of the parameters of lower levels. It must also take into account the specific features of the studied level of competitiveness.

For example, the competitiveness of the industry complex will be characterized by two integral parameters: 1) directly by the competitiveness of the industry complex in conjunction with similar objects (for example, the sugar complex of the Kursk region, the sugar complex of the Orel region, etc.); 2) by the competitiveness of its constituent enterprises (in case of sugar complex – sugar factories). In its turn, each integrated indicator is composed of several groups of specific indicators. The competitiveness of the industry complex: suppliers, providing processing with raw materials, manufacturing, export-import balance. Competitiveness of an enterprise: the competitiveness of products; financial condition; marketing activities; the effectiveness of production management; the business cooperation with suppliers[7,10].

The process of competitiveness assessment can be represented in the form of a diagram (Fig. 2).

Fig. 2: Scheme for competitiveness assessment

All specific indicators of the third level have different dimensions; therefore, it is necessary to assess the criteria on a unified scale in order to include them adequately in the analysis process and the construction of an integral indicator. It should be noted that the factors of competitiveness could play a stimulating role (stimulants) and disincentive (disincentives). The example of the first ones is the yield of sugar beet, the example of the second ones is the losses of sugar in production[8]. Taking into account this factor we propose to use the formulas (5-6) for scaling by analogy with the calculation of Human Development Index used by the UN:

$$Xmij = \frac{Xij - X\min j}{X\max j - X\min j} \text{ – for stimulants} \quad (5)$$

$$Xmij = \frac{X\max j - Xij}{X\max j - X\min j} \text{ – for disincentives} \quad (6)$$

where X mij – the scaled value of an indicator *(j)* for a region *(i)* in a year *(n)*; Xij - the actual value of an indicator *(j)* for a region *(i)* in a year *(n)*; Xminj – the minimum value of an indicator *(j)* for the number of years *(n)* across regions *(i)*; Xmaxj – the maximum value of an indicator for the number of years *(n)* across regions *(i)*.

In the function of $X\max j$ and $X\min j$ there can be respectively offered the maximum and the minimum value of the criterion *(j)* based on the values of this index for the number of years *(n)* for the analyzed objects, i.e., $X\max j$ = max (Xij for the number of years *n*), $X\min j$ = min(Xij for the number of years *n*).

For the formation of integral indicator, the degree of closeness of the actual sample to the model sample is calculated with the help of a formula [5, p. 127]:

$$Yi = 1 - \frac{dio}{Co}, \tag{7}$$

где $dio = \left[\sum_{j=1}^{n} (xij - xoj)^2 \right]^{\frac{1}{2}}$, $Co = x'' + 2Sd$

$x'' = \frac{1}{t} \sum_{i=1}^{t} dio$, $Sd = \left[\frac{1}{t} \sum_{i=1}^{t} (dio - x'')^2 \right]^{\frac{1}{2}}$

xij – the implementation of property *(j)* in the object *(i)*;

xoj – the implementation of property *(j)* in model sample.

Conclusions

After evaluating competitiveness, it is necessary to choose the most priority investment project due to the limited investment funds. With the help of cluster analysis, we propose to divide industrial complexes and enterprises into three groups depending on the obtained integral indicators: high competitiveness, medium competitiveness, low competitiveness. The following algorithm is supposed to be used (Fig. 3)

Fig.3: The algorithm for selection of priority investment facilities

If the competitiveness of a particular industry is high, then priority investment facilities are companies with low and medium competitiveness in order to prevent monopolization of the market and competition development. The allocation of investment funds among enterprises is determined by their size and their objectives. If their quantity is limited, then the targets of investment are selected from the best companies in the group. If the competitiveness of a particular industry is medium and has potential for development, priority is given to the enterprises with high and medium marketability in order to achieve a leading position[11]. If there is no potential for development, i.e., further increase of competitiveness is limited, for example, due to geographical features, priority is given to investment facilities with medium and low competitive ability, similarly, as in the case of high competitiveness of the industry complex[8,9]. In a situation where the competitiveness of a particular industry is low and there is potential for development, priority investment facilities are companies with high competitiveness in order to withdraw the industry from crisis and establish themselves as a leader.

The proposed algorithm for the selection of priority investment facilities enables to develop a comprehensive mechanism of improving and maintaining the sustainability of competitive positions. The specific approach will make it possible to consider the features of internal and external environment of the studied systems. Besides, to assess the implementation of an investment project one can use the change of integral index of competitiveness as the most meaningful criterion. Its peculiarity consists in the reflection of a significant number of factors that characterize different aspects of the main structural components of the studied object.

Abstract

This paper presents the concept of using ML methods to infer the reason of the people missing. The issue of determining the reason of disappearing of persons is extremely important and orientates police action as well as has huge impact on the effectiveness of the search. In consideration of the amount and diversity of information collected in the process of searching for missing persons, the police services should rely on templates that are both readable to humans and have a structured form for the purposes of computer support methods. The formal model, we propose for description of a missing person, ensures consistency and completeness of data. Based on historical cases, an aggregated model of disappearances was built. Six ML methods were selected and calibrated on the basis of historical cases, and then their quality was compared. Due to the relatively small set of real cases available in the system, 40 000 synthetic cases were generated. In order to identify the best method of classification, several selected methods were studied: Bayesian networks, naive Bayesian classifier, decision trees and random forests, and multilayer perceptron.

Keywords: Machine Learning, Missing Person, Prediction of Reasons of Disappearance.

Introduction

The importance of the issue of searching for missing persons results from the number of events involving the disappearance of persons occurring in subsequent years. Figures Fig.1 and Fig.2 present numbers concerning Poland from 1997 to 2017.

Fig.1: Number of missing persons in Poland in the years 1997 – 2017

It can be seen that these are significant numbers, many of them concerning children and youth. The search activities of the Police often require decisions to be made with highly incomplete information under time constraints. Wrong decisions may result in a threat to the health or life of missing persons, especially children. In this context, it seems necessary to use modern IT methods of data collection and processing to facilitate decision making and improve the quality of these decisions. The literature contains a number of descriptions of applications of Machine Learning methods (ML) Blackmore K. (2002, 2003a,2003b,2005) methods of image recognition Chackravarthy, S. (2018), methods based on GIS systems Anderson P. et al. (2013)., Koester, R. J. (2008), supporting police work in the execution of search tasks.

In Poland, a project called "Developing a database and tools for semantic information and knowledge management in the area of disappearances and searches for people", financed by the National Center for Research and Development is coming to an end. The result of the project will be an IT system enabling, among other things, collection of data on both completed and currently ongoing searches. Historical cases will be the basis for calibration of ML methods used, among other things, to draw conclusions about: the level of searches, typing the cause of the disappearance, building behavioral models of different types of missing persons, developing standard operating procedures for the police, indicating normative documents and searching from the database, documents related to the disappearance cases, similar to the currently implemented ones. A separate functionality is a GIS module supporting the field search process.

The subject of this article is the use of ML methods to select the cause of disappearance based on the data collected during the search process. By analyzing historical cases of disappearances, they can be classified according to the cause of disappearance. Determining the cause of the disappearance may facilitate taking appropriate action in the search process. It may indicate the places of search, appropriate operational activities, predict the behavior of the missing person. It can therefore be assumed that on the basis of classified disappearances where the cause of the disappearance is known, a method of classification can be developed which will assign the new disappearance to one of the known classes. Thus, the problem of selecting the cause of disappearance will be considered as a problem of classification. ML methods are calibrated on the basis of records registered in the database describing historical cases of disappearances.

The rest of the work was divided into five parts. In the "Related work" section there will be an overview of missing persons' search methods, ML methods and GIS systems. The "Data description" section contains the definition of the data model describing the disappearances and the aggregated model and relations between the models. Aggregate model is used directly in ML methods. The method of generating synthetic data is also described. The real data available for the time being covers less than 600 cases. Therefore, in order to verify the ability of ML methods to predict the cause of disappearances, a method of generating synthetic data was developed, based on the previously developed model of disappearances in the form of Bayesian Network. The section "Classification methods" reviews the ML methods that have been used to infer the cause of the disappearance. The "Multiclass methods validation"

section discusses methods of quality assessment of classification methods when objects are classified into more than two classes. At the end, a chapter presenting the results of a computational experiment performed on data containing a large number of records of disappearances is presented.

Related Work

Works devoted to the issue of searching for missing persons can be divided into three categories, due to their subject matter:

a) general studies;
b) "Search and rescue - SAR" issues;
c) the use of ML methods to search for missing persons.

The group a) includes publications that generally describe the problems of missing persons. The report NCA (2017) as declared by the authors, “provides key statistical data regarding missing people.“ . The statistics included in the study cover the fiscal years 2012/2013 to 2015/2016 and include the following: the number of missing persons in the administrative division of the United Kingdom, data broken down by gender and age of missing persons, broken down by reasons for the disappearance, duration of the search. Factors that can be used to assess the risk to the missing person are indicated. In particular, statistical data were provided on: the distance between the point of disappearance and the place of finding, the duration of the search from the moment of reporting the disappearance to finding. The main types of causes of disappearance are classified. The report Newiss G. (2011) contains an analysis of 280 disappearances ending with the death of missing persons. It analyses the circumstances of the disappearance, the duration of the search and the time from disappearance to death, the vulnerability of the missing persons to the crime, the identified threat factors and methods of assessing the risk of disappearance. The works and reports discussed above contain primarily sets of statistics and observations on the behaviour of missing persons of different categories. These data are of course helpful in planning the search for missing persons, but they do not explicitly describe the tools that could speed up and improve the quality of the search conducted by the police. A very comprehensive set of publications includes the work Morewitz, S. and Sturdy Colls, C. (2016),. The Handbook contains articles of such character as described above. However, the Handbook does not include works on the use of IT systems, including artificial intelligence methods, ML or GIS.

An extensive group of publications includes group b), devoted to the search for missing persons, especially in the extra-urban area. These issues are called "Search and rescue - SAR". The name was taken from the military action of searching for missing ships or pilots of planes shot down or landed as a result of an accident in an unknown area. A classic position in the field of modeling and evaluation of the effectiveness of the search for these objects is the work Koopman B.O. (1946) The way of using Koopman's theory in the field of searching for missing persons in an out-of-town (undeveloped) area is presented, among others, in the works: Frost J.R (2000), Frost J.R (2001), Cooper D. (2000), Cooper, D., et al. (2003). Issues related to search process optimization are presented in the works Stone, L. D., (2016) Stone, L. D. (1977). The most extensive and frequently quoted study is the book Koester, R. J. (2008), It contains~~, first of all,~~ defined many types of disappearances, elements of behavioral models of persons missing in the field, rules of planning field searches, schedules and sets of actions to be performed during the execution of the search. Based on theoretical studies, a number of practical guides for planning and conducting the search have been developed. A good example of such a guide is the work Anderson P. et al. (2013).

The most interesting, from the point of view of the subject of this article, is the group c) of works, devoted to the application of artificial intelligence (AI) methods, including ML methods in the search for missing persons. The issue of using AI and ML methods for detecting criminal offences has a relatively broad literature. The book McCue C. (2006), and a number of scientific articles can be mentioned here. The paper Nath, S., V. (2006) presents the use of clustering methods to identify patterns of crime with regard to the spatial location of crimes. The article Chackravarthy, S. (2018), presents the use of deep learning algorithms to analyze recordings from city cameras to automatically detect criminal activity. The article Prabakaran, S. and Mitra, S. (2018), provides an overview of the use of data mining algorithms to detect and analyse many different types of crime, such as fraud, robbery, murder, rape, traffic crime, cybercrime. The paper McClendon, L. and Meghanathan, N. (2015), presents the use of regression algorithms to detect and compare crime patterns identified in two different crime data sets. The work Wang, T. et al. (2013),] describes a tool for automatic detection of crime patterns.

However, the above mentioned works do not address the issue of missing persons. The use of AI and ML in the search for missing persons is not widely available in the literature. Interesting works Blackmore K. (2002, 2003a,2003b,2005) can be pointed out here. They contain a precise description of research aimed at building an

inquiry system to support police work in searching for missing persons. It was assumed that only cases of disappearances involving the greatest threat to the lives of missing persons, murder, victims of criminal crimes and runaway will be considered. Of the many data, 357 cases were selected, which were used to calibrate the selected classification method. It has been assumed that the most appropriate method of classification will be the classification rules. It was assumed that the rules will be the method best supporting the intuition of the police officers carrying out the search process. The results of the research are presented in detail in (Blackmore K. (2002, 2005). The results obtained were not very satisfactory. The average Accuracy was 71%. However, the analysis of the error matrix showed that the quality of the classification for the different causes of disappearance was definitely different. The algorithm classified correctly 84% of runaway and only 39% of homicides and 47% of cases of victims of criminal crimes. The works Blackmore K. (2003a, 2003b) describe the use of artificial neural network (ANN) methods to classify cases of disappearances. The use of ANN has significantly increased the accuracy of the classification of disappearances to 99%. However, in order to obtain a set of classification rules, methods combining the ANN method and genetic algorithm to extract a set of rules from the neural network were used. Thus, obtained a set of rules, obtained a classification accuracy of 86%.

The problem considered in this paper is formulated similarly to that in the papers Blackmore K. (2002, 2005). However, it has been assumed that methods will be developed to conclude all identified causes of disappearance, which also include the causes considered in the paper Blackmore K. (2002, 2005). The data being the basis for the analysis came from the archives of the Polish Police. In order to identify the best method of classification, several selected methods were studied: Bayesian networks, naive Bayesian classifier, decision trees and random forests, and multilayer perceptron. Due to the fact that the number of real disappearances currently available in the computer database was relatively small, in the order of 500 cases, a synthetic case generator was built. It allowed to effectively increase the available research material and to compare the quality of the methods used and to indicate those that are most promising for further research.

Data Description

The information collected on the missing person and its surroundings (including the circumstances of the disappearance, weather conditions, relations to other persons) we shortly describe in a formal model. On the basis of the model, there will be defined the methods dedicated to generation of synthetic data and aggregation of the features. Hence, we will further assume that:

- S – a set of "missing persons" cases;
- F^1 – non-empty and finite set of possible "detailed" features describing the case (first-order features). This is information collected in the course of the investigation;
- L^1 – number of features in set F^1;
- F^2 – non-empty and finite set of possible "aggregated" features describing the case. This is "the secondary" information, determined on the basis of the values of the features in set F^1;
- L^2 – the number of attributes in the set F^2;
- $F=F^1 \cup F^2$ – non-empty and finite set of all possible "aggregated" attributes describing the case;
- $f \in F$ – feature *f*, defined by the ordered pair $<id_f, D_f>$, where:
    - id_f – identifier of feature *f*,
    - D_f – domain of values for feature *f*;
- $D = \bigcup_{f \in F} D_f$ – domain of values for features describing the case.

Each case $s \in S$ is described by a feature vector consisting of two subvectors $s=<S^1, S^2>$, where:

- the vector of "detailed" features:
    - $S^1 = <s^1_1,\ldots, s^1_i, \ldots, s^1_{L1}>$, $s^1_i \in F^1$, $i=1..L^1$;
- vector of "aggregate" features:
    - $S^2 = <s^2_1,\ldots, s^2_i, \ldots, s^2_{L2}>$, $s^2_i \in F^2$, $i=1..L^2$.

The value of each feature of vector S^1 in the case *s* at the moment *t* – this is the so-called "information on the case" established at the moment *t*:

- $v: S \times F^1 \times T \rightarrow D$,
- $v(s,f,t) \in D_f$, $f \in F^1$, $s \in S$.

If the information is not time-dependent, a fixed value may be assumed:

- $V: S \times F^1 \rightarrow D$,
- $V(s,f) \in D_f$, $f \in F^1$, $s \in S$.

A value of feature *f* defined by the domain D_f might be nominal, ordinal or numerical.

The following are selected features from F^1 collection, constituting "information on the case":

- s^1_1: Gender of the missing person:
  - id_{s11} = "sex"
  - D_{s11} = { 0: "male, "1: "female" }
- s^1_2: Previous suicide attempts:
  - id_{s12} = "suicide_attempts"
  - D_{s12} = { 0: "Unknown",1: "Not registered ",2: "Simulated", 3: "Real"}
- s^1_3: Somatic illnesses:
  - id_{s13} = "somatic_illness"
  - D_{s13} = { 0: "hypertension", 1: "chronic coronary artery disease", 2: "cancer", 3: "chronic respiratory diseases", 4: "diabetes", 5: "life-threatening", 6: "non-life-threatening" }
- s^1_4: Traumatic events/experience:
  - id_{s14} = "traumatic_events"
  - D_{s14} = { 0: "abandonment by someone", 1: "death of a relative", 2: "unforeseen situations difficult to handle", 3: "rape of a person", 4: "violence against a person", 5: "formal/legal problems", 6: "change of marital status", 7: "birth of a child", 8: "a disappointment to sb./sth." }

The data constituting "case information" are collected during the investigation of missing persons at different stages and therefore at different moments in time. This means that at a given point in time *t* not all of the features of the S^1 vector in case *s* have to be fixed - can be considered to be non-existent. In the proposed model we use a complete set of features with the length L^1 (vector S^1).

