Average realized return	17.2%	69%
Standard deviation	26.0%	72%

It can be concluded that Company B has the shares almost 3 times (72% : 26% = 2.8 times) riskier than the shares of Company A are. The investor also wants to know how these two financial instruments would behave together. He cannot find it out from the variance or the standard deviation, although these are the most well-known and the most frequently used dispersion measures. These measures were used to estimate the average deviation from the arithmetic mean. The investor also wants to know the difference between the realized return and the average return in both companies. It is necessary to calculate covariance and the correlation coefficient, which are the measures of the degree of the linear relationship between the shares.

The covariance between the shares of the companies A and B is calculated by not squaring the deviations, i.e. the differences of the individual returns from the arithmetic mean of the returns of these companies, but multiplying them by each other instead, as follows:

Table 6 : The calculation of covariance

Year	The realized return of the company A (1)	The realized return of the company B (2)	The deviation of the return from the arithmetic mean of the company A (3)	The deviation of the return from the arithmetic mean of the company B (4)	The product of the deviations of the companies A and B (5 = 3 x 4)
2015	11%	48%	-0.062	-0.215	0.01333
2016	56%	-30%	0.388	-0.995	-0.38606
2017	-12%	5%	-0292	-0.645	0.18834
2018	-10%	120%	-0.272	0.505	-0.13736
2019	26%	124%	0.088	0.545	0.04796
2020	32%	150%	0.148	0.805	0.11914
Total					**-0.15465**

$$\text{Covariance}_{A,B} = \frac{-0.15465}{5} = -0.03093$$

The negative value of the covariance indicates the fact that the shares of the companies A and B tended to move in the opposite directions in the period from 2015 to 2020. The negative covariance indicates the fact that there is no direct linear relationship between the shares of these companies. As the degree of the correlation between the stocks increases, the (positive) value of the covariance also does.

The correlation coefficient is calculated by dividing the covariance by the product of the standard deviations: (Copeland et al., 1988)

$$\text{Correlation coefficient} = \frac{\text{Covariance}}{(\text{Standard deviation for company shares A})\text{x}\,(\text{Standard deviation for company shares B})}$$

$$= \frac{-0.03093}{0.26\ x\ 0.72} = \frac{-0.03093}{0.1872} = -\ 0.1652$$

According to the correlation coefficient equation, it can be noticed that both the covariance and the correlation have the same (either positive or negative) value. The correlation value ranges from -1 (when there is a complete negative, i.e. inverse correlation) to +1 (when there is a completely positive, or direct correlation). In our case, the correlation coefficient is -0.1652. which indicates the fact that there is no relatively high degree of the negative correlation

between the shares of these companies, i.e. this correlation has 16% of the "strength" of a completely negative correlation.

Portfolio Diversification as a Way to Reduce Market Investment Risk

Faced with different risks of investing in securities, investors take appropriate countermeasures, depending on the type of investment risk. An investor cannot neutralize general (market) risks, but the effects of risk can significantly be reduced if financial instruments are diversified. (McMenamin, 1999) In practice, the largest number of investors opt for forming a portfolio from only a few securities. This determination arises as a result of the knowledge of the following:

a) most benefits of diversification can be realized based upon the ownership of only a few securities,
b) the expansion of the portfolio structure leads to a decrease in the marginal benefits of diversification and an increase in the marginal costs of such a movement (the transaction costs of monitoring), and
c) many investors are reluctant to buy the securities that they consider to be at unrealistic (overvalued) market prices, convinced that they can find undervalued financial instruments.

Company risks are much more easily and much faster coped with by the investor. If the investor has encountered risky securities for the first time (on the financial market), he can avoid being exposed to specific risk by choosing the instrument of the company that he considers to be risk-free. If the investor has a risky instrument, he will try to get rid of such an instrument by a further sale.

In the previous question, the past of the companies A and B, i.e. their respective returns, was realized on the basis of the investments in shares in the period from 2015 to 2020. Based on this analysis, the investor should make a decision for the future – a decision to invest money in stocks, convinced that the central tendencies (the average returns, i.e. the arithmetic means) will be maintained in the future.

There are two options for the investor to choose: the one implying forming a portfolio only from the shares of one company, and the other implying a combination of shares with their different shares in a single portfolio. The selection of the optimal combination is made based upon the analysis of the expected returns and standard deviations with the different combinations of the shares of both companies. The analysis is performed with the assumption that the performance indicators of these companies in the previous period (2015-2020) will be maintained in the future: the returns, the standard deviations and the covariances, which means that the expected return in the future will be at the level of the realized return from the period from 2005 to 2020, as follows: 17.22% for the company A and 69.5% for the company B. Starting from these assumptions, the investor will make the following calculation for one of the possible portfolio options (a total of 11 options are analyzed and presented in Table 7) that will be formed on the basis of an equal participation (50% of the shares of the company A and 50% of the shares of the company B):

The expected
average portfolio return = 0.5 (17.17%) + 0.5 (69.5%) = 43.44%
(50% : 50%)

The portfolio
variance = $(0.5)^2 (0.26)^2 + (0.5)^2 (0.72)^2 + 2 (0.5) (0.5) (-0.1652) (0.26) (0.72) = 0.1311$
(50% : 50%)

The portfolio standard
deviation = $\sqrt{0.1311} = 0.3621$, i.e. 36.21%
(50% : 50%)

The obtained data for the expected return and the standard deviation are entered into Table 7, under the sequence number 6, which is one of the possible portfolio options (if the investor opts for it): 50% of the shares of both companies. In the identical way, the expected return is calculated for ten different portfolio options more. Thus, for a portfolio formed on the 90 : 10% basis (the shares of the company A against the shares of the company B), the following would be appropriate:

The expected return = 0.9 (17.17) + 0.1 (69.5) = 22.40%
(90% : 10%)

The variance (Compendium, 2008) = $w_1^2 \sigma_1^2 + w_2^2 \sigma_2^2 + 2 w_1 w_2 \rho_{12} \sigma_1 \sigma_2$. $(0.9)^2 (0.26)^2 + (0.1)^2 (0.72)^2 + 2 (0.9) (0.1) (-0.1652) (0.26) (0.72) = 0.0543$
(90% : 10%)
The standard deviation = $\sqrt{0.0543} = 0.2330 = 23.30\%$
(90% : 10%)

Table 7: The expected returns and the standard deviations with the different combinations of equity participation in the portfolio

Seq. no.	Weight (the participation of the company shares in the investor's portfolio)		The expected return	Standard Deviation
	Company A	Company B		
1	100%	0%	17.2%	26.00%
2	90%	10%	22.40%	23.30%
3	80%	20%	27.64%	18.82%
4	70%	30%	32.87%	25.83%
5	60%	40%	38.10%	30.68%
6	50%	50%	43.44%	36.21%
7	40%	60%	48.57%	42.73%
8	30%	70%	53.80%	49.71%
9	20%	80%	59.03%	56.97%
10	10%	90%	64.27%	64.42%
11	0%	100%	69.50%	72.00%

With the different weights of the companies A and B, the investor may expect different returns: the lowest expected return (17.2%) can be achieved if the ratio of the shares in the total portfolio is 100% to 0%, in favor of the shares of the company A; the highest return (69.50%) is achievable with a portfolio of 100% of the shares of the company B. However, the lowest standard deviation (18.82%) is achieved with the third combination, when the shares of the company B have a 100% share in the total investor's portfolio.

If the investor does not want to take risk, he will opt for a portfolio formed from 80% of the shares of the company A and 20% of the shares of the company B, when the standard deviation is the smallest. He will do so because he wants to avoid investment risk, regardless of the fact that he could then expect a return of 27.64%, which is 2.65 times lower than the highest return (69.50 : 27.64 = 2.5). Of course, he can also opt for a portfolio providing him with the highest return, regardless of the risks. That would be the 11th combination, when the portfolio only consists of the shares of the company B, with the expected return of 69.50%. With such a choice, however, the greatest possibility of varying the return was estimated (as much as 72%), which not every investor will accept, because he does not agree to such a risk. If the investor only owned the shares of the company B, his return would vary almost three times more than they would if he only owned the shares of the company A (72% : 26% = 2.77). Therefore, the investor will not opt for a portfolio exclusively composed of the shares of Company B, nor of the shares of Company A. He will form a diversified portfolio. He will opt for one of the combinations (from 2 to 10 in Table 7), according to his personal affinity for the estimated risk and the expected rate of return.

Conclusion

It can be concluded that the risks of investing funds in one financial instrument are higher than those of investing in two or a larger number of financial instruments. Unlike a diversified investor, a non-diversified investor bears the risk specific to the company. If a portfolio is formed from two instruments (from the shares of the companies A and B), the standard deviation of such a portfolio is the function of correlating the return between these securities. As a correlation coefficient decreases, the standard deviation of the portfolio decreases as well. Then, the benefit of diversification increases. With an increase in the correlation coefficient of the return between these two instruments, the benefit of the portfolio diversification becomes smaller. Benefits will (to a greater or lesser extent) exist as long as a correlation coefficient is less than 1. (Copeland et al.)

Based on the previous analysis of the portfolio of the two financial instruments that confirmed the greater usefulness of investing in two securities rather than in a single security, it is logical to conclude that the investor will consider the usefulness of forming a portfolio from three or a larger number of instruments. However, there must be a measure

in that. The marginal benefits of diversification diminish with each introduction of a new instrument to the portfolio. This is because diversification can be expensive due to the fact that the costs of collecting necessary data, making an analysis and so forth are high. The diversified investors who already have a portfolio of the shares of a number of companies and who now want to include the shares of another company also ask themselves the question of market risk. That is the reason why they are referred to as marginal investors.

A diversified investor seeks to provide less risky financial instruments in his possession based upon a market risk assessment, which serves him as the basis for making an appropriate investment decision, which he makes being aware of the fact that a higher risk is a real challenge and an opportunity to earn more. As is shown in the paper, diversified investors successfully overcome the problem of return and risk assessment by applying the methods that are an indispensable tool in investment decision-making. Hence the investors' motivation to measure the risk and return of the securities portfolio by using the presented methods. The previous analysis shows how investors choose the optimal combination with the different shares of company shares in their portfolios, faced with the different risks of investing in securities. For that reason, they are also called diversified investors, who try to provide less risky financial instruments in their possession based upon this assessment. Only on the basis of this assessment will the investor make an investment decision appropriate for him, being aware of the fact that the expected return on investment and risk are interrelated, which means that a potential investor will invest in the securities that bring him a satisfactory return, with a risk acceptable for him.

Abstract

La literatura previa es equívoca respecto al nivel de endeudamiento de la empresa familiar, a pesar de que el análisis de la estructura de capital ha generado gran interés en el campo de las finanzas. Los motivos que impulsan al propietario-gerente a endeudarse se encuentran aún inexplorados, surgiendo evidencia empírica opuesta. En consecuencia, la alfabetización financiera del propietario-gerente, entendida como el conjunto de conocimiento financiero y su utilización en la toma de decisiones, podría ayudarnos a explicar esta variación en los niveles de endeudamiento de la empresa familiar. Así mismo, la generación familiar en la que se encuentra la empresa es un importante determinante a tener en cuenta, así como su posible efecto moderador entre la alfabetización financiera y el nivel de endeudamiento de la empresa. Este estudio utiliza una muestra de 179 empresas familiares españolas, haciendo uso de cuatro regresiones lineales múltiples para contrastar los objetivos antes planteados. Además, se analiza la robustez de los resultados a través de una medición alternativa del endeudamiento. Se encuentra que un nivel elevado de alfabetización financiera incide de manera negativa y significativa en los niveles de endeudamiento de la empresa familiar, no dándose así para el transcurso generacional, siendo más propensas a la utilización de deuda las empresas familiares de segunda y posterior generación en comparación a las de primera generación. Sin embargo, y en contra de lo que cabría pensar, no se obtiene que la generación modere la relación entre alfabetización financiera y nivel de endeudamiento de la empresa familiar

Abstract

Project financing is an innovative financing technique that is used to raise large amounts of capital. It is currently applied to funded long-term and costly projects such as real estate. The objective of the present article is to provide an analytical overview of the issue of real estate development through innovative forms of project financing in selected countries. The present paper consists of four parts. For the first parts paper, it deals with the issue of project financing and theoretical backgrounds. The second part focuses on methods of financing investment projects through bank loans, namely investment loans, mortgage loans or supplier loans. Also describes how to obtain the results of the analysis carried out. The survey involved 15 countries where banks from leading financial companies operating in each individual country were approached and selected. The survey included 70 banks, all of which were active in the market. The third part deals with the specific results of the analysis carried out. The analysis was carried out on selected countries on the basis of geographical locations and two categories of analysis were created. The first is "Central and Eastern European Economies" and the second category is "Other European Economies". The fourth part of the article focuses on discussion and the fifth part deals with the conclusions of the addressed issue. As a result of the present paper, a comprehensive view of real estate development through innovative forms of project financing in selected countries is the result. A descriptive method, analysis, mathematical-statistical methods, graphic methods, comparison and synthesis were used in the processing of the submitted paper creation.

Keywords: Real Estate, Project Financing, Innovation, Loan Portfolios,

Introduction

Funding is a key area of each project. Each project should take into account the possibilities of the project promoter or client. The choice of the type of project financing in enterprises is important both from the point of view of the enterprise, which will make a real profit from the final plan and from the position of the lender that invests the funds in the project. He will expect a return in the form of an agreed interest on his deposit. In recent years, project funding has recorded a significant increase in funded projects. This mainly concerned towing industry, energy, water management as well as development infrastructure projects. The growing interest in project financing has prompted economists, authors to dedicate themselves and explore this alternative form of financing for investment-intensive projects. In publications, we can meet several definitions of the concept of project financing. However, most authors agree and assign this form of financing to the investment banking component. (Aimurzina, Kamenova, Omarova, Bodaubayeva, Dzhunusova, Kabdullina, 2019)

Project financing as individual financing of an economic unit that first takes into account the future earnings and cash flow of the project from which the loan will be repaid. (Marquis, Raynard, 2015) Project financing is financing the development or use of rights, natural resources or other assets where the bulk of the financing is not used from own

resources and must be mainly covered by the revenue of the project in question. (Yescombe, 2014) Project funding is tailored individually to the basic specific features and needs of each project. The main feature of project financing is that the borrower vis-à-vis the bank is a legally self-established special project company for a specific project, which is financed by credit lines without penalising the founders of the project company who put capital into it. (Feng, Gramlich, Gupta, 2009) This is financing that does not appear on the parent company's balance sheet and has no feedback on it. We can therefore say that the hallmark of project financing is the separation of project financing from other business activities of the investment unit. Both the granting and repayment of the loan are closely linked to the cash flows of the project both at the construction stage and in its subsequent operation. (Jakimowicz, Rzeczkowski, 2019)

Ultimately, we can define project financing as an innovative financing technique that is used to raise large amounts of capital. It shall also apply to funded long-term projects as well as specific, costly projects. This technique makes it possible to spread investment risk among the different stakeholders. (Kral, Janoskova, 2015) The advantage of this type of financing is that lenders usually do not require historical information from the potential borrower. When deciding whether or not to provide funds, the anticipated cash flow of the project is considered in particular as a source of repayment of the loan. (Michalkova, Frajtova Michalikova, Tanase, 2019) We can therefore conclude that it is most often about financing debt projects for infrastructure, industrial projects as well as public services. We define cooperation in these projects as a group of agreements and contracts between project sponsors, creditors and other partners forming a business unit that operates in a particular industry and determines the amount of credit required.

Over the last twenty years, financial instruments have been developed on the market, which expands the possibilities of obtaining funds for financing real estate projects. The choice of the appropriate method of financing depends on the specific structure and nature of the project. In practice, it is usually true that each project is unique. Lenders often look for projects with easily foreseeable political and economic risks. In general, we can say that financing is an activity that deals with obtaining financial resources for the establishment, operation and development of the company, in the necessary volume, time and structure, at the optimal cost of their procurement and with a defined price for their use. (Pazilov, Bimendiyeva, Ivashchenko, Aitymbetova, 2020)

When financing real estate development projects, the banking and financial sector is mostly an important source of finance. Especially in cases where own resources are usually not sufficient to finance projects. The financing of investment projects is a crucial aspect in the context of their preparation and implementation. Documentation needs to be prepared to secure sources of funding, whether from the bank or other partners. The whole negotiation of capital providers with the investor takes place in several phases. In the first phase, the investment plan of the project is presented. At the same time, the ideas of the stakeholders about the goals and parameters of the project are clarified. After a detailed analysis and verification of the investment plan of the project, at the end of the second phase, a method of financial security of the project is proposed. (Lyakina, Sheehy, Podhorska, 2019) Following the approval, in the third phase, the final terms of the contract are negotiated and the necessary financial resources are secured. When financing investments, objectives such as: securing the amount of capital for the investments envisaged or meeting the required rate of return should be pursued. Also, achieving the lowest possible average cost of capital, not disturbing the financial stability of the company together with other economic instruments creating pressure on the efficiency of investment. (Bartosova, Kral, 2016)

As a project-funded entity, the bank can act in two different positions. The first position is the arranger. Banks negotiate credit terms, assess project risks and project benefits. They also decide on the approval or rejection of the project. The second position is the agent position. Then the bank is not responsible for the loan decision but is responsible for the mechanical aspects of the loan. (Satish, 2019) Such as the coordination of loan drawdown and repayment, communication between financing participants, but also as a notification and information. Loans form a category among the most frequently used external sources of financing for the implementation of real estate projects. Most banks base their decision to grant a loan on a technical and economic study. (Hollowell, Kollar, Vrbka, Kovalova 2019) Thus, each application for a bank loan is subject to an analysis of the investment project and the creditworthiness of the applicant. Based on the results of these analyses, the bank then decides whether to grant the bank loan application and under what conditions or not. The basic factors for assessing the possibility of financing by the bank and factors influencing the price of bank loans can include the professional history of the investor, his financial health, reference projects, but also the amount of turnover. Also, the quality of the investment project, its risk, assessment of its economic efficiency, budget costs of the project, or type of contract. Proposal of the method of financing the project with the share of own funds, type of bank loan, amount, time and method of repayment, fixation of interest rate, etc.

When investing in bank loans, it is important to focus on the method of repayment. The loan may be repaid in a lump sum in the full amount of the loan provided, either at a specified maturity period or in the case of a loan granted for an indefinite period or after the expiry of the notice period. In both cases, the interest is paid gradually over agreed periods. With interim repayment, repayments may be irregular. For example, in the case of overdrafts associated with a current account, which the client draws by payment from the account and repays by incoming payments. Interim repayment may take the form of regular annuities or instalments. Annuity repayment is characterized by the fact that the client repays the principal and interest in regular amounts in regular constant instalments. (Esty, Sesia, 2010) When repaid in regular instalments, the principal payment does not change for the entire maturity period. Here, however, the interest payment changes according to the current amount of the loan balance. The maturity of the loan is also associated with the degree of credit risk for the provider of financial capital. Long-term loans represent a higher level of credit risk for the creditor, which also requires a higher return for higher risk. This causes higher costs for the financing company. This is mainly due to the fact that the degree of uncertainty of the development of the future economic conditions of the debtor increases with the length of time. In general, however, with increasing risk. (Valaskova, Kliestik, Kovacova, 2018) For that, the bank as a subject of project financing is very important and, given that it provides most of the financial resources of the project, it is irreplaceable.

Methods

The company most often obtains a bank loan in the form of investment loans, mortgage loans or supplier loans from banks to finance long-term investment projects.

Investment loans, which in practice are referred to as term loans. When financing, banks usually provide only a certain share of the estimated capital expenditure and, in order to reduce risk, require the company to participate in the financing. Term loans are characterized by a fixed interest rate and gradual amortization over its maturity period. Due to the higher degree of risk, term loans are more intensively associated with various guarantees, protective arrangements and set conditions in the event of default. Mortgage loans are loans that a company obtains from the development of the real estate. The loan is refinanced by issuing mortgage bonds issued only by duly authorized banks. Annual annuities are a common method of repayment. An important issue in mortgage lending is estimating the market price of real estate and its dynamics in the future. For a business, obtaining mortgage loans is usually longer and more complicated than with other types of loans. In addition to a bank loan provided by commercial banks, insurance companies, the company can also obtain a supplier loan for financing. It is provided by suppliers of fixed assets to customers. This type of loan does not involve the provision of direct cash but is a deferral or decomposition of the payment of the purchase price. In that case, the customer repays the delivered property together with interest for an agreed period, either once or gradually. Supplier loans most often occur in the supply of investment units for export.

The aim of this article is to provide an analytical overview of real estate development issues through innovative forms of project financing in selected countries. In 2019, a survey was conducted on the possible development of the loan, the one which is way the method of project financing real estate in selected countries. The survey involved 15 countries, where banks from the leading financial companies of the institution operating in each individual country were contacted and selected. The survey included almost 70 banks, all of which were active in the market. Banks were selected from among the leading financial institutions operating in each individual country. The majority the survey participant banks were local, i.e. those operating predominantly within one European country, whilst the rest were mainly regional banks, as well some multinational banks participated. Collected primarily via in-depth interviews and online questionnaires. Representatives from leading financial institutions have provided their views on the key issues influencing property lending. The questionnaire survey was conducted for the whole year 2019. Selected countries: Croatia, Serbia, Slovakia, Cyprus, Finland, Germany, Poland, Hungary, Ireland, the Netherlands, Greece, Romania, the Czech Republic, Slovenia, Bulgaria. Selected countries were compared on the basis of geographical locations and two categories of analysis were created. The first is the "Economies of Central and Eastern Europe". These countries are located in Central and Eastern Europe, including most of the Balkans. Due to their geographical proximity and the relatively comparable stage of economic and development of these countries, they are assumed to be similar mainly due to their advantages and challenges. Unlike Central and Eastern Europe, other European countries form the second category: "Other European Economies". Precisely because of their different economic capabilities, they provide a benchmark for evaluating data from Central and Eastern Europe.

Results

Lending as an external source of project financing is the most important and most frequent alternative to the implementation of real estate projects. The analysis will be based primarily on lending in selected countries.

This part of the survey focuses on banks' expectations with regard to the future of lending in real estate development. Also, on their development and strategic approach to real estate financing compared to other opportunities. Table 1 shows the strategic importance of real estate development financing for banks.

Fig 1. The strategic importance of real estate development financing for banks.

Source: Own processing according to Lending Barometer 2019.

The results of the survey revealed that the long-term gap between more functioning economies and those in Central and Eastern Europe in terms of the strategic importance of real estate financing has gradually narrowed. Banks from Ireland, Poland and the Czech Republic responded most positively. Most of the surveyed banks confirmed that they see the significant strategic importance of financing a real estate development project. Representatives of only a few countries, including Finland, Croatia and Slovakia, see average importance.

Figures 2 and 3 show the attractiveness of real estate financing compared to other industries in each country.

Fig 2. The attractiveness of real estate financing Central and Eastern European economies

Source: Own processing according to Lending Barometer 2019.

Fig 3. The attractiveness of real estate financing other European economies

Source: Own processing according to Lending Barometer 2019.

The survey examined how attractive real estate loan financing is with another industry. Overall, the food and manufacturing industries were the highest. This is followed by information technology, healthcare, energy, public services and, last but not least, telecommunications. Industries that proved to be less attractive than real estate were in the entertainment, automotive, financial services and agriculture sectors. Although the results potentially vary significantly from country to country, they show the relative strength of the different industries in each of them in the market. The survey also revealed even a regional comparison of responses. There were differences between Central and Eastern Europe and other lower-income economies, such as energy.

Another partial result was, as it turned out, their actual real estate financing with a loan compared to the previous year. The result is shown in figure 4 and 5.

Fig 4. Actual real estate financing with a loan compared to the previous year in Central and Eastern European economies

Fig 4. Actual real estate financing with a loan compared to the previous year in other European economies

Source: Own processing according to Lending Barometer 2019.

Banks in almost all countries indicated a significant impact compared to last year. The exception was in Romania, where banks said they had a decline in real estate financing compared to last year. Countries like Slovakia, Netherlands and Ireland have stated that they neither do not rise nor falling from last year. As a result, real estate financing is maintained in approximately the same way in both years. The most significant increases were recorded in countries such as Greece and Slovenia.

The last step to achieve the set goal of the research was to analyse the most important factors influencing real estate loan financing. The results of the survey are shown in table 1.

Table 1: Analyse the most important factors influencing real estate loan financing

Factor	Central and Eastern European economies	Other European economies
Macroeconomic conditions in the local market	* * * * *	* * * * *
Activities of European Central/National Banks	* * * *	* * *
Lack of prime properties	* * * *	* * * * *
Increased property values	* * *	* * *
Macroeconomic conditions in Europe	* * *	* * * *
Lack of equity	* *	* *
Lack of active investors	* *	* *
New strategy	*	*
Brexit effects	*	* * *

Source: *own processing according to Lending Barometer 2019.*

Representatives of banks in the survey identified key factors influencing the real estate market. The long-term trend prevailed, which was confirmed as the most serious factor for banks, namely Macroeconomic conditions in the local market. Increased identification uncertainty has arisen in a global and economic environment that keeps this aspect highly relevant to decision-making banks. Differences in the identification of factors were also in the factor Brexit effects, where it is the least important for Central and Eastern European economies, where in other countries they take it more into account. These were countries such as Ireland and Germany.

There have been no radical historical changes in the availability of credit in banks based on research. Countries have not shown a willingness to get rid of part of the loan. In the Czech Republic, Slovakia and Cyprus, they did not show interest in getting rid of part of the real estate loan. Only three countries, such as Greece, Ireland and the Netherlands, have shown a willingness.

Discussion

From the research, we can say that banks have their funding based on specific criteria, which, if you meet, you have no problem obtaining funding. So, let's look at the basic requirements:

1. Real estate management - the bank will lend only against a solid real estate. The criteria according to which the bank assesses real estate are mainly the location, employment opportunities in the area, transport connections, civic amenities in the area, etc. A safe investment in real estate must meet the same criteria as required by the bank. Therefore, the bank's opinion on the property is a kind of test of whether followed all the rules when choosing the right property.

2. The right type of real estate - The bank will provide financing only for real estate that is of interest in the real estate market. For example, apartments in apartment buildings with structural problems (statics, leaks, leaking roof, etc.) are very difficult to finance.

3. Repayment of the loan - the bank requires that companies have sufficient funds to repay the loan from income. A safe repayment amount is considered to be 30-40% of income. Banks have different criteria according to which they re-evaluate this factor, so it is best to discuss it with a mortgage broker. Unfortunately, as a novice investor, the bank will not accept rental income to assess a loan application. The reason is that you do not have the income for a long period of time. After about a year, however, some banks will also accept this income.

4. Loan to value ratio - the bank does not normally refinance the full purchase price. Usually, banks are willing to finance 80-90% of property value. However, it is important to say that the bank does not consider the purchase price as the value of the real estate. Banks rely on expert opinion and their own criteria. It may happen that even though the bank promises 80% of the financing, the bank can say that it will prefinance only 70 thousand euros if it thinks that the property has a value of only 90 thousand euros. (Kral, Valjaskova, Janoskova, 2019),

(Lyakina, Heaphy, Konecny, Kliestik, 2019), (Zabolotniaia, Cheng, Dacko-Pikiewicz, 2019), (Thierie, De Moor, 2019)

After applying for a loan, the bank will start checking situation in the credit register, a social insurance company, health insurance companies, etc. The bank is trying to find out if companies have any past mistakes regarding past outstanding loans, credit cards, overdrafts, payments to the health insurance company, etc.

Conclusion

Each project that is subject to bank financing by this financing technique is individual, and therefore it is important for the bank to treat all risks as much as possible so that the potential for loss in the future is minimized. For this reason, as well as the impact of the economic crisis, the current tightening of the conditions for providing project financing to banks, as well as the suspension of financing for some projects already under construction, is appropriate in today's situation.

Development projects are financed by banks depending on whether foreign resources are also needed for their implementation, or whether the developer decides to use the credit resources advantageous for him. Most large projects are financed from the own resources and payments of future property owners as well as from the resources of financing banks. One of the most costly requirements on the part of banks is to prove the developer's own resources. Each bank determines the amount of proof of the developer's own resources for an individual project individually. At least their required volume is 30%, in recent years up to 50% of the total cost of project implementation. When projecting real estate financing, banks provide short-term construction loans for a maximum period of two years. In the case of residential real estate, depending on the construction period of the project, it is usually for a period of 18 + 6 months, if necessary, it is extended by the time required for the sale of real estate. When financing a project with an investment loan, a shorter loan maturity is preferred. Currently, banks prefer a maximum loan maturity of eight years. When financing development projects, loan security is required, mainly due to the high risk of the business. The basic security of the loan is a lien on land and buildings in the first place, recorded as a debit on the title deed in favour of the financing bank at the relevant cadastral office. In the case of construction, the lien is registered immediately after reaching the disposition necessary for the registration of the property as under construction, in accordance with the conditions of the Building Act. The establishment of collateral for real estate is one of the basic contractual conditions for drawing credit resources.

Abstract

The paper addresses the methodology of research on the sustainable development of the Eurasian Economic Union (EAEU) financial market, the main elements of which include relevant concepts, hypotheses and approaches to testing these hypotheses. The paper describes the most important initiatives in the field of financial integration of the EAEU. The author's interpretation of the concepts of sustainable finance, joint priorities for sustainable financial development, and sustainable investment is presented. Research hypotheses are formulated regarding the choice of priorities and vectors of the EAEU financial market sustainable development. Methodological approaches to testing these hypotheses are proposed and approbated. The developed methodology allows to specify the directions for implementing the sustainable Finance paradigm in the strategy for forming the common financial market of the EAEU, with an emphasis on institutional conditions and new classes of financial assets in the context of national priorities for sustainable development and the specifics of financial systems. The reported study was funded by RFBR according to the research project № 19-010-00526.

Keywords: sustainable finance, sustainable financial development, Eurasian Economic Union (EAEU), financial markets.

Introduction

Research on the practice of introducing sustainable finance in developed and emerging markets shows that the industry of new financial services is represented unevenly (Financing for Sustainable Development Report, 2020). Notable progress, largely determining the future prospects for the development of sustainable financial systems, has been achieved in the sustainable investment sector (The rise of green finance in Europe, 2019; Lvova et al, 2020b). The sustainable segments of financial markets are actively developing, including the markets for green, social, and thematic bonds (Designing a sustainable financial system, 2018). The implementation of sustainable investment principles in the global economy contributes to the achievement of the Sustainable Development Goals (hereinafter referred to as the SDGs), allowing us to attract financing for significant projects, expand the classes of financial assets, provide new tools for managing financial risks, and improve the level of financial involvement and the quality of corporate governance.

The potential for sustainable investment is higher for developed markets and commercially attractive projects. For emerging markets and projects with relatively low expected returns, sustainable investments are intended to act

DARUSHIN "Sustainable Development of the EAEU Financial Market: Refining Research Methodology" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

more like an element of blended finance. Non-investment sustainable financing mechanisms are relatively more important in emerging markets than in developed ones. For the least developed economic territories, the availability of these mechanisms is crucial in the process of achieving the SDGs. The largest financial institutions show a noticeable interest in sustainable finance, imposing the demand for specialized financial services. However, we are still talking mainly about developed markets, while in emerging markets, including the markets of the Eurasian Economic Union member countries (hereinafter – the Union, the EAEU), sustainable finance is in its early stage.

What contributes to their formation and further development in the EAEU? Environmental challenges create a key impetus for this. An assessment of global sustainable development initiatives shows that the speed of the transition to sustainable financial system will largely depend on the ambitions of national governments in the domain of climate policy. These conclusions are confirmed by the results of generalization of scientific and information sources, in which sustainable finance is primarily associated with green finance. The development of green financial markets, including the climate segment, is extremely important for countries exporting hydrocarbon resources, providing an opportunity to increase investment attractiveness, bring a wide range of investors, and hedge the risks of hydrocarbon assets depreciation. It is no coincidence that the formation of sustainable finance in Russia started primarily with green initiatives, as can be judged by the program documents of VEB.RF and the Central Bank of the Russian Federation. A similar situation is observed in Kazakhstan. In particular, within the framework of the new world financial centre in Nur-Sultan (MFC "Astana"), along with other main segments, the sector of green finance functions.

The second most important impetus for the development of sustainable finance in the EAEU space is regionalisation, which in the face of current challenges is giving way to the globalisation of financial relations. Regionalisation creates a demand for the development of new segments of the financial market. Green and social segments can become drivers of financial development, helping to overcome the crisis, increasing competitiveness and expanding opportunities for interaction with other regions and countries. The expediency of developing these segments should be reflected in the strategy of Eurasian integration.

Thus, the topic of sustainable development of the EAEU financial market is extremely relevant, which determined the direction of the study. In the article, we will disclose a refined methodology for studying the sustainable development of the EAEU financial market, the main elements of which are relevant concepts, testable hypotheses and approaches to examining these hypotheses.

Research Background

The Eurasian Economic Union (hereinafter – the Union, the EAEU) is an international organization, the functioning of which is aimed at regional economic integration. The Treaty on the Eurasian Economic Union (2014) entered into force in 2015. The development of the EAEU presupposes a gradual transition to free movement of goods, services, labour and capital within the Union. Thus, not only economic, but also financial integration is planned – the creation of a common financial market for the EAEU. Moreover, according to the Treaty on the EAEU (cl. 130), the initial stage of financial integration should be completed within the next five years (until 2025). Upon completion of this stage, it is planned to harmonize the financial legislation of the Union countries and form a supranational financial Mega-regulator of the EAEU.

Since 2015, the EAEU member states have made some progress in ensuring conditions for financial integration. Basically, this progress can be traced in the field of legislation. Thus, a landmark event in October 2019 was the approval of the Concept for the formation of a common financial market of the EAEU (the Concept of formation of the common financial market of the Eurasian Economic Union, 2019a), including the banking, insurance segments and the securities market (hereinafter – the Concept of the common financial market). It specifies goals, principles, stages, criteria and main directions of financial integration of the EAEU. The following goals of creating a common financial market in the countries of the Union are recognized: firstly, increasing the availability, quality and variety of financial services for the private sector of the Union member states; secondly, the intensification of growth and competition, increasing efficiency in the financial services sector. It is noteworthy that the Concept of the common financial market identifies two stages in the formation of the common financial market – before and after 2025, whereas earlier the planning horizon for financial integration was limited to 2025.

In the review of this Concept prepared by the Central Bank of the Russian Federation (the Concept of formation of the common financial market of the Eurasian Economic Union, 2019b), the contribution of the document to the creation of conditions for financial integration of the EAEU, in addition to specifying the strategy and legal aspects of its implementation, is characterized by the following main direction: supervisory, administrative, informational cooperation within the framework of financial integration of the EAEU is provided; a vision of the development of

the financial market infrastructure is presented, including the declared task of forming a single exchange space of the EAEU; the importance of protecting the interests and rights of providers of financial resources, as well as of financial services consumers, is recognized; significant attention is paid to the issues of cyber security; directions for the development of the common payment space are established; tasks and powers of the supranational financial Mega-regulator are presented. It is important to note the envisaged provision of mutual recognition of licenses, that is, mutual admission of financial market participants in the EAEU countries. For this, a mechanism of the so-called "standardized license" is proposed, which will operate in all of the above sectors of financial services. Despite the fruitful international cooperation in the field of creating the necessary institutional conditions for the functioning of the common financial market of the EAEU, the challenges, exemptions and restrictions in this area do not lose their relevance. Let's consider the general profile of these challenges, which can be roughly divided into two main groups – exogenous and endogenous:

- Exogenous threats to the financial development of the EAEU countries and, above all, the Russian Federation, were realized according to a rather pessimistic scenario. Against the background of the coronavirus crisis, international financial sanctions against Russia significantly worsen the investment climate, impede the normal functioning of the financial market, limit the borrowing potential of the largest financial corporations and, in general, adversely affect the financial situation in the EAEU. This issue has been carefully reviewed in the literature, and general conclusions in this regard come to the fact that sanctions are a new reality, and participants in financial relations in the Union countries cannot radically change it.

- As for endogenous challenges, the key ones can be summarized by the phrase "financial development imbalances". These imbalances are observed in terms of spatial, institutional, instrumental characteristics. For example, we are talking about a dominant financial importance of the Russian Federation, and within it – about the financial dominance of Moscow, etc. For example, Russia accumulates over 90% of banking assets and the total capitalization of the EAEU share markets, almost the entire total volume of trading on stock exchanges, about 85% of the total number of banks, about 75% of insurance companies and 89% of financial infrastructure institutions (Lvova, Voronova, Ivanov, 2019).

Thus, on the one hand, Russia is capable of becoming a driver of financial integration of the EAEU, which has undoubted advantages for all countries of the Union. On the other hand, the imperfections of the Russian model of financial development will be translated region-wide, distorting the overall profile of the financial sector. What imperfections are we talking about? First of all, these are the previously noted financial imbalances. Russia demonstrates increased levels of concentration in certain segments of the financial system, financial instruments, key financial service providers and territories. Accordingly, financial accessibility in Russia (as well as in the EAEU as a whole) is uneven and not high enough.

In essence, this means that the Russian financial system is intermittently performing a distribution function. This is largely due to the influence of financial instability, but at the same time it is a prerequisite for financial instability (the "vicious circle" effect). It is characteristic that a low level of banking stability is observed in Russia in comparison not only with comparable, but also with financially less developed countries. At the same time, banks account for the bulk of financial assets in the scale of the Russian financial system, while non-bank financial services are relatively underdeveloped. In addition, the already high concentration of capital in the financial sector is increasing.

According to the authors, the key to understanding this situation, and, therefore, to overcoming the internal challenges of financial integration of the EAEU, is to stimulate competition. However, an inverse trend is observed in the financial systems of the Union countries. This cannot but be reflected in increased inefficiency. In the context of low competition, financial institutions have no effective incentives to fight for the consumer, which leads to a lack of financial accessibility. It is no coincidence that Russia remains practically aloof from the processes of sustainable financial development, which impose new requirements on the efficiency of financial services, tightening the conditions for competition in the financial sector.

Summarizing the foregoing, it should be noted that the Concept for the formation of a common financial market of the EAEU introduces important innovations, offering a popular set of tools for stimulating financial integration. However, the strategy of joint financial development needs to be improved with an emphasis on internal challenges. The dominance of Russia in the financial space of the EAEU, while the existing model of the financial market is preserved, calls into question the achievement of the stated goals of financial integration. Real rather than formal compliance with the requirements of fair competition and of improving the efficiency of financial services is required. The goals of financial integration should directly correspond to the goals of sustainable development of

the Union countries, envisaged by the world agenda for the period up to 2030, which are still reflected in the new Concept.

Conceptual research framework

C.1 An integrated sustainable finance concept

First (external) component of the integrated concept is connected with the fact that the phenomenon of sustainable finance must be studied in connection with sustainable development and sustainable investment. The integrated concept of sustainable finance integrates and refines current scientific concepts in the field of study. According to the authors, against the background of recognition of the importance of sustainable development, the concept of sustainable finance can claim the role of a new paradigm of financial science and financial development, reflecting the process of transformation of financial systems in response to the desire for *inclusive society* using flexible, maximally individualized mechanisms to overcome economic, social and environmental challenges.

Second (internal) component of the concept under examination concerns the content of sustainable finance, which combines three components: instrumental, institutional, functional (Lvova et al, 2019). In the first definition, sustainable finance is understood as an introduction of financial instruments that ensure compliance with environmental, social and organizational principles in the financial decision-making process. In the second – as institutional financial conditions for sustainable development, including the necessary financial resources to achieve the relevant goals and objectives. In the third, as the transformation of financial systems, including the acquisition of new, previously uncharacteristic functions (not only economic, but also social and environmental), under the influence of new financial thinking, which manifests itself on the supply and demand of financial services in the process of achieving sustainable development goals.

The interpretations of sustainable finance are inextricably intertwined, reflecting the vector of modern financial systems development (fig. 1).

Fig. 1 The integrated concept of sustainable finance

Source: authoring.

C.2 Concept of joint priorities for sustainable financial development

Investment needs in the areas of sustainable development differ, but in general reach colossal levels, contributing to the introduction of sustainable finance in different forms and at different levels of the economy. For the poorest countries with underdeveloped financial systems, economic and social challenges come to the fore. For moderately prosperous countries, increasing environmental risks are becoming a priority. The latter are also significant for developed countries that have effective financial mechanisms to improve the economic, social, and environmental conditions for residents, but, in fact, "export" environmental problems to countries with less developed markets.

Different financial opportunities and uneven progress in achieving the SDGs predetermine ambiguous national priorities, which makes the search for compromise solutions urgent. However, this search should take into account the comparative financial potential of the participants.

C.3 Integrated sustainable investment concept

Generalization and analysis of scientific ideas about sustainable investment allows us to conclude that the terminology in this area is characterized by significant discrepancies. In a closely related sense, the categories "responsible investment", "socially responsible investment", "social investment", etc. are used. The systematization of the definitions of these categories with an emphasis on their defining features shows that the term "responsible investment" prevails in the analysis and assessment of the development of sustainable financial services. However, in the context of the concept of sustainable finance, one should speak rather not about responsible, but about sustainable investment. The latter is considered by us in a broad sense, integrating responsible, socially responsible and socially oriented investment (fig. 2).

Fig. 2 The integrated concept of sustainable investment

Source: authoring based on (Lvova et al, 2020b)

The market system for responsible investing brings together actors (institutional and private investors), objects (companies and projects that meet the criteria for responsible investment), instruments (equity and debt), strategies (negative regulatory and positive screening, ESG integration, active ownership, etc.). However, in general, investing in sustainable development is not limited to the market component, including the public segment, as well as investments mobilized using blended finance mechanisms.

Research hypotheses and approaches to their verification

G.1 The first series of hypotheses consist in the fact that the priorities for sustainable development of the EAEU financial market are determined by: a) common sustainable development priorities for the Union countries; b) the comparative financial capacity of these countries.

M.1 Methodological approaches to assessing the importance of sustainable development of the EAEU financial market

On the one hand, in order to achieve the SDGs, one cannot abstract from the issues of financial development. On the other hand, it is the SDG system, in our opinion, that should underlie the substantiation of promising directions for the development of sustainable finance. This approach is introduced and evaluated by the authors for a more detailed assessment of the importance of sustainable finance in the SDG system (Lvova et al, 2020a). Identification of joint challenges for the Union countries based on information from the global monitoring of the SDGs achievement (Sachs et al, 2020), in turn, gives a preliminary idea of the priorities and significant vectors of sustainable development of the EAEU common financial market.

However, the concept of joint priorities for sustainable financial development implies a search for compromises in overcoming critical challenges. We propose to summarize these challenges taking into account a factor of *financial gravity*. By analogy with the foreign trade gravity models (Tinbergen, 1962; Anderson, 1979; Mogilat, Salnikov, 2015), the stylized financial gravity model combines the factors of financial depth and financial distance:

$$F = \alpha * \frac{FD}{FDIS}$$

F – the level of "financial attraction" of the economic territory;
FD – is the financial depth of the economic territory;
FDIS – financial distance of the economic territory;
α is a constant.

The model needs improvement and empirical approbation:

a) it is necessary to clarify the methodology for assessing financial depth – at this stage, it seems that preference should be given to absolute indicators of financial depth, including indicators of total financial assets and capital market capitalization;

b) the numerator of the formula (*FD*) can be adjusted to take into account the variety of financial instruments, which will allow you to get a more comprehensive idea of the attractiveness of the national market;

c) it is necessary to justify the methodology for assessing financial distance (*FDIS*); for this, for instance, rating methodology for global financial centres are applicable where such a distance or 'connectivity' is evaluated by an expert method (see f. i.: The Global Financial Centres Index 28, 2020).

Previously, we assume that the highest level of "financial attraction" will be shown by the Russian Federation and Kazakhstan. This assumption is confirmed by a comparative assessment of the financial depth of the Union countries (Lvova, Voronova, Ivanov, 2019), as well as the rating of global financial centres, which includes only these countries of the Union (The Global Financial Centres Index 28, 2020).

The proposed methodological approaches are combined to reveal the priority challenges for sustainable development of the EAEU financial market. The authors propose a cumulative algorithm to evaluating of comparative significance of SDGs, according to which 1 point is assigned for a specific goal for each corresponding "significant challenge" in the Union; 2 points – for each "main challenge"; 1 point – for the presence of such challenges in Kazakhstan; 2 points – in the Russian Federation. (tab. 1).

Table 1: the priorities for sustainable development of the EAEU financial market in 2020

Countries / SDGs	BY	KG	RU	KZ	AM	Points
Goal 1: No poverty						0
Goal 2: Zero hunger						9
Goal 3: Good health and well-being						10
Goal 4: Quality education						0
Goal 5: Gender equality						5
Goal 6: Clean water and sanitation						6
Goal 7: Affordable and clean energy						0
Goal 8: Decent work and economic growth						7
Goal 9: Industry, innovation, infrastructure						9
Goal 10: Reduced inequalities						9
Goal 11: Sustainable cities and communities						4
Goal 12: Responsible consumption, production						6
Goal 13: Climate action						5
Goal 14: Life below water						3
Goal 15: Life on land						6
Goal 16: Peace, justice and strong institutions						11
Goal 17: Partnerships for the goals						3

Countries / SDGs	BY	KG	RU	KZ	AM	Points
Number of priority goals	8	8	11	10	11	
Global SDG rank	18	52	57	65	75	
EAEU SDG rank	1	2	3	4	5	

_____

- achieving the goal is one of the main challenges for the country;
- achieving a goal is one of significant challenges;
- data not available.

Source: authoring based on (Sachs et al, 2020).

G.2 The second series of hypotheses concerns the vectors of sustainable development of the EAEU financial market, which are predetermined by: a) affordable financial solutions in the field of sustainable development; b) the range of sustainable financial services implemented in international practice; c) the specifics of the neo-continental model of financial development of the EAEU member states.

M.2 Methodical approaches to substantiating the vectors of EAEU financial market sustainable development

Justification of the vectors of sustainable development of the EAEU financial market, in turn, is divided into three successive stages: systematization of financial decisions in the field of sustainable development; structural and functional characteristics of the modern market for sustainable financial services; identification of the features of the EAEU member states financial development.

In order to systematize available financial solutions in the field of sustainable development, we start from the results of the United Nations Development Program (UNDP) project (Financing Solutions for Sustainable Development, 2020), which is a specification of the Addis Ababa Action Agenda (2015) and allows us to classify the sought solutions in the context of the SDGs (for more details see also: Financing for Sustainable Development Report, 2020). In the development of this approach, financial solutions for sustainable development are divided by us into three groups: investment tools; grant financing; financial regulation and/or risk management. The application of this approach is illustrated by the example of financial solutions for SDG 9 (tab. 2).

Table 2: Financial solutions to achieve SDG 9 "Industry, innovation, infrastructure"

Implementation tools / Financial solutions	Investment tools	Grant financing	Financial regulation and (or) risk management instruments
Social and development bonds	+	+	+
Crowdfunding	+	+	
Impact investments	+		
Diaspora funding	+		
Lotteries		+	
Corporate funds		+	
Compensation measures for the damage to biodiversity			+
Financial standards			+
State guarantees			+

Source: (Lvova, 2020).

To characterize the market for sustainable financial services, we introduce a classification matrix, which appeals to the characteristics of the financial corporations sector in the current version of the System of National Accounts (tab. 3).

Table 3: Characteristics of sustainable financial services market

Sustainable financial service providers	Sustainable financial services	Role in market development	Professional initiatives
Central banks	Auxiliary financial services	Support and promotion of sustainable financial development initiatives	National, regional, international
	Financial intermediation		
Financial intermediaries			
Depository corporations	Financial intermediation, financial risk management, liquidity transformation, auxiliary financial services	Reallocation of financial resources in the sustainable financial services industry	National, regional, international, in the context of individual market segments
Investment funds of the monetary and non-monetary market			
Insurance corporations			
Non-state pension funds			
Other financial intermediaries			
Auxiliary financial institutions			
Stock exchanges	Auxiliary financial services	Support and promotion of sustainable financial development initiatives	National, regional, international, in the context of individual market segments
Specialized financial information institutions			
Other auxiliary financial institutions			

Source: (Lvova, Rakhimov, Voronova, 2020).

Thus, financial institutions are structured according to the main groups of the financial corporations sector (classification by the *hierarchical method*). In this case, the second and third groups of financial institutions can be structured by the types, as presented in the table, or in more detail. This allows you to form a generalized or detailed description of financial services in the context of individual countries, regions and areas of financial activity (classification by the *faceted method*). The matrix has been validated by the authors for sustainable financial services provided by central banks, depository corporations and stock exchanges (Lvova et al, 2020b).

As for the neo-continental model of financial development, we are talking about the financial systems of post-socialist countries, which are associated with, against the background of institutional imperfections, the dominant position of banks, underdevelopment of direct financing mechanisms, a high concentration of ownership, a relatively small variety of financial instruments as well as with a high share of governmental ownership in financial sectors (Zhukova, 2015). It is curious that in Russia, which is the financial dominant in the EAEU space, the key features of the neo-continental financial system have become more and more distinct in recent years (Lvova, Voronova, Ivanov, 2019).

Accordingly, the prospects for sustainable development of the EAEU common financial market, including in specialized segments, will be associated primarily with large financial institutions (first of all, with Russian banks). However, Eurasian banks are also suffering from specific constraints, including insufficient level of competition, relatively low financial stability; increased importance of budget and corporate financing mechanisms (see in particular: Pak &, 2020). Therefore, development banks can play a leading role in this development, whose mission is to finance investment projects of strategic importance. Thus, sustainable investment will be in demand in blended finance projects that combine expertise, private and public resources.

Without denying the high importance of the development of collective investment institutions, the authors come to the conclusion that the prospects for the formation of a sustainable investment market in the EAEU according to the model of developed countries with a characteristically high role of non-bank financial intermediaries should be regarded with restraint (the culture of investment is not developed, the necessary infrastructure is absent, national financial markets, not excluding Russian, are not deep enough and diversified). Risks associated with the decarbonization of the global economy require special attention in the context of the EAEU financial market sustainable development. The realization of these risks entails the depreciation of carbon-intensive assets,

complicates access to international capital markets. Thus, for the EAEU as a whole, and for Russia in particular, the issues of participation in the global trade in carbon units and the creation of a supranational carbon exchange are extremely relevant.

Research Results and Discussion

The author's methodology for studying the sustainable development of the EAEU financial market contains theoretical concepts, hypotheses and approaches to their verification. Let's summarize the main components of the methodology, assessing their novelty and scientific significance (tab. 4).

Table 4: Assessment of the novelty of the research results

Results	Methodology component	Clarification of scientific concepts	New scientific result
C1	Integrated concept of sustainable finance	+	
C2	Concept of joint priorities of sustainable financial development		+
G1	A series of hypotheses on the priorities for sustainable development of the EAEU financial market		+
M1	Methodological approaches to assessing the priorities for sustainable development of the EAEU financial market	+	+
G2	A series of hypotheses on the vectors of sustainable development of the EAEU financial market		+
M2	Methodological approaches to substantiating the vectors of sustainable development of the EAEU financial market	+	+

Source: authoring.

Thus, the developed methodology makes it possible to specificate the directions of introducing the sustainable finance paradigm into the strategy of forming the common financial market of the EAEU with an emphasis on institutional conditions and new classes of financial assets in the context of national priorities for sustainable development and the specifics of financial systems. The methodology is consistent with such issues of government research as the institutional conditions for the development of sustainable finance in the EAEU; characteristics of the financial markets of the Union countries from the perspective of the prospects for the introduction of sustainable financial services; the potential for the formation of new segments of the EAEU financial market; effective financial solutions in support of the EAEU sustainable development priorities; the possibility of introducing new financial assets into the EAEU practice. Continued research in this area makes it possible to develop proposals for the inclusion of sustainable financial institutions and new financial instruments in the EAEU financial integration strategy.

Abstract

The article is devoted to the study of current problems of development of the tourism industry in the fight against COVID-19. The main trends in the development of the tourism sector are identified, as well as the tools that provide streamlining and regulation of the tourism industry in different countries.
The analysis of the state of the tourist industry in the conditions of pandemic spread is carried out. It is proved that the revival of the tourism industry is possible only based on the effective organization of the tourism business by forecasting and eliminating possible risks and dangers that cause significant losses to the industry.
The main problems and threats that affect the activities of the tourism business are identified. The reasons for the deterioration of tourism enterprises, the main of which is the inability to adapt to the conditions of doing business in a pandemic. Based on the conducted analysis the threats and dangers which can arise in the course of activity of the tourist enterprises of Ukraine are formed. This approach made it possible to propose stabilization measures that will revive the tourism sector in a pandemic. At the same time, strategic changes in the conditions of coronavirus spread should be quite flexible to changes in the external environment of the tourist enterprise.
It is established that ensuring the creation of a high-quality competitive product of the tourism industry is possible due to the training of specialists in the tourism business. Besides, the elimination of shortcomings in the regulatory framework for the regulation of the tourism industry should be a key prerequisite for the effective functioning of tourism businesses at all levels.
Based on the conducted researches it is established that revival of tourist activity in the conditions of a pandemic should take place in the direction of strengthening of cooperation with such elements of the infrastructure of hospitable business as tourist agencies, excursion bureaus, insurance companies, trade enterprises, advertising agencies, etc. agencies.
It is proved that measures to stabilize the tourism sector in the context of a pandemic must be adapted to new challenges and threats, as well as use effective tools to achieve new opportunities in the field of tourism.

Keywords: tourism industry, international tourism, sphere of tourism, COVID-19, pandemic.

Introduction

Tourism is one of the few sectors of the economy that is developing rapidly. The tourism industry provides leisure, contributes to the preservation of the historical and cultural heritage of society, has a stimulating effect on international trade, maintains a high rate of development of a large number of industries, stimulates economic growth in general.

Cite this Article as: Inna LEVYTSKA, Alona KLYMCHUK , Valentina POSTOVA and Nataliia KOTSERUBA“ New Challenges and Threats to The Tourism Industry in The Fighting Against COVID-19” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Tourism companies provide customer preferences for all tastes, thus guaranteeing competitive advantages and the opportunity to conquer the global market based on advanced technologies.
With access to booking systems, the presence of brands and business management strategies, meeting the needs of customers based on a wide range of knowledge, the tourism industry provides potential benefits to the national economy.

In this regard, the study of theoretical and methodological and scientific-practical issues of tourism development, identifying the main problems of the tourism services market in a pandemic and the formation of measures to prevent the negative impact of preventive tools associated with the spread of COVID -19, is an extremely important issue.

Materials and Methods

Analysis of recent research and publications. Important scientific achievements in the study of theoretical and methodological aspects of international tourism are the works of such well-known foreign scientists as R. Barton, F. Kotler, M. Porter, N. Taylor, J. Holloway, and others.

Scientific issues of tourism industry development are also covered in the works of such economists as Yu. Gorban, K. Zhadko, O. Zhykhor, A. Zanuda, V. Kyfyak, O. Kolesnyk, O. Lebedeva, O. Sakharchuk, O. Fedulin, and others. The scientific achievements of these authors are devoted to the formation and development of the tourism industry, determining its place in the world market of tourist services, highlighting the main aspects of the modern tourism industry, analysis of general and specific areas of industry.

However, it should be noted that to date, insufficient research has been disclosed on the development of the tourism industry in the fight against COVID-19 with the identification of major risks and threats. Solving this problem requires further research to study tourism and develop measures to improve the functioning of tourism.

Research methods allow to substantiate the scientific approach to defining the essence of the tourism industry, to summarize existing approaches to ensuring the effective functioning of tourism, to identify the main problems, challenges, and threats to the tourism industry in the fight against COVID-19, to justify the formation and use of sub-measures objects of tourist business, it is logical to generalize theoretical bases and to formulate conclusions of the research.

The theoretical and methodological basis of the study consists of the fundamental provisions of economic theory, scientific achievements of domestic and foreign scientists who have studied the tourism industry.

The information base of the research is normative-legal acts of Ukraine, official statistical materials, scientific publications on the mentioned problems.

The main method of research is the system analysis which is used for complex studying of problems of development of the tourist industry. Also in the research process, the following methods were used: theoretical generalization and abstract-logical - to study approaches to the development of tourism, substantiate the importance of the tourism industry and improve the functioning of the industry in the fight against COVID-19, the formation of conceptual foundations of pandemic impact on tourism. services both in the world and in Ukraine; system, comparative and economic-statistical analysis - for processing economic statistics related to determining the negative effects of COVID-19 on the tourism industry, graphic - for visual representation and schematic and graphical construction of theoretical and practical provisions of the study.

The purpose of the research

The purpose of the study is to identify new challenges and threats to the tourism industry in the fight against COVID-19 and to propose stabilization measures to revive the functioning of tourism entities.

Results and Discussion

Activation of tourism development due insignificant compared with other sectors of the need for capital investments at of organizations of tourist activity, the availability of natural, historical, cultural and ethnographic and infrastructural resources, the growing desire of society to visit other places, get acquainted with the culture of

other peoples, as well as the desire to meet the needs of organized recreation and recreation Based on the preferences of customers for a variety of travel services, most companies in the tourism industry organize domestic and international tourism.
During its existence, the tourism industry as a service sector has undergone many changes similar to the production of material goods. As a sphere of economic activity, tourism, on the one hand, is determined by the demand and consumption of visitors, and on the other - belongs to the goods and services that are produced to meet this demand. Thus, tourism covers a wide range of activities, including international and domestic transport, catering, entertainment, tour operators, and travel agents.

The tourism industry is formed from the enterprises letting out the goods and services without which modern tourism cannot exist, namely: the enterprises providing services in accommodation (hotels, motels, campings, boarding houses, furnished rooms, rest houses, etc.) , as well as catering establishments, which are an integral part of enterprises providing accommodation services (restaurants in hotels, canteens in boarding houses and rest homes, etc.); travel companies engaged in the organization and sale of tourist trips; transport organizations engaged in tourist transportation; educational institutions for training and advanced training of specialists in the tourism industry; information and advertising services; tourism management bodies (state foundations, the function of which includes managing tourism development in the country and in the regions) and research organizations engaged in the collection and processing of tourism statistics, streamlining scientific forecasts and research in the field of economics and sociology of tourism; enterprises for the production of tourist demand goods; retail enterprises for the sale of goods of tourist demand.

In addition to these enterprises, tourists are also engaged in those that may exist without them, but provided that the stay of tourists in the range of their activities expands. These are taxi parks, restaurants, cafes, leisure enterprises (sports clubs, museums, theaters, zoos, casinos, exhibition and congress halls, etc.).

The functioning of tourism entities is ensured on the basis of attracting effective public policy instruments:

- construction of new, restoration and improvement of existing tourism facilities;
- formation of a favorable climate for the development of active types of tourism;
- intensification of internal convertibility of tourist products on the basis of improving their quality and expanding the range, improving the conditions of tourist service;
- setting up the production of environmentally friendly agricultural products to meet the needs of consumers of tourist services in high-quality food products;
- establishing effective communication links in the direction of opening representative offices for the provision of tourist services abroad;
- attraction of funds of business structures, enterprises of the tourist sphere for development of infrastructure (roads, checkpoints, water supply and sewerage systems, communications, service services);
- improving the organization of insurance of compatriots traveling in Ukraine and abroad;
- R&D in the direction of development of recreational and tourist potential, use of natural resources and historical and cultural potential of the state;
- guaranteeing safe conditions for transport services for tourists;
- creation of a scientific center for the development of tourism.

For the dynamic development of tourism entities and integration into the world tourism space, the formation of conceptual foundations of organizational, legal and economic conditions for tourism development as a profitable sector of the economy, the government should consolidate efforts to support domestic and foreign (inbound) tourism; intensification of privatization of tourism business facilities; ensuring the effective use and restoration of natural and historical and cultural heritage; simplification in accordance with the world practice of visa, customs and border formalities.

It is worth noting that the effective development of tourism should be carried out on the basis of partnership, which provides for responsibility and trust in the direction of sustainable development. The emergence of socially responsible tourism, which develops on the basis of public interest and public need, thus ensuring social and economic justice, cultural heritage, respect for national identity, human rights, etc. [1].

A clear reflection of the essence of the partnership is the activities of the Italian Association of Responsible Tourism (AITR), a non-profit organization founded in 1998. The association actually acts as an intermediary, providing interaction between tourism enterprises, local communities and consumers of tourism. Over time, namely in 2004, the World Tourism Organization developed the concept of sustainable tourism development: “Standards and practices of sustainable tourism management can be applied to all types of areas, including mass tourism and

various niches. The principles of sustainability relate to the protection of the environment, economic and socio-cultural aspects of tourism development, and a balance must be established between these three aspects.

The domestic tourism business is currently open to international partnerships in the field of tourism, as such cooperation fully reflects the pan-European political, legal and socio-economic processes, based on basic national priorities. Taking into account national interests, the instruments of Ukraine's international policy in the field of tourism services are multifaceted and comprehensive, as they are based on economic feasibility and mutually beneficial partnerships with a particular country or region, taking into account the specifics of a particular tourism market. International policy in the field of tourism in Ukraine provides for the formation and implementation of a number of internationalmeasures aimed at promoting the sustainable development of the tourism industry, streamlining tourism services, ensuring their coordinated interaction and rational management of certain areas of tourism.Today, purposeful and systematic activities in the direction of development of international tourist services are the factor that brings Ukraine's integration into the European economic space, the development of socio-economic and cultural aspects of the country, the effective use of existing tourist products.

The creation of numerous world tourism organizations provides streamlining and regulation of the tourism industry in different countries. This is due to the intensive growth and expansion of the borders of world tourism, which occupies one of the leading positions in the international economy. World tourism organizations are one of the most effective tools for multilateral cooperation between Ukraine and other countries that are their members [2].

World tourism organizations are associations of state and national non-governmental organizations designed to achieve common goals in the field of tourism. There are intergovernmental and non-governmental international organizations. If only states are members of international organizations, then such organizations are called intergovernmental. If the members of the organization are national associations, unions or associations, and they are called non-governmental. The main purpose of activities in the field of international regulation of the tourism industry is to expand the legal framework of foreign relations, the conclusion of international agreements of intergovernmental and interdepartmental nature on cooperation in the field of tourism.

The conceptual basis for the establishment of international relations is the development of partnerships on an institutional basis, as through direct participation in the activities of world and international structures of all levels of Ukraine are practically implemented contractual agreements. 87].

In the current situation due to the spread of coronavirus infection, it is difficult to predict the further development of the tourism business. The crisis in the field of tourism in the pandemic is exacerbated by increased competition and deepening socio-economic conflicts that threaten the security of the tourism industry.

How innovative and creative tourism actors can be will determine the further development of this severely affected industry.

The revival of the tourism industry is possible only on the basis of effective organization of tourist and recreational potential by forecasting and eliminating possible risks and dangers that cause significant damage to tourism.

For a long time, tourism has been a major driver in many countries in the economic sector and job creation.COVID-19 in the global sense has probably had the most devastating effect on the industry. First of all, it is necessary to take into account international or outbound tourism, when the client leaves his usual living environment for a long period (up to several months).

According to the International Labor Organization (ILO), in 2019, 330 million employees were involved in tourism in the world (approximately 10.3% of the global employment rate). Among them, 144 million people - the staff of resorts, hotels and restaurants. Approximately 30% of those employed in this industry work in small businesses with up to ten employees.

Nearly 51 million such small companies are in danger of ruin and bankruptcy due to the seasonality of their activities, limited resources and difficult access to credit and credit.

According to the latest ILO estimates, the pandemic could affect 305 million people employed in tourism and tourist services: 100 million of them may lose their jobs, the rest will be transferred to part-time work with reduced wages. The most affected are women, who are mainly engaged in the tourism business [4].

The International Tourism Organization, given that coronavirus control measures and restrictions on freedom of movement have now affected half the world's population, estimates the industry could fall by 60-80%. In real terms,

this is a loss of 950 billion to 1.24 trillion dollars. However, some experts call the amount of losses in excess of $ 2 trillion.
According to Ukrinform, the UN has released disappointing statistics on the prospects for the recovery of the tourism industry in the context of the coronavirus crisis. According to the analytical report "Tourism and COVID-19", according to experts, the number of international tourists in 2020 may decrease from 58% to 78%, which will reduce the cost of visitors from $ 1.5 trillion (in 2019) to 310 -570 billion Further fight against the pandemic could lead to the loss of about 120 million people in this sector.

In turn, according to UN Secretary General Antonio Guterres, every 10th person on Earth works in the tourism industry and provides a livelihood for hundreds of millions of people, ie the industry is an integral part of the world economy and one of the key elements of conservation. natural and cultural heritage. "In fact, we can say that tourism itself is one of the wonders of the world. That is why it is so painful to see how the COVID-19 pandemic is ruining the tourism sector, ”Antonio Guterres said in his speech [5; 6].

However, Ulf Sonntag of the Institute for Tourism and Resort Research in Northern Europe notes that tour operators and their partners in the target regions are using the coronavirus crisis towards quality tourism to make their offerings more environmentally friendly.

"It is, of course, painful that a number of travel companies go bankrupt through no fault of their own. But even if competition declines at the end of the coronavirus crisis, demand will also decline at first. Because of the fears and warnings that people have, and because many of them will want to and will have to save first. Therefore, we do not expect prices to rise dramatically. But you shouldn't count on solid cheap offers either, ”Ulf Sonntag rightly argues.As for the situation in the field of tourism in Ukraine in the conditions of the pandemic, tourism was in a state of improvement after a significant decline due to the events of 2014.

In recent years, there has been a positive trend in the annual growth of total revenues from the tourist tax and tax payments from the tourism industry of Ukraine. As noted in a study by domestic tourism experts: "The fact that Ukraine is becoming increasingly popular among foreign visitors is evidenced by the fact that CNN, one of the world's most famous TV companies, has compiled a separate ranking of the top 11 tourist cities in Ukraine. It includes Lviv, Chernivtsi, Uman, Kyiv, Pereyaslav-Khmelnytskyi, Kharkiv, Chernihiv, Odesa, Uzhhorod and Kamyanets-Podilskyi. Ukraine has many beautiful places with a lot of tourist activities. Lively cities, ancient castles, stunning countryside, a variety of landscapes and hospitality - all this makes Ukraine a special place… "[7].
According to the updated document "Roadmap for Competitive Tourism Development in Ukraine", the Government of Ukraine continues to work to minimize the effects of the pandemic in the national economy and has proposed a number of measures, both financial and non-financial, to reduce the impact on the population and economics.