Aggregated Data Model

The number of features in the set of F^1 contains more than 30 "detailed" features describing the case ($L^1 \approx 30$), with different levels of detail - they represent qualitatively different values. Most methods of data analysis require sets with a large amount of data - assuming that L^1 is the largest possible number of different "detailed" features, the number of all potential combinations of features can be determined as "2^{L1}-1". The "curse of dimensionality" has a negative impact on the quality of prediction, exceeds the requirements for computing power, worsens the response times of the implemented methods. In order to reduce the length of the features' vector, it is possible to (1) select significant features and discard excessive ones, and (2) apply aggregation of detailed features into generalised ones. The first step is the selection of traits - in the proposed model we have selected a subset of mandatory features from set F^1, ensuring the consistency and completeness of the information collected in the case. The next step is to aggregate the "detailed" characteristics into "aggregated" characteristics. For this purpose, we specify a set of functions corresponding to methods, which for each case $s=<S^1, S^2>$, $s \in S$ determine the values of attributes in the S^2 vector (of length $L^2 < L^1$) on the basis of values of attributes in the S^1 vector:

- $X = \{X_i: (F^1)^{L1} \rightarrow F^2, i=1..L^1\}$

The idea of aggregation can be illustrated as follows:

$$S^1 = <s^1_1,\ldots, \mathbf{s^1_3},\ldots, \mathbf{s^1_{14}}, \mathbf{s^1_{15}}, \ldots, s^1_i, \ldots, \mathbf{s^1_{20}}, \ldots, s^1_{L1}>, s^1_i \in F^1, i=1..L^1$$

$$\mathbf{X_3}$$

$$S^2 = <s^2_1 ,\ldots, \mathbf{s^2_3},\ldots, \mathbf{s^2_8},\ldots, s^2_i, \ldots, s^2_{L2}>, s^2_i \in F^2, i=1..L^2, L^2 < L^1$$

The aggregation function for characteristic s^1_3 ("Somatic diseases") is presented below:

- X_3: $(F^1)^{L1} \rightarrow F^2$;
- $X_3(s^1_1,\ldots, s^1_i, \ldots, s^1_{L1}) = \begin{cases} 0, & when\ s_3^1 = 0 \text{ v } s_3^1 = 2 \text{ v } s_3^1 = 4 \text{ v } s_3^1 = 5 \\ 1, & when\ s_3^1 = 1 \text{ v } s_3^1 = 3 \text{ v } s_3^1 = 6 \end{cases}$.

Other aggregation functions concern the following characteristics are as follows: age, ability_impl, life_threat, adjustment, suicides, medication, health_condition, temporary_hardness, relations_with_other_people, traumatic_events, higher_mood, negative_self, negative_others, behaviour_change, leave_preparation, weather, terrain.

Synthetic Data Generation

Synthetic data are all data that describe a specific phenomenon or condition and that have not been obtained by direct observation, but have been produced on the basis of a model of the phenomenon (e.g. simulation). They are generated when: (1) there is not sufficient real data, (2) in order to obtain specific data that are infrequent in nature, (3) if real data cannot be used due to privacy concerns (i.e. protection of the privacy of the individuals represented in the real data). Synthetic data allows methods and algorithms to be analysed across a wider range of scenarios and under very different conditions. In this paper, the synthetic data set (in contrast to the imbalanced dataset with real data, provided for research) is expected to contain samples for all causes of disappearance.

Generation of synthetic data is widely used in scientific research in various fields, e.g.: pattern recognition in a research study by Varga and Bunke (2003), data mining in a study by Liu et al (2011). There are a lot of different tools with functions to generate synthetic data. In the presented method we used GeNIe software which is an environment for building graphical Bayesian network models. GeNIe was developed at the University of Pittsburgh and further BayesFusion, LLC – as one can read in the book by BayesFusion (2020). With support of GeNIE/SMILE, we have implemented model of belief networks as Bayesian network to generate the values both of detailed and aggregated features. Since we are predominantly interested in proving the legitimacy of the synthetic data cases, and considering that no complete and comprehensive data exists in the available databases, a particular focus was required on developing an adequate network model. Bayesian networks are acyclic directed graphs where nodes represent random variables and arcs represent direct probabilistic dependences between them. The selection of variables for the model and the definition of links were accomplished with the help of several independent field experts. Further, to parameterise the model (in tables of conditional probabilities), values estimated on the basis of statistics from real case databases were used. In this way, both high compliance of the model with reality and the fact that the "causes" are approximately equally represented was ensured.

Synthetic data generation is a "inverse problem" to Bayesian network modelling. Having an evaluated model, in the first step, values for each root node are sampled from their unconditional distribution. Random values are generated in the nodes (without parents) according to estimated distributions and parameters. In the next step, the "child nodes" resulting from relationships with the "parent nodes" and the random values generated there are updated. That cycle is repeated iteratively until values have been sampled for all nodes in the model. Further, given the distributions, we generated several data files to teach and test the algorithms for prediction of reason for disappearance. Each individual record of the generated file contains values of the features randomly generated from the joint distribution modelled by set of nodes in the network. In order to balance the causes of disappearances we have used the function "Bias samples by existing evidence". It resulted in data related to the posterior joint probability distribution (i.e., biased by the observations) rather than from the original distribution.

The Table 1 shows examples of values of several features that were generated using the Bayesian network model within the GeNIe package.

Table 1: Examples of the generated random values of chosen features

sex	*suicides attempts*	*somatic illnesses*	*traumatic events/experience*	*relations to other persons*
male	real	no	abuse against a person	threat from a criminal group
male	no	cancer	difficult situations	no
male	simulated	no	abandonment by somebody	conflict at school

female	no	diabetes mellitus	no	unknown
female	no	hypertension	unknown	conflict in the relatives

Case Study

In the project supporting the process of searching for missing persons, the following methods were chosen to solve the problem of selecting the cause of the disappearance:

- Bayesian network;
- Decision trees;
- Random forests;
- Multilayer perceptron;
- SVM.

The application of many methods for the study resulted from the need to verify the quality of these methods in real life and to select the best one based on the quality of the classification of the causes of disappearance.

Bayesian networks were chosen as a method of selecting the cause of disappearance for two reasons. It can be used relatively easily to build a classification model based on expert knowledge. This is particularly important in the absence of real data to teach (calibrate) the model. Secondly, Bayesian Network could be used as a synthetic data generator to test other classification methods and other functionalities of the designed IT system. The rules of generating synthetic data using Bayesian networks are described in the previous section.

The structure of the Bayesian Network developed for the project is shown in Fig. 3. The indicated probability values correspond to the case of disappearance caused by a suicide.

Fig.3: The structure of the Bayesian Network and the result of the inference in the node "Disappearance reason", with specified values of other network nodes.

The Accuracy Index, defined as follows, was used to evaluate the classification methods:

$$Accuracy = \frac{properly\ classified\ cases}{all\ cases}$$

To verify the relevance of the selected methods of classification to the cause of disappearance identification, a computational experiment was conducted. For this purpose, two sets of data were used:

- Set 1: 617 real and 40000 synthetic cases,
- Set 2: 617 real cases.

The first dataset is a complete one, which means that it contains all cases. The latter is a subset of the previous one. It does not contain cases that occurred in the following months: January, April, July, and October. The second set of data allowed us to assess how much a reduction in the size of the training set can reduce the quality of classification. Table 2 shows the abbreviation of disappearance causes for the simplicity of the tables presented in this section.

Table 2: Contribution of each disappearance reason in the whole dataset.

Disappearance reason	Abbr.	Number of cases in Set 1 (%)	Number of cases in Set 2 (%)
Accident	AC	4146 (10,2%)	52 (8,4%)
Family abandoning	FA	3966 (9,8%)	59 (9,6%)
Walk away from hospital	WA	1891 (4,7%)	53 (8,6%)
Crime victim	CV	4057 (10%)	21 (3,4%)
Minor escape	ME	7995 (19,7%)	89 (14,2%)
Suicide	SU	7887 (19,4%)	80 (13%)
Family homicide	FH	2068 (5,1%)	43 (7%)
Getting lost	GL	8332 (20,5%)	116 (18,9%)
Drowning	DR	47 (0,1%)	11 (1,8%)
Natural death	ND	201 (0,5%)	93 (15,1%)

The main dataset is imbalanced meaning, that there is an unequal distribution of classes within it. Table 2 shows the distribution of classes in the main dataset with their percentage share. Table 3 shows the results we got after training several machine learning algorithms on the main and “real” datasets.

Table 3: Quality of classification for various methods and two datasets

Method	Accuracy (Set 1)	Accuracy (Set 2)
Multi-layer Perceptron	0.85	0.33
Decision Trees	0.70	0.44
Random Forests	0.78	0.46
Bayes Network	0.88	0.48
Support Vector Machines	0.52	0.29

The first set was divided into training and test data (respectively 75% and 25% of the datasets) using a 4-fold stratified cross-validation technique. The learning process was conducted 4 times for each method using different parts of the data. For the second set the synthetic cases were used as training data and the methods were tested using real cases. To train the Neural Network model, we performed feature scaling for the whole dataset using Min-Max Scaling. To find best suited NN hyper-parameters we used the Grid Search method. Best results were achieved for the model with two hidden layers with 23 and 57 neurons respectively with ReLU activation function across the network.

The best performing methods on real data set are Bayes Network and Random Forest. In the case of synthetic data test, Bayes Network and Neural Network respectively. Data that was used for the learning and the testing purposes of this paper was generated via the Bayes Network method. That can be the reason for good results in the case of Set 1. Low results of the second set are due to poor data quality (many records had missing features and output class) and a small number of examples. Despite that, Random Forest altogether with Decision Trees and Bayes Network show promising results. Table 4 and Table 5 show confusion matrices for the best-performing methods. Table 6 and Table 7 presents the outcomes of testing on a real dataset.

Making use of synthetic data allowed us to check whether ML methods work in the discussed setting. Although results for real data are not great, we strongly believe that after more real data will be gathered the methods will give real-world results.

Conclusion

Statistical data indicate a significant size of the phenomenon of missing persons in Poland. In that problem, the time from the moment of disappearance to the moment of making a decision should be as short as possible. Equally, decisions taken by the police, with limited knowledge, should be appropriate to the situation, reason and possible threats. Currently, the Police do not have any IT tools to facilitate the gathering and processing of data on historical cases. The purpose of such processing would be to use the experience of historical cases to increase the efficiency and effectiveness of searches in new cases of disappearances.

The formal model for the description of collected information about the missing person and its surroundings (including the circumstances of the disappearance, weather conditions, relations with other people) ensures data consistency and completeness in decision support, especially regarding a reason of disappearance.

This paper presents the concept of using ML methods to infer the cause of the people missing. Based on historical cases, an aggregated model of disappearances was built. Six ML methods were selected and calibrated on the basis of historical cases, and then their quality was compared. Due to the relatively small set of real cases available in the system, 40 000 synthetic cases were generated. The model of disappearances in the form of the Bayesian Network was used to generate synthetic cases.

ML methods are sensitive to the size of data sets, therefore dimensional reduction is a key issue which determines the quality of classification results. In the proposed solution, the reduction of data volume was achieved by selecting features and aggregating retail features to generalised ones. This has reduced the complexity of the classification tasks, including the space of possible vectors of feature value combinations.

The numerical example shows that the random forest method shows the highest quality of classification. A good matching of the Bayesian Network is probably due to the fact that it was used to generate synthetic data. Further research to compare the usefulness of ML methods for identifying the cause of missing persons will be carried out using an appropriate amount of data from real sources. Studies are also planned to investigate the impact of changes in data structure on the need to recalibrate classification models.

Abstract

This article is devoted to the development of a method of long-term assessment of technological competitiveness of enterprises taking into account the indicators of absolute and specific technological value of mechanical engineering products by areas of manifestation and using a scenario approach. Technological competition that exists at the macro, meso and micro levels of the economic system improves the solution of economic and organizational development problems and strengthens the market position of machine-building enterprises. Economic-mathematical modelling is carried out by combining asynchronous elements of situational modelling and features of Seidel's method as the most effective way of modelling technological competitiveness of products, companies and clusters in the national system of competitiveness as a complex system. The outlined combination makes it possible to obtain combinational equations at all stages of the iteration, as well as to form alternative calculations that describe the state of the finite elements of the state in cases of statistical and other disruptions and changes during the implementation of a particular scenario. This allows us to identify critical elements of the effect of increasing technological competitiveness. The results of the research will allow machine-building enterprises to assess the prospects of technological competitiveness of products based on absolute technological cost and specific technological cost in the areas of its manifestation.

Keywords: High-Tech Products, Export, Clustering of High-Tech Products, Mechanical Engineering Enterprises.

Introduction

The ability to create, to effectively attract, and to use technological innovation contributes to enterprise competitiveness, which is a significant advantage in the highly competitive environment. Technological competition, which exists at the macro-, meso- and micro-levels of the economic system, improves solving economic and organizational development problems and strengthens the market position of engineering enterprises. In this context, the need for assessment of mechanical engineering enterprise technological competitiveness is relevant.

Literature Review

In research (Measures and programs …, 1996: 92), it is proposed to determine the competitiveness of products under static conditions adjusted for the share of the *i*-th product in sales volume over the studied period, the importance rate of the *j*-th market in which the product is presented and the competitiveness of the *i*-th product in the *j*-th market. The disadvantage of the differential approach is its inability to determine the impact of parameters on consumer preferences. The combined method enables to express the ability of the product to compete under certain market conditions through comprehensive quantitative rate - competitiveness indicator (Safronov, 1998: 237). For a diversified enterprise that produces a variety of products, competitiveness indicator of the mass of commodities can be calculated as an average weighted of competitiveness indicators of each product using a formula (Measures and programs …, 1996: 68-173). The paper of Shkardun V.D., Akhtiamova T.M. (2000) (Shkardun, Akhtiamova, 2000: 49-51) considers a method of enterprise competitiveness assessment, which is represented as the ratio of properties of products to the amount of claims to them; the technology of a product is determined according to its characteristics: economic, technical, environmental, socio-psychological and legal ones. The competitiveness is defined as the average geometrical of the competitiveness indicators of each factor group. Other researchers define the problem of enterprise competitiveness assessment the way that Shmulevich T.V. (1999) stated it: to determine the values of competitiveness indicators, one should identify the numbers of most similar ones relative to the reference enterprises (Shmulevich, 1999: 115). Competitiveness indicators mentioned were as follows: return on assets, on investments, on fixed assets, on production; capital productivity; turnover ratio of current assets, autonomy, flexibility and absolute liquidity. Some researchers suggest to use a model approach for integrated competitiveness indicators determination, the essence of which is to develop economic and mathematical model of the competition object, for example, such as the problem of the effect of the acquisition and use of the optimization of a product, the maximizing of the market share which is occupied by this or another manufacturer and comparison of the model (forecasting) indicators of economic development or state. According to Chernyshevskii, L.M. (Chernyshevskii, 2008), the application of an individual indicator system is objectively stipulated by the complexity and ambiguity of this level, and he proposes to combine technical indicators with a scientific approach and, as a result, to consider the scientific and technological level of production.

The purpose of the article

is developing a long-term assessment of mechanical engineering enterprise technological competitiveness method on the basis of indicators of absolute and specific technological cost of mechanical engineering enterprise products according to areas of manifestation and with the use of scenario approach.

The main results of the research

Technological competitiveness of products, enterprises and clusters in the national competitiveness system is a complex system, because it consists of a significant number of interacting components; consequently, it acquires some qualitatively new features which are not typical for each of its constituents considered in isolation from others. This statement is confirmed by research.

Determining the competitiveness of a technological product.

O. Andreeva gives a more complete definition of product competitiveness: “competitiveness is a characteristic of the product-competitor depending on compliance with competitive public needs and with cost to meet it” (Andreeva, 1997:118-125). Besides, the measure of product compliance with public needs for various markets is different, which is not included in the definition. These shortcomings are eliminated in the following definition (Grosheva, 1991: 72): “competitiveness is nothing else than demonstration of product quality in the market relations; it is defined by the ability of products to be sold in a particular market to the maximum possible extent and without losses for the manufacturer.” A systemic definition of product competitiveness is provided by Faskhiev, K.A., Kostin, I.M.: “Competitiveness of a product is estimated by the ability to outperform, at some time, without losses, in terms of quality and price, the characteristics of the counterparts in a particular segment of the market” (Faskhiev, Kostin, 2001). From our point of view, the most comprehensive description of competitiveness is its definition as a market product feature, which represents its demand in the market, the ability to bring profit (Antoniuk, 2005: 275). Competitiveness is the ability to stay ahead of competitors in the market and to ensure the efficiency of enterprises activity through technological innovations, scientific and innovative potential management, technical level of production, technological capabilities, information activities. It is closely related to financial and organizational competencies, whereby technological product competitiveness is a set of competitive advantages of technological, technical, qualitative nature, corresponding to its functionality and customer value.

Determinants implementation of situational modeling of technological competitiveness

During modelling technological competitiveness of products, enterprises and clusters, it is reasonable to be guided by the following determinants: 1) all material intensity indicators define the cost value according to the type of technological construction of products; 2) a work package to reduce the labour-intensity and technological cost of products in use includes the application of design solutions that help reduce the cost of training and make-ready, technical control, transportation of products; reduce resource consumption, replace components of the product while maintaining its quality; enhance harmonization and standardization of the product components; facilitate and simplify conditions for maintenance and repair in order to limit the requirements for personnel qualification; 3) technological production cost is determined in monetary terms as the sum of all expenditure and used when the cost parameters are essential for the enterprise or cluster to improve its technological competitiveness; or it is determined as a percentage of the total production cost; 4) along with the absolute technological cost, the technology specific cost is applied for the area of its manifestation. Therefore, we propose to carry out mechanical engineering enterprise product technology competitiveness modelling in order to assess the competitiveness potential of the entity and its possible changing after taking a number of strategic measures.

During the implementation of situational modelling technological competitiveness of products, companies and clusters with asynchronous nature, one includes in the scheme functional (logical) elements, and their individual components in their integrated form (as a multitude) in the outputs of the scheme, are designated as $x_1, x_2, ..., x_n$. Thus, $e_1, e_2, ..., e_k$ are characteristics of the system. For example, technological competitiveness of certain products in the system of national competitiveness (as a simple multitude of elements) can form a scheme with a single output pole that characterizes its value during certain change, where *e* will respectively have two values: 0 (constant value) and 1 (variable value) at the output. To characterize the technological competitiveness of enterprises and clusters, we can form a scheme with four poles, which characterizes 16 states ($e_1, e_2 ... e_{16}$); thus, each element of the scheme has to perform a certain function of the current multitude $f_1, f_2, ..., f_k$. The function is understood as a system of logical equations from the description of a single parameter of enterprise or cluster technological competitiveness.

Scenario approach to modeling the increase of technological competitiveness

Let us carry out modelling the material intensity and the technological competitiveness of ACURA PJSC "Stakhanov Wagon Works" remote starting devices with the conditions given in Figure 1.

We presented the input data for modelling the material intensity and the overall technological design of ACURA devices in Table 1.

Table 1: The input data for modelling the material intensity and the overall technological design of ACURA devices

e_2	Value	e_3	Value	e_4	Value
R_p	0,09	E_p	0,1	M_p	0,06
R_t	0,10	E_t	0,09	M_t	0,06
R_r	0,08	E_r	0,05	M_r	0,01
$\boldsymbol{R_{total}}$	**0,27**	$\boldsymbol{E_{total}}$	**0,24**	$\boldsymbol{M_{total}}$	**0,13**

(compiled by the author)

Based on the results of modelling the material intensity and the overall technological design of ACURA remote starting devices (for scenario 1), we can conclude that only 2.4% reduction of the planned technological chip design cost reduction in the retail price per ACURA unit sales can be achieved. Thus, enterprise will not achieve the planned increase of technological competitiveness of ACURA remote starting devices in the national market, although some positive effect of these activities will be observed.

Figure 1: Scheme of the material intensity and TPC of ACURA devices modelling
(*adapted by the author on the basis of Matviichuk, 2009*)

Let us work out a mathematical equations system, which evaluates the changing of state factors for the 1-st scenario (Figure 2).

(compiled by the author)

On the basis of the results, let us work out a mathematical equation system which evaluates the changing factors of state for the 2-nd scenario.

From the results of modelling the material intensity and of the general technological design of ACURA remote starting devices (for scenario 2, see Figure 3), we can conclude that, from the planned reduction of chips technology design cost (in case of mechanized production precision lines acquisition), the planned reduction in retail prices (4.7%) per ACURA unit sales can be achieved. Thus, the enterprise will reach the planned increase of ACURA remote starting device technological competitiveness in the national market.

The modelling results show the scheme elements state changing process, but the function changing at the input – approximately, as there are interim results, and, therefore, there exists a statistical risk of failure within the iteration. Therefore, in the process of enterprise and cluster technological competitiveness modelling, it is reasonable to use methods of simultaneous nature (for example, economic researchers used Seidel method (Strategy 2010, 2009)). According to this modelling method, it is appropriate to use the mathematical equations shown in Figure 4.

Changing of e	Changing R_{total}	Changing of e_k total per unit	Period
0,09*1+0,1*1+0,06*1= 0,09*1+0,1*1+0,06*1 0,1- (0,1*0,016)+0,09-(0,09*0,0002)+0,06-(0,06*0,008) = 0,1*1+0,09*1+0,06*1 0,08*1+0,05*1+0,01*1=0,08*1+0,05*1+0,01*1	0,638	10,15 10,02	t t+1
0,09*1+0,1*1+0,06*1= 0,09*1+0,1*1+0,06*1 0,0984 – (0,0984*-0,016)+ 0,0899-(0,0899-0,0002)+0,0595-(0,0595-0,008) = 0,1- (0,1*0,016)+0,09-(0,09*0,0002)+0,06-(0,06*0,008) 0,08*1+0,05*1+0,01*1=0,08*1+0,05*1+0,01*1	0,635	9,92	t+2
0,09*1+0,1*1+0,06*1= 0,09*1+0,1*1+0,06*1 0,0968-(0,0968*0,016)+ 0,0898-(0,0898*0,0002)+0,059-(0,059*0,008) = 0,0984 – (0,0984*-0,016)+ 0,0899-(0,0899-0,0002)+0,0595-(0,0595-0,008) 0,08*1+0,05*1+0,01*1=0,08*1+0,05*1+0,01*1	0,633	9,83	t+3
0,09*1+0,1*1+0,06*1= 0,09*1+0,1*1+0,06*1 0,0952-(0,0952*0,016)+0,0897-(0,0897-0,0002)+0,0585-(0,0585-0,008) = 0,0968-(0,0968*0,016)+ 0,0898-(0,0898*0,0002)+0,059-(0,059*0,008) 0,08*1+0,05*1+0,01*1=0,08*1+0,05*1+0,01*1	0,631	9,75	t+4
0,09*1+0,1*1+0,06*1= 0,09*1+0,1*1+0,06*1 0,0936 –(0,0936-0,0-16)+0,0896-(0,0896-0,0002)+0,058-(0,058*0,008)= 0,0952-(0,0952*0,016)+0,0897-(0,0897-0,0002)+0,0585-(0,0585-0,008) 0,08*1+0,05*1+0,01*1=0,08*1+0,05*1+0,01*1	0,628	9,67	t+5

Figure 3. The mathematical equations system which evaluates the changing of state factors for the scenario 2*.

Note: * Changing of $e_1..e_n$ is uniform over 5 years
(compiled by the author)

Topological numbering of input for the equation variables is based on rank assigning. If the variable will affect the output element (e_k), it can be assigned rank 1; if value has the probability of changing (which can affect e_k), it is assigned rank 2. Thus, we receive several equations systems for the same sequence of input data sets. However, one of them will use the simple iteration method (asynchronous modelling), and the other one will provide alternative calculations that characterize the state e_k in cases of statistical and other disruptions and changes within the iteration.

To the left, the value of state element at the time t is substituted, according to the topological numbering scheme

$$
\begin{aligned}
e1(t) &= f1(x1(t), \dots, xn(t), e1(t-1));\\
e2(t) &= f2(x1(t), \dots, xn(t), e1(t), e2(t-1));\\
&\quad \dots = \dots\\
ek(t) &= fk(x1(t), \dots, xn(t), e1(t), \dots, ek-1(t),\\
&\quad ek(t-1)).
\end{aligned}
$$

To the right, the input values of state elements obtained in the same iteration and only for the element that is calculated are substituted

Figure 4: The mathematical equations system of the determining of state of elements which characterize elements during iteration t*

*Note. * To get the most accurate state of the scheme before the modelling, it is reasonable to arrange the equation, namely to record the exact order of its valuation because the state of i-th element can be calculated only if all states of the elements, which are included into the equation and can affect the value of this element, will be estimated.*
(compiled by the author)

However, in the process of the synchronous modelling, in one iteration, combinational equations (which show the final result) can be obtained. This, inevitably, leads to the impossibility of intermediate states of element and its impact on e_k researching (although it reduces the amount of calculations). In this regard, it is appropriate to add the asynchronous modelling to each iteration phase through alternative calculations, which describe the e_k state in cases of the statistical failures within iteration. For example, on the basis of data calculations for scenario 2 (Fig. 3), we assume that at the 3rd stage, there is a possibility of statistical and other disruptions and changes; due to this, the cost can be additionally reduced by reducing the labour-intensity of the repair TPC by 7% and at the 5-th stage by 3%. Thus, the system of mathematical equations that calculate the state factors changing for scenario 2 and the possibility of statistical failures are shown in Fig. 5.

Fig. 5: The system of mathematical equations that calculate state factors changing for scenario 2 and the possibility of statistical failures

(compiled by the author)

As a result of the modelling, it was found that the implementation of the scenario 2, in case of failures due to which there is a possibility of additional cost reducing by reducing the labour-intensity of the repair TPC at the 3-rd stage (by 7%) and the 5-th stage (by 3%), the enterprise can get additional opportunity to reduce retail prices by 5.8%.

Thus, the proposed combination of situational asynchronous modelling elements and Seidel method features (used in modelling of a synchronous nature) is the most effective way for modelling the technological competitiveness of products, companies and clusters in the national competitiveness system as a complex system. Due to the outlined combination, combinational equations at all stages of iteration could be obtained, and the alternative calculations that describe the state of finite elements of state in cases of statistical and other disruptions and changes during the implementation of a specific scenario could be formed.

Conclusion

The long-term assessment of enterprise technological competitiveness method is based on the synthesis of indicators of specific and absolute technology product cost according to the areas of manifestation and involves using a scenario approach, combining situational and asynchronous modelling elements with Seidel method features (Milko, 2014). Modelling the material intensity and the technological competitiveness of ACURA remote starting devices made it possible to determine that, under scenario 1, only 2.4% reduction of the planned technological chip design cost reduction in the retail price per ACURA unit sales can be achieved, and under scenario 2, the planned technological chip design cost reduction in retail prices (4.7%) per ACURA unit sales (in case of mechanized precision production lines acquisition) can be achieved. As a result of the modelling, it was found that, in case of Scenario 2 implementation, there is probability of failures, which can result in possible additional cost reduction with the labour-intensity of the repair TPC reducing at the 3-rd stage (by 7%) and the 5-th stage (by 3%) - the enterprise can get an additional opportunity to reduce retail prices by 5.8%. Assessment of mechanical engineering enterprise technological competitiveness prospects should be based on the following determinants: cost according to type of technological competitiveness of products based on material intensity including all expenditure; along with absolute technological cost, it is advisable to use the specific technological cost according to areas of its manifestation.

On Heuristic Linear Decomposition of Symmetric Index Generation Functions

Tomasz MAZURKIEWICZ

Faculty of Cybernetics, Military University of Technology, Warsaw, Poland, tomasz.mazurkiewicz@wat.edu.pl, ORCID: 0000-0001-7305-2379

Abstract

Decomposition methods of index generation functions gained a lot of interest lately due to their impact on memory size in hardware realizations. In this paper, we focus on a special class of those functions, i.e. symmetric index generation functions. We analyze the properties of this class, and how they influence on searching for a linear decomposition of index generation functions. In particular, we focus on a heuristic algorithm that uses discernibility sets, which efficiently reduces index generation functions. We present experimental results to prove the efficiency of this algorithm. Furthermore, we prove that the properties of symmetric index generation functions lead to better time efficiency of this algorithm, due to significant variables reduction.

Keywords: lndex generation functions, Logic synthesis, Linear decomposition, Symmetric functions, Variables reduction

Introduction

Memory-based logic synthesis of index generation functions (IGF) gained a lot of interest due to the applications of those functions (Sasao (2011, 2017, 2020)) in realizing pattern matching circuits. In the literature, there are many examples of using those functions in Internet of Things for devices such as virtual routers and malicious data detection systems. What is more, the concept of hardware implementation of index generation functions has been reported by Sasao (2020) as ”the key device in the network hardware”.

Index generation function maps unique integer value $\{1,2, \dots, K\}$ to elements of a set that consists of K different binary vectors, whose length equals N. Other assignments are left unspecified. The important property of those functions is that they are not fully defined, i.e. $K \ll 2^N$. Thus, they can be efficiently minimized and implemented using fewer variables than N.

In the literature, techniques such as variables reduction (Borowik and Łuba (2014)) and functional decomposition (Mazurkiewicz (2020a,2020b)) are used to minimize memory usage. However, linear decomposition has been identified as being the most efficient (Łuba et al. (2016), Mazurkiewicz and Łuba (2019), Sasao (2017)). Interestingly, those methods can be easily transferred and adapted to the field of knowledge discovery and data mining (Borowik (2014), Borowik and Łuba (2014)), i.e. to minimize the number of attributes and remove redundant decision rules.

Using the linear decomposition, an index generation function is implemented as a composition of a linear transformation L (using EXOR gates) and a general function G that is implemented using memory. Linear transformation, i.e. a composition of several linear functions, reduces the number of variables from N to P. Thus, $2^P Q$-bit memory is required to implement function G.

In this paper, we analyze the application of existing heuristic linear decomposition algorithm by Mazurkiewicz and Łuba (2019) in the minimization of a special class of index generation functions. Symmetric index generation functions are functions such that any permutation of input variables does not change the function. We prove that existing heuristic methods can be easily applied to minimize those classes of functions. What is more, properties of symmetric index generation functions simplify the computations, i.e. the number of variables can be efficiently reduced. According to our best knowledge, other studies (Nagayama et al. (2020)) addressed only optimum algorithms. The proposed approach was presented in Fig. 1.

Fig. 1: Proposed approach.

The rest of this paper is organized as follows: the second section defines symmetric index generation functions and compound degree. The linear decomposition algorithm using discernibility sets is described in the next section. In Section 4, we analyze the properties of symmetric index generation functions and the influence on the number of variables. The experimental results using experimental software are presented in Section 5. The efficiency of the linear decomposition algorithm after variables reduction is investigated in that section. The last section concludes the paper.

Preliminaries

An **index generation function** represents the following mapping:

$$F: D^N \rightarrow \{1,2,\dots,K\} \tag{1}$$

where D^N is a set of different binary vectors, called registered vectors, i.e. $D^N \subseteq \{0,1\}^N$. The important property of this function is that $|D^N| = K \ll 2^N$. Function F assigns the corresponding index (unique integer value from 1 to K) for every vector $v \in D^N$.

A **characteristic function** χ of an index generation function is

$$\chi : \{0,1\}^N \rightarrow \{0,1\} \tag{2}$$

where

$$\chi(v) = \begin{cases} 1 & \Leftrightarrow \quad v \in D^N \\ 0 & \Leftrightarrow \quad otherwise \end{cases} \tag{3}$$

In this paper, we focus on **symmetric index generation functions**, i.e. index generation functions whose characteristic function is symmetric.

M-out-of-N coders are often used as standard benchmark functions of linear decomposition algorithms. They consist of $K = \binom{N}{M}$ binary vectors, whose length is N and Hamming weight is M. Such functions represent symmetric index generation functions and are denoted S_M^N. An example of such function was presented in Table 1.

Table 1: Symmetric function S_1^6.

x_1	x_2	x_3	x_4	x_5	x_6	$F(X)$
1	0	0	0	0	0	1
0	1	0	0	0	0	2
0	0	1	0	0	0	3
0	0	0	1	0	0	4
0	0	0	0	1	0	5
0	0	0	0	0	1	6

To minimize such functions, linear decomposition can be used. In that case, an input function *F(X)* is realized using a general function *G(Y)* and *P* linear functions. Consider a linear function $y = \bigoplus_{i=1}^{N} x_i c_i$, where $x_i \in X$, $c_i \in \{0,1\}$. The compound degree of such function is $\delta = \sum_{i=1}^{N} c_i$. Therefore, the compound degree of the function *G(Y)* is equal to $\max_{i=1,2,\dots,P} \delta$.