On the other hand, the government reorganized the Department of Tourism and Resorts of the Ministry of Economy and Trade of Ukraine and created the State Agency for Tourism Development. Currently, efforts are aimed at strengthening the position of the State Agency through human resources and financial support from the state budget [8, p. 18].

In turn, the Verkhovna Rada of Ukraine on June 16, 2020 supported in the second reading the draft Law "On Amendments to Certain Legislative Acts on State Support of Culture, Creative Industries, Tourism, Small and Medium Business in Connection with Restrictive Measures, associated with the spread of coronavirus disease (COVID-19) "[9].

On July 13, 2020, the President of Ukraine signed Bill № 3377, which means the implementation of the envisaged anti-crisis measures in the listed areas of Ukraine's economy during the quarantine period. In addition, on May 27, 2020, the Cabinet of Ministers approved the "Economic Incentive Program to Overcome the Consequences of the Covid-19 Epidemic" [10].

According to the Program, support measures should be extended to such sectors as: services (trade, hotel and restaurant business, education, creative industries, personal services); agriculture; industry; transport and infrastructure; energy; information and communication technologies. However, although the government document envisages a number of initiative programs to regulate the tourism sector (the implementation of which may take time), experts estimate that domestic tourism has not received adequate support from the state, which means that its stabilization will lag far behind the pace of tourism recovery. other countries.Before proposing measures that will revive the tourism sector in a pandemic, it is necessary to identify the main problems and threats that affect the activities of the tourism business. Increased competition due to the emergence of new competitors in the market,

which quickly adapted to the conditions of doing business in a pandemic and in a short period of time to update the range of travel goods and services, is one of the reasons for the deterioration of tourism enterprises.
In addition to the factors caused by the spread of coronavirus infection and the introduction of measures to combat the pandemic, the tourism industry has a number of other problems, among which are:

- ignorance of the management of the legal framework;
- unfavorable tourism policy of the state;
- instability of the political and administrative sphere within the state;
- selection of partners and investors with a dubious reputation;
- negative image of the tourism industry among partners and consumers;
- significant gaps in both tactical and strategic planning.
- inefficient management and unqualified staff.

In today's rapidly changing economic environment, professional development of specialists in the tourism business is due to the expansion of the needs of tourism enterprises in qualified personnel able to ensure the creation of a high-quality competitive product of the tourism industry.

Significant adjustments in the functioning of tourism businesses at all levels should primarily be to eliminate the shortcomings of regulatory and legal support, which regulate issues in the field of tourism and have an impact on the safety of tourism entities.

As a group of authors rightly points out, the lack of clearly defined relationships between executive bodies at all levels of government negatively affects the results of their activities in the field of tourism [11]. At the same time, OB Zhykhor, NV Kuzminchuk [12] singled out among the reasons for the decrease in the effectiveness of modern mechanisms of state regulation the imperfection of regulatory and legal support and the institutional framework of public policy, which led to uncoordinated actions of public administration.

At the same time, OO Kolesnyk [13] emphasizes that the imperfection and inefficiency of regulatory and legal regulation of the process of management of tourism entities in Ukraine is one of the problems of ensuring the development of the tourism industry [14].

Today, tourism management is associated with the imperfection of the legal regulation of tourism businesses at the regional and local levels, which is exacerbated by the lack of planning for the systematic development of tourist areas.

Based on the analysis of threats and dangers that may arise in the process of tourism enterprises of Ukraine, special relevance and significant impact have stabilization measures in the field of tourism in a pandemic (Fig. 1).

Among the expected negative consequences of the exacerbation of COVID-19 and preventive measures related to the spread of the virus, Ukraine is projected to fall in GDP to 7.7%, and the unemployment rate could reach 10% (IMF forecast, April 2020)

It is assumed that the countries of the world will probably be able to restore their economic situation in 2021, but it is impossible to fully compensate for the negative consequences caused in 2020 by the countries.

It is projected that the international economy will be able to reach the state of 2020 only in 2022.

According to the forecasts, not all economic spheres suffer serious negative consequences from the pandemic. And the most "affected" will be the economies of those countries that are directly dependent on transport and tourism [15].

Probable variants of the economic recovery model are presented by two possible scenarios:

- The first scenario: the restoration of both the global economic model and economic relations between the countries will take place according to the V-shaped scheme, which provides for the continuation of the situation in the "as is" state (according to analysts, this is the most likely option for Ukraine)
- the second scenario: a longer period of crisis (even recession) with significant social consequences, indefinite duration of the pandemic period, restrictions on movement. Which can lead to significant changes in the global socio-economic model.
According to the United Nations World Tourism Organization (UNWTO), quarantine measures in the world have led to the introduction of restrictions on the movement of 100% of all international destinations.
According to the UNWTO report of 29 April 2020:

- 97 destinations (45%) completely or partially closed their borders to tourists;
- 65 destinations (30%) completely or partially suspended international flights;

Clarification of the conceptual foundations of tourism development in a pandemic: threats, dangers and stabilization measures

The main risk factors in the field of tourism

-ineffective adaptation of management in a pandemic, the use of outdated or ineffective methods and tools;
- loss of attractiveness for consumers due to outdated material and technical base;
- ineffective marketing, advertising, and information policy;
-lack of use of effective communication technologies with partners, consumers, government agencies, and other contact audiences;
- incorrect assessment of the company's capabilities, errors in forecasting changes.

The main threats to tourism and the world economy due to the exacerbation of the coronovirus

- ineffective state regulation of the process of licensing and certification of tourism entities;
- incoordination of actions of public administration bodies;
- reduction of socio-economic development, which affects the standard of living and purchasing power of the population;
- unreliability of partners (enterprises and organizations that provide services for accommodation, meals, and transportation of tourists, etc.);
- threats of natural, man-made, biological nature, which pose risks to the life and health of tourists during the trip, for which the tourist enterprise is not aware;
- the threat of bankruptcy as a result of the inability to pay financial obligations to consumers of tourist products.

Measures to stabilize the tourism sector in a pandemic

- state support and stimulation of the activity of subjects of the tourist industry: continuation of the policy of cancellation of obligations from payment of the profit tax and the VAT;
- gradual introduction of the permission for the organization of open terraces, platforms for establishments of a cafe, restaurants (at the preservation of all necessary safety measures for protection);
- intensification of measures of the digital transformation of the domestic sphere of tourism;
- development of tourist vouchers for domestic tourism (as a variant of introducing a tourist card for a certain amount, which is exempt from taxation);
-introduction of a transparent mechanism for the use of funds received from local budgets from the tourist tax exclusively for the development of domestic tourism and related infrastructure;
- strengthening the staffing and technical capacity of medical institutions and providing medical care in areas with a significant seasonal influx of tourist flows;
- conducting an active information campaign to increase interest in domestic tourism, recreation
- rationalization of the use of available resources by the enterprises of the tourist industry;
- elimination of shortcomings in the system of management decisions that regulate relations in the field of tourism;
- coherence and coordination of actions of power structures, the system to manage the tourist-resort sphere;
- Improving the regulation of the tourism industry at the regional level due to the lack of effective regional programs for tourism development and real steps for their implementation;
- development of an effective mechanism for managing the development of tourism, the market of tourist services, security and protection of tourists in the regions;
-state support for financing projects in the field of tourism, which intensifies investments and financing the development of tourism activities;
- application in practice of the client-oriented approach in service of consumers of the tourist industry;
- improvement of financial control measures by the management, which will lead to the effective use of financial resources.

Figure 1: Clarification of the conceptual foundations of tourism development in a pandemic: threats, dangers and stabilization measures

Complited by authors on the basis of [8; 14]

- 39 destinations (18%) closed their borders on a more differentiated basis, prohibiting entry for passengers from certain countries of origin
The cruise business has also suffered from quarantine restrictions. Shares of Carnival Corporation, which owns Diamond Princess, as well as other leading cruise companies (Norwegian, Royal Caribbean) have fallen 60-70% since January 2020/

The practice of refusing cruise liners to park in ports has become widespread. Royal Caribbean has canceled 18 flights to Asia (causing $ 130 million in losses to the company). Norwegian has canceled 40 flights to Asia by the end of 2020 (causing the company a loss of $ 16 million). Carnival estimates its losses at about $ 440 million [8, p. 7-9; 14]

In order to minimize risks for owners and managers of companies providing tourism services in Ukraine, recommendations for the following categories are offered:

- hotels and other accommodation establishments,
- catering establishments;
- tourist and transport enterprises.

A number of specific recommendations were made and explained for each group, including: training and awareness, precautions, measures for cleaning and disinfection, control of disease spread [8, p. 19].

Based on the above research, the authorities of each country should focus their efforts on stabilization measures for tourism enterprises aimed at minimizing the negative impact of preventive actions related to the spread of COVID-19.

Achieving the optimal balance between safety, health, the environment and economic interests should be the main tool for revitalizing the tourism sector.

With regard to measures implemented at the national level to minimize the effects of the pandemic, Bill № 337911 was submitted to the Verkhovna Rada of Ukraine, which addresses the following issues:

- exemption of tourism service providers from: payment of VAT, payment of income tax and the Single Social Contribution (SSC), payment of land tax and tax on non-residential real estate;
- abolition of payment of tourist tax by the end of 2020;
- exemption from taxation when paying rent and land use, tenants of state and public property.Even if we take into account the fact that in the summer of 2020 the EU countries (which had the dynamics of improving the epidemiological situation and maintaining all necessary security measures for health) opened their borders and lifted restrictions on movement, it did not restore the previous level of tourism flows.

Countries that have opened their borders have introduced mandatory temperature measurements (or coronavirus tests) at airports when boarding planes. The main problem here is two issues: the reliability of rapid tests for coronavirus and the justification of the need for which time before departure passengers must pass the test. Some countries are raising the issue of introducing so-called health passports for all travelers, who will be informed about the presence of immunity to coronavirus. According to the updated document "Roadmap for competitive development of tourism in Ukraine" [8, p. 8], vaccination and medicines, unfortunately, "give little hope for economic recovery in the short term, especially with regard to travel and tourism."

It is also worth noting that the hotel and restaurant business is an integral part of ensuring effective business processes in the field of tourism. When ensuring the occupancy of accommodation facilities, hotel enterprises should be considered in terms of cooperation with the tourism industry.

In order for the tourism sector to intensify its activities in a difficult period, it is necessary to cooperate with a hotel company that has a good reputation in the market, a stable financial position and has a strong brand.

Revival of tourist activity in the conditions of a pandemic should take place in the direction of strengthening of cooperation with other elements of infrastructure of hospitality business: travel agencies, excursion bureaus, insurance companies, trade enterprises, advertising agencies, sports establishments, sports establishments.

The system of strategic changes in the conditions of coronavirus spread should be quite flexible to changes in the external environment of the tourist enterprise. At the same time, measures to stabilize the tourism sector in the

context of a pandemic must be adapted to new challenges and threats, using effective tools to achieve new opportunities in the field of tourism.
Implementation of measures to revive tourism in modern conditions should take into account the high level of dynamism and uncertainty of environmental factors, different scale of management and a high level of differentiation of economic activities in the tourism business, meaningful diversity of tourism industry and shaky starting positions of Ukrainian enterprises on the world tourism market.

Conclusions

According to the results of the research, it can be stated that today the identification of the main problems of this industry and the formation of a set of measures to adapt tourism to unstable environmental conditions is of particular practical importance for the effective functioning of the tourism industry in the fight against COVID-19.

Thus, the sphere of tourist services in Ukraine today suffers from the spread of the pandemic and the introduction of preventive measures related to the fight against COVID-19. It is revealed that the modern system of functioning of tourism business entities in Ukraine is fragmented and unsystematic, which is due to the lack of comprehensive interaction between the consumer and the tourism product.

At the same time, the lack of understanding of the need to form an interconnected systematic approach to the adaptation of the tourism sector in extremely difficult and uncertain environmental conditions demonstrates the low effectiveness of tools aimed at improving the performance of the industry.

The research made it possible to identify the main challenges and threats of the tourism sector at the macro-and microeconomic levels, which indicate the need to adapt the management of institutions to the requirements and financial capabilities of different categories of customers. Based on this, a list of recommended measures aimed at revitalizing the tourism sector in a pandemic that can adapt to changes in the market of tourist services.

Sustainable tourism development through the introduction of stabilization and loss reduction measures due to COVID-19 can be achieved in various ways. The diversity of directions and methods of achieving the set goals is an integral part of the implementation of certain principles in the direction of implementing management measures and ensuring the effective development of such an important sector of the economy as tourism.

In order to choose the most optimal tools for reviving the tourism industry in a pandemic, it is necessary to take into account industry specifics, territorial distribution of accommodation, seasonality of tourist services, capacity and technology of personnel selection and accounting.

Abstract

The study is devoted to the problem of improving Russian legislation in the field of housing construction from the point of view of analyzing the modern experience of the European Union. It is recommended to use the approaches and methods of formation and implementation of the EU Green Deal strategy in the legislative practice of state regulation for the Russian territories development.

Keywords: sustainable development, integrated development of territories, Green Deal, Renovation Wave, housing stock renovation, the COVID-19 pandemic

Introduction

The construction sector has a huge impact on the social, economic and environmental aspects of the industrial and domestic spheres of life in most countries of the world. In the EU countries, it accounts for 5.6% of value added (OECD. Stat, 2019.), in the Russian Federation – 6.4% (Rosstat, 2016). It should be borne in mind that this sector includes not only the housebuilding, but also the construction of power plants, auto routes and railways, airports and water supply facilities. At the same time, it is necessary to take into account the entire life cycle of the construction system, including the operation stage, which is one of the most important and longest. During the period of industrialization and post-industrial development various types of cities and towns as the areas with the maximum concentration of people become the main centers of contradictions in the human-nature system. Cities, raising the standard of living, at the same time reduce its quality and make the habitat too fragile, which becomes the main problem of the civilization development. In conditions when the costs of providing cities reach 80% of the world's energy, of which 40% are for buildings, the increase of their energy efficiency can significantly affect the saving of resources (Lunyakov, M.A., Akhmetov, I.A., 2019).

The problem of the integrated development of built-up areas and the demolition of dilapidated housing in the Russian Federation, despite the fact that much attention has been paid to its solution for several decades, it is still acute for the authorities in almost all country regions. Moreover, according to First Vice Prime Minister *Marat Khusnulin*, many regional leaders hide the volume of emergency housing stock in order to evade additional financial obligations to relocate the residents of such houses after their recognizing as unfit for habitation (With new housing ..., 2020). He emphasizes that the key task of integrated development is, in addition to the construction of new high-quality housing, the creation of all the necessary accessible infrastructure, including schools, kindergartens and clinics.

Housing construction in the context of a downturn in business activity and the spread of the COVID-19 pandemic, as well as the general low growth rates of the Russian economy over the past ten years, is considered as the main driver of economic growth. Over the past three years, the Russian government has been actively developing and

implementing plans to renovate the housing stock: since 2017, the Moscow Housing Renovation Program has been implemented, which provides for the resettlement of more than 350 thousand apartments and 5,174 houses; an address list of 472 starting building yards has been approved; it is planned to build more than 7 million sq. meters of real estate$ an indicative list of resettlement was formed (Program of housing renovation, 2020). Since 2018, the National Project "Housing and Urban Environment" has been implemented, which includes four federal projects: "Mortgage", "Housing", "Formation of a Comfortable Urban Environment" and "Ensuring a Sustainable Reduction of Unsuitable Housing Stock" (Decree of the President of the Russian Federation ..., 2018). The goal of raising annual residential buildings construction to 120 million sq. m by 2024 is within the framework of the National Project. The "Standard for the Integrated Development of Territories" (Standard for the Integrated Development of Territories, 2020) was adopted, which suggests such areas as vacant territories development for housing construction, residential and multifunctional buildings and the improvement of open public spaces.

In September-November 2020, the problem of the housing stock reconstruction in Russia, or as it is commonly called renovation, was further developed at the legislative level. Two bills were submitted to the State Duma for consideration – "On the Renovation of the Housing Stock in the Russian Federation" (hereinafter "on Renovation") (Federal Law "On the renovation of the housing stock in the Russian Federation", 2018), prepared by deputies S.M. Mironov and G.P. Khovanskaya, and "On Amendments to the Urban Planning Code of the Russian Federation and Certain Acts of the Russian Federation (on Improving the Institute for Comprehensive Development of Territories and Mechanisms for Resetting Emergency and Dilapidated Housing)" (Federal Law "On Amending the Urban Planning Code ...", 2020; Senators proposed their own version ..., 2020) (hereinafter "on Amendments to the Urban Planning Code") by senators N.A. Zhuravlev, O.V. Melnichenko, A.A. Shevchenko and deputy E.S. Moskvichev. The first bill was rejected, and the second was adopted in the first reading on November 17, 2020.

There are overlapping positions on a number of key issues between these projects: both of them create a legal basis for the simultaneous renovation of the housing stock in all regions of Russia. However, you can find many differences. So, the draft law on Renovation clarifies the concept of "renovation", which means the reconstruction or demolition of housing facilities subject to capital repairs, housing construction on the vacated territory of communal, transport, social infrastructure facilities, as well as measures for the improvement of residential areas ". By contrast in the bill on Amendments to the Urban Planning Code Then the word" renovation "is not mentioned at all. The authors of the first draft law attach great social significance to the renovation process, emphasizing that it is carried out with "the aim of ... realizing the right to a high-quality urban environment by improving the living conditions of citizens, increasing the comfort and performance of the housing stock, preserving the architectural value of the urban environment" (Federal Law "On the Renovation of the Housing fund in the Russian Federation ", 2018).

The second drafted law completely excludes from the text the previously used concept of "sustainable development of territories" and replaced it with "integrated development of territories". A significant part of the amendments text of this document is devoted to describing a new mechanism for the territories development through the definition of their boundaries, obtaining and distributing building rights, etc. It is assumed that 2 trillion rubles will be spent on the implementation of only the first stage of this program within 10 years, including funds from the developers themselves and attracted financing from regional, municipal and federal budgets.

Consideration of these bills almost coincided with the adoption in October 2020 of a new European Union renovation strategy entitled "A Renovation Wave for Europe - greening our buildings, creating jobs, improving lives" (A Renovation Wave for Europe…, 2020), aimed at doubling the annual rate of renovation of private and public buildings in the Union countries over the next ten years. Analyzing the text of this document, as well as other EU documents directly related to it, allowed us to highlight significant points that need to be taken into account in the subsequent revision of the adopted laws in the field of mass housing construction and land improvement.

Review of relevant studies and problem statement

A large number of studies by Russian scientists have been devoted to the problems of modern housing construction and land development. So, in the article (Afanasyeva E., Blednova A., 2020), based on the analysis of foreign experience in the renovation of industrial zones in order to create comfortable environmentally friendly zones for living and recreation, spatial tools for working with built-up areas of large agglomeration have been determined. The paper of (Golubev Ya.A., Veretennikov D.I., Korotych V.I., Krutenko L.V., Malyshev G.N., Nizamutdinova G.R., 2019), based on the typification of the urban landscape, proposes the author's model of intensive development of urbanized territories (as an alternative to the model of extensive development implemented during the renovation in Moscow), which allows to compact the city tissue by the forces of owners and small developers, relying on the principles of self-organization and sustainable development (Golubeva , Ya.A. & Co, 2019). Anton Murzin (Murzin, A.D., 2014) pays attention to the problems that hinder the sustainable development of Russian urban areas: he

demonstrates that their failure by local governments can lead to socio-economic damage and environmental degradation of territories. In the study (Fokin, A.E., 2015) the author proposes the own layout to determine the maximum productivity of using a built-up residential area for renovation by identifying the most significant criteria for the housing comfort. T.A. Vereshchagina, P. Ya. Degtyarev, A. I. Tyunin, using the example of one of the regions of the Russian Federation, analyzed the typical life cycle of a small town and assessed the intensity of depopulation processes, revealing the causes of the crisis in the traditional model of small towns' development (Vereshchagina, T.A. , Degtyarev, P. Ya., Tyunin, A. I., 2018). In the article (Lunyakov, M.A., Akhmetov, I.A., 2019) calculations were made to reduce the building operation cost by means of heating and ventilation energy consumption reduction and achieve savings of up to 60%.

Among the studies of foreign scientists the work (Canelo-Perez, JI, Mas-Alique, P, 2018) should be highlighted, which proposes a model for the selection and analysis of documentation, which allows transforming qualitative variables into quantitative ones and, therefore, prioritizing the company that is consistent with the sustainable development goals and socially responsible behavior principles. Study of (Albertí, J., Balaguera, A., Brodhag, C., Fullana-i-Palmer, P., 2017) attempts to develop sustainability standards for cities and urban areas through an integrated approach, taking into account the cities life cycle and the sustainable development principles. The authors found that, as a rule, existing tools for assessing the cities sustainability miss one of such aspects as the integrity of the assessment, focus on various environmental impacts, life cycle perspectives and the possibility of comparing the obtained assessments for different cities or urban regions. The study (Nematchoua, M.K, Nishimwe, M-R, A., Reiter, S., 2021), taking into account the main factors of energy consumption, including climate change, buildings reconstruction, the use of photovoltaic panels, sustainable mobility, and also urban areas classification, is devoted to a new scenario approach to improvement of the cities energy needs (example of Belgium). The study results showed that more than 90% of current energy consumption can be reduced on a district scale by combining factors such as intensive buildings renovation, use of electric vehicles and photovoltaic panels.

Research Methodology

The methodological basis of the research is the content analysis of legal documents and scientific publications of the European Union and Russia through the use of instrumental and methodological technologies of heuristic knowledge, including complex abstract hypothetical and logical tools, evaluative search methods, typology, comparison of expert assessments, classification and comparisons, identifying cause-and-effect relationships and constructing logical generalizations.

Results

A Renovation Wave is essentially a document integrated into the EU's long-term strategy for building a climate-neutral economy – the Green Deal, and is considered primarily from the point of view of improving the energy efficiency of buildings and the construction sector, which is one of the largest energy consumers in Europe - it accounts for more than one third of CO2 emissions in the European Union. Let's clarify that today 75% of construction funds in the EU are already energy efficient, and 85-95% of buildings will be in operation until 2050. Buildings take about 40% of all energy produced in the EU, while energy renovation comprises only 1%, which indicates the available opportunities to increase the efficiency of their operation (Stakeholder Consultation …, 2020). Living quarters, like industrial buildings, must meet the main goal of the Green Deal – to create a climate neutral habitat. It should be particularly emphasized that the Green Deal is underpinned by a clear action plan for the transition to a clean circular economy, reduction of environmental pollution and restoration of biodiversity, indicating the required investment to achieve the objectives. The goal of energy efficiency in buildings is one of the interrelated and interdependent goals of the Green Deal, which include the development of clean technologies, stimulating innovation in the industrial sector, the introduction of clean modes of transport, decarbonizing the energy sector and raising global environmental standards. The adoption of the main document on renovation in the EU was preceded by consultations and exchanges of views with a very wide range of stakeholders in January-August 2020 in order to identify positions and ideas on how to launch this project at the earliest stage, identify the main obstacles to its implementation and possible measures to overcome them.

As a result of the analysis of the existing barriers to the buildings renovation, it was revealed that the majority (70% or more) of respondents consider the lack of transparent and reliable information, simple and affordable financing instruments and government incentive measures$ the presence of risks and additional transaction costs (unpredictability of costs); the inability to recoup financial costs: interests divergence of participants (owners, residents, owners); difficulties in obtaining a bank loan for renovating residential buildings; insufficient technical experience of local and regional authorities and financial institutions; lack of skilled labor; lack of necessary knowledge for home owners – to be the most significant problems (see table 1).

Table 1: Main barriers to building renovation in the EU

Barriers to renovation of residential buildings in the EU	Percentage of respondents	Barriers to renovation of non-residential buildings in the EU	Percentage of respondents
Insufficient understanding of energy use and savings associated with various energy efficiency measures	85%	Lack of funding for public buildings	79%
Lack of simple, attractive and easily accessible government incentives for renovation (grants or tax)	83%	Lack of attractive and readily available financial incentives (loans, grants, tax breaks, etc.)	77%
Energy renewal does not pay off within a reasonable time frame	82%	Reluctance of organizations to allocate sufficient financial resources due to lack of interest in sustainable development	77%
Disagreement between several owners (apartment buildings)	79%	Lack of staff with the skills to handle the repair process	77%
Low awareness of available public and / or private financial products for building renovation	77%	Energy renewal does not pay off within a reasonable timeframe	75%
Onerous procedures and / or financial constraints to access government financial support	76%	Insufficient information on energy use and energy efficiency (no energy audit conducted)	73%
Lack of confidence or assurance that the repair will bring energy and cost savings or other benefits, lack of quality assurance	76%	Restrictive rules for procurement, annual budgeting and accounting	72%
Mismatch of interests between the landlord and the tenant	75%	Alleged lack of government support, unambitious politics	71%
Lack of simple, attractive and affordable private financial repair products (such as loans)	74%	Lack of major financial products (energy efficiency mortgages) that offer renovation costs coverage	70%
Reluctance to make repairs to reduce energy consumption, need for additional incentives	70%		
Regulatory and administrative barriers and planning complexity, including required permits, etc.	70%		
Alleged lack of government support, non-ambitious politicians	70%		

Source: Compiled from Stakeholder Consultation on the Renovation Wave Initiative. Synthesis Report, (2020). European Commission. Directotate-General for Energy. Directorate C - Renewables, Research and Innovation, Energy Efficiency. October 2020, p.18-21.

Decisions regarding renovation are influenced by factors such as multi-apartment buildings; environmental friendliness of materials (with a low carbon footprint); awareness of the new benefits of renovation; the complexity of public procurement procedures, etc. Representatives of the construction sector are concerned about such problems as the inability to reduce operating costs after complex repairs, the possible increase in the cost of buying and renting buildings after renovation, which generally makes the renovation process economically unattractive. It should be noted that more than a third of respondents consider the buildings reconstruction not only from the point of view of improving energy efficiency, but more comprehensively, including a circular economy, the buildings usability, its sanitary conditions improvement, preparedness for climatic influences, natural disasters, as well as an element of adaptation to climate change (Stakeholder Consultation …, 2020).

It is important that the renovation is complemented by the European Climate Bill, which translates political statements into legal obligations of countries (Proposal for a Regulation…, 2020). Regions, for which the Green Transition will be particularly difficult, will receive financial assistance in the amount of 100 billion euros during 2021-2017. The EU has already made great progress in tackling the negative effects of climate change. So, with GDP growth in 1990-2018 by 61% greenhouse gas emissions decreased by 23%. The promotion of sustainable product design translates into annual savings of up to € 150 per European. At the same time, the implementation of a broad program to improve the efficiency of energy use in construction, greening buildings, increasing the availability of heating, cooling, and lighting services can significantly improve the quality of Europeans life, preserving health and reducing the possible emergence of global warming risks in the future. According to experts, if the goals of the global climate policy are not realized in the coming decades, about 90 thousand people in the EU may die from overheating due to a temperature rise of 5 degrees, the number of asylum seekers in the EU may increase by 660 thousand people (The EU's track record ..., 2019).

At present, the rate of growth of energy renovation does not satisfy the EU authorities, since deep reconstruction, which reduces energy consumption by at least 60%, is carried out only in 0.2% of the housing stock per year; in some regions of the EU, energy repairs are not performed at all. If this situation persists, the energy transition to zero emissions in the construction sector for centuries could stretch. Therefore, it is planned that by 2030 the annual rate of energy renewal of residential and non-residential buildings will at least double, and their maintenance will contribute to the achievement of the goal of climate neutrality across the European Union by 2050 (A Renovation Wave for Europe ..., 2020). Within the framework of the renovation strategy, the EU countries set themselves specific quantitative targets. For example, Bulgaria plans to renovate more than 5% of public buildings per year, and Latvia intends to reconstruct 2 thousand multi-apartment and 3 thousand single-family houses by 2030 (National Energy and Climate Plans ..., 2020).

At the same time, the new renovation strategy is not limited to the goals of reducing electricity consumption and carbon emissions, but opens up opportunities for a variety of social, environmental and economic benefits, including sustainable buildings, resistant to natural disasters, a convenient network of charging points for electric vehicles and parking lots, new methods of planning and maintenance of smart buildings, reducing the new buildings construction pressure, preserving biodiversity and agricultural land, etc. Energy renovation can become a driver of growth for the green economy sectors, significantly affected during the current COVID-19 crisis, stimulating the creation of new workers places and supporting the business activity of small and medium-sized businesses. It is estimated that 160 thousand new green jobs will be created in the construction sector by 2030 (A Renovation Wave for Europe ..., 2020).

One of the priorities of the EU Renovation Wave is to combat energy poverty, which refers to a situation where households cannot properly heat their homes or receive other necessary energy services at an affordable price. In the EU, this is one of the key indicators of the social policy effectiveness in the energy saving availability field. Currently, about 34 million Europeans are affected by the problem of energy poverty and 800 thousand units of social housing stock are in need of repair, therefore the EU views the problem of energy poverty as its urgent task and plans to allocate an additional 57 billion euros to address it (A Renovation Wave for Europe…, 2020). All EU members have a responsibility to develop national measures to reduce energy poverty as part of their long-term strategies for the renovation of the residential and non-residential buildings stock in accordance with the revised version of the Energy Efficiency in Buildings Directive 2018/844. Social policy measures in the housing sector involve identifying categories of beneficiaries (households) that have insufficient own resources and limited access to commercial loans, cannot overcome the high initial costs of repairs and therefore need assistance to finance them. Thus, complex policy decisions, including social politics and energy efficiency in the residential sector, must reinforce each other without hindering the free functioning of energy markets (Commission Recommendation …, 2020). As KPMG studies have shown, in terms of energy poverty, Russia is 1.5 times higher than the EU, where 16% of Europeans have high energy costs (Cross-subsidization in the electricity industry in Russia ..., 2020).

Conclusions

The construction sector plays a huge role in any country, including the EU and Russia, primarily because it is dominated by local companies and is a labor-intensive sector that provides employment for a large number of people. As a pandemic spread, it can significantly support economic growth.

Our review of modern Russian research in the buildings renovation shows that this topic is comprehensively and deeply studied, while a number of publications contain an integrated, multi-aspect (environmental, social and economic) approach to solving the problems of sustainable urban development. Construction renovation is only part of a more general problem of ineffectiveness of the spatial organization of Russia, the damage from which is estimated at 2-3% of GDP. Losses associated with the operation of buildings are also significant: 75% of the existing Russian

housing stock represents the most energy-intensive houses in the world, and at least 45% of energy resources are spent on heating this stock, which is 2.3 times more than fuel consumption for electricity generation (Murzin, AD, 2014).

Based on the analysis of EU legislation, it can be recommended to closely link the adopted laws in the field of demolition of dilapidated housing, resettlement of citizens and the integrated development of territories with the already adopted laws and projects in this area and outline clear guidelines for long-term construction, taking into account climate goals and sustainable development. The official documents adopted by the European Commission (EC) - regulations, recommendations and messages - can be such examples of interconnection. Thus, only a one-page section on energy poverty of the EC Communication contains about two dozen references to legal and other clarifying documents on this issue (see A Renovation Wave for Europe ..., 2020).

Many developed and developing countries have adopted political programs for sustainable development, ratified international treaties, and made commitments. This concept is not an abstraction and distant from the real life of people. The EU holds a special place in the implementation of sustainable development strategies. Already in the 1970s the main provisions of the general European policy in the field of environmental protection were developed, generating impulses for qualitative changes in the economy, ecology and society. The Treaty in Amsterdam (1999), the Lisbon Agreements (2001), the Treaty on the EU (2007) contain the main directions of the macroregion's sustainability policy. Since the European Union positions itself on a global scale as a flagship of sustainable development policy and has achieved significant results, its experience should be used in the rule-making practice of Russia.

In the housing renovation legislation special attention should be paid to the concept of energy poverty: it is necessary to identify the causes and consequences of this phenomenon, to develop assessment criteria and indicators for monitoring, taking into account the peculiarities of Russian regions, and use this indicator providing new housing to socially vulnerable citizens. It will allow targeting these unprotected consumer groups, determining the form and amount of support needed, which will have a multiplier effect in terms of improving energy efficiency of the entire economy and implementing inclusive growth.

Acknowledgment

This study was prepared with the support of the Russian University of Economics. G.V. Plekhanov, Order No. 1167 of September 25, 2020 (as amended by Order No. 1232 of October 8, 2020) on the topic: "Development of international business in the Eurasian space in the face of new global challenges."

Authentication and Authorization of IOT Devices in Federated Environments Using a Distributed Ledger

Michal JAROSZ and Zbigniew ZIELINSKI

Military University of Technology, Warsaw, Poland, michal.jarosz@wat.edu.pl
Military University of Technology, Warsaw, Poland, zbigniew.zielinski@wat.edu.pl

Abstract

This article describes how to authenticate and authorize IoT devices in federated environments. In our solution, we propose the use a distributed ledgers as a replicated database, which enforces consensus among federations. We also presented our performance results.

Keywords: Internet of Things, Authentication, Authorization, Federation environments, Distributed ledger

Introduction

The development of the Internet of Things is a rapidly growing branch of computer science that has become a permanent fixture in our homes. Nowadays we can observe many applications of the IoT like Health Care, Logistics, Smart City, Smart Home, Smart Grid, Industry 4.0, Smart Agriculture, and many others. In some of this application many of the assets that are included and managed in the networked environment belongs to different cooperating parties. For instance, Smart City [2] is an example of such environment that include local departments information systems, schools, libraries, transportation systems, hospitals, power plants, water supply networks, etc.

In general, federation may include various cooperating entities with limited trust relationships, and its primary goal is information integration, which will enable the use of resources belonging to individual partners. In federated environments, where parties (federations) can be various bodies of government administration, local governments or enterprises. One of the critical challenges in deploying and using a federated environment is maintaining the security of information exchange. In order to ensure confidentiality and integrity of communication channels between IoT devices, a secure and reliable trust management mechanism must be implemented. Such a mechanism must meet a number of requirements, the most important of which include: scalability, IoT device authentication, support for resource-limited IoT devices, and resistance to compromising individual IoT devices. The limitations of IoT devices [1] mean that not every device can use the solutions used in normal computers. This leads to develop special algorithms adapted to this type of devices. In federated environments several device owners want/need to cooperate and must grant access to their devices. At present, this problem is being solved by using PKI and certificates[□]. However, this solution has several limitations. Firstly, the device must use asymmetric cryptography which requires more computing power than symmetric cryptography. Secondly it must store its certificate along with a pair of its keys and certificates of root CA. Thirdly, checking certificates and sending them over the network requires more bandwidth and consumes more electricity.

A distributed ledger is a decentralized, replicated database that requires consensus among nodes when we want to add new data. The data stored in a distributed ledger is immutable. Distributed ledgers are used in a situation where data must be shared between two or more parties (the parties want/have to cooperate with each other, but do not fully trust each other – "Trust but verify"). The conditions for adding data to the ledger are entered in the form of a program called a smart contract. Distributed ledgers are an example of a recent paradigm that has evolved into a practical approach to implementing reliable distributed trust management and authorization infrastructure. Especially interesting are permissioned distributed ledger solutions, such as Hyperledger Fabric [□]. Hyperledger Fabric could be used for support integration with existing federated identity and access management systems.

In the paper we proposed a solution that meets the above-mentioned requirements and is based on the use of distributed register technology and the entropy of the IoT devices themselves. As part of the work, a protocol was developed and implemented using the Hyperledger Fabric, performance tests and security assessment were also carried out.

Cite this Article as: Michal JAROSZ and Zbigniew ZIELINSKI " Authentication and Authorization of IOT Devices in Federated Environments Using A Distributed Ledger" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Description of the proposed solution

The proposed solution is based on a some "fingerprint" of each IoT device. Each device has its own parameter array. The parameter array consists of n-parameters and each parameter has a minimum 32 bits of entropy. The parameters can be:

1) Generated random values. In this case, the device stores the parameter array in memory.
2) Values generated from the unique characteristics of the device and files stored on this device. If the device has only parameters based on its traits then there is no need to store any additional data on the device because the parameter value can be obtained by executing a command. The program responsible for authentication and authorization will have the required commands in its code.

Figure 1: General architecture of the proposed solution.

Figure 1 shows the general system architecture. Access to the ledger is only possible via smart contracts. The execution of a smart contract requires appropriate permissions, therefore access to the smart contract is only available through the application gateway. In our case, the application gateway additionally performs data conversion from COAP + CBOR, which is used by IoT devices to save transfer to the TCP + TLS format used by Hyperledger Fabric.

To be trusted, a IoT device must be registered in a distributed ledger through a special registration procedure. In the registration phase the parameter array is sent to the distributed ledger node. Communication between the device and the node can take place in a protected environment or using a one-time password. As a result, only the device and the distributed ledger store the parameter array. The device receives a unique identifier from a distributed ledger node. In the described concept, authentication is based on the confidence that only the device and the ledger have a parameter array that is used to create the data encryption key. Authorization is performed on a distributed ledger node based on the rules stored in the distributed ledger. A device that wants to check whether another device can perform a specific operation on it must send a query to any node. The node responds with either acceptance or rejection.

In a situation where the device wants to send data to the distributed ledger, it must randomly select m-parameters from the parameters array. Then computes a hash function for concatenating of these parameters. The result of the hash function is a key using to secure communication between the device and the distributed ledger node. The device then encrypts the data and the current timestamp using this key and a randomly generated nonce. Timestamp is required to check when the message was sent. It must send to the distributed ledger node: device identifier, numbers of parameters that were selected to create the key, nonce value and ciphertext. Since only the device and the distributed ledger have an array of parameters, only they can create the key with which the data is encrypted. A distributed ledger node decrypts the packet and based on the decrypted data, decides what to do next. The response is generated similarly: the node take random j-parameters from the parameter array stored by the distributed ledger. It then creates a key to encrypt the message as a hash value of the parameter concatenation. The response with the

current timestamp is encrypted with this key. The packet with encrypted response contains also the device ID, the numbers of the parameters used and the nonce used to encrypt the data. The communication diagram is presented in Figure 2.

Figure 2: A scheme for communication between a device and a distributed ledger node to perform operations on it (e.g., check permissions).[1]

In case the IoT device wants to communicate with another IoT device, it must ask the distributed ledger node for the communication key. The operation of the device is similar to the previous scenario, except that the device in the data field transmits the ID of the device with which it wants to communicate and the ledger node checks if the devices can talk to each other. If they can communicate, the ledger node generates a key for communication between devices. This key is the result of a hash function of concatenating the following data: device IDs, the current timestamp, and k-parameter values randomly selected by the node. Created key, timestamp and parameter numbers are encrypted in the same way as in the previous scenario. These items are used by the device requesting the key to secure communication with another IoT device. After the device receives a packet from another device, it generates a key using its stored parameter array, identifiers and timestamps sent in the packet. Timestamp is required to check when the key was generated – the message will be rejected if the key was generated long ago. The key is used to decrypt the data. If the ciphertext is successfully decrypted, it means that the key was created by the distributed ledger node - because only it has this parameter table outside the device. This method of communication also provides that the devices can communicate with each other – otherwise the other device would not receive the communication key from the distributed ledger node. The communication diagram is presented in Figure 3.

Figure 3: A scheme for communicating a device with a distributed ledger node to obtain a key to communicate with another IoT device.[2]

Results

The above concept has been implemented and pretested in terms of performance. The first test tested how many requests the device can generate. We used RaspberryPi 4, RaspberryPi 3B + and RaspberryPi zero WH for these tests. The results are presented in the Table 1. In this test, the device sends a request of writing data to a distributed ledger node. Several scenarios with different amounts of saved data were tested.

Table 1: The number of requests per second that the device can make, depending on the size of the data

The size of data	RaspberryPi 4 8GB	RaspberryPi 3 B+	RaspberryPi zero WH
20B	752,6	461,9	76,9
100B	726,0	445,7	76,1
1KB	373,3	231,8	53,38
15KB	49,45	30,56	6,75
30KB	26,21	16,08	3,42
50KB	16,4	9,78	1,68
100KB	8,3	4,98	Not tested

We tested the latency in generating keys for communication between devices. For this purpose, we simulated sending 25 requests generated by 4,000 devices. We conducted tests for a different number of distributed ledger organizations. Each node was a separate virtual machine with the following parameters: 4 vCPU (@ 2.6GHz), 16 GB RAM, 1Gb/s network interface, disk: SCSI HDD. The results are shown in Figure 3.

Figure 3: Delay in generating the key for communication between devices by distributed ledger nodes (peer) depending on the number of organizations. Each organization has 2 nodes.

Conclusions

In the paper, we proposed a fully scalable, distributed and decentralized solution to the problem of IoT device authentication and authorization in federated environments. Because it uses only symmetric cryptography and the encryption key is generated directly on the device - it is very effective - it does not require a lot of transfer to communicate with other system components. Establishing communication between two IoT devices requires only 3 messages while maintaining device authentication, data confidentiality, and authorization. In some distributed ledger implementations (such as Hyperledger Fabric), one can only force access to private data on certain nodes - thus extraneous nodes belonging to other organizations will not be able to create the encryption key. We are currently working on refining the details of our solutions. We also conduct further research on the performance and security of the proposed solution. Currently, we are also developing mathematical models to test the performance of the proposed solution using Hyperledger Fabric for various configurations.

Endnotes

1. Legend: ID – identifier of device; $[PN]_m$-m values of parameter numbers; H() – hash value of concatenation; $[P]_m$ – m value of parameters; E{key,nonce,data} – Encrypt *data* using *key* and *nonce*. Key is not transmitted.
2. Legend: IDA, IDB – identifier of device A and device B; $[PN]_m$-m values of parameter numbers; H() – hash value of concatenation; $[P]_m$ – m value of parameters; E{key,nonce,data} – Encrypt *data* using *key* and *nonce*. Key is not transmitted.

Application of RAPP Method in Service Relationship Marketing with A Special Focus on Environmental Aspects

Ewa KORELESKA

UTP University of Science and Technologie in Bydgoszcz, Bydgoszcz, Poland

ewa.koreleska@utp.edu.pl

Abstract

The aim of this study is to present the possibilities of using the RAPP model in service relationship marketing. The subject of the study are catering outlets located on premises of Bydgoszcz universities. The research hypothesis assumes that students' expectations from catering outlets and the remaining elements of marketing, as set out in the RAPP model, are not fully met. Moreover, it is assumed that there is no significant link between the students' gender and their preferences concerning introduction of organic products into the offer of catering outlets. The survey was carried out in 2019 and 2020, and was divided into a few stages. Data collection methods such as a direct survey, group interviews and observations. The data was analyzed with the use of mathematical statistical methods. The survey results show that students' expectations from the offer of catering outlets situated on premises of the universities in Bydgoszcz are not fully met, especially in terms of 'Relations', and 'Arena of Presentation'. The element of marketing referred to as 'People' was the best rated. Moreover, no significant relation between the gender of students and their preferences regarding introduction of organic products into the offer of catering outlets was found. This confirms the research hypothesis. Summing up, it needs to be noted that the RAPP method proved to be useful in the survey, as it highlighted weaknesses and strengths of canteens functioning in Bydgoszcz universities, indicating the direction of changes to be followed by entrepreneurs in service marketing management.

Keywords: Marketing, Management, Healthier Lifestyle, Model RAPP, Service Relationship Marketing, Marketing Mix, Universities, Organic Food, Internet, Services Gastronomic

Introduction

In 2018 the number of catering outlets in Poland was 69829, (935 belonged to the public sector and 68894 was owned by private entrepreneurs (Rocznik … 2019). A part of them operated on premises of universities. Out of concern for student health, the quality of the services should be the highest. The goal of the survey was to check whether it was possible to use the RAPP model for assessment of marketing activity in these places. So far this model has been used in few domestic publications (Chłodnicki 2010, Rogozińska 2016). In turn, foreign and domestic publications contain numerous articles on quality and safety, as well as marketing of food offered by enterprises, including service ones (Dospinescu N., Dospinescu O., M. 2018; Dospinescu N., Dospinescu O., Tatarusanu M. 2020).

Research Goal, Material and Methods

The aim of this study is to present the possibility of using the RAPP model and service relationship marketing. The research objects were catering outlets located on premises of universities in Bydgoszcz. The outlets were assessed by students who had been using them. It was found that the time of studying was enough for students to become experts in this field. It was also found that university canteens should provide services of higher quality than the conventional ones.

The research hypothesis assumed that students' expectations from services provided by university canteens and the remaining elements of marketing, as set out the RAPP model, were not fully met. Moreover, it was assumed that there was no significant relation between the students' gender and their preferences regarding introduction of organic food into the offer of university catering outlets.

Cite this Article as: Ewa KORELESKA " Application of RAPP Method in Service Relationship Marketing with A Special Focus on Environmental Aspects" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The survey was divided into several stages. In the beginning, there was a literature review. The concepts of service and marketing and their significance in Poland were analyzed in reference to the RAPP model.

The next model was developed in the academic year 2019/2020 for Bydgoszcz universities by means of a direct survey carried out among students and with the use of a prepared measurement tool – a survey questionnaire. The initial assumption was a minimal size of the sample suggested for scope studies of regional character – 200 respondents (Kędzior 2005). Eventually 300 students took part in the survey.

The method of group interview was used in the successive stage of the survey. The sample was matched in a nonrandomized manner with 15 participants and in 3 repetitions. The survey enabled better interpretation of earlier results and presentation of marketing proposals for service companies for the period of the pandemic.

The next stage involved an analysis of 21 WWW websites of Bydgoszcz universities and of Kujavian-Pomeranian Voivodship universities from the perspective of information on the subject of canteens functioning on premises of the schools. In the next step, an example of a university with properly working catering outlets was presented.

The results were analyzed by means of mathematical statistical methods. Pearson's chi-squared test χ^2 was used.

The form of statistics is expressed by a formula (Sagan, Mynarski 2002):

$$\chi^2 = \sum_{i=1}^{r}\sum_{j=1}^{k}\frac{(n_{ij} - n_{ij}^{'})^2}{n_{ij}^{'}}$$

where:

n_{ij} - observed populations in the *i* th verse of the *j* th column,

$n_{ij}^{'}$ - expected populations in the *i* – th verse and the *j* – th column.

The concept and significance of services in the Polish economy

According to The dictionary of the Polish language (1982), a service is defined as follows: ‘action of helping or doing work to meet someone’s needs, e.g. crafting, delivery of goods, food protection, health care, artistic activity, etc.” (Słownik Języka Polskiego 1982). In turn, Payna defines a service as a mathematical action which has an impact on people or objects that are at their disposal, without causing property transfer; after taking advantage of a service it cannot be resold or given to other persons (Payna 1997).

Since the beginning of the transformation of the Polish economy into a free market economy, the Polish service sector has dynamically developed due to:

- an increase in the society prosperity,
- higher level of education,
- more leisure time,
- more intensive use of modern technologies and the subsequent risks (Management Encyclopedia).

The role of services in the Polish economy after Poland’s accession into the European Union is presented by means of gross added value and its share in the service sector as compared to other sectors of economy, the number and percentage of people employed in other sectors of economy and investment outlays in other economy sectors.
In the analyzed period, gross added value (GAV) in services increased up to app. 93%, and accounted for 62.8% to 64.5% of GAV. It means that in that period gross added value created by the sector of services was higher than that of other sectors combined including: agriculture, forestry, hunting, fishing or the sector of industry and construction.

Table 1: Gross added value and its share in the sector of services as compared to other economy sectors

Years	Total	Agriculture Forestry Hunting Fishing		Industry Construction		Services	
	mln PLKN	mln PLN	%	mln PLN	%	mln PLN	%

The data included in table 2 shows that the most working people are employed in services. In thee considered period they accounted for 55.5% to 58,0% of all the number of employees in Poland. More than twice fewer people were employed worked in the sector of industry and construction (25.9% to 28.4%). The fewest employees represented the sector of agriculture, hunting and fishing (15.1% to 16.8%).

Relationship marketing of services

Marketing of services means all the marketing activities involved in the sector of services (Encyclopedia of Management). This Marketing involves the need to take into account the consumer co-participation in the process of service provision. In connection with this, marketing of services uses separate instruments to carry out the process of service provision. New elements are being added to the classic marketing-mix 4P composition – e.g. Process, Material certificate, People. Hence, 5P or 7P concepts are used (Koreleska 2018, 2019). Modern marketing of services tends to develop relations with the customer and maintain them for possibly the longest time (Prus, Berger 2013). Thus, there is a strong link between marketing of services and relationship marketing offering such tools as 5I composition (Sagan 2003) or RAPP (Rogoziński, 2000, Chłodnicki 2010). Sometimes it is assumed that services should be marketed exclusively using the relationship marketing (Dobska 2020). Table 4 presents features characteristic of the relationship marketing as compared to transactional marketing .

Table 4: Comparison of transactional marketing with relationship marketing.

Transactional marketing	Relationship marketing
The goal of transactional marketing is measured by the share in the market, penetration degree and the number of transactions	These actions are defined by the share in the customer 'heart', 'mind' and 'pocket', customer maintenance indicators, long term relations with a customer, Consumer Lifetime Value
Marketing is understood as a function to be performed in an enterprise	Marketing is understood as an integrator of relations between the company and the environment.
Gathered information is of ad hoc and cross-sectional character	Significance of continuous, the so called 'longitudinal', information, integrated with the system of decision support
Product understood as 'an object' or a stream of benefits for the consumer, innovations are of incidental character	Product' – service, understood as a 'process', series of episodes making up a relationship with a customer, diversified, innovations are implemented in a constant manner

Cost oriented price	Customer perceived value oriented price
Anonymous distribution	Personalized, virtual disribution
Communication is of mass character, is repeatable, one - directional, usually initiated by the 'sender' (company), who has the dominant position	Communication is of personalized, individual character, two – directional, also initiated by the 'recipient' (customer)

Sagan, A. (2003). Relationship marketing Marketing. Economic Academy in Kraków, Department of Market Analysis and Market Research, StatSoft editorial office, Kraków

Elements of the RAPP model and their interpretation

The RAPP concept consists of 4 marketing elements, i.e. Relations, Arena of Presentation, Product, Participants (Personnel and Buyers) (Rogoziński 2000). These terms are intended to mean:

- Product – a service to be offered, its scope, adjustment to the customer requirements, customer satisfaction, etc.
- Arena of Presentation – locations where services are provided, smell, wall color, lighting, equipment, cleanliness, marking, styling, atmosphere, etc.,
- Participants/Actors – including People/Personnel who are in direct contact with customers/Personnel to support /Customers/Stakeholders (directly connected with the company, e.g. financial companies, employees' families, etc.) – employees, their knowledge, politeness, greeting and parting formula, personal culture, customers, etc.,
- Relations– a relationship of the company with the customer, use of instruments (e.g. loyalty cards) to develop loyalty of customers who like the offered product (service), who would choose the product from products offered by other companies, who declare to purchase the service in the future, who are attached to ta given brand, company or product, etc.

Fig. 1: RAPP model and its elements

Source: own study based on Rogoziński K. (1998). New service marketing. Poznań: Publishing House of the Poznań University of Economics. [W:] Chłodnicki M. Professional services: the way to a customer is through the product quality, 2004.

Results

Assessment of catering outlets was carried out according to the RAPP concept. The first element to be assessed was 'Product' (fig.2). The offered assortment was well rated by many students because as many as 40% of respondents said it was good or very good. Students declared that the meals were very good in terms of taste and appearance. The next group of the respondents - 32% found the meals to be average. 30% of students declared dissatisfaction with the offered meals describing them as 'bad' or 'very bad'. Although there were fewer dissatisfied students, they made up a significant group of respondents. They said that is was poor quality of the offered products and poor assortment that affected their opinion. Some students said it was necessary to increase the assortment. The respondents indicated that 'although the number of people who refrain from eating animal products has significantly increased, no vegan meals are offered, therefore (…) there are customers who cannot order dishes they would like to choose". Moreover, more 'fit, healthy and dietetic food' was expected, including organic products, two course meals, hot meals, 'better choice of warm dishes' 'new products' which are not fast foods. On the contrary, other students proposed to reduce the number of dishes, claiming that 'it is better to focus on the quality and standardization which can help customers to

identify dishes, thus making it easier for them to make a good choice. Students postulated to improve the product quality and suggested more self-prepared products and less frozen food'.

Fig. 2: 'Product' in catering outlets according to students

Source: own study

The next assessed element was 'Presentation Arena' (fig. 3). Its evaluation involved, among others, the outlet size and localization on premises of universities where the catering services are provided, smell, wall color lighting, equipment, cleanliness, marking, stylization, atmosphere. The outlets/canteens were criticized mostly for the size, as they were found to be too small to accommodate students in the peak hours, and for unpleasant smell associated with poor ventilation in one of the analyzed school. This proves that although earlier studies (Mazurek-Łopacińska, Sobocińska 2013) imply that it is the need to satisfy hunger or thirst as well as a lack of time that motivate students to buy meals in catering outlets situated on premises of their schools, the needs to be met while having a meal are also of post materialistic character. This has also been confirmed by the respondents for whom the possibility of spending a nice time with friends was the reason to use catering services provided by outlets situated within their schools. This motive was indicated by students at the third position (Mazurek-Łopacińska, Sobocińska 2013).

Fig. 3: 'Arena of Presentation' in catering outlets in the opinion of students

Source: own study

Actors/ People were best rated by a great majority of students. The study shows that the employees of most canteens located on premises of universities are polite, nice, laborious, competent and well qualified. Respondents described them positively using the following expressions: 'they always greet students and say good bye. They give advice and provide information on the offered food", 'very polite', 'always polite'. However, the respondents indicated one disadvantage, that is, a longer time of waiting for the order to be taken or too long staying of the personnel in the backroom.

Fig.4: 'Participiens/Actors' of catering outlets in the opinion of the respondents

Source: own study

The next step involved assessment of 'Relationship' between the catering outlet and a student. The questions to be answered were: 'is there a relationship between a service company and a customer?' 'Do students prefer to purchase a catering service at the university or in other bars situated near their schools?' 'Does the outlet use any instruments for development of loyalty of its customers? The respondents' answers were diversified as 36% of students said that the relationship was very good and good and the same number (36%) said it was bad and very bad. It is worth noting that the relationship that is developed between people depends on the attitude of both sides. Despite a positive assessment of the previous marketing element – People, some students had negative feelings caused by a lack of loyalty programs, in creation of which not only the employees but also the outlet owners need to participate.

Fig. 5: 'Relations' in catering outlets in the opinion of students

Source: own study

Students also expressed their opinions on the possibility of introduction of organic food into the menu. A great majority of students - 83% declare that they discern such a necessity which is consistent with a growing interest of consumers in organic food (Szczepanek, Prus, Knapowski 2018, Roman, Roman, Prus 2020). It has been observed that more women than men are interested in a purchase of a catering service prepared from organic products. The observed difference between the share of women and men is not, however, of significant character (the value of consistence test is 3.24 and does not exceed cri $\lambda_{0,05} = 3.841$, $\lambda_{0,01} = 6.635$).

Fig. 6: The need to introduce organic products into catering outlets in the opinion of students
Source: own study

In the second stage of the study, students were asked to provide marketing proposals regarding actions to be taken by university catering outlets in the current situation of pandemic in Poland. It was postulated to introduce, among others, changes to the marketing element 'Relationship' of the RAPP concept. This modifications of 'Relationship' are supposed to deepen the bond of a customer with the company. Students advised the outlets to use social media marketing – 'being in contact with customers, providing information about the offer, or the company actions that are worth promoting" by means of the Internet. Such information placed in social media (e.g. Facebook) can be later made available for students' friends and relatives. This in turn would increase the number of potential customers. It needs to be noted that nowadays to reach a vast number of customers it is necessary to develop a website.

One of the respondents' proposals was also to add information about the canteen/outlet operation to the university website with the possibility of forwarding it to the website of the outlet. Therefore, the survey included additional assessment of 21 WWW websites of Bydgoszcz universities (Akademia Muzyczna im. Feliksa Nowowieskiego w Bydgoszczy, Bydgoska Szkoła Wyższa, Collegium Medicum im. Ludwika Rydygiera w Bydgoszczy Uniwersytetu Mikołaja Kopernika w Toruniu, Kujawsko-Pomorska Szkoła Wyższa w Bydgoszczy, Uniwersytet Kazimierza Wielkiego w Bydgoszczy, Uniwersytet Technologiczno-Przyrodniczy im. Jana i Jędrzeja Śniadeckich w Bydgoszczy, Wyższa Szkoła Bankowa w Bydgoszczy, Wyższa Szkoła Gospodarki w Bydgoszczy, Wyższa Szkoła Informatyki i Umiejętości w Łodzi – Wydział Zamiejscowy w Bydgoszczy, Wyższa Szkoła Nauk o Zdrowiu w Bydgoszczy) and of Kujavian-Pomeranian Voivodship universities (Kolegium Jagiellońskie – Toruńska Szkoła Wyższa, Kujawska Szkoła Wyższa we Włocławku – Wydział Zamiejscowy w Grudziądzu, Kujawska Szkoła Wyższa we Włocławku; Państwowa Uczelnia Zawodowa we Włocławku, Uczelnia Lingistyczno-Technologiczna w Przasnyszu, filia w Świeciu, Uniwersytet Mikołaja Kopernika w Toruniu, Wyższa Szkoła Bankowa w Toruniu, Wyższa Szkoła Demokracji im ks. Jerzego Popiełuszki w Grudziądzu, Wyższa Szkoła Kultury Społecznej i Medialnej w Toruniu, Wyższa Szkoła Przedsiębiorczości im. Księcia Kazimierza Kujawskiego w Inowrocławiu, Wyższa Szkoła Zarządzania Środowiskiem w Tucholi). The question was whether any of the academic centers took up this kind of initiative. The answer is 'none'. Only one non-public school in both branches added a general mention on the subject of vendor machines with snacks and coffee and bistros, where students can eat hot and a tasty meal at a good price (Wyższa Szkoła Bankowa w Bydgoszczy i w Toruniu). Two non-public universities in the region (Kujawsko-Pomorska Szkoła we Włocławku, Wyższa Szkoła Demokraji im. Ks. Jerzego Popiełuszki w Grudziądzu) showed a bar in a film promoting universities (a film available on the university's website). However, only one public school in Bydgoszcz mentioned the dormitory bufet (Akademia Muzyczna im. Feliksa Nowowiejskiego w Bydgoszczy).

Poznan University of Technology is a good example of how to provide online information on the subject of an academic catering outlet (fig. 7). In a tag ‘For students’ including, apart from typical news concerning scholarships, regulations, student exchange, a tag ‘Student life’ including, apart from student organizations, dormitories and assistance for people with disabilities, a tag ‘Canteen’, where one can find information about the canteen localization, prices of meals, subscriptions, opening hours and additional services -catering of conferences, training courses, student balls, take away meals, etc. Most importantly, there is a possibility to forward the menu onto a website of the canteen where students can find a detailed menu for the next days (fig. 8).

University for students recruitment cooperation for staff
Student canteen
Meals are sold from 6.50 to 11PLN. Two course meals are on the offer. Catering of conferences and student balls. Catering of meetings held in any building of the university. We offer a VIP room for organization of meetings, mid-term-parties, or Ph.D defense or habilitation parties. Student canteen is also open during holidays, that is, in July, August and September.

Services offered for hospital staff in the form of hot meals could support development of good relations with this environment. According to students 'a company can improve its image" in this way. Moreover, it was found that 'if the staff is satisfied with the meal they will certainly remember it and recommend the catering services to other people'. In the opinion of the respondents the next step could be sale of meals to go. In fact, the postulate is already being implemented as currently organizations are switching to this form of running a business because of restrictions connected with the coronavirus pandemic.

Conclusions

According to the survey, students are not fully satisfied with the services offered by catering outlets, situated on premises of universities in Bydgoszcz, especially with 'Relations' and 'Arena of Presentation'. The best rated element were 'People'. Moreover, no significant relation between the gender of students and their preferences to introduce organic products into the offer of university canteens was found, which was confirmed by the assumed research hypothesis. Summing up, it needs to be said that the accepted RAPP model proved to be useful in the marketing assessment, it highlighted weaknesses and strengths of catering outlets operating on premises of universities, indicating the direction of changes to be introduced by entrepreneurs in the process of service marketing management. Based on the results obtained in this article, have been identified several future research directions. One of these could be the analysis of marketing, marketing-mix in catering outlets located on premises of universities a comparative manner by including other countries or geographical regions.

Business Agility & Strategic Management. Parametric Strategic Management Concept Meets Agile-Methods II.

Alexander OBYDENOV

Financial University under the Government of the Russian Federation, Moscow, Russia,
alexander.obydenov@gmail.com

Abstract

We are developing an idea that Parametric Strategic Management represents business-agility of organizations very well. Moreover, Agile methods comply with the emergent strategy concept quite isomorphically, and follows it in a consistent manner. Renunciation of strategic planning in management of organizational development happens to a significant degree in that context. At the same time, inasmuch as it remains it takes on new, more flexible forms. The concept of self-organization management? which essentially appears to be Parametric Strategic Management, holds a special place in such trends.. In a case study of a Russian teal supermarket chain «VkusVille», we analyze, how such management can be practically applied. That case, as well as exploring limits and necessary conditions for implementation of managed self-organization, indicate that Parametric management is relevant for business practice.

Keywords: business agility, agile management, parametric strategic management, managed self-organization

Introduction

Same as our previous studies, this article is dedicated to the issues in organization functioning and development, which relate directly to one out of fifteen sections included in the principals of modern scientific research in management (Wankel, 2007).

This time we are discussing not only the correlation between the concept of Parametric Strategic Management, introduced earlier (Obydenov, 2016), and the Agile Management methods that became widespread in the business practice, but also the deep connection between Strategic Management and Agile Management methods as a whole.

It ought to be noted, that the interest in conceptual approach towards Agile has been growing as of late. For instance, one of the Extreme Programming developers and a signatory of the Agile Manifesto Ron Jeffries wonders: what is Agile – is it management or anti-management? If the former, then which type? Ron suggests, that it is more of an anti-tayloristic and pro-dumping management (Jeffries, 2019).

Business agility & Parametric Strategic Management

Drawing parallels between the concept of Parametric Strategic Management and Agile methods, we should mention that both serve as alternatives to the command-and-control method (Rigby, Sutherland, 2016).

Overall, business agility can be perceived as a part of Parametric Strategic Management. It is customary to view business agility as organization's ability to rapidly respond to alterations in market conditions (Felipe, Roldan, Leal-Rodríguez, 2016). Within Parametric Strategic Management we perceive self-organization as a basis for agility. And self-organization is viewed as a freedom to distribute and redistribute resources between various activity areas of an organization. It provides a good opportunity for businesses to adapt to the ever changing

Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

external environment. We may note, that elements of self-organization can be found in any establishment, even in a one-man company – it appears in a form of time division between work and play that the worker selects themself, which is also an element of business agility. "Rapid adaptation to the external environment is obtained through the seemingly chaotic process of receiving various feedbacks" (Grant, 2008). While discussing specific Agile framework, here's an example of how ScrumTrek (a leading consulting company, dedicated to promotion of Agile in Russia) defines Scrum in their report from 2017 (Report, 2017): "Scrum is the most easy-to-understand approach: a concrete set of rules that a self-organizing team should abide by". That is what managed self-organization is, in other words, Parametric Strategic Management via institutions.

Agile Management Methods and emergent strategies

We should note that the first serious inquiry into Agile Management methods was Hirotaki Takeuchi and Ikujiro Nonaki's «The New New Product Development Game» research, published in Harvard Business review in 1986 (Takeuchi, Nonaka, 1986), wherein authors analyzed the experience of using small self-organizing teams for innovative product development in Japanese corporations. Team-oriented product development approach was used in creation of «Xerox», «Honda» auto engines, «Canon» photo cameras, etc. One of the key elements of Agile methods is team self-organization, where a certain dynamic order emerges (Takeuchi, Nonaka, 1986). To avoid chaos, it is necessary to lay out how exactly each team member (and the department behind them) participate in the overall process, and the rules for interaction between all the members involved in the process. Moreover, lots of sources dedicated to Agile point out that instead of positions, roles are used.

To explore correlation between Agile Management methods and Strategic Management concept, we shall look into «Kenevin model», developed by David Snowden (Kurtz, Snowden, 2003). We are looking at a complex domain, where it's not always possible to retrace the inner communication within the organization, especially during it's early development stage. In a complex domain the connection between cause and effect can be mostly revealed in retrospect only, and results are often unpredictable (Konnor, 2018). The essential research technique and hypothesis testing in an organization like that would be by conducting an experiment. However, it is agreed a priori, that the experiment might not result in success. Various experiments may be conducted simultaneously or even contradict each other. While managing these systems one should mange those experiments in such a way, so that failing wouldn't hurt the overall organization, instead of attempting to create a "fool proof" environment within it.

A rather important point we should make for Strategic Management in a complex domain is that we cannot solve that domain's issues just by using cutting-edge practices, such as benchmarking. One's own successful practice is achieved through conducting these "non-destructive experiments", which reveal the weak spots in the organization that lead to failure of those experiments ex post, while highlighting strong points that lead to their success. That way, we obtain emergent procedures and practices, that are often unique in the field of complexity (Bridge). The existence of such practices within the complex domain allows to connect the dots between Agile Management methods and emergent strategies.

Conceptually, the essence of emergent strategies, which appear spontaneously in the course of implementing managerial decisions directed at reaching organizational goals and create a particular pattern of actions, was clarified by G. Mintzberg (Mintzberg, Ghoshal, Quinn, 2002). As it is known, spontaneous (emergent) strategies surface and unravel without any priorly settled planning, and do not follow company's laid out path to success (D. Good, 2018). Emergent strategies must generate permanently, as every company operates in an ever changing environment. It is believed that emergent strategies are resultative, if an organization follows a consistent action pattern (Bovaird, 2008) in unpredictable conditions (F. Neugebauer, F. Figge, T. Hahn, 2016) and have an improvisational quality, that results in creating unforeknown, yet successful products (Brown, 1998). In Stacey's opinion, implementation of self-organizing teams considerably increases the emergent strategies' strength (Stacey, 1992).

From the Parametric Strategic Management (managed self-organization) concept's point of view, certain guidelines must exist for a successful application of an emergent strategy. That strategy may be formed and applied with a simple set of rules (Eisenhardt, Sull, 2001), or strategic principles (Gadish, Gilbert, 2007). That subject is thoroughly explored in (Obydenov, 2018).

Agile Management methods and planning

The topic of planning within Agile Management methods deserves a special mention. It is considered that white-collar planning has become passé, and according to that, an updated idea is offered, of a more flexible planning that

makes requests which Agile Management has to comply with (Fiore, 2018). But planning company's financials is exactly what attracts investors! How does that work within Agile methods?

The solution is applying a hybrid of both agile and planned approaches based on risk analysis (Boehm, Turner, 2004). If the risks are higher for agile approach, then planning is selected. And vice versa.

As we promote the concept of Strategic Management, we are interested in placing it within Agile framework. For example, we offers transition to iterated prediction as part of the strategic planning (Hodgson, 2018), as well as moving from traditional and static planning methods to dynamic and flexible strategy, which adapts to alterations in market conditions, as a part of corporate strategic planning. That way, a "self-learning organization" is formed, based on a "review-and-adapt" feedback loop for a constantly developing and improving corporate strategy. As is the case with traditional strategic planning, the attention is directed to achieving balance between the vision of business and business results. The main difference, however, is that instead of wasting months on forming and finalizing plans, the company's management rather decides on HOW to plan (Leyborn, 2016).

Managed self-organization

Managed self-organization – that is what essentially both Parametric Strategic Management and Agile Management methods are. That unites them, among other things. We shall recall, that by self-organization within Parametric Strategic Management we mean title-for-title, resource, authority and responsibility exchange between different stakeholders, and the practice itself is carried through the selected managerial criteria – rules of the game.

Managed self-organization behind the Agile manifesto in particular, may be seen as an intention to discover a middle way between order and chaos (Appelo, 2010). Limit setting is of great importance in Management 3.0. Appelo concludes though, that sole self-organization is not enough, that it could and should be directed as well. In order to do that, we have to define certain boundaries, terms and rules. Manager's goal is to fine tune such settings, as: considering diverse competence of different team members, uninterrupted data exchange between employees and unobstructed communication between teams (Appelo, 2010).

Bill McKelvey states, that Jack Welch ran General Electric through simple directives (e.g. "Place at least first or second in your segment", "Simplicity... Self-esteem", "Ensure quality by using model 6Sigma", etc.) combined with powerful call-to-actions, deriving from the heritage of complex thinking (McKelvey,2001).

Glen Alleman points at the difference between ability to self-organize and ability to direct one's growth (Alleman, 2008). In accordance with that, self-organizing and self-directing teams are distinguished in Agile. By self-directing teams we mean those that select and define their own goals.

By setting boundaries and introducing regulations, managers affect the pattern of results that the self-organizing team produces (Lewin, Regine, 2001). In biology it is called «managed evolution» (Kelly, 1994). We can find mentions of evolving organizations in Robertson book as well (Robertson, 2015). Appelo distinguishes three main functions of a manager, which they should apply while setting limits within an organization: 1) system enhancement, 2) system protection, and 3) system direction (Appelo, 2010). In order to manage a group we must: put it together, set limits and goals for each member of it, and observe.

Appelo admits, which is fully compliant with our Parametric Strategic Management approach, that we should set an overall goal and limits to direct self-organization towards an attractor (an organization state with a ready-to-use product may be considered as such). That being said, we may destabilize the situation using external factors and change system's settings in order to switch between attractors (Appelo, 2010).

If we regard holacracy as a subset of agile management methods, we may mention that Chief Representative of David Allen Company in Russia states the following: "In holacracy, rules are given the authority to distribute responsibilities in such a way, that people can become leaders within their assigned roles" [Inshakov, 2018, p. 5]. Peter Drucker pointed out that "Culture eats strategy for breakfast", meaning that the company can execute it's long-term agenda only if it is consonant with the inner culture of an organization, which basically presents as a playbook of informal rules. So everything that contradicts the organizational culture is not being implemented. More than 500 companies introduced holacracy, Zappos and David Allen Company being among the most notable.
According to Robertson (Robertson, 2007), the founder of holacracy, it is not a mere theory, but praxis forged by trial and error. Holacracy includes following elements:

- The Constitution, that defines rules and redistributes competence territories;

- A new approach to organization structuring and role assignment, with regard to people's competencies;
- A unique process of decision-making while updating and reassigning roles and competencies;
- Holding meetings that are aimed at team activity synchronization and collaboration to obtain results.

All that points to the fact that holacracy also represents a managed self-organization, which stands behind the "rules of the game" of Parametric Strategic Management, where coordination is an essential component.

Case Study. Managed self-organization within «VkusVill» brand

Let's take a look at a case of managed self-organization in the «VkusVill» supermarket chain (Shepin, 2019). They are using a system of individual contributor commitments, which essentially present a system of guidelines, around 120 commitments overall. As the result of that approach, corporate management takes up just 1,5% of the revenue, which is considerably less than hierarchic management. Let's find out how that works.

One of the biggest advantages of Agile methods over hierarchy is employee's local knowledge. Why not simply hand out tasks to employees and just supervise? In «VkusVill» the person who knows best, whether one or the other goal is achievable and how resource-consuming it is, is the person who is carrying out the task. Completion of each commitment becomes employee's sole responsibility.

In comparison, as hierarchic organizations continue to grow and evolve they add extra layers of authority. For instance, at the fixed manageability rate (maximum possible number of subordinates for one executive director) of three people, the firm that consists of 4 people (including the CEO) has two-leveled hierarchy, firm of 5-13 colleagues – three levels, 14-41 members – four levels, 42-122 employees – five levels, etc. (Grant, 2008). If the hierarchy is of a bureaucratical sort and wields central authority, the growth of such company implies a constant increase in managing staff, relative to the number of subordinates; slower decision-making and accumulative loss of control (Williamson, 1967). That's why such corporate giants as Unilever, British Petroleum and General Electric carried through some organizational adjustments that included: reduction of hierarchy levels, decentralized decision-making, decrease in HQ staff. The main focus shifted from vertical communication to horizontal, from supervision and control to personal accountability (Whittington, Pettigrew, 1999).

But let's get back to our case, and take a look past the boundaries of commitments. «VkusVill» employees are presented with a variety of choices:

(1) There is no, nor there ever has been any form of dress code. Staff is free to clothe however they see fit.
(2) There is no penalty system in place.
(3) There is no "9 to 5" schedule. Strict timetable and attendance are not as vital as most employers think. As practice shows, employees with flexible hours work much more than those with fixed hours.
(4) There is no budget. Each employee may spend as much as suffices, but all the expenditures are transparent and become immediately known in the company. So the employee must at all times be ready to explain to his superiors, where did the money go and what have those expenses brought to the table.
(5) There is no HR in «VkusVill». Staff recruitment and selection may be done by managers or via head hunting agency. Moreover, applicant's competence and potential are not being evaluated. A "decent human being" is what they company is looking for, while the "time will show" theirs potential. That approach forms a team of likeminded people and intra-team culture, although the responsibility for the rookie is taken by the staff member, who employed them. That fact somewhat contradicts the hypothesis within the concept of Parametric Strategic Management, that only motivated and professional employees may work inside a managed self-organization.
(6) There is no planning in «VkusVill». At it's inception, strategic sessions were held every year, where the agenda was laid out for the next 12 months. But the experience has shown, that those projects haven't always been fulfilled, and other emerged that nobody planned or thought of.

To sum that up, «VkusVill» is a successful example of implementation of a managed self-organization in Russian business, in a possible form of Parametric Strategic Management. We can clearly see the following elements of that executive system:

(1) self-organization (employees' ability to assign their own tasks and explore ways of redistributing resources between those; ability to choose their own working hours by dividing time between work and play; ability to evaluate financial resources for the completion of tasks-at-hand).
(2) rules of the game that regulate self-organization.
(3) freedom from planning and finding other forms of management to replace it.

Limits to applicability of Parametric Strategic Management

In an attempt to summarize the presented analysis of correlation between Agile Management methods and Strategic Management, and the specific case study above, an interesting question arises – which type of organizations would benefit from implementing Parametric Strategic Management. As that approach substantiates self-organization in various ways, it would be appropriate to consider research work in the field of holacracy. As recent study shows [Velinov, Cassilev, Denisov, 2018], holacracy is mostly used in consulting and education (42%), followed by IT and digital marketing (27%). In more than 80% of the cases holacracy is used in small to medium enterprises (up to 250 employees), 23% of microcompanies (1-10 employees) and 45% of small companies (11-50 employees).

Holacracy implementation examples – Zappos company, Russian company Knopka /russian for «button»/ (Velinov, Cassilev, Denisov, 2018). At the time of the 2018 research, companies that use holacracy were mostly established in year 2004. On average, holacracy is introduced after 3,5 years, which is mostly due to the recent uprise in the application of holacracy.

When we talk about limits to applicability of Agile Management methods, the biggest obstacle would be the type of corporate culture that rejects core values of Agile (State of Agile, 2016; 2018). That issue is most notable in bigger companies.

The Parametric Strategic Management concept has a systemic and economic justification, which lays the foundation for a thorough study of necessary conditions for effective operation and of certain boundaries that help achieve successful implementation of Agile methods in business practice. We should note that it is considered that "there is no scientific proof as of now, that self-managing (read «managed self-organization» - A.O.) affects business profitability" (Fukolova, 2019).

Conclusion

While exploring correlation between Parametric Strategic Management and Agile Management methods, we reached a common level of reference between Strategic Management and Agile Management methods as a whole. Particularly in the area of emergent strategies and strategic planning, which are of great importance for a company's evolvement and attraction of investors.

We studied a case of a Russian supermarket chain «VkusVill», positioning itself as a teal level organization, and revealed certain elements of a managed self-organization which are compliant with the concept of Parametric Strategic Management.

The Parametric Strategic Management concept has a systemic and economic justification, which allows us to apply Agile Management methods more consciously: using conceptual analytical models and considering the necessary conditions for an effective introduction of Agile methods.

Management of Contagion Risk in a Carpooling System

Abstract

Carpooling as a means of reducing travel costs is a popular mode of transportation. Typically, passengers choose drivers based on a variety of factors, such as travel cost, travel time, comfort, and safety. In this paper, we explore the possibility of adding contagion risk as a key factor in the decision-making process. We consider a global coordinating system that provides passenger assignments and driver routes to a set of participating carpoolers..

Keywords: Transportation Management, Carpooling, Contagion Risk, Multicriteria Optimization.

Introduction

In essence, carpooling is a way of organizing transportation in such a way so that a group of participating carpoolers: drivers and passengers, can share resources -- cars -- in a way that optimizes a variety of criteria, such as travel cost, travel time, comfort and safety (Jamal et al. 2016). This requires solving at least two interconnected problems: passenger to driver assignment and vehicle routing, all the while satisfying constraints and preferences of participating stakeholders (Petrillo et al. 2017).

Multiple criteria can be considered jointly, which leads to multi-objective optimization problems (Filcek et al. 2017) that are especially difficult to solve as they often require interactions with the stakeholders to guide the solution towards an acceptable optimum in the Pareto sense (Żak et al. 2019). Transportation in a pandemic situation has suffered significant losses overall with passengers losing trust in public transportation. In consequence, many approaches to revitalize the transportation sector by making it safer have been made (Chen et al. 2020; Tan and Ma 2020; Tirachini and Cats 2020). Consequently, under the ongoing risk of contagion, further precautions have to be put in place to ensure that carpooling remains a safe method of organizing transportation. This results in new models and new decision-making algorithms.

In this paper, we propose a model for solving the carpooling problem, i.e. passenger to driver assignment and vehicle routing in a way that minimizes the total risk of contagion while keeping travel cost at reasonable levels. We introduce a multicriteria optimization problem where contagion risk is defined by several criteria. We propose to aggregate the criteria which results in a problem that can then be solved with the use of standard optimization methods such as genetic algorithms.

Carpooling model

We consider a map given by a graph $\mathbf{G} =< \mathbf{V}, \mathbf{E} >$, where $\mathbf{V} = \{1, 2, \ldots, V\}$ is the set of (indexes of) nodes and $\mathbf{E} = \{1, 2, \ldots, E\}$ is the set of (indexes of) arcs. We denote the set of (indexes of) drivers as $\mathbf{D} = \{1, 2, \ldots, D\}$ and an extended set $\tilde{\mathbf{D}} = \mathbf{D} \cup \{0\}$ (driver with index 0 is an artificial driver, to which passengers who do not carpool are assigned) and the set of (indexes of) passengers as $\mathbf{P} = \{1+D, 2+D, \ldots, P+D\}$. The set of all carpoolers (without the artificial driver) is $\mathbf{C} = \mathbf{P} \cup \mathbf{D}$ and an extended set is $\tilde{\mathbf{C}} = \mathbf{C} \cup \{0\}$. For each carpooler, we have a set of rides $\mathbf{R}_c = \{1, 2, \ldots, R_c\}$ to be performed over a period of time. For each ride $r \in \mathbf{R}_c$ we have an origin node $org_c^r \in \mathbf{V}$ and a destination node $dst_c^r \in \mathbf{V}$. In fact, we assume that $\mathbf{V}$ consists only of those nodes. We also assume that those nodes are unique for each carpooler and that each carpooler has to depart from his/her origin in time period $[\underline{s}_{c,r}, \overline{s}_{c,r}]$

Cite this Article as: Grzegorz FILCEK and Maciej HOJDA "Management of Contagion Risk in a Carpooling System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and arrive at the destination in time period $[\underline{t}_{c,r}, \overline{t}_{c,r}]$. Travel cost between nodes (i, j) for driver d is denoted as $q_{i,j}^{d} \geq 0$ and minimal travel times are denoted as $e_{i,j} \geq 0$. We also assume that pick-up and drop-off times are included in $e_{i,j}$. Effective car capacity is denoted as $a_d \in \{1, 2, 3, \ldots\}$.

Historical data about the number of recently underwent joint travels between two carpoolers c_1, c_2 is given by $\alpha_{c_1,c_2} \in \{0, 1, \ldots\}$. The aggregated risk that the carpooler c poses by participating in the carpooling process is given as $\beta_c \in [0,1]$. The aggregated risk that other carpoolers pose a threat to carpooler c is given by $\gamma_c \in [0,1]$. Aggregation can be done over multiple internal parameters of the carpooler, including the time since the last vaccination or the time since the last infection, as well as general resilience. In a realistic situation, some or all of the data might be unavailable, in which case the best guess based on statistical data has to be made. The risk of being infected could be estimated based on an assessment test composed of questions provided by WHO (World Health Organization), e.g. a test implemented in a mobile application "STOP COVID - ProteGO Safe" (STOP COVID 2020) or a BMA document (BMA 2020). We consider several safety-based criteria that describe the (negative) impact of carpooling on the spread of the disease. Passengers who choose not to participate in carpooling, are expected to use alternative transportation methods cost of which is $ATC_p^r \geq 0$ for passenger p in ride r.

We define the following type of variables $y_{p,r_1}^{d,r_2} \in \{0,1\}$ which is the assignment of passenger p in his/her ride r_1 to driver d in this driver's ride r_2 ($=1$ if assigned). The second type of variables is the route of the carpooler $x_{c,r}^{v_1,v_2} \in \{0,1\}$ which defines if carpooler c in ride r moves directly from node v_1 to node v_2 ($=1$ if so). For each carpooler c and ride $r \in \mathbf{R}_c$, we denote as $\underline{\tau}_{c,r}^{v}$ the arrival time in node v and as $\overline{\tau}_{c,r}^{v}$ the departure time from that node.

Carpooling Constraints

What follows is a brief description of constraints of the decision making problem. Constraint (1) ensures that for each carpooler c and their ride r, origin and destination nodes are on the route (and in correct place) and that the route is not disjoint. Constraint (2) guarantees that there are no subcycles. Then we use (3) to ensure that each passenger p and their ride r are assigned to exactly one driver. Following constraint (4) makes it certain that passengers assigned to drivers share portions of the same route. Number of passengers travelling in car at the same time is kept valid by constraint (5). Arrival $\underline{\tau}_{c,r}^{v}$ and departure $\overline{\tau}_{c,r}^{v}$ times need to fit into time windows which is ensured in (6).

$$\sum_{v \in \mathbf{V}} x_{c,r}^{v,w} - \sum_{v \in \mathbf{V}} x_{c,r}^{w,v} = \begin{cases} 0 & w \neq org_c^r \wedge w \neq dst_c^r \\ 1 & w = dst_c^r \\ -1 & w = org_c^r \end{cases}, c \in \mathbf{C}, r \in \mathbf{R}_c, w \in \mathbf{V}. \tag{1}$$

$$\sum_{v \in S} \sum_{w \in S} x_{c,r}^{v,w} \leq |S| - 1, c \in C, r \in R_c, S \in V, S \neq \emptyset, S \neq V \tag{2}$$

$$\sum_{d \in \mathbf{D}} \sum_{r_2 \in \mathbf{R}_d} y_{p,r_1}^{d,r_2} = 1, \ p \in \mathbf{P}, r_1 \in \mathbf{R}_p. \tag{3}$$

$$x_{d,r_2}^{w,v} \geq y_{p,r_1}^{d,r_2} x_{p,r_1}^{w,v}, \ p \in \mathbf{P}, r_1 \in \mathbf{R}_p, d \in \mathbf{D}, r_2 \in \mathbf{R}_d, v \in \mathbf{V}, w \in \mathbf{V}. \tag{4}$$

$$pn_{d,r}^{v} \leq a_d, \ d \in \mathbf{D}, r \in \mathbf{R}_d, v \in \mathbf{V}. \tag{5}$$

$$\begin{gathered} \overline{\tau}_{c,r}^{org_c^r} \in [\underline{s}_{c,r}, \overline{s}_{c,r}], \ \underline{\tau}_{c,r}^{dst_c^r} \in [\underline{t}_{c,r}, \overline{t}_{c,r}], \ \underline{\tau}_{c,r}^{v} \leq \overline{\tau}_{c,r}^{v}, \ \underline{\tau}_{c,r}^{w} - \overline{\tau}_{c,r}^{v} \geq x_{c,r}^{v,w} e_{v,w}, c \in \mathbf{C}, r \in \mathbf{R}_c, v \in \mathbf{V}, w \in \mathbf{V}, \\ y_{p,r_2}^{d,r_1} \overline{\tau}_{d,r_1}^{org_p^{r_2}} \in [y_{p,r_2}^{d,r_1} \underline{s}_{p,r_2}, y_{p,r_2}^{d,r_1} \overline{s}_{p,r_2}], \ y_{p,r_2}^{d,r_1} \underline{\tau}_{d,r_1}^{dst_p^{r_2}} \in [y_{p,r_2}^{d,r_1} \underline{t}_{p,r_2}, y_{p,r_2}^{d,r_1} \overline{t}_{p,r_2}], d \in \mathbf{D}, r_1 \in \mathbf{R}_d, p \in \mathbf{P}, r_2 \in \mathbf{R}_p, \end{gathered} \tag{6}$$

The number of passengers $pn_{d,r}^{v}$ in each node v of a route for driver d and ride r, which is used in (5) can be calculated the following way

$$pn_{d,r}^{org_d^r} = 0,\ \ pn_{d,r_2}^{v} = \sum_{w\in\mathbf{V}} x_{d,r_2}^{w,v}\, pn_{d,r_2}^{w} + \sum_{p\in\mathbf{P}}\sum_{r_1\in\mathbf{R}_p} y_{p,r_1}^{d,r_2} x_{p,r_1}^{org_c^r,v} - \sum_{p\in\mathbf{P}}\sum_{r_1\in\mathbf{R}_p} y_{p,r_1}^{d,r_2} x_{p,r_1}^{dst_c^r,v} \tag{7}$$

Travel cost for a carpooler c in ride r and then for and for the passenger p in ride r are given next

$$tc_{d,r}^{org_d^r} = 0,\ \ tc_{d,r}^{v} = \sum_{w\in\mathbf{V}} x_{d,r}^{w,v}(tc_{d,r}^{w} + q_{w,v}^{d}),\ \ d\in\mathbf{D},\ r\in\mathbf{R}_d,\ v\in\mathbf{V}, \tag{8}$$

$$tc_{p,r}^{org_p^r} = 0,\ tc_{p,r}^{v} = y_{p,r}^{0,1} ATC_p^r + (1-y_{p,r}^{0,1})\sum_{w\in\mathbf{V}} x_{p,r}^{w,v}(tc_{p,r}^{w} + \sum_{d\in\mathbf{D}}\sum_{r_1\in\mathbf{R_d}} \frac{y_{p,r}^{d,r_1} q_{w,v}^{d} P_d}{(1+pn_{d,r_1}^{w})}),\ p\in\mathbf{P},\ r\in\mathbf{R}_p,\ v\in\mathbf{V}, \tag{9}$$

under the assumption that the passengers and the driver in route split costs over each route fragment. The coefficient P_d expresses how is the cost split between driver d and their passengers (typically, $P_d \geq 1$). Then total travel cost for a carpooler c in ride r is equal to $tc_{c,r}^{dst_d^r}$. By splitting costs, driver d in raid r gains $((P_d-1)pn_{d,r}^{v}-1)/(pn_{d,r}^{v}+1)$ of the route cost from node v to the following node, so the income $ti_{d,r}$ from carpooling for driver d in raid r is as follows:

$$ti_{d,r} = \sum_{v\in V}\sum_{w\in V} x_{d,r}^{v,w} q_{v,w}^{d}((P_d-1)pn_{d,r}^{v}-1)/(pn_{d,r}^{v}+1),\ \ d\in\mathbf{D},\ r\in\mathbf{R}_d. \tag{10}$$

We assume, that the drivers expect, for their participation in the carpooling process, a payout, or at least a reduction in costs. The minimal benefit of $mb_{d,r}$ has to be met

$$ti_{d,r} - (tc_{d,r}^{dst_d^r} - q_{org_d^r,dst_d^r}^{d}) \geq mb_{d,r} \max_{p\in\mathbf{P}} \max_{r_1\in\mathbf{R}_p} y_{p,r_1}^{d,r}, d\in\mathbf{D},\ r\in\mathbf{R}_d. \tag{11}$$

Safety Criteria

For carpooler c, the risk of contamination consists of many factors. We represent them as different decision making criteria. The first one is the the average susceptibility to contamination based on the number of common travels with different carpoolers (12). Second is the average utilization of car capacity by passengers traveling jointly together per car (13). What follows is the average utilization of the drivers' travel times by average number of passengers while carpooling (14). Finally we have part of passengers' rides that were not assigned to any driver (15).

$$SF_1 = \sum_{c_1\in\mathbf{C}}\sum_{c_2\in\mathbf{C},\ \{c_1\}} \beta_{c_1}\gamma_{c_2}(\theta_{c_1,c_2}) / (\sum_{c_1\in\mathbf{C}}\sum_{c_2\in\mathbf{C},\ \{c_1\}} \alpha_{c_1,c_2} + \sum_{c\in\mathbf{C}_c} R_c), \tag{12}$$

$$SF_2 = \frac{1}{D}\sum_{d\in\mathbf{D}}\sum_{r\in\mathbf{R}_d}\sum_{v\in\mathbf{V}}((pn_{d,r}^{v}+1) / \sum_{w_1\in\mathbf{V}}\sum_{w_2\in\mathbf{V}}(a_d+1)x_{d,r}^{w_1,w_2}). \tag{13}$$

$$SF_3 = \sum_{d\in\mathbf{D}}\sum_{r\in\mathbf{R}_d}\sum_{v\in\mathbf{V}} pn_{d,r}^{v}((\overline{\tau}_{d,r}^{v} - \underline{\tau}_{d,r}^{v}) + \sum_{w\in\mathbf{V}} x_{d,r}^{v,w}(\underline{\tau}_{d,r}^{w} - \overline{\tau}_{d,r}^{v})) / \sum_{d\in\mathbf{D}}\sum_{r\in\mathbf{R}_d}((\overline{\tau}_{d,r}^{dst_d^r} - \underline{\tau}_{d,r}^{org_d^r}) \max_{v\in\mathbf{V}} pn_{d,r}^{v}). \tag{14}$$

$$SF_4 = \sum_{p\in\mathbf{P}}\sum_{r\in\mathbf{R}_p} \lambda_p y_{p,r}^{0,1} / \sum_{c\in\mathbf{P}} R_c. \tag{15}$$

Used in (12), the indicator θ_{c_1,c_2} of at least one common route between two carpoolers is calculated as follows

$$\theta_{c_1,c_2} = \max\{\min\{1,\alpha_{c_1,c_2}\},\{\max_{r_1\in\mathbf{R}_{c_1},r_2\in\mathbf{R}_{c_2},v\in\mathbf{V},w\in\mathbf{V}} x_{c_1,r_1}^{v,w} x_{c_2,r_2}^{v,w}\}\}, \tag{16}$$

Optimization problem

Anti-Contagion Carpooling Problem (ACCP)

$$\min[SF_1, SF_2, SF_3, SF_4] \tag{17}$$

under constraints (1)-(11).

This multi-criteria optimization problem can be solved using dedicated algorithms for multi-criteria optimization such as NSGA-II (Deb et al. 2002) in order to generate a Pareto front. However, to avoid the need for a separate decision-maker required for selecting a final solution from the Pareto front, we propose a different approach. The idea is to aggregate the quality criteria within a weighted sum and minimize the distance to the ideal point, which is $\overline{0}$. In conclusion, the goal is as follows

$$\min \sum_{i=1}^{4} (sw_i SF_i)^2 \tag{18}$$

under constraints (1)-(11), where sw_i are coefficients expressing the relative importance of each SF_i.

Conclusion and Further Works

In this paper, we present a way of modeling a multicriteria carpooling problem with an aggregated quality coefficient based on passenger safety in a pandemic environment. Minimizing this coefficient can serve to manage the global risk of contagion between participating carpoolers. This model can be used to represent realistic carpooling situations where the safety of drivers and passengers is paramount.

Further works should aim at evaluating the efficiency of standard methods of artificial intelligence, such as evolutionary or genetic algorithms. Another goal is to introduce more risk-related criteria and constraints, to better reflect the contagion risk.

Resumen

El objetivo del estudio fue realizar una revisión sistemática de la literatura sobre Ingeniería de Requisitos durante los últimos 10 años (2009-2019). La Ingeniería de Requisitos se ha convertido en un área de gran interés para los investigadores de software, pero su crecimiento ha llevado al desarrollo de diferentes enfoques y nuevos campos de estudio dentro del área. Esta investigación es de tipo exploratorio, con un enfoque cuantitativo a través de la teoría del enfoque metaanalítico consolidado. Se realizó una revisión sistemática de la literatura en las bases de datos Web of Science y Scopus. Se encontraron 2418 trabajos en WoS, 8168 en SCO. Como resultados se presentaron los autores más relevantes, los enfoques más importantes, los principales frentes de investigación en el área. Se encontró que las bases de datos investigadas están alineadas y ven como posibles frentes la validación empírica de requisitos, diseño del sistema, contexto del sistema, requisitos específicos de seguridad, actualizaciones y nuevas versiones de software y categorización en el sistema.

Palabra clave: Ingeniería de requisitos, revisión de literatura, nuevos campos.

Introducción

A medida que se desarrolla un área existe la necesidad de crear subáreas (Khurum Gorschek & Wilson, 2013; Jarke et. al., 2011; Avital & Te'Enin, 2009) como ocurrió con la Ingeniería de Requisitos, que nació de la Ingeniería de Software. Este estudio tiene como problema de investigación señalar ¿qué posibles frentes de investigación pueden ser campos dentro del área en el futuro? Para dar respuesta a este problema es necesario consolidar los hallazgos hasta el momento y observar los estudios que se destacan. Para ello se utilizaron análisis bibliométricos y de cocitación, que muestran los enfoques más importantes y el acoplamiento, que vislumbra posibles frentes de investigación (Mariano, & Rocha, 2017). Así, el objetivo de este estudio es consolidar las principales aportaciones de la literatura científica de los últimos 10 años, en el área de la Ingeniería de Requisitos.

Metodología

La investigación es exploratoria, con enfoque cuantitativo y cualitativo, a través de la Teoría del Enfoque Metaanalítico Consolidado - TEMAC de Mariano e Rocha (2017), con tres etapas. Los pasos están disponibles en la plataforma www.pesquisatemac.com, a través de lecciones en video gratuitas. Se eligieron las bases de datos Web of Science y Scopus porque son dos bases de datos que ofrecen resultados de investigación de calidad. Los resultados se analizaron con la ayuda de Microsoft Excel y Vosviewer.

Revisión de la literatura y resultados

Preparación de la investigación

La búsqueda, en las bases elegidas, se realizó con las palabras clave "Ingeniería de Requisitos" y "software". Se encontraron 2.134 registros WoS, 8.778 registros SCO. Se aplicaron dos filtros, uno de los últimos 10 años (2009-2019) y otro de tipo de documento = artículo, y los resultados finales fueron 407 artículos de WoS y 851 SCO.

Presentación e interrelación de datos

El artículo más antiguo de WoS se refiere a Jureta et al. (2009) [5] y se considera un artículo fundamental, donde los autores establecen una ontología central para formular el problema de requisitos. El artículo más antiguo de SCO es de Patel & Ramachandran (2009), que establece una metodología de mejora basada en tarjetas (SMM-Story Maturity Model), en entornos ágiles de desarrollo de software. El artículo de WOS más citado fue “A survey of traceability in requirements engineering and model-driven development” de Winkler & von Pilgrim (2010), con 91 citas, donde los autores abordan la trazabilidad, avances en obras, eventos y los autores concluyen que el tema seguirá ganando importancia. El artículo más citado de SCO es “Wireless network cloud: Architecture and system requirements”, de Lin et. al. (2010), con 148 citas. Los autores abordan las generaciones de redes de comunicaciones móviles y la necesidad de utilizar requisitos para evaluar los desafíos de las cambiantes generaciones inalámbricas.

El autor que más publicó en WoS fue Gorschek, T, con 17 publicaciones, y sus artículos más importantes son “A method for evaluating rigor and industrial relevance of technology evaluations” (Ivarsson & Gorschek, 2011), con 76 citas que aborda un método para evaluar la aplicabilidad , rigor y relevancia industrial y “The software value map - an exhaustive collection of value aspects for the development of software intensive products” (Khurum Gorschek & Wilson, 2013), con 22 citas, donde el autor presenta un estudio de mapa de valor para el software. El estudio más citado por el autor reveló que la mayoría de las investigaciones necesitan validación, ya que el segundo estudio encontró beneficios sustanciales en la adopción del mapa de valores. En SCO se repite el mismo autor (Gorschek, T) como el que más publicó, pero el primero El estudio más citado aquí es " Handshaking with implementation proposals: Negotiating requirements understanding" (Fricker, Gorschek, Byman, & Schmidle, 2010), con 46 citas, que explica las buenas prácticas de especificación de requisitos, como Handshaking, a Técnica eficiente y flexible para entender los requerimientos, tomar decisiones de implementación creando valor y favoreciendo la estabilidad del proyecto.

En WoS, las revistas que más publicaron fueron Requirements Engineering (56), Journal of Systems and Software (36) e Information and Software Technology (34), mientras que en SCO se repiten los dos primeros lugares con (78) y (48) respectivamente y software IEE con 44 publicaciones.

Finalmente, se extrajeron las palabras clave WoS y SCO y se creó una nube de palabras utilizando el software Tagcrow.

Fig 1. Web of Science Word Cloud

Fig 2. Scopus Word Cloud

Modelo Integrador Y Validación De Evidencias

Se crearon mapas de calor de co-citación y acoplamiento con el fin de encontrar los principales enfoques y los frentes de investigación.

Fig 3. Mapa de Calor de cocitación *Web of Science*.

Fig 4. Mapa de Calor de cocitación *Scopus*.

En un primer Cluster se encuentran los trabajos de Karlsson, Gorschek, Sommerville y Wiegers, donde los autores tienen una preocupación concreta por clasificar, organizar y presentar soluciones en la Taxonomía de Requisitos. En el Clúster de la izquierda, el autor Cao, I, en su trabajo, explica 16 casos a través de 7 prácticas de desarrollo de software vía metodología ágil en Ingeniería de Requisitos En el Núcleo Wohlin y Cheng, los autores se preocupan por el futuro investigación sobre requisitos y enfoques prometedores en el área. Nuseibeh, por otro lado, dibuja una hoja de ruta para la Ingeniería de Requisitos. El siguiente grupo, formado por Pohi, K. y Van, L. y Variabilidad de requisitos y trazabilidad. Finalmente, en el último Clúster a continuación, se encuentran los trabajos de Yu Esk, Dardenne A y Bresciane B, que explican la importancia de los requisitos y cómo su uso ha ido creciendo para varios usos, incluida la interrelación con los objetivos organizacionales.

Se puede observar que el mapa de calor en SCO es muy similar al anterior, y que se repiten muchos Clusters. Atención especial a Ramesh y Jarke, quienes ratifican la trazabilidad de requisitos como un enfoque importante. Después de los mapas de co-citación de WoS y SCO, se realizaron mapas de acoplamiento con el fin de encontrar los principales frentes de investigación.

Fig 5. Mapa de Calor de Acoplamiento Web of Science.

Figura 6. Mapa de Calor de Acoplamiento Scopus.

Se puede ver tres grandes núcleos rojos. El primero con Daneva, et al, (2014), Cox (2009), Jarke, et al (2011), Ramesh, et al (2010), Ivarsson y Gorschek (2011) y Winkler y Pilgrim (2010), donde los autores abordan el crecimiento de la Ingeniería de Requisitos y la necesidad de un uso más cuidadoso de las teorías en la investigación empírica, así como un mayor número de encuentros, adicionalmente, los estudios reclaman una mayor validez en los estudios, especialmente en lo que se refiere a su adherencia a la realidad del software. El segundo núcleo principal son Jureta et al (2009) y Avital y Dov (2009) señalan una preocupación por los diseños de los sistemas de información, así como por los nuevos enfoques de la ontología de requisitos. El tercer núcleo de Ali et al (2010) y Elahi et al. (2010) abordan la necesidad de observar el contexto en el que se inserta el sistema, además de las posibles vulnerabilidades que ocasionan problemas de seguridad, que pueden evitarse con una buena elicitación. Adicionalmente, Salini y Kanmani (2012), se enfocan en la seguridad, con su estudio de requisitos para este propósito.

Asnar et al (2011) en un núcleo cercano, más claro al lado adopta el discurso de la vulnerabilidad a través de la gestión de riesgos. Finalmente, los dos núcleos adicionales con Durillo, et al (2010) y Xuan, et al (2005) explican el problema relacionado con las próximas versiones de software y los problemas involucrados en las actualizaciones, mientras que Maalej, et al. (2015), aborda el tema de la clasificación automática de comentarios. En el segundo mapa de calor realizado en *Scopus* (figura 6) para encontrar los frentes de investigación, se encontraron los mismos núcleos de *Web of Science*, con pocas diferencias.

Los frentes de investigación encontrados que pueden ser en el futuro campos dentro del área son: validación empírica de requisitos, diseño del sistema, contexto del sistema, requisitos específicos de seguridad, actualizaciones y nuevas versiones de software y categorización en el sistema.

Conclusiones

El objetivo de este estudio se logró al presentar las principales aportaciones de la literatura científica de los últimos 10 años, en el área de Ingeniería de Requisitos en la Web of Science y Scopus. Para trabajos futuros, se espera validar con profesionales la fortaleza de los principales frentes para convertirse en nuevos campos.

Resumen

Esta investigación tiene como objetivo identificar qué dimensiones entre "calidad del sistema", "calidad de la información", "calidad del servicio" y "utilidad percibida" tienen más impactos en la satisfacción del usuario en el uso de sistemas de información académica en entornos virtuales. Los resultados identificaron que la satisfacción general del usuario se explicó en 72,2%, siendo la calidad del sistema responsable de explicar 32,30% y Utilidad Percibida en 30,93%, considerando las dos variables significativas en este modelo. El tamaño del efecto de la calidad del sistema y la utilidad percibida fue moderado.

Palabras clave: Sistema de información académico, Satisfacción del usuario, Brasil.

Introducción

En el contexto de las Instituciones de Educación Superior (IES), la necesidad de sistemas que satisfagan las necesidades de los usuarios es una constante. Estas instituciones están equipadas con una gran base de datos, que va desde la información de registro de los estudiantes hasta el acceso a información, como la reserva de libros, el estado de inscripción regular y el rendimiento de los estudiantes, entre otros. Así, las IES han buscado innovar y mejorar la gestión de estos datos para facilitar el acceso al más diverso espectro de información por parte de estudiantes y colaboradores (Reis, Pitassi & Bouzada).

Varias investigaciones nacionales e internacionales ya han estudiado este contexto, tales como: Faria-Duarte, Costa-Vieira & Magalhães da Silva (2016), Gaspar, Donaire, dos Santos & Silva (2009), Novo-Corti, Varela-Candamio & Ramil-Díaz (2013), Ainin, Bahri & Ahmad (2012), Chang (2013) e Harrati, Bouchrika, Tari,& Ladjailia (2016), entre otras. Analizaron la satisfacción del usuario, los factores que fomentan el uso continuado de los sistemas, la eficacia del e-learning y las dimensiones que impactan en la satisfacción del usuario. Considerando que este es un contexto que tiene una evolución continúa y considerando la constante evolución tecnológica, siempre es necesario investigar este entorno, buscando desarrollar los productos y servicios virtuales que ofrecen las IES a sus estudiantes y colaboradores. ¿Así el problema que guía esta investigación es cuál los factores que influyen en la calidad global de los sistemas de información académica?

Cite this Article as: Patricio E. RAMIREZ-CORREA, Ari MELO-MARIANO, Eduardo KEMPER DA SILVA, Eduardo N. OLIVEIRA SENA, Giovanna P. SOUZA MALNATI, João Pedro FRANCO SAMPAIO and Matheus BRITO FECHINE ROCHA "Factores Que Influyen En El Uso De Cloud Computing En Las Universidades" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Por tanto, este artículo tiene como objetivo identificar qué dimensiones "calidad del sistema", "calidad de la información", "calidad del servicio" y "utilidad percibida" tienen el mayor impacto en la satisfacción del usuario en el uso de sistemas de información académica en entornos virtuales.

Marco Teórico

Según Petter, DeLone & McLean (2013), no existe un factor aislado que pueda ser utilizado para determinar el éxito de un SI, sino que se deben considerar varios factores para medir el buen desempeño del sistema y, en consecuencia, la satisfacción del usuario. Además de estas investigaciones, Ainin, Bahri & Ahmad (2012), afirman que el desempeño de un SI se puede ver en términos de satisfacción del usuario (es decir, desde la perspectiva de los estudiantes). En su estudio, Ainin, Bahri & Ahmad (2012), incorporarán los tres constructos (calidad del sistema, calidad de la información y calidad del servicio) introducidos por DeLone & McLean (1992), así como la utilidad percibida introducida por primera vez en los modelos de aceptación de la tecnología.

Aclarando los constructos adoptados, la calidad del sistema se restringirá a los aspectos técnicos y de diseño del sistema que permitan al usuario tener una interacción ágil y práctica y satisfacer las respectivas necesidades. La calidad del servicio estará correlacionada con el compromiso de resolver las dudas y situaciones que el usuario presente al sistema, involucrando o no - si es necesario - la ayuda de un agente externo capaz de demostrar disposición para resolver lo presentado. La calidad de la información, aunque no se puede medir fácilmente, estará representada por el nivel de satisfacción del usuario con el contenido de lo que se le presentó en respuesta a sus preguntas y si entiende cómo proceder.

Así, comprender si la satisfacción de los usuarios con el uso de la información académica virtual depende directamente de la calidad (sistema, información y servicio) y la utilidad percibida y si estas dimensiones están correlacionadas positivamente agregará conocimiento y permitirá la mejora continua de estos sistemas.

Metodología

Esta investigación es exploratoria, con un enfoque cuantitativo a través de ecuaciones estructurales vía varianza. El sitio de estudio fue Brasilia, Distrito Federal-Brasil. El objeto de estudio fueron estudiantes de educación a distancia de la Universidad de Brasilia-UnB. El instrumento de recogida de datos fue un cuestionario elaborado a partir del modelo de [6], con 5 dimensiones y 17 preguntas con una escala con ítem likert. El cuestionario fue validado (α = 0.915, Rhoa = 0.914, Cc = 0.943). La recolección de datos se realizó entre el 11 y el 14 de febrero de 2019 y se obtuvieron 100 respuestas. La muestra se calculó mediante el software G * Power 3.16, utilizando el tamaño del efecto como 0,15, la significancia fue del 5% y el nivel de poder estadístico fue de 0,8. Como el nivel más alto de complejidad de la relación es 4, el tamaño de muestra requerido fue de 85 encuestados. El total alcanzado fue de 100 personas, los datos fueron procesados en Microsoft Excel y calculados con el software SmartPLS 3.2.8. Los análisis se realizaron desde el enfoque de ecuaciones estructurales vía varianza (PLS-SEM).

Resultados

Según Ramírez, Mariano & Salazar (2014), la evaluación de modelos debe realizarse en dos etapas, valoración del modelo de medición y valoración del modelo estructural. La valoración de ambos modelos seguirá las instrucciones de Hair, Hult, Ringle & Sarstedt (2016). La valoración del modelo de medida alcanzó todos los índices recomendados por Ramírez, Mariano & Salazar (2014), en cuanto a validez y fiabilidad. Se realizaron pruebas de colinealidad y los resultados fueron inferiores a 3,3 (Hair, Hult, Ringle & Sarstedt, 2016).

La valoración del modelo estructural se realiza a través de las pruebas de magnitud del coeficiente de dirección, significancia, coeficiente de determinación (R2), descomposición del coeficiente R2 y tamaño del efecto (f2) (Figura 2) (Tabla 1).

Tabla 1- Modelo estructural

	Coeficiente estructural	t-value	p-value	F2	%	R2
H1. QI→SG	0,04	1,115	0,26	0,016	2,87%	0,722
H2. QS→SG	0,133	1,646	0,10	0,024	6,10%	
H3. QSI→SG	0,464	4,559	0	0,268	32,30%	
H4. UP→SG	0,441	4,298	0	0,197	30,93	

IQ (calidad de la información), calidad del servicio (QS), calidad del sistema (QSI), utilidad percibida (UP) y satisfacción global (SG).

Se puede observar que la satisfacción global de los usuarios se explicó en 72,2%, siendo la calidad del sistema responsable de explicar 32,30% y la Utilidad Percibida en 30,93%, considerando las dos variables significativas de este modelo. El tamaño del efecto de la calidad del sistema y la utilidad percibida es moderado. Los resultados confirman parcialmente el trabajo de (DeLone & McLean, 1992; Venkatesh, Morris, Davis & Davis, 2003), y demuestran la consistencia del modelo presentado por Ainin, Bahri & Ahmad (2012), encontrando las mismas variables como significativas.

Los resultados encontrados revelan que para mejorar la percepción de satisfacción global es necesario garantizar la calidad del sistema a través de instrucciones efectivas sobre el uso del sistema, facilidad de corrección de errores, información útil y velocidad de acceso entre páginas. El segundo factor que pareció predominar fue la utilidad percibida, que se materializa a través de un sistema de fácil manejo, hasta el punto de resultar intuitivo para el usuario. Así, en ambos casos, una correcta elicitación de los requisitos puede mejorar la satisfacción general del usuario de los sistemas de información académica al favorecer instrucciones claras para un sistema, la simplicidad operativa y el perfil del cliente (sus deseos y necesidades en relación con el sistema). Así, las instituciones deben consultar a los diferentes grupos de usuarios de sus sistemas para conocer sus expectativas y necesidades.

Conclusiones

Esta investigación tuvo como problema presentado en este estudio saber ¿qué factores influyen en la calidad global de los sistemas de información académica? El problema fue respondido a través de las Hipótesis H3: La calidad del sistema influye en la satisfacción global de los usuarios de los sistemas de información y H4: La utilidad percibida influye en la satisfacción global de los usuarios de los sistemas de información, teniendo como factores que más influyen en ellos. De esta manera se logró el objetivo de la investigación, revelando la calidad del sistema y la utilidad percibida como las dimensiones más importantes del modelo. Para futuros estudios pretendemos realizar una búsqueda descriptiva de mayor representación.

Resumen

Este estudio tiene como objetivo presentar los factores que más influyen en el uso de Big Data Analytics en un Hospital público del Distrito Federal. Para ello, se realizó una investigación exploratoria de carácter cuantitativo aplicada al sector responsable de implementar el uso de Big Data Analytics en el hospital mediante ecuaciones estructurales. Los resultados desvelaran que la expectativa de rendimiento explica la intención de utilizar Big Data Analytics en un 38,42% y la expectativa de esfuerzo en un 31,83%.

Palabras Clave: Big Data, Hospital Público, Brasil.

Introducción

El Big Data Analytics en Healthcare es una de las áreas de más rápido crecimiento, debido a los beneficios inmediatos que puede generar para los pacientes y el hospital (Luo, Wu, Gopukumar, & Zhao, 2016). Sin embargo, tanto en el uso de Big Data Analytics (BDA) para la salud como para las organizaciones en general, la mayoría de los estudios y trabajos centran sus objetivos en cuestiones técnicas de uso, características de herramientas y aplicaciones (Vale et al., 2019). De este modo son pocos estudios que se fundamentan en la intención de uso por parte del individuo (Cabrera-Sánchez & Villarejo-Ramos, 2020).

Un Hospital Público del Distrito Federal se interesó en conocer la intención de utilizar BDA por parte de a sus empleados involucrados en la transformación digital del hospital actual, para una organización que usa inteligencia de los datos con Big Data Analytics. En base a esta necesidad, si tornó importante medir los factores que más implican la intención de utilizar BDA para mejorarlo e implementarlo en su unidad.

Así, este estudio tiene como objetivo presentar los factores que más influyen en el uso de Big Data Analytics en un Hospital público del Distrito Federal.

Revisión de la Literatura

Pacheco et al., (2020), definen Big Data como un conjunto grande y complejo de datos que requieren tecnologías complejas para su almacenamiento, gestión, análisis y visualización avanzada. El uso del análisis de datos aplicado al escenario Big Data fue conocido en la literatura como Big Data Analytics (BDA). Así, BDA se ha convertido en una prioridad para las organizaciones, especialmente para aquellas que tienen un historial de uso de datos como parte de sus funciones, como los hospitales, por ejemplo.

RAMIREZ-CORREA, Ari MELO-MARIANO, Simone Borges Simao MONTEIRO and Ronaldo Rodrigues PACHECO "Comportamiento De Uso De Big Data: Estudio Aplicado En Un Hospital Publico En Brasil" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Cabrera-Sánchez & Villarejo-Ramos (2020) investigaron los factores que inciden en la adopción de Big Data Analytics a través de un modelo extendido de UTAUT (teoría unificada de aceptación y uso de la tecnología), al que se suman dos variables: resistencia al cambio, que explica el grado en que el usuario está de acuerdo o no en realizar cambios en las actividades diarias y el riesgo percibido (el grado que el usuario percibe sobre los riesgos de la actividad que realiza o de sí mismo) (Cabrera-Sánchez & Villarejo-Ramos, 2020).

Metodología

Esta investigación es exploratoria, a través del estudio de caso de una organización de salud, con un enfoque cuantitativo utilizando ecuaciones estructurales vía varianza. El lugar de estudio fue Brasilia y el objeto de estudio fue la percepción de los usuarios de los sistemas de información que trabajan en la implementación del hospital para el uso de inteligencia de datos a través de Big Data Analytics. El instrumento de recogida de datos fue un cuestionario adaptado de Cabrera-Sánchez & Villarejo-Ramos (2020). El sector estuvo formado por 40 profesionales, de los cuales 33 respondieron a la encuesta. Entre los encuestados, el 29% son mujeres y el 71% hombres. A partir de estos datos, se realizó un análisis software SmartPls 3.3.2, por ser un programa completo que ofrece análisis de validación de modelos previos.

Resultados

Antes de calcular el modelo estructural, es necesario asegurarse de que el modelo sea confiable y válido. Por eso, según Hair. et al. (2019) Se requieren 2 (dos) pruebas de confiabilidad y 2 (dos) pruebas de validez. Fueran realizadas las pruebas de confiabilidad del ítem, confiabilidad interna ($\alpha = 0.88$), asegurando la confiabilidad del modelo y la validez convergente (AVE$\geq$ 0.5) y la validez discriminante (HTMT <0.9), asegurando la validez del modelo. Por tanto, el modelo se considera fiable y válido. También se observó si existía multicolinealidad y todas las variables estaban por debajo de 3.3, como lo requiere la literatura (Hair, et.al., 2019)

4.1. Modelo estructural

Una vez que se garantiza la confiabilidad y validez del modelo, se puede calcular el modelo estructural. La Figura 2 representa el modelo calculado luego de que fue estabilizado usando los criterios de confiabilidad y validez.

Fig 2. Modelo estructural calculado

Tabla 1: Resultado prueba de hipótesis

	Path (B)	%	t-valor	p-valor	Suportada?
H1: PE--> IC	0,58	38,42%	4,29	0,00	Sim
H2a: EE--> IC	0,46	31,83%	3,23	0,00	Sim
H2b: EE--> R	-0,36	12,60%	1,98	0,05	Sim
H3: IS--> IC	0,08	3,62%	0,76	0,45	Não
H4a: CF--> IC	0,15	4,81%	0,95	0,34	Não
H4b: CF--> BI	0,08	2,16%	0,34	0,73	Não
H5a: R--> CI	0,15	-5,71%	0,54	0,59	Não
H5b: R--> RC	0,33	10,89%	1,73	0,08	Não
H5c: R --> PE	-0,59	34,22%	5,82	0,00	Sim
H6: RC- -> CI	-0,06	1,98%	0,48	0,63	Não
H7: IC --> BI	0,55	32,19%	2,81	0,01	Sim
Condiciones facilitadoras (CF), Expectativa de esfuerzo (EE), Expectativa de desempeño (PE), Influencia social (IS), Intención comportamiento (CI), Conducta de uso (BI), Resistencia al cambio (CR), Riesgo percibido (R)					

Conclusiones

Los resultados muestran que las variables más influyentes son la Expectativa de rendimiento con 38,42% de grado de influencia. Esto significa que, para los usuarios de hospitales, mejorar la productividad, disminuir el tiempo de realización de la tarea e incluso aumentar sus ganancias financieras son buenas razones para adoptar Big Data Analytics.

La segunda variable más importante para la disposición a adoptar Big Data Analytics es la expectativa de esfuerzo (31,83%) (H2a). Por tanto, si el usuario cree que el uso gastará mucha energía, no adoptará el uso de Big Data Analytics. Se puede observar que estas dos variables (Expectativa de rendimiento y esfuerzo) explican la intención comportamental de utilizar Big Data Analytics en un 70,25%.

Así, disminuir la percepción de esfuerzo a través de la información y la formación y además explicar cómo el Big Data Analytics puede ser útil en las actividades que realizan los empleados del Hospital, aumentará la intención de utilizar Big Data Analytics. Otras hipótesis también se apoyaron estadísticamente.

La expectativa de esfuerzo está directamente relacionada con la percepción de riesgo (H2b). Así, si el usuario siente que el esfuerzo empleado para utilizar Big Data Analytics es mayor de lo que esperaba, existe la posibilidad de que vea Big Data Analytics como algo incómodo.

El riesgo a su vez impacta directamente en la expectativa de rendimiento en un 34.22% (H5c), en una relación inversamente proporcional, cuanto más grande el riesgo, más pequeña es la expectativa de rendimiento, es decir, si el usuario piensa que Big Data Analytics puede ser un riesgo, tiende a hacer consideraciones sobre el desempeño que ofrecerá.

Finalmente, la intención de uso y su relación con el uso en sí (H7). Aunque se espera que la preparación se convierta en uso, en la práctica hay varios factores que pueden afectar. Así, el Hospital debe trabajar asiduamente en la formación y en la información, además de mantener un centro de apoyo constante para las dudas y asistencia a los empleados, pues una vez que se sientan cómodos con el uso de Big Data Analytics, menor es la expectativa de esfuerzo. De ese modo, al disminuir la sensación de esfuerzo y aumentar las expectativas de mejora en el desempeño de los empleados, Big Data Analytics tendrá un mayor grado de aceptación de uso.

Resumen

Este trabajo explora el efecto de la intención de continuar teletrabajando sobre la ambigüedad de rol y el agotamiento en el teletrabajo en una muestra de teletrabajadores costarricenses que se encontraban teletrabajando en confinamiento preventivo por el COVID-19. Los resultados muestran que una actitud positiva hacia el teletrabajo es capaz de mediar de forma parcial los efectos negativos de la ambigüedad de rol sobre los niveles de agotamiento al trabajar en casa.

Palabras Clave: Actitud positiva, teletrabajo, Costa Rica, COVID-19.

Introducción

Las organizaciones además de diagnosticar factores psicosociales para prevenir amenazas y riesgos de la salud de los trabajadores deben ayudar a desarrollar recursos que se asocian al bienestar y a la promoción de la felicidad laboral. Abordar solo los aspectos higiénicos del teletrabajo nos puede distanciar de identificar los beneficios de esta modalidad y las actitudes que se deberían considerar para promover conductas saludables al trabajar desde casa.

Dada la naturaleza dinámica de las tecnologías, es importante evaluar los efectos de su uso en teletrabajadores (Salazar-Concha, Ficapal-Cusí and Boada-Grau, 2020). Los efectos del teletrabajo han trascendido la esfera del mundo del trabajo y de las organizaciones. Hoy es considerado por decenas de países como una forma de mantener la economía y el empleo. En este trabajo analizaremos el efecto mediador de la actitud positiva de en la intención de continuar teletrabajando (ICT) por sobre factores que potencian el agotamiento y la falta de vitalidad.

Hipótesis

La actitud positiva en el trabajo implica una disposición optimista y entusiasta dirigida a nuestra actividad laboral y a todas las personas involucradas en él (Kasemsukprakarn and Dowpiset, 2020). No obstante, existen elementos del ambiente laboral que tienen el potencial de deteriorar la salud mental de los trabajadores (Leka *et al.*, 2003). Uno de estos factores psicosociales es la ambigüedad de rol (AR) (Karasek, 1979), la cual puede aumentar los niveles de agotamiento en el teletrabajo (AGT) (Weinert, Maier and Laumer, 2015). De acuerdo con Schaufeli and Bakker (2004), existen elementos del ambiente de trabajo que tienen el potencial de generar bienestar y facilitar la realización del trabajo. Considerando que la ICT se asocia con un recurso que propicia una actitud positiva en el teletrabajo, proponemos:

H1: La AR aumenta los niveles de AGT.
H2: La AR disminuye la ICT.
H3: La ICT media la relación entre la AR y el AGT.

RAMIREZ-CORREA "Ambigüedad De Rol Y El Agotamiento En El Teletrabajo: Un Análisis Exploratorio En Costa Rica" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Metodología

Se obtuvieron 52 encuestas *online* válidas aplicadas a teletrabajadores costarricences. La Tabla 1 muestra una población mayoritariamente con estudios universitarios, con edades entre 36-45 años, que viven en familia y teletrabajan entre 8-12 diarias.

Tabla 1: Antecedentes sociodemográficos

Variable	Categorías	Frecuencia	Porcentaje
Género	Femenino	32	,62
	Masculino	20	,38
Rango edad	20-35	10	,19
	36-45	31	,60
	Más de 45	11	,21
Estado Civil	Soltero(a)	14	,27
	Casado(a) / conviviendo	29	,56
	Separado	9	,17
Lugar en casa para teletrabajar	Si	42	,81
	No	10	,19
Formación para teletrabajar	Si	35	,67
	No	17	,33
Horas diarias de TT	Media Jornada	1	,02
	7-8 horas	17	,33
	8-12 horas	31	,60
	Más de 12 horas	3	,06
Nivel Educación	Universitario	33	,63
	Máster	17	,33
	Doctorado	2	,04

Dado que la técnica de modelos de ecuaciones estructurales (SEM) es apropiada en investigaciones de las ciencias sociales (Hair *et al.*, 2017), se realizaron los análisis a través del software SmartPLS v.3.3.2.

Resultados

Los datos obtenidos validan satisfactoriamente el ajuste del modelo, cumpliéndose todos los criterios (Hair *et al.*, 2017). La Tabla 2 muestra un resumen de la evaluación del modelo luego de la depuración de escalas. La ratio HTMT fue menor a 0,81.

Tabla 2: Análisis de fiabilidad y validez convergente

Variable	AC	FC	AVE	AGT	AR	ICT
AGT	0,893	0,934	0,825	0,908		
AR	0,750	0,858	0,669	0,671	0,818	
ICT	0,877	0,923	0,801	-0,665	-0,393	0,895

La evaluación del modelo estructural se presenta en la Figura 1. Se soportan H1 y H2. La variación del AGT es explicada en un 64,1% por AR. La ICT es explicada en un 15,4% por AR. Complementariamente, la AR afecta indirectamente y de manera positiva al AGT a través de la ICT. El efecto mediador de ICT es parcial dado que el VAF tiene un valor de 21%, por lo cual se soporta H3.

Fig. 1. Resultados PLS-SEM

Conclusiones

Se concluye que una ICT positiva media los efectos negativos de la AR. Recomendamos a las organizaciones promover una actitud saludable y positiva hacia el teletrabajo, mejorando canales de comunicación y entregando información clara sobre las metas y las responsabilidades que cada empleado debe cumplir. Futuros trabajos podrían medir el efecto de otros recursos laborales como mediadores/moderadores de las relaciones que afectan las emociones y la salud en el teletrabajo.

Explorando El Efecto Mediador Del Conflicto De Trabajo Hogar Entre La Sobrecarga Y El Agotamiento En Teletrabajo

Patricio E. RAMIREZ-CORREA
Universidad Catolica del Norte, Coquimbo, Chile, patricio.ramirez@ucn.cl

Cristian SALAZAR-CONCHA
Universidad Austral de Chile, Valdivia, Chile, cristiansalazar@uach.cl

Luis J. CAMACHO
SUNY Empire State College, New York, USA, luis.camacho@esc.edu

Abstract

Utilizando modelamiento de ecuaciones estructurales se estudia la influencia de la sobrecarga de trabajo sobre el agotamiento y la intención de continuar teletrabajando en una muestra de teletrabajadores chilenos. Los resultados muestran que la sobrecarga de trabajo afecta el conflicto trabajo-hogar y el agotamiento, a su vez, esta sobrecarga y el conflicto trabajo-hogar influyen negativamente en la intención de continuar teletrabajando.

Keywords: teletrabajo, ecuaciones estructurales, Chile, COVID-19.

Introducción

Producto del COVID-19 las organizaciones adoptaron el teletrabajo (TT) como una medida para mantener la continuidad sus operaciones y su estabilidad financiera. El TT fue adoptado por distintos empleados, algunos con competencias para el teletrabajo y con espacio en su hogar para trabajar y otros no. Estudios han reportado que el TT en confinamiento puede aumentar distintos estresores laborales y poner en riesgo el deseo de teletrabajar en el futuro.

El presente estudio evalúa la mediación del conflicto trabajo-hogar (CTH) entre la sobrecarga de trabajo (ST) y el agotamiento (AGT) y analizará efectos directos e indirectos que influyen en la intención de continuar teletrabajando (ICT).

Hipótesis

TT transforma generando nuevas reglas organizacionales (Salazar and Pacheco, 2006; Salazar and Sanhueza, 2017), y se ha extendido mundialmente por COVID-19 (Kan et al., 2020). La ST y el CTH son estresores en el teletrabajo y afectan directa e indirectamente el AGT y la ICT (Baruch, 2000; Ayyagari et al., 2011; Golden, 2012; Weinert et al., 2015). El AGT es uno de los factores estresantes asociados al TT (Weinert et al., 2015) y quienes usan tecnologías para trabajar son más vulnerables a percibirlo (Moore, 2000). Teletrabajar puede afectar a las personas de manera distinta. La literatura sobre conciliación laboral-personal no es concluyente (Song and Gao, 2020), por tanto, deseamos medir el efecto de la mediación del CTH sobre la ST y el AGT. En este contexto se proponen:

H1: La ST incide positivamente en el CTH.
H2: EL CTH afecta positivamente el AGT.
H3: La ST afecta positivamente el AGT.
H4: El AGT incide negativamente en la ICT.
H5: El CTH media la relación entre la ST y el AGT.

Metodología

Se obtuvieron 64 encuestas de teletrabajadores chilenos. La Tabla 1 presenta una muestra compuesta en su mayoría por trabajadores entre 36-45 años, viviendo en pareja y sin formación previa para TT.

	Separado	4	,06
Espacio en el hogar para teletrabajar	Si	44	,69
	No	20	,31
Formación para teletrabajar	Si	27	,42
	No	37	,58
% uso de TIC para TT (respuesta múltiple)	Email	51	,80
	WhatsApp	45	,70
	Teléfono	28	,44
	Videoconferencia	50	,78
Apoyo para teletrabajar (respuesta múltiple)	Dinero	25	,39
	Ordenador	30	,47
	Internet	13	,20
	Cuenta de luz	4	,06
	Materiales oficina	0	0

Para los análisis se utilizó SmartPLS v.3.3.2. La técnica de modelos de ecuaciones estructurales (SEM) es apropiada en investigaciones de las ciencias sociales (Hair et al., 2017).

Resultados

Los datos obtenidos validan satisfactoriamente el ajuste del modelo, cumpliéndose los criterios exigidos para validar SEM. La Tabla 2 muestra un resumen de la evaluación del modelo luego de la depuración de escalas. La ratio HTMT mayor fue de 0,787.

Tabla 2: Análisis de la validez convergente y fiabilidad

Variable	AC	FC	AVE	AGT	CTH	ICT	ST
AGT	0,915	0,948	0,859	0,927			
CTH	0,877	0,942	0,891	0,687	0,944		
ICT	0,930	0,955	0,876	-0,505	-0,397	0,936	
ST	0,784	0,872	0,696	0,633	0,674	-0,536	0,834

La evaluación del modelo estructural se presenta en la Figura 1, soportándose H1, H2, H3, H4. La variación del CTH es explicada en un 44,6% por ST. El AGT es explicado en un 50,9% por la variación de la ST y del CTH. La variación de ICT es explicada en un 24,3% por AGT. El efecto mediador de CTH es parcial, con un VAF de 34%.

Fig. 1: Resultados PLS-SEM

Conclusiones

Los resultados muestran que la ICT es afectada de manera directa e indirecta y de forma negativa por todas las variables del estudio. El CTH media parcialmente ST y AGT. A la luz de estos resultados, las organizaciones deberían generar condiciones protectoras que ayuden a disminuir los factores de riesgos psicosociales que pueden experimentar sus empleados por el TT en confinamiento COVID-19 y establecer mecanismos de intervención.

Big Data Y Empleo: Una Revision De Los Topicos En La Literatura De Administracion Y Sistemas De Informacion

Patricio E. RAMIREZ-CORREA

Universidad Catolica del Norte, Coquimbo, Chile, patricio.ramirez@ucn.cl

Abstract

Utilizando minería de texto se exploran los tópicos latentes en la literatura sobre *Big Data* y empleo.

Keywords: Big Data, empleo, LDA.

Introducción

Las implicaciones del *Big Data* en toda la sociedad es un punto de discusión (Kappler *et al*., 2018). Dentro de estas implicaciones, su relación con el empleo se considera clave en el desarrollo de las economías (Jeske y Calvard, 2020), tanto en países desarrollados como en vías de desarrollo (Hilbert, 2013). En este contexto, investigadores de diversas áreas han analizado forma creciente diversos fenómenos asociados a este foco en la última década. No obstante, la carencia de una revisión de los temas o tópicos que se han analizado obstaculiza la propuesta de una agenda de investigación útil para acelerar la generación de conocimiento en este ámbito.

En este documento entregamos los primeros resultados de un análisis sistemático dentro de las diciplinas de administración y sistemas de información cuyo objetivo es descubrir los tópicos latentes en la literatura sobre *Big Data* y empleo.

Metodología

El estudio utilizó para la exploración 160 artículos científicos Web of Science (WoS) publicados en revistas categorizados por WoS en MANAGEMENT, COMPUTER SCIENCE INFORMATION SYSTEMS, BUSINESS y INFORMATION SCIENCE LIBRARY SCIENCE entre los años 2012 y 2020. En la base de datos WoS se buscó como tema <'*big data*' *and employment*>.

Para el análisis de aplicó la técnica de aprendizaje automático *latent Dirichlet allocation* (LDA) de Blei *et al.* (2003).

Resultados

La Figura 1 muestra un análisis descriptivo de los artículos analizados, la mayoría de estos estudios son de autores de países desarrollados, como Estados Unidos y Reino Unido; por otro lado, *Management Information Systems Quarterly* es la revista que más se destaca y la clave *Big Data*, seguida de rendimiento y administración, es la más utilizada.

Cite this Article as: Patricio E. RAMIREZ-CORREA "Big Data Y Empleo: Una Revision De Los Topicos En La Literatura De Administracion Y Sistemas De Informacion" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig 1. Análisis descriptivo de artículos

Se analizaron los resúmenes de los artículos con LDA. Antes de este análisis, los textos fueron procesados para eliminar *stopwords* (generales y de publicaciones científicas) y reducir las palabras a su raíz. Para determinar el número óptimo de tópicos se usó el índice propuesto por Cao *et al.* (2009), este análisis señala 7 tópicos latentes (ver Figura 2).

Fig 2. Número de tópicos y métrica de Cao

Seguidamente se examinaron las palabras que componen estos 7 tópicos y se les etiquetó. La Figura 3 muestra como una nube de palabras los primeros 10 tokens de cada tópico, y las Tablas 1a y 1b muestran las etiquetas propuestas con una lista de 25 tokens. En resumen, los tópicos latentes en *Big Data* y empleo son problemas de ciudad, oportunidades de empleo, entrenamiento de modelos predictivos, discriminación en la toma de decisiones, industria inteligente, mercado laboral y educación.

Fig 3. Tópicos de *Big Data* y empleo

Resumen

El objetivo de esta investigación fue presentar una opción para operacionalizar la evaluación de madurez de datos de Carvalho, et al. (2019a, 2019b, 2018 y 2017) en una organización hospitalaria. Se presentó un modelo operativo en tres etapas que logró satisfactoriamente el propuesto. Las etapas futuras serán las validaciones estadísticas y la predicción del modelo. Al probar el modelo en un Hospital del Distrito Federal en Brasil, la organización alcanzó el 50,15% de madurez en Análisis de Datos.

Palabras Clave: Modelo de madurez, instrumento, Hospitales.