Linear Decomposition

To find a linear decomposition of an index generation function a discernibility set might be used. In this section, we shortly present an iterative algorithm using such sets. For a detailed description please refer to the original paper by Mazurkiewicz and Łuba (2019). Efficiency of this algorithm for general index generation functions was already proven.

A discernibility set, denoted as C_{pq} is defined as follows:

$$C_{pq} = \{x \in X, p \neq q: x(p) \neq x(q)\} \tag{4}$$

p and q are indexes of registered vectors. Each vector $v \in D^N$ has index p iff $F(v) = p$.

The collection of all C_{pq} sets, i.e. for $p, q \in \{1,2, \dots, K\}$ and $p < q$, will be denoted as RC_{pq} and it's complement as $COM(RC_{pq})$. Additionally, the complement limited to sets with cardinality r will be denoted as $COM(RC_{pq}^r), r \leq N$.

To find decomposition of a function into several linear functions, the simple test can be used (Łuba et al. (2016), Mazurkiewicz and Łuba (2019)). Function $x_i \oplus x_j$ $(x_i, x_j \in X)$ is a decomposition function of F iff $\{x_i, x_j\} \notin RC_{pq}$. In that case, $\{x_i, x_j\} \in COM(RC_{pq})$. This simple test can be generalized. For example, pair of two linear functions: $x_i \oplus x_j$ and $x_j \oplus x_k$ $(x_k \in X)$ are decomposition functions of F iff $\{x_i, x_j, x_k\} \in COM(RC_{pq})$.

The discernibility matrix can be used to represent RC_{pq}. To improve the time efficiency of the algorithm, the repeating values are removed from this matrix.

To illustrate the idea of discernibility sets, all C_{pq} sets generated for S_1^6 function, i.e. RC_{pq}, were presented in Table 2. Additionally, the discernibility matrix was presented in Table 3. In each row, $x_i = 1$ iff $x_i \in C_{pq}$. Notice that each row can be generated using EXOR operation on p-th and q-th vectors from the truth table.

0	0	0	0	1	1	5,6

To find linear functions that decompose an index generation function, an iterative approach was proposed Mazurkiewicz and Łuba (2019). In this paper, we assume that the input function is not preprocessed using argument reduction procedure. For symmetric functions S_M^N, this procedure leads to a single row of all zeroes, which heavily affects the properties of analyzed functions.

The mentioned algorithm works as follows. Firstly, the algorithm searches for a decomposition function of F using discernibility sets. Next, the discernibility matrix is regenerated based on a linear transformation that was found. As long as $COM(RC_{pq}) \neq \emptyset$, another decomposition functions can be found. Thus, the algorithm iteratively finds a decomposition function and regenerates the discernibility matrix.

The key element of the algorithm is the proper selection of a decomposition function. The most time-efficient approach, called First-Fit or simply FF, chooses the first (in the lexicographic order) decomposition that was found. Unfortunately, the solution provided by this method is not always optimal, i.e. for *M-out-of-N* coders. Thus, another approach called MinR was proposed. It uses the number R of distinct row vectors in a truth table of a function limited to a subset of input variables $X \backslash d$, where d denotes variables used in a linear function and $|d| = r$. For example, if $y = x_1 \oplus x_2$, then $d = \{x_1, x_2\}$ and $X \backslash d = \{x_3, x_4, \dots, x_N\}$. The function that provides the minimum value of R is chosen as a decomposition function. If two or more subsets have the same value of R, then the first function found is chosen. Thus, in this place we proceed similarly to the FF method.

Due to the additional calculations in a decomposition selection procedure, the MinR approach is more time-consuming than the FF approach. However, the results presented in the literature proves that it provides better results for *M-out-of-N* coders.

What is important, in both approaches in each iteration the algorithm searches for a decomposition function with as small compound degree as possible. Thus, firstly $COM(RC_{pq}^2)$ is analyzed, then $COM(RC_{pq}^3)$, and so on.

Properties of Symmetric Functions

In this section, we analyze the properties of symmetric functions. We determine how they can be used for reducing the number of variables. Due to the space limitation, we focus on symmetric index generation functions with $M = 1$, i.e. S_1^N.

Basic Minimization

Let $M = 1$ and $N \geq 3$. In that case, $K = N$. In a symmetric index generation function S_1^N variable $x_i = 1$ ($x_i \in X$) in each registered vector $v \in D^N$ iff $i = F(v)$. Recall that Table 1 illustrates this property. In that case, any C_{pq} set contains only two variables: x_p and x_q since registered vectors with indexes p and q will always differ on those two variables. Therefore, the generation of RC_{pq} leads to a discernibility matrix that contains all possible vectors, whose length is N and Hamming weight is two. Any variable $x_i = 1$ iff $i = p \vee i = q$. Thus, $COM(RC_{pq}^2) = \emptyset$ and no function with compound degree two can be used as a decomposition function.

On the other hand, RC_{pq} does not contain any set with cardinality bigger than two. Therefore, since $\{x_1, x_2, x_3\} \in COM(RC_{pq})$ the algorithm chooses a pair of functions: $y_1 = x_1 \oplus x_2$ and $y_2 = x_2 \oplus x_3$ as decomposition functions in the FF approach. Recall that the MinR approach requires additional computations. However, the discernibility matrix of the analyzed symmetric index generation function can be also treated as a symmetric function. Thus, the value of R will be the same for all possible subsets d. This leads to the conclusion that the same pair of functions is chosen also in the MinR approach.

Notice that a pair of functions will be used as decomposition functions for any symmetric index generation function S_1^N. What is important, that the pair is known in advance without any computations whatsoever. The number of variables is reduced from N to $N' = N - 1$.

Consider now the function after first iteration of the algorithm if $N \geq 6$, i.e. $F(X) = G(x_4, x_5, \dots, x_N, y_1, y_2)$. Notice that first and third vectors are vectors, whose Hamming weight equals one. On the other hand, the second vector has 1 on both y_1 and y_2 variables. Thus, the truth table of a function still contains all possible vectors with Hamming weight one. The length of those vectors equals $N' = N - 1$. Therefore, $COM(RC_{pq}^2) = \emptyset$ one more time.

Decomposed function S_1^6 and all C_{pq} sets with cardinality two were presented in Tables 4 and 5 accordingly to illustrate described theoretical considerations.

Table 4: Decomposition of symmetric function S_1^6.

(a) Function after first iteration. (b) Function after second iteration.

x_4	x_5	x_6	y_1	y_2	$G(X')$		y_1	y_2	y_3	y_4	$G(X'')$
0	0	0	1	0	1		1	0	0	0	1
0	0	0	1	1	2		1	1	0	0	2
0	0	0	0	1	3		0	1	0	0	3
1	0	0	0	0	4		0	0	1	0	4
0	1	0	0	0	5		0	0	1	1	5
0	0	1	0	0	6		0	0	0	1	6

Table 5: C_{pq}^2 sets in the second iteration.

p,q	C_{pq}^2	p,q	C_{pq}^2
1,3	$\{y_1, y_2\}$	3,5	$\{y_2, x_5\}$
1,4	$\{y_1, x_4\}$	3,6	$\{y_2, x_6\}$
1,5	$\{y_1, x_5\}$	4,5	$\{x_4, x_5\}$
1,6	$\{y_1, x_6\}$	4,6	$\{x_4, x_6\}$
3,4	$\{y_2, x_4\}$	5,6	$\{x_5, x_6\}$

Using the FF approach we proceed similarly as previously. This leads to choosing a pair of functions $y_3 = x_4 \oplus x_5$ and $y_4 = x_5 \oplus x_6$ as decomposition functions. Notice that for the FF approach the described procedure will be used iteratively $\zeta = \left\lfloor \frac{N}{3} \right\rfloor$ times. Thus, the number of variables can be reduced to $N' = N - \zeta$ without any computations. In the next subsection, we investigate if some additional improvement can be achieved.

On the other hand, for the MinR approach, we have to proceed differently after finding the first pair of decomposition functions. Notice that if subset d contains only variables x_i, then all rows in a truth table are distinct. Thus, $R = K$. Recall that in the MinR approach, we look for a subset d that minimizes the value of R. If $y_1 \in d$, then second and third row are the same, i.e. all variables x_i are zeroes and $y_2 = 1$. Other rows are distinct. Thus, $R = K - 1$ and pair of functions: $x_4 \oplus x_5$ and $x_5 \oplus y_1$ is chosen as decomposition functions. In the end, the number of variables is reduced by two without any computations.

Further Minimization

From this point, we analyze only the FF approach. Let $N = 3 \cdot n$, $n \in \mathbb{N}$ and $F(X) = G(y_1, y_2, \dots, y_P)$. If $n = 2$, then $COM(RC_{pq}) \neq \emptyset$ and no further minimization is possible. If $n > 2$, then the vectors from the truth table of a function can be represented as a composition of the following two matrices:

$$A = \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix}_{3\times 2} \quad B = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}_{3\times 2} \tag{5}$$

In the result, we get the following matrix:

$$M = \begin{bmatrix} A & B & \cdots & B \\ B & A & \cdots & B \\ \vdots & \vdots & \ddots & \vdots \\ B & B & \cdots & A \end{bmatrix}_{n\times(2\cdot n)} \tag{6}$$

Notice that matrix B contains only zeroes. Matrix A contains two rows with Hamming weight equal to one and one with Hamming weight equal to two. What is more, this matrix contains all possible vectors, whose length is two, and Hamming weight is one. In the matrix M, every row and every column contain only one matrix A. Thus, the matrix M contains all possible vectors, whose length is $2 \cdot n$, and Hamming weight is one. In that case, $COM(RC_{pq}^2) = \emptyset$ and no function with compound degree two can be used as a decomposition function.

Since matrix A contains a row of all ones, it is not possible to find a pair of decomposition functions $y_i \oplus y_j$ and $y_j \oplus y_k$ such that $j - i = 1 \vee k - j = 1$. Thus, the following pair is chosen: $y_1 \oplus y_3$ and $y_3 \oplus y_5$. In that case, the number of variables was reduced to $N' = \frac{2}{3}N - 1$ without any computations.

On the other hand, if $N \neq 3 \cdot n$ $(N \geq 7)$, then we have $F(X) = G(x_N, y_1, y_2, \dots, y_{P-1})$ or $F(X) = G(x_{N-1}, x_N, y_1, y_2, \dots, y_{P-2})$. In that case, instead of the matrix M we get one of the following matrices accordingly:

$$M_1 = \begin{bmatrix} 0 & M \\ 1 & 0 \end{bmatrix}_{(n+1)\times(2\cdot n+1)} \tag{7}$$

$$M_2 = \begin{bmatrix} 0 & 0 & M \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}_{(n+2)\times(2\cdot n+2)} \tag{8}$$

Recall that the matrix M contains all possible rows with Hamming weight equal one, whose length is $2 \cdot n$. Thus, both M_1 and M_2 matrices contain all possible $2 \cdot n + 1$ and $2 \cdot n$+2-bit length vectors accordingly. Therefore, again $COM(RC_{pq}^2) = \emptyset$.

Notice that the M_1 matrix contains a row such that only y_1 and y_2 are one. Thus, $\{x_N, y_1, y_2\} \in RC_{pq}$ and a pair of functions $x_N \oplus y_1$ and $y_1 \oplus y_2$ cannot be used as decomposition functions. On the other hand, $\{x_N, y_1, y_3\} \in COM(RC_{pq})$ and one more variable is reduced without computations. Similarly, the M_2 matrix contains a row such that only y_1 is one. Thus, $\{x_{N-1}, x_N, y_1\} \in RC_{pq}$ and $\{x_{N-1}, x_N, y_2\} \in COM(RC_{pq})$.

As a result, for both matrices, we obtain a reduction of variables by $\left\lfloor \frac{N}{3} \right\rfloor - 1$ without any computations whatsoever.

Evaluation

To evaluate the efficiency of the described approach, we analyze some basic symmetric index generation functions. The same functions were used by other authors (Nagayama et al. (2020)) to analyze the optimum algorithm. Table 6 shows obtained results, i.e. the reduction of the number of variables (from N to N'), using the described properties of symmetric functions and the FF approach. In that table, *S. 4a* denotes results obtained using the approach described in Section 4a of this paper. Column *S. 4b* shows the results after applying further minimization. Notice that the number of variables was significantly reduced without any computations. The linear decomposition algorithms can be applied to further reduce that number. Since the time efficiency of all heuristic linear decomposition algorithms depends on the number of input variables, reducing it leads to better efficiency.

Table 6: Obtained results using the properties of symmetric functions and the FF approach.

Funcion	N	*S. 4a*	*S. 4b*
S_1^{10}	10	7	6
S_1^{20}	20	14	13
S_1^{30}	30	20	19
S_1^{40}	40	27	26
S_1^{50}	50	34	33
S_1^{60}	60	40	39
S_1^{70}	70	47	46
S_1^{80}	80	54	53

Table 7 shows the obtained results after minimizing symmetric functions using original heuristic algorithms by Mazurkiewicz and Łuba (2019). The column denoted *Opt* shows results obtained using the optimum method by Nagayama et al. (2020). However, this method searches only for solutions with a compound degree less or equal to five. Thus, it is possible to find a decomposition with fewer input variables than *Opt*. The column denoted κ presents the optimum theoretical solution calculated using the following formula

$$\kappa = \lceil \log_2 K \rceil \tag{9}$$

Table 7: Results obtained using heuristic algorithms.

Function	*Opt*	κ	FF	MinR
S_1^{10}	4	4	4	4
S_1^{20}	7	5	6	5
S_1^{30}	10	5	6	5
S_1^{40}	13	6	7	6
S_1^{50}	17	6	7	6
S_1^{60}	20	6	7	6
S_1^{70}	23	7	8	7
S_1^{80}	27	7	8	7

Table 8 shows the compound degree for results obtained using FF and MinR methods. The most remarkable result to emerge from the data is that the application of heuristic methods leads to better results in terms of the number of input variables. Results obtained using FF approach are close to κ, while the MinR method leads to results equal κ for all analyzed functions. However, the obtained compound degrees are generally high. It is worth mentioning that both methods, FF and MinR, were not designed to minimize the compound degree of a decomposed function.

Using the approach described in this paper, we obtain result worse by one variable for S_1^{60} function using the FF method. The main reason for this is that the argument reduction procedure is not applied. Thus, an input function is slightly different. For other analyzed symmetric functions we get the same number of the variables P after linear decomposition.

Table 8: Compound degree.

Method	S_1^{10}	S_1^{20}	S_1^{30}	S_1^{40}	S_1^{50}	S_1^{60}	S_1^{70}	S_1^{80}
FF	4	9	15	22	29	29	38	36
MinR	5	10	16	20	32	32	26	40

Figure 2 shows computation time (in seconds) of heuristic decomposition of symmetric index generation functions S_1^N. The experiments were conducted using experimental software implemented in Python (using NumPy), and run on the following computer environment: CPU: Intel Xeon E5-2650v2 2.6Hz, memory: 64 GB, OS: Windows 7, interpreter: Python 3.8. Computation time using original algorithms was presented. Additionally, the computation time after reducing the number of variables using the approach proposed in this paper was presented to evaluate its efficiency. It was denoted FF_p and $MinR_p$ accordingly.

(a) The FF method. (b) The MinR method.

Fig. 2: Computation time (in seconds) for symmetric functions.

The FF method is much faster than the optimum method by Nagayama et al. (2020) implemented in the C language and leads to quite good results. For example, it finds the solution for S_1^{80} function that is worse than the theoretical optimum by only one variable in 1.2 seconds. On the other hand, the time efficiency of the MinR method is much

worse. Notice that the reduction of the number of variables leads to better time efficiency of both algorithms. Time FF_p is up to 2.3 times shorter than the computation time of the original method. On the other hand, the MinR method has been accelerated only by 5%.

Conclusion

In this paper, the properties of symmetric index generation functions were analyzed. Additionally, we proved that those properties can be used to efficiently reduce the number of variables. This leads to a lower computation time of the heuristic linear decomposition algorithms. In particular, the FF method was accelerated by 2.3 times. What is more, we proved that heuristic algorithms can provide better results than the optimum algorithm in terms of the number of variables. However, the compound degrees are much higher.

In this paper, we focused on symmetric functions with $M = 1$. Therefore, our future work includes analysis of properties of functions with $M \geq 2$ and their influence on heuristic linear decomposition algorithms.