Introducción

Según Vidal, Rocha, Vasconcelos & Abreu (2018) en las últimas cinco décadas se han aplicado modelos de madurez para sistemas de información (SI) a diferentes empresas y, específicamente en salud, estos modelos de madurez tienen la función de atender una amplia variedad desafíos y la alta demanda de implementaciones de SI (HIS) en los hospitales. Observando este contexto, en 2019, y después de una larga revisión de la literatura y validación de contenido con 46 expertos, Carvalho (2019a), Carvalho et al. (2017), presentó un modelo de madurez, no solo para parte de los datos, sino para toda la organización, ayudando a comprender la unión entre la madurez de los datos, denominada Análisis de datos y las otras etapas de madurez organizacional.

Para mejorar su conocimiento en el uso de datos, muchas organizaciones hospitalarias han buscado comprender dónde se encuentran y qué pasos deben tomarse para mejorar esta madurez. Así, el objetivo de este estudio será presentar una opción para operacionalizar la evaluación de madurez de datos de Carvalho, et al. (2019a, 2019b, 2018 y 2017) en una organización hospitalaria.

Revisión de la Literatura

En el dominio de la salud, se utilizaron modelos de madurez para enfrentar una amplia variedad de desafíos y la alta demanda de implementaciones de IS Hospital (SIH) (Carvalho et al., 2016, 2019; Gomes & Romão, 2018). Al aplicar un modelo de madurez al sector salud, (Gomes & Romão, 2018) afirman que la madurez de los sistemas de información en salud (SIH) son de crucial importancia para mejorar la eficiencia, costo-efectividad, calidad y seguridad de la prestación de atención. doctores. Según Carvalho (2019a), la madurez del análisis de datos es solo un pilar de la madurez organizacional. Carvalho (2019a) explica que hay 4 capas de madurez (Figura 1).

RAMIREZ-CORREA, Ari MELO-MARIANO, Simone Borges Simao MONTEIRO and Ronaldo Rodrigues PACHECO "Evaluando La Madurez De Datos: Un Estudio Empirico En Un Hospital De Brasil" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Fig. 1: Capas de madurez

Fuente: Adaptado de Carvalho (2019a)

Según Carvalho (2019a), la madurez es una gran capa que tiene un conjunto de seis pilares (1. análisis de datos, 2. estrategia, 3. personas, 4. historia clínica electrónica, 5. seguridad de los sistemas de información y 6. sistemas e infraestructura de TI). Cada uno de estos pilares de madurez es parte de la madurez organizacional. En este estudio, el pilar analizado fue el Análisis de Datos. Cada uno de los pilares a su vez se puede contemplar en 6 etapas diferentes (a. Atención, b. Justificación, c. Datos concentrados, d. Cooperación de datos, e. Oportunidad de negocio y f. Relaciones integradas.).

Una organización no necesariamente debe tener una fase completada para pasar a otra, son transversales como la cadena de valor y su presencia en una fase no implica la no presencia en otra. En otras palabras, la organización puede estar presente en diferentes niveles de madurez. Así, en este estudio se calculó el nivel de madurez del Hospital do Distrito Federal, según el modelo de (Carvalho et al., 2019).

Metodología

Se trata de una investigación exploratoria con enfoque cualitativo y cuantitativo. El objeto de estudio, la madurez en Análisis de Datos de un Hospital de Brasilia. Para la investigación, el modelo de Carvalho, et al. (2019a, 2019b, 2018 y 2017). Participaron 30 personas que trabajan directamente con datos en el Hospital. Este modelo se aplicó mediante cuestionarios a los usuarios de datos internos del hospital (profesionales que utilizan datos). Las etapas de la operacionalización propuesta se dividen en tres partes, a. Cálculo de la etapa de madurez; b. Cálculo del puntaje de madurez total y c. Validación de rostro y contenido.

a. Cálculo de la etapa de madurez

Para calcular la etapa de madurez, cada respuesta se convirtió de acuerdo con los siguientes criterios: 1. En desacuerdo (0 puntos), 2. Parcialmente en desacuerdo (1 punto), 3. Ni en desacuerdo, ni de acuerdo (neutral) (2 puntos), 4. Parcialmente de acuerdo (3 puntos) y 5. De acuerdo (4 puntos). Se consideró la puntuación máxima a alcanzar en las preguntas de cada etapa, calculada por separado, donde cada grupo de preguntas representa una etapa.

Por lo tanto, para cada etapa de madurez del análisis de datos, la puntuación se calculó de la siguiente manera (ecuación 1):

$$PF = \left(\frac{\mu_{\Sigma p}}{p_{máx}}\right)*100\% \quad (1)$$

Donde,

PF = Puntuación de la etapa

$\mu_{\Sigma p}$ = Suma del promedio de las preguntas

$P_{máx}$ = Puntuación máxima posible por etapa

De esta forma, cada fase tiene su propio porcentaje, y la organización puede participar en diferentes etapas de madurez, siendo la puntuación más alta la etapa más característica de la organización.

b. Cálculo del puntaje de madurez total

Carvalho (2019a), explica que existen 6 etapas posibles para una organización Hospitalaria en cuanto a madurez de datos, por lo que la madurez del Análisis de Datos se divide en 6 partes, equivalentes a 16.67 puntos por etapa. Para calcular el índice de madurez total en Análisis de datos, el valor de cada fase se multiplicó por 16.67 (como se explicó anteriormente) y se realizó una suma (ecuación 2).

$$PP = \sum_{(PF \times 16{,}67)} \quad (2)$$

Donde,
PP = Puntuación del pilar (puntuación de madurez total)
PF = Puntuación de la etapa

El promedio de la suma de los promedios de cada pregunta genera el puntaje promedio.

c. Validación presencial y de contenido

La validación presencial y de contenido se realizó con profesores y profesionales hospitalarios en reuniones presenciales de grupo. También se puso a disposición un cuestionario abierto (anónimo) de testimonios, con el fin de verificar los resultados de la escala y los descritos por los profesionales entrevistados.

Resultados

Una vez recolectados los datos a través de un cuestionario, se realizó el cálculo para encontrar el nivel de madurez en el análisis de datos del hospital. Como se preconiza (Carvalho et al., 2019), el comportamiento de madurez es fluido, pero una organización siempre tendrá un nivel preponderante.

Los resultados encontrados fueron qué el Hospital tiene un 50,15% de madurez. Entre las seis etapas posibles, la que mayor puntuación tiene el Hospital es la etapa I- Atención, con 64,29% de la puntuación que podría alcanzar y 10,72 puntos acumulados de 16,67. Así, la etapa más prevalente del Hospital es la etapa I. Aunque puntúa en todas las etapas, las etapas I. La atención y II Justificación son de suma importancia, ya que significan urgencia y fundamentos para apoyar el uso de diferentes análisis de datos, como BI, Data Science, Big Data, modelos predictivos y prescriptivos. En el estadio II, el Hospital obtuvo el 51,94% de la puntuación total posible, en una puntuación total de 8,66 de 16,67.

Establecer prioridades de acuerdo con la información encontrada en el análisis de madurez del Análisis de Datos, creando metas en base a los puntos a reforzar, en la etapa de “atención” y “razonamiento”. El Hospital también puntúa en el resto de las etapas, pero solo en las etapas I y II existe el compromiso de estar incluido en su duración, ya que son requisitos previos para el correcto uso de los datos.

Como paso de validación, se realizó un análisis de contenido de acuerdo con la opinión de los encuestados sobre posibles obstáculos para mejorar la madurez de los datos con el fin de confrontar lo encontrado en el resultado (Figura 2).

Fig. 2: Nube de palabras sobre obstáculos al análisis de datos

En opinión de los encuestados, existe falta de uniformidad de datos, falta de integración, falta de personal capacitado para trabajar con los datos, necesidad de comunicación formal sobre la importancia de los datos y conciencia del correcto llenado de los Insumos, mejora en la infraestructura, mejora en la calidad de los datos. Así, se puede observar que muchos de los problemas están directamente relacionados con las Etapas I y II, como se encontró. Sin embargo, aparecen otros puntos relacionados con los pilares "personas" e "infraestructura y TI" que pueden medirse en un análisis futuro. De esta forma, la operacionalización de Carvalho, et al. (2019a, 2019b, 2018 y 2017) en tres etapas: a. Cálculo de la etapa de madurez; b. Cálculo del puntaje de madurez total y c. Validación de rostro y contenido.

Conclusiones

Esta investigación tuvo la opción de operacionalizar la evaluación de madurez de datos de Carvalho et al. en una organización hospitalaria. Se presentó un modelo operativo en tres etapas que logró satisfactoriamente lo propuesto. Las etapas futuras serán las validaciones estadísticas y de predicción del modelo.

bkolosowska@gmail.com

Abstract

The changes in the pension schemes of the Central and Eastern Europe countries, and first of all in the Polish national pension scheme are the subject of the paper. The study aims at reviewing the changes in the pension schemes and their impact on the public finance including the government budget. Research show that activities undertaken by the governments whose aim is to limit or even suspend the payments of contributions to capital funds cannot be described as reformative, but they are rather short-term solutions of the problem of deficit in the government budget. They improve the situation of the pay-as-you-go part of the public pension systems only temporarily, however threatening with a disassembly of the pension reform, which was very hard to introduce. Undoubtedly, the impact of the changes in the pension scheme on the public finance is significant due to a long-term imbalance in the government budget and the accumulating public debt. Evaluating the ongoing changes, the Authors notice that the solutions suggested by the government can be described as choosing between responsibility for the present and responsibility for the future.

Keywords: Pension scheme, Open Pension Funds, Occupational Pension Schemes, budgetary deficit and public debt

JEL Classification: H55, H62, H63

Introduction

As it has been seen for a long time, people live to old age, which creates the necessity to secure old age through a fair pension. It is a social and also economic problem. The fact that the society is ageing does not help the functioning of the contemporary social security systems, on the contrary, it brings challenges for governments.

Those issues are also observed in the countries of Central and Eastern Europe, and in Poland, where since 2010 solutions designed to finance current budgetary needs of the state have been sought. National budgets have to frequently face budgetary deficits and consequently high public debts, which makes the correct functioning of the public finance systems difficult, and social security systems constitute their part. The aim of the article is to present the changes in the pension schemes in the countries of Central and Eastern Europe and first of all in the Polish national pension system and their influence on the public finance including the state budget. Evaluating the current changes, the Authors discern that the changes suggested by the government can be assessed as the choice between being responsible for present and being responsible for the future. It is also significant that the impact of demographic changes on the state economy and budget is contemporarily connected with two trends – a decline in the population and the aforementioned ageing of the society. It should be underlined that the effects of the current changes in the pension system will burden the future generations and the sources of their financing will depend on the pursued in the future financial policy including the fiscal policy.

The Aim of and Reason for Creating Pension Systems

For many years, it has been societies' aim to live a dignified old age, when for natural reasons people are not able to work and be professionally active. For a long time, the solution of the problem was building extended families, in

Cite this Article as: Jolanta Maria CIAK and Bożena KOŁOSOWSKA "The Pension Scheme in Poland And in Selected Countries of Central and Eastern Europe And Its Changes in The Context of Budgetary Deficit and Public Debt to The Year 2019" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

which the younger generation satisfied not only their own material needs, but also those of their parents or even grandparents, when they were no longer capable of earning money. Soon it was clear that such a method of guaranteeing a safe old age was not enough taking into consideration countries' socio-economic development and people's living long. Such a considerable social problem encouraged creating a state system of social security for old age. The first solutions in Europe were introduced in Germany in 1889 and they were elements of a reform introduced by Otto von Bismarck. Other pension systems followed in 1908 in England, also in 1910 in France. In 1935 the first formal pension system was established in the United States. The introduced solutions were a part of the New Deal economic program developed by president F.D. Roosevelt's administration (Chybalski 2009).

Nowadays pension funds constitute a part of the social security system, separated on the side of the object, for which the term "system" is also used. The pension system, also called the retirement security system, is frequently defined in the national and foreign literature.

The retirement security system can be based on both insurance construction and supply construction. Then the advantage of the social part over the economic effectiveness becomes its key element. Public institutions are the main executor of the social objectives and values (Jackowski, Abramowicz 2007).

Examples of the definition can be quoted after Chybalski (2009): "The retirement security system (retirement security, the pension scheme) can be defined as existing institutional solutions aiming generally through establishing the rules of 1) accumulating retirement savings and 2) paying pensions at providing system participants with appropriate non-profit means of subsistence for the old age." Also "The pension system is a method of dividing the current GDP between the working generation and the generation of pensioners. From the point of view of an individual participant of the system, it is also a tool of allocation of his income in the life cycle."

The first definition places emphasis on institutional arrangements as a form of accumulating saved funds for old age. The other definition is wider, it describes the pension system as a total of sources of social security for old age including individual forms of saving.

It can be seen that the pension system by creating new pension products becomes more flexible and tailored to people's needs in both short and long period of time. The society becomes a co-creator of the system not only by participating but also by forcing its changes. For this reason, the pension system can be treated as an element of the social security created with mandatory and voluntary forms of accumulating pension capital of a public and private, individual and collective character, which is paid once or in the form of multiple payments upon the acquisition of retirement benefits.

The main criterion deciding about the form and functioning of this system is the method of accumulating funds for paying pension benefits. Taking this determinant into account, two basic models of financing pensions can be indicated – a pay-as-you-go system and the capital system (Kołosowska 2004).

The premise of the first of the two, the pay-as-you-go (PAYG) system, is intergenerational solidarity (Jedynak 2014; Ciak 2002), and here benefits paid to today's pensioners are financed from social security contributions paid by working people (Szczepański 2006; Ciak, Kołosowska 2015; Ciak, Kołosowska, Piotrowska-Marczak 2019). The pay-as-you-go system is public and it constitutes the first plane of retirement security. Its advantages and disadvantages are indicated. This system is resistant to financial crises and inflation. Through using different arrangements, retiring people are guaranteed to receive benefits permanently regardless of the economic situation of a given country. The system is sensitive to the demographic situation, and first of all to the problem of ageing society and lengthening lifespan. For this reason, among the disadvantages of the pay-as-you-go system, longer lifespan, a low birth rate, also its sensitivity to political manipulations, unemployment and the level of wages can be found.

The other pension system functioning in the world is a model based on the capital fund, which constitutes the second plane of retirement security. It is usually of a sectoral character, though in some countries it is represented by private entities, which manage contributions. Allowing private entities to become a part of the public system was a new arrangement used in Europe in first of all the pension systems of the Central and Eastern Europe countries. Contributions paid by the insured are transferred to a pension fund, which, multiplying their value, deposits them in the financial market instruments. The fact that this system is not sensitive to demographic changes in the society of a given country constitutes its advantage over the aforementioned system. The supporters of capital funding claim that it makes the system resistant to negative impact of the demographic factor and that the rate of return on investments allows much higher benefits than in the case of the pay-as-you-go system (Czepulis-Rutkowska 2000). The negative aspects of such a solution include a significant correlation with the economic situation in a given country through its strong connection with for instance unemployment, inflation and crises on the financial market. Creating mixed systems led to minimalizing the disadvantages of the aforementioned arrangements. A three-pillar structure, in which

the entity responsible for financing the contribution is the main criterion for dividing into pillars, is the most often functioning form of a mixed model (Szumlicz 2005). Two kinds of such a model exist: a classic three-pillar model and the World Bank's concept. The former is characteristic for the Western Europe countries and the majority of countries of the Organisation for Economic Cooperation and Development. The World Bank's concept was used in creating the systems in Latin America and Central and Eastern Europe. The most considerable differences can be seen in the second pillar of the used arrangements. The one in the classic system is created by the employer, who is responsible for the employees' pension fund, whereas the World Bank's concept includes private entities managing contributions paid to capital pension funds based on the state's legal regulation and operating under the state's supervision.

Pension System in the World Bank's Concept

The key solution applied in the pension systems of the countries of Central and Eastern Europe was the one developed by the World Bank. In the years 1984 – 2004 the World Bank implemented a program for supporting the building and implementing of pension systems in 68 countries. The strategy advised the governments of the countries participating in the program to create a multi-pillar system. The institution, apart from financial help supported with loans, also offered consulting in the area of pension reform and it concentrated on the following: short-term and long-term financial stability of the proposed solutions, the impact of a reform of the system on the economic growth of a given country, the level of equivalence and distributiveness of the new system, also the risk accompanying the new arrangement (Holzmann 1999, pp. 3-6).

In 1994 the World Bank recommended the many countries that they should introduce a multi-pillar pension system consisting of three planes (Żukowski 2006, p. 61) with the following parts: a mandatory managed by the state part of the pay-as-you-go system, a mandatory capital part managed by private entities, and voluntary accompanying plans of individual saving for old age. Table 1 presents the three-pillar pension system proposed by the World Bank in 1994.

Table 1: The three-pillar pension system proposed by the World Bank in 1994.

Criteria	1st pillar	2nd pillar	3rd pillar
Subjective	State	Employer or person	Employer or person
Income	civic or minimal pension	employee or individual pension	employee or individual pension
Part of the system	Base	Base	additional
Way of joining	mandatory	mandatory	voluntary
Management	Public	Private	Private
Financing	Pay-as-you-go, that is provision method	Capital	Capital
Pension formula	defined benefits	defined contributions	defined contributions

Source: Averting the Old Age Crisis. Policies to Protect the Old and Promote Growth, Oxford: World Bank Policy Research Report, Oxford University Press, 1994, pp. 15 – 16.

The first pillar was of a public character and it was mandatory. It was supposed to guarantee the basic minimum subsistence in the form of a basic, civic pension financed from taxes. It was to prevent pensioners' poverty and had a redistributive nature. The second pillar, basing on the formula of a defined contribution, included mandatory and privately managed pension schemes financed with the capital method. Individual and voluntary capital pension plans, which were supposed to provide additional benefits, constituted the third pillar. The presented World Bank's concept was implemented to varying extent in the pension systems in the Central and Eastern Europe and in Latin America.

In 2005 the World Bank presented a new concept of the multi-pillar pension system suggesting a bigger diversification of the sources and methods of accumulating pension capital. Its solutions used differentiation of the financing methods and a bigger number of entities offering retirement security. The new planes included a social part financed with taxes, employee pension plans, a mandatory part with benefits depending on earnings and additional individual security for old age, also those of informal character of pension support. In this way, the model presumed the existence of five planes, that is pillars, which were supposed to finance pensions. The new solution was expected to limit the risk of poverty of people ending their professional activity and also to use the funds accumulated during working in a more efficient way. The differentiation of the sources of pension financing was supposed to limit the possibility of

reducing pension benefits when the economic growth lowed down and had a negative impact on the growth rate of payroll fund generating lower contributions. It also included mitigating the negative effects of the demographic factor, that is the increase in the number of pensioners in relation to the number of contributing people. Such a phenomenon can be observed when the birth rate decreases, an average lifespan gets longer or emigration increases. The third factor of political nature which can concern decisions about for instance pension valorisation, lengthening or shortening the retirement age resulting in limiting public expenditure is also indicated (Holzmann 2005). Table 2 presents the pension system pillars developed by the World Bank (Holzmann, Hinz, Dorfman 2008).

Table 2: Pension system pillars created by the World Bank

Pillar	Way of pension benefits financing
Zero Pillar	Basic benefits not linked to the amount of contribution financed by the state depending on its financial condition.
First Pillar	A mandatory pay-as-you-go system linked to earnings.
Second Pillar	A mandatory capital system of defined contribution with independent management of pension capital.
Third Pillar	A voluntary system with different forms (e.g. defined contribution, individual savings, sponsored by the employer).
Fourth Pillar	A form of an informal support (e.g. by family), other formal social programs (health care or housing) and other assets (e.g. property or reverse mortgage).

Source: Holzmann R., Hinz R., Dorfman C. (2008), Pension Systems and Reform Conceptual Framework 2008, http://documents.worldbank.org/curated/en/716871468156888545/Pension-systems-and-reform-conceptual-framework.

The aim of the applied solution is to guarantee comprehensive protection for old age taking into account needs of different groups of citizens, thus limiting the risk to which the pension system is exposed. It also includes using numerous subjects like the state, the employer, an individual entity, family, subjects offered by informal social programs and methods of financing such as taxes, contributions, individual income, financial and non-financial resources (Żukowski 2006).

The zero pillar, which provides social pension in connection with having a citizenship of a given country, aims at preventing poverty among the elderly including those who did not participate in the retirement security system or whose participation was only marginal. Basic pension is provided by the first pillar, which offers a particular replacement rate financed with the pay-as-you-go method. It is mandatory, which is supposed to prevent the risk of short-sightedness and longevity, and its sensitivity to demographic and political risks must be mentioned. The second pillar includes mandatory occupational and individual as well as capital pension systems providing additional pension. Capital pension plans of a voluntary nature are included in the third pillar. The last element of the model concept takes into consideration non-financial pension security offered by family and the state, also assets, which can also constitute the source of income in old age, like a property, which enables taking reverse mortgage (Holzmann 1999).

Nowadays the five-pillar concept of the World Bank is frequently used for comparing retirement security systems functioning in different countries. It is of a particular use for evaluating their mandatory and base or voluntary elements.

General Characteristics of Retirement Security Systems in the Countries of Central and Eastern Europe

The turn of 1980s and 1990s brings political changes in most of the countries of Central and Eastern Europe, owing to which the countries changed from centrally-planned economy to market economy. Numerous changes were observed, new expectations and possibilities emerged along with new challenges which needed to be met. In order to ensure the correct functioning of the market economy system, the countries' governments were obligated to introduce a number of new laws and reforms, also to create new institutions or reform those already existing (Siporowska 2001).

Reforming pension systems carries a high political risk, and the results of right decisions, but also of mistakes and omissions in this area can be felt by whole generations.
Changes were needed in the functioning pension systems, which in the post-communist countries shared numerous features like the following (Kołosowska 2004; Adamiak, Kołosowska 2011; Adamiak, Kołosowska, Mosionek-Schweda 2012):

- public pay-as-you-go pension systems, so sensitive to demographic changes, were the only source of pension benefits;
- numerous pension privileges, e.g. lower retirement age or a more favourable formula of pension, not burdened with an additional contribution;
- pensions were easily accessible as the established retirement age was low, numerous possibilities of retiring earlier were present, invalidity pension was relatively easily accessible;
- pensions were financed from contributions paid by employer only and their amount was not linked to the amount of contributions and established according to the rule of defined benefit;
- a systematic growth of the social security contribution, including retirement security, took place;
- contributions were not registered in individual accounts of the insured;

The threat of catastrophe of public finance and unfavourable demographic changes led to the fact that the governments of numerous countries chose introducing changes in pension systems. At the end of 1990s, in other countries of Central and Eastern Europe with the view to establishing a balance between pension income and expenditure and to maintaining financial stability, the formula of a defined contribution and capital financing was adopted. To some extent, an exemplary solution for the introduced changes was the fully capital system with a defined contribution introduced in Chile in 1981 (WIeprzowski 2016). Similar arrangements started to be successively adopted in a few countries of Latin America and Central and Eastern Europe. Other reforms aimed at introducing multi-pillar pension solutions based on capital and pay-as-you-go financing (Owczarek 2011).

Considerable importance was attached to the capital part, which was supposed to trigger the development of the capital market, and create a new institutional investor in the form of pension funds. Open pension funds managed by private institutions were therefore introduced in the public system.

After several years, in the period of crisis, the imperfections of pension systems were seen and the topic of their reform returned. Hungary was the only country in which the second wave of reforms forecast a complete, and in the case of other countries (including Poland) partial, withdrawal of the solutions introduced in the first wave of reforms (Żukowski 2013, the author indicates that the second wave of pension reforms after the financial crisis in this region can be seen as an adjustment of the pension systems to current conditions only).

Structural Pension Reforms in the Countries of Central and Eastern Europe

A considerable part of the countries of Central and Eastern Europe introduced structural pension reforms. They concerned creating multi-level pension systems with a mandatory second pillar of privately managed pension funds. Taking into consideration the fact that the new second pillar replaced a part of the pay-as-you-go public system, the reforms were also called a (partial) privatisation of the retirement security. Hungary (1998) Poland (1999) were among the first countries which introduced these reforms. Latvia (2001), Bulgaria (2002), Croatia (2002), Estonia (2002), the former Yugoslav Republic of Macedonia (2003), Slovakia (2005) and Romania (2008) followed. Only the Czech Republic, Lithuania and Slovenia keep their "Bismarckian" pay-as-you-go systems without the mandatory pension funds (Żukowski 2013).

The pension systems in the countries of Central and Eastern Europe from before the reforms can be specified as two-pillar systems. The first pillar, called a common one, based on the pay-as-you-go system. The second pillar included all voluntary forms of accumulating pension capital creating an informal, non-institutionalised and not so popular capital system.

The aim of the conducted reforms of the pension systems in our part of Europe was to introduce a three-pillar system. The first pillar is still the pay-as-you-go system, but in a few cases combined with a defined contribution, and not like before the reforms with a defined benefit. The second pillar, the capital one, is created by pension funds, the membership in which is mostly mandatory. The third pillar, also a capital one, is a voluntary, more or less formalised and institutionalised form of accumulating of pension capital (Chybalski 2009). The constructions of pension systems in the selected countries of Central and Eastern Europe from the first period of the reforms are presented in table 3.

Table 3: Constructions of pension systems in the selected countries of Central and Eastern Europe

Country	First pillar	Second pillar	Third pillar
Bulgaria	defined benefit system	mandatory pension funds	voluntary pension funds, employee pension plans managed by pension funds (also classified as the fourth pillar)
Croatia	defined contribution system	mandatory pension funds	voluntary pension plans offered by pension funds, trade unions or employers
The Czech Republic	defined benefit system (since 2010 defined contribution system	-	voluntary pension plans managed by pension funds
Estonia	defined benefit system	mandatory pension funds	voluntary pension funds or pension insurances offered by life insurance companies
Hungary	defined benefit system	mandatory pension funds	voluntary pension funds or pension accounts managed by banks or investment advisors (also classified as the fourth pillar)
Latvia	defined contribution system	mandatory pension funds	voluntary pension plans managed by loan institutions, life insurance companies
Lithuania	defined contribution system	voluntary pension funds which a part of contribution is transferred from the first pillar	voluntary pension funds
Poland	defined contribution system	mandatory pension funds	voluntary employee pension plans or individual pension accounts (also classified as the fourth pillar)
Romania	defined benefit system	since 1.01.2008 mandatory pension funds	functioning since 2007 in the form of employee pension plans
Slovakia	defined benefit system	mandatory pension funds	voluntary pension plans managed by pension funds, banks and life insurance companies
Slovenia	defined benefit system	Pension schemes (mandatory for selected groups of professions and voluntary for the other ones) managed by insurance or pension funds	voluntary pension plans managed by insurance companies or pension funds

New Pension System in Poland after 1999

The reform of 1999 was the crucial element of the process of creating a new pension system and its introduction was justified by the following (see: *Bezpieczeństwo dzięki różnorodności. Reforma system emerytalnego w Polsce* 1997):

- a threat of a disaster in the social insurance finance and in the public finance as a result of demographic changes that were to occur after 2010
- a large share of the budget in financing pension benefits
- a poor condition of the social insurance finance
- heavy burdening of employers with the labour cost
- a low level of benefits

As early as at the very beginning of the reform implementation, a lot of economists pointed out the existence of numerous unknown factors. Jan Czekaj claimed that not completely specified financial results of the reform in relation to the budget caused concern, also the pension funds' actual ability to maintain and multiply the value of the funds obtained from pension contributions raised reservations (Czekaj 1997). Unequivocal specification of the financial consequences of introducing the new system appeared particularly difficult due to the considerable number of variables, such as the activities rationalising the existing system and their effectiveness, the rate of GDP growth, the rate of the labour productivity growth, the impact of the reform on the economic growth and the shadow economy absorptions.

The alterations that have occurred in the social insurance system since 1st January 1999 have caused the growth in the expenditure borne by the state budget. It has been triggered by the following (Kołosowska 2004):

- transferring of a part of social insurance contributions to Open Pension Funds (20% of paid contribution),
- lowering social insurance contribution for the highest paid people due to the fact that contributions are deducted from the monthly income up to 2.5 of an average salary,
- an employer having the possibility of transferring a part of contribution (up to 7%) to an employee pension plan, the results of which are discussed later,
- introducing the obligation to pay social insurance contributions from the state budget (e.g. for employees taking child care leave, army soldiers),
- the increase in the costs of ZUS functioning resulting from among other things introducing a new information management system, correcting errors in the information management system and other things.

Considering the loss of a part of contribution transferred to Open Pension Funds (OFE), the Social Insurance Fund's (FUS's) liquidity ought to be secured through increasing the aids from the national budget. The situation is worsened by the fact that the existing deficit increased in connection with the reform being introduced. Since 1999 the amounts from the state budget transferred to the Social Insurance Fund have been increasing. In 1998 the aids amounted to about PLN 6.8 billion, a year later it amounted to PLN 9.6 billion, and in 2001 to over PLN 21 billion. The close-end grant and supplementary subsidy to the Social Insurance Fund amounted to as much as PLN 27 billion in 2002. These are the amounts that supplement the FUS funds on account of transferring a part of the funds to Open Pension Funds (OFE), exceeding the thirty times of the contribution assessment basis for the compulsory social insurance and supplement of funds for payment of benefits.

Over the years, other essential activities structuring the Polish pension system followed, and they were as follows (Jedynak 2014):

- re-establishment of the special pension system of uniformed services, excluding them form the standard pension system in 2003
- passing an amended act on the employee pension programs (PPE) and introducing individual retirement accounts (IKE) in 2004
- by way of trade unions' protests and pressing preferential pensions for miners were introduced in 2005
- the introduction of changes in the functioning of the second pillar in 2011
- raising and equalisation of the retirement age in 2012
- modification in the functioning of the Open Pension Funds and the possibility to transfer a part of funds from the Open Pension Funds (OFE) to the Social Insurance Institution (ZUS) in 2014

Changes in the Architecture of the Polish Pension System after 2012

Another significant stage of creating of the Polish pension system in 2012 was the decision to raise the retirement age to 67 and its equalisation for men and women. Until 2012 the retirement age was 60 for women and 65 for men, which corresponded to the retirement age in the 'old' system. The Act of 11th May 2012 stated that the modifications would be gradually introduced from 1st January 2013, raising it every three months by one month (the Act of 11th May 2012 *to amend Act on Old-age and Disability Pensions…*). Through such assumptions, men retiring after 2020 and women retiring after 2040 will reach the age of 67. However, there appear some derogations from this rule, such as among other things early retirement for people born before the 1st January 1969 who did not join OFE, bridging pensions, uniformed service pensions, miners, etc.

In 2014 again on grounds of a bad condition of the public finance and the poor performance of the second pillar, another correction in the pension system was introduced. The serious risk of exceeding the so-called second safety threshold (a situation when the public debt exceeds 55% of GDP) was an obvious symptom of a bad condition of the public finance. An annual deficit in FUS constituted only a part of burden to the budget that led to the difficult situation of the public finance. The claims of the poor performance of the second pillar concerned, above all, the functioning of the Open Pension Funds. The issues raised related to among other things the rationality of OFE purchasing the State Treasury bonds. (The Treasury borrowing requirements, connected above all with the necessity to cover the deficit in FUS, were in this way financed. Thus, through the State Treasury bonds being purchased by

OFE, other costs of transferring funds within the pension system were generated.) Moreover, the problem also concerned the obligation to transfer a part of contributions to OFE, the effectiveness of the mechanism of competition between individual OFE and also the limits of investing in particular categories of assets imposed on OFE. Additionally, the issues of relatively high charges collected by OFE caused uncertainty (Jedynak 2014, p. 56). Finally, by virtue of the Act of 6th December 2013 on the amendment of certain acts in connection with the determination of the rules for payment of pension from resources collected in the Open Pension Funds, the following corrections in the pension system were implemented (the Act of 6th December 2013 on the amendment of certain acts…):

- the transfer of the State Treasury bonds owned by OFE to ZUS and also their redemption with a simultaneous entry resulting from the rights of insured persons on capital sub-accounts in ZUS
- specifying the amount of contributions transferred to OFE as 2.92% of the basis of assessment
- enabling insured persons to make a choice concerning the participation in OFE
- the abolition of the mechanism of the minimum rate of return and the change of investment limits of OFE
- modification in the system of charges collected by OFE

In the period from 1st April to 31st July 2014, the members of OFE made a decision whether the contribution amounting to 2.92% of the basis of assessment is to be transferred to OFE. The members were asked to decide whether the part of the contribution was to be still transferred to OFE or recorded on a ZUS sub-account along with already transferred to this sub-account contribution amounting to 4.38%.

Contributions paid to ZUS are subject to an annual indexation, i.e. they are multiplied by an indexation ratio, contributions transferred to Open Pension Funds are multiplied through investments in financial markets. The indexation of the funds in ZUS pension accounts depends on the inflation and the increase in wages in the economy. The funds accrued on sub-accounts are subject to an indexation by a ratio equal to average annual dynamics of GDP in the last five years.

Contribution amounting to 19.52% of the contribution assessment basis, i.e. of gross wage, are paid to pension insurance.

From 1st February 2014 to the end of June 2014 the amount of pension insurance contribution was divided as follows:

- 12.22% recorded on a ZUS account
- 4.38% recorded on a ZUS sub-account
- 2.92% paid to an account in an Open Pension Fund.

Since July 2014, depending on the choice made by an insured person, a part of a pension insurance contribution amounting to 2.92% has been paid by the Social Insurance Institution to a selected by an insured person Open Pension Fund (OFE) or recorded on a person's ZUS sub-account (total of 7.3%).

The present form of the national pension system after all the changes and corrections is presented in table 4.

The introduction of prohibition on investments in treasury bonds was also connected with the changes in Open Pension Funds. It entailed the necessity to transfer the funds invested in debt securities to Social Insurance Institution (*Appeals taken on decisions by ZUS 2014*).

Benefit payment was another amended area. As a result of the enforced Act, pensions were supposed to be paid by one institution. The amount of the future benefit would be calculated by dividing the value of funds accumulated in an account by an average further life expectancy. The main change concerns however an introduction of gradual transfer of funds accumulated in Open Pension Funds to the Social Insurance Fund. The process begins 10 years before a given person reaches the minimum retirement age. In this period of time, the whole contribution is transferred to the Social Insurance Institution (*Appeals taken on decisions by ZUS 2014*). The previous transfer of funds from OFE to ZUS is called a "security slide".

The changes also concerned the third pillar of the retirement security, and more precisely its part, IKZE, that is Individual Retirement Protection Account. From the moment of the introduction of this form of voluntary saving for old age, contributions to IKZE were exempted from the income tax unlike payments, which were taxed. The changes introduced in 2014 concerned a reduction of the tax rate for payments from IKZE. The preferential tax rate was to encourage using IKZE. As a result of those changes, "a lump-sum tax" of 10% of payments from IKZE accounts was introduced" (Rutecka 2014).

In the following year, further changes in the Polish pension scheme were introduced. On 1st May 2015 the Act of 5th March 2015 amending the Act on Old-age and Disability Pensions from the Social Insurance Fund was introduced.

Pension System Functioning after 2017

Citizens' lack of adequate awareness and their dissatisfaction with the current pension scheme constituted one of the main reasons for developing and implementing further changes, whose objective was to improve the existing system. In 2017 more modifications regulating provisions entering into force on 1st October 2017 were introduced.

A part of the society did not conceal dissatisfaction when the retirement age was increased in 2013, therefore during the preparation of new regulations concerning the pension scheme, the issue of the minimum retirement age was the main concern. The previous retirement age, that is age 60 for women and age 65 for men, was restored. Those changes also involve the rules concerning pre-retirement protection. The four-year period of protection against dismissal for women is set to age 56, and for men to age 61 (Piec-waznych-zmian-w-emeryturach-w-2017-rokuobnizony-wiek.html 2017). It should be added that currently women are entitled to a minimum pension after 20 years of professional activity and men after 25 years.

The introduced changes also concerned the second pillar of retirement security, that is OFE. The current regulations specify that the majority of funds accumulated in the Open Pension Funds should be transferred to Individual Retirement Protection Accounts (IKZE). The remaining funds will be transferred to the Demographic Reserve Fund.

In July 2016 the Capital Building Program, one of the pillars of the Strategy for Responsible Development, was presented by the Prime Minister Mateusz Morawiecki. It states that the Open Pension Funds should be transformed into investment funds – 75% of the funds should be transferred to Individual Retirement Protection Accounts (IKZE). The remaining 25% is to be transferred to the Demographic Reserve Fund, whose management is to be taken over by the Polish Development Fund (PFR).

The first objective of the Program is to create Employee Capital Programmes (PPK), which would constitute "the government's plan for the citizens to save systematically" (morawiecki-i-plan-budowy-kapitalu-co-sie-stanie-zofe-ike/m6v81r6 2017).

Employee Capital Programmes are supposed to become an additional source of saving for retirement, to which funds would be transferred by both an employer and an employee. They were to be introduced in 2019. Public Real Estate Funds, which would focus on investing in property, were a novelty in connection with the programme.

In connection with the changes introduced on 1st October 2017, further development of Employee Pension Programs (PPE), a type of organised, group and systematic saving for future retirement, was announced. Currently they are created by employers, who finance the basic contribution, which is transferred to a selected financial institution managing it until its payment.

In 2019 a final liquidation of pension funds (OFE) was announced and two alternative solutions to the problem of the remaining funds accumulated in the Open Pension Funds were presented. According to the draft bill, each of the 15.5 million Polish citizens with an account in OFE will have to decide whether all the pension fund savings will go to a

private Individual Retirement Pension Account (IKE) or to FUS. However, all those who will decide to transfer the retirement savings from OFE to IKE will have to pay 15% of so called transformation fee. Transferring money from OFE to IKE or to FUS is supposed to take place in January 2020. In the case of the latter, all pension contributions (19.52%) will go to ZUS, and the whole state pension will come from one source, that is from FUS.

Situation of the Polish Public Finance in the Context of Changes in the Pension System in the Years 2010 – 2019

During a crisis employment shows declining trends, and so do incomes from work. It results in a decrease in revenues from contributions (social insurance contributions are smaller) and in an increase in pension expenditure for disability pensions and earlier pensions (Kalina-Prasznic 2010).

The pension system formed in the last years, functioning within the framework of the public finance, has greatly influenced the financial situation of this sector. Both the earlier (2014) changes in OFE and the current changes (OFE liquidation, the introduction of PPK) in this area have an impact on the whole government sector. It is therefore useful to analyse the impact on the state budget deficit and the public debt and the public debt-to-GDP ratio. The analysis will start from the financial situation of the Social Insurance Fund (FUS) and of the state budget. Table 5 presents selected indicators in connection with the functioning of the Social Insurance Fund in the years 2010 – 2019.

Table 5: Situation of FUS in the years 2010 – 2019 (in PLN billion)

Specification	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019

Source: Own study based on: *Egzekucja należności z tytułu składek na ubezpieczenie społeczne. Informacja o wynikach kontroli*, *Sprawozdanie z wykonania budżetu państwa za lata 2010 - 2018* (2019) NIK, Warszawa; *Sprawozdanie z wykonania budżetu państwa za lata 2010 – 2019,* Council of Ministers.

The analysis of the data included in table 5 leads to drawing the following conclusions.

Firstly, FUS revenues to 2015 were insufficient to cover current expenditure. From 2010 to 2014, a growing deficit in FUS budget despite considerable funds in the form of a budget grant transferred annually was visible. Those funds constituted on average in that period 26% of the total FUS income. After 2014 a reverse tendency manifested itself. In 2016 FUS reached a small financial surplus, which in 2017 grew significantly to PLN 43.1 billion. It was the first such a considerable surplus achieved by FUS. IN the following year 2018 the surplus decreased significantly. In 2019 a deficit appeared again.

Secondly, every year FUS was co-financed with a budget grant (23.3% of its total income), whereby the highest contribution of a grant in FUS income was observed in 2010 (31.9%), and the lowest in the years 2017 – 2018 (15.7% and 15% respectively). It should be underlined that a lower demand for a state budget grant in those years resulted from a beneficial financial situation of FUS, which was influenced by the economic situation and prosperity on the labour market (*Sprawozdanie z wykonania budżetu państwa ..., 2019).*

Thirdly, FUS income is supplemented by funds from the Demographic Reserve Fund. In the years 2010 – 2014 they varied and ranged from PLN 2.5 billion to PLN 7.5 billion. In the following years (2017 – 2018) funds from the Demographic Reserve Fund were not used.

Fourtly, FUS permanent deficit was additionally supported with a loan from the budget outgoings, which means the flow of funds outside the budget. Such funds do not contribute to the increase of the state budget. FUS liabilities arising out of this amounted to PLN 45.3 billion at the end of 2016 (compared with an even higher amount in 2015). The reduction of FUS liabilities resulted first of all from the amortisation of interest-free loans from the outgoings of the state budget First, on the 1st January 2017, on the basis of the act of 2nd December 2016 on particular solutions for the realisation of the budget act for the year 2017, loans from the state budget in the years 2009 – 2014, whose period of repayment was due to expire on 31st March 2017 (PLN 39.2 billion) were cancelled. Then pursuant to the act of 8th December 2017 on particular solutions for the realisation of the budget act for the year 2018, on 1st January 2018 loans for FUS from the state budget in the years 2014 – 2016, whose period of repayment was due to expire on 31st March 2018, were cancelled (PLN 7.2 billion).

Fifthly, the necessity to transfer a part of pension contribution from ZUS to OFE resulted in a systematic loss of social security contributions in FUS. This loss was reimbursed by the state budget in the form of funds transferred to FUS in an amount equivalent to contributions for OFE. Their amount was different and in the years 2010 – 2018 it ranged from PLN 22.3 billion to PLN 2.3 billion. The fact that when in 2014 the bond part of OFE was transferred to ZUS (and amortised) and not many future pensioners stayed in OFE contributed to such a reduction. A part of people decided to stay in ZUS, in connection to which ZUS received funds from a transfer with so called "retirement slider". In 2019 it increased to PLN 3.4 billion.

Sixthly, despite the slight improvement of the situation of FUS, the earlier imbalances will come back (though only at the level of PLN -0.4 billion) as according to the information included in the publication after controls of the Supreme Chamber of Control, debit balance of FUS is supposed to increase in the forthcoming years and amount to PLN 56.4 billion in 2020, PLN 64.5 billion in 2025 (*Egzekucja należności z tytułu składek ...,* 2014). Also, worrying demographic indicators concerning the birth rate, a systematic growth in the number of people at the retirement age and emigration are of permanent character and will significantly worsen the financial situation of FUS.

Seventhly, the Covid-19 pandemic introduced in Poland in March 2020 unprecedently disturbed the functioning of economies all over the world, also in Poland. The effects of the pandemic are having (and will have) a negative influence on the FUS's financial situation. As the information on the FUS's financial situation presents, after two quarters of this year (2020), the expenditure is covered with contributions and derivatives only in 70% and this level is the highest since 2016 (*Informacja o sytuacji finansowej FUS…*, 2020).
It should be emphasised that the mentioned activities adversely affect the public finance, the state budget in particular. They also cause an increase of the borrowing requirements of the whole public finance sector. The government's permanent help for FUS (though reduced in recent years) has resulted in an imbalance in the state budget, which requires additional source of financing and increased borrowing needs of the state (Ciak 2012; Redo, Wójtowicz, Ciak 2018, Ciak, Kołosowska, Piotrowska-Marczak, 2019). The issues of income, expenditure and the government budget balance are presented in table 6.

Table 6: Income, expenditure and the government budget balance in Poland in the years 2010 – 2019 (in PLN billion)

Specification	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Income	250.3	277.6	287.6	279.2	283.5	289.1	314.7	350.4	380.1	400.5
Expenditure	294.9	302.7	318.0	321.4	312.5	331.7	360.8	375.8	390.5	414.3
Deficit	44.6	25.1	30.4	42.2	29.0	42.6	46.1	25.4	10.4	13.8

Source: Own study based on: The Minister of Finance on the State Budget Execution in the years 2010 – 2019.

In the period of time indicated in the table, significant divergences between the income and expenditure can be observed. The income tended to increase (apart from 2013), and the expenditure increased throughout he whole period (except 2014 with a smaller costs of the public debt servicing resulting from the amortisation of the bond part of OFE). The higher expenditure in the whole examined period resulted in a budgetary deficit amounting to from PLN 10.4 billion in 2018 to PLN 46.1 billion in 2016.

It should also be underlined that the budgetary deficit represented the highest share of the deficit of the whole public finance sector. It was significantly intensified by the requirements of the social insurance sector. For instance, in 2013 the budgetary deficit and the social insurance sector deficit amounted to PLN 74.1 billion. In 2018, owing to a better situation both in the social insurance sector (including FUS) and in the state budget (a low budgetary deficit), the

balance of the whole public finance sector was positive and amounted to PLN 1.3 billion (a surplus of 0.1% of GDP). *(Sprawozdanie z wykonania budżetu państwa…, 2020)*

As it was mentioned earlier, the loss of income from the social insurance contributions causes an increase in the state budget deficit. Additionally, its amount was influenced by the costs of the servicing of public debt for OFE. As indicated in the source literature, without the need to finance additional requirements for OFE (to finance earlier contributions to OFE), the debt to GDP ratio would have been much lower and even in the crisis years, i.e. 2009 – 2012, it would have amounted to 40% of GDP (*Przegląd funkcjonowania systemu* … 2013), and its amount would not have exceeded PLN 1 trillion (*Na liczniku długu* … 2015). Currently, the public debt has risen above PLN 1 trillion despite the mentioned above activities undertaken by the public authorities in the context of the acquisition of PLN 153 billion of OFE funds in 2014.

Table 7 presents the costs of the state debt servicing in the years 2010 – 2019.

Table 7: Costs of the state debt servicing in the years 2010-2019

	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Costs of the state debt servicing in total (in PLN billion):	34.1	36.0	42.1	42.5	34.5	29.2	32.1	29.6	29.5	27.3
- national:	26.8	27.1	31.8	32.3	24.8	19.4	22.2	20.7	21.5	19.7
- foreign:	7.4	8.8	10.3	10.1	9.6	9.7	9.8	8.9	8.0	7.6
Costs in total as % of GDP:	2.4	2.3	2.6	2.6	2.0	1.6	1.7	1.5	1.4	1.3
Costs in total to state budget expenditure ratio (%):	11.6	11.9	13.2	13.2	11.0	8.8	8.9	7.9	7.6	6.6

Source: Own work based on: Dług publiczny. Raport roczny 2018 (2019), Ministry of Finance, Warszawa, p.93; Sprawozdanie z wykonania budżetu państwa za okres od 1 stycznia do 31 grudnia 2019r. (Reports on implementation of the state budget from 1st January to 31st December 2019), the Council of Ministers, Warszawa 2020, p. 78.

Taking into account the data included in table 7 , a slow improvement in the costs of the public debt servicing, particularly in the context of costs in total to GDP ratio and in relation to the state budget expenditure can be seen. However, the upward trend of the public debt itself in 2018 and for the forthcoming years (i.e. 2019 – 2021 – PLN 1.093 billion, PLN 1.131 billion and PLN 1.142 billion respectively) should not be neglected.

Conclusion

The aim of the article was to show the changes in the pension systems of the countries of Central and Eastern Europe, and most of all in the Polish national pension system, and their impact on the public finance. In each of those countries, reforms similar to those conducted in Poland in 1999 took place. Currently, the dispute concerning the role of the state and the market in the area of old age security can be heard again. Because of its construction, the current pension system becomes sensitive to crisis situations appearing in the changing environment. New solutions aiming at financing the current needs of the state budget are sought in order to decease deficits.

The actions taken so far by the governments, whose objective is to limit and even suspend the transfer of contributions to capital funds, cannot be described as reformative; they are rather short-term solutions of the problem of deficit in the government budget. They improve the situation of the pay-as-you-go part of the public pension system only temporarily threatening to undo the reform architected so painstakingly several years ago. The need to introduce necessary corrections in the system is not negated and acceleration of pro-development structural reforms in economy which would contribute to a lasting improvement of the state of the public finance should be demanded as numerous distinguished economists indicate. The changes aiming at introducing employee capital programmes can mitigate the negative tendency to reduce the future pensions only to some extent.

The conducted analysis indicates an unfavourable situation both in the state budget (budgetary deficits observed every year of various levels before 2019 and in 2020, according to the novelised budget act for 2020, the level of even PLN 109 billion: the Draft act *amending the budget act for 2020…*) and in the Social Insurance Fund before 2016, which

was not able to satisfy the needs of the new social insurance system (additional loans from the state budget). After 2017 an short-term improvement can be seen. The improvement resulted on the one hand from a good economic situation, on the other hand from a good situation on the labour market. Moreover, owing to the amortisation of FUS's liabilities resulting from loans from the state budget (from expenses) for the years 2009 -2016, FUS's liabilities decreased considerably. It should be underlined, that the demographic situation observed in Poland for a long time will have a negative influence on FUS's finance. Even now current contributions for social insurance are not sufficient to cover expenses connected with paying pensions. A higher number of recipients and a smaller number of contributors will build up the imbalance in the years to come and thus, according to the information included in the publication of the Supreme Chamber of Control, FUS's debit balance is expected to grow in the forthcoming years and amount to PLN 56.4 billion in 2020, and to PLN 64.5 billion in 2025 (*Egzekucja należności z tytułu składek…* 2014). Taking into account the situation with the Covid-19 pandemic, the debit balance can be even higher.

It means that the future generations will have to deal with the negative effects of the current situation and the effects of introducing a system in which – during the several decades of the transition period – the cost of the pension system functioning is doubled through financing current pensions and funding of capital pillar of social insurance. To what extent the cost for the future generations will have the form of higher taxes, smaller public expenses or a higher public debt will depend on the fiscal policy pursued in the futures**.**

The Russian Market Waste: Trends Analysis

Natalia A. SHCHUKINA

Plekhanov Russian University of Economics, Moscow, Russia, e-mail: shchukinan@yandex.ru
Financial University under the Government of the Russian Federation, Moscow, Russia; e-mail: shchukinan@yandex.ru

Abstract

The research is devoted to the analysis of the waste processing industry in Russia. The volume of waste generation and processing in the EU and Russia was estimated. In Russia, there is a tendency to increase the volume of generated production and consumption waste. Most of the generated waste is industrial waste. Coal mining is the most waste-intensive of all industries. In 2019, this industry generated 5.2 billion tons of waste, or 67% of all industrial waste in the country. It should be noted that most of this waste is reused. The main method of waste disposal in Russia is landfill, while global trends are focused on recycling and backfilling. For the waste trade market, the most significant direction in Russia can be considered the waste paper market. Despite the global trends of decrease in the volume of MSW formation per capita, the accumulation rate in Russia tends to increase. This is due to an increase in the level of housing improvement and an increase in the number of packaging materials. About 10% of municipal solid waste is recycled annually. However, changes in the waste processing industry in Russia create prerequisites for the development of the waste management market.

Keywords: waste, waste management, recycling, municipal solid waste, waste market.

JEL Classification: Q53; Q56.

Introduction

The amount of waste generated in the world is increasing every year. Waste is a significant problem for all countries of the world. Unfortunately, the lack of available and comparable data does not always allow for a complete and reliable assessment of waste-related problems. Waste accumulates as a result of all sectors of the economy and is usually considered an unavoidable by-product of economic activity. The impact of waste on the environment, resources, and human health depends on both its quantity and nature. The environmental burden of waste generation and management includes emissions to the atmosphere, water, and soil that have potential impacts on human health and the environment. Most of the city's waste is disposed of, which leads to a significant burden on the environment. At the same time, only a small part of the waste goes to recycling. According to a world Bank study [Kaza & etc., 2018], about 2.01 billion tons of waste was generated worldwide in 2016.Around the world, almost 40 percent of waste is disposed of in landfills. About 19 percent undergoes materials recovery through recycling and composting, and 11 percent is treated through modern incineration [Kaza & etc., 2018].

There are various methods for dealing with waste, such as burying, landfilling, incineration, and recycling. Recycling is considered a more promising method. If you compare storage and incineration, incineration causes less damage to the environment. On the other hand, the economic benefits of recycling are lost during incineration. Despite constantly developing and implementing new technologies for waste disposal and recycling, their storage at the landfill remains a common practice for most countries.

Trends in waste management in European countries

Despite the economic difficulties faced by many States, the steady trend of increasing waste volumes in the world continues. The volume of TCL generation exceeded 1.3 billion tons. At the same time, according to the report Of the Department of Urban Development of the World Bank [Kazan & etm., 2018], by 2025 the number of MSW generated in the world will increase to 2.2 billion tons. The main contribution to this growth will be made by fast-growing cities in developing countries. Most of the consumption waste is generated by countries with developed economies. Thus, according to the world Bank report [Kazan & etm., 2018], the organization for European Economic Cooperation (OEEC) countries account for 44% in the structure of municipal solid waste generation. The

Cite this Article as: Natalia A. SHCHUKINA“ The Russian Market Waste: Trends Analysis” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

dependence of waste generation on the level of well-being is confirmed by international experience. The specific indicator of total municipal waste generation per unit of GDP in the EU countries is shown in figure 1.

Figure 1: Generation of waste excluding major mineral wastes per GDP unit in 2016 and 2018
Source: Author

There is a direct correlation between the country's economic level of development and waste management. In a number of European countries, the share of waste recycling exceeds 60%. Figure 2 shows the trend of waste management in the EU countries: developed countries process a large share of waste, while countries in southern and Eastern Europe practice disposal.

Figure 2: Waste management structure in the European Union countries in 2017

Source: Author

According to various estimates, the volume of municipal solid waste generation in the world currently amounts to approximately 3.6 million tons per day and may grow to more than 6 million tons per day by 2025. For some countries, the amount of municipal solid waste collected per capita in 2018 reached the following values (kg/person): Austria – 579, Bulgaria – 407, Germany – 615, the Netherlands – 511, the United Kingdom – 463. In some countries, there are trends towards stabilization and a slight decrease in the volume of MSW [Eurostat, 2020]. Thus, since 2010, some countries (Belgium, Hungary, Slovenia, Finland, Estonia, etc.) have experienced a decrease in the total volume of MSW per capita. In Russia, the situation is the opposite. Every year, Russia generates more than 60 million tons of MSW, which is about 480 kg of waste per person per year. The average specific volumes of MSW generation in EU countries are shown in Figure 3 [Eurostat, 2020]. According to the data obtained, high-income countries are characterized by a large share of waste generation. Figure 3 shows the number of municipal waste per capita in EU in 2018.

Figure 3: Generation of municipal waste per capita in EU in 2017-2018

Source: Author

European countries analyzed the extent of environmental damage caused by waste disposal, calculated the cost of lost resources, added huge areas occupied by waste, and concluded that waste management policies should be directed towards their reuse and recycling. To bring to the processing of the developed countries are introducing incentive or restrictive measures. The incentive consists in preferential taxation. The sale of waste by the population is not taxed in any developed country in the world [Mitina, 2020].

The state policy of most countries is focused on minimizing the generation and accumulation of waste. Developed countries consider waste recycling as one of the sources of profit. The global waste market is estimated at $ 320 billion, of which 20% is imports and exports, which for most countries is a key element of the smooth operation of the waste processing industry. The main players in the global waste market are the USA, EU countries, Japan and China [Wang, Chao and etc., 2019; Kellenberg, 2015; Wen Xu and etc., 2020]. In 2019, the world export of waste paper amounted to $46.665 billion). Exports of the world market of plastic waste amounted to $4.041 billion, glass

waste is at the level of $0.408 billion; rubber waste – $0.234 billion. European countries deliver about 87% of the collected plastic via Hong Kong to China. Japan and the US also export their plastic waste to China [ITC Trade Map, 2020]. The dynamics of world trade in scrap and scrap waste is shown in Table 1.

Trends in waste management in Russian Federation

At the moment, the waste management industry in Russia is at the stage of formation. Solving the problem of environmental pollution by production and consumption waste is a complex of serious problems that require a systematic solution. The need to return production and consumption waste to circulation is obvious both from the point of view of environmental safety and economic feasibility. In the last few years, significant changes have been introduced to the legislation and regulations of the Russian Federation concerning the sphere of waste processing. The strategy of industrial development for processing, recycling and neutralization of wastes of production and consumption for the period up to 2030 [Industrial development strategy, 2018] provides for increasing the share of recycled and disposed waste in total waste from 59.6% in 2016 to 86% by 2030; increase the share of MSW sent for processing in the total volume removed from the field of education almost 10 times from 8.9% in 2016 and 80% by 2030. The fundamentals of the state policy in the field of environmental development of the Russian Federation for the period up to 2030 provide for the introduction of innovative resource-saving, environmentally safe and efficient technologies based on a single technological platform; sustainable use of renewable and rational use of non-renewable natural resources; stimulating investment in the introduction of resource-saving technologies, production of environmentally friendly products, research and development, etc.

Statistics can track the dynamics of waste generation and disposal/disposal. However, it should be noted that the system of state statistical observation covers only legal entities and individual entrepreneurs who carry out activities related to the management of production and consumption waste. The volume of waste generation, taking into account the population and other enterprises in the Russian Federation as a whole, has higher values.

According to official statistics [Rosstat, 2020], in 2019, the country generated 7,751 billion tons of industrial and household bypasses, or 144.65 kg per person per day. This is 6.7% higher than in 2018 and more than 2 times higher

than in 2009. In 2019, 3.882 billion tons of waste were disposed of and neutralized, and 3.801 billion tons were sent for storage or disposal, which is 49% of the volume of all generated production and consumption waste. Most of the generated waste is industrial waste. Therefore, the dynamics of changes in the volume of waste generation is closely dependent on the situation in production.

According to statistics, the volume of recycling and disposal of industrial and consumer waste has increased significantly in recent years. Compared to 2009, it increased by 2.34 times. Since the growth rate of this indicator is faster than the growth rate of generated waste, we can say that the situation in the waste management industry is changing for the better. A comparison of the volumes of waste disposal and disposal with the volumes of waste generation shows that the ratio of these indicators increased from 40% in 2006 and 2013 to 60% in 2016. However, in 2018 and 2019, it fell again to 53% and 50%, respectively. At the same time, the volume of waste sent to landfills for storage and disposal has shown a negative trend over the past three years. If in 2015 the volume of waste sent to landfills for storage and disposal amounted to 2.333 billion tons, in 2016 this figure was 2.609 billion tons, and in 2017, 2018 and 2019 – 3.204 million tons, 3.575 million tons and 3.801 million tons, respectively. Therefore, we cannot yet talk about reducing the harmful impact on the environment. Figure 4 shows the dynamics of production and consumption waste generation, utilization, and disposal.

Over the period from 2003 to 2019, the amount of waste generated annually increased from 2.613 billion tons to 7.751 billion tons, or 2.97 times (figure 5). In recent years (2017-2019), there has been an increase in waste generation by 14.3%, 16.8% and 6.7%, respectively. The change in the share of total waste generation per GDP unit was characterized by similar trends. The total increase in the specific indicator from 2011 to 2019 was 32.9 tons per 1 million rubles, or 62.5%. The dynamics of production and consumption waste generation in the Russian Federation and the specific waste generation per GDP unit (in 2016 prices) in 2011-2019 are shown in Figure 5.

In the territorial context, the largest amount of waste generated in 2018 was recorded in the Siberian Federal district (4809.6 million tons, or 66.18% of the total amount in the country), and the smallest – in the North Caucasus Federal district (3,230 million tons, or 0.04 %) (figure 6). Such large volumes of waste generation in the Siberian Federal district are associated with mining (coal) in the Kemerovo region, the main coal-producing region of the Russian Federation. The structure of production and consumption waste accumulation in the Russian Federation varies slightly from year to year, as can be seen in Figure 6.

Figure 6: Distribution of production and consumption waste generation by Federal districts in 2017 and 2018

Source: Author

In all Federal districts for the period 2011-2018, the volume of waste generation increased, with the largest increase observed in the far Eastern (from 364.371 million tons to 1,230.454 million tons, or 238%), North Caucasus (from 1,636 million tons to 3,230 million tons, or 97%) and southern (from 16.457 million tons to 27.732 million tons, or 69%) Federal districts. In the Volga Federal district, the volume of waste generation in 2015 decreased from 149.131 million tons, but in 2017 and 2018, the growth trend resumed and for the entire period from 2011-2018, the increase was 6.171 million tons, or 4%. Indicators of the dynamics of production and consumption waste generation for 2011-2018 in the context of Federal districts are presented in Table 2.

In terms of economic activity type, the largest volume of production and consumption waste generation in 2019 was accounted for by the type of economic activity "mining" – 7257 million tons, or 93.6% of the total amount of waste generated. The share of waste by economic activity type "manufacturing industries" in the total volume of waste generation was 3.8% of the total amount of waste, or 296.4 million tons of waste. The share of the economic activity type "agriculture, forestry, hunting, fishing and fish farming" in 2019 it accounted for 0.6% of the total amount of waste generated (47.7 million tons of waste). According to the economic activity type "electricity, gas and steam supply; air conditioning; water supply" and "water supply; water disposal, waste collection and disposal, wastewater disposal activities" in 2019, 0.4% of the total amount of production and consumption waste (30.9 million tons of waste) was formed. The dynamics of production volumes, as well as the volume of utilization and neutralization of production and consumption waste for 2016-2019 by economic activity type is presented in Table 3.

The foreign trade volume is an important indicator of the Russian waste processing market. As can be seen from table 4, for the waste paper market, foreign markets are a significant supply direction (in 2019, waste paper raw materials were exported for $50,225 million). For other markets, the share of deliveries to foreign markets is no less significant. However, significant volumes of processing are accounted for by imports. From the point of view of the cost of secondary raw materials and the demand for it, the plastics market is extremely attractive for processors. However, the lack of a well-established system for collecting polymer waste causes a low share of their recovery and disposal [Volkova, 2018]. Among the wastes considered in this study, waste paper is not the most profitable, but the most affordable raw material. For this reason, the waste paper market is the flagship of the Russian waste disposal industry, which is in second place in terms of capacity after the scrap market [Table 4].

The volume of MSW formation in Russia tends to grow, despite the decline in the population. According to Rosstat, the volume of MSW waste increased by 26% between 2005 and 2010. A significant increase in the amount of MSW is due to an increase in the specific volume (intensity) of waste generation. In 2000, the average person accounted for about 220 kg of MSW per year, in 2010 this figure increased to 330 kg, and in 2019 – 450-480 kg.

According to Rosstat, the volume of municipal solid waste (MSW) exported from urban settlements in the Russian Federation as a whole in 2018 amounted to 275.4 million m3, or 0.88% of the total amount of waste generated. The volume of municipal solid waste exported to waste processing plants in 2018 amounted to 28.1 million m3, or 10.2% of the total volume of MSW. This volume corresponds to 1.87 m3 per person per year. For the period 2010-2018, the volume of MSW export increased by 40.023 million m3, or 17%; the rate of export of MSW to waste processing plants for the period under review decreased from 63.03% to 37.91% of the total volume of production and consumption waste (Figure 7).

Figure 7: Volume of municipal solid waste removed during the year

Source: Authors

The increase in consumption and changes in its structure in Russia since 2000 is due to the growth of the population's wealth and purchasing power. The structure of consumption changed towards more "waste-intensive" goods and services, the share of non-food products in the consumer basket increased, the use of which is associated with the formation of a large amount of packaging waste. Systematic studies of the composition of MSW in Russia have not been conducted.

Conclusion

Taking into account the fact that the waste management industry in Russia is at the stage of formation and is defined in official documents as a new one [Industrial development strategy, 2018]. The targets outlined in the approved document suggest faster growth than expected in other areas of the Russian economy. At the same time, even in the innovative scenario, which is the target in the developed Strategy, a noticeable decrease in the amount of generated and buried waste and a radical increase in the share of disposed and neutralized waste is expected no earlier than the period 2025-2030.

The concept of a closed-loop economy opens the way to more than just sustainable development. but also health and decent working conditions with a careful attitude to the environment and natural resources. In recent years, this concept has played an increasing role in policy-making at the international and national levels of governance. as well as in consumer behavior. However, new waste management practices are complex and involve both infrastructure and management, as well as financial and socio-cultural components.

Further development of the waste processing industry should be based on a detailed analysis and forecast in the context of each market segment, and not only "clean" waste from production and commercial enterprises, but also useful MSW fractions should be taken into account. A correct forecast of the development of the situation is possible only if there are correct statistical data that take into account the dynamics of volumes and morphology.

Abstract

This article discusses about risk assessment of financial statements using the CFEBT model and its modification. The financial statements of the entity serve as an information base for both external and internal users. Their function is to give a true and fair view of the financial position, performance and changes in the financial position of the entity. It is the effort to present the accounting entity in a more favorable image that leads the company's management to artificially improve the achieved financial results. This paper captures the development of profit or loss and cash flow, as well as the mismatch of accounting items in the entity's financial statements for a period of six years. Based on the CFEBT model and the modified CFEBT model, it is possible to assess whether deviations in the achieved values pose a risk of manipulation of financial statements beyond the scope of legislative rules. In the paper we use the analysis of selected models in order to evaluate the ability of users to detect the risk arising from the manipulation of financial statements beyond the true and fair view of accounting.

Keywords: Financial Statement, CFEBT Model, Creative Accounting, Financial Manipulation.

Introduction

The topic of this paper is an issue that appears continuously in accounting, both purposefully and unconsciously. Recent history has shown how fragile the confidence of investors and the public in the financial results presented is, and how easily any company can look successful in the minds of third parties, although the reality may be quite the opposite. From the very beginning of the accounting profession, there has been pressure from owners and management to "beautify" information about the performance and status of their business in the financial statements. It was only a matter of time before the company's management or employees began to abuse their more favorable position over all users of financial statements, such as investors, the state, customers, competitors and other stakeholders. This allows entities to make their results more attractive by using information superiority, while the reality may be quite different. (Huynh, 2019) However, an uninformed user usually has no idea. For most interest groups, accounting information is one of the basic and essential sources of information about a given company. (Kliestik et al., 2020) It is therefore logical that each interest group will expect different values to meet its objectives. (Valaskova et al., 2018) Evaluation of companies on the basis of mathematical apparatus or decomposition of indicators may not always yield an accurate result. This is where creative activity and accounting enter the process, and it also dreams of the possibilities that the company has within creative accounting. In certain circumstances, there may be a deliberate pursuit of objectives in order to present better financial results, which are reflected in the accounts and subsequently in the financial statements. (Hoang and Joseph, 2019) In practice, therefore, there may be opportunities to influence accounting information through the use of different methods and techniques of creative accounting, as a result of which the financial statements lose their function and thus lead to distortion of accounting data and profit manipulation. (Drabkova, 2017) Misleading financial reporting has negative impact on all stakeholders since financial records are the primary source of information on financial stability, economic activity, and financial health of any company. (Svabova et al., 2020) In the conditions of today's rapidly changing and growing global market, only the best will succeed, or only those with the best results. (Siekelova and Podhorska, 2020) And this fact is one of the motives that leads entities to make dishonest adjustments to financial results through increasingly frequent accounting manipulations.