Abstract

Dynamic changes in the control system are due to changes in the external and / or internal environment. The risks of negative results after the introduction of changes are significantly reduced by using systemic training methodologies. Such methodologies are flexible management methodologies based on the Agile Manifesto. The authors propose the adaptation of known approaches to the introduction of flexible management methodologies together with the principles of change management. This uses a synergistic combination of the principles of the Agile Manifesto and the rules for implementing Cotter's changes. Among them: creating a sense of urgency; support groups, the vision of change, informing, removing obstacles, creating short-term victories, consolidating improvements, fixing changes. The authors consider a practical example of using the proposed method of implementing changes in the universities of Ukraine in the restructuring of the educational process in a pandemic. This adaptation takes into account the peculiarities of educational management. The introduction of changes concerned the translation of the educational process into a full distance format. Educational management has its own characteristics. The quarantine experience of VNTU and NUBIP universities testifies to positive changes based on already existing distance and blended learning portals. But the full remote format revealed problems of the unwillingness of a group of teachers and students to work completely remotely, insufficient server power, vulnerabilities of the testing module. To solve such problems, special training of teachers was organized, for students in rural areas - the use of various information channels, changes in the testing system. In addition, it was important to introduce changes for active teacher-student communication; teacher-teacher (at the suggestion of users); to introduce the electronic dean's office module at all faculties, to start using the procedures of forming the electronic archive and to implement the procedures of free choice of disciplines by students. It was also necessary to use security tools. Comparative tables of the introduction results of dynamic project groups of improvement of management systems of training and procedures of processes realization of training online testify to the efficiency of using flexible methodologies taking into account theories and practices of the introduction of changes. This approach allows you to create a dynamic management system of the organization, which quickly perceives and implements change.

Introduction

The urgency of introducing dynamic changes in the management system is confirmed by the needs of entrepreneurs and managers who offers to the market a variety of products and services for a variety of target audiences in a competitive market. Such methodologies are actively used for IT projects and IT products. But the tendency to use them in other areas and in everyday life is increasing day by day [Sutherland].

The introduction of changes in the management system also has its scientific and applied basis. For example, 8 Cotter's rules show that changes cannot be made randomly without preparation.

Steps such as creating a sense of urgency, forming a support group, creating a vision of change, informing, removing obstacles, creating short-term victories, consolidating improvements, fixing change - can be quite stable and dynamic and each can be implemented using flexible management methodologies [Cotter].

Materials and Methods

Methods of analysis of known approaches to flexible management and implementation of changes; synthesis of synergetic rules for the introduction of dynamic changes based on flexible methodologies; an experiment in the real educational process of the university; summarizing the results of changes.

The purpose of the research

Modern management actively uses flexible methodologies and adapts them to their needs [Ralph von Rusmalen, Management 3.0.]. The purpose of the study is to identify the features of flexible methodologies and their implementation for the formation of a dynamic management system of the organization. Approbation of the recommendations was performed on the example of the introduction of changes in the management of the university during the transition to distance learning during the pandemic.

Results and Discussion

The Agile Manifesto contains four basic principles [3].

- Engage People and their Interactions
- Improve the System
- Delight all clients
- Manage the system, not the people
- Co-create work

These principles support the priority orientation of personnel and their needs, the creation of values for customers and an environment where all participants in the production and management system can express themselves in the best way. The manifesto can be implemented using the Scrum methodology. This is the most popular implementation that can be used for university, business and student education [Tronin].

Let's analyze the principles of the Agile Manifesto, a flexible methodology according to Cotter's steps.

Creating a sense of urgency is the basis for change in motivation of employees in time and in the importance of the decision. There are also external signals of a sense of urgency. For example, the pandemic and the announcement of quarantine have made changes necessary for remote work, the introduction of distance learning, online negotiations, changes in the distribution of services and goods. Flexible methodology involves the active use of functional iterations and step-by-step work with constant monitoring and improvement, which corresponds to effective and dynamic time management.

Creating a support group or a project team is a good idea. Even better, when creative groups are already in the units and in general as strategic management groups. Each department should feel identified in the draft changes and be able to make suggestions and participate in the discussion. To do this, flexible methodologies use short daily discussions and mandatory analysis of iterative results, visualization of processes using special boards.

Creating a vision of changes is formed through clear texts and visualizations to achieve the goals in a timely manner. They become specific through special orders, decrees, statutes, regulations, or amendments to existing

documents. The ideal case is the only electronic environment where each employee has access to documents and visualization of the vision at the moment.

The next step - informing - resonates with previous and active dynamic support of information processes through daily and iterative meetings and discussions, visualization of processes, making changes to documents and their publication.

Removing obstacles is, first and foremost, work with the staff who resists the changes. This is a targeted training of staff, taking into account their suggestions, motivation and belief in the feasibility of changes. Flexible methodologies include dynamic training of staff, updating their skills and competencies, active work in pairs an in teams.

Creating short-term victories. Each iteration has specific results that are demonstrated and analyzed by all departments. Only positive results are followed by employee motivation. Therefore, negative results should be carefully analyzed for further improvements.

Consolidation of improvements. Psychologically, change is a slow process. That is why iteration after iteration adds positive changes, reduces the risks of negative results. It is important to consolidate all the positive achievements in the selected project area that were received before the implementation of changes and a specific project.

Fixing changes. In the electronic space, a special environment of dynamic electronic documents, a blog for implementing changes, task boards, new standards and regulations are being formed. Consolidation of such changes forms a new corporate culture, new concepts of the organization, and regular evaluations and discussions help to consolidate changes.

Educational management has its own characteristics. On the one hand, there are sustainable institutions and educational processes, on the other - the development of modern learning technologies forces school leaders to use new management methods and flexible technologies. One example of the introduction of rapid change has been and is the need to transfer learning processes to a completely remote mode. The implementation of distance learning was carried out most successfully in those universities, colleges and schools where learning management systems have already been introduced, teams have been formed to introduce innovative technologies, and so on. But the introduction of flexible methodologies and their adapted principles allow more effective projects to use distance format for quality learning during a pandemic in such conditions.

Flexible responses to mines in the environment are often intuitive. But this approach involves a lot of risk, duplication and leads to negative results. Let’s consider the example of the introduction of an iterative Agile approach in the process of implementing full distance learning during a pandemic in higher education. It should be noted that this approach was used at the university, which had already sufficient experience in the use of electronic resources in a mixed format. For example, scientific and practical developments of specialists of VNTU and NUBIP universities allowed to form special educational portals with access for applicants for higher education to electronic resources, use of tests, forums, etc. But the full distance learning format, introduced in a limited time, was a new and rather crisis process, taking into account that it was necessary to transfer all students and teachers of the university to this format. Online teaching required new approaches and concepts using the existing experience of blended learning and crisis education management [Kuzminskaya, Bisikalo, crisis].

Figure 1 shows the portals for blended and distance learning of NUBIP and VNTU, which demonstrate the high level of readiness of universities to use digital technologies. Each of the universities has its own approaches to building electronic services and using technology. But the main principle - the formation of quality content by discipline, creating an environment for effective communication between the administration, students and teachers is implemented in both environments.

Figure 1: Main pages of learning management system portals universities

Access to electronic resources, communication tools, and university repositories is organized on the main pages of educational portals. There are information pages on the implementation of changes in the educational process and communications.

But the full distance learning format introduced in a limited time was a new and rather crisis process, given that all students and faculty of the university had to be transferred to such a format.

Online teaching required new approaches and concepts using the existing experience of blended learning and crisis education management.

For example, on the first day of the introduction of quarantine teachers received instructions on the use of existing electronic resources and video communication, dynamic orders, and change orders that have been generated educational processes.

Consider the introduction of a flexible methodology for implementing change and adherence to Agile principles on the example of changes in educational processes services and other activities in the Vinnytsia National Technical University at the beginning of quarantine.

1. The group of senior management of the university in the center of change, respectively problems posed the interests of people - students and teachers, and also a priority area of activity that needed the largest changes - the provision of educational services. The first principle of the Agile Manifesto, which prioritizes people and collaboration rather than processes and tools.
2. The analysis of existing electronic resources, server architecture and other tools for distance learning. 2 The principle of the Agile Manifesto is the importance of working products, not documents.
But integration is also important for educational processes existing products and the introduction of new or previously passive one's tools.
In this case, it is the use of video communication with Google Meet and other student support channels, especially in rural areas.
3. Formed a support group for teachers and students that consists of representatives of each faculty, center distance learning, computer center, technical specialists working with electronic learning systems on each faculty.
Such a group develops and maintains readiness for change users of the learning management system, advises, helps, solves problem situations. Support channels have been formed for this purpose in social networks, special training sessions for teachers and students.
Cooperation with students and has been actively introduced to teachers.
The customer of educational services are students, readiness for changes are supported by dynamic discussions and changes in current documents.
4. Procedures for approving changes in documents have not changed and carried out according to previous plans. But dynamic orders of the administrative group allow making changes for the situation.
5. Monitoring the implementation of changes in accordance with the situation also has its own features.
5.1. A special notification system has been introduced for scheduled classes.
5.2. An electronic scheduling system with permanent links to online classes has been developed and implemented.

5.3. The basic learning management system contains instructions for working in the system in the form of Wikipedia, as well as a blog for technical and content changes in the system.
As the quarantine experience has shown, during this period there were detected the following problems:
1. Unwillingness of a group of teachers and students to work completely remotely. Solution: training; motivation; for students in rural areas - the use of various information channels.
2. Insufficient capacity of university servers. Decision: introduction of new capacities and formation of a special technical group.
3. Vulnerability of the testing module for the following reasons:
multifunctionality and the need for special knowledge (execution of instructions) when creating test tasks, the interest of hacker groups in access to answers to questions and failure of final control; large simultaneous server load.

Table 1: Dynamic results of certain modules of electronic information educational environment of VNTU

Modules	Up to quarantine	During quarantine	Changes	Usage statistics
Personal repository	Repository of personal methodical and scientific resources of the teacher		Activation of syllabus publication; electronic communi-cation between repositories	Downloaded materials from personal repositories - 1366483 times
Navigator of educational resources	Discipline resource navigator for students		Navigators for all actual disciplines and disciplines of free choice have been created	Created navigators of educational resources: 3873
Electronic magazine	Service formation of documentatio n of flow line and final control .	Service the formation of documenta-ti on is connected with the electronic archive.	Added blocks for forming course work archives.	All students and teachers of the university are covered
Test-IQ	Student knowledge testing service.		Modules work with increased security, google services and e-mail are partially separated	Answers to the questions of electronic tests TestIQ: 2880640 were received
Communications	Messaging service, corporate mail, file exchange	Google communi-cations services are built.		All students and teachers of the university are covered

In addition to the testing module, during the quarantine changes were made in the module of file communications teacher-student; teacher-teacher (at the suggestion of users); the electronic dean's office was introduced at all faculties, the use of procedures for the formation of the electronic archive and the implementation of procedures for the free choice of disciplines by students began; built-in corporate mail and video services. Also, security measures have been implemented, the consequences of hacker attacks have been eliminated, and G Suite for Education services have been partially separated. Table 1 presents the results of the stress testing of the electronic information educational environment of Vinnytsia National Technical University.

Based on the performed research and experience of implementing changes, the following recommendations were formed.

1. Agile approach should be used for projects and management situations, limited in time, in crises, and insufficiently defined situations, with limited resources and the need for consistent rapid change.
2. Management decisions are based on the results of analysis and forecast of the impact of actions on people and their cooperation.
3. Adapter's Cotter methodology involves the use of iterations and follows all steps of the change cycle with a repeat cycle to achieve the desired results.

The proposed methods can be used in the educational process as training of flexible management methodologies using practical cases and change boards. Such training can be conducted both online and offline. During the training, students work in teams and gain skills of teamwork, creating iterations, a daily brief discussion of changes, and their rapid implementation of situations.

Conclusions

The results of research indicate that the developed flexible methodologies for IT cannot be used directly in the general and project management of other areas. But Agilemanifest and the chosen methodologies must be adapted to the specific organization, projects and staff teams. The proposed recommendations for implementing changes using the tools of flexible methodologies allow you to form your own dynamic management system of the organization, which quickly perceives and implements changes in management in accordance with external market signals and changes in the internal environment.

We thank IT specialists and distance education centers of universities - Vinnytsia National Technical University and the National University of Life and Environmental Sciences of Ukraine for the opportunity to analyze the features of electronic resources and the experience of implementing dynamic changes in educational formats during the pandemic.

The Link Between the Development of Road Transport Infrastructure in Poland And the Changes in Transport Accessibility at Regional Scale

Tomasz KWARCIŃSKI

Chair of Transport Management, Institute of Management, University of Szczecin, Szczecin, Poland
tomasz.kwarcinski@usz.edu.pl

Abstract

Transport infrastructure affects the level of transport accessibility. The impact can be direct or indirect. The development of transport infrastructure directly affects the spatial and temporal accessibility of transport, shortening the distance and travel time. The indirect impact of transport infrastructure on transport accessibility manifests itself in improving the competitive position of the region and individual companies. The article aims at presenting the impact of the development of road transport infrastructure on changes in the level of regional transport accessibility in Poland. Separate attention is paid to the changes in the spatial layout of transport availability. The evaluation considered the most recent data from the Central Statistical Office, and the scope of the analysis looks at 2008 to 2018. In the context of improving transport accessibility, an assessment of the investment consisting in the construction of the S3 expressway was also presented.

Keywords: Road transport infrastructure, transport accessibility, Poland.

Introduction

Transport infrastructure is recognized as the biggest determinant of the proper functioning of a given area. It results from the functions performed by transport in the economy and in society. Transport infrastructure with good qualitative and quantitative parameters betters the quality of life, including the mobility of citizens. Beyond the social aspect, transport infrastructure is also important for all activities of economic operators. First and foremost, it has a positive impact on their competitive capacities. The quality of transport infrastructure also has an impact on the environment.

Transport infrastructure is the result of the economic activity of previous and current generations, which will be reflected in the asset intensity and capital intensity ratios. It is assumed that about 10% of the national assets are in the form of infrastructure, including transport infrastructure. At the same time, after assessing the capital intensity of transport infrastructure, it should be noted that it is characterized by high production and maintenance costs. The cost of building and maintaining infrastructure increases with its quantitative level, reflected in the road category.

The role of transport infrastructure in socio-economic development - literature review

Transport infrastructure is an important factor, which contributes to socio-economic development. Such views are common in the literature. In domestic literature, especially since the 1960s, this subject has been brought up by many researchers (W. Grzywacz, 1982, K. Wojewódzka-Król, R. Rolbiecki 2008, M. Ciesielski 1992, M. Ratajczak, 1999, Z. Dziembowski 1995).This perspective includes general assumptions regarding transport infrastructure (social and economic characteristics, functions and classification) and attempts to identify the effects of economic, social and environmental development (P. Rosik, B. Szuster, 2008). On the other hand, foreign literature deals with the impact of transport infrastructure on socio-economic development, which is related to the primary and secondary impact (D. Banister, J. Berechman, 2000) [i], as well as direct and indirect effects, and demand and supply (J.G. Heggie, 1978) [ii].

Research connected with the impact of transport infrastructure on socio-economic development concerns:

a) time of travel - quantitative growth and qualitative development of transport infrastructure reduce travel time;
b) costs of transport – the development of infrastructure improves the investment attractiveness of a given area, capital productivity, it contributes to technical progress;

Cite this Article as: Tomasz KWARCIŃSKI " The Link Between the Development of Road Transport Infrastructure in Poland And the Changes in Transport Accessibility at Regional Scale" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

c) efficiency of the transport process - the transport infrastructure impacts on the progress of the transport process, and directly affects the efficiency of manufacturing companies and household budgets (e.g. lower operating costs of passenger cars).

The development of transport infrastructure is particularly relevant in the less-developed regions. This thesis is confirmed by assigning different weights to transport infrastructure as a factor shaping the competitiveness of the region[iii]. Of value are reports presented by the IMD – *International Institute for Management Development* and the WEF – *World Economic Forum*, where transport infrastructure is among the basic requirements that shapes the competitiveness of a given area, K. Schwab, 2019 (most often a country). The approach of W. Grzywacz coincides with this; it distinguishes three groups of countries (low, medium and highly developed) and postulates different shaping of outlays on social and economic transport infrastructure.

E. Załoga (2006) points out that transport infrastructure is a determinant of the competitiveness of countries and economic groups. He stresses the increasing role of transport infrastructure as a driver of supporting the group's competitiveness in the global economy. In the EU countries, transport infrastructure is considered an extremely important strategic factor used to achieve development goals, including the group's competitiveness, the efficiency of the use of resources and climate neutrality. An important position in these programs is occupied by the T-TEN trans-European transport network.