Theoretical Background

Creative Accounting

In the literature, however, we find several different perspectives on the issue of creative accounting, which can be understood as a process of manipulating accounting data to transform financial statements into the desired results or as a process in which economic transactions are carried out to achieve a more favorable result in accounting accounting units. (Karim et al., 2014) Creative accounting can represent abuse of accounting perceived by the general public and points to the constant lack of serious materials that would clarify the issue of creative accounting in more detail and define this phenomenon in more depth. It is a process of manipulating accounting data in order to transform financial accounting statements (Fizza and Qaisar, 2015) from the form as if they should be properly kept in a true and true representation of the accounting fact to the form that those responsible for keeping accounting data would like. and conducting economic transactions with the intent to recognize the required financial performance and cash flows of the entity. Drabkova (2017) points to the existing problem of defining the boundaries of accounting creativity or the so-called gray economy and identifying accounting fraud, also known as the black economy, which we already call economic crime. Shah, Butt and Tarig (2011) define the phenomenon of creative accounting as a purposeful intervention in the external financial reporting process with the intention of making an exclusive profit. Griffiths (1995) points out that companies present results that do not give a true and fair view of their transactions, but rather adjust them to the desired objectives. The economic results that enterprises report are based on appropriate, adjusted or changed data. (Svabova and Durica, 2019) These practices used in reporting business operations or performance are considered creative accounting. Naser (1994) explains creative accounting as a process of modifying economic results from the real picture to the desired results. This can be achieved by improper use, or even by abusing existing rules or omitting other rules. Naser sees the accounting system, especially in Anglo-Saxon countries, as an extremely receptive environment for creative accounting. Matica et al. (2009) refers to creative accounting as enronitis. This term is understood in the literature as a criminal offense of distorting accounting data on the state of management and capital, which in the case of capital markets poses a serious problem pointing to the error of the system in reporting assets and profits and misuse of information in business. In the professional literature, the definition of creative accounting varies considerably. However, it is possible to compare the prevailing views of the authors dealing with the issue, which show that if the determination of accounting procedures does not violate the Accounting Act or other related accounting regulations, it is creative accounting and not accounting fraud. Creativity in accounting thus represents a manipulation of financial statements (Khanh and Thu, 2019), which consists in adjusting the true and true image of accounting, which changes the accounting reality, but only to the extent that it is not illegal. Users of financial statements are subject to distorted information, which may not lead to objective decisions. Steker and Ortusinova (2016) describe which of the accounting information is important for internal as well as external users of financial statements. Internal users, such as shareholders, partners or owners, monitor the return on invested funds, and accounting serves as a tool for controlling managers, as managers have access to all accounting records and thus gain an advantage over other users of financial statements. The role of managers is also to ensure that the internal objectives set by the owners are met (Kristofik et al., 2019), thus opening up space for the manipulation of financial statements. External users of financial statements include banks that monitor a company's financial situation for the purpose of granting or not providing credit, insurance companies and financial authorities that oversee tax compliance, statistical offices that collect data for the government, ministries and the public. business partners that focus on performance and settlement of liabilities or competition that compares the financial indicators of entities and monitors their market position. Based on publicly available accounting data, not only internal but also external entities evaluate the financial health of the company, which means that if they are manipulated, it can have a negative impact on all stakeholders. For the most part, creative accounting is seen as a negative phenomenon. According to Shah, Butt and Tarig (2011), the use of creative accounting can also have a positive impact on users of accounting information in the case of a company in times of crisis, when the company meets the expectations of external companies.

Reasons for Manipulating Financial Information

The motives for using creative accounting vary depending on the type of groups of people who practice it. (Remantic and Kenfelja, 2018) Each entity involved in creative accounting practices has different interests, resulting in differing motives, and several may take place simultaneously.

- **Internal profit**

Shah, Butt, and Triga (2011) cite the need for managers to falsify books in order to meet internal goals set by top management, taking into account sales, performance, and stock price, as the main motives for practicing creative accounting. The motives leading to the implementation of creative accounting are also accompanied by the achievement of the manager's financial success, based on the results resulting from the financial statements, where the manager is financially motivated depending on the achievement of set goals. One of the motives for practicing creative accounting is the prestige of the manager. According to Drabkova (2017), modern theory points to various variants of managers' behavior, where their effort is either to maximize profits or to maximize their usefulness in order to report high values of profits. Another motive may be poor business management, where the use of creative accounting can have a positive impact on delaying the impending bankruptcy. The author also focuses on the issue of valuation as one of the motives for the implementation of creative accounting, drawing attention to the fact that the company may slip into off-balance sheet financing.

- **External Expectations**

The company has to face several expectations of stakeholders, the company's employees demand long-term presence in the company, customers expect their needs to be met, suppliers emphasize payments and long-term relationship with the company. (Pisar and Bilkova, 2019) The motivation for using creative accounting practices is also to obtain a loan, lease or other source of financing. Companies trading on the stock exchange adjust their financial statements in order to ensure a constant flow of income in order to attract the attention of investors and thus ensure stable share prices.

- **Tax Optimization**

One of the motives for practicing creative accounting is tax optimization. Shah, Butt and Tarig (2011) point to the high interest of top management in certain tax benefits, especially where corporate income taxation is high and the calculation of the tax base itself and consequently the tax itself is relatively complicated. In connection with creative accounting on the issue of taxes, Drabkova (2017) states that the given reason prevails primarily in countries where financial accounting is closely connected with tax accounting.

- **Management Change**

Another of the motives for the implementation of creative accounting is the change of management. (Merchant and Rockness, 1994) For newly hired managers taking over the management of the company after the previous management, the trend is to point out that the results of previous managers are even worse than they actually appear, with the result that new managers start at a lower level and thus create space for their future.

CFEBT Model

The CFEBT model was designed as a detection model for use in recognizing possible manipulation of financial statements. The CFEBT model is based on the hypothesis of a relationship between the pre-tax profit or loss and the development of cash flows. The CFEBT model is designed in the form of an audit test: in the 1st phase as an analytical test of factual accuracy (CFEBT M-score), where the resulting score is compared with materiality (level of significance). Phase 2 represents a modified version of the CFEBT model respectively, detailed test of relationships at the level of significance. The relationship between pre-tax profit development and cash flow over time can be detected in phase 1 by means of the detected M-score value. If the detected M-score value is higher than the determined materiality. This is followed by a test of the 2nd phase respectively, a detailed analysis of significant deviations in the development of accounting relationships of the tested accounting periods, when individual significant deviations are identified at the level of the development of significant values of financial statements and the development of cash flow. Through a detailed test, it is possible to detect risk areas in the reported book values and assess the risk of manipulating the results of financial analysis, especially for owners, investors, those charged with governance and management. (Kovalova and Michalikova, 2020)

Methods

In our research we use the analysis of selected models in order to evaluate the ability of users to detect the risk arising from the manipulation of financial statements beyond the true and fair view of accounting.

Results and Discussion

In this paper, we focus on an entity whose financial health is at risk. The individual financial statements of this accounting entity underwent an analysis of selected models in order to evaluate the ability of users to detect the risk arising from the manipulation of financial statements beyond the true and fair view of accounting. The following table presents the results of detecting the risk of manipulation of the financial statements of a given entity using the CFEBT model in five consecutive accounting periods. EBT represents the result of management before tax and CF represents the increase in cash flow.

Table 1: Assessment of the risk of manipulation of financial statements using the CFEBT M-score

Accounting items	Period						Sum
	2013	2014	2015	2016	2017	2018	
EBT (€)	-277,000	-328,000	-219,000	-174,000	-65,000	-312,000	-1,375,000
CF (€)	5,000	-3,000	247,000	39,000	-82,000	-63,000	138,000
Cash and cash equivalents (€)	5,000	2,000	249,000	288,000	205,000	142,000	891,000

Source: Made by authors

Based on the results from the table, it is clear that the EBT values and the change in cash flow differ significantly in the analyzed period from 2013 to 2018. The table further shows that the M-score of the CFEBT model reaches a high value. The results of cash flow increments in the analyzed accounting period point to the tendency of the risk of manipulation with financial statements in the accounting unit. In the period from 2013 to 2018, the entity reported a negative value of the profit before tax, which represents an accounting loss of -1,375,000 euros. The total value of cash flow increments reached a positive value of 138,000 euros. Based on the calculation of the M-score of the CFEBT model, this represents 110%, which is a higher percentage than the value of the considered materiality in the range of 5 to 10%. If the financial statements in a given entity were manipulated, two cases of such manipulation could occur here. The first direction of manipulation with financial statements points to manipulation with the economic result. The second direction of manipulation of financial statements refers to the manipulation of cash flow, which means that the cash flow was not reflected in the reported profit or loss, which means that the entity overstated the reported cash flow. The subject of manipulation of financial statements in a given accounting unit may be the reporting of costs and revenues or the maximization of operating revenues and the minimization of operating expenses. In the case of costs, they are incorrectly reported, which means that the reported costs were not reflected as expenses in the given accounting period 2013 to 2018, and thus the entity transfers them to the next accounting period in the form of provisions or reserves. Manipulation of financial statements in a given entity may cause an overstatement of costs. Overestimation of costs is caused by the implementation of techniques for manipulating financial statements, such as the use of big bath techniques or tax optimization of artificially created costs or the use of earnings management. Manipulation of the financial statements of a given entity may cause their understatement to be understated. Undervaluation of revenues arises as a result of incorrect valuation or the use of earnings management, which includes non-recognition of realized orders of the given accounting unit.

Table 2: Assessment of the risk of manipulation of financial statements using the Modified CFEBT

CFEBT and its adjustment for significant items in period 2013-2018	€
EBT before adjustment	-1,375,000
EBT underestimation	
Change in reserves and provisions	110,000
Amortization	45,000
Modified EBT	*-1,220,000*
Cash flow increment before modification	138,000
Overestimation of cash flow increase	
Reserves	0
Increase in short-term trade payables	-727,000
Increase in liabilities to controlled entities	-884,000
Change received advances	0
Modified cash flow increment	*-1,473,000*
CFEBT after modification	**21%**

Source: Made by authors

As part of maintaining a true and fair view of the accounting in the entity and by analyzing individual cost and revenue items, we identify risk items in order to detect manipulation that leads the entity to underestimate profit. Individual items that cause deviations in the development of EBT and cash flow increments, taking into account the true and fair view of the accounting, are adjusted for the differences that have arisen. The table shows the modified values of the CFEBT model and from these values a new value of the modified CFEBT model is subsequently calculated, which is at the level of 21%.

Based on the results shown in both tables, the difference between the achieved value of the CFEBT model and the modified CFEBT model is visible. The value of the modified CFEBT model decreased from 110% to 21%, but it should be noted that the achieved value of the modified CFBET model is still above the considered materiality of the deviation.

Based on the results of both models, it is clear that in order to achieve relevant results indicating the detection of manipulation of financial statements, it is appropriate to use a combination of several models that can more accurately identify risk points and reveal whether or not manipulation of financial statements has occurred. The CFEBT model provides a comprehensive view not only of the financial statements themselves, but also of the links related to the creation of profit and loss and cash flow, while capturing the development of financial statements and their links over several accounting periods, at least for a period of 5 years. A modified version of the CFEBT model provides insight that identifies risk factors arising from inconsistencies in cash flow and profit or loss, while respecting the individuality of the entity's financial statements.

Conclusion

Users of financial statements who choose to assess the financial health of an entity based on its reported financial statements should perform an analysis of risk items in their bookkeeping. In order to evaluate the risk of manipulation of financial statements beyond the true and true presentation of accounting, it is appropriate to monitor the development of risk items for at least 5 years. This paper captures the development of profit or loss and cash flow, as well as the mismatch of accounting items in the entity's financial statements for a period of six years. Based on the CFEBT model and the modified CFEBT model, it is possible to assess whether deviations in the achieved values pose a risk of manipulation of financial statements beyond the scope of legislative rules. The results

resulting from the CFEBT model reach a higher percentage than the considered materiality at the level of 110%, which indicates the fact that the entity manipulates the financial statements. Under the modified CFEBT model, while the percentage of manipulation risk is lower, its value is still above the level of materiality considered, which again points to the fact that the entity manipulates the financial statements.

Abstract

In this article we examine the mechanisms of ensuring educational opportunities for racial and national minorities. This article provides the comprehensive examination of how race discrimination in the US education system is prevented. It examines the practice of the US Supreme Court on equal access to education for representatives of all racial and ethnic groups.

Keywords: Race, Education, US Constitutional Law, US Supreme Court, Principle of Equality, Discrimination

Funding: The study was funded by the Russian Foundation for Basic Research and Expert Institute for Social Research № 20-011-31773

The problem of racial and ethnic discrimination remains paramount for the entire North American society [Nikolaev, 2018: 128-129] despite the increasing attention drawn to the protection of other discriminated groups: disabled people, senior citizens [Nikolaev, Pavlova, 2016: 10875-10877], and sexual minorities.

Education in the modern world plays an increasing role generating broader economic growth as well as individual success. It is framed as a competitive necessity in which every person can win – through the partnerships it generates, the opportunities it opens, the fields and the minds it expands. Education nurtures the hopes of the country solving challenges and transmitting cultural values. It builds political understanding, models civic education and electoral culture. [Nikolaev, Emelin, Pavlova, 2020: 7715-7716].

American society as well as the education system tend to be ethnically and racially diverse and they have become more diverse in recent years. Moreover, official statistics indicate alarming trends regarding educational opportunities for various racial and ethnic groups.

About 2/3 of black children under 18 in the United States are raised in single-parent families (55% by single mothers, and 8% by single fathers) compared to 41% of Hispanic children, 24% of white children, and 14% of Asian children. Almost a third live in poverty (32%), compared to 25% of Hispanic children, 10% of white children and 9% of Asian children. This is also associated with parents' educational level: 65% of children live in poverty if their parents have a school education, compared with 8% if they have a bachelor degree [Hussar 2020: 4-5]. 67 percent of private elementary and secondary school students were White, 11 percent were Hispanic, 9 percent were Black, 6 percent were Asian, and 5 percent were students of two or more races. Pacific Islander and American Indian/Alaska Native students each constituted 1 percent of private school enrollment in 2017. [Hussar 2020: 31] Between fall 2000 and fall 2017, the percentage of students (enrolled in public elementary and secondary schools)

" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

who were White decreased from 61 to 48 percent, and the number of White students decreased from 28.9 million to 24.1 million. Similarly, the percentage of students who were Black decreased from 17 to 15 percent, and the number of Black students decreased from 8.1 million to 7.7 million. In contrast, the percentage of students who were Hispanic increased from 16 to 27 percent.
Among students ages 14–21 served under IDEA who exited school in school year 2017–18, the percentages who graduated with a regular high school diploma was highest for Asian students (79 percent) and lowest for Black students (66 percent). [Hussar 2020: 42-43]

In fall 2018, there were 16.6 million undergraduate students and 3.0 million graduate students attending degree-granting postsecondary institutions in the United States. Distribution of U.S. resident undergraduates (full- and part-time) by racial or ethnic groups varied among public, private nonprofit, and private for-profit institutions and between 2- and 4-year institutions. 64 percent of undergraduate students at private nonprofit 4-year institutions in fall 2018 were White, which was higher than the percentages of undergraduate students at public (56 percent) and private for-profit (44 percent) 4-year institutions who were White. The percentage of undergraduate students at private for-profit 4-year institutions who were Black (29 percent) was more than double the percentages at private nonprofit (13 percent) and public (12 percent) 4-year institutions. The percentage of undergraduate students who were Hispanic was higher at public 4-year institutions (20 percent) than at private for-profit 4-year institutions (18 percent), which in turn was higher than the percentage at private nonprofit 4-year institutions (13 percent).

The percentages of U.S. resident undergraduate students at public 2-year institutions in fall 2018 who were White or Asian (49 and 6 percent, respectively) were higher than the corresponding percentages at private nonprofit (39 and 3 percent, respectively) and private for-profit (35 and 4 percent, respectively) 2-year institutions. In contrast, the percentage of undergraduate students at private nonprofit 2-year institutions who were Black (41 percent) was higher than the corresponding percentages at private for-profit and public 2-year institutions (28 and 14 percent, respectively). Higher percentages of undergraduate students at public and private for-profit 2-year institutions (27 and 26 percent, respectively) were Hispanic than at private nonprofit 2-year institutions (11 percent). [Hussar 2020: 141-142] Thus, Blacks and Hispanic Americans are enrolled in less high-quality institutions of higher education, primarily in two-year colleges and four-year private for-profit institutions. On the contrary, the most prestigious private nonprofit and public colleges and universities cannot boast the large numbers of Black and Hispanic student populations.

The teaching staff development structure is quite evident. 79 percent of public school teachers were White and non-Hispanic. About 9 percent of teachers were Hispanic (of any race), and 7 percent were Black and non-Hispanic. [Race, 2020] Of all full-time faculty in degree-granting postsecondary institutions in fall 2018, some 75 percent were Whites; 12 percent were Asian/Pacific Islanders and 6 percent Blacks, 6 percent Hispanics. Among full-time professors, 80 percent were Whites, 11 percent were Asian/Pacific Islanders, for 4 percent Blacks, 3 percent Hispanics. [Hussar 2020: 151]

Thus, this context implies a strictly hierarchical conservative system in which a higher educational level means a decrease in the number of Hispanic Americans, and especially Black Americans, and, conversely, an increase in the number of White students and Asian Americans.

One of the newest and at the same time traditional trends for the United States is the increase in the number of "ethnic" universities targeted at applicants from various ethnic minorities such as Native Americans, Asian Americans, and Hispanic Americans. "Historically black colleges and universities" play a major role in giving Black Americans the platform to obtain higher education and agitate for their freedom. Many of these institutions are protected by law and their rights are guaranteed, both at the federal and state levels. Many researchers, including L. Fuchs, called this trend "voluntary diversity" [Fuchs, 1990: 5], and considered it a positive phenomenon that put an end to the "melting pot" and gave rise to the ethnic "kaleidoscope" [Arthurs, 1994: 262].

At the same time, this tendency manifests itself in the doctrine of "separate but equal", previously condemned by the public, court decisions and legislation. The doctrine has played such a dramatic and unsavoury role in the history of constitutionalism and the US education system. And although ethnic and racial minorities themselves gave an impetus to their educational opportunities the basic trends in this area were inconsistent and contradictory. Although the total number of black students in higher education institutions is increasing, the growth in the number of "historically black colleges and universities" stopped after 1967. In 1954, 5/6 of all black students enrolled in "historically black institutions of higher education". Even today they remain highly segregated and grant an advantage to Blacks because they continue to face barriers to equal access and opportunity and do not increase the white percentage of enrollment. [Clotfelter, 2004: 153-154, 160].

The US Supreme Court continues to play a key role in promoting the ideals of equality in various areas of American life. By its decisions, the US Supreme Court not only expanded the scope of constitutional and legislative rulings, but in some cases actively encouraged the executive branch to effectively implement the orders. Such judicial activism, especially manifested during the difficult stages of the desegregation process in the United States, was controversial, and in some cases contributed to the legal consolidation of the most reactionary norms and institutions.

Thus, one of the most significant decisions concerning higher education was the decision of the Supreme Court in the case of *Plessy v. Ferguson*, 163 U.S., 537, 544 (1896) [Plessy, 1997]. The "separate but equal" doctrine, "one of the most significant in US constitutional history" [Kern, 1972: 308], was first proclaimed by a Massachusetts court in *Roberts v. Boston* in 1850 Roberts v. Boston. Boston, 59 Mass. (5 Cush.) 198 (1850) The court stated that "the principle of equality of all before the law cannot be applied to diverse social conditions, since the infinite variety of circumstances of the social environment" presupposes legislative regulation that takes into account such conditions of life, including education [Kern, 1972: 13-14].

On behalf of the majority, Judge Brown stated that the purpose of passing the Amendment [XIV] to the U.S. Constitution was undoubtedly to enforce the absolute equality of the two races before the law, but, in the nature of things, it could not have been intended to abolish distinctions based upon color, or to enforce social, as distinguished from political, equality, or a commingling of the two races upon terms unsatisfactory to either. Laws permitting, and even requiring, their separation in places where they are liable to be brought into contact do not necessarily imply the inferiority of either race to the other, and have been generally, if not universally, recognized as within the competency of the state legislatures in the exercise of their police power. The most common instance of this is connected with the establishment of separate schools for white and colored children, which has been held to be a valid exercise of the legislative power even by courts of States where the political rights of the colored race have been longest and most earnestly enforced.

Judge John Marshall Harlan argued in his dissent stating that the purpose of segregation was to exclude the unification of blacks and whites and maintained the status of whites as the dominant race though he said "Our Constitution is color-blind, and neither knows nor tolerates classes among citizens. All citizens are equal before the law."

For almost half a century, *the Plessy v. Ferguson case* put in dead storage the policy of racial discrimination and segregation in the United States, including higher education. In 1906, in *Berea College v. Kentucky*, the US Supreme Court applied this doctrine to higher education institutions, affirming the state's right to prohibit the education of white and black students in the same classroom even in a private college [Millington, 1979: 312]. Berea College, since its founding in 1859, taught Whites and Blacks in its institution. However, the state of Kentucky obliged the institution on legal grounds to train white and black students in different premises at different times stating that "If the twentieth century is the progress of civilization, it will be due to the unadultered blood of the Anglo-Saxon white race and the outstanding representatives and geniuses of this race."
The US Supreme Court dispassionately and without delay upheld such a "racist" legislative decision [Lewis, 2004: 24]. Thus, the principle of the constitutionality of state segregation legislation was first applied to private institutions of higher education. Justice Harlan reiterated his opposition to "the arbitrary violation of personal freedom and property rights guaranteed by the XIV Amendment against state hostility" [Kern, 1972: 519].
Brown v. Board of Education examined by the US Supreme Court in 1954 (Brown v. Board of Education 347 US 483 (1954)) and in 1955 (Brown v. Board of Education 349 US 294 (1955)) was the decision that revolutionized the theory and practice of desegregation, including that in education. It is still one of the most cited precedents in the practice of federal and state courts.

Considering appeals from the courts of Kansas, South Carolina, Virginia and Delaware to prohibit the admission of black children to schools on a non-segregated basis (Plaintiffs saw a violation of the principle of equal protection by the law under the XIVth Amendment), the Court recognized the applicability of the doctrine "separate but equal" in several cases with respect to educational institutions, and for the first time it voiced the main concept of the dispute – which is "the impact of segregation on public education."

In addition, the court considered a broader approach to the consideration of this case and did not limit itself to referring to two dates - 1868, the time when the amendment was adopted, or 1896 - the year when the decision in the case of *Plessy v. Ferguson* was rendered. "We must consider public education in its full development in the life of the Nation." Thus, the court initially rejected the position of the minimalists, who insisted either on the classical precedent interpretation of this case, or on the equally classic interpretation of the will of the legislators who adopted the amendment. The court recognized education as "the most important aspect of state and local authorities" and "the foundation of good citizenship" and concluded that "the doctrine of "separate but equal"

cannot be found in public education". "Separate educational opportunities are essentially unequal." Therefore, the court found a violation of the provision of the XIV amendment on equal protection by the law in the cases under consideration. In May 1955, the Court outlined the basic procedures for ensuring the transformation of segregated systems into fully integrated ones.
Researchers describe the significance of this case as "striking a death blow to the doctrine of" separate but equal "[Millington, 1979: 317], as" the most important American national act, other than victories in the Civil War and World War II " [Kern, 1972: 529. That was "a turning point in America's willingness to face the consequences of centuries of racial discrimination dating back to the first settlements in the New World" [Kluger, 1977: X]. On December 22, 2005, the Brown 50th Anniversary Commemorative Coin Act was passed, emphasizing that the case "changed American history by setting an example for building greater equality" (Little Rock Central High School Desegregation 50th Anniversary Commemorative Coin Act, HR 358 / Public Law 109-146, Dec. 22, 2005; 119 Stat. 2676).

It was also in 1955 when the principles of the Brown case were applied to higher education in *Fraser v. Regents of the University of North Carolina*. Judicial practice has repeatedly confirmed adherence to the "Brown Doctrine" in combating racial discrimination in the education system.

American researcher Charles Clotfelter identifies five main factors that differentiate desegregation in US higher education from similar processes in primary and secondary schools:

"historically black institutions of higher education", voluntary admission practices and high tuition costs, well-developed federal and state laws and court practice on to civil rights protection in higher education, a large number of private educational institutions and the significant size of higher education institutions [Clotfelter, 2004: 153-158].

The Brown case decision fueled the growth of social activism and the development of legislation aimed at overcoming the practice of racial and ethnic discrimination. This very moment became a turning point in terms of political and public perception of the problem of racial segregation and other forms of discrimination. Thus, at Harvard, the share of students of color increased from 1.6 percent in 1954 to 32.8 percent in 2002 [Clotfelter, 2004: 148]. At the same time, racism in higher education persists in the United States, and "difficulties in establishing interethnic dialogue in academic environments" are noted [Simpson, 2003: 5, 18].

The Brown doctrine has had many implications for the legal regulation of higher education. The most radical legal institution generated by this court decision was "affirmative action". State authorities aimed not only to prevent discrimination in the future, but to create conditions for redressing apparent past wrongs, harms, or hindrances by providing additional advantages and more favorable conditions to discriminated racial and ethnic minorities, as well as women and persons with disabilities in employment and education.

In *Adams v. Richardson* 480 F. 2d 1159 (D.C. Cir. 1973) a federal district court ruled in favor of the plaintiffs and ordered the Department to enforce proceedings in ten state higher education systems. In the court's view, the Department's continued provision of financial aid to segregated higher education systems long after the amendment was changed violates the rights of plaintiffs and others in a similar position under the Civil Rights Act.

The Court of Appeal fully upheld the District Court's ruling for primary and secondary education, but changed the higher education order. The Department insisted that the enforcement of Title VI was the Department's discretionary power and was not, therefore, within the jurisdiction of the court.

The court identified significant differences in desegregation in colleges and universities from those in schools and pointed to the Department's lack of experience in this area. However, the court agreed with the District Court that the Department is still obliged to exercise its powers: "it has not yet formulated guidelines for desegregating state-wide systems of higher learning, nor has it commented formally upon the desegregation plans of the five states which have submitted them".

As regrettable as these revelations are, the stark truth of the matter is that HEW must carefully assess the significance of a variety of new factors as it moves into an unaccustomed area. None of these factors justifies a failure to comply with a Congressional mandate; they may, however, warrant a more deliberate opportunity to identify and accommodate them. «The problem of integrating higher education must be dealt with on a statewide rather than a school-by-school basis … A predicate for minority access to quality post-graduate programs is a viable, co-ordinated state-wide higher education policy that takes into account the special problems of minority students and of Black colleges».

The Court stated that, since a considerable time had passed since the Department requested plans for desegregation of higher education in the states, it was quite adequate to require that plans be submitted within 120 days, and then take active action against the states whose plans had failed. If an eligible plan was not filed within the additional 180 days, the Department must initiate enforcement proceedings, and bringing the case to a hearing did not preclude agreement between the parties.

Over the past decades, the response to this practice has varied in terms of different social, political groups, legal theories, court decisions, branches of government, states and, finally, different stages of social development.

T. Sowell, a conservative African American scholar, believes that affirmative doctrine and practice "sets in motion complex reactions that contrast minority and majority students and generate a state of stress and negativism between faculty, administration, and external interests" [Butler, 2005: 333]. Another minority member of the California State University Board of Regents, Ward Connerly, is a staunch opponent of this practice. He titled his policy paper as "My Struggle Against Racial Preference" [Connerly, 2000: B6-8].

In 2013 the US Supreme Court (Fisher v. University of Texas, 570 US (2013)) and 2016 (Fisher v. University of Texas, 579 US ___ (2016)) re-examined the theory and practice of affirmative action and determined its own doctrine on this issue.

The plaintiff in the new "reverse discrimination" case was Abigail Noel Fisher, who was denied admission to the University of Texas solely in her opinion on the basis of her race and the university's support for racial minorities. The University of Texas is one of the nation's leading institutions for awarding academic degrees to members of ethnic minorities. This admission policy has resulted in a 50% increase in Hispanic graduates and nearly double the number of African Americans. President of the University B. Powers in an official statement reaffirmed his commitment to a policy of admission that ensures a diversity of the student body reflecting the diversity of the American nation and its compliance with the orders of the Supreme Court in the Grütter case [Statement, 2012].

On June 24, 2013, the Supreme Court overturned the District Court's decision and returned it for further consideration. Thus, the court did not revise the concept of "affirmative actions" and did not set out its understanding of the constitutionality of the doctrine and practice of "affirmative actions". On June 23, 2016, the US Supreme Court ruled that at the time the race-sensitive admissions program was legal under the equal protection clause.

In general, the main features of the policy of the US Supreme Court in cases related to issues of equality can be formulated as follows. First, the principle of equal protection is not questioned, serving as the basis for all cases in this category. Secondly, the approach to equality issues is not just the prevention of discrimination in the future, but also the creation of conditions for overcoming the consequences of past discrimination by providing additional advantages and more favorable conditions to discriminated racial and national minorities, as well as women and persons with disabilities. Thirdly, favorable conditions are allowed only in case of a very specific state necessity. At the same time, adverse influence on representatives of minorities is not allowed.

The principle of equality continues to be fundamental for the entire American constitutional system [Nikolaev, Pavlova, 2018: 391-392]. The core of the anti-discrimination policy of the American state is combating racial and national discrimination. Recent events in the United States related to police brutality against black residents only exposed a wider range of problems of interracial relations in the political, economic, social and cultural life of the country.

Education is one of the key contexts. Ensuring equal educational opportunities for all Americans, regardless of race or nationality, can help create a socioeconomic environment to overcome racial discrimination and the consequences of legal and de facto segregation.

This requires more consistent and balanced legislation and judicial practice with regard to ensuring the principle of racial and national equality in the education system.

Possibilities of Venture Investments for Slovak Small and Medium-Sized Enterprises and Effect on Their Capital Structure

Veronika VRABLOVA

University of Zilina, Faculty of Operation and Economics of Transport and Communications, Department of Economics, Univerzitna 8215/1, 010 26 Zilina, Slovakia, veronika.vrablova@stud.uniza.sk

Abstract

Financing of small and medium sized enterprises (SME) is very discussed topic. In these times we can see that SME more concerning about alternative ways of financing such as venture capital. Because of this, we decided to focus on this financing among Slovak SME. Aim of this paper is to describe available venture capital opportunities for small and medium size and identify the effect of venture capital investments on capital structure of an enterprise. Main methods used to fulfill the aim were analysis of available studies and available literature. The effect of venture investments on company capital structure was demonstrated on case study of Slovak startup. We have reached several findings. Firstly, venture capital investments are very low in Slovakia, although there are several funds providing this financing. In 2017, SMEs raised only 2,9 million € by venture capital. Secondly, Slovak SME do not have high demand for this financing. And finally, the use of venture capital reduces indebtedness of the company.

Keywords: Venture capital, small and medium-sized enterprises, capital structure

Introduction

Nowadays, small and medium-sized enterprises use in more extent as a source of financing venture capital. Venture capital is capital invested by investors in startups with an innovative idea and the potential for rapid growth. An investor usually acquires a minority stake in a company for his contribution, which he may sell back to the company after some time or offer it to another investor (Sobeková-Majková et al., 2016).

Venture capital is a specific type of external financing, where the investor invests funds in a company with growth potential. This capital acts as equity in the enterprise, as the investor enters the company and, in exchange for the invested funds, acquires the usual share in the management of the company.

Venture capital and private equity investors can be described as formal investors, usually provide their free cash through funds or various organizations. Venture capital seem to be best way of financing for startups, because they do not have any history and thus, for banks and other institutions it is very risky to fund young enterprises such as startups. Therefore, venture capital investor are major entities in helping startups to overcome their resource constraints (Manigart and Sapienza, 2017). On the other side, invested capital can be provided also to established company. In that case it is called private equity.

When formal investors want to invest in a company, they will have to make detailed due diligence about the company. One of the most important things to look at are earnings of the company. Investors have doubts about a company which profits are very consistent, because they want to invest in a company that are stable and grow slowly. Consequently, the study about earning management (Kliestik et al., 2020) shows that among V4 countries are the biggest manipulators of earnings Polish enterprises and the smallest Slovak enterprises. On the other side, executive managers and accounting researchers in general should deeply consider the wrong link between earnings quality and financial performance, and the mediation of organizational reputation when analyzing earnings performance (Huynh, 2019). Moreover, according to Podhorska et al. (2019) earnings in its various forms enters in the lot of financial ratio. For investors is important to monitor the situation of the company they invested in. That is because bad financial health of the enterprise can negatively affect the operation of the company itself and can change the financial performance of investors that come into close contact with the enterprise (Valaskova et al., 2020).

Capital structure of an enterprise provide an information about share of own – internal capital and debt - external capital. 1 Identifying optimal capital structure of an enterprise is crucial for their business. On the other side

Cite this Article as: Veronika VRABLOVA "Possibilities of Venture Investments for Slovak Small and Medium-Sized Enterprises and Effect on Their Capital Structure" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

enterprises face difficulties in determining the optimal capital structure. Belas et al. (2018) made a research, where they find out that the size of the company effects its attitude to volume of foreign and own capital used to finance its activities. SMEs do not see the debt negatively and do not connect it to the risk of failure (Kramolis and Dobes, 2020). According to Buzinskiene (2019) in order to increase business value, companies and their managers need a better understanding of the measurement of the intangible asset structure.

Importance of identifying and removing barriers to the development of SME enterprises is currently increasing in all countries with developed economies (Belas et al., 2020). Especially, when it comes to trade sector, small group of enterprises influences the development of this sector the most (Vrbka et al., 2019). Some of the factors which are affecting prosperity of enterprises are net return on capital, net working capital, current debt ratio or financial debt ratio (Valaskova et al., 2018).

Methods

Main method used in this paper is comparative analysis. Using this analysis, we were comparing usage and possibilities of Slovak small and medium-sized enterprises to fund their business through venture capital or private equity. For the comparison we were using several studies, such as Survey on the access to finance enterprises (SAFE) for years 2015 – 2019 and OECD evaluation report for years 2014 – 2017.

Other used method was synthesis, which was used to summarize fonds providing venture capital and private equity we used all available literature. To demonstrate positive or negative effect of venture capital on the capital structure, we choose a case study of one random Slovak small and medium-sized enterprise (SME) called Datamolino. Thus, we analyzed balance sheet from years 2013 and 2014 of the company for identifying related effects. Balance sheet is available online at Register of Financial Statements for Slovak Republic.

Results

Venture investment is relatively new way of financing. Thus, we can see only small amount of invested capital through venture capital in Slovak SME, where only 2,9 mil. € was invested in 2017. In comparison with other years, this amount was the lowest between 2014 – 2017. The biggest investments of venture capital funds were made in 2016, when investors fund 17,1 million €, as we can see in figure 1.

Fig. 1: Venture capital investments for Slovak SME from 2014 – 2017

Venture capital investments are not so widespread among European companies. In 2019, in the EU venture capital was relevant for 1768 companies, which accounted for 11.5% of all companies. The use of this type of financing in Slovakia is below the EU average. In Slovakia it was relevant only for 1,9 % of surveyed enterprises in that year. In comparison with previous years we can see decreasing demand for venture capital in Slovakia and also in Europe, as suggests the figure 2 below. The use of VC in Slovakia drops by almost 1 % and in Europe in general it was more than 2 % between years 2015 and 2019.

Fig. 2: Use of Venture capital in EU and Slovakia from 2015 to 2019

Possibilities of using venture capital in Slovakia are very wide. By analyzing available literature, we find out that in Slovakia there are several organizations and individuals providing venture capital financing. They usually collaborate in many different funds. Such funds operating in Slovakia are, for example, the Innovation and Technology Fund or Slovak Venture Capital and Private Equity Association (SLOVCA). Others available funds are described in the table 1 below. In the table 1 we can see weather the fund is providing venture capital for startups or private equity for established enterprises.

Table 1: An overview of some venture capital and private equity funds available to Slovak SMEs

Name of the fund	Investment interval	Investment horizont	Equity stake	Venture capital	Private equity
Innovation and Technology Fund	20 000 – 1 500 000 €	4 – 6	10% - 50%	✓	✓
Slovak Growth Capital Fund	500 000 – 5 000 000 €	3 – 4	minority (minimum of 25%)		✓
Neulogy Ventures	50 000 – 200 000 €	N/A	N/A	✓	
	300 000 – 1 500 000 €	N/A	N/A		✓
Limerock Fund Manager	500 000 – 2 000 000 €	4 – 6	–	✓	✓
CREDO VENTURES	50 000 – 3 000 000 €	N/A	5% - 25%	✓	
	2 500 000 € and more	N/A	15% - 35%		✓
Slovak Development Fund	500 000 – 2 300 000 €	3 – 5	34% - 75%		✓
National Holding Hund	individually	1 – 5	N/A	✓	✓

Case Study

For the case study we choose an enterprise which is classified as small and it is categorized as startup. This startup was founded in 2013 and has developed an application that allows other companies to have their paper invoices in

electronic form, so it can significantly save time for other companies. At the beginning of its business in 2013, Datamolino received a seed investment from the startup accelerator Wayra of total amount of 39 250 €. At the beginning of 2014, the company applied for another investment. They raised 500, 000 € from the Innovation and Technology Fund. This investment was divided into two stages. At first stage Datamolino received 300,000 € in exchange for a 12% stake. At the second stage, after a thorough preparation of the expansion plan to the markets, the startup got remaining 200,000 € in exchange for a minority stake of 8%.

From the balance sheet of the enterprise Datamolino for years 2013 – 2014 we can assume that using venture capital has a positive impact on the company capital structure. Total indebtedness decreased from 90,3 % in 2013 to 12,7 % in 2014. This led to smaller dependability of debt capital, because venture capital acts as own capital. In long term conditions is for the enterprise more suitable to use other sources of financing to rise debt capital, because own capital – equity is more expensive and produce more costs for the company.

Conclusions

Aim of this paper was to describe available venture capital opportunities for small and medium size and identify the effect of venture capital investments on capital structure of an enterprise.

Based on data from SAFE survey and OECD valuation report we can say that venture capital is not very used financing in Slovakia, although SMEs have lot of possibilities of venture capital financing. There are lots of VC and PE funds, which invest money into innovative small and medium-sized enterprises.

In capital structure venture capital acts as own capital, because investor enter to the enterprise, so he became one of the company owners. Thus, investor request share on the company in exchange for the invested capital. The effect of venture capital investments on capital structure is increased share of own capital. This way of getting fund for enterprise is suitable for enterprises which do not want to take bank or other loan and increase their indebtedness. In case study we demonstrated that the company used venture capital to decrease its indebtedness in short terms.

Abstract

The current market environment is characterized by strong competition between companies. Therefore, if companies want to succeed in the market, they must constantly work to set and achieve their goals. The process by which an effective business operates is called a marketing strategy. A marketing strategy can be implemented by a combination of different tools. The goals that the company wants to achieve are important. If a company wants to be successful, it must create a certain position in the market and must also focus its activities on current as well as potential customers. Satisfying customer needs is the main task of marketing and is achieved through a marketing mix that represents the integration of 4 elements. One of the tools of the marketing mix is communication, which is important especially because it ensures the addressing of customers and the promotion of products as well as the entire company. The aim of the article is to point out the theoretical basis of marketing strategy with emphasis on its tools and channels. The practical part is focused on the analysis of secondary data with a focus on consumer preferred channels of brand communication during the coronavirus pandemic worldwide.

Keywords: Communication, Channels, Marketing, Strategy, Tools

Introduction

Companies are leading to respond flexibly to the activities of competing companies in the market and to constantly monitor changing customer requirements. According to Kramolis and Dopes (2020) the flexibility of a company makes it possible to eliminate the occurrence of certain risks. For a company to be able to respond effectively to the stimuli of competitors and customers, it must have developed a good marketing strategy, which results in customer satisfaction and profitability of the company. Marketing strategy is defined as a management tool that should contain general principles, in the application of which the company's management expects to achieve its marketing and economic goals within the selected target market (Jemala 2007). The choice of marketing strategy depends on how specific marketing tools are used. The marketing mix can be described as the basic source of marketing tools. This concept includes four main marketing tools that serve to realize long-term and short-term goals of the company. The basic marketing mix includes product, price, promotion and distribution. It is the marketing communication that we deal with in this paper that is an important and most visible part of the marketing mix. Communication itself is one of the most important components of everyday life, which can be described as a process of exchanging information either orally or in writing, which takes place at least between several participants (Nagyova, 2012). In the communication process, everyone expresses their ideas in a certain way and gives them a certain form. Communication is influenced by many factors based on the physical, social and cultural environment (Dedina and Odchazel, 2007). Marketing communication is an important tool of the marketing mix. If the company uses appropriate communication tools, it can effectively communicate with its environment and it helps it achieve its goals. As there are a large number of communication tools, the most suitable combination is that clearly, consistently and convincingly speaks about the company's products and services (Vastikova, 2014)

Marketing communication strategy is defined as a tool that a company uses to inform, persuade or influence today's or future potential customers. Its main characteristic is the communication of information and its content in order to guide the opinion, attitudes, expectations and behavior of consumers in accordance with the specific objectives of the company (Heskova and Starchon, 2009). Comprehensive marketing communication (promotional mix) in the

Cite this Article as: Veronika OLEXOVA and Lubica GAJANOVA "Channels and Tools of Marketing Communication Strategy" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

practice of modern companies means communication with customers, suppliers, intermediaries and the public (Jemala, 2007).

Before the Internet became a popular marketing communication channel, traditional media channels such as newspapers, magazines, radio, television, direct mail, and the old favorite channel were the only options. Developing a marketing communication channel strategy for business has been easier in the past. In today's modern globalized world, with new technologies, advanced possibilities (Pisar and Bilkova, 2019and innovation one of the main characteristics of today is one of the most important communication just the internet. Thanks to the Internet, the conditions have also been leveled for smaller companies, which can compete with larger companies even with a smaller marketing budget. Businesses must use innovation in their activities. Innovation is an important source of economic growth (Jakimowicz and Rzeczkowski, 2019). Choosing the right marketing channel strategy to communicate with the target audience and build strong relationships with customers is more complicated due to strong competition. Therefore, companies must focus on choosing the right traditional and modern communication channels for business.

The paper is divided into two basic parts, theoretical and practical. In the theoretical part we deal with the definition of the basic theoretical background with emphasis on marketing communication and its tools and channels. In the practical part we deal with the analysis of secondary data through descriptive statistics. The aim of the practical part is to point out consumer preferred channels of brand communication during the coronavirus pandemic worldwide.

Theoretical background

A business communication understood Balmer (2000) as a system process comprising the three spheres, the primary, secondary and tertiary. In many companies, all three are balanced. Primary communication should present a positive image of the company and set the stage for a strong reputation. Secondary communication should be designed so that promote and strengthen primary communication. Tertiary communication should be positive and should result in a good reputation of the company. In the event, that corporate communication is properly designed, the head of personnel who carry out corporate communication can get venture into competitive advantage. Corporate communication is particularly important in that it creates a connection between the corporate identity of the organization and the set strategic goal, and it is possible to achieve a favorable reputation of the company through it. Horakova et al. (2008) define corporate communication as a process, which converts corporate identity to the image of the company, and not through a controlled and planned communications with critical target and interest groups. Communication is essential to it that all interest groups - employees, customers, shareholders and others understand the identity of the organization, its values and strategy. Business communication based on a well-chosen communication mix leads to increased consumer loyalty to products and their better placement in the market. For this reason, it is also important to create and build a long- term relationship between the company and customers through communication (Moise and Cruceru, 2012). Corporate communication is a term, which includes all methods, which the organization communicates with its surroundings and with various interested parties (Melewar and Karaosmanoglu, 2006). The aim of corporate communication is to adequately address individual target groups so that positive attitudes to the company are created, so that corporate communication becomes an important and inseparable part of the company because without appropriate communication and presentation of strategy and company values it is not possible to create the desired image (Vysekalova and Mikes, 2009). Kosiciarova (2017) considers strengthening the corporate image, providing information, stimulating and creating an offer, differentiating the product, emphasizing the value and usefulness of the product and stabilizing turnover as the main goals of corporate communication. The overall marketing communication program is also called the communication mix and consists of a combination of communication tools. Several authors (Cihovsky, 2001; Jemala, 2007) will agree on the fact that the basic marketing communication tools include advertising, promotion sales, personal selling, public relations and direct marketing (direct marketing). This as well as other tools will devote in a separate subsection within the framework of the theoretical part.

In connection with the communication Dedina and Odchazel (2007) point out the significance of electronic communications, that despite the fact that it has many forms, due to the rapid development of information technology it is possible to expect the emergence of its other forms. Enterprises use for electronic communications both Internet as a global network, and secondly their own intranets. Internet contains a vast amount of information about different products, companies, technologies and opportunities, so that the worker rather than a problem, something to find, addresses how to choose it necessary and current. Intranet has become a new distribution channel that is limited to the environment of corporate computer networks, includes a centralized corporate information and employees here can find various documents. Compared to the Internet is its content clearly defined and usually cataloged, employee thus can bet on certainty and not spend their time searching for data as in the case of the Internet. Sometimes contains sensitive information about the company, therefore, it is to place the adequate

security. The main objective of marketing communication is mainly: informed customers about the products or services, build preference services with customers, to persuade customers that have purchased this product or service, differentiate their offer from the competition (Vastikova, 2014). If customers have a better ability to express their preferences, it means a significant involvement for them (Kliestikova, et al. 2018) in the very process of buying and selling.

Marketing communication strategy is a combination of marketing communication activities, the company implements. The goal is to get the selected information to the target market segment through the most suitable channel. The communication channels are tools, which companies use to establish the relationship and communication with its audience. Communication channels increase the experience between the customer and the brand. Brand building is an important part of marketing strategy (Kliestikova, et al. 2019). Communication channels further increases the relational marketing and the result affect overall sales company. Enterprise can through communication channels, for example, to introduce customers to a new product or service; inform customers about all what the concerns of the business and respond and react to stimuli customers. Communication channels help build the brand and help to better understand the behavior of the target segment. According to Nadanyiova (2017) it is important to examine consumer behavior, because decisions about buying can be to a large extent influenced by emotions.

The traditional tools of marketing communication include advertising, sales support, personal sales, public relations. For reasons specific needs of customers and the development of information technologies arise new ways and tools of marketing communication: direct marketing, internet communication, communication on social networks, marketing events (event marketing), guerilla marketing, viral marketing and product placement. Advertising as a form of marketing communication is one of the oldest and most important tools. Advertising can have various forms, for example, a form of print advertising (posters, billboards); large or illuminated advertisements; printed advertisements contained is in the newspapers, leaflets, magazines, catalogs, brochures, audiovisual advertising (on television, in film); 3D advertising; new technologies and internet advertising. The advantage of personal sales is direct contact with several customers. The main goal is to achieve sales. Depending on the specific customer and situation, the seller can adjust the method of communication. This is a very expensive way of marketing communications for it, however, very effective, because the acts of communication, which is taking place between the two directions, where the possibility of confrontation between the seller and the buyer. When the service is a vital relationship, which is the personal interaction between providers of services and customers. Thanks to personal contact with the customer, relationships are strengthened, which is not possible with other types of communication strategy. Support sales associated with additional activities related to the sale of services. Often it is used to conviction buyer that you bought the product or service. The main disadvantage is that it works in the short term, use is just to meet the specific measures. For services, the most common way to promote sales is in the form of price discounts, which can be quantity or seasonal. Public relations is the deliberate, planned and sustained effort of the organization for securing and monitoring of understanding between the organization and the public to be improved its image. This is therefore the effort is mainly to get into the awareness of the general public and the favorable aspects of the work of the organization, probably the best people create the right image. The main task of public relations is building the credibility of the organization in the eyes of the public, and also facilitate the communication as externally, as well as inside, ie the employees of the organization (Vastikova, 2014).

In today's environment where technology is significantly impacted, digital marketing and online marketing channels are important for businesses. Online marketing channels consist of any e- marketing campaigns or programs, or longer terms of optimizing service internet search engines (SEO) programs paying for a real visit to the presentation (pay-per-click), partner programs, email, banners, or the latest internet channels for seminars on the internet (webinar), blogs, microblogs, RSS, recording audio and video transmissions (podcast), live web radio and web TV. Important they are also channels of social media, such as, for example, Instagram, Facebook, LinkedIn, Twitter, Pinterest, YouTube. Marketing on social networks (Ashander et al., 2019) is today the time for businesses invaluable marketing tools. People on social networks seek and follow the signs and businesses who are they liked and for that they have a potential interest. Social media makes it possible to create a branded community. This is a group of people, who are not interested in just about your products and services, but it really is committed to investing in your brand. Regular communication with these types of customers they not only keep, but also, they encourage to share your brand with their friends and family. It is a digital version of oral advertising. Social media is widely used as a strategy to strengthen the relationship with customers, because it allows, in addition to interaction with the brand, also direct interaction with the audience. Another important online channel is the company's website. Web pages are one of the most important communication channels. Thanks to the website, the company is more trustworthy for its target segment. Among the digital channels of marketing communications is content marketing, blogging and video content. Blogs and video content are two of the best types of communication channels for small and medium businesses. Using blogs can create a cycle of contributions and create new ways, as is closer to his audience. The most valuable way of communication is e- mail marketing. The main reason why is

this form of marketing importance, the database of e-mail list of customers, with whom can venture work. It can directly reach customers in the form of newsletters (Kotler, et al. 2007; Prykrylova, et al., 2019).

Methods

Due to the COVID-19 pandemic, the whole market environment has changed significantly. One of the areas affected by this pandemic is the perception of marketing activities by consumers. The aim of the practical part is to point out consumer preferred channels of brand communication during the coronavirus pandemic worldwide as of March 2020. It is an analysis of secondary data from Statista. The study was published by A. Guttmann, Apr 8, 2020. Survey was realized worldwide in 12 countries in time period March 23 to 26, 2020. Number of respondents was 12,000. Respondents had the opportunity to comment on 9 selected channels of brand communication. The average results from this survey can be found in Table 1. For a clearer descriptive analysis of the data, we used a graphical representation of the data in Figure 1.

Table 1: Consumer preferred channels of brand communication

Channels of brand communication	Average
TV, radio or newspapers	45%
E-mail	42%
The brand's website	33%
Facebook	31%
Instagram	21%
Twitter	19%
Texts	18%
Streaming videos	17%
Regular mail	11%

Source: own processing based on statista.com

Fig. 1: Consumer preferred channels of brand communication

Source: own processing based on statista.com

Table 1 and Figure 1 show consumer preferred channels of brand communication during the coronavirus pandemic worldwide as of March 2020. Based on the above data, we see that the most preferred communication channel is TV, radio or newspapers (45 %), subsequently e-mail (42 %), the brand´s website (33 %), social networks as Facebook (31 %), Instagram (21 %) and twitter (19 %). Other communication channels are texts (18 %), streaming videos (17 %) and regular mail (11 %).

Results and Discussion

In today's market environment, companies must constantly strive to make the best possible market position, competitiveness and overall business efficiency. In connection with individual activities, companies must make several decisions. Constant competitive pressure, developed in hypercompetition in developed countries, forces companies to adapt flexibly to the situation (Zeman & Bogdan, 2019). Customers expect companies to interact, engage, and continually improve products and services (Deggans, et al. 2019). Many consumers currently require businesses to implement sustainable production (Hayhoe, 2019) as well as sustainability, which businesses must emphasize in their marketing activities. There are also risk factors associated with business that can influence a decision-making situation and which should be considered by managers (Buc, et al. 2013).

The current time when the COVID-19 pandemic has significantly affected a number of companies is forcing companies to implement a number of decisions much more efficiently. Some marketing communication tools can be significantly costly for businesses. However, there are communication channels that are affordable as well as effective. Such communication channels include, for example, marketing on social networks, such as: Facebook, Twitter, Instagram, Pinterest, LinkedIn, YouTube. Other channels are the company's website, Content Marketing: blogs and video content, and email marketing. These are tools that are at least financially expensive, but if the company devotes enough time to them, such a way of implementing a marketing communication strategy can be effective enough. Regarding the very choice of communication channel, it is important that the company chooses a combination of communication channels with respect to the target customers. It must adapt communication channels and their content to customer requirements and preferences. Corporate communication is all means of communication, a complex of all forms of behavior by which a company shares something about itself, whether with an external or internal environment. In connection with the communication in the company Dedina and Odchazel (2007), they state that communication clearly directly affects the performance of the entire organization, and therefore it is necessary to pay sufficient attention to it. Managing communication can give the company a competitive advantage and, conversely, its underestimation can lead to problems for the company. Therefore, it is necessary to pay attention not only to classical communication, but also to communication influenced by technological changes. In the process of globalization, these are the Internet, discussion groups and other new forms of communication between individuals and between organizations and the individual. Marketing communication helps to develop brand awareness, which means that consumers translate product information into a perception of a product's attributes and its position in the markets. Businesses also use marketing communications to maintain the product's current customer base and to strengthen relationships with customers and suppliers. A marketing communication strategy defines a business plan to disseminate product information and develop brand awareness. The built brand has the ability to facilitate the development, development and achievement of a competitive advantage of the company (Valaskova, et al. 2018). It is therefore important for companies to design an effective marketing communication strategy with one or more marketing communication tools. Advertising allows a product to reach a large audience through mass market or market targeting. Personal selling allows a company to communicate the benefits of a product directly to a customer in a retail environment. Direct marketing allows you to reach customers without third-party media. Sales promotion provides the customer with an incentive to buy a product from a company, such as a company that makes a charitable contribution with each sale.

Conclusion

Meeting the needs and requirements of today's consumers is currently a major challenge for businesses. One of the specific ways in which a company can fulfill its goals and reach the customer is the right marketing communication strategy. An appropriately chosen strategy increases the company's chances of success in the market. The company must adapt the marketing communication strategy to the target customers, as well as the product it offers and the market in which it operates. With the right combination of communication channels, a company can build brand awareness and reach new customers and thus create a larger customer portfolio. As technological progress significantly affects both traditional and modern tools, companies must constantly monitor trends and developments in this area.

Abstract

The basis and a comprehensive part of the company's marketing efforts is a marketing communication. It is a strategy within a company or individual to reach the target market through various types of communication tools. Proper and effective marketing communication not only ensures the improvement of services but also provides for the constantly growing profit of the company. The increased intensity of communication with the target subject or group is not only the perception of corporate identity, achieving awareness but also better understanding. Regardless of what the goal of the marketing activity is - whether it is a new product, brand, product line, or the entire business activity - the development and application of communication forms is the task of marketing. In this article, we provide a theoretical background in the field of marketing communication tools. Based on the analysis of data from surveys in the Slovak Republic and abroad, we found that customers most trust the recommendations from people they know. The results can be used by companies to innovate or modify communication mix tools.

Keywords: Marketing Communication, Tools, Customers, Advertising.

Introduction

Every communication together with customer interaction represents marketing. From the very beginning, the company should have clearly defined who its customers and audience are. Therefore, a thorough analysis is needed. There is a difference in communication with entrepreneurs in the B2B market and directly with consumers in the B2C market. Here it is necessary to clarify and choose what language the company will use when communicating, but also what tools it will prefer when communicating with the customer in order to address him as much as possible. The second important thing is to know what values the company creates and what is important for the company (blog.Besteron, 2016). Companies with quality marketing communication are able to convince customers to perceive their products positively. Through this, they build a differentiated image and brand awareness (Murray et al., 2011). Marketing communication emphasizes two-way communication with the primary goal of supporting interactivity within a large marketing environment (Luxton, Reid, & Mavondo, 2017). The basis of marketing communication is in the exchange of information between customers, channel members, competitors, and the wider market environment. (Kumar, Keller, & Lemon, 2016). Under conditions of higher technological turbulence, new international companies with less marketing capabilities and less marketing communication are likely to be harmed, as customers would prefer companies with higher marketing capabilities and marketing communication. The higher the environment of technological turbulence, the higher the need for new international companies to use marketing communication for a stronger competitive strategy (Martin et al., 2020). According to surveys, up to 84% of people expect brands to create content. Approximately 45% of B2C marketers believe that visual content is their most important type of content, while 88% of B2B marketers agree that content creation sees their audience as a trusted source (Dautovic, 2020). The essence of marketing communication is to influence the shopping behavior of consumers through the means of the communication system, which includes the following main tools of marketing communication: advertising, sales promotion, personal sales, public relations. In the professional literature, we quite often encounter the extension of the basic tools of marketing communication by the item of direct marketing (Kotler & Armstrong, 2004; Birnerova & Krizanova, 2012). In addition, we know the division of marketing communication into over-line and under-line activities (Hornak, 2015). Due to constant technological progress, communication for understanding the external marketing environment is largely at the forefront of the past. Its key role is to attract and

retain customers (Batra & Lane Keller, 2016). The profile of the customer's purchasing intentions and product perception is made up of visual media such as radio, television, newspapers, Internet advertisements, word of mouth, books, and more. Advances in technology mean that customers now have access to a variety of communication channels. That's why the visual and multimedia side of content has become part of marketing communication tools (John & De'Villiers, 2020). For example, budgets for social media advertising began to grow enormously, from $ 16 billion in 2014 to $ 31 billion in 2016 (Dautovic, 2020). The impact of electronic word of mouth in the case of a purchase project has long been known (Bickart & Schindler, 2001; Chevalier & Mayzlin, 2006; Park, Lee & Han, 2007). In the research of the comparison of electronic oral submission via websites or social networks, the information from the website has a greater influence on the customer's purchase intention due to the aspects of quality, reliability, usefulness, and acceptance of information (Erkan & Evans, 2016). The theoretical basis for convincing the consumer about the choice of goods or services in connection with marketing communication is the ELM model, which was created by Petty and Cacioppo in 1986. The scheme outlines two ways of individual belief, namely central and peripheral. (Li and Suh, 2015; Scott and Shu, 2014). The preferences in the choice of path depend on the motivation and ability of the individual to process the received message, i.e. information. Many circumstances may reduce the buyer's motivation, may result in a lower buyer's decision-making ability, or may cause both. In addition, when goods are cheap and low-risk, there is a tendency for transactional transactions and buyers tend to make quick purchasing decisions (Prince, Kwak & Priporas, 2019). John and De'Villiers (2020) used the ELM model in their research, which applies to visual media, especially online marketing communication. If a company sets itself the goal of acquiring a new customer, it needs on average six times more resources than in the case of retaining an existing customer. (Chlebovsky, 2005; Kotler & Keller, 2012; Krizanova, 2015). Currently, various studies show that the probability of sale to an existing customer is around 60-70%, while the probability of sale to a new customer is between only 5-20% (Starova, 2003). Businesses very often invest in groups of passively loyal and devoted customers (Aaker, 2003). According to Karlicek (2013), companies tend to take loyal customers for granted and put more importance on acquiring new customers. However, this approach can be very risky (Gajanova, Nadanyiova & Moravcikova, 2019). Over the years, marketing theorists have followed the behavior of message recipients and developed a number of models to show what marketing communication follows and what it wants to achieve. One of them is known as the AIDA model. Each letter represents the state of thought processes and behaviors of a certain group of customers: A = Attention, I = Interest, D = Desire, A = Action. The customer goes through this process, which begins with attracting attention, continues by arousing interest in the service, grows into a desire to own the product, and ends with the purchase of the product. This concept is very simple and attractive but ignores the intermediate stages of the customer's response to an advertising campaign or marketing communication campaign (Rostasova, 2006). In recent months, developments around the global COVID-19 pandemic have strongly accelerated the shift to online relationships. Equally, the rapid and partially ad hoc transfer of customer-company relationships to the online realm has revealed rich opportunities and unresolved challenges, focusing marketers on relationships to the strengths and weaknesses of their relational strategies (Steinhoff & Palmatier, 2020). At the beginning of the 21st century, we saw a boom in media development. For decades, Internet advertising has expanded the marketing communication tools used by marketers. However, traditional media will not disappear. Radio is experiencing a new boom with the advent of satellite and other digital formats. Outdoor advertising is becoming more creative, digital technology increases the potential for interactivity with customers in urban areas. Finally, although newspapers and magazines are most negatively affected by the new media, they are still important, among other things, among businesses and retailers. With the transition to an environment called the "hypermedia" environment (Hoffman and Novak, 1996), the nature of the communication model has changed and the concept of flow has become more important (Hoffman & Novak 2009). The central themes of the present are interactivity and digitality (Kim, Jun & Kim, 2018).

Methods

In the article, we focused on the theoretical background of marketing communication, specifically we examined the tools of the communication mix that companies use to interact with their customers. The aim of the paper was based on data from the survey conducted in 2016 to analyze the various tools of marketing communication and the degree of trust that customers perceive with specific tools. A representative sample, 1650 respondents, was made up of the adult population of the Slovak Republic. The results are also up-to-date over time, but over a period of several years, it would be necessary to repeat the survey and verify compliance or disagreement with the survey conducted in 2016. Respondents had to indicate on a dichotomous scale the instruments, which they considered credible. The foreign survey was conducted by Nielsen in a report entitled Global Trust in Advertising and Brand Messages, which was conducted online in 2013 in 58 countries. The survey was conducted during the third quarter of 2013. The agency's report also compared data from 2007 obtained in the first quarter. While the methodology of the online survey uses an enormous scope and global reach, it only reflects the attitudes of Internet users, not all residents of the countries where the survey is conducted. The analysis of individual results obtains an overview of the credibility or unreliability of specific tools of the communication mix by customers, and the comparison will show how Slovak data differ from foreign ones.

Results and Discussion

Marketing communication uses traditional but also new technologies and media, which serve as a channel for the transmission of information to the customer. Marketing communication tools can be divided into traditional and modern, which are related to the development of scientific and technical progress, information and communication technologies, and innovation. Traditional tools include advertising, sales promotion, personal selling, public relations, and direct marketing.

Traditional tools of marketing communication

Advertising

Advertising is any form of impersonal paid presentation and promotion of the sale of products, services, or ideas (Kotler Armstrong, 2004). The advertisement is mediated based on the media (*television, radio, cinema, newspapers, magazines, outdoor advertisement (billboards), internet, direct advertisement, point of sale*), which publishes the content of the advertisement to the target segment. Advertising is the most important communication tool, but we classify it in a sensitive category, which means that its incorrect use can cause the opposite effect and cause disgust or discouragement to the target entity (Birnerova & Krizanova, 2012)

Sales Support

All activities that serve to support the purchase or sale of services and products are another tool of marketing communication and that is sales promotion. Its goal is to increase the company's sales in the short term. For customer orientation, there are several tools with which sales support is provided and they are *samples, coupons, cash discounts, price packages, bonuses, client rewards, competitions, lotteries, games, promotional gifts, and others* (Kotler & Armstrong, 2004; Birnerova & Krizanova, 2012).

Public Relations

Another means of communication is public relations. PR is defined as the creation of planned and systematically maintained relations of the company with the public. The characteristic of this tool is building a positive corporate image.

Typical tools are press releases, speeches, written materials, websites, publishing your own corporate newspapers and magazines, sponsorship, charitable donations, support for the environmental movement, open days, and the like.

- Event marketing focuses mainly on the emotional component of each recipient. The recipient does not have to think for long but is guided by feelings from the environment. The main focus of event marketing is an event. If we were to go for a deeper search in event marketing, then it is mostly associated with Public Relations. Mutual ties create closer relationships with existing and new potential customers. In practice, this means an important link to the brand (Lenhart, 2007).
- Sponsorship is currently considered by many authors as a separate tool of the communication mix (Birnerova & Krizanova, 2012).

Personal sale

Personal selling means the oral presentation of a product to an individual or group of customers. The purpose of this instrument is to conclude a purchase agreement. The sales process includes individual steps:

- Identification and evaluation of potential customers
- Collection of customer data
- Making contact
- Product presentation
- Clarification of objections
- Conclusion of a purchase agreement
- Customer care after the sale

Within personal sales, we can also talk about relationship marketing, when there is a long-term relationship between the company and the customer. Based on his satisfaction and the creation of values, the customer remains loyal to the company (Kotler & Armstrong, 2004).

Direct Marketing

We define direct marketing as marketing activities that, through one or more media, offer products as nearly as possible to their target segment. The most commonly used tools are *mail, catalog marketing, direct response advertising in print, radio, and television, telemarketing, e-marketing, SMS-marketing, order vending machine.*

- E-marketing - is the most dynamic and revolutionary communication tool. The main tools of online marketing include: *online advertising, affiliate marketing, pay per click, search engine marketing, search engine optimization, Google AdWords, social media, eWOM, Website development, E-mail marketing* (Oancea et a., 2016).

Modern tools of marketing communication

We divide the tools of modern marketing communication into two groups. The first group is tools based on traditional media. This includes:

- guerilla marketing is the advertisement is placed in non-traditional places and is attractive for the recipient.
- ambient media is the placement of ads at seemingly unconventional places, thus utilizing ambient media denotes the formats wherein ads are placed other than the usual media consumed by people every day.
- shockvertising was created to define any advertising campaign which tries to attract the audience's attention by deliberately violating social values and norms. The aim of shockvertising is to create a strong emotion and reaction in the public.
- product placement is a method of advertising used by companies that want to make their product visible in a non-traditional way. Most often so that the product appears in the film - just so inconspicuously in the background or the character uses it in some way.
- advergaming is the creation of games in which the product is placed so that the user remembers it.
- viral marketing is a style of promotion that relies on an audience to generate the message of a product or service. It is characterized by low costs and works only if it creates a buzz (Ankiel, 2018).
    - Influencer marketing forms a subcategory of viral marketing. At present, we can monitor companies in choosing the most suitable way of communication with customers, which is the most financially affordable. One of them is influencer marketing. It most often uses tools such as blogs, Facebook, Youtube, Instagram, etc. In addition to the products themselves, potential customers are mainly interested in the opinion and experience with the product, the so-called reviews. The provision of information about an experience with products and services of the so-called word-of-mouth (WOM) has been going on among people since time immemorial, most often in the face-to-face form (Prikrylova & Jahodova, 2010). Kotler et al. (2007) define WOM as a form of personal communication that involves the exchange of information about a product or service between target customers, neighbors, friends, relatives, or colleagues. It basically gives the impression of selfless help or advice from a friend (Gundova & Cvoligova, 2019).

The second group of tools based on modern media consists of *social networking sites, blogs, discussion forums, virtual reality, services, and data sharing services* (Ankiel, 2018).

In the following section, we will analyze the data from the individual surveys. First, we will focus on data obtained through the adult population of the Slovak Republic. The credibility of the tools (Table 1) was determined in the third quarter of 2016 (Gubiniova et al., 2018). The next step will be the analysis of the data of the Nielsen agency survey from 2013 in comparison with 2007. The last part will be a comparison of the results of the Slovak Republic and abroad.

Table 1: Credibility of marketing communication tools in SR

Tools in marketing communications	Credibility
SMS Advertising	24%
Online banners	24%
Social Media Advertising	27%
Products placed in TV shows, series, video clips	32%
Advertising in cinemas	31%
Advertising in TV	35%
Advertising in radio	37%

Advertising in newspapers, magazines	44%
Billboards and external advertising	34%
Sponsorship advertising	55%
Required e-mail communication, newsletters	52%
Company Websites	63%
Reviews, customer blogs on the Internet	87%
Recommendations of Acquaintances	97%

For Slovak consumers, the most trustworthy tool of marketing communication is the recommendations of friends and acquaintances. They also trust the reviews and blogs of Internet users the most, they have the least trust in social media ads, online banners, and other marketing communication tools. These results could be useful for organizations that could use this survey to customize and innovate individual marketing communication tools.

In the case of a survey conducted in 58 countries around the world in 2013 (3rd quarter), recommendations from people known to customers became a credible tool. Compared to 2007 (1st quarter), this represents a difference of 6%. The second tool that customers trust the most is branded websites, whose credibility has increased by 9% compared to 2007. We've seen a 2% drop in magazine ads. If we look at the other side of the spectrum, we find that the tools that consumers least trust are the least text ads for mobile phones, online banner ads, and more. While companies may not be able to directly control news in earned media, such as consumer opinions published online, they can create a positive presence for their brands on their channels.

Table 2: Credibility of marketing communication tools abroad

Tools in marketing communications	Credibility	
	2013	**2007**
Recommendations from people I know	84%	78%
Branded websites	69%	60%
consumer opinions posted online	68%	61%
Editorial content such as newspaper articles	67%	-
Ads on TV	62%	56%
Brand sponsorships	61%	49%
Ads in newspapers	61%	63%
Ads in magazines	60%	56%
Billboards and other outdoor advertising	57%	-
Ads on radio	57%	54%
E-mails I signed up for	56%	49%
Ads before movies	56%	38%
TV program product placements	55%	-
Ads serves in search engine results	48%	34%
Online video ads	48%	-
Adss on soaicla networks	48%	-
Display ads on mobile devices	45%	-
Online banner ads	42%	26%
Text ads on mobile phones	37%	18%

If we compare the data from the tables in both cases (whether it is a survey conducted in Slovakia or abroad) people most trust the recommendations from their loved ones, friends, and acquaintances. And a 2018 BrightLocal report found that 91% of people aged 18-34 trust online reviews as well as personal recommendations. TrustYou, in its recent blog about “The Psychology of Online Reviews” pointed out another interesting statistic from research by social commerce company Reevoo: 68% of consumers trust reviews more when they see both good and bad scores,

while 30% suspect censorship or faked reviews when they don't see anything negative at all. (Lye, 2019). The average customer begins to trust the business after reading ten reviews (Murphy, 2019).

Conclusion

The foundation of an effective marketing communication mix is thus a clear definition of the goals and purpose for which the campaign is created. The clearer the objectives are defined, the easier it will be to measure the partial results (Rostasova, 2006) The aim of the paper was to theoretically define the issue of marketing communication tools. In terms of trust towards individual tools of marketing communication, we concluded that Slovak respondents trust the recommendations the most, traditional tools of marketing communication were placed at the bottom. When comparing results from abroad, the same phenomenon occurs. It is necessary to realize that marketing communication plays a decisive and important role in gaining new customers, and retaining existing ones.

Abstract

The paper discusses current trends affecting customer behaviour in order to briefly summarize what aspects affect clients when making purchasing decisions in the current turbulent times. Most attention is focused on the instruments that contribute most effectively to the success of sales of either new or existing tourism products. The contribution includes, among other things, graphically illustrated models with trends in popularity of individual forms of online marketing, examples of customer behaviour when buying tourist products and, last but not least, recommendations for companies, including an emphasis on sustainable development. In particular, secondary data from publicly available sources were used.

Keywords: Tourism, product, customer behaviour, modern marketing approaches and technologies

Introduction

People's preferences and behavior are constantly evolving, and with them the range of tourism services and products. Whereas in the past supply determined demand, today it is just the opposite. Increasing market saturation, growing consumer interest in themselves, higher disposable income and a growing leisure fund are affecting the success of tourism service providers. Being able to compete will become more and more challenging.

Companies face the difficult task of satisfying the needs and wishes of customers who have increasing demands not only on the product itself, on the way it is sold, on the level of communication from sellers, but also on the criterion of sustainability. Customers are increasingly interested in the origin and way of processing the raw materials used, prefer organic products and prefer regional suppliers, which is reflected in the decision-making process and consumer behavior in the provision of tourism services.

In today's turbulent times, it is necessary for all companies operating not only in tourism to find ways to satisfy clients' requirements for high quality services while maintaining a favorable price, using the most effective method of communication and meeting many other factors that influence their clients in purchase.

Due to the fact that it is easy to copy the competition in services, the best ones must be able to come up with constantly new ideas, offers, experiences and a unique overall customer care, of course in order to retain existing clients, but also to reach and gain new customers. This involves the "ant" work of all employees on whom the success or failure of the company depends. Therefore, in the article we focus on the activities necessary to achieve success in the form of the necessary volume of sales, turnover and especially a satisfied customer who will become a loyal client, hotel, restaurant, travel agency, transport company and other companies operating in tourism. This is not a list of all the steps that companies have to take, but selected factors affecting customer behavior, and in addition to traditional steps associated with building a brand, improving product quality or affecting customer emotions, we present trends that have been applied in recent years and they are mainly related to the use of new modern approaches and technologies. In addition, all companies are struggling to cope with the radical limitations of their operations due to "anticovid" measures, which are a completely new experience worldwide and that no one could have prepared for in advance. And so they try to look for ways to survive a difficult period. Those companies

that use this time for their development, especially in the field of technology, will be ready to respond quickly to changes in the behavior of their existing and potential customers.

Traditional Factors Influencing The Success Of The Sale Of Services

Of course, the product/service itself, its price, the method of distribution and promotion as essential tools of the marketing mix are among the key factors that contribute in no small part to the success of sales of either new or existing tourism products. At the same time, workers, product packages, cooperation and material environment (physical evidence) cannot be ignored as part of an extended marketing mix (Vaštíková, 2014). In the following text, we focus on other important factors that are closely related to the above-mentioned marketing tools and at the same time have a significant influence on customer behaviour.

Brand Building

The brand is essential not only for easy identification of the company, but also helps to keep these companies the right employees, attract new suitable job seekers, increase the company's performance and, of course, attract customers. Brand building is important for companies of all sizes, not just the largest ones (Kotler, Keller, 2013). The basis of building a brand is long-term thoughtful communication not only outwards, ie. primarily to customers and business partners, but also within the company, which is related to corporate culture. The main principle is not to rush anything and to put your employees first, communication and cooperation with them. It is ideal to follow the principle of everything starting inside and start finding out the status from all employees. The essence of branding is to create strong relationships with current customers and motivate them to repeat purchases and disseminate positive references, which is not possible without satisfied employees. To achieve such a state, it is necessary to continuously monitor their changing needs and respond to them. The brand affects almost all aspects of a company, whether it's marketing, interest in products or services, or how the company works. According to Forbes, the main advantage of the brand that customers love is the increase in profits. In addition, TLS Marketing adds that a successfully built brand brings benefits in the form of a better company image and customer loyalty. The Content Marketing Institution survey shows that, according to 89% of marketing managers, the most important goal is brand awareness followed by the sale itself. Given the current unfavorable situation in tourism, it is important to realize that improving pre-crisis quality accelerates the building of goodwill before the crisis and also helps revitalize the post-crisis regime (LU, L., 2020). Here are ten steps companies can take to improve their brand: get to know your customers, differentiate yourself from your competition, be personal, pamper your customers, invest in your brand, be consistent, communicate with your customers, don't forget to measure, that is, monitor The number of visitors to the site, the number of fans, and the average number of minutes that customers spend on your site, and try to learn from these numbers and constantly improve them. Measurement will help you get to know your customer and his needs better, and will also reveal which marketing activities will be most effective for you. Build trust and keep up with the times - watch what is happening around you and react to it.

Quality

Quality is one of the most watched criteria, the concept of quality is very individual and depends on the client's expectations, his previous experience and especially on the ability to maintain its long-term stability. (Kotler, 2007) Probably therefore, the effort is to set parameters on the basis of which the quality can be assessed even in tourism companies, where it is not possible to fully apply, for example, ISO standards. Today, quality has actually become a competitive necessity, in the 21st century only those companies that offer the highest quality of their products will prosper.

Current studies of customer behavior state that price ceases to be a fundamental and decisive factor in purchasing and that demands on quality, equipment and staff are rising. In the Czech Republic, the following examples of quality measurement in the field can be mentioned, there is a Czech service quality system, which is a certified project suitable for all organizations in tourism, which cares about further development and strengthening its position in the market. The aim of this system is to pass on to managers and entrepreneurs the appropriate know-how on quality management, which they will then use to improve services, whether accommodation, catering, travel agency services, tourist information centers, golf, winter sports, public and private organizations. non-profit sector, etc. Organizations that meet the appropriate requirements will receive a certificate and the privilege of using the quality mark "Q", which people know from abroad, similar systems have been operating for many years in Spain, Switzerland, France, Great Britain and other European countries (www.csks.cz). Accommodation facilities also have the opportunity to obtain a certificate from the Association of Hotels and Restaurants of the Czech Republic, depending on the extent to which they meet the criteria given in the Official Uniform Classification of

Accommodation Facilities in the Czech Republic; Tourist information centers and other organizations operating in tourism are also certified. Whatever the entity, it is important to realize that it is a never-ending process and it is necessary to constantly look for ways not only to maintain quality, but also to improve it. There are certainly a number of companies that provide quality services even without a certificate, but it is more difficult for clients to find such facilities. You can also contribute to increasing quality by using other techniques and methods, such as Mystery shopping.

Effect on emotions

Tourism and the hotel industry are to a large extent a trade with emotions and trust, the technologies mentioned above can also help us, but they will never completely replace the human factor (Vysekalová, 2014). For example, nothing inspires more positive emotions at the moment than when, after a long journey, a housekeeping worker shows up at your hotel room door with a portable container, extra bathroom salt and a cotton towel, because he has received a message from the receptionist that you have mentioned that you are travelling in new shoes and that your feet are broken, and because your room has no bath but only a shower, he will also address you by name. Of course, there are a number of other ways to impress the guest with a personal approach, e.g. in the hotel Terasa U Zlaté studně in Prague, permanent guests have their own personal bathrobes embroidered with their name, or pillow service. It is important to realize which target group of customers we are targeting and to use emotional appeals that are in line with their mission. At the same time, ethical principles and approaches, including sustainability, must be borne in mind.

Modern Approaches And Technologies Used To Influence Customer Behavior

The use of modern approaches and technologies contributes significantly to the success of companies, which is why it is increasingly used in tourism companies. It is one of the effective marketing tools, but its portfolio is subject to fashion trends, which must be regularly analyzed and new creative approaches found. We also provide specific examples of the latest trends that are part of the so-called online marketing, which is on average the fastest growing sector. In the Czech Republic alone, the volume of Internet advertising in 2017 reached more than 23 billion crowns. Compared to 2016, this is an 18% increase, in which display advertising and search advertising contributed the most in absolute values. The highest relative growth was recorded in search advertising (+ 26%), catalogs and in-line advertising increased by 17% and display advertising by 16%. From the point of view of the method of purchasing advertising space, the programmatic purchase of display advertising grew by 20% and the highest, 68% growth for purchases in real-time auctions (RTB). Expectations for next year are again optimistic. Survey participants expect online advertising to grow by at least 13% to CZK 26.4 billion in the coming years. Online advertising accounts for more than a fifth (22.5%) of total advertising spending across all media types. The data come from a survey of the advertising performance of Internet advertising, which is carried out for SPIR by the Median agency. (www.spir.cz) The data was commented by the chairman of SPIR Ján Simkanič with the following words.

"Record investments in online advertising confirm its increasing importance, especially in the area of programmatic trading, where the increase is most pronounced. From the point of view of the advertising space, the internet in the Czech Republic, as in the previous year, further strengthened its position as the second most important mediatype." The increase in investment and the development of forms of online advertising is also evident from the figures No. 1 and 2.

Fig. 1: Development of total expenditure on Internet advertising in the Czech Republic in 2008 to 2017 in billions CZK

Fig. 2: Performance of individual forms of Internet advertising in the Czech Republic in the years 2008-2017 in millions CZK

IAB Europe announced at its annual Interact conference that digital advertising grew by 13.2% to 48 billion EUR in 2017 due to a large increase in investment in advertising on social and mobile platforms and video advertising. The AdEx Benchmark study provides a report on the state of the European digital advertising market. Twenty European markets grew by double digits, with investment in mobile advertising growing by double digits in all 27 markets mapped by the study. Display ads on mobile have increased by more than 40% and now account for 42% of total display advertising, while video accounts for more than a quarter of total display advertising. Social media advertising grew at the same 38% rate and increased its share of the display, while video grew at 35% rate, four times faster than non-video display advertising. The increase in video advertising was driven by out-stream advertising, which recorded a 73.4% growth compared to in-stream, which was up 6.9%, is also evident from the figure below No. 3.

Fig. 3: Total digital ad spend: historical perspective in the years 2006-2017 in millions EUR

Mobile Advertising

Mobile advertising accounted for 17% of display advertising worth 2.87 billion in the Czech Republic in 2017. This represents an increase of 64% compared to 2016. For 2018, growth is estimated at 19%. If you are looking for some certainty, you can focus on mobile advertising, as it is expected to increase in 2019 and beyond. Why is that? We spend too much time on mobile phones. (Patrovský, 2018) According to the September NetMonitor 2018, the most visited days are Sundays and Mondays.

Video Marketing

Static banner advertising is a marketing trend of the past years. If nothing moves on the internet, you won't notice it. In the USA, they know this well, and this is where video advertising will account for 25% of campaigns as early as 2018 (eMarketer.com report: October 9, 2018). Believe that, in addition to burgers, the Czech Republic is also taking over this trend, and video formats will be seen on the Internet much more often in the coming years.

The growth of video advertising will be noticeable especially on social networks and YouTube, where it is a programmatic purchase. It is worth mentioning the fact that the video format presents the message better than a static banner and the website visitor will also notice it thanks to the movement. If you purchase a static banner ad, it will only appear to a large extent on computers or mobile devices. The video will run "cross-device" and we can say with certainty that it will increase your CTR (click through ratio) above the level of 1%. (SPIR, 2019)

Influencer Marketing

Recently, video marketing, which is closely linked to influencer marketing, has been increasingly used. An influencer is a person who has built a large community of people around him on social networks, where he expresses himself on various topics. If we look at the matter in general, influencers on social networks share experiences from their lives. They allow people to look into their privacy. But there are also influencers who specialize in one selected topic. On social networks, we can find a traveler who recommends specific destinations and hotels, a gourmet motivating others to a healthy lifestyle and more. Their huge advantage is that people trust them because they can present their ideas and opinions, address and engage potential customers of the company. Although they may not be experts, a large number of people trust them! The most successful Czech influencers have a community of several hundred thousand people around them. However, when cooperating with such large influencers, high costs must be taken into account. Therefore, especially among smaller companies, so-called microinfluencers have become popular, with, for example, around 10,000 followers, but their target audience is highly relevant. Influencers are very good at being able to incorporate a product into their content on social networks in a non-violent way, and thus become a bit of a modern star on social networks. The company's advertising does not only take the form of banners on the Internet, commercials on television or billboards around the roads, but is also placed, for example, on the Instagram profile of influecer in the form of product placement. However, it is important to be able to choose the right influencer to work with and consider who our customer is. Then it is no less important to agree on the content, style, budget and deadlines, then draw up a publication plan. It is necessary to keep in mind that no one will praise, for example, non-functional outdated hotel equipment, if this is not true, therefore it is necessary to always come up with a quality and proven product.

If a company has a problem with the presentation of its product or does not know how to sell it, it is important to entrust it to the right person from the ranks of influencers, who will then ensure a sufficient connection of your brand with the public. That is why many companies use influencers and associate their name with them. Influencers then incorporate the product into their posts and create the right impression. Influencer marketing trends include instastories or live video. Influencers can be addressed at trade fairs, use Google or use one of the influencer platforms for searching, such as Agorapulse, Buzzsumo or Achoo. If a company wants to be sure, it should contact one of the marketing or media agencies. It's important to find an influencer, because the trend is clear, which we can see in the figure No. 4 created in Google Trends.

Fig. 4*: Worldwide development of interest in influencer marketing and in the years 2014-2018*

Robots

Robots are helping in the online environment more and more often. They index pages, collect information or respond in e-shops, when searching for flights, accommodation, etc. For example, when a customer just can't find their favorite hotel in a new destination. The goal is clear, cost savings and automation. It could be assumed that this is more of an example of Japan or the USA, but even in the Czech Republic it is beginning to expand. (Patrovský, 2018) For example, in April 2018, Kofola presented the campaign of a robot Karel looking for love. He was everywhere on the Internet, television and billboards, where he tried to find his desired partner and learn to love. On the Internet, the chatbot was behind the ad, which, after clicking on the banner, took you through its long, albeit passionate, conversation in the Messenger application. Interestingly, no one knew anything. So we use robots more and more often and working with them is very specific and requires an individual approach. However, with the right design, they will save you costs and give you the speed you need for your business.

Bluetooth Marketing

It is one of the latest trends, it works on the principle that an advertising message is first made in the form of an image, text, web link or QR code, then uploaded to the memory of the transmitter unit, which automatically sends it to devices with active Bluetooth technology, usually 100 meters in the open. space and according to the technology used, it is possible to increase the range. Of course, it is necessary for the customer to agree to receive these messages. The main advantages are low costs, the possibility of a campaign 24 hours a day, the possibility to operatively change the content of the message, a clear and regular evaluation of the success of the advertising campaign. The main disadvantage is the requirement to constantly turn on bluetooth on the target mobile device.

Sustainable Development

In addition to the use of modern technology, it is increasingly important to realize that the importance of ecology will continue to grow, in all fields. In tourism, this will cause increased demand for destinations in which nature and population will play an increasingly important role. The importance of individual regions within the destination is constantly growing, destination preferences are increasingly associated with the support of the local population and their friendly attitude to the growing number of arriving tourists. At the same time, ecotourism should not be confused with sustainable tourism development (ETC).

A fundamental aspect of sustainable development is defined in the Report to the United Nations World Commission on Environment and Development (WCED), which identifies the needs of the present as sustainable development without compromising the ability to meet the needs of future generations to meet their own needs. Another definition in the materials of the Ministry of Regional Development is particularly apt. Sustainable development does not only mean protecting the environment, but also trying to combine economic and social development with environmental aspects. Nor is he a scarecrow that "normal people" should be afraid of, because perhaps they would be in danger of living in caves by candlelight. It is not a step back, into the past. On the

contrary, it strives for modernization, the use of new efficient technologies and techniques that save time, energy, fuel and the environment. But even that is not enough, only a responsible life is sustainable, not a waste, a considerate life, not a selfish one. (MMR Czech Republic, 2007)

Conclusion

With the advent of the COVID-19 pandemic, there has been a great challenge to change behavior and approach to shopping, not just on the part of customers. Likewise, the supply side must adapt to the new situation, which involves a number of restrictions. Due to the fact that this is not a short-term matter, changes in established patterns of behavior are necessary. Many companies are literally struggling to survive because state assistance is very limited and they are trying to find new ways to communicate with the customer or distribution channels. Unfortunately, tourism companies are most affected by the new situation, they cannot, like other producers of tangible goods, supply their services through the e-shop. If the situation does not stabilize as soon as possible and tourism does not recover, at least in part, the number of tourism service providers will be expanded and forced to close down, but it will also mean leaving the market for many of their subcontractors.

At the same time, it should be borne in mind that the positive effects of a pandemic, such as the effect on environment, cannot be overlooked, and there is an opportunity to prepare for clients' interest after anti-epidemiological measures and to focus on introducing or improving, for example, their online marketing tools. even potential clients currently spend much more time on the Internet. There is also the fact that even though Czechs are still sensitive to price, the way it is perceived is changing. Customers are more concerned with the total value associated with meeting their expectations and appreciate fair dealing. Which leads to the need to constantly identify the needs of customers and strive to satisfy them to the maximum in the form of a quality product. It is important not to promise something that the customer cannot get. It is necessary to keep in mind that it is much harder to keep an existing client than to acquire a new one and adapt all business activities accordingly, and keep in mind that the best technology will not replace the human factor in providing services.

In terms of future developments, it can be assumed that clients will have greater demands on time savings, sustainability and will place even greater emphasis on individuality, experience and connection with lifestyle. While digitization and other modern technologies have helped make customers more informed, they are still people with all their needs, doubts, emotions and psychological characteristics that influence their decisions. We can only believe that hyperconsumption will become a thing of the past and people will increasingly think about so-called sustainable tourism when shopping.

Abstract

In recent years, the dental implant market has grown significantly due to high demand. The main dental implants are commercially pure titanium (cpTi - grade 4) and zirconia (ZiO2). The aim of this paper is to analyze performances of both dental implants, in terms of mechanical and biological properties, and their growth on global market. Moreover, the paper follows the results of comparing the two dental implamts, in order to decide which one is more suitable.

Keywords: Titanium Implants, Zirconia Implants, Market Demand, Implant Price.

Introduction

Medical implants have been used since the 19th century, at a time when the metal industry was developing in various fields. Implantable materials and their design help to restore bone tissue as close as possible to normal functions.

Stomatology was one of the first fields to adopt the use of metallic biomaterials. Today, due to the evolution of manufacturing technologies, a much wider range of biomaterials is used in dentistry than in the past. The main biomaterials used are titanium and its alloys, cobalt-chromium alloys and zirconium oxide (zirconia).

Since the 1950s, titanium has been used in orthopedic applications. Nowadays, pure titanium is still used in implantology, especially in dentistry due to its low modulus of elasticity which is closer to that of bone compared to other metallic materials, good mechanical strength, great corrosion resistance and excellent biocompatibility (Saini et. al., 2015).

Dental implants made of zirconia have appeared on the market more recently, starting with 2007. Being a ceramic material and having a crystalline structure, it shows an excellent hardness and corrosion resistance. In addition, another advantage over metallic materials is the customizable aesthetics (Apratim, Abhishek, et al., (2015).

Given that the market for dental implants is dominated by materials based on titanium and zirconia, this paper will study the performance of each type of implant and their relationship with the price variation in Europe.

Comparative Analysis of Implant Performance

Worldwide, more than 1,000 tons of titanium devices are implanted in patients each year. The dental implant biomaterial is a decisive factor for long term functionality of implants. The biologic environment does not accept completely any material, thereby the biologic performance must be optimized. A successful implant is represented by a fixed bond between the implant and the bone tissue. The type of biomaterial should be selected in order to reduce the negative biologic response. Dental implants are exposed to loads and fatigue cycles in function, thereby good mechanical properties are required (Daniel Jogaib Fernandesa, et al. 2015).

Biomaterials used in the manufacture of dental implants tend to corrode because of physiological conditions, therefore there is the possibility of high reactivity to the body (Saini et. al., 2015).

Composition and topography of implant surface induce high impact on the success of implant treatment (Liqiang and Zhang, 2018).

Fig. 1: Clinical requirements of dental implants (Daniel Jogaib Fernandesa, et al. 2015, Eliaz, Noam, ed., 2012).

Titanium Implants

Titanium has been successfully used as dental implant material due to its excellent biocompatibility, a result of formation of stable oxide layer (TiO2) on its surface. Biomaterials used in the manufacture of dental implants tend to corrode because of physiological, therefore there is the possibility of high reactivity to the body. The layer of TiO2 will not stop the corrosion process but it will significantly reduce the corrosion rate.

The commercially pure titanium (cpTi) is the most used as dental implant, because of its biocompatibility, strong osseointegration and toxic-free character. CpTi is classified into 4 grades, differentiated by their oxygen content. From a biomechanically poin of view fit for purpose and the succes rates are high over many years of functionality.

The elastic modulus of cortical bone is 20 GPa, and the most used commercial alloys have an elastic modulus ranging from 110 GPa for Ti6Al4V to 220 GPa for the cobalt-chrome alloys (Liqiang and Zhang, 2018).

Commercially pure titanium has an elastic modulus of 105 GPa, lower than most other biomaterials implant, which mean a low stress shileding effect. The aesthetic of titanium implants is not well apreciated by patients because of the gray color of titanium or, in some situations, the recession of soft tissue recession which highlights the metal components (Gubbi and Wojtisek, 2018).

Table 1: Mechanical properties of cp-Ti grade 4

Material	Compressive strength (MPa)	Poisson's ratio	Modulus of Elasticity (GPa)
cp - Ti grade 4	510	0.37	105

Zirconia Implants

Zirconia is a crystalline dioxide of zirconium (ZrO_2). Its mechanical properties are very similar to those of metals and is well known for the similar color with tooth color.

Over the years many all-ceramic systems have been proposed for a restorative material with a closer aesthetic of tooth. Nowadays dental research companies tend to prefer metal-free prosthetic restorations to improve aesthetical outcome of fixed partial dentures restorations. Natural look of soft tissue in contact with fixed partial dentures is influenced by two factors: mucosal thickness and typology of restorative material. The use of metal-free restorations conducts to a closer look of soft tissue to the natural one, compared to porcelain fused to metal restorations (Apratim, Abhishek, et al., 2015).

Zirconia is a well-known polymorph that occurs in three forms: monoclinic (M), cubic (C) and tetragonal (T). In fixed partial dentures restorations, the most used ones are ceramics produced at room temperature with a tetragonal phase only, called Tetragonal Stabilized Zirconia (TZP) TZP materials, containing approximately 2–3% mol Y2O3, are completely constituted by tetragonal grains at a nanometer scale. Yttria stabilized TZP is compatible for biomedical application due to low porosity, high density, high bending, and compression strength (Saini et. al., 2015, Apratim, Abhishek, et al., 2015).

The mechanical properties of Zirconia are similar to those of stainless steel. Its resistance to traction can reach 900-1200 MPa and its compression resistance is approximately 2000 MPa. This biomaterial also on cyclical stress (Manicone et. al.,2007).

Table 2: Mechanical properties of Zirconia

Material	Compressive strength (MPa)	Poisson's ratio	Modulus of Elasticity (GPa)
Zirconia (Y-TZP)	2200	0.32	210

Comparision of performance

As it can be seen form the graphic, cpTi and zirconia have different properties, each of the them having advantages and disadvantages.

In terms of modulus of elasticity, titanium has an advantage. Its lower modulus of elasticity is closer to that of human bone (15-20GPa) than the one of zirconia.

Fig. 2 : Comparison of mechanical properties

As it can be seen form the graphic, cpTi and zirconia have different properties, each of them having advantages and disadvantages.

In terms of modulus of elasticity, titanium has an advantage. Its lower modulus of elasticity is closer to that of human bone (15-20 GPa) than the one of zirconia. Poisson's ratio values of both biomaterials are close, with zirconia having a lower value. The cortical bone Poisson's ratio is around 0.3, thereby zirconia presents a better value.

Compression strenght is the category where the two materials differ greatly, zirconia having a value 4 times higher than cpTi. This translates into a much higher hardness, but also associated with increased fragility.

Economic analysis of titanium and zirconia implants in Europe

The major factor which influence the growth of the market is the increase in elderly population and the patients choices of Eastern Europe due to a more affordable dental treatment, Western Europe having the most expensive treatments in medical healthcare (iData Research Inc., 2019),.

There are five segments of dental implants market:

- Material
- Type of material
- Geography
- Implant design
- End - user

End - user segmentation can be reflected in figure 3, which contain six main stakeholders.

Fig. 3 Stakeholders of dental implants market

In Europe there are several companies that supply dental implants, between them being a high competition for gaining more of the market share. The competition is accentuated by the rapid advancement of technology, the prices of rivals, and changes of government policies (Straumann's Annual Reports for online users, 2019).

In Europe the main suppliers of dental implants made of titanium and zirconia are the following:

- Straumann Group;
- Dentsply Sirona;
- Zimmer Biomet;
- Danaher Corporation;
- 3M, Inc.;
- Astra Tech AB;
- Sweden & Martina S.p.A;
- ZL-Microdent Attachment GmbH & Co. KG;
- Timplant Ltd.;
- Leone S.p.A.;
- Tekka SA;
- OsteoCare Implant System Limited (iData Research Inc., 2019, Straumann's Annual Reports for online users, 2019).

Market demand for titan and zirconium implants

The popularity of the implants, mainly dental implants, is a result of extensive research done in the field of biomaterials, which suggested for implants improved systems. The disadvantages that were proved for metallic implants for instance, proved to scientists the fact that the materials used needed to be changed. Thus, titan and zirconium were the material proposed which proved to have a high demand on the market and respond to the same characteristics, even improving some aspects.

Although the market size for dental implant was evaluated in 2019 at 4.6 billion dollars, from 2020 to 2027 the size is expected to increase with an annual rate of over 9%. One reason for this increase can be found in the accidents that occur every year, data presented by the World Health Organization (WHO) (Grand View Research, 2020).

Fig. 4: Market evolution of dental implants (Grand View Research, 2020)

The price for a dental treatment cannot be mentioned without considering other aspects that are involved in total cost, these elements usually being unknown by a future patient because the level of data of information might not be enough of the future patient chooses a cheaper dental treatment. For these people it is necessary to answer one important question: how much does an implant cost?

This question is often misunderstood, or it is a wrong question because the doctor is not the one that sells the implant, he is the one responsible for a medical treatment using dental implant. The appropriate question, for the correct assessment would be" how much does a dental rehabilitation treatment with implant cost?"

Since the implant is actually, formed out of 3 main elements it is necessary to consider all these when conducting ana analysis regarding the price of the dental implant. Thus, the price is estimated between 600 – 2500 euros for the dental implant, 50 – 500 euros for implant screw and 150 – 1000 euros the crown, resulting in a treatment between 830 to 4000 euro.

Table 3: Implant costs in Romania (just for one implant)

No.	Company Name	Implant Type	Implant Price (euro)
1	Ortho Implant Center https://orthoimplantcenter.ro/	Dental implant Megagen AnyOne	450
		Dental implant Megagen AnyRidge	500
		Dental implant BIOMET 3I	750
2	Omnia Dental https://www.omniadental.ro/	Dental implant Bredent Sky Classic/ Dental Implant Bredent Blue Sky	595
3	Clinica Dr. Melnic www.clinicadrmelnic.ro	Dental implant AlphaBio (includes healing abutment and healing screw)	400
		Dental implant Sweden & Martina (includes healing abutment and healing screw)	500
		Dental implant Straumann Roxolide SLA	715
		Dental implant Straumann Roxolide SLA ACTIVE	775
		Straumann screw	245
4	DELTA CLINIC DENT https://www.dental-med.ro/implant-dentar-pret/	Monolithic Zirconia crown	210
		Monolithic Zirconia crown - multilayer	250
		Zirconia - ceramic crown	275
5	Velvet Dental https://velvetdental.ro/ro/	Zirconia implant crown	860
		Dental Implant ALPHA BIO (Israel)	515
		Dental Implant MEGAGEN (Coreea)	655
		Dental Implant STRAUMANN (Switzerland)	1100
		Zirconia screw - STRAUMANN	290

As it can be seen in table 3 the prices are variable for each implant but are in the range mention before. The material also is a very important part in the price establishment, and it also influences the quality of the work done. Thus, the main findings refer to the fact that the evolution in technology and in the quality of the implants should be considered by people when going to the doctor for a dental implant. The biomaterial domain is still developing thus prices today are changes according to the advances made in this area.

Conclusions

Both Zirconia and Titanium implant materials perform and integrate well with the bone, due to their mechanical and biocompatible properties. Titanium implants performance are well known, while Zirconia is still under research as it has not been used long enough to tell long-term success. Titanium implants are incredibly strong, have high flexural properties and resist fracture. Zirconia has a lower modulus of elasticity which can lead to a more compatibility with the bone, but it's lower elasticity can lead to more microfractures than titanium. Patients prefers zirconia implants when it comes to aesthetics, due similar color with tooth, but most of them choose titanium for its lower prices. Extensive research needs to be addressed when considering any kind of dental implant. The quality is a very important part which is also expressed by the material from which the implant is made of. The characteristics like osseointegration, durability, quality - benefits facts of dental implants are of interest and will be further analyzed.

Abstract

In today's business environment, the global economy creates more opportunities for everyone, but also more risks, as it is scaled by a wide dimension of information and communication technologies, international integration or the maturity of domestic markets. There are several possibilities for increasing the attractiveness of each country for foreign investors, while many of them also have favourable effects on the economy as a whole. The paper focuses on the evaluation of the macroeconomic development of regional disparities of individual regions of the Slovak Republic through the forecast of economic development in individual blocks of the macroeconomic module of Slovakia's regionalization. The aim of the article is to assess the attractiveness of the market of the Slovak Republic for foreign investors in terms of regional disparities and to assess the possibilities of eliminating the identified disparities through the use of foreign capital. The hypothesis we are working on in the article proved to be true, because it was confirmed on the basis of the analytical part of the article.

Keywords: Region; Regional Disparities; Labour Force; Economically Active Population; Foreign Investment.

Introduction

At present, the issue of regional development is one of the most serious problems of any global society. The main reason for the emergence and deepening of regional differences in countries is the different possibilities of regions to adapt to the requirements of economic and social transformation, adaptation to new development conditions, there is also a difference in the starting positions of individual regions. However, these differences are conditioned by the complex dispositions of financial and human resources, infrastructural, civil-cultural, but also positional, which increase, resp. reduce their developmental dispositions (Alvaro-Moya et al., 2020). The workforce is an important factor in achieving the country's prosperity, not only the number of the workforce is important, but also its distribution and structure in the country, especially gender, age and education. Several characteristics are used to measure changes in the age composition of the population, e.g. average age, aging index, load indices. These characteristics take into account only changes in the age structure of the population and do not take into account the impact of economic activity (Pazilov et al., 2020). It is therefore appropriate to use special characteristics to characterize changes in the age structure of the workforce. These are indicators that tell us how the workforce is burdened by the economically inactive population or. a certain group of the economically inactive population (Zygmunt, 2019). Another important indicator is the group representing the economically active population. The economically active population represents all persons, regardless of gender, who make up the supply of labour for the production of goods and services for a defined period of time, i.e. reporting period (Cruddas and Pitts, 2020). The production of goods and services must include the production and processing of primary products, whether for the market, for exchange or own consumption, the production of all other goods and services for the market and, in the case of households producing such goods and services for the market, the relevant part of production for own consumption. Furthermore, the economically active population can be represented by all persons, regardless of age, including persons younger than the age intended for measuring the economically active population who have not been economically active. The labour market models the development of employment, unemployment and wage development in individual regions of the country and determines the determinants of employment, including economic activity rate, unemployment rate, employment by sector of national economy, population structure, educational and professional structure, place of work and work productivity, etc. (Hraskova and Bartosova, 2014).

Cite this Article as: Zuzana ROSNEROVA and Ladislav VAGNER "Attractiveness of The Slovak Market in Terms of Development of The Working Environment for Foreign Investors" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

According to Silvestri et al. (2020) there are divergent processes between the regions of the countries, which can be more stabilized at some levels through the financial capital of foreign investors. The macroeconomic view of foreign investment is based on the classical theory of international trade, especially the theory of comparative advantages; a more modern view of foreign investment is provided by Dunning's "Investment development path5", which describes their development in the country in five stages. The first phase is characterized by a low inflow of investment and almost no outflow, when domestic companies are unable to take advantage of their comparative advantages. In the second phase, foreign investment is gaining in importance, the country's production and productivity are increasing, but wages remain low, and domestic investors rarely invest abroad, especially in neighbouring countries, through export investments. In the third phase, there is an increase in wages, which loses the country's attractiveness of cheap labour, for investors there are new benefits, such as. growing consumption, technological and scientific development, involvement of domestic economic entities in foreign markets. In the fourth stage, domestic economic agents become major investors abroad, and in the final phase there is a convergence of import and export investment, accompanied by a slight increase in foreign investment inflows, which is determined by other variables than in the first stages (Duran-Nebreda et al. 2020). The possibility of increasing the well-being of citizens is derived from uninterrupted economic growth (Jakimowicz and Rzeczkowski, 2019). According to Kowo and Akinbola (2019) at the microeconomic level we can explain the determinants of foreign investment and the company's behaviour by product life cycle theory, which explains the various stages of the company's entry into foreign markets by dividing product life into 3 stages.

In the context of investment definitions, there is a wide variety of typologies that divide foreign investment according to different aspects. In terms of the target market, we encounter foreign investments that are oriented only to the domestic market, while the investor's effort is to satisfy the demand for products in the host economy, or to prevent competition from taking over market share. Foreign market-oriented investments are defined as export-oriented investments that take advantage of the host country but export most of their output (Ahmad et al. 2020). In terms of structure, investments are selected for horizontal and vertical investments. Horizontal investments flow into the same sector as in the investor's home country in order to meet demand and reduce the costs associated with the transport of goods. Vertical investments consist in dividing the production process into several levels and relocating part of the production abroad due to lower production costs. Vertical investments can be further divided into "backward" investments, which means that a company abroad produces an intermediate product that is exported to the investor's home country, and "forward" investments aimed at finalizing the product (Oliinyk et al., 2018).

In the past, foreign investment was almost exclusively linked to the area of production, recently the trend has changed significantly and is also used in the services sector. The positives of foreign investment also affect the government's efforts to support their inflow into the home country. Foreign investment can help a country in terms of economic growth or growth of the country's competitiveness (Janoskova and Kral, 2019). The main benefits that usually accrue to the host country include the inflow of capital that is lacking in the economy and at the same time long-term, it is also the influx of new technologies into the country, which over time are transferred to other companies in the country, resulting in increased productivity in the economy (Durana[1] et al., 2020). Foreign direct investment also brings new management concepts, marketing knowledge and thus improves the qualifications of employees, they have access to a number of professionals from around the world who help with business start-ups, training and coaching employees. Other advantages of foreign investment often include the improvement of environmental standards, infrastructure, development of regions, competitive environment (Kowo and Akinbola, 2019). In addition to the positive impact, however, foreign investment also has a negative side. The most frequently mentioned negatives include the crowding-out effect of domestic investment, the pressure to strengthen the currency, which disadvantages export-oriented entities, a temporary reduction in employment caused by the restructuring process, crowding out domestic competition unable to compete with economically strong competitors in terms of productivity and labour costs (Ludbrook et al., 2019). In addition to labour costs, the investor must also take into account the availability of labour (Durana[2] et al. 2020). If wages are low but employment is full in the country, the investor may have difficulty finding enough skilled workers, especially with a greenfield investment, which will cause a significant increase in wage costs (Wang et al., 2020). Therefore, in addition to wages, the investor must take into account the development of unemployment, the level of qualification of workers, the development of long-term unemployment or the structure of the unemployed by industry. Another negative impact of foreign investment is a situation during which the balance of payments may deteriorate through the repatriation of profits, which means that profits do not remain in the home country where they could be reinvested and help the country further develop, but are transferred to investors' foreign accounts. From the above effects, it is clear that any investment can have a positive but also a negative impact on the host country. However, in the final assessment of foreign investment, it is important to compare all the effects that the investment brings.

The aim of the article is to assess the attractiveness of the Slovak market for foreign investors in terms of unemployment indicators in individual regions, to evaluate the state of foreign direct investment in the Slovak

Republic and to derive the interest of investors in doing business on the Slovak market. We work with the hypothesis that more developed regions will be more interesting for foreign investors compared to less developed regions of Slovakia.

Methods

In this article, we deal with two basic macroeconomic factors on which a country's prosperity depends. We have chosen the issue of the workforce, which is a very important determinant for assessing the prosperity of the Slovak Republic. As the second important factor, we have chosen the issue of foreign investments and their inflow for the Slovak Republic, because the use of foreign investments is closely linked to regional development, which affects the issue of employment of individual regions. The following table shows the division of the Slovak Republic from a regional point of view. According to the regional division, Slovakia is divided into 8 regions depending on the regional cities, of which there are eight in Slovakia. This breakdown is given in Table 1.

Table 1: Amounth of residents within regions by permanent residence in 2019

Region	Amounth of residents
Bratislava Region	669 592
Trnava Region	564 917
Trencin Region	584 569
Nitra Region	674 306
Zilina Region	691 509
Banska Bystrica Region	645 276
Presov Region	826 244
Kosice Region	801 460
SLOVAKIA	**5 457 873**

Figure 1: Division of the Slovak Republic according to regions

We used comparative methods to evaluate the above factors. To assess the development of the workforce, we selected the period March 2020 and March 2019, which we will evaluate one year on the basis of the findings with emphasis on the structure of the economically active population and the state of unemployment in Slovakia in the regional selection.

A: Labor force - economically active population

The workforce is an important factor in assessing the attractiveness of the environment for an investor who is considering investing in business in a given country. The labor force is the part of the population represented by the

employed and the unemployed who are actively looking for work. The work potential that is applied in the work is considered a real workforce and thus forms an economically active population, to which the following analysis is devoted.

Within the structure of the economically active population, we determined the number of job seekers in the mentioned periods on the basis of available statistics. The following table provides information on the volume of the economically active population for March 2020. It also includes information on the available number of jobseekers and also on the unemployment rate, which was registered in March 2020 according to the regional breakdown of the Slovak Republic.

Table 2: Basic indicators on unemployment in the Slovak Republic in March 2020

2020			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	361 501	10 511	2,91%
Trnava Region	283 363	8 329	2,94%
Trencin Region	300 720	9 825	3,27%
Nitra Region	341 915	11 961	3,50%
Zilina Region	346 898	14 191	4,09%
Banska Bystrica Region	332 068	23 655	7,12%
Presov Region	403 714	35 128	8,70%
Kosice Region	382 575	29 393	7,68%
SLOVAKIA	**2 752 754**	**142 993**	**5,19%**

According to the data in the table, the lowest unemployment rate according to the regional breakdown in March 2020 was in the Bratislava countries with a rate of 2.91%, the worst situation was recorded in the Presov region, which recorded an unemployment rate of 8.70%. The largest volume of economically active population was recorded in the Presov region with 403,714 inhabitants and the lowest volume of economically active population was recorded in the Trnava region. The highest available number of job seekers was in the Presov Region and, conversely, the lowest number was in the Trnava Region.

Another breakdown of the workforce is the gender breakdown. The following table shows the state of the economically active population, the number of applicants available and the unemployment rate for the period March 2020, broken down by gender - women.

Table 3: Basic indicators on unemployment in the Slovak Republic by sex - women - March 2020

Basic indicators on unemployment in the Slovak Republic – women 2020			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	174 565	5 696	3,26%
Trnava Region	130 332	4 541	3,48%
Trencin Region	137 334	5 040	3,67%
Nitra Region	156 291	6 738	4,31%
Zilina Region	152 114	7 235	4,76%
Banska Bystrica Region	158 664	12 896	8,13%
Presov Region	179 345	17 914	9,99%
Kosice Region	172 127	15 498	9,00%
SLOVAKIA	**1 260 772**	**75 558**	**5,99%**

The lowest unemployment rate by gender for women in March 2020 was recorded in the Bratislava region with 3.26%. The highest unemployment rate for women was in the Presov Region with 9.99%. The largest number of women who belong to the economically active population was in the Presov Region, on the contrary, the lowest number was recorded in the Trnava Region.

Table 4: Basic indicators on unemployment in the Slovak Republic by sex – men – March 2020

Basic indicators on unemployment in the Slovak Republic - men 2020			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	186 936	4 815	2,56%
Trnava Region	153 031	3 788	2,40%
Trencin Region	163 386	4 785	2,87%
Nitra Region	185 624	5 223	2,69%
Zilina Region	194 784	6 956	3,42%
Banska Bystrica Region	173 404	10 759	6,11%
Presov Region	224 369	17 214	7,41%
Kosice Region	210 448	13 895	6,36%
SLOVAKIA	**1 491 982**	**67 435**	**4,39%**

The lowest unemployment rate by gender - men for the period March 2020 was recorded in the Trnava region with 2.40%. The highest unemployment rate for men was in the Presov Region with 7.41%.

Table 5: Basic indicators on unemployment in the Slovak Republic in March 2019

2019			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	352 498	9 474	2,91%
Trnava Region	285 330	6 793	2,38%
Trencin Region	303 705	8 782	3,27%
Nitra Region	343 801	10 473	3,50%
Zilina Region	340 741	13 312	4,09%
Banska Bystrica Region	333 689	23 182	7,12%
Presov Region	400 733	34 955	8,70%
Kosice Region	382 003	30 991	8,11%
SLOVAKIA	**2 742 500**	**137 962**	**5,03%**

Based on Table 5, the lowest unemployment rate in March 2019 was in Slovakia in the Trnava Region, when the unemployment rate reached 2.38%, and the highest unemployment rate was in the Presov Region, where it reached 8.70%.

Table 6: Basic indicators on unemployment in the Slovak Republic by sex - women - March 2019

Basic indicators on unemployment in the Slovak Republic - women 2019			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	172 664	5 354	3,10%
Trnava Region	127 866	3 902	3,05%
Trencin Region	138 846	4 641	3,34%
Nitra Region	157 024	6 191	3,94%
Zilina Region	148 330	7 052	4,75%
Banska Bystrica Region	158 208	12 957	8,19%
Presov Region	175 945	18 250	10,37%
Kosice Region	173 641	16 655	9,59%
SLOVAKIA	**1 252 524**	**75 002**	**5,99%**

The lowest unemployment rate by gender for women in March 2019 was recorded in the Trnava region with 3.05%. The highest unemployment rate for women was in the Presov Region with 10.37%.

Table 7: Basic indicators on unemployment in the Slovak Republic by sex - men - March 2019

Basic indicators on unemployment in the Slovak Republic - men 2020			
Region	**Economically active population**	**Available number of job seekers**	**Unemployment rate**
Bratislava Region	179 834	4 120	2,72%
Trnava Region	157 464	2 891	1,71%
Trencin Region	164 859	4 141	3,20%
Nitra Region	186 777	4 282	3,06%
Zilina Region	192 411	6 260	3,43%
Banska Bystrica Region	175 481	10 225	6,05%
Presov Region	224 788	16 705	7,03%
Kosice Region	208 362	14 336	6,63%
SLOVAKIA	**1 489 976**	**62 960**	**4,07%**

The lowest unemployment rate by gender - men for the period March 2020 was recorded in the Trnava region with 1.71%. The highest unemployment rate for men was in the Presov Region at 7.03%.

It is important for foreign investors to monitor the state of the workforce in the target market also by age. The following table shows the numbers of job seekers in Slovakia in the period March 2020.

Table 8: Job seekers in the Slovak Republic by age in the period of March 2020

	<25 years			25-54 years					55 years and older		Σ
Region	<20 years	20-25 years	25-29y.	30-34y..	35-39y.	40-44y.	45-49y.	50-54y.	55-59y.	60y. and older	
Bratislava Region	157	845	1 310	1 592	1 768	1 650	1 187	987	1 132	728	**11 356**
Trnava Region	249	948	1 164	1 189	1 282	1 278	1 079	1 023	1 125	654	**9 991**
Trencin Region	242	1 092	1 336	1 317	1 410	1 387	1 252	1 341	1 610	869	**11 856**
Nitra Region	370	1 322	1 521	1 580	1 721	1 835	1 622	1 746	2 026	1 277	**15 020**
Zilina Region	406	1 723	1 844	1 944	1 863	1 873	1 867	1 973	2 232	1 196	**16 921**
Banska Bystrica Re	711	2 515	2 976	3 200	3 372	3 554	3 352	3 520	4 011	1 889	**29 100**
Presov Region	1 785	4 573	5 035	4 872	5 033	4 744	4 589	4 324	4 532	1 921	**41 408**
Kosice Region	1 104	3 371	3 726	3 984	4 106	4 305	4 183	3 950	4 374	2 112	**35 215**
SLOVAKIA	**5 024**	**16 389**	**18 912**	**19 678**	**20 555**	**20 626**	**19 131**	**18 864**	**21 042**	**10 646**	**170 867**

Based on the table, we see that the highest number of job seekers by age was recorded for people aged 40-44 and the lowest number of job seekers in terms of age was recorded for the age category under 20 years. During this period, a total of 170,867 applicants applied for the job.

To approximate the state of unemployment, we present Graph 1, which shows the development of unemployment in the Slovak Republic for the period 2010 - 2021.

Figure 2: Development of the number of unemployed in Slovakia in the period 2010 – 2021

As Figure 2 shows, after a high level of unemployment, which was most pronounced in 2010, the unemployment rate gradually began to decline. The lowest unemployment rate was reached for 2019. A forecast is set for 2020 and 2021, which works with increasing unemployment.

For foreign investors, the development of wages in a given country is also a very important aspect when making decisions. The following table provides an overview of the amount of nominal wages achieved in Slovakia in 2019 according to the quarterly statement.

Table 9: Average nominal wage, nominal wage index and real wage index in 2019 in Slovakia by quarter

Indicator	2019			
	1. Q	2. Q	3. Q	4. Q
Average nominal monthly wage of an employee in the Slovak economy	1 023	1 101	1 068	1 177
Nominal wage index	107,10	109,70	107,70	106,90
Real wage index	104,60	107,00	104,70	103,90

According to Table 9, the nominal wage was the highest in the 4th quarter of last year at € 1,177.

B: Foreign investments

A relatively large number of countries around the world use different types of initiatives to attract investment. The main goal is to attract investors to specific sectors of the economy or localities and create positive externalities. For the investor, government support means reducing risks, costs and increasing profits. However, a prerequisite for successful development is the fact that the government can correctly determine which field is advantageous for the country and in which location. If it fails, allocation inefficiencies occur. Therefore, government agencies are created that reduce information asymmetries with the investor and help him decide on the location of the future business. With the removal of barriers to global capital movements, competition for investment began to intensify. According to statistical data, the main investment countries in Slovakia are the Netherlands, the Czech Republic, Austria and Germany. According to sectors, investors invest the most in manufacturing, financial and insurance services, wholesale and retail. These percentage figures show the following two graphs, which provide an overview for the period of 2017.

Figure 3: Main foreign investors for the Slovak Republic by country in 2017

Figure 4: The most attractive industry areas for investors in the Slovak Republic in 2017

Table 10: Basic indicators of foreign investment in Slovakia in the period 2016-2018 (in billions of USD)

Foreign Direct Investment	2016	2017	2018
FDI Inward (in million USD)	805	2 277	475
FDI Stock (in million USD)	47 593	55 838	57 109
Number of Greenfield Investments	53	48	44

According to available statistics, the volume of foreign direct investment for Slovakia in 2016 was USD 805 million, in 2017 it was USD 2,277 million and in 2018 it was the volume of foreign direct investment of USD 475 million.

In comparing the level of unemployment with the level of distribution of foreign capital, we can state a certain relationship. Despite the fact that the level of unemployment is affected by many influences, it can be assumed that the entry of foreign investors has positive effects on regional demand for labor. In this sense, foreign investment can contribute to the regional reduction of unemployment in the host regions, as well as to the economic equalization of the regions concerned.

Results and Discussion

Based on data obtained through the analysis, unemployment in March 2020 was 5.19% and compared to March 2019, when unemployment was 5.03%, it was higher by 0.16%. In both 2019 and 2020, the unemployment rate in March was more unfavourable in terms of gender for women, when the unemployment rate reached a higher level compared to men. For 2020 and 2021, the development of unemployment in Slovakia is estimated in a negative sense, when forecasts predict an increase in unemployment. This knowledge is important for investors and can be an important factor for investors in terms of deciding on the release of investments for the Slovak Republic. Before entering the market, the investor notices the state of employment in the country and also the educational structure of the population, which becomes his potential workforce. An investor who will employ a workforce with an emphasis on working in a demanding sector prefers a sufficient number of cheap, albeit less educated, labour. The opposite is an investment in science and research, where there are enough experts, universities and scientific capacities at the forefront.

The regional demographic analysis showed that the best in terms of aggregate indicators of demographic development is the Presov Region, followed by the Kosice Region, which has the best development of the number of working age population as well as the number of economically active population. The worst development in terms of aggregate indicators occurred in the Trnava and Trencin regions. The lowest number of people of working age was in the Trnava Region in March 2020 and the largest number of people of working age was recorded in the Presov Region.

Among the eight regional cities of Slovakia, Bratislava, as an economic centre with an excellent geographical location, is destined for the inflow of foreign direct investment. It has a qualified workforce, more than 40% of Slovak university students study here and it is an important connecting point with Slovakia's neighbouring countries. Significant differences in the inflow of foreign direct investment in favour of western Slovakia are determined by several factors, especially the educational structure of the population - western Slovakia has a qualified workforce, also has a significant share of university-educated workers, transport infrastructure - good highway and rail connections and geographical location and thus related proximity to export markets, i.e. to Slovakia's largest trading partners.

The east and south of Slovakia suffer from a lack of educated professionals who go to western Slovakia or abroad, weaker technical infrastructure and transport services. The west of Slovakia benefits from the development of the automotive industry and good transport accessibility. Most of the large investments in the "green field" went here. Large investors require flexibility from their suppliers, which means that they try to set up businesses close to the largest customer. No significant investment in the east of Slovakia is expected in the near future, so it is important to use other options that would guarantee the sustainable development of this region. EU funds are a great opportunity to kick-start tourism and small and medium-sized enterprises. Eastern Slovakia is rich in natural and cultural monuments, there are four of the six Slovak monuments inscribed on the UNESCO World Heritage List. However, the completion of the infrastructure remains a necessity, without which further development is limited

In terms of the attractiveness of the Slovak market for foreign investors, we would highlight the important strategic position, political stability and favourable international relations. Alani, et al. states in its publication that in the case of investment, it is very important to address the strategic elements of investment (Alani et al., 2019). The labour available to investors in Slovakia is relatively cheap for them. Another important fact is that the Slovak Republic has adopted the euro as its currency and belongs to the Eurozone. Thus, it is possible to eliminate the risks associated with the exchange rates of other currencies and thus lead to financial stability.
In terms of the established hypothesis, we can state that our assumption, namely that the interest of foreign investors in Slovakia is focused more on more developed regions, has been confirmed.

Conclusion

The entry of the Slovak Republic into the European Union was a significant impetus for solving the problems of Slovak regions in the general ranking of socially perceived problems. The process of regionalization of Slovakia entered into a broader European context, became part of the processes of regionalization in the European area, which created the conditions for regional development through the inflow of foreign investment into the territory of the Slovak Republic. Slovakia's accession to the EU highlighted its unfavourable regional situation and the urgency of its solution also within the framework of EU regional policy. Current economic globalization processes are widening the cracks between regions by increasingly preferring regions with favourable development dispositions and high-quality human potential, which is again reflected in the increase in interregional disparities and the Slovak Republic is not bypassing this problem.

Abstract

The article discusses topical issues of ensuring freedom of religion and the prevention of religious discrimination in the US education system. The article examines the position of the presidential administrations and the practice of the US Supreme Court on conducting school prayers, as well as ensuring academic freedom given the struggle between the theories of Creationism and Darwinism in the American education system.

Keywords: Religion, US Education, School Prayer, Creationism, US Supreme Court, Principle Of Equality, Discrimination

Funding: The study was funded by the Russian Foundation for Basic Research № 19-011-00559.

Introduction

In recent years the United States has witnessed far-reaching changes in the implementation of the principle of equality, which forms the cornerstone of the American constitutional system [Nikolaev, Pavlova, 2018: 391-392]. The last decades have been marked by massive and noticeable efforts to protect against discrimination on the new grounds: health, sexual identity, age [Nikolaev, Pavlova, 2016: 10875-10877]. The past year has seen mayhem amid racial (fundamental for the United States [Nikolaev, 2018: 128-129]) relations, which again have colored the American public landscape black and white.

As most Americans think, hardly any issue has divided the American public and the highest judicial body in the United States as much as religious expressions and symbols used in public. Thus, attempts are made to reconcile "the requirements of the Constitutional Clause of the Establishment of the US "with the need for a unifying belief system and the importance and prevalence of religion in the lives of American citizens and the United States as a whole " [Smith, 2016: 846].

In this regard, education is a kind of borderline area. In modern society, education (at various levels) is becoming of more and more importance for the development of civil society, the electoral and civic culture of the population [Nikolaev, Emelin, Pavlova, 2020: 7715-7716], and the development of innovative forms of social consciousness and behavior.

Secondary and higher education in the United States have traditionally been a kind of testing ground for judicial lawmaking both on issues of racial equality and the separation of church and state, on the one hand, and, on guarantees of the free exercise of religion by every American citizen on the other.

State and religious relations have been massively aggravated in recent years. The Democratic presidential administrations of W.J. Clinton and B. Obama made large-scale, sometimes overly radical innovations related to genetic engineering, the widespread permission of abortion, legalization of same-sex marriage and gender reassignment surgery, all with guaranteed government funding. This could not help but cause a conservative response from a significant part of North American society and the political establishment.

In this regard, Donald Trump's policy is indicative of this issue and was reflected in his public statements and executive orders. Executive Order on Promoting Free Speech and Religious Liberty (Executive Order 1379. May 04, 2017) stated that "The Founders envisioned a Nation in which religious voices and views were integral to a vibrant public square, and in which religious people and institutions were free to practice their faith without fear of discrimination or retaliation by the Federal Government". In particular, freedom of religious and political expression was guaranteed. The Ministry of Finance was prohibited from any adverse actions against individuals or organizations after their statements on political or moral issues with religious overtones. In addition, there were the intentions to change the policy of B. Obama to promote the idea of same-sex marriage and protect the rights of sexual minorities and transgender people and in health care.

Another executive order established a White House Faith and Opportunity Initiative (Executive Order 13831. May 03, 2018). Ensuring religious freedom has been declared a priority in US foreign policy (Executive Order 13926 — Advancing International Religious Freedom. June 02, 2020). The founding fathers of the Constitution who understood "religious freedom not as a creation of the state, but as a gift of God to every person and a right that is fundamental for the flourishing of our sockets our Founders understood" were mentioned over and over again. An order of May 28, 2020 (Executive Order 13925 — Preventing Online Censorship. May 28, 2020) prohibited online censorship condemning the "fundamentally un-American and anti-democratic" practices of leading media and online platforms (Twitter, Facebook, Instagram, and YouTube) by censoring opinions that contradict their own views (just within a few weeks, the White House received more than 16 complaints about political censorship on online platforms).

In recent months, a widespread protest movement in the United States has been accompanied by acts of vandalism unprecedented for the country. All that immediately led to the adoption of an Executive Order for the protection of American monuments (Executive Order 13933 — Protecting American Monuments, Memorials, and Statues and Combating Recent Criminal Violence. June 26, 2020) from "rioters, arsonists, and left-wing extremists." As D. Trump noted, Christian values were also under attack, since representatives of the protesters declared "that many existing religious depictions of Jesus and the Holy Family should be purged from our places of worship".

Thus, in the past quarter of the century the Trump administration has probably proposed the most detailed and varied agenda for the protection of religious values. He ensured religious freedom, including the constitutional right to prayer in public schools. Moreover, the following statement is perhaps one of the most pro-religious in recent decades: "In America, we don't punish prayer. We don't tear down crosses. We don't ban symbols of faith. We don't muzzle preachers and pastors. In America, we celebrate faith, we cherish religion, we lift our voices in prayer, and we raise our sights to the glory of God. In total, the word "God" was mentioned 9 times, along with the use of the words "prayer", "church", "cross", "faith", "preachers and pastors". In his recent official speeches D. Trump calls the upcoming elections the most important in the history of the country, noting that the last Democrat Convention removed the words "under God from the Pledge of Allegiance", not once, but twice." [Trump, 2020/27]

Although legislative activity and presidential lawmaking on religious relations are important, it is the US Supreme Court that stands as the real creator of legal regulation between the state, religion and the educational system. In this regard, we can consider two, perhaps the most significant and fascinating aspects of the Court practice in this area, namely the teaching of creationism and the conduct of prayer in education institutions.

The clash of religious and scientific worldviews in the US education system was most clearly manifested in the dispute between supporters of creationism and evolutionism. Researchers distinguish three stages of a complex judicial struggle between representatives of the two doctrines [Larson, 2013: 998]. Until the early twentieth century, the theory of the divine creation of man, or creationism, dominated widespread circles in American society and education, and was widely recognized as a fundamental value by the courts.

The triumph of the doctrine of creationism is related to the so-called "monkey process", a dispute between the government of Tennessee and school teacher J. Scopes (Scopes v. State, 289 S.W. 363 (Tenn. 1927)). The court openly supported the state authorities in opposing the spread of Darwin’s theory of evolution in the school system. However, most of the 20th century was marked by the gradual retreat of creationism under the pressure of Darwinism. Scopes' defeat was successfully made up for by another school biology teacher in Little Rock, Susan

Epperson. In 1968, the US Supreme Court (Epperson v. Arkansas, 393 US 97 (1968)) unanimously ruled the Arkansas law prohibiting the teaching of evolutionary descent in public schools and universities as contrary to the First Amendment to the US Constitution prohibiting the government to establish religion. In addition, the Court in this case defined the limits of possible judicial intrusion into the school educational process: the court, as a general rule, should not interfere with "the day-to-day functioning of the school system, except in cases that directly and definitely affect basic constitutional values".

In the second phase, the supporters of creationism changed tactics and strategy, challenging the exclusiveness of evolutionary theory in the school system, as well as putting forward the theory of "scientific creationism". This process culminated in the case of *Edwards v. Aguillard, 482 U.S. 578 (1987*). The state of Louisiana passed the Creation Act, which prohibited the teaching of evolutionism in public schools unless they taught creationism. The court by a majority vote (7 to 2) upheld the decisions of the lower courts on the contradiction of the above-mentioned law with the same clause on the prohibition of the state establishment of religion of the First Constitutional Amendment. By applying the Lemon test, the Court found that this act does not have a clearly expressed secular goal, does not contribute to ensuring academic freedom, "undermines the principles of scientific education, unacceptably supports religion, contributing to the spread of religious belief in the creation of mankind by a supernatural entity."

It should also be noted that only a few religious organizations (3) sent amicus curiae in support of Louisiana, while a wider range of organizations (10 in total) did that in favor of the other side. Among the organizations were the American Association of University Professors, the American teachers' association, 72 Nobel laureates, New York State, the American Jewish Congress, the National Academy of Sciences. The dissenting opinion of the majority of the Court was presented by the judge appointed in 1986, Antonín Scalia. He served on the Court until 2016 and was known as one of the most prominent and consistent spokesmen for the conservative wing of the US Supreme Court for three decades.

Supported by Chief Justice U. Renquist, A. Scalia spoke out against the "indoctrination" of students who, in his opinion, had the right to independently decide on the origin of life based on "faith and balanced scientific data". In addition, Scalia criticized one of the criteria of the Lemon test, which defines the secular or religious nature of the legislator's goal as vague and contrived. Perhaps this opinion of the minority determined the further strategy of the supporters of the theory of the divine origin of man.

In 1990, in a review of the book by W.R. Byrd, creationists were encouraged to abandon religious context and language in disputes with Darwinists, and rather challenge the exclusivity of evolutionary theory and the need to support freedom of critical evaluation of theory and academic freedom. "Nothing in the Constitution prevents the university from providing a forum for those who disagree with the theory of natural evolution, including dissenting atheists. The main difficulty lies in the prejudice of many intellectuals who identify naturalism with reason, prompting them to uncritically accept the views of Darwinists, who believe that all who disagree with Darwinism either do not know about the available evidence, or misunderstand "how science" works [Johnson , 1990: 434].

The concept of "intelligent design" is becoming a new slogan of creationists in the struggle for pluralism of opinions in the education system. The main obstacle is the first element of the triune Lemon test: "government action must have a decidedly secular purpose," as was in the case of *Freiler v. Tangipahoa Parish Bd. Of Educ., 185 F.3d 337 (5th Cir. 1999))*. The Conservative Christianity and Creationist majority of the Tanjipahoa Board of Education promoted (by a minimum majority of 5 to 4) the adoption of the rule that "classes concerning the origin of life and matter ... must aim to inform students of scientific concept and must not be intended to convince students against the biblical version of Creation or any other concept."

In addition, the Council recognized "the fundamental right of every student to form their own opinion and support the beliefs of their parents in this very important issue of the origin of life and matter." The court received a statement of claim concerning "forcing citizens to adopt fundamentalist Christian views." This appeal was supported by the American Civil Rights Union. Based on the first element of the Lemon test of the state's secular purpose, the trial court found that the main purpose of the Board of Education was to adapt the curriculum to a specific religious doctrine. The appellate instance, unlike the district court, considered it possible to take religious views and values into account in lawmaking, but generally supported the decision of the lower court. The US Supreme Court by a majority vote (6 to 3) refused to review the decision. Chief Justice Renquist, judges A. Scalia and Cl. Thomas voted against this decision.

In a similar case in Alabama, the Council also adopted an educational standard according to which "the explanation of the origin of life, plants and animals should be presented as theory, not fact." Subsequently, the Council approved of a more moderate version of the standard. Both versions were not challenged in court, and that threatened legal uncertainty in such a significant issue for the education system [Larson, 2013:1017-1018].

The situation was further complicated by the adoption of the so-called Santorum Amendment (named after Conservative Senator Rick Santorum) in the 2001 law committee report "No Child Should Be Left Behind": "Curricula should ensure that students understand why biological evolution is so controversial." In the revised final version, this passage read: "A quality science education should prepare students to distinguish between facts and verifiable scientific theories, on the one hand, and religious and philosophical beliefs that are claimed in the name of science, on the other. When exploring controversial issues (such as biological evolution), the curriculum should help students understand the full range of existing scientific views, and why such issues are controversial and how scientific discoveries can profoundly affect society" [Larson, 2013: 1020]

In *Selman v. Cobb Cnty. Sch. Dist., 390 F. Supp. 2d 1286 (ND Ga. 2005*)), Georgia, the state court recognized at least two secular goals in a school council document on the rules for studying evolution: to promote the development of critical thinking in students and to take into account the views of those residents of the local community whose religious beliefs are incompatible with Darwinism. However, despite the formally secular goals, the informed intelligent observer "must be aware of the "implicit" religious nature of the respective actions".