In the social dimension, the role of transport infrastructure stems from its function as a determinant of social mobility. Thanks to ensuring spatial connections, the transport infrastructure enables access to jobs, science, health care and culture. On the wider stage, transport infrastructure positively impacts the leveling of social disproportions in regional terms. As K. Wojewódzka-Król and R. Rolbiecki (2018) notes, the development of transport infrastructure may also contribute to mitigating the implications of unemployment.

In the spatial aspect, the transport infrastructure influences, inter alia, the mobility of inhabitants as well as the market of goods and services. Its improvement allows the inhabitants (at the same time) to cover a greater distance. On the other hand, for market entities it means the possibility of reaching more customers. Owing to better transport infrastructure, producers can offer their products in a wider area.

In environmental terms, attention is drawn to the role of transport infrastructure in reducing external costs of transport. Improving transport infrastructure could contribute to constraints related to the reduction of pollutant emissions and noise.

Despite the generally expressed opinion about the positive impact of transport infrastructure on the socio-economic development, this impact has not been explicitly identified in terms of quantity and quality. Based on statistical analyses, it is only possible to confirm the relationship between the quality of infrastructure and the level of safety, speed of transport, production efficiency and travel time.

The link between the development of transport infrastructure and transport accessibility

The literature lists several approaches to transport accessibility, which etymologically derives from the words access and ability and is related to the ability of achieving a goal using transport infrastructure (linear and nodal) and transport services (A.M. El-Geneidy, D.M. Levinson, 2006).

Many researchers point to the important role of transport infrastructure in shaping transport accessibility. M.Q. Dalvi and K.M. Martin (1974) find that it provides the opportunity to achieve specific goals and locations. On the other hand, K. Spikermann and J. Neubauer (2002) believe that transport accessibility is the core product of the transport system in a given area, which presents the advantages of the location of a given area (region, city or route) in relation to other areas. P. Rosik (2008) refers transport accessibility to indicators based on transport infrastructure. He distinguishes between simple and composite indicators. Simple indicators related to the network density in a given area (network length per 100 km2, per 1,000 inhabitants or a weighted average indicator taking into account both the area and the number of inhabitants). Composite indicators consider access to a given area from the outside (e.g. interregional or national connections). I. Tarski (1973) states that transport infrastructure has an impact on the formation of transport accessibility, while M. Madeyski has a broader approach to the issue of transport accessibility, referring it to transport infrastructure and transport services. According to Madeyski (1976), accessibility is a parameter that allows to determine the degree of transport development of a given area. It is conditioned by the density of transport points and the frequency of connections between them.

The linear infrastructure of transport itself falls short of the demand for accessibility, as transport customers can use it only through transport points (communication stops). This reservation does not apply to the users of individual transport whose transport needs are attended to as a result of access to the linear infrastructure.

Amongst the types of transport accessibility (economic, spatial, temporal and informational), transport infrastructure has a particularly close interaction with spatial and temporal accessibility. Spatial accessibility is related to the ease of achieving the assumed objective using the transport network. It depends on the transport policies (equipment with nodal and linear transport infrastructure) of a given area (region, state). Time availability means the actual time needed to travel between specified points using the means of transport P. Śleszyński (2014). As P. Śleszyński notes, time accessibility is one of the easiest ways to identify spatial accessibility. It results from universality and comparability allowing the analysis of various transport systems. The conditions for such a defined time transport accessibility are created by the density of the transport network.

Improving transport accessibility requires continuous activity of the state and local governments, inter alia, in the field of development of transport infrastructure. This will be confirmed by R.S. Tolley and B.J. Turton (2014), who state that the development of the transport system makes for improved transport accessibility by reducing the time and cost needed to travel a given distance, for example between the place of residence and the destination.

Besides the density of the network of transport infrastructure, the quality of it affects the ease of reaching the travel destinations. The network of infrastructure connections is characterized by a radial design, which means that larger units (e.g. cities) have a greater number of possible directions of transport connections with the environment, which increases their spatial availability. That said, such organization of transport implies automatically that the inhabitants of smaller centers have limited transport accessibility, which in practice means that they can only travel in one direction. The inhabitants of towns located on the communication routes connecting larger towns are in a more favorable position.

Transport infrastructure, in the context of transport accessibility, has a positive impact on territorial cohesion. The issue concerns in particular areas located on the periphery of the country, region (peripheral) that is socially or economically backward. This thesis is confirmed by K. Spiekermann and M. Wegner (2004), according to whom the transport infrastructure enables spatial interaction, improving social cohesion. The role of accessibility also stems from its importance to overall economic growth, which additionally influences social development. In this aspect, accessibility of transport remains an important factor in providing people with access goods and services; and in more general terms it has a positive impact on the quality of life of inhabitants in the region.

The link between the development of transport infrastructure and the level of transport accessibility of regions in Poland

The empirical analysis presents an assessment of the impact of the development of transport infrastructure in Poland on transport accessibility in the regional dimension (in each voivodeship). In the analysis of the level of transport accessibility at the regional level in Poland, two indicators were taken into account (Table 1):

– spatial density of the road network as the quotient of the length of hard surface roads[iv] to area (of the country and voivodships),
– demographic density of the transport network as the quotient of the length of hard surface roads to the number of population (of the country and voivodships).

Table 1: Transport accessibility of regions in Poland in 2018 – spatial aspect

Specification	Length of hard surface roads (in thousand km).	Surface (in thousand km2)	Number of people (thousand)	Spatial density (in km/100km2)	Demographic density (in km/thousand inhabitants)	Weighted average road network density index
Polska	307,7	312,6	38 300	98,21	8,02	88,72

Source: prepared by the author based on Transport wyniki działalności 2018; GUS Warszawa 2019, Rocznik demograficzny 2020, GUS Warszawa 2020.

The presented calculations provide grounds for drawing the following general conclusions regarding the availability of road transport infrastructure in Polish regions:

1. Taking into account the area, as a criterion for assessing transport accessibility one could identify several voivodeships with a higher spatial density index than the national average (approx. 100 km/100 km2). This group includes regions located in the southern part of Poland (Małopolskie, Świętokrzyskie and Śląskie). On the other hand, the area of northern and north-western Poland (Zachodniopomorskie, Pomorskie, Warmińsko-Mazurskie and Lubuskie) are characterized by lower spatial density indicators of the road network.
2. Given the population as a criterion for assessing transport accessibility, it can be noted that the voivodeships characterized by higher road demographic density indicators than the national average (8 km/thousand inhabitants) are Podlaskie, Zachodniopomorskie, Kujawsko-Pomorskie, Warmińsko-Mazurskie and Lubuskie, while lower indicators concern Małopolskie, Podkarpacie, Śląskie and Pomorskie.
3. Indicators of demographic density of the road network and spatial density of the road network can be used for comparative assessment of one quality. To distinguish regions with better and worse transport accessibility, one can use the balanced indicator of road network density[v], which reflects the degree of development of the transport network, taking into account the area and population. Considering this indicator, it can be concluded that prime availability of road transport infrastructure is in the Świętokrzyskie, Małopolskie, Kujawsko-Pomorskie and Łódzkie Voivodships. Pomorskie, Zachodniopomorskie and Lubuskie showed a worse result.

The increase in the level of transport accessibility in regions depends on the development of transport infrastructure. Table 2 and Figure 1 present the development of the sustainable road network indicator in 2008, 2013 and 2018 as a result of the development of the length of transport infrastructure in Poland.

Table 2: Changes in transport accessibility in Poland in 2008–2018 - road infrastructure

Specification	Weighted average road network density index (2008)	Weighted average road network density index (2013)	Weighted average road network density index (2018)	Change in 2018: 2008 (in %)
Polska	79,14	85,88	88,72	12
Dolnośląskie	80,78	85,60	86,85	8
Kujawsko-pomorskie	80,66	95,26	100,95	25

2008 *2018*

Fig. 1: Weighted average road network density index in Poland (2008-2018)

Source: prepared by the author using ArcGIS software.

Changes in the length of road infrastructure seen in Poland in 2008–2018 positively influenced the improvement of the level of spatial accessibility in Poland and in particular regions. An exception consists in one voivodeship (Śląskie) where the indicator of the level of transport accessibility expressed by the balanced road network density indicator has decreased. A high growth rate of the weighted average road network density indicator was recorded in the following voivodeships: Kujawsko-Pomorskie, Lubelskie, Podlaskie and Podkarpackie.

Taking into account the indicator of the density of balanced road network, the situation in this respect is more favorable in southern Poland (especially in the Małopolskie and Świętokrzyskie Voivodeships). That said, this indicator is lower in the northern Poland voivodeships (Zachodniopomorskie, Pomorskie and Warmińsko-Mazurskie Voivodships).

The positive effect of improving transport accessibility in the regions of eastern Poland could be related to a special program implemented from the European Union funds, taking into account the development of transport infrastructure (OP Development of Eastern Poland). The improvement is also related to the decline in population numbers in some regions. In the analyzed period, such a situation took place in the following voivodeships: Lubelskie, where there were 40,000 inhabitants less, and also: Łódzkie (-81,000), Opolskie (-48,000), Podlaskie (-9,000), Śląskie (-109,000), and Świętokrzyskie (-27,000). On the other hand, in the remaining regions, there was an increase in the number of people, and the largest was seen in the following voivodships: Małopolskie (+111,000), Mazowieckie (+192,000), Pomorskie (+113,000) and Wielkopolskie (+102,000). The migration of inhabitants is related to the choice, especially of younger people, of places offering better conditions for the development of education and later work opportunities. Undoubtedly, large urban centers and suburban areas located in close proximity are places that offer such conditions. Weaker improvement in spatial accessibility can be noticed in the Łódzkie and Zachodniopomorskie Voivodeships.

The impact of the development of transport infrastructure on the level of regional transport accessibility can also be analyzed taking into account road categories. In Poland, roads are divided into: national (including motorways, express roads), voivodeship, district and commune roads. Roads of a higher category are important for the accessibility of interregional transport, while roads of a lower category (district, commune) are relevant for intra-regional mobility. Changes in road length in 2008-2018 are shown in Table 3.

Table 3: Changes in road length in Poland in 2008-2018

Specification	National roads		Voivodeship roads		District roads		Commune roads	
	2018 (in km)	2018: 2008 (in %)	2018 (in km)	2018: 2008 (in %)	2018 (in km)	2018: 2008 (in %)	2018 (in km)	2018: 2008 (in %)

Source: prepared by the author based on Transport wyniki działalności 2018, GUS, Warszawa 2020, Transport wyniki działalności 2008, GUS Warszawa 2009.

In 2008-2018, the length of almost all road categories increased, and only the length of district roads remained unchanged. That said, when analyzing this process, one should take into account the possibility of transferring roads to new road operators, which changes their status. In addition, in accordance with the applicable regulations, the commissioning of a new national road (motorway, expressway) meant that the old route, pursuant to the Public Roads Act, passed under the management of Municipal Executive Boards. This resulted in numerous protests from communes, which could not provide appropriate financing for maintenance of the transferred roads. After the change in regulations, national roads are handed over to provincial local governments, which is a better option.

In the period 2008-2018, among all road categories in Poland, the roads with the highest categories (motorways, expressways) underwent the greatest development. Such an extraordinary growth dynamics (114% motorways, 360% expressways) is partly due to the short length of the roads that had been built in Poland until 2008. The problem was the financing of road transport infrastructure, in particular roads of the highest category. Financing provided from the budget of the European Union proved helpful; co-financing from EU funds amounted to 75% of the value of investment. Generally, the length of motorways in the years 2008-2018 has increased from 765 km to 1636 km and the length of expressways has increased from 451 km to 2077 km. Currently, there is no region in Poland without a motorway or expressway.

The basic network in the regional perspective consists of district and commune roads. Especially in the latter category, a high growth dynamic was recorded in Poland (increase in commune roads by 41%). Most of them were recorded in the following voivodships: Kujawsko-Pomorskie, Lubelskie, Podlaskie and Warmińsko-Mazurskie, so in the area of Eastern Poland.

To conclude, the development of road transport infrastructure in Poland has improved the spatial accessibility of regions. The increased transport accessibility in interregional terms is positively influenced by the expansion of the network of higher-category roads, i.e. motorways and expressways. These roads are beneficial in faster and safer

movement of passengers and cargo between regions. More widely, a modern road network of international importance has a positive effect on international traffic, increasing the competitiveness of economic entities and thus positively influencing the competitiveness of regions and the country. Improving accessibility in the intra-regional area is also important. This is enabled through the expansion of district and commune roads, in which case the provincial local government and the state are actively involved in their financing.

The link between the development of transport infrastructure and transport accessibility as seen in the case of the S-3 expressway (section from Szczecin (Płonia) to Gorzów Wielkopolski)

The S-3 expressway connecting Szczecin (Klucz) with Gorzów Wielkopolski was put into use at the end of 2010. The total length of the new road was 81 km. In the coming years, the road was extended towards Świnoujście (north) and Lubawka (south). Until commissioning of the new S-3 road, car traffic took place on National Road No. 3 (currently district road no. 119) Szczecin (Płonia) - Gorzów Wielkopolski.

After a decade of commissioning the S-3 road, a number of positive social, economic, spatial and environmental benefits can be noticed, including:

1. **Improving safety in the carriage of passengers and cargo.** The section of National Road No. 3 Szczecin (Płonia) - Gorzów Wielkopolski was considered very dangerous in the Zachodniopomorskie Voivodeship. Many tragic traffic incidents took place there. In 2010, there were 15 accidents on National Road No. 3 on this section, while in 2019 there were 7. At the same time, no road accident occurred in 2019 on the new S-3 road.[vi]
2. **Improving traffic flow, shortening the travel time between cities.** National Road No. 3 (currently voivodeship road no. 119) in the section Szczecin – Gorzów Wielkopolski is a single carriageway running through towns and rural settlements. Until commissioning of the new road, the S 3 road was one of the most trafficked roads in the voivodeship. Its task was to handle international and regional traffic, and especially in cities through which the local traffic ran. In the years 2000-2010, the average daily traffic of vehicles on this road increased by 20%. The increase concerned both passenger cars and trucks. The most difficult situation occurred in the city of Pyrzyce, where the average daily traffic in vehicles exceeded 18,000 in 2010. This resulted in many kilometers of congestion, long travel times through the city, and was also burdensome for the inhabitants in everyday life.
Research conducted in 2015, already on the new S-3 road, confirmed further development of the average daily traffic on the section Szczecin (Klucz) - Gorzów Wielkopolski. In 2015 traffic amounted to 14.5 thousand vehicles, including 11 thousand passenger cars and about 2.2 thousand trucks.[vii]

Execution of the investment resulted in a major reduction in travel time between the cities in the south of the voivodeship (and also Gorzów Wielkopolski) and the northern part of the voivodeship (including Szczecin).
According to data supplied by Google Maps, the travel time between Szczecin (city center) and Gorzów Wielkopolski (city center) is currently about 1 hour (distance 110 km). The same route, but using district road 119 (old National Road No. 3) takes about 1.45 hours (distance 102 km). However, it is to be remembered that currently, traffic on Route 119 is smooth. Before road S 3 was commissioned, it took from 2.5 to 3 hours to travel between Szczecin and Gorzów Wielkopolski.

3. **The positive impact of investments on the labor, goods and services market.** The commissioning of a new road had a positive impact on the possibility of accessing better paid jobs in the area of the Szczecin agglomeration. This also applies to the possibility of satisfying other needs related to science, health centers or cultural institutions. It is also important in handling cargo for the ports of Szczecin and further in Świnoujście and in handling tourist traffic
4. **Improving the living conditions for the locals.** The increasing traffic of road vehicles made it particularly difficult for the inhabitants of the villages along National Road No. 3, i.e. Szczecin Płonia, Żabowo, Pyrzyce, Mielęcin, Mielęcinek, Lipiany, Renice and Gorzów Wielkopolski. The commissioning of road S – 3 improved the living conditions of the inhabitants, including their safety, and limited exhaust and noise emissions.
5. **Improved comfort of the travel.** The construction of Passenger Service Areas with service and recreational functions has improved the comfort of the journey and the possibility of rest during travel. The new expressway is adapted to the load-bearing capacity requirements, which was not ensured by the old National Road No. 3. This resulted in the formation of ruts on the old road, which created an additional hazard for travelers. Taking into account the current parameters of the S-3 road, it is possible to use it for loads of abnormal weights oraz sizes.
6. **Strengthening the position of the region as a cross-border transport and logistics center.** Taking advantage of the location of the Zachodniopomorskie Voivodeship at the north-south junction, connecting southern Scandinavia through Świnoujście, Szczecin, the Oder River Trail, the Czech Republic, Austria with the ports of the Mediterranean Sea requires the construction and maintenance of high-quality transport infrastructure. Undoubtedly,

the S-3 road helps to strengthen this position. Just as important as this is the development of the railway line ("Nadodrzanka") and the Oder River Waterway.