Kitzmiller v. Dover Area School District, 400 F. Supp. 2d 707 (MD Pa. 2005) challenged the changes in the teaching of evolutionary theory through the compulsory study of intelligent design theory based on the book "About Pandas and People". The court ruled against the school district, recognizing the concept of intelligent design as "a religious doctrine, a mere re-labeling of creationism, not a scientific theory." In addition, this case, according to the court, has a religious purpose, which provides a double violation of the Lemon test. Another area of opposition to evolutionism was the so-called academic freedom laws, which affirmed the right of students and teachers to freely express their views on controversial issues of the origin of biological species. In 2008, a similar law called the Science Education Act was passed in Louisiana.

A religious organization in *the Association of Christian Schools International v. Stearns* (678 F. Supp. 2d 980 (CD Cal. 2008)) sought protection from religious discrimination after the University of California had rejected five courses. The court supported the University in this case, confirming the unscientific and religious nature of the courses and textbooks offered for training.

Despite some anachronism, the traditional dispute between supporters of creationism and Darwinism remains very relevant and significant for modern judicial and social practice. Recent changes in the composition of the Supreme Court, the non-application of the Lemon test in some of the latest cases considered by the Court, the increasing activity of the Court in the application of the clause on freedom of religion allows us to predict the emergence of new cases and relevant decisions on balancing the application of the principle of scientific education and freedom of religious belief among students and teachers.

The Supreme Court upheld the right of followers of Jehovah's Witnesses to reject obligatory honors to the national flag because it would conflict with their faith (West Virginia Board of Education v. Barnett 319 US 624 (1943)), but denied the constitutionality of the daily denial of denominational prayer recited by teachers in public schools even if students are free to participate in such ceremonies (Engel v. Vitale 370 US 421 (1962)). The latter can lead to an extensive deterioration in the relationship between children who refuse to participate in such events and their peers and teachers as well as school administration (School District of Abington Township v. Schempp, 374 US 203 (1963)).

The judgment in *Santa Fe Independent School District v. Jane Doe 503 U.S. 290 (2000*) prohibited the conduct of prayers during public football matches, even when the students themselves performed such prayers and voted for the conduct of prayer and appointed the one who read the prayer. Chief Justice Renquist, supported by Judges Scalia and Thomas, expressed strong disagreement with the court's decision and regretted the violation of the existing precedent, and "the very tone of the court, showing hostility to everything religious in public life." (Irons, 2006: 489)

Despite the existing injunction, according to a 2019 Pew Center survey, 8% of public school students aged 13 to 17 declared their involvement in such unconstitutional practices (with more than 12% in the South of the country and only 2% in the North -East of the country). Moreover, 41% of students (including 68% of evangelical Protestant teens) of this age feel it's appropriate for a teacher to lead a class in prayer, of whom 29% know about banning such practices. (Fahmy, 2020)

It should be noted that the contradictory nature of legislation and court practice regarding the conduct of prayers in education institutions is evident both in the states and in the country as a whole. The Missouri Religious Freedom in Public Places amendment also known as the "Right to Pray" amendment was on the August 7, 2012 primary

election ballot in the state of Missouri. The amendment guaranteed students to express their religious beliefs in school assignments, as well as the right not to do the assignments that violated their religious beliefs [Schlacter, 2014: 293-294].
At the same time, such legislative initiatives can lead to discrimination against religious minorities, since it is quite challenging to organize the educational process in such a way as to meet the requirements of all religious denominations and groups represented in the United States, including those in education. It is even more difficult to organize prayers or ceremonies for all religious groups while taking into account the rights of atheists.

House of Representatives Speaker Newt Gingrich announced his intention to push for adoption of his proposal to amend the US Constitution relating to voluntary school prayer: "Nothing in this Constitution shall be construed to prohibit individual or group prayer in public schools or other public institutions. No person shall be required by the United States or by any State to participate in prayer. Neither the United States nor any State shall compose the words of any prayer to be said in public schools."

Legislation and court practice regarding prayer in education environments remain rather controversial. So, on the one hand, there are federal legal prohibitions on forcing children to pray during school hours, or to pray under the guidance of school teachers or other staff, as well as to organize prayer after school at some extracurricular events (graduation ceremonies or football matches) regardless of whether they are held under the guidance of a priest, teacher or student. On the other hand, legislation and court practice guarantee freedom of prayer for some students while eating lunch, taking school exams and tests, etc.

One of the most recent decisions of the Supreme Court on prayer came into conflict with criminal law. In *Mary Ann Sause v. Timothy J. Bauer* (et al. 585 U.S. (2018) 30) the court ruled per curiam. The lawsuit said two police officers visited Mary Anna Sauze's apartment after complaining about noise disturbing her neighbors and behaved "oddly and offensively." When Sauze tried to kneel down and start praying, one of the officers ordered her to stop praying, thereby violating her right to freely practice religion under the First Amendment to the US Constitution (along with the fourth Amendment's guarantees against warrantless searches and frivolous arrests). The US Supreme Court, on the one hand, recognized "the undoubted guarantee of the First Amendment to say prayers," but, on the other hand, pointed to the circumstances that could explain the police officer's order to interrupt the prayer at a certain time in a certain place (for example, when arrested and taken to a police car) . However, since the materials of the case did not contain any indication of the specific circumstances and motives of the police officer, the Court was unable to consider the case on its merits, therefore the case was sent to the Court of Appeal for a new examination. The court provided for consideration of all the previous comments made.

In 2019, the American Civil Rights (Liberties) Union filed a lawsuit against Smith County Schools on behalf of an atheist, military veteran and father to several children who said the school system regularly incorporated prayer into school events and proselytized students.

The family's accounts spanned several school years and included things like school-directed prayer during mandatory assemblies, the distribution and display of Bibles during classes, Bible verses posted in hallways and shared in notes from school staff to students, prayers broadcast through loudspeakers at school sporting events, coaches leading or participating in prayer with student athletes, and a large cross painted on the wall of a school athletic facility. The District Federal Court tried to find a balanced solution in this case. The court defined "prayer" as a communication (written or audible) with a deity, including, but not limited to, a benediction, an invocation, the Lord's Prayer, or otherwise calling upon a deity to offer guidance, assistance, or a blessing. Accordingly, "Prayer" does not include customaiy, polite expressions and greetings, including "God Bless You" or "Thank Heavens," or a student's religious expression responsive to a legitimate academic class assignment. "Prayer" also does not include a moment of silence, provided that School Officials do not direct, encourage, or imply that students should use the moment of silence for Prayer. The court ordered the school management to comply with a number of rules: school staff must refrain from organizing, facilitating, performing or participating in prayers during or in connection with school events. However, keeping the school staff quiet out of respect for prayer will not be interpreted as offering or participating in prayer. School staff should prevent third parties (including clerics) from organizing religious events. They are also prohibited from including prayer in various school events and activities, or appointing a time for it (which does not prohibit the so-called "quiet time", unless the staff encourages children to pray during this period). Any a religious title of a school event is prohibited. The school should allow a student to give a religiously neutral speech at school events and exclude prayer during such performance.

Thus, it should be concluded that the US legislation and judicial practice in the field of religious relations in education are contradictory. This can lead to severe clashes between various religious groups and atheists, to significantly lower the level of guarantees of citizens for the free exercise of their religious beliefs.

Abstract

Most studies focused on the causes of road traffic accident, this study looks beyond the effects of traffic crashes by examining the response of motorists to traffic law and its enforcement in a populous region as a countermeasure. The study focuses on the response of drivers to the enacted traffic law 2012 in Lagos, Nigeria. Responses of drivers to the traffic law were analysed using routine activity theory and deterrence theory to reflect the offenders and the law as means of social control perspectives. Qualitative data was elicited from the unobtrusive observation; commercial drivers (n=100), private drivers (n=100) and law enforcement officers (n = 60) using simple random sampling and purposive sampling techniques. Data were analyzed through content analysis. The study revealed that in spite of the fact that the law is embedded with some elements of draconian law, most of the drivers have no in-depth knowledge of the law. Although taking the deterrence theory approach, the traffic law has a great influence on the behaviour of drivers on the road. Furthermore, it was concluded the heterogeneity nature of Lagos requires a stiffer law that will deter potential offenders from violating the state's traffic laws which serves to regulate drivers and reduce road traffic jams and accidents.

Keywords: Road users, Traffic law, Compliance; Lagos.

Introduction

The official statistics showed that over 3,000 people die per day and about 1.3million deaths are recorded annually as a result of Road Traffic Accidents (RTA) World Health Organization WHO, (2013). Likewise, given the current trend without countermeasures, RTA can be the seventh cause of death by the year 2030 with an estimation of about 90 percent in developing countries WHO, (2015). It was also reported that 50 million people sustain different degrees of injuries from such road fatalities. Traffic accidents continue to inflict severe health and economic repercussions worldwide Ahmad & Emhaidy, 2011; Ihueze & Onwurah, (2018). This can be attributed to different factors among which include lack of adequate driver training, bad roads, unsafe vehicles, inadequate road facilities, inadequate awareness of road safety, non-compliance to the traffic rules and regulations. A study has shown that in Germany, the risk of road accidents is more among emergency responders driving with lights and siren, Prohn,& Herbig, (2020). In Saudi Arabia, young male drivers' behaviors (aggressive and speedy driving) which are related to attitudes towards road safety policies are linked to road accidents, Mohamed, & Bromfield, (2017). Studies have equally revealed that law enforcement agents, particularly the Nigeria Police are being overwhelmed with crime and are unable to effectively enforce rules and prosecute offenders, Arisukwu, (2012).

Cite this Article as: Ogadimma ARISUKWU, Abiola ASALEYE and Tunde ADEBISI "Road Traffic law and Drivers' Response: Evidence from Lagos, Nigeria" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Ironically in Nigeria, studies have documented that good road facilities have been accompanied by an increasing number of road accidents and fatalities Atubi & Onakala, (2009); Olawole, (2016). Despite major efforts to improve traffic safety and maintain good roads, traffic accidents have increased steadily over the last three decades. This alarming increase could be due to the violation of traffic rules and regulations by motorists. As of 2011, Nigeria is ranked 191 out of 192 countries in the world with 162 death rates per 100,000 population and 1,042 road accidents per 100,000 motor vehicles WHO, (2011). Despite the establishment of various institutions such as Federal Road Safety Commission (FRSC), Police Traffic Warders, Vehicle Inspection Officers (VIO), and Lagos State Traffic Management Authority (LASTMA), traffic management in Lagos is still a major challenge. It is important to examine the attitudes of the drivers towards Lagos State Traffic law 2012 to assess the impact of the law on road traffic management in Lagos. Urban centers often throw up the challenges of traffic and refuse management by government, Arisukwu, (2011). Also, the attitudes of drivers towards other road users equally constitute a problem to traffic management, Fruhen, Rossen & Griffin, (2019).

Other factors that cause road accidents include reckless driving, speeding, drunk-driving, and indiscriminate parking Batool & Carsten, (2018). Vranes and Mikanovic, Lazovic and Kosanovic (2018) emphasized the importance of road traffic laws to reduce road accidents. Poor feeding habit equally affects drivers conduct and performance on the road Arisukwu, Olasebikan, Asaleye,& Asamu, (2019). However, the roles and the perceptions of the agents and drivers about the law are vital to its success, Teye-Kwadjo, Salia Mensah.& Robert (2019). Poverty and ignorance equally affect various aspects of social life and decisions including driving, Arisukwu. Igbolekwu. Efugha INwogu, Eyitayo & Osueke, (2019).

Theoretically, the routine activity theory elucidates why drivers commit traffic offenses. The theory provides an in-depth understanding of crime from an offender's perspectives, which are expected to be the drivers. A likely or motivated offender will first assess the situation of things in the environment before embarking on the act Felson & Cohen, (1979). On the other hand, the deterrence theory explains how traffic law shapes the behavior of motorists, which are imposed by the law enforcement agency. Deterrence theory assumes that people will be deterred from committing a crime if the consequence of committing such crime outweighs the benefit of the crime Gibbs, (1975). The theory posits that individuals are affected by both the potential punishment and potential reward that constitute the consequence of a particular behavior. The conclusion that can be drawn from the theoretical perspectives is that to reduce road accidents, a country or state can introduce a traffic law that attaches a severe punishment to the violators.

Recent studies have focused on road accident and its causes; yet, there are scanty studies on the implications of road traffic law on drivers' responses Ortiz, Rammarayan & Mizenko, (2017); Rolison, Regev, Moutari & Feeney, (2018); Ihueze & Onuwurah, (2018); Farahmand & Boroujerdian, (2018); among others). Implementation of road traffic law can serve as preventive measures to ensure safe driving behavior, which on the other hand will have a significant effect on the reduction of the road accident Vranes, Mikanovic, Lazovic & Kosanovic, (2018). This study is however designed to enhance existing literature on traffic management; the research seeks to focus beyond the effect of traffic crashes by assessing the response of motorists to traffic law and its enforcement in a populous region. Therefore, the study focuses on Lagos, Nigeria, and the response of drivers to the enacted traffic law 2012 by the State Government.

Objectives of the study

The general objective of this study is to examine drivers' responses to the Lagos state traffic law 2012. The specific objectives include;

1. Level of awareness of the traffic law in Lagos.
2. To assess the level of compliance by drivers and examine the effect of the law on accidents, traffic jam and drivers behavior while driving in Lagos roads.
3. To examine drivers' perception of the traffic law to be harsh or friendly.

Review of the Literature

Traffic law and regulations play a prominent role in the reduction of traffic accidents in the world. These laws were designed to protect the general public, road users, and drivers from incessant road fatalities as well as the unhealthy environment Wood & Johnson, (1983); Ihueze & Onwurah, (2018); Teye-Kwadjo, Salia Mensah.& Robert (2019). Meanwhile, as societies experience a reduction in an outbreak of infectious diseases, road accident rates tend to be on the increase, particularly in the developing countries Varma, Souba, Faiz, & Sinha,(1992); WHO, (2015).

Studies in the literature have documented that causes of RTA include Human, Mechanical, and Environmental factors (European Transport Safety Council ETSC), (2011). However, these causes can be curtailed by the implementation of adequate traffic law, Douglas, Swartz, Richery, & Roberts, (2019). The human factor is attributed to such factors as speeding, drunk driving, indiscriminate parking, overloading of vehicles with both goods and passengers, lack of knowledge of road signs, poor eyesight, and over-confidence which accounts for about 90 percent of accidents. Studies by Arosanyin, Olowosulu, & Oyeyemi, (2012) and Ifeoma, et al, (2013) supported this argument. This shows that drivers' errors are prone to a large portion of RTA that was recorded. In a similar study by Rolison Regev, Moutari, and Feeney (2018), that investigated the factor responsible for the road accident. The assessment of the scholars was carried out with interviews with law enforcement agents and ordinary drivers. The findings of the scholars showed that there is a relationship between the sensitivities of the agents to the causes of the road accident. Some of the factors documented include inadequacies in law enforcement practices, drug and alcohol impairments, and defective eyesight.

Consequently, the mechanical factors are attributed to poor vehicle maintenance such as poor lights, broken down vehicles, and un-roadworthy vehicles. The environmental factors are associated with accidents caused as a result of rainfall, sun reflection, heavy wind, storm, potholes, and un-tarred road ETSC (2011). However, Olawole (2016) studied the impact of weather, specifically rainfall and temperature on RTA in Nigeria. The author reported that the correlation between RTA and the element of weather is quite low. Similarly, in Africa, there are cultural and traditional beliefs that misfortunes such as road accidents are caused as a result of supernatural forces Pelzer & Renner, (2003). However, these traditional and cultural beliefs are gradually going into extinction, but it is important to mention that they are functional to African economic and political situation. Nevertheless, several studies had indicated that non-compliance to road traffic regulations by road users is largely responsible for road traffic accident Al-Ghamdi, (2003) & Bendak, (2005). In a recent study by Sagbery (2018), it was stated that inadequacies of road traffic laws are accountable for the majority of RTA in Norway. In China, a study has shown that road policy promotes drivers' environmental awareness and pro-environmental behavior among road freight transportation, Fu, SunZha, Liu, He, Sun, Jing (2020).

Several approaches have been adopted by both government and non-governmental organizations to prevent the insurgent of RTA but the level of awareness was inadequate. Meanwhile, the literature had revealed that good knowledge of road signs and speed limits by drivers is paramount to road safety. Ifeoma, et al, (2013) investigated the relationship between road accidents and knowledge of safety measures in Nigeria using data from 407 commercial minibus drivers. The scholars reported 59 percent of the drivers had poor knowledge of road signs while only 3.2 percent of the drivers knew their maximum speed limit. The result further indicated that the drivers between 40 and 49 years old have the odds of a better knowledge three times higher than those between 20-29 years. In a similar study by Ogunnika (2013), the same view in line with Ifeoma et al (2013) was reported. However, lack of awareness of road traffic laws is not only peculiar to African countries. It was reported that in the United Kingdom 80 percent of commercial drivers have poor knowledge of their speed limit Ifeoma, et al, (2013). A similar result emerged in Vietnam, the statistics of Hanoi Traffic Police Apartment showed that out of 360 drivers studied, only 8 percent said they know and understand all of the traffic regulations, while 78 percent just knew some simple regulations and 16 percent do not know any traffic rule (Hanoi Traffic Police Apartment (HTPA), (2006).

A strand of the recent studies focused on the causes of RTA with scanty studies on the response of drivers to traffic laws. For example, Farahmand and Boroujerdian (2018) examined the effect of road geometry on driver fatigue in rural areas of Iran. In a similar study, Ortiz, Rammarayan, and Mizenko (2017) investigated the relationship between distraction and road user behavior in the United States of America. Although, the study by Vranes, Mikanovic, Lazovic, and Kosanovic (2018) analyzed the relationship between road traffic safety and public health in Serbia, the examination of drivers' responses is still under-researched. The study by Vranes et al. (2018) pointed out that an inverse relationship exists between the implementation of road safety law and RTA. This was observed due to the law implemented in 2009 and a significant reduction in RTA afterward. The benefit of implementing traffic laws to ensure safe driving across highways in developing countries cannot be under-valued. Batool and Carsten (2018) stressed that uncontrolled driving is one of the main causes of the accident in Pakistan. Likewise, Ihueze and Onwurah (2018) echoed that increase in the rate of RTA is one of the major problems in society, with preponderance occurrences in low and middle-income countries.

The Nigerian Government established the Federal Road Safety Commission (FRSC). The FRSC is the enforcement agency that ensures adherence to road traffic regulations as embedded in the Nigerian Highway Code. The body restored sanity by apprehending violators and applies punishment. Furthermore, drivers in Lagos, Nigeria often violate traffic rules daily. Lagos drivers are rated amongst the worst drivers in the world in terms of their road culture, respect for traffic laws, and respect for fellow road users Williams, (2013). The introduction of the Lagos state traffic law (2012) which was accompanied by severe punishment to the violators taking the approach of

deterrence theory aimed to put a measure and restore orderliness on the road, which on the other hand will reduce the rate of road accident within the state. The law's emphasis on the nonchalant attitude of road users prompted the criminalization of traffic offenses. In light of the importance and the gap identified in the literature, this study examined the relationship between traffic law and the response of drivers in Lagos, Nigeria.

Methodology

The combination of descriptive and exploratory designs was chosen because the problem being investigated (Lagos State Traffic Law 2012) is a relatively new realm of sociological inquiry that little has been done on it and for this reason, qualitative method of data collection was used. Moreover, to gain in-depth knowledge about the response of drivers to Lagos State Traffic Law 2012, the research instruments that were adopted are In-depth and key informant interviews. The study was carried out in Lagos State. Lagos State came into existence on May 27, 1967, by the virtue of state creation and transitional provisions Decree No 14 which restructure Nigeria's Federation into 12 states. The state is located in the South-Western part of Nigeria. It shares boundaries with Ogun State both in the North and East, on the West, with the Republic of Benin and in the South; it stretches for 180 kilometers along the coast of the Atlantic Ocean (Atubi, 2012).

Lagos State is the smallest of Nigeria's States with an area of 3,577 square kilometers, 22 percent of which consists of Lagoons and Creeks, yet it is the second most populous with more than 9.01million as at 2006 census NPC, (2006). However, the Lagos population is estimated to be around 15,000,000 with about 12,000,000 of this population living in Lagos, making the city as the fifth largest metropolis in the World Williams, (2013). The state has a total of 20 Local Government areas and 37 Local Council Development Areas. Lagos state is called 'Centre of Excellence' because of her role in the economy of Nigeria and remains the commercial nerve center of the country. Thus, it attracts a lot of travelers, the majority of whom travel by road. Lagos State was purposively chosen for this study because it is arguably the fastest growing city in Africa and heavily motorized city in Nigeria Atubi, (2012), with 224 vehicles per kilometer compared to a world average of 24 vehicles Williams, (2013).

Due to the heterogeneity nature of Lagos, the study population was redesigned. The study locations and populations were purposively selected to include private, public drivers, gender-mix, age, and other significant others in transportation management in Lagos. Lagos State was divided into two Areas which are: Lagos Island and Ikeja Local Government Areas. These two areas were selected because of their metropolitan status and prevalence of traffic congestion as a result of big markets they have, which attract a lot of motorists. The population of this study included both commercial and private drivers, officials of National Union of Road Transport Workers (NURTW) and a few stakeholders in the area of traffic management such as, officials of Lagos State Traffic Management Authority (LASTMA) and Federal Road Safety Commission (FRSC), who are directly involved in the enforcement of the traffic law. Given the nature and peculiarities of the participants of this study, probability and non-probability sampling methods were adopted. Thus, to select the commercial drivers, the study adopted a simple random sampling method to select one major motor park from each of the two Local Governments while purposive and accidental sampling methods were used to select the commercial and private drivers respectively. On the other hand, officials of the NURTW, LASTMA, and FRSC were selected purposively by their status and position in the area of traffic management. The method of data collection used for this study was qualitative data through primary sources of data. Collected data were analyzed through content analysis.

Theoretical Framework of the State Traffic Law

The theoretical framework upon which this study dwells on is Routine Activity theory and Deterrence theory. Routine activity theory was adopted to give an explanation on why drivers commit traffic offences. However, the theory is not adequately sufficient to explain this issue because it only explains from the perspective of the offender. On the other hand, the deterrence theory was adopted to analyze how the traffic law shapes the behaviour of motorists.

Routine activity theory is a sub-field of the rational choice theory that was propounded by Felson and Cohen (1979). The theory holds that for a crime to occur, three elements must be present at the same time and in the same space: a suitable target, the lack of capable guardian, and a likely and motivated offender. That is, when a crime occurs, the criminal must have identified a suitable target which could be a person, object or place coupled with an absence of capable guardian whose presence could have discouraged the motivated offender from committing the crime. The theory provides an in-depth understanding of crime from an offender's point of view. A likely or motivated offender will first assess the situation of things in the environment before embarking on the act. It suffices to note that, an offender will only commit a crime if he thinks that a target is suitable (opportunity), and a capable guardian is absent (security).

However, Felson and Cohen (1997) routine activity theory is relevant to this study in that it provides a straightforward explanation of why drivers violate traffic rules and regulations. For instance, most drivers will violate traffic rules when the traffic law enforcement agents are unavailable on the road. This implies that absent of capable law enforcement officers is an inducement for crime commission for rationally calculating offenders. It is paramount to indicate that a rationally calculating traffic offender will firstly take into consideration, the availability or effectiveness of traffic law enforcement agents before violating the traffic law.

The concept of deterrence is the use of punishment as a threat to deter people from offending. Deterrence is often contrasted with the act of retribution, which holds that punishment is a necessary consequence of a crime and should be calculated based on the gravity of the offence. This theory is adopted to explain how law and punishment seek to prevent drivers from committing the traffic offence. The assumption of deterrence theory is that people will be deterred from committing a crime if the consequence of committing such crime outweighs the benefit of the crime. This theory was developed by Cesare Beccaria and Jeremy Bentham as an explanation of crime and method of reducing it, Hagan, Gills & Brownfield, (1996). According to Gibbs (1975), 'Deterrence is the omission or curtailment of a crime for a fear of legal punishment '. That is, people may refrain entirely from committing a crime for a fear of being punished, or they may only restrict their commission of it. The theory posits that individuals are affected by both the potential punishment and potential reward that are the consequences of a particular behaviour. For example, Section 7 of the Lagos state traffic Law (2012) provides the penalties for neglect of traffic directions. Anyone who either

> "neglects or refuses to stop the vehicle or to make it proceed or to keep to a particular lane or direction of traffic when directed to do so by the officer in the execution of his duty; or drives his vehicle against oncoming traffic or fails to conform to the direction or indication given by the traffic sign, shall be guilty of an offence…"

On conviction, first-time offenders shall be liable to one-year imprisonment and forfeiture of the vehicle to the State, and second and subsequent offenders get three years imprisonment and forfeiture of the vehicle to the State. A driver that is aware that the punishment for just neglecting traffic signs is huge may choose to obey the traffic signs. In deterrence, the utmost importance is that punishment prevents crime Dambazau, (2011), the fear of future punishment will determine the actions people choose. The higher the certainty, severity, and celerity of legal punishment for a particular type of crime, the lower the rate of that crime. However, the most relevant aspect of deterrence theory to this study is that whatever punishment that must be given out for an offence, must serve a utilitarian purpose whereby it must refrain recidivism and also serve as deterrence to others.

The Lagos state traffic law 2012 can be said to be triggered by the assertion of deterrence theory so as to convince potential offenders to refrain from committing traffic offences. For instance, the fine in monetary value for not wearing seat belt while driving was increased from two thousand Naira to twenty thousand Naira, about 900 per cent increment. The deterrence mechanism can take two forms; these are Specific deterrence and general deterrence.

Specific deterrence implies that the punishment that a violator gets is severe enough to discourage him from committing a similar crime in future. This is the rationale behind the sudden increase in the amount payable for violating traffic laws in Lagos state. A driver that was fined for not using seat belt may not likely violate such law again because of the high penalty involved. The general deterrence, on the other hand, implies that the punishment given to the offender 'A' should be severe enough to discourage offender 'B' from committing a similar offence. This explains why most drivers in Lagos state are always conscious and afraid to break traffic rules knowing fully-well that if they are caught they will be punished severely.

Presentation of Findings

Socio-economic and Demographic Characteristics of the Respondents

A total of 260 participants were interviewed during the course of this study. It includes; 200 drivers (both commercial and private drivers), and 20 personnel each of National Union of Road Transport Workers (NURTW), Lagos State Traffic Management Authority (LASTMA), and Federal Road Safety Corps (FRSC). Tables 1 and 2 show the socio-demographic characteristics of the participants.

Table 1: Characteristic of Participants on Age, Gender, Religion, Education, driving experience, and Marital Status

Variable	Category	Number Interviewed
Age	20-29	20
	30-39	100
	40-49	100
	50-59	30
	60 above	10
Total Number (Age)		**260**
Gender	Male	240
	Female	20
Total Number (Gender)		**260**
Religious Affiliation	Islam	120
	Christianity	90
	Traditional	50
Total Number (Religious affiliation)		**260**
Marital Status	Married	150
	Single	50
	Divorced	30
	Widowed	10
	Separated	20
Total Number (Marital Status)		**260**

Variable	Category	Number Interviewed
Level of Education	Primary	50
	J.S.S	20
	S.S.C.E	100
	O.N.D	30
	B.SC	60
Total Number (Level of Education)		**260**
Driving experience	1-5	50
	6-10	100
	11-15	60
	16 above	50
Total Number (Driving experience)		**260**
Years in Service	1-5	8
	6-10	35
	11 – above	17
Total Number (Years in Service)		**60**

Source: Authors' Field Survey 2016

The table above shows that the majority of the participants were in the age group 30-39, and 40-49 years which means that most participants in this study were adults. Also, the majority of the participants were male, only 20 out of 260 participants were female and this is because the percentage of male drivers is more than female drivers especially among the commercial drivers. This is not peculiar to Nigeria alone this result confirms the statistics of WHO (2011) on road traffic deaths based on gender, which shows that 30.8 males die as a result of road crashes compare to 11.0 females. The table illustrates the marital status of the participants with 150 out of the total 260 married while 50 were single.

The drivers were asked about their level of education with 50 of the participants claiming that they only had primary school education while the rest claimed that they had both secondary and tertiary education. This implies that most of the drivers had formal education to some extent. Moreover, the drivers and officers were asked about their years of driving, most fell in the category of 6-10 and 11-15 years of driving, with 100 and 60 of the total 260 drivers respectively. There is the need to categorize the years of driving in this way because one cannot compare the experience of a 2 years driver with that of a 9 years driver. The implication of this is that data gathered from the participants would be a good sample for qualitative research. In the same vein, the personnel of NURTW, LASTMA, and FRSC were asked about their years in service to ensure that those interviewed were indeed key informants. Only eight out of total 60 claimed to have spent less than 5 years in service while others have spent more than 5 years.

Responses to Traffic Law Awareness

Traffic law and regulations play a prominent role in shaping the attitude of drivers towards the reduction of traffic congestion and traffic accidents. Hence, to examine drivers' response to the Lagos State traffic law, it was necessary to ascertain that the participants are aware of the law.

Figure 1: Awareness of Drivers to the Road State Traffic Law

Source: Authors' computation from Field Survey (2016)

Figure 1 presents the outcome of the response when asked questions as regards the awareness of the traffic law 2012. The majority of the participants claimed they have full knowledge of the Lagos State traffic law while less than twenty are incognizant of the law. These are parts of their acknowledgment 'Yes, am aware of it. I do not think there will be a driver that is in Lagos that will say he has not heard of the traffic law'. After affirming that the participants are aware of the traffic law, it is important to sample the opinion of drivers on the traffic law because they are the most targeted group. Drivers' opinion was sought on whether the law is driver-friendly or repressive. However, of all the participants interviewed, some drivers have contrary opinions on the awareness of the traffic law. One driver's response is as follows: 'I am aware of the traffic law but I don't know the details of the law because we were not well informed about it'.

Opinion of Drivers to the Road State Traffic Law

At the level of an individual, most of the drivers especially the private drivers opined that the law was friendly, a participant opined as follows: 'the law is friendly to me in the sense that no matter how soft law is, some people will still complain about it'. The above response is very important to achieve the objectives of this study. Although most of the commercial drivers have a contrary opinion on the traffic law some of them were quick to applaud the state government on the traffic law. They are of the view that the heterogeneity nature of Lagos city required a stiffer law that will deter potential offenders from violating the state laws. They are quoted as follows: 'the law is somehow severe especially to the commercial drivers but it will bring positive effect.

Also, another commercial driver that has a similar opinion stated that: 'the law is okay as it is because it will not deter people if the law is too friendly. But the problem with the law is that it can generate negative externalities such as corruption among law enforcement agents. Drivers may be compelled to bribe them because if you don't give them voluntarily, they will arrest you in-discriminatorily'. This is not surprising, studies by Asaleye, Ogunriola, Oloni and Ogunjobi (2017), Asaleye, Okodua, Oloni and Ogunjobi (2018) and, Oloni, Asaleye, Abiodun & Adeyemi (2017) have stressed that low standard of living, low income, and high unemployment rate are problems faced by the Nigerian government which has social effects on the country. Likewise, the Transparency International Corruption Perception Index (2017) revealed that Nigeria was ranked 148th out of 180 nations. Consequently, studies by Fashina, Asaleye, Ogunjobi, & Adedoyin (2018) and, Asaleye, Adama, and Ogunjobi (2018) pointed out that the Nigerian government should go beyond the attempt made to manage mismanagement of resources. The commercial drivers that have a contrary opinion to the law are of the view that the fines for most offenses highly outweigh the offenses. They cite the issue of the seatbelt as a case study. The fine for not wearing a seatbelt was increased in the traffic law 2012.

Even though there are elements of draconian law in some parts of the law, it beat one imagination to discover that some drivers still violate traffic rules. As observed in some areas, drivers especially commercial drivers only use a seatbelt when they sight traffic officials or when they are about to approach a checkpoint. One can deduce from the responses that the law is serving the purpose of deterrence but there is the need for government to flush out those corrupt officials who see the law as an avenue to enrich themselves. It is a general belief that whenever a change occurs in societal law, there is going to be a change in the behavior of the people. Consequently, there is a need to train law enforcement agents on how to conduct themselves while enforcing the new law and community members should be carried along, Arisukwu & Okunola, (2013); & Arisukwu, Igbolekwu, Oye, Oyeyipo, Asamu, Rasak, and Oyekola, (2020). So far law does not operate in a vacuum, at times, changes in the law are expected to generate reactions from the public. Therefore, an attempt was made to ascertain whether the punitive threat posed by the traffic law of Lagos state had a measurable effect on the level of compliance with traffic rules and regulations.

Effects of the Road State Traffic Law

Most of the drivers and law enforcement agents that were interviewed reported that the traffic law has a great influence on the behavior of drivers on the road. An informant stated thus: 'Yes since the law came into being; there has been a great difference in motorist's attitude'. The majority of the responses of the participants were not particularly different from the aforementioned except few participants who have a different view. One observed thus: 'I can say the law has a little influence on the way we drive because the enforcement is not that effective, before you came now, I saw a driver receiving a call while driving'.

Observation and findings from the study revealed that traffic law influenced the driving culture of motorists. Since there is no crime-free society, it will be unfair to conclude that the law only has a mere influence on drivers just because few people still violate the law. When asked about the factors responsible for traffic congestion, opinion differs as some of them believed that growth in population and high rate of motorized vehicles are the main factors responsible for the congestion of traffic.

Factors Responsible for Traffic Congestion

A member of the National Union of Road Transport Workers (NURTW) commented thus 'Population is the major cause of traffic congestion in Lagos and again numbers of vehicles on our roads are too much'. The responses above supported the existing statistics that Lagos State is one of the most populated states in Nigeria with about 10 million inhabitants as of 2006 census (NPC, 2006). Also, the state is the most heavily motorized in the country with about 224 vehicles per kilometer as compared to a world average of 24 vehicles (Williams, 2013). On the other hand, some participants rate other factors such as bad roads, impatience, and bad vehicles.

Predictably, all the drivers responded affirmatively to have heard about the Lagos State traffic law 2012. However, on whether they have in-depth knowledge of the traffic law; not surprisingly, the drivers stated that they have no in-depth knowledge of the law. The response of the drivers goes further to reveal the poor awareness campaign of the traffic law on the part of the state government. The findings of this study supported the view of Ifeoma, et al, (2013), in a similar study that assessed the knowledge of commercial bus drivers about road safety measures in Lagos. The result of which indicated that less than one-fifth of the drivers could interpret the road sign 'carriageway narrows' and only 3.2 percent of them knew the maximum speed limit on expressways. It is paramount to note that this finding is not peculiar to Nigeria alone, as it was observed in a study carried out among selected drivers in Saudi Arabia; that a relatively high number of participants lacked the knowledge of important traffic signs, especially signs designated for yielding to traffic and pedestrians (Ahmad & Emhaidy, 2011). Similarly, poor

knowledge of speed limits was also observed among drivers in the U.K where a large proportion of 80 percent of commercial drivers studied showed a lack of speed limit knowledge (Ifeoma, et al, 2013).

Conclusion

A road traffic accident is a ubiquitous phenomenon that mostly occurs every day in all existing human society. Although, the incidence of RTA has become a social problem in both developed and developing countries due to the immense socio-economic and health implication it posed to the victims, their families, and the society at large, the rate at which it occurs differs from one society to another. In developing countries, Nigeria in particular, human factors such as impatience, reckless driving, drunk-driving, lack of respect for fellow road users among other factors have been attributed to the high rate of road traffic deaths. This has triggered various state governments especially Lagos state government to come up with the law that criminalizes traffic offenses. Most studies focused on the causes of a road traffic accident, this study focuses beyond the effect of traffic crashes by assessing the response of motorists to traffic law and its enforcement in a populous region as a countermeasure. Consequently, the study focuses on Lagos, Nigeria, and the response of drivers to the enacted traffic law 2012 by the State Government. Responses of drivers to the traffic law were analyzed using routine activity theory from the offender's perspectives and deterrence theory from the perspective on how the traffic law can shape the behavior of motorists.

Qualitative data was elicited from the observation; commercial drivers, private drivers, and law enforcement officers using simple random sampling and purposive sampling techniques. Data were analyzed through content analysis. However, this study asserts that the extent at which such traffic law will help to reduce the incidence of road traffic accidents and congestion will depend on the quality of information at the disposal of the targeted group (drivers) an investigation has revealed that drivers lack the basic knowledge of road safety measures and traffic law. This implies that traffic education goes beyond the medium of both print and electronic media which the Lagos state government solely relied upon to educate the drivers on the new traffic law, as it is apparent that most of these drivers especially the commercial drivers that are prone to violation of traffic law are set of people who do not listen to radio nor watch television because they spend much of their time on the road. Suffice it to note that, as the state of knowledge of road safety measures among drivers gets worse, it is feared that the rate of road crashes will inversely increase if drastic measures are not taken. The study concluded that taking the deterrence theory approach by imposing severe punishment on the violators of the traffic law will serve as a countermeasure to causes of road accident in the city. This conclusion is in agreement with a study in Accra Ghana by Agyapong, & Ojo, (2018). Also Ernstberger, Joeris, Daigl, Kiss, Angerpointner, Nerlich, & Schmucker, (2015) Posited that road traffic enforcement leads to reduced deaths from accidents. However, there is a need to reduce the negative externalities such as corruption that arises from enforcement, for the law to have significant impacts.

Based on the findings, the study suggested: the need for adequate and continuous enlightenment of motorists on road safety measures; that government should reduce the speed limit on our roadways; government should genuinely improve on road infrastructure and invest more on an inter-modal system of transportation such as waterways and railways as this will reduce traffic congestion on our highly concentrated road; the traffic management authorities should be equipped. Finally, the government should ensure a framework that will reduce corruption among the enforcement agents. Furthermore, responses generated from the study showed that corruption may have an indirect effect on the implementation of traffic laws most especially in developing economies. This study suggested that future research should examine the nexus among traffic law, corruption, and its implications on the traffic road accident.

Compliance with Ethical Standards

This study complied with ethical standards in social science research. The drivers who constituted the unit of analysis were not coerced to take part in the study. Their confidentiality was equally maintained throughout the research. They were equally at liberty to discontinue the study any time they felt uncomfortable.

Research Involving human participants

This study involved human participants (drivers), and they were not exposed to any form of physical or emotional harm or danger during the study. The research team made sure all drivers who participated in the study were not driving during the interview sessions. This was done to avoid accidents due to distractions by the research team. Commercial drivers were allowed to go for their turn and continue after they have dropped their passengers and return to their park. This was done to ensure that they do not suffer any financial loss as a result of their participation in the study. The dignity and comfort of the participants were ensured during the study. They were not stressed out and disrespected in any form during the study.

Informed Consent

The informed consent of participants was obtained before they were allowed to participate in the study. The aim and objectives of the study were made known to them and they were free to decide and choose to participate or not. Their decisions were respected by the research team.

Disclosure of Potential Conflict of Interest

On behalf of the authors, the corresponding author states that there is no conflict of interest among the authors. There is also no funding for this study.

Abstract

Post-harvest preservation is a fundamental aspect in agricultural production. Farmers strive to preserve their grains after harvest for so many reasons which include maximizing profit during scarcity and preserving seeds for next planting season. Although the adoption of chemical method seems effective, there has been some health risks linked to it as recorded over the years. This incidence has caused serious social apprehension to the people. Therefore, this study examines the level of perceived fear of consumption of contaminated beans among the people of Ganye. Rational choice theory was adopted for the framework. Research design for the study was exploratory and survey in nature. Data was collected using well-structured questionnaire The findings show that 61.1% of the respondents have observed a lot of post-harvest losses of beans in their area hence the common use of chemicals to preserve it. Also, 65.4% were apprehensive of consuming chemically preserved beans due to fear of food poising.

This study recommends the traditional storage facility which has low or no health risk. Farmers and merchants should be enlightened through the mass media on safer ways of preserving their grains.

Keywords: Post-harvest preservation; contamination; apprehension; Beans

Introduction

In Nigeria beans is a staple food consumed by many irrespective of their social class, religion or ethnic identity. It is eaten alongside other staple foods in Nigeria, like rice, cassava and yam. Beans is one of the cheaper sources of protean, multiple vitamins, minerals, and fiber, making it the ideal healthy meal for any household in Africa. The major challenge rural farmers encounter is how to preserve their produce after harvest to reduce post-harvest loss. Also, rural farmers lack the financial capacity to access some modern technology for beans preservation. Rural farmers often resort to cultural and traditional means of farming, transporting and preserving farm produce. Study has shown that, the cultural transmission of food habits is extremely relevant, given that it brings cohesion to and

forges the identity of human groups (Quintero-Angel, Mendoza, Quintero-Angel, 2010). In Nigeria, beans also known as cowpea is prepared and served in many delicacies such as 'moimoi', 'gbegiri', 'akara; or 'beans cake', 'boiled white' and 'jollof'. Beans is usually in demand by many families across rural and urban markets in Nigeria. However, one of the major challenges confronting most farmers has been the method to be adopted in post-harvest preservation of beans to reduce loss and poison (Abubakar, 2008).

In food production, postharvest management is the phase of crop production directly succeeding harvest, as well as processing, sorting and packing or storing. Immediately a crop is harvested from the farm, or detached from its main plant, it begins to depreciate. Postharvest management basically standardizes last quality. The most significant goals of post-harvest treatment are storing the product, to avoid dampness loss and deliberately slow down unwanted acid shifts, preventing and delaying significant damage such as abrasions. When is preserved effectively and efficiently, it leads to food security within the rural community. Post- harvest wastages are drastically reduced. Farmers and sellers get return on their farming investment, while consumers get value for their money.

Spoilage and aggregate depletion leading to waste of foodstuff can be reduced using good preservation techniques or processes (Strahan and Page, 2003). Preservation is a technique or a procedure whereby agricultural harvest or produces are stored up for future usage (Thamaga-Chitja, Hendriks, Ortmana and Green, 2004). Study has shown that grains stored in Purdue Improved Crop Storage (PICS bags) are safer. The grains retain its weight without spoiling (Mutungi, Affognon, Njoroge, Baributse & Murdock, 2014). Research has shown that consumers are now interested in how food products are preserved and fortified with nutrients, (Ghoshal & Kansal, 2019).

Loss of grain in large quantity has been a serious problem to farmers, marketers and consumers of grain in Ganye Local Government. The insufficiency of grain after the time of harvest has led to food scarcity and has made the income of farmers and marketers to dwindle. Therefore, in an attempt to solve this problem, farmers, marketers and consumers employed several means of preserving their grain to prevent spoilage, waste and to allow the use of these grains in and out of season or to avoid its purchase when it's most expensive in the market. Post-harvest damages add to high cost of food items thereby making prices of supplies to be inflated (De Lucia & Assennato 1994). Lack of knowledge, inadequate technology or unavailable infrastructure has contributed greatly to the challenge of post-harvest losses. Thus, significant quantity is being lost annually to food spoilage, which leads to loss in quantity and value affecting the livelihoods of the population (FAO, 2010). Poor handling of grains, poor storage and insects or rodents' infestations also contribute immensely to postharvest losses in developing countries. (FAO, 2013). Despite efforts made in reducing food contamination and poising by chemicals, it has continued to be a public health concern in Africa, Patchimaporn, Tesfamicheal, Nsharwasi, CharitY, Bernard and Ranajit. (2018). With continued post-harvest losses of beans and other grains in rural communities, youths who ought to be the work foce of the community will be discouraged to participate in farming. Many youths may choose to migrate to urban centers in search of elusive jobs and exacerbate the challenges of urban poverty and crime.

Resolving the post-harvest management challenges in beans preservation involves the use of various post-harvest preservation methods. This includes the use of chemicals which often results in food poisoning. Beans could be preserved using either traditional or modern methods. The traditional methods include but are not limited to, sun drying- on drying floors, putting powdered chili pepper in sacks of beans, storing in local silos locally called humbum in Hausa language, in earthenware pots, jars, use of barns, local cribs and others (Nukenine 2010). While modern storage methods include the use of sophisticated steel silos, use of insecticides, rodenticides, or sprays of these chemicals, the use of metal or plastic drums, the use of improved storage bags.

The issues of preservation of grains faced by local famers have spurred the use of chemicals to preserve the grains. The chemicals last longer and sometimes farmers bring the grains with toxic residues to market. This leads to food poising and even death of innocent consumers. Effective grain preservation technique has major role in guaranteeing subsistent food production, and also alleviate food insufficiency at the domestic scale. (Adejumo and Raji, 2007, Tefera, Kanampiu, DeGroote., Hellin, Mugo, Kimenju, et al. 2011).

Grain pollution with pesticide pose severe danger to consumers of beans, (Nnamonu and Onekutu,2015) & Nukenine,2010). The occurrence of beans poisoning in some parts of Lagos and Gombi Local Government of Adamawa state Nigeria, led to hospitalization and death of many in the past. The indiscriminate use of chemicals to preserve beans after harvest, poses a significant risk to farmers, grain dealers and public health throughout the world. (Ochii, 2010). Though beans is a commonly consumed by families in Nigeria as it serves as a source of protein, the incidents of killer beans in Lagos in September 1996 made consumers afraid. The fear of killer beans spread around the country, resulting in beans being avoided by many households. What was known as 'killer beans' hit the South-Western region of Nigeria. (Ayomide 2017). During that period, at least sixteen people in the South-Western area of Nigeria were reported to have died from eating beans. A bean cake *(akara)* seller in Ogun state died

after eating her own beans cakes when she wanted to prove to her customers that her *akara* were not poisoned. (Ayomide, 2017).

Poverty and illiteracy are key factors that may cause people to consume contaminated beans products. When there is insufficient food, people are forced to consume stored foods, despite the effect of the chemical preservatives. Illiteracy has also played a role, as lack of understanding of the instructions on the use of chemicals and its duration in serving its purpose may result to consumption of active chemicals that are inimical to health. Indiscreet use of chemicals to preserve beans has both economic and health implications on the sellers and buyers (Alavanja, Hoppin, Kamel 2004), Erhunmwunse, Darrius, and Olomukoro. 2012). & (Devon, 2016).

This research is motivated by the desire to find lasting solutions to the apprehension caused by the fear of eating poisonous beans due to chemical method of post-harvest preservation in Ganye, Nigeria. The inability of people to identify the chemically preserved beans in the market by mere observation has become a major challenge. The dangers posed by eating poisoned beans on both human beings and livestock have become a challenge that needs to be investigated. Therefore, this study investigated the social implications of adopted methods of beans preservation in Ganye LGA. Methods of preservation and food poisoning are areas considered in most literature; however this research intends to fill the gap in knowledge, by uncovering the social implications of fear of consuming contaminated beans in the society. The study seeks to improve food security in rural Nigeria. When a safer method is adopted in beans preservation it saves beans after harvest and prevents scarcity associated with post-harvest loss. When the method of preservation is perceived to be safe, many consumers will buy it and farmers and seller will make profit. This financial reward will encourage them to plant beans again in the community. When farmers are in business, their livelihood is sustainably improved.

Theoretical Framework

Rational choice theory, also known as choice theory or rational action theory was pioneered by a sociologist George Homans (1961). Rational choice theory concept is a framework for comprehension and frequently officially demonstrating social and financial conduct. The theory places emphases on the determining factor on person's distinct selections (individualistic principles). Rational choice theory attempts to explain why human beings make choices and moves which have unique consequences, how they achieve this and to predict the selections they may make given positive situations. Rational choice theory suggests that individuals weigh risks and rewards when deciding whether to engage (Ray, Baker,& Caudy, 2020). Rational choice theory says that operators and others make decisions by systematically and consciously weighing all possible outcomes along all relevant criteria (Dekker, 2017).

The theory assumes that Individuals, acts rationally in pursuit of her personal self-interest and not in the pursuits of others. Individuals are looking for opportunities to maximize their gains and minimize their losses. An individual has enough statistics upon which to establish her possibilities and perform her rational analysis. Preferences are transitive in nature. This is a logical principle that sounds greater complex than it surely is. Rational choice involves a cost-benefit analysis before decisions or choice is made. Rational choice often comes from previous experience and perceptions of a commodity influencing your attitude and actions towards the commodity (Chen, Feng. Liu, Tian,2019). In this case past experience with poisoned beans will make the consumer to avoid or be careful next time the person wants to buy or eat beans.

Rational choice theory believes that people carry out calculative decisions to weigh the cost and benefits of their actions before execution. This decision making and action is applicable to the practices of farmers and other consumers of beans in this research as they individually decide on the method they will use in preserving their beans, taking into cognizance, its profits and consequences. Therefore farmers, traders or household consumers of grain carefully evaluate the outcome, and in turn, choose their preference based totally on their own alternatives and the limitations. These limitations coupled with poverty lead to poor feeding habits and its negative consequences on the people, (Arisukwu.O, Olaosebikan .D, Asaleye. A. & Asamu. F, 2019).The emphasis in Rational choice theory is in the consistent act of individuals in pursuing their preferred goods or services (Bridge, 2020).

In this research it is assumed that the consumer of beans prefers the grain that is not chemically preserved to that which is chemically stored out of anxiety or fear that something bad or unpleasant may happen if one consumes chemically preserved beans. It is assumed that consumers make their choice over alternative grains which are chemically preserved and those that are not. Study has shown that preference of food diets is affected by level of affluence of consumers, (Lusk, 2019). This means that the rural poor have less choice to make as beans remains the cheapest source of protein among them.

An individual is left to make decisions on the type of grains to purchase. This choice can be influenced by various exposures to health implications such as sicknesses, diseases or even death as a result of unintended food contamination initiated by residue from chemically preserved beans.

Methodology

The cluster sampling technique was employed to divide the community into smaller groups, thereafter; the simple random sampling was used to select the respondents. The study population comprises 250 farmers, marketers and consumers of beans within the Ganye community in Ganye local government area of Adamawa state, Nigeria. It included men, women, the young and old, from age 15 and above, who are active in farming within the study location, and who also, practice various storage methods of food grains preservation. The survey design was employed in this research; hence the quantitative data was elicited with the use of questionnaires. The questionnaire was structured with both close and open-ended questions.

The statistical package for social sciences (SPSS) was deployed to run the analysis. Data was analyzed using percentages and frequency counts.

Ethical considerations were duly observed, as respondents were informed, and their consent forms were obtained. Confidentiality, anonymity of the participants was guaranteed and adhered to. Those without formal western education had the content translated to them in their local dialect (Hausa). Respondents were also informed that they had the right to withdraw at any time they feel uncomfortable with the study.

Presentation of Results

Table 1: Demographic characteristics of the respondents

Categories	**Frequency**	**Percent**
Age		
15-20years	82	39.3
21-25years	38	18.3
25years and above	88	42.3
Total	**208**	**100.0**
Sex		
Male	114	54.8
Female	94	45.2
Total	**208**	**100.0**
Marital status		
Single	125	60.1
Married	65	31.3
Separated	18	8.7
Total	**208**	**100.0**
Religion		
Christian	110	52.9
Muslim	74	35.6

Traditionalist	24	11.5
Total	**208**	**100.0**
Occupation		
Farmer	51	24.5
Student	104	50.0
Merchant	20	12.0
Others	28	13.5
Total	**208**	**100.0**

Table 1 shows the demographic characteristics of the respondents. A large number (88%) of respondents used for this study falls within the age range of 25years and above in Ganye LGA. Similarly, (54.8%) of the respondents in this study are males.

The marital status of respondents revealed that (60.1%) respondents are Single, (31.3%) are married, and (8.7%) are separated. This shows that the respondents are predominantly single. As singles, they may therefore depend on farming of beans to improve their livelihood. The data on occupation of the respondents showed that (50%) respondents were students, (24.5%) are farmers, (12%) are merchants, and (13.5%) had other occupational categories. This revealed that majority of the respondents are students.

Table2: Distribution of Respondents by preferred methods for preserving beans.

Which method do you consider best for beans preservation	**Frequency**	**Percent**
Traditional	92	43.8
Use of chemicals	81	39.4
Use of PICS bags	35	16.8
TOTAL	208	100.0

Source: Researcher's fieldwork 2019

Results from table 2 shows that (43.8%) of the respondents prefer traditional methods, while (39.4%) consider the use of chemicals and (16.8%) chose PICS bags as the best method of preserving beans. This shows that larger population of the citizens of Ganye LGA prefers the traditional methods of storage to any other method. The preference of traditional method could be as a result of transference of indigenous knowledge of beans preservation from one generation to another. This local way of preserving beans may have been internalized as part of the Ganye culture. It could also be an evidence of lack of access to modern technology of food preservation among the rural farmers.

Table 3 : Distribution of Respondents by reasons for preference of traditional method of Beans preservation.

Reason for the preferred method of beans preservation	**Frequency**	**Percent**
It is safe and simple	50	24.0
It is cheap and common	34	16.3
No danger or health hazard	31	14.9
Its more effective	93	44.7
Total	208	100.0

Source: Researcher's fieldwork 2019

The above table shows that (44.7%) claim that traditional method of preservation is more effective, (24.0%) say that it is safer, (16.3%) claim it is cheap and common, and (14.9%) posited that it has no danger or health hazard attached. This result is in agreement with the rational choice theory adopted for this study. This theory believes that human beings do not just act, there is always reasons or motivations behind human actions.

Table 4: Distribution of Respondents by possible awareness strategies for safe methods of beans preservation

Suggest best **ways of creating awareness**	**Frequency**	**Percent**
Use of mass media	143	68.8
Community awareness/house to house campaign	45	21.6
Through government agencies	20	9.6
Total	208	100.0

Source: Researcher's field work 2019

Based on the analysis on table 4, (68.8%) of the population suggested the use of mass media as the best way of creating awareness on safe means of beans preservation, (21.6%) posited that the use of community awareness campaigns is preferable, (9.6%) are of the opinion that using government agencies is the best way of creating awareness. A greater percentage of the study shows that the use of mass media is the best. Mass media has been recognized as a vital tool for public enlightenment and advocacy. In addition, play lets, local songs, radio and agricultural extension officers should be used in enlightening rural farmers on beans preservation methods to reduce food poising.

Discussion of major findings

The study revealed that respondents prefer traditional storage method as they presumed that it was less hazardous to health. This is in comparison with the modern chemical methods which they perceived to be detrimental to both human health and livestock. Study has shown that traditional methods of food preservation still hold sway among indigenous people in Nigeria, especially where improved technology were absent or not enough (Adesulu-Dahunsi.A.T, Dahunsi.S.O &Olayanju.A, (2020). The use of traditional techniques was also preferred because it is considered to be cheaper by farmers and merchants in a bid to maximize value income. This traditional method can also be considered preferable as it is the technique handed over from past generation (Joke Falaju, (2018), Hence it is employed to prolong cultural values. Again, this is a typical reflection that Africa or Nigerian cultural heritage cannot completely go into extinct as feared by some scholars (UN, News 2012). The food practices in a society including preservation methods are product of cultural values of particular societies (Reddy, & Van Dam, 2020). Study has shown that to ensure safety and stability, without nutritional and sensory losses, suitable, effective and economic food preservation methods should be selected,(Taxman, Otles, Glaue & Gogus, 2019). The people and their way of life should be the centre of food production and post harvest handling. The government and its agencies should work with community members to enhance and adopt a sustainable food preservation method to reduce waste, loss and fear of consumption of poisoned beans, Arisukwu, Igbolekwu, Oye, Oyeyipo, Asamu, Rasak, & Oyekola, (2020). The activities of bacterial, virus, microorganisms and fungal on grains especially beans affect food supply in the community, (Fung, 2009).

Similarly, on the perceived fear of consumption of contaminated beans in the study area, a greater percentage of the respondents attested to the fear of buying chemically treated beans which has high possibility of being contaminated and can lead to unintended food poisoning. This makes the fear of consuming chemicals from food preservatives a public health phenomenon as agued by (Patchimaporn U.et al (2018). This is also consistent with the findings of Alavanja Hoppin , Kamel. (2004). This situation may further be compounded by the inability of the respondents to identify a chemically treated bean in the market before purchase, and the awareness of the health problems related to consuming contaminated produce has been minimal among rural dwellers.

Furthermore, the results of this research reveal high knowledge about the health implications perceived by consumers on the effects of storage methods of beans, as also reported by PAN (2012). Respondents were able to identify and list out some of the perceived health issues related to the techniques of preserving beans. These health challenges that consumers could encounter included; stomach pain, purging, stomach inflammation, vomiting and even death. This health hazards may not have been experienced by the respondents as individuals but they may have been heard from significant others or through rumors. Individuals believe that the system used to store grain have implication on consumption (Adegbola, Bamishaiye, and Olayemi (2011). Therefore, a storage process has likelihood of exposing consumers to certain health risk.

Furthermore, in line with the rational choice theory which believes that people make calculative decisions to weigh the cost and benefits of their actions before execution. This decision making and action is applicable to the practices

of farmers and other consumers of beans in this research as they individually decide on the method they will engage in preserving considering its profits and consequences. Decision is also taken by consumers of beans and its produce as to either purchase chemically stored grain or to purchase traditionally preserved grain. Their choice is being influence by their experience, stories of incidences of food poisoning or just perceived fear within them as individuals. These factors makes them to weigh the benefits of buying such produce and its cost be it economic (price value), or its health implications. Therefore farmers, traders or household consumers of grain carefully weigh the outcome, and then in turn, choose based on personal priorities and limitations.

Recommendations

The following recommendations were therefore made.

Farmers and merchants of beans in Ganye should be encouraged to adopt the traditional method of beans preservation in addition to use of the PICS bags. This will increase public confidence, consumption and trust of beans within the community.

The mass media should be utilized for enlightenment and advocacy on the best ways of applying chemicals for beans preservation and accessing modern technology for beans preservation among the rural populace in Ganye. The state and local government areas should take interest in rural agriculture and support farmers with subsidized farm tools and inputs. This will motivate youth's participation in farming and sustain food security in rural areas.

Declaration section

I write to confirm that ethical approval was obtained to conduct participate, and publish the article. The data is available and will be supplied on request. There are no conflict of interest and funding for this study. All authors participated fully at every stage of the study and the efforts of all the authors and field team are hereby acknowledged.

Simulation of an Educational Mobile Robot

Paul Ciprian PATIC

Valahia University of Targoviste, Romania
patic@valahia.ro

Abstract

One important aspects in the evolution human is the use of tools that simplify the physical work. Robots also fall into this category, but they occupy a privileged position due to their complexity. Humans imagined intelligent mechanized devices that would take over a significant part of the physical effort. Thus its has built automatic devices and intelligent mechanisms or different robots.Robots are automatic electromechanical machines. Some of the robots are not fully automatic but are controlled by humans by remote control, using video cameras or other control systems. Most robots are used in manufacturing processes. Others can be used as remote-controlled, deep-sea manipulators. Another category of robots can be used in various laboratories where they work with radioactive substances or there are high temperatures or other dangerous places. Some robots are mobile, with a built-in locomotion system, being able to move on land, on water, in the air. The modes of propulsion are among the most diverse, such as on wheels, water, water jet or air etc.In this paper, one tried to present a simulation of an educational mobile robot, imposing a rather complex wiring diagram, a command and control of the robot made by a PIC16F84A microcontroller. This robot can be used in teaching activities, but also in surveillance tasks, monitoring of spaces difficult for humans to penetrate.

Keywords: Driving System, Mobile Robot Simulation, Microcontroller, Programming Controller, Sensor System, Simulation Program.

Introduction

In general, robots are a class of technical systems that mimic or substitute human motor or intellectual functions. This is achieved by combining different types of handling systems or locomotives, determining the anthropomorphic character of the robot, with different types of computing or logical equipment, which determines its intellectual functions. Robots operate in a specific environment, whose characteristics may remain constant or variable over time. Automatic control varies in complexity from simple relays to highly sophisticated computerized methods. Mobile robots, in most situations, are equipped with video cameras or other sensors to perceive the environment in which they operate. Human control is achieved by using simple buttons up to complicated logistics with responsive power.

Control systems include communication modules based on radio waves, sonar (acoustic), echolocation (screen guidance), fiber optics or cables. Many robots are built by chaining components that mimic segments of the human arm. All methods are limited by the impossibility of perfect matching with the maneuverability of the human hand under the control of the human eye and brain. Robot engineering has been heavily influenced by fiction, in the sense that it has its dose of utopia. However, a lot of money is still spent on research into obtaining artificial beings by duplicating hands and propelling by bipedal walking, as Armaș I. (2011) and Starețu I. (2012) said.

Presentation of the Mobile Robots

The uses for which mobile robots have been, are and will be designed are diverse and cannot be exhausted in such a small space. Many robots in the micro area find their use in medicine, being able to move along the vessels and tubes of the human body, for the purpose of investigations, surgeries, dosing and distribution of pills etc. Equally spectacular are many uses of macro-robots in: medicine, industry, agriculture, forestry, the military, public utilities, entertainment and recreation, services, security, rescue operations, space research etc.The mobile robot is a complex system that can perform various activities in a variety of real-world situations. It is a combination of devices equipped with servomotors and sensors (under the control of a hierarchical computer system) that operate in a real space, marked by a series of physical properties (eg. gravity that influences the movement of all robots

Cite this Article as: Paul Ciprian PATIC "Simulation of an Educational Mobile Robot" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

operating on earth) and which must plan the movements so that the robot can perform a task according to the initial state of the system and according to the `a-priori` existing information related to the working environment.

Success in performing these tasks depends both on the knowledge that the robot has on the initial configuration of the work-space, and on those obtained during its evolution.The specific problems that occur in mobile robots would be the following: avoiding the impact with stationary or moving objects, determining the position and orientation of the robot on the ground, planning an optimal trajectory of movement , as Borangiu T. and Ionescu F. (2002) said.

In the case of an automatically distributed robotic system, the spatial positions are of extreme importance and the fulfillment of the desired goals and the functioning of the entire system depend on them. In other words, the robot must be able to plan its movements, to automatically decide which movements to execute to perform a task, depending on the current arrangement of objects in the work-space.Movement planning does not consist of a single and well-defined problem, but of a set of problems, some of which are more or less variants of others.Avoiding collisions with fixed or mobile obstacles in the robot's workspace can be done by several methods: making a mechanical guard that stops the robot by deformation, using sensors that measure the distance to obstacles in the direction of travel, use of proximity sensors, use of correlated information from several types of sensors.

The location of objects can also be achieved by physical contact, but it imposes restrictions on the speed of movement of the manipulated structure. Physical contact between the robot and objects in the environment generates reaction forces that change the state of the robot. High working speeds make the dynamic effects of physical contact with obstacles or manipulated objects risky (they can damage objects or the robot), as Berian S. and Maties V. (2011) uses in their research.

Robot navigation is also possible without a determination of position and orientation relative to a fixed coordinate system, but this information is useful for motion control systems.Among the most frequently used navigation methods can be mentioned: measuring the number of rotations made by the driving wheels, the use of accelerators and gyroscopes, electromagnetic buoys installed in the field, passive or semi-passive signals of optical or magnetic type.

Mechanical structure of a Mobile Robot

The mechanical structure of mobile robots consists of:

- locomotion system (on tracks or wheels), which ensures the movement of the robot on a work surface (within an increased autonomy);

- the handling system, which ensures the positioning and orientation of the working body.

The mobile robot in the process of moving on a certain trajectory is characterized by 3 functions:

1. locomotion function;

2. the perception-decision function;

3. location function.

The locomotion function includes the electric drive system (propulsion) and the support system (suspension). The propulsion modes are among the most diverse, such as: on wheels, with water jet, with air etc . Mobile robots can be equipped with a video camera or other sensors to perceive the environment in which they operate. The robot's memory contained in the microcontroller stores the knowledge necessary to locate all possible path segments, as Berian S. and Maties V. (2011) uses in their research.

Action driving of Mobile Robots

The action of a Mobile Robot is made with low power electric motors, with low inertia torque, with overload capacity, with high ratio reducers (i>100) and low inertia torque of processional or harmonic type. Integrated motor-reducer units can also be used. . Used low inertia electric motors:

- DC or induced disc motors;

- synchronous motors with permanent magnets;

- stepper motors with variable reluctance with induced glass and radial air gap or with induced disc type and radial air gap;

- synchronous motors with permanent magnets.

Dynamic performance analysis of drives based on $H_d(s)$ transfer function involves determining the parameters:

1. Accuracy that is determined using the transfer function by calculating the error stationary:
2. Promptness, which is calculated using the transfer site considering an optimal compromise accuracy-stability for a phase edge $M\Phi = 25 \div 45^{O}$

The tracking capability can be assessed with the help of the Bode feature. In order to improve the dynamic performances of the drives in certain frequency ranges, series or parallel correction elements with the transfer function are used. The operation of the educational mobile robot will be done using stepper motors. These are electro-mechanical converters that transform a digital pulse train into a proportional motion of its axis.

The movement of the stepper motor rotor consists of discrete, successive angular displacements of equal size and representing the steps of the motor. The stepper motor also has the property of being able to synchronize with the control pulses even at rest, operating without slipping and braking is also performed without leaving the synchronicity. Due to this fact, sudden starts, stops and reversals are ensured without loss of steps throughout the work area.

The speed of a stepper motor can be adjusted within wide limits by changing the frequency of the input pulses. Thus, if the angular pitch of the motor is 1.8 ° the number of pulses required to perform a complete rotation is 200, and for an input signal with a frequency of 400 pulses per second the motor speed is 120 revolutions per minute. Stepper motors can work for frequencies between 1.000 and 20.000 steps / second, with angular steps between 180° and 0.3°.

Stepper motor applications are limited to situations where no high power is required (usual power between micro-watt and kilowatt ranges).Stepper motors are used in low power applications, characterized by fast, precise, repeatable movements: XY plotters, floppy disk drives, print-head movement to printers, actuation of orientation and pressure mechanisms to robots, axial displacement of system elements optical, 2D positioning tables, for drilling machines etc.

The Sensory System

The mobile robot is put in a situation to perform actions similar to those of the human operator. This determines the existence of certain devices through which to collect information from the work environment, which can perform the robot interaction. environment with the help of environmental characteristics or objects in the environment and a central unit that processes in real time the sensory information, to transform it into a useful form for the control system, as Held G. (2008) uses in his research.

The sensory system is also called the measurement system. It ensures the measurement of physical quantities and possibly the perception of significant changes in these quantities.