7. **Reducing the adverse impact of road construction and operation on the natural environment.** The conducive factors include specially built bridges (25) ensuring the continuity of wildlife migration routes (overground and underground wildlife crossings).

Conclusion

The development of transport infrastructure has a positive impact on the mobility of passengers and goods. It also contributes to the safety and comfort of travel, and the reduction of transport costs, including external costs (air pollution, accidents, congestion), and it positively affects the employment rate (directly and indirectly).

The development of transport infrastructure has a positive effect on the level of transport accessibility. It undeniably contributes to the improvement of transport accessibility in terms of space and time. In this aspect, it facilitates the achievement of goals and reduces the time associated with it. The advancement of transport infrastructure, in the context of transport accessibility, has a positive effect on the social and economic cohesion of the region.

The presented analysis of the impact of development of transport infrastructure on the level of transport accessibility confirmed the betterment of transport accessibility index in spatial terms. The advancement in this indicator primarily resulted from the development of hard surface roads in Poland. Importantly, it concerned virtually all road categories. The development of expressways and motorways streamlined transport accessibility in the interregional perspective, while the development of commune roads contributed to a better situation in the intraregional perspective.

The construction of the S-3 road had a positive impact on the social, economic and spatial cohesion of the Zachodniopomorskie Voivodeship and improved the quality of life of the locals. In the context of transport accessibility, beside improving cohesion, the time aspect of the investment's implementation proved important, as it allowed to shorten the travel time between cities and through the voivodeship. In any case it has, however, to be noted that the planned completion of the entire investment will take place in 2024. Only then will it be possible to assess the full effects of the investment. The new S-3 road has improved transport accessibility (especially interregional) and reduced external costs of transport, but the question is whether it has not limited the development of cities and rural areas through which the National Road No. 3 (currently voivodeship road no. 119) ran.

---

[i]Primary impact can be defined as a current one, while a secondary impact occurs over time. In a short period of time one can observe changes as a result of traffic, benefits from lower vehicle operation costs, a reduction in travel time, improved traffic flow, and in the long term, there are shifts related to the location of settlement and production.

[ii]Demand effects are related to the direct benefits achieved from implementation of the investment (the use of materials for construction or demand for labor). Supply effects are related to implementation of the infrastructure investment and its impact on the environment.

[iii] That said, the impact on competitiveness depends on the stage of development of a given country - higher in relatively underdeveloped countries, and lower in highly developed countries. The segmentation criterion is most often based on the purchasing power of an individual citizen, expressed in USD. It is true that the measure used by the World Economic Forum (GDP per capita) has come in for a lot of criticism. There are calls for taking into account more elements in measuring the level of development of countries. A good example is the HDI measure, which takes into account not only GDP per capita, but also life expectancy and school education.

[iv] Unpaved roads, used by farmers and foresters to access fields, were omitted.

[v] The weighted average density index takes into account spatial and demographic density. It is a quotient of the length of network (e.g. road network) and the square root of the product of the area and the population of the studied area.

[vi] For more information on this subject see www.obserwatoriumbrd.pl

[vii] The decrease in the number of trucks is most likely due to the fact that the use of expressway S3 by them is paid. Some of the vehicles use the old national road S-3, which is free for passenger cars. This status can be confirmed by research conducted on national and district roads that is carried out in 2020, and whose results will be known at the end of 2021.

The Relevance of the Local Touristic Actors for the Destination Communication: The Case of Terras de Trás-os-Montes

Abstract

The destination communication is carried out by a diversity of actors, from the local community, to the tourists, the public and the private sector The local community has taken on an increasingly active role with regard the communication of a destination, since it is in direct contact with the tourist, assuming a informal role of the destination promoters. This communication is progressively generated through information and communication technologies (ICT), namely social networks. In this article the communication contribution of the tourist entities of the Trás-os-Montes lands (a region in the northeast part of Portugal) is analyzed. For that an evaluation was carried out on their online presence and its way of communicating the region. The findings offer relevant insights for the destination managers and policy makers.

Keywords: Local community, tourist entities, communication, destination, information and communication technologies (ICT).

Introduction

The local community of a territory is one of the most important elements in the construction of the territorial offer, since it is at the same time producer and consumer of such offer (Hankison, 2007, Correia &Brito 2020). From this community the touristic actors connected to the hospitality industry have the capacity to promote the destination individually by their actions and promotional tools. If they are aware, involved, and identified with their region desired image, these local actors tend to act as true promoters of the region by conveying, in contact with other audiences, messages consistent and appropriate to the characteristics of the offer (García et al., 2012). However when they are not aligned with the destination vision or simply are not aware of it, their communication may generate an unclear image for the tourist.

Although the relevance and potential of these local tourist actors in promoting a destination are undeniable, Aitken and Campelo (2011) mention that residents and the local community are often left out of the brand creation process, and therefore do not participate in the implementation of the territorial marketing strategy (Kavaratzis & Ashworth, 2008), nor, in turn, are aligned with the communication of the brand / destination.

Depending on the characteristics of the territory, local community can vary in size, diversity, dispersion, as well as interests. This heterogeneity makes the alignment of the local community with the values and territorial vision a complex driving force.

The relevance of the local tourist actors was amplified with the technological promotional tools that are now available both for companies and individuals. In fact if, since the 1980s, Information and Communication Technologies (ICT) began to transform tourism (Buhalis & Law, 2008), they are currently essential in tourist organizations (Drosos, Chalikias, Skordoulis, Kalantonis, & Papagrigoriou, 2017). ICTs are crucial not only as internal sales tools (Martins et al 2017) but also for interaction, dialogue and connectivity with customers. These

Cite this Article as: Madalena MARINHO, Ricardo Fontes CORREIA and Elisabete Paulo MORAIS "The Relevance of the Local Touristic Actors for the Destination Communication: The Case of Terras de Trás-os-Montes" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

technologies have made available to tourist actors, even if small, instruments to communicate directly and interactively with their audiences, influencing not only their image but also that of the region where they are located.

The main objective of this article is to understand the online presence of tourist entities and how they communicate the destination where they are inserted. The destination chosen for this analysis comprises the 9 municipalities ascribed to the Lands of Trás-os-Montes (a region in the northeast part of Portugal). In a first stage, it was important to understand the presence of various local tourist entities, on social networks and how they make use of their website. Then, we analyze whether they communicate the destination and whether they do so effectively.

The article is structured as follows. Section 2 offers a comprehensive overview of the theoretical background where the role of the local community in the communication of a destination and the importance of online communication is highlighted. Section 3 presents the methodology used, and after in section 4 the results are discuss. Finally section 5 summarizes the main contributions of the paper and concludes with limitations and suggestions for further research.

Conceptual Background

The role of the local community in promoting a destination

Everything that happens territorially (e.g. local production, local brands, security, economic performance and climate change), or carried out by entity's related to the territory (such as politicians and public figures) daily communicates the characteristics of the territorial offer, thus having the potential to influence its image and attractiveness (Correia, 2014, Correia & Brito 2020). At the same time, some of these entities themselves actively communicate messages about the territory. Hotels communicate characteristics of the territory to which they are related, just as food and landscape. The restaurants are also attached to the local characteristics and may communicate them while promoting their services, the same happens with other actors related to the touristic industry.

The way, in which the locals interact with tourists, even the menus in the restaurants or the shops windows are important sources of communications that should be as much as possible influenced by the vision and territorial brand. Considering the number of the local actors (that can vary from less than one hundred to many thousands) it will be difficult to align them all in a unified territorial vision and to control (or at least influence) their promotional messages.

Given the diversity the offer elements, one of the most common problems of territorial marketing is the transmission of messages with many appeals, becoming easily confusing and/or inconsistent. Territories should not pretend to be everything, but turn out to be experts in some particular features. Thus, the message/promise associated with the territorial brand should be clear and differentiating. The associated positioning of the territorial brand should serve as a unifying framework by which the territory intends to be recognized while acting as a territorial promise – that is, the brand is an element that fosters the identity of the place (Sousa, Casais & Pina, 2017). As mentioned above, it is essential that this positioning will be identified with the local community, as its realization depends greatly on its behaviour.

As Sousa and Rocha (2019, p. 189) state, "territorial marketing is a fundamental tool in the promotion of places, one that must be present in the strategies of local government representatives, helping and promoting a sustainable economic and social development of the regions". Only by being aware of how the territory intends to communicate externally and the image that it intends to build, can local territorial agents behave in a manner that coincides with that intended image (García et al., 2012). Thus, one of the most important measures of territorial image construction involves communication with territorial agents in order to influence their behavior.

The importance of online communication

The evolution of the ICT has been notable and the effects of this evolution applied to tourism are clearly visible. ICT allows tourists to access accurate and reliable information about the place they want to visit. They also allow reservations to be made more quickly, with easy comparison of costs and in a much more convenient physical and temporal way. In general, ICTs contribute to a higher quality of service and to a higher overall satisfaction of guests (Buhalis, 1998).

ICTs enable local people to become more involved in the dissemination of the destination brand, and they do so, in a more accessible way (Kavaratzis, Braun & Zenker, 2013). They facilitate the creation of contacts that help in the development of companies, in the acquisition of more capable and cheaper suppliers and even in the dissemination and delivery of products (Buhalis, 2000; Manente & Minghetti, 2006).

The technologies now available allow the development of solutions to enhance the consumer experience and increase their involvement with the touristic players and the destination. Social networks with the extremely easy way how they alllow the acess and share of information are now one the main sources of promotional messages. Social networks have been an increasingly regular practice for the dissemination of the image that entities want to create around a destination brand. In addition, these networks are one of the most pivotal points in the online aspect of marketing management, helping to reach and interact with the target audience (Xiang & Gretzel, 2010; Kotler et al. 2011). The use of various digital platforms by stakeholders is extremely used and efficient, making "(...) network communication one of the main communication strategies" (Navío-Marco, Ruiz-Gómez & Sevilla-Sevilla, 2018, p.463).

All of this highlights the importance of the ICTs in the ability to arouse the interest and desire of tourists in the face of a destination brand. In the same order, this offers a greater notoriety to the territory. Finally, ICTs are a breaking point in the financial and notoriety gap between tourism agents, facilitating contact with the market and providing higher quality of service to smaller companies. Through this greater competitiveness, the region ends up gaining more financial and social capacity (Buhalis, 2000).

Adapting this information to the Portuguese territory, the northern region of Portugal has the lowest internet penetration (69%), and the most purchased services online are accommodation (57%), transport tickets (44%) and entertainment tickets (37%) (ACEPI, 2019). Taking these tourist services into account, it is important that the different tourist entities are present online and communicate the destination in order to attract tourists.

Methodology

To analyze the online presence of tourist entities and their communication of the destination, quantitative and qualitative approaches were used. In a first stage, the presence of tourism agents on social networks was verified and they had a website. Regarding the quantitative analysis, it was ascertained how many followers and publications they had in each network. The social networks analyzed were Facebook, Instagram and Youtube, as they are the most used by Internet users (Marktest, 2019).

In a second phase, which corresponds to the qualitative approach, the objective was to understand if the entities communicated their destiny. In the case of communicating, an analysis was made that consisted in finding out on which platform they communicate, how they communicate, and which are the target themes of communication. The analysis comprises the periodic interval from January 1, 2020 to May 31, 2020.

Sample Selection Criteria

For the selection of the sample was considered the territorial unit NUT III, which corresponds to the Lands of Trás-os-Montes. This region in the north of Portugal is composed of nine municipalities: Alfândega da Fé, Bragança, Macedo de Cavaleiros, Miranda do Douro, Mirandela, Mogadouro, Vila Flor, Vimioso and Vinhais. The tourist entities of these counties were selected based on three categories: accommodation, catering, and activities. The accommodation and restaurants were taken from the book Boa Cama, Boa Mesa 2020 (Expresso, 2020). This book contemplates several criteria for the selection of the spaces awarded with the reference, such as: considered ambassadors of the region's gastronomy; users and promoters of local products; recognized in the region for their active role. This book is also known to contain the best accommodation and restaurants in each region of Portugal. As far as tourist activities are concerned, these were chosen based on the website of each City Hall under analysis and the Tripadvisor platform

Sample

In total, 29 entities from the 9 municipalities were analyzed: 10 accommodations; 9 restaurants and 10 entities with tourist activities.

Table 1 shows the nine municipalities that correspond to the Lands of Trás-os-Montes, the data on the arrival of guests in 2018 (INE, 2018), the tourist entities analyzed and the due designation of abbreviations in legend for better interpretation of the data. It is possible to observe that the municipality of Bragança presents a larger number

of entities for analysis. This is justified because it is the capital of the district and the target of the demand for more tourists.

Table 1: Sample of tourist entities analyzed.

Counties	Guest arrivals (2018)	Tourist entities	Denomination
Alfândega da Fé	7822	Bela Vista Silo Housing	A1
Bragança	65243	Pousada de Bragança	A2
		Bétula Studios	A3
		Quinta da Rica Fé	A4
		Restaurante G	R1
		D. Roberto	R2
		O Abel	R3
		O Geadas	R4
		Tasca Zé Tuga	R5
		Anda D'I	ATV1
		Nordeste Park	ATV2
		Montesinho Aventura	ATV3
Macedo de Cavaleiros	6411	Solar do Morgado Oliveira	A5
		Brasa	R6
Miranda do Douro	25587	Casa dos Edras	A6
		Casa Belharino	A7
		Douro Pula Canhada	ATV4
Mirandela	22936	Dona Fina Guest House	A8
		Flor de Sal	R7
		Maria Rita	R8
		Naturthoughts	ATV5
		Anitudes	ATV6
Mogadouro	1975	Casa das Quintas	A9
		A Lareira	R9
Vila Flor	3136	Quinta Barracão da Vilariça	A10
Vimioso	1366	P.I.N.T.A	ATV8
		Coordenadas de aventura	ATV9
Vinhais	6712	Parque Biológico de Vinhais	ATV10

Results

In a first phase, the analysis consisted in knowing the online presence of the selected tourist entities, and out of 29, only 2 do not have any online presence (2 restaurants). Regarding the most used platform, Facebook stands out (26 entities), 17 entities are present in Instagram and have a website (graph 1).

Graph 1: Online presence of tourist entities.

Although most of the entities are present on the platforms presented, many of them, during the analysis period, did not interact with their followers. We can also withdraw that 8 entities placed between 0 and 5 posts (in five months) on the Facebook social network, this being an extremely low number compared to other entities.

The followers of the two most used social networks (Facebook and Instagram) were also studied to know their impact on these same networks (graph 2). The entities with more followers on Facebook correspond to restaurants (6 have more than 3000 followers) and activities (2 have more than 3000 followers).

Graph 2: Followers of social networks of tourism entities.

The analysis proceeded with the objective to find which of the 29 entities communicate the destination. In a first stage, the existence or not of some type of content on the platforms that portrayed the destination was verified. Of the 29 entities analyzed only 18 communicate the destination. The results obtained show that the most used platform to communicate is Facebook, and of the 18 that communicate, 15 use this social network (graph 3). It can also be seen that 10 entities have information about the destination on the website, information that corresponds to static pages.

Graph 3: Platforms where tourist entities communicate the destination.

Should also be mentioned what form of sharing was chosen by the entities to communicate the destination. Four categories were considered: photos, sharing, text and videos. As for sharing, it is important to inform for consideration that these consist of shared content from other people, blogs, or news. Graph 4 shows that the most used way to communicate the destination are the photos. This represents the identity of a destination and can trigger emotions and desires to visit a destination (Pérez-García, 2020). Many of the photographs used are accompanied by explanatory text about the content that is the target of the communication.

Graph 4: Ways used by tourist entities to communicate the destination.

Regarding the themes addressed by the entities, these were categorized based on the nine dimensions/attributes of image perception of destiny, proposed by Beerli and Martín (2004). The categories are the following: natural resources; general infrastructure; tourist infrastructure; leisure and recreational tourism; culture, history, and heritage; natural environment; social environment; atmosphere of the place; political and economic factors. Despite the existence of 9 dimensions, for the following analysis only 4 categories were considered, since they are those related to the data under study.

- Natural resources: time, beaches, flora and fauna, parks, and natural reserves.
- Tourist infrastructures: hotels, restaurants, bars, discotheques, tourist office, etc.
- Leisure and recreational tourism: entertainment and sports activities.
- Culture, history, and art: museums, monuments, gastronomy, religion, customs, etc.

Therefore, of the communicated themes, the majority comprises the category natural resources, namely the theme Natural Park of Douro International. Soon after, the category corresponding to culture, history and art stands out, being the events of the region and local gastronomy the most communicated

The Facebook platform was chosen for a more detailed analysis, as it is the most used by entities. The purpose of this analysis is to know the activity of the entities in this social network and the frequency of their communication of destination. The quantification of this frequency was made based on the total of publications in the period stipulated for analysis. From this we conclude that only 15 tourist entities communicate through this social network (graph 5).

Although many entities communicate the destination, it is important to understand the number of posts registered during a period of five months and how many of these correspond to the communication of the destination.

Graph 5: Comparison between the total of facebook posts and the posts that communicate the destination

This importance is related to the idea that an entity that makes several posts but only communicates the destination once, is in a situation substantially different from another that communicates the territory weekly, which is here the intended objective to improve the capacity and notoriety of the destination brand. For graph 5, only tourist entities that communicate the destination were considered.

The most active entities on the Facebook platform are respectively a restaurant and a tourist entertainment company in the municipality of Mirandela. It is also these two entities that most communicate the destination, followed by ATV1 and A6.

The analysis made shows that about 62% (18) of the tourist entities analyzed communicate the destination, but although this number represents more than half of the total sample we must take into account that 16.6% (3) of these entities communicate through a website, where the information is on a static page, not contributing so effectively. The remaining entities communicate through the Facebook and Instagram platform, but during the five months analyzed only 4 entities communicated more than five times the destination.

Final Considerations

We must stress that, based on some studies (Correia & Brito, 2017; Kavaratzis, Braun, & Zenker, 2013), we can conclude that uncontrolled sources, where tourist entities are included, are more significant and effective in communicating a destination. This is because the less controlled the information, the more credibility and influence it will have on the creation of the image of the destination, with consumers (tourists). As Correia and Brito (2017,

p.819) states "(...) the territorial offer is co-produced by a multiplicity of entities, each one of them will be able to function through their behaviors and activities as a communication element of the territory".

The use of technologies has allowed the various entities a lower dependence on intermediary companies for the distribution and communication of their products (Buhalis, 2000), allowing a better interaction between the various tourism agents and an integral marketing communication.

The study made it possible to verify the complexity that involves the communication of a destination by local entities. We concluded then that it is not enough to sporadically communicate a destination to attract tourists' attention; the message communicated must be constant, clear, and attractive. However, most tourist entities in Trás-os-Montes do not communicate the destination regularly.

Most tourist entities are small and micro enterprises, a number that is even more intensified in the region under study. This type of entity suffers from a greater difficulty in accessing social capital and technological investments. However, according to Lee and Hallak (2020) small and micro enterprises have the capacity to become competitive through the appropriate use of online platforms and the support of destination governments and tourism associations in connecting all these enterprises.

This article presents some limitations, particularly regarding the selected sample. Not all the entities chosen matched the top demand in terms of tourism.

Another limitation in this study relates to the method of analysis - observation. This method when applied by different researchers may eventually generate different collected data, since different points of view may lead to the consideration of different types of posts as a form of communication. However, it should be made clear that there has been an effort for the analysis to be totally impartial and built from the position of the tourist. For example, some posts were not considered "communication" because the photographs were not visually perceptible.

For a future line of research, it would be interesting to consider a larger sample of tourist entities in order to draw more assertive conclusions. It would also be interesting to cover other types of tourist entities such as: museums, regional product shops, bars, tourist services etc as well to analyze the alignment between the messages conveyed by the touristic actors and the position and vision of the destination brand.

The Possibility of Developing and Management of Direct Sales In The Conditions Of Electronic Economy

Ewa KORELESKA

UTP University of Science and Technologie in Bydgoszcz, Bydgoszcz, Poland

ewa.koreleska@utp.edu.pl

Abstract

The aim of this study is to present development possibilities of direct sales of food products under the conditions of electronic economy. Secondary data was obtained from - CEBOS reports from the years 2002 to 2020, as well as from the Central Statistical Office and primary data were obtained from three interviews with the Internet users for better interpretation of the secondary data. A case study method was also employed which involved analyzing Rural e-box' project (2020). For this purpose, secondary and primary data obtained from an interview with the project manager were. It was found that a vast number of the Polish Internet users (85%) do used the Internet for shopping. However, as compared to other countries, Poles use this form of sale much more rarely (19 position among 29 European countries in 2020). Purchasing food via the Internet is not yet very popular among the Internet users (7% of Internet users), though it is worth noting that for the last year it has gained in importance. In the opinion of the Internet users it was caused by a wider assortment of products offered by online stores and manufactures and better equipment and access to the Internet and the pandemic. It seems that the concepts of the type of *Rural e-box* which are of regional character with the use of modern internet, informatic technologies, modern management methods reduce the concerns about the food quality and its delivery time, are very likely to find followers in Poland.

Keywords: Internet, management, direct sales, distribution, electronic economy, food, organic food, online shopping,

Introduction

The role of the Internet is getting more and more important. The newest data of the Central Statistical Office shows that in 2020 as many as 90.4% of Polish households have access to the Internet. Considering the place of residence, the percentage of households with the access to the Internet is higher in towns than in rural areas (Społeczeństwo informacyjne … 2020). At the same time the role of the Internet has been undergoing changes as from the source of information it has also become a communication channel as well as a distribution channel for goods and services.

Goal, material and research methods

The aim of this study is to present development possibilities of direct sales of food products under the conditions of electronic economy. In the beginning, literature publications were reviewed (e.g. based on the Web of Science). The major concepts were defined, including a definition of direct sales, their form and management of the process of distribution. In Poland online shopping is less popular European countries and the popularity of online food product shopping is smaller as compared to other categories of products. Secondary data was obtained from - CEBEOS reports from the years 2002 to 2020, as well as from the Central Statistical Office and primary data were obtained from three interviews with the Internet users for better interpretation of the secondary data. Three scenarios were prepared to be used as measurement tools. At the end of the research, a case study method was employed which involved analyzing 'Rural e-box' project. For this purpose, secondary and primary data obtained from an interview with the project manager were used (measurement instrument – interview questionnaire was employed). The survey was conducted in 2020. Then, the collected data was analyzed.

Shopping via the Internet

Shopping via the Internet in Poland as compared to other European countries

There are differences regarding shopping via the Internet between the European countries. This form of shopping is most frequently used by the Danish, whereas it is least frequently used by the Romanians. Poland occupies the 19th position in this respect (fig.1).

Online shopping in Poland – according to the product category

According to the Center of Public Opinion Research in 2002 shopping on the Internet was not very popular in Poland. Only less than 0.5% of the whole population declared that they had bought something via the Internet in the month preceding the survey. In the following years the number of online shoppers was still small, though it was fast growing. Thus, in 2004, 3% of all Poles (that is 13% of the Internet users) declared that during the previous three months they had bought something online. In turn in 2005, 4% of Poles (14% of Internet users) declared that during the previous month they had bought something on the Internet. In 2008 the percentage of people doing online shopping was higher and it doubled as compared to 2005. A systematic increase was recorded in the following years. In 2020 this percentage has risen up to 57% (that is 85% of Internet users) (tab. 1).

It was found that in the month preceding the study, clothes and shoes were the most commonly purchased products. It is worth noticing that during the whole considered period, that is, from 2007 to 2020, this category of products enjoyed the biggest interest of the Internet users (tab.2). Moreover, it was observed that the dynamics of growth in the percentage of people who buy clothes and shoes online was the highest. Their number has increased four times so that in 2020 they accounted for more than one third of all the Internet users.

Electronic equipment was found to be on the second position in terms of the number of its online buyers. The share of people who bought this kind of equipment was, however, twice lower that the number of those who purchased clothes and shoes. It needs to be noted that the dynamics of growth, being only 45%. was not so rapid as in comparison with 2007.

The next position was occupied by cosmetics. As compared to 2007 the share of people who bought cosmetics on the Interned was doubled.

The number of the Internet users who are interested in a purchase of books maintained at a similar level in 2007 and 2020. A drop down to 6% was reported only in 2014.

In the considered period, the interest in a purchase of toys and other products for children as well as motorization articles has increased three times.

Sports equipment, food, medicines, and access to services and content are found to be less frequently purchased. Although the use of paid online content, such as, e.g. newspaper archives, photographs, is not very popular it has been slowly gaining popularity.

As for medicines, despite of intensive advertising they do not attract a vast number of buyers. In 2020 their sale has increased by 6%. It is probably due to that fact that unknown suppliers are less trustworthy and some medicines are available on prescription.
Percentage of online food buyers in the years 2009-2019 ranged at a very low level from 1% do 3%. No sooner than in 2020 a purchase of food became more popular among the Internet users and increased by 1,3 times as compared to the previous year (7% Internet users).

The least interest of the Internet users was found for multimedia (programs, computer games music, movies) as well as bus, train or plane tickets, whereas plane tickets have been less popular in 2020 as compared to the previous years, due to the pandemic. The number of people buying plane tickets has decreased more than half as compared to 2019, which results from a drop in the number of travels in the times of the epidemic.

Some respondents listed other types of products to be bought on the Internet which are not included in the list, e.g. house or apartment interior equipment, construction materials and tools, machines and devices, garden tools, animal accessories, cleaning and hygienic agents.

It should be noted that definitely more people than last year – which, as it seems, should be attributed to the situation of the pandemic – have been using the Internet to buy shoes and clothes, electronic equipment, cosmetics or even food products.

Analysis of results of the Internet Shopping in the opinion of the Internet Users – own study

To enable better interpretation of the results the Internet users were interviewed. Asked to indicate advantages of electronic commerce they listed the following benefits: convenience, lower price, shorter time, wider assortment, better availability of products, free delivery. They expressed the following comments: ‘ I am not in a hurry, I do shopping at 22:00, when I have some leisure time’. When it comes to disadvantages they most frequently mentioned delivery problems and damage of the package content. It needs to be noted, though, that recently the Internet users have noticed improvement in this field. Suppliers take care of their shipments to be delivered as they believe that ‘one negative comment can make people be more cautious which can decrease their profits”.

The Internet users are not surprised at an increased interest in online shopping of clothes and shoes. They think that this kind of shopping is more convenient. The respondents are not afraid that the size may not be right as there is a possibility of using an esize.me scanner, which provides a precise 3D model of feet in merely 5 seconds. This model includes all dimensions needed to correctly match the shoes including width, instep height and circumference. The scan is performed only once and the service is free. It can be performed in the shop (200 shops) CCC or by a smartphone application. However, when the size is not correct the customers know that they can use a free return of the order with time, as they claim, long enough to do it.

Besides, some Internet users said that they had gone to the store to try on a given model and then they bought it online thus, saving as much as 150 PLN.

Internet users explained a relatively stable level of interest in electronic equipment by preferences for shopping in stationary stores. Respondents indicate that these products are of specialist character that requires counseling, turning on and off, checking and configuration.

A similar situation associated with a purchase of books was interpreted by a drop in the interest in reading and the fact that people are still not used to online shopping.

High dynamics of a growth in purchasing children products was explained by introduction of social programs including (Rodzina) Family 500 plus.

A purchase of motorization products, as has already been mentioned, increased by four times. The Internet users were of the opinion that it was caused by an increase in the number of motor vehicles in Poland including second hand cars which require more repairs and replacement of parts. According to the newest data of CSO , the index of motorization (number of passenger cars falling on 1000 people) in 2017 was 586, whereas the majority of the registered passenger cars (90.1%) were 6 years old and more [CSO].

Moreover, the respondents indicated that the waiting time for the parts to be ordered online and those bought in a conventional store is similar whereas a their price is at a similar level.

A drop in the interest in online programs, computer games results from a huge technological progress. In 2008 the number of free games available online was smaller. There was no play store. Nowadays people use free games.

In turn, CD records are getting out of use. The Internet users take advantage of free VoD services. Sometimes they use pirated VoD services, which are losing popularity in Poland. A wider access to legal sources and an increase in expectations concerning the quality of services have a definite impact on this phenomenon.

A small interest in an online purchase of food products was explained by a concern about the product freshness.

Besides, it was found that the delivery was sometimes too long while 'I need the product right now' 'I prefer to go to the store and have it right now than wait'. According to the respondents, a interest in food online shopping was the effect of a limited food offer. Only selected stores offered such an option. However, the time of the pandemic slightly changed the attitude of the Internet users which is reflected by an increase in the share of online food buyers. In the opinion of the Internet users, it was caused by a wider assortment offered by online stores and producers, better 'equipment – tablets, computers, smartphones', to be used by consumers and spread of the coronavirus pandemic.

The Internet users believe that in the time of the pandemic, the significance of online sales will keep growing and once people get used to online shopping it will have even a bigger share in the market.

Concept, advantages and disadvantages and direct sales management - theoretical approach

According to the Polish legal regulations, the supply of food from the manufacturer to the consumer can be carried out with the use of a direct sales formula or agricultural retail trading. So understood direct sales apply exclusively to unprocessed products of animal origin. They are supplied in the form of direct deliveries to end consumers or to local retail companies supplying products directly to end consumers and on the territory of the household. The second formula , that is, agricultural retail trading applies to each type of food, that is, food of animal origin and nonanimal origin, unprocessed and delivered directly to end consumers, e.g. to a farm and to a market (Rozporządznie 2015, Śmigielski 2019).

The literature provides three models of direct sale (Waszczyk, Radacki 2005, Brzeziński, Bogusz, Kania 2014):

- classical direct model which involves a direct contact between the seller and the customer,
- classical shipping model (by means of post office),
- non classical shipping model (by means of the Internet), in the case of the two latter models there is no contact between the seller and the customer.

Direct sales is one of the best forms of distribution channel between a food manufacturer and a customer. Direct contact provides measurable benefits for both sides of the chain, it is favorable for increasing the quality of the offered products and making the customers aware of the properties of products (Koreleska 2008, 2017, Nowak, Tanska-Hus, Minta 2011, Bogusz 2018; Wojcieszak-Zbierska, Bogusz 2020).

Selling in short distribution channels is the subject of scientific studies around the world (especially in the context of a pandemic). (Al-Adwan, Kokash 2019; Atkociuniene, Vaznoniene, Kiausiene, Pakeltiene 2019; Corsi, Mazzocchi 2019; Jablonski, Sullins, McFadden 2019; Bareja-Wawryszuk 2020; Jovanovic, Vujadinovic, ,Mitreva, Fragassa, Vujovic 2020; Jurado, Moral, Viruel, Ucles 2020; Kumar, R ., Kumar, N., Bishnoi, Malik, Kumar, P. 2020; Rover, Pugas, De Gennaro, Vittori, Roselli 2020; Thilmany, Canales, Low, Boys 2020).

Sales management includes determination of tactical sales purposes, creation and monitoring of the current operation plan, planning and management of resources to be used for current sales support (Tracy, Scheelen 2000).

Regular management process involves, among others:

- monitoring of sales and settlement of all financial transactions,
- determination of prices and payment methods, management of rebates and credit programs, implementation of special programs for regular customers,
- assessment of the dynamic of sales, identification of leaders and sales outsiders,
- control of the state of mutual settlements between the company and the customer,
- management of customer relations (system CRM),
- management of the sales process in separate channels (Grzybek 2015).

Project 'Rural e-box' an example of a direct sale

The project Rural e-box' was created in order to shorten the delivery chains of food coming from agricultural farms. The core of the project is the concept of collective action.
The project assumes implementation of innovative sales models of food manufactured by farmers and small enterprises:

1. Farm shop.

2. Sales platform.
3. Purchase groups.

Rural e-box includes local food manufacturers from the Kujawsko -Pomorskie province, among others, farmers who are involved in Agricultural Retail Trade (ART), Marginal Local Activity (MLA), organic and apiarian farms (Farmers (13 including: ART, organic farms, direct sale, apiarian farms) Enterprises (4 including 3 MLA*)
The assortment offer includes: meat, diary, herbal products, fruits and vegetables. Kujawsko-Pomorski Center for Agricultural Counseling in Minikowo is the initiator and leader of the created operational group. In the beginning, the workers of the Center considered taking up such an initiative only for regional manufacturers and sellers of cheese. However, only three out of 30 willing farmers remained in the group of regional entrepreneurs. Therefore, to take advantage of financial support from 'Cooperation' as part of Rural Area Development Program for the years 2014-2020, it was necessary to additionally convince farmers or entrepreneurs who were involved in production or selling of other food products. Eventually, the Agency for Restructuring and Modernization of Agriculture acceptance of financial support in the amount of (Funding 726 682 PLN) was obtained. The total value of the project was 1 110 512.55 PLN (Rozporządzenie 2016).

In order to test different sales models of food manufactured by farmers, the Center and the University of Science and Technology have created a consortium on the basis of the 'Cooperation' initiative.

The project has been implemented since December 2019. Thanks to it an Internet platform will be created as well as farm shops, and a potential customer will have the possibility to choose a convenient form of shopping.