Due to the sensory system, the geometric and chemical characteristics of the objects in the work environment can also be highlighted. The sensors due to their characteristics can explore the work area, the contact area, the near, the far, and the very powerful sensors even very far areas. The information gathered with the help of the sensory system serves to build a model of the world in which the robot evolves, a model according to which it will generate its future action plans.Depending on the constructive solution, the sensors are passive or active. Active sensors use the intrinsic characteristics of the environment, and passive ones generate changes in the environment to measure some characteristics.

Two other categories of sensors that a mobile robot can be equipped with are: sensors of internal dimensions of the robot (position, speed or acceleration of its own mechanical components) and sensors of external sizes (weight, shape, position, temperature, color, etc. of objects on which the robot acts), as Dutta A. (2015) said.

Systems and intelligent control

According with Borangiu T., Dumitrache A. and Anton F.D. (2010), the notion of "intelligent control" cannot be debated other than that of "intelligent system", which in fact means a nuance of the term "intelligent" used in the

two phrases. In fact, this term is found in the literature and in connection with "artificial intelligence". It is obvious that intelligent controllers are also designed to emulate faculties of mental behavior such as adaptation and training (learning), planning in imprecise conditions (uncertainty), the association of various information. Perhaps an alternative definition to "intelligent control" could be "autonomous control" to emphasize the pronounced degree of autonomy that an intelligent control system must provide.

An intelligent system has the ability to act appropriately in incompletely defined environments, by appropriate action meaning an action that maximizes the probability of success, success being the fulfillment of one of the partial objectives whose set is the ultimate goal.An intelligent system can be characterized by a number of attributes, or dimensions. These are degrees or levels of intelligence. A minimum level would be that of the capacity to recognize the environment, make decisions and take action to enforce them. A higher level of intelligence may involve recognizing events or objects, representing them in a model (eg a knowledge base), and compiling a long-term plan. The highest levels require the ability to perceive and understand, to choose wisely and to act appropriately in all circumstances, including in hostile environmental conditions.

An intelligent control system must be designed to achieve high-level objectives autonomously, even if the installation or process model and the structure and objectives of the system are not fully defined, either due to partial knowledge or due to changes. unanticipated.

A system is considered autonomous when it has the ability to act correctly in incompletely defined environments without external intervention over a long period of time. There are several degrees of autonomy, which could be associated with the control functions included in the intelligent control: a control system with fixed parameters has the minimum degree of autonomy; adaptive control systems have a higher degree of autonomy. To the extent that a system has a greater degree of autonomy, it is accepted that it also has a higher level of intelligence. Other criteria can be adopted to differentiate the degrees of intelligence, such as: the computing power of the system; the degree of complexity of the algorithms used for the acquisition, processing and evaluation of data obtained from the environment; data storage capacity. In most artificial systems, increasing the level of intelligence reflected by computing power and storage capacity is due to the increasing complexity of hardware structures and therefore can become an obstacle to application either by too high a cost or by the impossibility of real-time processing. of stored information.

The PIC16F877 Microcontroller

The best placed manufacturer on the PIC microcontroller market is Microchip. Another major manufacturer of PIC microcontrollers is Motorola. There are several families of PIC mirrors: PIC12, PIC16, PIC17, PIC18. The microcontroller used in this application is PIC16F877. PIC16F84A belongs to a class of 8-bit microcontrollers with RISC architecture. Its general structure is shown in the following sketch representing the basic blocks.
Program memory (FLASH) is for storing a written program. Because the memory that is made in FLASH technology can be programmed and erased more than once, it makes the microcontroller suitable for component development. EEPROM-data memory to be saved when there is no more power. It is usually used to store important data that should not be lost if the power supply is suddenly interrupted. For example, such a date is a preset temperature in the temperature controllers. If this data is lost during the power failure, we will have to make the adjustment once again when the power returns. Thus our component loses in terms of self-maintenance, as Gheorghe G.I (1996) said.

RAM-data memory used by a program during its execution. All intermediate results or temporary data that are not crucial when the power supply is interrupted are stored in RAM.The block diagram of PIC16F877`s Microcontroller is shown below, in figure 1, like Patic P. C. and Zemouri R. (2020) said.

Fig. 1: Internal block diagram of the PIC16F877 microcontroller

Simulation and realization of the educational mobile robot

The following tasks are implemented in this application:

- stepper motor control;
- obstacle detection and change of direction of travel.

To make the application we used the following components:

- two stepper motors;
- two PIC16F84A microcontrollers and their assemblies;
- mechanical sensors made of mouse buttons and LEDs that light up when the sensors are activated;
- 9V batteries for powering circuits;
- wireless transmission modules.

Below, in figure 2 is a picture from the construction of the mobile robot., as Coșaru C.I. (2010) uses in his research

Fig. 2. The Skeleton and the stepper DC motors

Design of The Electrical Circuits

The wiring diagram software interface used is called: *Eagle Professional.* This program is a utility that is used to create and verify wiring diagrams, create and check wiring, position electronic components on the board, direct signals and self-route them. The following image shows the interface of the Eagle electronic design program.Following the realization of the electrical diagrams, the wiring related to the two assemblies of the robot prototype resulted. Both the wiring diagrams and the related wiring are presented below, in figure 3.

Fig. 3: Eagle Professional Interface

The transmission module has 5 inputs. These are located on port B of the RB2, RB3, RB4, RB5, RB6 pin microcontroller. The data is transmitted further through port A via pin RA0. For this module one made the following wiring diagram, presented in figure 4:

Fig. 4: Wiring diagram wireless module

Microcontroller Programming

The first step is to initialize the process which includes:

- declaration of engine outputs (1);
- declaration of engine outputs (2);
- declaring the input of the sensor (1) (the sensor placed at the top);
- declaring the input of the sensor (2) (the sensor placed at the bottom).

After declarations, the engines start maintaining their direction until one of the sensors is actuated. If one sensor is actuated, it is checked whether it is the sensor on the left or the right, if it is the one on the left, the robot will go backwards and then go to the right and vice versa for the other sensor.

Creating the simulation program

In a research study by Logofatu D. (2007), the software used to create the program to be implemented in the microcontroller is MikroC. MikroC is an application development utility for PIC microcontrollers. This software has a rich set of hardware libraries and is an easy way to program PIC microcontrollers.

MikroC is a high-level language, as is MikroPascal or MikroBasic, which simplifies programming, allowing you to write in one line or a few lines what many lines of programming in assembly language would require, as one shown in figure 5.

Fig. 5: MikroC programming language interface

According with Margineanu I. (2005), MPLAB is a Windows program package that makes writing and developing a program easier. It can best be described as a development environment for a standard programming language that is intended for programming a PC computer. Some operations that were done from the instruction line with a large number of parameters until the discovery of the IDE, "Integrated Development Environment", are now made easier by using MPLAB. However, our tastes differ, so even today some programmers prefer the standard editors and compilers in the instruction line. In any case, the written program is easy to read, and a well-documented help is available.

MPLAB consists of several parts:

- Grouping files of the same project into a single project (Project Manager);

- Generating and processing a program (Text Editor).

According with Coșaru C.I. (2010) and Patic P.C. And Zemoury R. (2020), written program simulator used to simulate the operation of the program in the microcontroller. In addition, there are support systems for Microchip products such as PICStart Plus and ICD (In Circuit Debugger). Because this book does not cover them, they will only be mentioned as options, in figure 6.

Fig. 6: MPLAB Interface

Conclusions

The mobile robot was designed to perform PC dependent tasks but with the possibility of modifying the program if other routines occur or you actually want to modify the program. All this is possible because the robot is equipped with a radio transmission / reception module, so commands are transmitted to the robot from the PC via the parallel port and the radio transmission module and information is received on whether or not to place the command. If various objects unforeseen by the work program appear in the robot's workspace, it can detect them with the help of mechanical sensors. After detecting the respective obstacle, the robot makes a detour subroutine, after which it returns and continues its routine that it had to execute, using this subroutine whenever necessary.

The power supply is made with 9V batteries, thus having autonomy for a very short time. The field of robotics is in a continuous development, and in the future we could see only robots working.

Some improvements and future research one could talk about a wide range of sensors that we could mount on the robot to increase its sensitivity to various objects or to use it to detect and catch objects with the help of arms mounted on it. Another improvement that could be made would be its programming using neural networks for making and storing maps. The field of robotics is in a continuous development, and in the future we could see only robots working.

Abstract

The main purpose of the paper is to conduct an energy audit for a mechanical and biological waste treatment plant. The energy audit consists in collecting data from a company or facility, about the devices used in the entire waste treatment process, and then on the analysis of proposing ways to improve the energy efficiency of the tested facility. The energy audit is based on the Energy Efficiency Act and the PN-EN 16247:2014 standard. Presented work consist two basic proposals for improving energy efficiency. The first suggestion is the optimization of the compressed air installation, which shows how much money can be saved by using a monitoring system and detecting air system leaks. The second proposal is the automation of electricity consumption and measurement systems. It is connected with saving electricity on the basis of continuous monitoring of electricity consumption, which is needed to power all devices on the installation.

Keywords: Energy, efficiency, optimization, line maintenance.

Introduction

Energy management, or energy consumption, is defined in a variety of ways in the literature. This definition is presented as, inter alia: systematic management and application of newer and newer technologies to improve the energy performance of the facility (ISO 50001:2018), control, monitoring and implementation of measures increasing energy efficiency (Bunse et al. 2011), continuous improvement of the plant's energy efficiency by introducing more and more effective measures and methods aimed at simplifying the implementation of pro-energy tasks, thanks to which the manager can provide a given facility with continuous utilities and reduce energy consumption costs (Javied et al. 2015). Regardless of the above definitions, it can be assumed that one of the main reasons for taking various actions related to the management of energy consumption and energy resources are the following points (after ISO 16247: 2014): willingness to increase energy efficiency, and hence - to reduce the costs of a plant or organization's operation, compliance with national or European legal acts related to energy efficiency, meeting European, national or customer standards. In order to facilitate the fulfilment of the above needs, environmental management systems, and more specifically energy management, are increasingly used in organizations. Energy management systems can be implemented on the basis of a specific standard, e.g. they can be based on the European standard ISO 50001:2018 or they can be dedicated systems created especially for a given organization. Regardless of the type of enterprise and the industry in which it operates, the energy management system should include (Abdelaziz et al. 2011; Weidong et al. 2011; ISO 50001:2018) the company's energy strategy along with operational and strategic goals, description of the current initial situation along with a detailed analysis of historical data - including a detailed report on the energy audit, description of procedures, measures and methodology for introducing optimization, a diagram of the entire organizational structure with precisely described responsibilities for staff assigned to implement changes, description of the training system, open and clear documentation keeping and the method of presenting the results in the report.
Poland as a member state of the European Union must constantly adapt to the EU policy. One such example is adaptation to the energy policy, which assumes that by 2020 Poland is to reduce electricity consumption by 20 percentage points in relation to the "business as usual" scenario (PEP2030). Currently, Poland is implementing the provisions of the EU energy policy very well. The energy intensity of GDP fell by 30% between 1999 and 2009, and it is further decreasing thanks to the greater awareness of people about this issue. This is a good result, however, the effectiveness of the Polish economy, converted as GDP per unit of energy (according to the euro exchange rate), is still two times lower than the European average (PEP2030). The significant economic development resulting from

Cite this Article as: Maciej GLINIAK, Piotr WALĄG and Mateusz SAMEK " Energy and Economic Efficiency of Municipal Waste Processing Plant" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

the modernization of the facilities and the automation of most plants translates into an increase in electricity consumption with a relative decrease in the availability of other forms of energy. Today, the issue of energy efficiency is the priority, and the progress that comes with it will have a significant impact on meeting all the goals (PEP2030). In 2014, the European Union's energy efficiency policy was slightly changed with a commitment to introduce 27% energy savings in relation to older forecasts. In 2018, this target was increased to 32.5% for all members of the European Union (PEP2040). Poland, as a member state, declared itself to make further progress related to increasing the energy efficiency of the economy. Based on the impact on GDP, the analysis of the effects of the measures taken and the savings potential, Poland declares a national target for improving energy efficiency by 2030 at the level of 23% in relation to the 2007 primary energy forecasts (PEP2040).

The purpose of the work is the energy audit usage to select the best method of improving plant efficiency, considering electricity, and then proposing modernization methods that will reduce electricity consumption, increase control over electricity consumption, which is associated with better management of energy consumption with overhead contact line, where it can reduce the cost of energy purchases.

Materials and Methods

The efficiency of the installation during the processing of municipal waste amounts to a maximum of 50 $Mg \cdot h^{-1}$, and during the processing of waste from selective collection, the efficiency is lower by half and amounts to approx. 25 $Mg \cdot h^{-1}$. The plant currently recovers nine recyclable raw materials - selective steel and aluminium scrap, paper, tetrapak (cartons of juices, drinks or milk), selective PET colourless, blue, green, polypropylene (PP), high-density polyethylene (HDPE), foil (LDPE) and cardboard box. Currently, work on the installation takes place in two shifts - first from 6.00 am to 2.00 pm, and the second from 2.00 pm to 10.00 pm.

The start of the process starts with loading the waste from the RTD bag breaker. Then, after cutting the larger bags, the machine evenly distributes the waste on a belt conveyor, where the waste is transported to a rotary sieve. Between the tear and the sieve there is a station where one person chooses cardboard and dimensions such as washing machines, refrigerators, carpets, tires or car bumpers. The sieve then divides the material into three fractions: below 80 mm, 80 - 340 mm, over 340 mm. The fraction above 340 mm goes straight to the containers and is treated as post-industrial waste, and then it is disposed of in a waste incineration plant in Kraków. The first two fractions, with separate conveyors, go to magnetic separators, where steel and aluminium scrap is recovered, which goes to the cabin and is cleaned manually by people. Then the waste goes to vibrating sieves, where the fraction below 80 mm is screened and treated as waste, and the rest of the material is divided into the 80 - 140 mm and 140 - 340 mm fractions. This is due to the fact that optical separators are able to separate different raw materials better. After sieving on vibrating screens, both fractions go to optical separators, which divide the material into paper and plastics. The partially separated paper is conveyed by conveyors to the next optical separators, where it is sorted more precisely. At the very end of the paper line, people clean the material, which in a loose form goes to the press and is formed into cubes for easier loading and storage. Plastics go to ballistic separators, and on them a foil is separated, which goes to optical separators and is later cleaned by people in the sorting cabin. The remaining plastics go to a series of six optical separators, which select three types of raw material: PET, tetrapack, polypropylene and high-density polyethylene. All these raw materials go to the sorting cabin for thorough cleaning by people, and then they are pressed into cubes and stored. Process residues go to a line leading through the NIHOT Air Separator to a waste shredder, where the waste is converted into alternative fuel (RDF).

The process of energy efficiency assessment begins with an initial visit to the tested facility. During the visit, the auditor should obtain an initial description of the site and process, and then agree with the facility authorities on the scope and boundaries of the energy audit. Next, the collection of data needed to conduct the audit begins, all data and information, at the request of the auditor, must be provided by the organization. If data is missing, then the auditor is required to complete the data by making measurements personally. The request for data may include: information on technological processes, information on the building, information on energy sources, shift system, installation operation time, efficiency and types of machines. After collecting the necessary data, the auditor reviews whether the information is sufficient for the agreed purpose, and then performs an initial analysis of the data held. If, after the analysis, there is still no data, the auditor should carry out additional measurements in order to, for example, confirm the suitability of the initial state or confirm energy consumption, energy balance or correction indicators. Then the auditor creates an extensive analysis, which includes the energy balance and energy distribution, energy performance indicators and the most important, i.e. identification and assessment of energy efficiency improvement opportunities (ISO 16247).

Results

In the process of waste segregation, the Installation uses 181 electrical devices with a total installed power of 1,605.35 kW. In average annual terms, the company processes approximately 105,000 Mg of waste. The most numerous groups of devices are belt conveyors (125 items), accounting for 69.1% of devices. In the balance of energy consumption, belt conveyors (417.55 kW) are in greatest demand, accounting for a total of 26% of the installed power in the plant. The production process uses three compressors with a total engine power of 360 kW. Other machines are dehumidifiers, electrical cabinets and blowers for heating the room. Compressed air is used to separate the waste stream after qualification by optical separators. The average annual energy consumption for production purposes was estimated at 4,822.05 $MWh \cdot yr^{-1}$. Converted to a unit of processed waste, we obtain consumption at the level of 0.05 $MWh \cdot Mg^{-1}$. The plant consumes a total of 414.62 Mg of oil equivalent (toe) of final energy per year (tab. 1).

One of the proposals to improve energy efficiency is the introduction of preventive controls of the compressed air distribution system. Detection of leaks and leaks has an impact on generating financial savings. The value of the total efficiency is the higher, the higher the partial efficiency in the form of manufacturing efficiency, accumulation, distribution, use of air. An example of an economic analysis of the installation of flow meters in a compressed air system is presented below (Table 2). As part of energy efficiency measures, it is recommended to install a heat energy recovery system from the compressor system. Table 3 shows an example of an economic analysis for the detection and repair of leaks in a compressed air system.

Table 2: Presentation of investment in the purchase of flow meters for compressed air installations

Total power of compressors (kW)	360,00
Air production cost per year	88 000,00 EUR
Air production savings - 10% per year	8 800,00 EUR
The cost of purchasing 1 2 "flow meter (up to 1000 $m^3 \cdot h^{-1}$) and a monitoring system	2 500,00 EUR
Return on investment	~ 1 yr

Table 3: Presentation of investments in the detection and repair of leaks from the compressed air system

Air consumption ($m^3 \cdot min^{-1}$) - compressor ~ 360 (kW)	~ 1060,00
Air consumption ($m^3 \cdot h^{-1}$)	~ 63 600,00
Compressor operating time per year (hr)	3 200,00
Air production cost per year	8 140 800,00 EUR
Cost of leak detection and repair	15 000,00 EUR
Savings from air production – 10% per year	814 080,00 EUR
Return on investment	~ 1 yr

Optimalization of the compressed air system may provide in few different areas. The first area where savings may be provided air production. It is possible, in its case, to improve efficiency by up to 5-20%. Recommendations for the

compressed air intake area contains leak detection and repair is an important process because thanks to it we are able to reduce energy consumption by compressors by ~ 10 ÷ 15%. Most leaks are not audible: 1% less pressure reduction means 7% less energy consumed by the compressors and 13% less leakage; reduction of incorrect consumption - in this case, consumption can be reduced by about 10%; appointment of 1 or more energy efficiency leaders, combined with training of informed and responsible compressed air users; awareness of the cost of compressed air contributes to the unit cost of production through the installation of measurement and monitoring. Another area of potential savings is the area of air transmission, where we can obtain energy efficiency improvement by 5-20%. Recommendations for the compressed air transmission area: checking the capacity of pipelines, what is their diameter and length of arteries, additionally carrying out calculations of capacity and transmission losses; in terms of determining transmission losses, there is a significant improvement in efficiency, for this purpose the pressure drop measurement on the network is used; appropriate selection of pipeline material, the pipeline is made of aluminum. Pipelines made in this technology are of high quality, guarantee tightness for 20 years, with the possibility of reconstruction; a properly made installation occurs when it has properly selected cross-sections and lengths, the installation is additionally closed in a loop, moreover, there are exits from the side or from the top, the correct number of valves, reinforcement tanks, inclination for drainage, proper fastenings, material certification and ready network, recommended pressure drop below 2 ÷ 5% of the initial state. The last of the possible areas for improving the energy efficiency of the compressed air system is the consumption area, where we can demonstrate an efficiency improvement of 10 ÷ 60%. The cost of air is twice as high in this area. Leaks account for approx. 20-30%, but even up to 70% of the total compressed air produced. These values can be easily reduced by at least half, even up to 80%. The use of a special detector can locate potential leaks and calculate losses.

The second proposal to improve energy efficiency is the use of a continuous monitoring system for energy utilities consumption. The solution that allows to effectively carry out this task is the use of the SCADA program. It is proposed to use SCADA ASIX software and build a BMS platform. The use of ASIX software allows for monitoring of energy consumption by devices and departments in terms of effectiveness with the possibility of online calculation of EnPI - Energy Performance Indicator, control of the set goals and notification of the fact that they have been exceeded by means of communication (SMS, e-mail), creating reports for both the management and technical staff (tables, charts, histograms), choosing the most favorable tariff - based on energy consumption cost analyzes, conducting an analysis of the distribution of energy costs into departments and technological lines, reorganizing technological processes by shifting the load to cheaper energy zones, avoiding unnecessary consumption, access to historical data at any time, comprehensive data analysis, elimination of manual writing down of data from meters. The ASIX software package in the package price provides about 100 communication drivers that allow communication with meters, meters and drivers available on the market. This provides access to data from all measurement points. ASIX is a software that fully complies with all the requirements of the ISO 50001 energy management system. The program supports the implementation and maintenance of the energy management system by automating many processes, as well as supporting the circulation and archiving of documents. The ASIX system supports the implementation of the objectives and tasks of the policy of efficient energy use, and also allows to measure the actual effects of this policy. Estimated savings from the introduction of electricity consumption metering constitute about 5% of electricity costs. The cost of the system depends on the number of measuring points. In the case of installations for mechanical-biological treatment of waste, at least 70 measuring points shall be provided. The estimated investment outlays and savings are presented in the tables 4 and 5.

Table 4: Initial parameters for the calculation of the economic efficiency of an investment in the SCADA ASIX media consumption monitoring system

Net capital expenditure [EUR]	250,000.00

Summary

Over the past few decades, one of the main goals of energy and climate policy has been to promote the reduction of energy consumption in energy-intensive sectors such as waste management. The goal of reducing energy consumption without disrupting plant operations requires increasing electricity savings. Such improvement, however, means a reduction in the marginal costs of the energy service, which in turn may stimulate an increase in its demand. This phenomenon, or the so-called rebound effect, is associated with an increase in energy consumption which may partially or fully offset the expected increase in energy efficiency. If the magnitude of this effect is not negligible, policies to reduce energy consumption by promoting energy efficiency may not be fully effective. The rebound effect may also have unexpected economic or environmental effects, such as higher GHG emissions than expected. In order to fill this gap in the literature, an empirical analysis of energy efficiency in the waste management industry was carried out in the model enterprise. The obtained results show the average fuel efficiency at the level of 78%. From a European perspective, the results show that additional benefits can be obtained from policies that encourage electricity savings in countries that are relatively fuel inefficient. These policies should be linked to the appropriate price signals in the sector, i.e. applying specific taxes, promoting industrial automation and, where possible, providing alternative and environmentally friendly machines for production.

Abstract

The paper introduces a problem of hazardous waste that constitute a threat both the environment and human health. Particular attention is paid to waste in form of soil contamination. The article presents a mobile processing line for waste solidification. This is one of the methods that neutralize hazardous waste. Another essential aspect of presented technology is a waste processing, where waste and cement are both used in concrete production. The simply economic analysis shows costs of the installation use, annual profit possible to gain and discounted annual income which presents costs of the investment for the subsequent years of use.

Keywords: solidification, waste, neutralizing, installation

Introduction

Solidification of waste is one of the methods of hazardous waste disposal. The American Environmental Protection Agency hailed it as the most effective technology for neutralizing hazardous waste (Shi and Fernandez-Jimenez 2006). The main goal of the technological processes is the chemical transformation of waste into the form that is most inert to the natural environment (e.g. reducing water absorption, increasing mechanical strength, reducing leaching of pollutants, etc.). In this technology, waste is combined with binders, which are designed to solidify and stabilize the waste (Pyssa 2008, Grabowski et al. 2017). As a result, hazardous substances are blocked in the transformed material, which reduces the risk of harmful substances escaping into the environment (Misra and Pandey 2005).
Usually cement is used as a binding material for the solidification process (Wasiak and Różalska 2003). Cement is used very often because it has many advantages. The main one is that it has the ability to bind heavy metals effectively. It is also not very susceptible to external physical; chemical or biological factors and it is poorly soluble in water (Wasiak and Różalska 2003). Solidification of waste with the use of cements is based on (Shi and Fernandez-Jimenez 2006): 1. chemical binding of pollutants, occurring during the hydration reaction of cement components, and pollutants, 2. adsorption of pollutants on the surface of hydrated cement, 3. permanent isolation of contaminated waste.

The solidification process is innovative and most often used method to neutralize hazardous inorganic waste (or waste containing traces of organic compounds). These wastes pose a threat to the environment because there is a risk of toxic chemical compounds of metals penetrating. The advantage of this process is that the waste after transformation and neutralization can be used as road aggregate or as various building materials (Fengler 2012).

Materials and Methods

The waste for solidification in studied installation was soil containing dangerous and toxic mercury. Most often, harmful chemical compounds appear in the soil near operating industrial plants or around objects that have already been excluded from use. Such pollutants pose a significant threat to the environment. It is from this type of place that the waste suitable for solidification and thus neutralization in the resulting installation will come from. The installation will receive waste, which will be pre-shredded, mixed and partially stabilized. The waste prepared in this way at the installation of "solidification of hazardous waste from technological processes" will be further processed and, as a result, will be neutralized in the resulting concrete. The capacity of the line is 10 - 12 $Mg \cdot h^{-1}$.

The process cost intensity, and the internal rate of return and investment (IRR) and its net present value (NPV) were determined. The following parameters were established for the economic analysis of the project: the value of net investment outlays was estimated at EUR 372,000.00; VAT 23%; annual income: EUR 90,044.40 (including profit from the sale of concrete); average annual cost of living: EUR 4 200.00; additional costs: EUR 6,000.00 (flat rate for operating costs related to the planned investment, including service costs, service costs). – The net present value of the investment (NPV) is calculated according to the formula (1):

$$NPV = \sum \left(\frac{D_t}{(1+r)^t}\right) - N_0 \quad (1)$$

where: D_t - net profit [EUR], r - discount rate [%] t - subsequent years of the forecast, N_0 - investment expenditure [EUR].

The calculations were made for the discount rate = 3% and the discount rate = 4%. The NPV indicator is helpful in considering whether the investment is profitable. If NPV ≥ 0, the investment is profitable and should be accepted. When NPV <0, the investments should be discarded.
The internal rate of return (IRR) is the value of the discount rate for which the NPV will be 0 (eq. 2):

$$IRR = r_1 + \frac{NPV_1 \cdot (r_2 - r_1)}{NPV_1 - NPV_2} \quad (2)$$

where: r_1 - 3% discount rate, r_2 - 4% discount rate, NPV_1 - present value of the net investment for the 3% discount rate, NPV_2 - present value of the net investment for the 4% discount rate.

Results

Wastes are delivered to the installations by cars with a covered trailer. After unloading materia lis transported into STELMAR BT-500 L4 hopper. From the charging hopper, the waste goes to a belt conveyor, which will be transported to a roller crusher. The belt conveyors will also come from STELMAR. In the crusher, wastes were crushed into a fraction with a maximum size of about 10 mm. A GR - 65 roller crusher from GOSTER was selected for this purpose. The shredded waste with a particle size of about 10 mm will fall by gravity into a charging hopper with conveyor belt. Subsequently, they will be transported by a conveyor belt to a mixer (mobile concrete batching plant). Proxy Trade's M1800 mobile concrete batching plant was selected for this technology. It has a double silo in which each silo container contains 2 x 2.4 m^3. The mixing container has adjustable mixing arms and scrapers which are made of steel and hard PVC. It is located on three electronic weighing sensors, which allow a weighing accuracy of +/- 0.5%. The advantage of the mixer is the possibility of automatic control of the entire process through the ICON 9000E control system, which controls all processes of the connected equipment. In the concrete batching plant, all concrete components are mixed and it is there that the ready concrete mix is formed. The silos are supplied with waste, sand, cement and a solution of sodium polysulfide to replace water. This solution is process water from another process that will be used in this plant. All ingredients in the correct quantities will be transported to a mixing container, where they will be mixed and made into concrete. The concrete created in this process is C16/20 class (similar to the former B20 class). This concrete is widely used in construction and road construction. The waste from the mixer will be transported to an intermediate tank from which the concrete will be peeled by other companies (fig. 1).

Fig. 1. Installation scheme

The NPV shows the flow of savings as a result of the investment. Initially, the NPV index is negative because it is the time it takes to build an installation, where there is no income but investment costs. In the following years, the installation will bring a net profit of 69,792.20 EUR (Table 1). The percentage present value of the capital employed for each of the periods in the year of the investment is presented in table 2. With the passage of time, the percentage present value of the investment, both at the 3% and 4% discount rates, decreases. The value of your investment decreases faster at a discount rate of 4%. The calculated values in Table 1 and 2 show the effect of discounting the residual value of the investment on its value in the subsequent years of use. It can be seen that with a discount rate of 3%, the values become positive after 6 year, and with a discount rate of 4% in 7 year of the investment. For the investment profitability analysis presented above, the following general profitability ratios were calculated: 1. Sum NPV - discount rate 3% is: 595,341.58 EUR; 2. Sum NPV - discount rate 4% is: 566,077.22 EUR; 3. NPV - the 3% discount rate is: 223,341.58 EUR; NPV - the 4% discount rate is: PLN 194,077.22; 4. Internal rate of return (IRR): 10.63%; 5. Payback period: 5.3 years.

Table 1 NPV values simulation

YEAR	NPV [EUR]	NPV 3% [EUR]	NPV 4% [EUR]
0	-372,000.00	-	-

Summary

There are three market-leading technologies in waste solidification in Poland. One of them is the technology derived from Sweden - "Geodur". On the Polish market, it is represented by CDF - TECHNOLOGIE DLA ŚRODOWISKA s.c. from Zabrze. This technology uses its own products, from which it creates chemical mixtures needed for the solidification process. It focuses primarily on making the waste as a result of the process characterized by previously assumed properties and meeting certain standards. Another well-known technology is EnviroMix®, which is handled by Ecotech Polska S.A. It is most often used to neutralize soils, sludge and other solid wastes contaminated with hazardous substances. This method uses a material based on magnesium oxide, which is designed to bind impurities contained in the waste. The third company dealing with the stabilization of hazardous waste is MARBET® WIL Sp. z o. o., which introduced the SULTECH® technology to the market. This technology is known to use a sulfur binder in the process. It is most often used for the disposal of ashes from incinerators containing large amounts of heavy metals. From the transformed waste, this company produces concrete products, e.g. in the form of road curbs.
The designed technological line enables the transformation of waste with hazardous properties into a completely safe material that does not pose any threat to the environment. This solution allows you to reduce the waste sent to the landfill and thus reduce the costs associated with it. As a result of this process, concrete of the C16/20 class will be created, which has good physical properties. This concrete will be intended for sale, which will provide additional income. This is a big advantage, because the process will not only neutralize the waste, but the process will create a product that can be used. The installation is a mobile plant, which may be transported to designated places and waste transport limited.

The economic analysis performed showed that the designed installation is profitable. It will bring profit from the sale of the resulting concrete, approx. 70 thousand per year. PLN. The advantage of this installation was also confirmed by the calculated NPV coefficient. For both the 3% discount rate and the 4% discount rate, it takes a value above zero, which confirms that the installation is acceptable and will bring benefits in the next years of use. The profitability of the investment is also indicated by the calculated internal rate of return (IRR), which amounted to 10.63%. This value is much higher than the discount rate, therefore it confirms that the investment is profitable. Even though the capital expenditure is large, the payback time is approximately 5 years. The prepared analysis proved that the design of the installation for solidification of hazardous waste is profitable and will bring material benefits in the next years of operation.

Abstract

A three-year analysis of data from actual measurements of gaseous (NOx and CO) and particulate (PM2.5) pollutants inside the city street canyon in Krakow (Poland) was presented. The measurement results from the analysed period from May to September show the impact of transport on the dispersion of pollutants. In order to check the possibility of predicting air pollution, the OSPM model was used for testing the level of contamination. It was used for direct modeling of measured pollutant concentrations in a street canyon. The results of the research on air quality within a street canyon have shown that all sources of emissions in its area should be considered, and the impact of individual meteorological factors on the state of air pollution should be considered.

Keywords: Car, Traffic, Air Pollution, Street Canyon

Introduction

Road transport is one of the main sources of air pollution. Emissions produced during the combustion of fuels in internal combustion engines have a direct impact on human health and the environment. The last decade has seen a decrease in emissions of pollutants from the transport sector. This is due to the publication of a number of legal regulations and standards by the European Union (EC, 2008) and the World Health Organization (WHO, 2000). The introduction of increasingly restrictive regulations results in the creation of "hot spots" in cities with significantly exceeded emission standards.

The most important air pollutants that are attributed to means of transport include nitrogen oxides (NOx), sulfur oxides (SOx) and dust particles with a diameter less than or equal to 10µm (PM10). They mainly come from exhaust gases and are formed during wear of tires and brake pads in vehicles. European Union countries, the USA and Russia have recognized these pollutants as particularly important in urban agglomerations and responsible for numerous diseases of society (Franco et al., 2016; Genikhovich and Sciermeier, 1995; Genikhovich et al., 2002; Jain and Tiwari, 2016; Khreis et al., 2018; Lozhkina and Lozhkin, 2015; Lozhkina et al., 2016; Ni et al., 2018; Ntziachristos et al., 2009; Silva and Mendes, 2012; Singh et al., 2014; Taha, 2015; Yumino et al., 2015; Zachariadis and Kouvaritakis, 2003). According to a report published by the European Environmental Agency (2017), 39% of NOx emissions and 11% of PM10 emissions were generated by road traffic. Since 1990, the European Union has been constantly monitoring levels of airborne pollutants and requires permanent monitoring from member states (EC, 2008). The basic method of monitoring is the use of special measuring stations, which are located in places representing specific sources of pollution and allowing estimation of the degree of public exposure.

Currently, there are several instruments and policies in the world related to reducing emissions from road transport sources. They are necessary for transport development and planning. Each element of these documents is an assessment of air quality, which is to locate, determine the causes and indicate possible solutions to air pollution problems.

The basic problem of the modern air quality monitoring system is the limited number of measuring points. In order to complete the missing measurements data, pollutant dispersion models are used (Hülsman, 2014; Boltze and Kohoutek, 2010).

The highest levels of air pollution in Europe are recorded around measuring stations representing the communication background. This fact results from the constant accumulation of pollution and poor street ventilation (Gliniak et al. 2015a; Gliniak et al. 2015b). In 2016, in Germany, about 50% of stations reporting exceedances of nitrogen oxides and particulate matter were communication stations (UBA, 2017). Lamsal et al. (2013), comparing NO2 emissions data and data on multinational urban populations, showed that a larger population contributes to increased air pollution by NO2.

The article presents the impact of various factors affecting air pollution in a street canyon. The aim of this study is to investigate the characteristics of emissions from road transport vehicles in the period May-September, in the years 2017-19. As part of the study, the distribution of pollutants related to the number of vehicles passing through the day was monitored. A typical municipal street canyon located in Krakow, which is one of the city's main thoroughfares, was selected for the study.

Materials and Methods

A typical municipal street canyon located on Krasinski Avenue in Krakow, which is part of the second ring road of the City, was selected for analysis (Fig. 1). It is a communication route with a significant amount of car traffic (over 3500 vehicles per hour). Within the street there is a communication pollution measuring station belonging to the Provincial Inspectorate for Environmental Protection in Krakow. The data used for the research comes from the above-mentioned station (http://krakow.pios.gov.pl/stan-srodowiska/monitoring-powietrza/).

Fig. 1: Location of the research.

Krasinskiego Avenue is one of the most important transit streets in Krakow. It lies in the city center and is oriented in a north-south direction, with a road lane width and a building height of about 45 m and 25 m respectively, arranged in a continuous manner on both sides of the street. The area of the canyon is about 13,000 m^2. The monitoring station is located in the central part of the canyon, with the air intake port at a height of 2.5 m above ground level. The street is a busy one-lane street with about 8,500 vehicles a day. The average vehicle speed is 18 $km \cdot h^{-1}$.

The OSPM dispersion model was developed by the team of National Environmental Research Institute of Denmark. It is based on a combination of partial box models of direct impact of traffic. Direct impact is calculated on the basis of the plume distribution of pollution in space. It is assumed that both traffic and emissions are evenly distributed throughout the canyon. Atmospheric recirculation within the street canyon is determined on the basis of the trapezoidal vortex. Its shape assumes the maximum length of the upper edge as half the vortex length. Ventilation of the recirculation zone occurs through trapeze edges and may be limited by the presence of a building with wind if the building passes through one of the edges (Berkowicz, 2000; Ziv et al., 2002; Ketzel et al., 2003).

OSPM for calculations requires hourly traffic and vehicle speed, background pollution concentrations, meteorological parameters (temperature and solar radiation; wind speed and direction), emissions from traffic and street geometry. Traffic intensity observations were carried out on 10 randomly selected days of the week, each month (Figure 2). The

diversity of the vehicle fleet on the street averaged 90% of passenger cars, 2% of delivery vehicles, 1% of trucks and 7% of buses for the measurement period. To calculate emissions from traffic, the following input data is needed: emission factors, vehicle movement and speed for each hour of the day and correction of cold engine start. Emission factors based on the European emission model COPERT III (http://vergina.eng.auth.gr/mech/lat/copert/copert.htm) were used in the calculations for particular vehicle types, technology and engine power, fuel type as well as emission reduction (catalysts, particulate filters). It was recognized that there is no percentage of vehicles with a cold engine (ADEME, 2002; Ziv et al., 2002; Ketzel et al., 2003).

Fig. 2: Vehicle number and speed for measured months (vertical lines indicate middle day of the month).

Results and Discussion

Figure 3 presents changes in wind speed (due to the location of the test site no change of direction occurred) of the measured and modeled concentrations of NO, CO and PM2.5 There is a strong positive correlation between the analyzed air pollutants. The presented measurement data show that the holiday months (July and August) have the lowest concentrations of pollutants.

Fig. 3: Time series of research in the years 2017-19 (vertical lines indicate middle day of the month).

Their presence is not correlated with the wind speed recorded in the audited street canyon. Typically, lower wind speeds were observed in July and August compared to the other months covered by the study. This phenomenon should lead to an increase in the concentration of pollutants, however, the analysis showed that during these periods the number of vehicles using the street will also decrease. Higher wind speeds (2017 and 2018) were observed in the months of May and September than in the summer, which also resulted in an increase in the concentration of pollutants that could have get into the street canyon from the surrounding areas.

Modeling of the content of pollutant concentrations in the air shows up to 3% difference in comparison with the measured value. The results of OSPM modeling for nitrogen oxides (Fig. 3) for 2017 and 2018 present a good mapping of the actual measurements (correlation coefficient is 0.98), while in 2019 the OSPM model overestimated the recorded concentrations reaching a correlation of 0.96. Modeling using the OSPM technique has proven successful for the concentration of carbon monoxide in the air and PM2.5 dust, obtaining a correlation between actual data and calculated at 0.99. The relative share of concentrations of individual pollutants depends on traffic, day of the month and meteorological conditions. This system achieves lower values in the summer months and higher values during spring and autumn. The average monthly values of the measured concentrations of pollutants are smaller than the values allowed by WHO (2003). Comparing periods of high and low traffic with each other, the OSPM model describes the variability of pollution concentrations in a satisfactory manner. When analysing the concentration of nitrogen oxides and particulates, a slight overestimation of the measured values can be observed. Differences resulting from model tests and actual measurements can be caused by errors associated with the measurement of vehicle speed and applied simplifications (e.g. no change in wind direction, correction of cold engine start). In the case of CO, the OSPM model shows almost 100% convergence of calculations with real measurements.

Conclusions

PM2.5 particulate matter and concentration of gaseous pollutants (NOx and CO) were monitored simultaneously for a period of five months for three consecutive years in a canyon street. Time series of wind speeds and pollution concentrations were presented in order to reveal dilution conditions on the street for various wind speeds, as well as in cases of a diverse traffic.

The OSPM model was used to simulate NOx, CO and PM2.5 concentrations (direct modeling) and road traffic emissions (inverse simulation) in a street canyon. Direct simulation of the distribution of pollutants showed satisfactory results for NOx and PM2.5 concentrations, but it is not appropriate for the CO concentration. Based on the conducted research, it was found that 94.4% of the surveyed days showed a significant dependence between the number of cars and the size of pollutant concentrations. According to Rozbicka (2007), nitrogen oxides concentration values depend on the days of the week. Research conducted by teams of Derwent (1995), Zickus et al. (1997) and Drzeniecka et al. (2000) prove the relations between the value of nitrogen oxides concentration and weather conditions.

The performed tests showed variable air dustiness regardless of the season. The obtained test results indicate a low share of transport in the emission of particulate air pollutants. Therefore, when conducting research on air quality within a street canyon, all emission sources in its area should be considered, as well as the impact of individual meteorological factors on the state of air pollution should be considered.

Abstract

The aim of the research was to analyze the impact of the development of the e-commerce industry on freight transport in Poland. As part of the work, the scale of interactivity of individual analyzed parameters was shown. Data from 2011-2019 were obtained to study the impact of the e-commerce industry on the transport of goods. All of the presented data describe the Polish market. The statistical analysis included the following tools: Pearson's linear correlation, least squares regression analysis, and the coefficient of determination R^2. A significance test was performed for each model. The conducted research has shown that the e-commerce industry has a direct impact on the development of road transport in Poland.

Keywords: E-Commerce, Regression, Transport, Simulation.

Introduction

The development of the Internet, the growing number of its users and the growing importance of information technologies are just some of the factors influencing the dynamic development of the e-commerce industry both in Poland and in the world. Market research shows that the e-commerce industry is one of the fastest growing in Poland. As a result, the number of consumers choosing this type of exchange of goods is increasing every year. Data contained in the Statista Digital Market Outlook report places Poland in 13th place in the ranking of the fastest growing e-commerce markets in the world. This is confirmed by the results achieved by this industry, which are growing every year. The value of sales on the Polish Internet in 2019 is estimated at PLN 51 billion, which is an increase of PLN 6 billion compared to the previous year. The number of online shoppers is also growing dynamically. In 2019, the group of e-consumers amounted to 26.3 million, while forecasts estimate their growth to approximately 29.5 million by 2023. Consumers are increasingly choosing to buy online. They are convinced by the convenience, simplicity, speed, as well as greater choice than those offered in stationary stores. The users' opinion on the security of online shopping is also improving every year. This contributes to the growing importance of non-cash transactions, which is why the ability to quickly transfer via the payment service is the most frequently chosen form of payment. The advantages of having an online store mean that an increasing number of entrepreneurs choose this form of distribution. Their greatest benefit is the lack of the need to have a point of sale, and thus no need to hire the necessary staff. This allows you to significantly reduce the costs of running a store. The growing competition on the e-commerce market poses more and more challenges to enterprises in the fight for customer acquisition. Companies are trying to better adapt to consumer requirements, which translates into the number of benefits from online shopping, i.e. free delivery or discount codes. More and more new technologies contribute to modification in the trade sector, and this means great changes in the industry in the following years.

Cite this Article as: Dominika KOTULSKA, Karolina TRZYNIEC, Maciej GLINIAK and Piotr WALĄG" The Impact of The E-Commerce Market on Freight Transport - The Use of Regression Analysis to Simulate Logistic Processes" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The e-commerce industry is closely related to logistics. Having an online store forces entrepreneur to adjust the appropriate model of e-store logistics service. The logistic service model should be best suited to the company's structure and clearly define the role of the logistics operator so that deliveries are organized in an efficient manner. In order to meet the growing demands of customers, entrepreneurs more and more often decide to entrust an external logistics company with additional tasks accompanying the distribution of goods, such as handling returns or order picking, which is called fulfillment. In order to improve the implementation of logistics processes, these companies implement modern solutions in the form of telematic systems that support all departments and areas of the company simultaneously.

There is a supposition that the development of e-commerce has a direct impact on freight. Based on this, it can be concluded that the sector that gains the greatest profit as a result of the development of e-commerce is the courier, express and parcel services (Horzela 2018). The progressive number of orders in online stores results in an increase in the volume of handled parcels. Courier companies more and more often decide to handle parcels cross-border. As a result, the length of the average load transport distance increases. The growing volume of transported goods and the distance of transport performed result in an increase in the transport performance in freight transport. The chapter examines the impact of the development of the e-commerce industry on freight transport in Poland. As part of the research, the scale of interactivity of individual analyzed parameters was shown.

Materials and Methods

The purpose of the research was to analyze the impact of the development of the e-commerce industry on freight transport in Poland. As part of the work, the scale of interactivity of individual analyzed parameters was shown.

The first stage of work was data collection. Data from 2011-2019 were obtained to study the impact of the e-commerce industry on the transport of goods. All of the presented data describe the Polish market. The data considered in the analysis are presented below (Table 1). The number of factors determining the development of transport, closely related to the phenomenon of online sales (marked as Y in Table 1), affects the accuracy of the results (the greater the number of factors, the more reliable the results of the analysis). Each of the analyzed Y is characterized by a different plane of the transport sector.

The second stage of work involved statistical analysis using tools such as Pearson's linear correlation, least squares regression analysis and the R^2 coefficient of determination. A significance test was performed for each model. The third stage is inference based on the calculations made.

Table1: Data used for analysis

Symbol	Verbal sign	Unit	Source
X1	number of Internet users	%	GUS
X2	value of the e-commerce market	mld PLN	UKE Report
X3	number of online stores	thousand pieces	Bisnode
Y1	average transport distance of 1t of cargo	kilometers	GUS
Y2	number of registered postal non-public operators	-	UKE Report
Y3	revenues from courier items	mln PLN	UKE Report
Y4	shipment volume	mln pcs.	UKE Report
Y5	number of operators in the courier items segment	-	UKE Report

The number of Internet users is the percentage of people aged between 16 and 74 who made an online purchase in a given year. These data are made available each year by the Central Statistical Office in the publication "Information society in Poland". This publication presents the use of information and communication technologies in enterprises, households and by individuals (GUS 2019a).

The value of the turnover generated by transactions concluded in electronic channels is defined as the value of the e-commerce market. Otherwise, it is the value of online sales. Data on the value of the Polish e-commerce market are presented in the Report on the state of the postal market for individual years, prepared by the Office of Electronic Communications (UKE Report 2020). Along with the increasing popularity of the Internet, the number of online stores on the Polish market is also growing. A large part of sellers decides to liquidate a stationary outlet in favor of an e-shop. At the end of June 2019, the number of online stores reached 31.7 thousand, which is the highest result on the Polish online sales market in history (Bisonde 2019).

More and more operators in the courier parcel sector decide to handle parcels across borders. The element of the European Union policy, which is the free movement of goods within the Member States, has a large impact on the distance of transported goods. Parameter Y1 specifies the average distance of transport of one ton of cargo and is expressed in kilometers. These data come from the report of the Central Statistical Office on road transport in Poland and concern only commercial transport (GUS 2019b).

The result of the ongoing evolution on the postal market is also a decline in interest in letter items. Increasingly, the exchange of private correspondence and documents in public administration units is carried out via the Internet. This means that the number of non-public postal operators is increasing on the market. They offer courier services and other postal services both in domestic and international traffic, including marketing parcels, commercial parcels or parcels weighing more than 10 kg. However, the strongest opponent for the postal items segment is the courier items market. This situation is the result of the prevailing trends and growing consumer requirements for deliveries. The services of courier companies, despite the higher price compared to the services of postal providers, are the most frequently chosen delivery channel in the e-commerce industry.

Data on the number of non-public postal operators and the number of operators in the segment of courier items in Poland are presented in the Report of the Office of Electronic Communications on the state of the postal market (UKE Report 2020). According to the UKE Report (2020), in recent years, the Polish market has seen an increase in revenues in each of the product categories. The highest revenue is observed in the courier shipment segment. The reason for this is the constantly growing volume of parcels purchased by e-consumers through online transactions (table 2).

Table 2: Data collected form years 2011-2019

Year	number of Internet users [%]	value of the e-commerce market [mld PLN]	number of online stores [thu pcs.]	average transport distance of 1t of cargo [km]	number of registered postal non-public operators	revenues from courier items [mln PLN]	shipment volume [mln pcs.]	number of operators in the courier items segment
	X1	X2	X3	Y1	Y2	Y3	Y4	Y5
2011	29.70	15	16.3	213	247	1489.12	90.96	81
2012	30.30	20	19.1	240	267	1575.04	110.06	85
2013	31.60	24	21.7	255	274	2290.56	136.46	99
2014	34.20	28	24.6	252	294	2708.12	194.46	93
2015	36.90	33	26.6	261	288	3208.30	216.44	101
2016	41.90	36	27,6	274	290	3585.20	264.30	98
2017	45,00	40	29.1	274	279	3978.00	308.10	89
2018	47.80	45	28.9	282	291	4643.50	368.70	94
2019	53.90	51	31.7	295	293	6017.20	457.25	95

Pearson's correlation coefficient is a measure of the linear relationship between two random variables X and Y. This coefficient is calculated by the formula:

$$r_{xy} = \frac{\sum_{i=1}^{n}(X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^{n}(X_i - \bar{X})^2 \sum_{i=1}^{n}(Y_i - \bar{Y})^2}}$$

where:

X_i, Y_i – i-th values of observations from the X and Y populations
$\bar{X}$, $\bar{Y}$ – X and Y population means
n – number of observations

The values of the correlation coefficient are in the range [-1.1]. Its sign indicates the direction of the relationship. When $|r_{xy}| = 1$, then there is an exact functional linear relationship between the variables. When the value of rxy is 0, then there is no linear relationship between the two variables (Dziechciarz 2003).

Interpretation of the correlation value (Greń 1974):

a) type of correlation

1. r > 0 positive correlation - when the value of X increases, the value of Y also increases
2. r = 0 no correlation - when X increases, Y sometimes increases and sometimes decreases
3. r < 0 negative correlation - when X increases, the value of Y decreases

b) the strength of the correlation for $|r_{xy}|$
1. < 0.2 - no linear relationship
2. 0.2 - 0.4 - weak dependence
3. 0.4 - 0.7 - moderate dependence
4. 0.7 - 0.9 - quite strong dependence
5. > 0.9 - very strong dependence

In order to test the relationship between the variables in the entire sample population, the Pearson correlation coefficient significance test is performed. In order to verify the hypotheses H_0 and H_1 should be defined.
H_0: $\rho = 0$ – no significance of the correlation coefficient,
H_1: $\rho \neq 0$ – the correlation coefficient is significant.

Statistics are used to test the truth of hypotheses t:

$$t = \frac{r\sqrt{n-2}}{\sqrt{1-r^2}}$$

where:

r - value of Pearson's linear correlation coefficient
n - sample size

Assuming that the H_0 hypothesis is true, the t statistic has the t-Student distribution. From the tables of this distribution, the critical value $t_{\alpha, n-2}$ (for the adopted significance level α and n-2 degrees of freedom) should be read. In the case when the critical value $t_{\alpha, n-2}$ belongs to the critical area $(-\infty; -t_{\alpha,n-2})\ U\ (t_{\alpha,n-2}, +\infty)$ then the hypothesis H_0 should be rejected in favor of the hypothesis H_1. When:

1. $|t| \geq t_\alpha$ – the hypothesis H_0 should be rejected,
2. $|t| < t_\alpha$ – there are no grounds for rejecting the hypothesis H_0.

The linear model parameters were estimated using the least squares method. The calculations were performed in the matrix notation for the variables X_3 (number of online stores) and each of the analyzed Y. After saving the vector of the observation of the dependent variable Y and the observation matrix of the explanatory variables X, the parameter vector should be determined using the formula:

$$a = (X^t X)^{-1} X^t Y$$

The parameter a explains by how many units the magnitude of the explained variable Y will change, if the explained variable X increases its value by one unit. Finally, the econometric model without the intercept can be written as follows:

$$y = Xa + \varepsilon$$

where ε is the random term.

The above calculations were performed both with the determination of the intercept b. The free word may inform about the value of Y in the case of a zero X, while in the case of this analysis it was adopted as an uninterpreted parameter.

The calculated simple regression parameters describe the sample population. In order to investigate the location of the general population regression line, it is necessary to define the confidence zone in which this line will be located. The probability of occurrence is selected individually. Simple confidence set $y = \alpha x + \beta$ it is limited by the confidence curves (the so-called Nevman curves). These curves determine the forecast range of the value of variable X for a given Y. Nevman curves are determined from the formula:

$$P\left\{\widehat{y_i} - t_\alpha s_{\widehat{y_i}} < \widehat{y_i} < \widehat{y_i} + t_\alpha s_{\widehat{y_i}}\right\} = 1 - \alpha$$

where:

$\widehat{y_i}$ – function value $\widehat{y_i} = \alpha x + b$

$\widehat{y_i}$ – wartość szacowanej funkcji regresji $y = \alpha x + \beta$
t_α - value of the variable with Student's t-distribution for the established confidence coefficient 1-α and for n-2 degrees of freedom
To calculate $s_{\widehat{y_i}}$, firstly determine the average deviation s_r to simple regression.

$$s_r = \sqrt{\frac{1}{n-2}\sum_{i=1}^{n}(y_i - \widehat{y_i})^2}$$

$$s_{\widehat{y_i}} = \sqrt{\frac{1}{n} + \frac{(x_i - \bar{x})^2}{\sum_{i=1}^{n}(x_i - \bar{x})^2}}$$

The confidence interval determined with the probability of 1-α covers the true regression function $y = \alpha x + \beta$ in the general population.

The test of significance of linear regression analysis assumes checking the hypothesis concerning the coefficient obtained as a result of the calculations. In order for the obtained function to be considered a suitable tool for forecasting the value of one feature using the value of the other, the coefficient must differ from 0. Obtaining a coefficient equal to 0 means that the regression function in the population is constant, which indicates no dependence between the studied variables. The significance of the estimated equation is checked by verifying the hypotheses:

$$H_0: \alpha = \alpha_0,\ H_1: \alpha \neq \alpha_0.$$

Based on the determined regression function of the formula $y = \alpha x + \beta$ the average deviation should be calculated s_r, then the statistic value t.

$$t = \frac{\alpha - \alpha_0}{s_r}\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}$$

The value of the t-statistic is the Student's t-distribution with n-2 degrees of freedom (assuming the H_0 hypothesis is true). From the Student's t-distribution tables, for the assumed significance level α, one should read the critical value tα satisfying the condition $P\{|t| \geq t_\alpha\} = y$. The comparison of the critical value tα and the calculated value of t is interpreted as follows:

1. $|t| \geq t_\alpha$ – the hypothesis H0 should be rejected,
2. $|t| < t_\alpha$ – no contradiction to the hypothesis H_0.

The R^2 coefficient, also known as the specificity coefficient, is a tool that allows to measure the fit of the model to empirical data. It shows what part of the dependent variable's variability is explained by this model. In other words, the R^2 determination coefficient carries with it information about what percentage of the dependent variable is explained by the explanatory variable. After determining the value of the determination coefficient, we are able to determine how much the value of X has an influence on the value of Y. The coefficient R^2 can assume values in the range [0.1], but most often its value is expressed as a percentage. The higher the R^2 value, the better the model fit is. The coefficient of determination is expressed by the formula (Gruszczyński 2004):

$$R^2 = 1 - \frac{\sum_{t=1}^{n}(\hat{y}_t - \bar{y})^2}{\sum_{t=1}^{n}(y_t - \bar{y})^2}$$

where:

y_t– the actual value of the variable Y at time t,
$\hat{y}_t$- theoretical value of the dependent variable (based on the model),
$\bar{y}$ - arithmetic mean of empirical values of the dependent variable.
Interpretation of the coefficient of determination [10]:

- 0.0 - 0.5 - unsatisfactory fit
- 0.5 - 0.6 - weak fit
- 0.6 - 0.8 - satisfactory fit
- 0.8 - 0.9 - good fit
- 0.9 - 1.0 - very good fit

The Fisher-Snedecor test is a tool that allows to test the significance of the R^2 coefficient. This method involves the verification of the following hypotheses:

H_0: $R^2 = 0$ – R^2 coefficient is not significant, regression is statistically insignificant,
H_1: $R^2 > 0$ – R^2 coefficient significant, regression statistically significant.
The first step in the calculation is to determine the value of the F-test statistic from the following formula:

$$F_{emp} = \frac{R^2}{k} : \frac{1 - R^2}{n - k - 1}$$

where:

R^2 – coefficient of determination
k - number of explanatory variables
n - number of observations in the model
Then, from the Fisher-Snedecor tables, the critical value Fα, v1, v2 should be read for the given significance level and the respective degrees of freedom v_1 (k) and v_2 (n-k-1). After determining the critical value, it is necessary to consider two cases:

1. $F_{emp} > F_{\alpha,V1,V2}$ – the hypothesis H_0 should be rejected,
2. $F_{emp} < F_{\alpha,V1,V2}$ – no grounds for rejection H_0.

Results

The purpose of the analysis was to show the impact of the e-commerce industry on freight transport in Poland. Thanks to calculations made with the use of statistical tools, the scale of interactivity of individual parameters was shown.

Interdependence of the e-commerce market and the transport of goods

One of the tools that allows to show the correlation between the variables is the Pearson correlation. The table 3 presents the values of the calculated coefficient of this correlation between the dependent variables and the potential exogenous variables.

Table 3: Pearson's correlation coefficient values

	Y1	Y2	Y3	Y4	Y5
X1	0.907	0.649	0.985	0.994	0.327
X2	0.961	0.770	0.986	0.988	0.476
X3	0.964	0.854	0.938	0.933	0.585

Nine out of fifteen calculated coefficients indicate a very strong correlation. The highest correlation is between the number of e-consumers and the volume of parcels, where the correlation coefficient is 0.994. This is a situation very close to a linear relationship because of the direct nature of the impact. The growing number of people shopping over the Internet generates more and more orders, and this translates into the volume of courier parcels served. The second highest correlation is between the value of the e-commerce market and the volume of parcels and amounts to 0.988. The growing number of transactions concluded via the Internet means that the number of parcels delivered to customers is also increasing. The value of this correlation is close to 1, which means that this correlation shows an almost exact linear functional relationship between these variables. This is the result of a situation where each new order placed in the online store generates one new shipment. The lack of a total functional linear relationship may be caused by the delivery option, which is self-collection, where the customer collects the order directly from the store, or consolidation of shipments in the case of picking a large order to the same recipient. A similarly high correlation exists between the value of the e-commerce market and revenues from courier services. It is directly related to the previously described situation, where the increasing number of shipments resulting from online transactions results in increasing revenues from these shipments. The smallest correlation is between the number of Internet users shopping online and the number of postal operators in the courier items segment and amounts to 0.327. This means that there is a weak relationship between these variables. The number of e-consumers is not a factor that significantly affects the number of courier companies on the market. This factor is the volume of orders generated by these internet users (table 4).

Table 4: The values of the Pearson correlation coefficient between potential explanatory variables

	X1	X2	X3
X1	1.000	0.979	0.920
X2	0.979	1.000	0.972
X3	0.920	0.972	1.000

According to the assumptions of the least square's method, used in the subsequent analysis, the correlation between the studied exogenous variables should be as small as possible. The greatest correlation occurs between the variable X_1 and X_2 (0.979), therefore it was decided to reject these observations from further analysis

The results of the test of significance of the correlation coefficient

To fully show the interactivity of the studied observations, the Pearson correlation coefficient significance test was performed (*r*) – table 5.

Table 5: The results of the test of significance of the correlation coefficient

Correlation	α	n-2	r	t	$t_{\alpha,n-2}$
X3-Y1	0.05	7	0.964	9.546	2.345
X3-Y2	0.05	7	0.854	4.337	2.345
X3-Y3	0.05	7	0.938	7.168	2.345
X3-Y4	0.05	7	0.933	6.865	2.345
X3-Y5	0.05	7	0.585	1.91	2.345

In the first four cases, the calculated t statistic is greater than the t-table value, which allows for rejecting the hypothesis H_0 that the correlation coefficient is irrelevant. For the last test between X_3 and Y_5, the value of t is not in the range$(-\infty; -2.345)\ U\ (2.345, +\infty)$, which conditions the rejection of the null hypothesis - the correlation in this case is not statistically significant. The obtained results are consistent with the correlation analysis. The undesirable low correlation between the number of online stores and the number of postal operators in the segment of courier items is not significant.

Least squares method - A model with a free expression

The calculations below present the estimation of the linear model parameters for the explanatory variable X_3 and the dependent variable Y_4. Due to the high interactivity of e-commerce and the industry and courier services, these variables were selected for the model. The X_3 variable representing the number of online stores is characterized by a high characteristic of the e-commerce industry, while the Y_4 variable describing the volume of online parcels is a parameter that clearly explains the state of the CEP market in Poland. In this method, the parameter α and the intercept were determined.

Table 6: Summary of data participating in the analysis along with the free word

Free word	X3	Y4
1	16.30	90.96
1	19.10	110.06
1	21.70	136.46
1	24.60	194.46
1	26.60	216.44
1	27.60	264.30
1	29.10	308.10
1	28.90	368.70
1	31.70	457.25

The table 6 presents a summary of the data that has been estimated. The first column contains the value of the intercept, which for each of the cases is 1. The first step in the least squares method is to transpose the matrix with X_3 values and the intercept.

$$X^T = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 16.3 & 19.1 & 21.7 & 24.6 & 26.6 & 27.6 & 29.1 & 28.9 & 31.7 \end{bmatrix}$$

Then the matrix product of the untransposed X and transposed X^T tables was calculated. The result of this operation is shown in the matrix below.

$$X^T X = \begin{bmatrix} 9 & 222.56 \\ 222.56 & 5862.78 \end{bmatrix}$$

In the next stage of calculations, it was determined $(X^t X)^{-1}$, that is, the matrix inverse to that resulting from the product.

$$(X^t X)^{-1} = \begin{bmatrix} 3.14 & -0.12 \\ -0.12 & 0.00 \end{bmatrix}$$

In the last step, the matrix product was made $X^T Y$ and $(X^t X)^{-1}$, to which the parameter α and the intercept were determined.

$$\begin{bmatrix} b \\ a \end{bmatrix} = \begin{bmatrix} -326.938 \\ 22.558 \end{bmatrix}$$

The value of the parameter *a* equal to 22.558 informs that in the case of an increase in the number of online stores by one unit, the value of the volume of parcels will increase by as many units as the size of the parameter *a*. The intercept is an uninterpretable parameter. Table 7 below shows the results of the estimation for X_3 and the remaining Y.

Table 7: Estimation results of other parameters - model with intercept

	Parameter *a*	**Free word**
X3-Y1	4.63	144.6
X3-Y2	2.61	214.87
X3-Y3	271.17	-3520.12
X3-Y5	0.76	73.64

The value of the parameter a gives information about how many units will increase in size Y_i (*i=1, 2, 3, 4, 5*), in the event that the number of online stores increases by 1 unit (1,000).

A model without an intercept

The estimate for the model built from the variables X_3 and Y_4 obtained as a result of the calculations was presented in the matrix form:

$$[a] = [9.978]$$

This means that when the number of online stores increases by one unit, the expected increase in the volume of parcels will be at the level of 9.978 units (table 8).

Table 8: Estimation results of other parameters - model without intercept

	PARAMETER *a*
Y1	10.20
Y2	10.88
Y3	135.72
Y5	3.6

The value of the parameter *a* informs by how many units the size will increase Y_i (*i=1, 2, 3, 4, 5*), when the number of online stores increases by 1,000.

Results of the test of significance of the regression coefficients

In order for the obtained regression function to be considered a suitable tool for forecasting the value of one feature using the value of the other, a test of the significance of the regression coefficient was performed. The calculations were made in the RStudio statistical program. The test results are illustrated by the code results below. The RStudio package reads the statistical test results based on the p-value. If this value is lower than the adopted significance level (α = 0.05), the null hypothesis that the analyzed parameter is irrelevant should be rejected. Additionally, the program

allows you to graphically read the significance test results by number „*" next to the P-value (max. number „*" = 3). Intercept represents the intercept, and X represents the values of the *a* parameter.

```
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept)  144.600     12.380  11.681 7.62e-06 ***
X              4.630      0.485   9.546 2.90e-05 ***
```

The p-value of the calculated estimates is smaller than the adopted α, therefore we can consider the significance of these parameters.

```
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) 214.8733    15.3691  13.981 2.27e-06 ***
X             2.6114     0.6022   4.337  0.00341 **
```

The p-value of the calculated estimates is smaller than the adopted α, therefore we can consider the significance of these parameters.

```
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) -3520.12     965.55  -3.646 0.008224 **
X             271.17      37.83   7.168 0.000182 ***
```

The p-value of the calculated estimates is smaller than the adopted α, therefore we can consider the significance of these parameters.

```
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) -326.938     83.868  -3.898 0.005912 **
X             22.558      3.286   6.865 0.000239 ***
```

The p-value of the calculated estimates is smaller than the adopted α, therefore we can consider the significance of these parameters.

```
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept)  73.6365    10.2037   7.217 0.000175 ***
X             0.7636     0.3998   1.910 0.097750 .
```

The p-value of the computed intercept is smaller than the assumed α, therefore we can consider the significance of this parameter. In the case of the parameter *a*, the p-value exceeds the adopted level of significance, therefore there is no significance of *a*.

Model Fitting

The calculated values of the coefficient of determination R^2 for each X and Y are presented in the table 8.

Table 9: The values of the coefficient of determination R^2 expressed in %

	Y1	Y2	Y3	Y4	Y5
X1	82%	42%	97%	99%	11%
X2	92%	59%	97%	98%	23%
X3	93%	73%	88%	87%	34%

The highest fit of the model is for the independent variable X_1 and the dependent variable Y_4 and is 99%. This means that the fit of the model is very good, close to 100%, and this indicates a very high usefulness of the regression equation when predicting the value of the Y_4 variable using the independent variable X_1. Almost entirely the volatility

of the parcel volume is the result of the volatility of the number of internet users. The smallest match is between the variables X_1 and Y_5. This value indicates an unsatisfactory fit. It means that only 11% of the data on the number of postal operators in the segment of courier items is explained by the impact of the variability of the number of internet users.

Results of the determination coefficient significance test R^2

In order to test the significance of the R^2 coefficient, the significance test was performed using the Fisher-Snedecor method. The adopted significance level α is 0.05. Value read $F_{\alpha,V1,V2}$ for the corresponding degrees of freedom from the F-Snedecor tables it is 5.59. The calculated F_{emp} values are shown in table 10.

Table 10. Calculated values F_{emp} for X_3

X3	93%	73%	88%	97%	34%
k	1	1	1	1	1
n	9	9	9	9	9
f	91.13	18.81	51.38	47.13	3. 65

For four of the five analyzed cases, the Femp value is greater than the F_ value (α, V_1, V_2). It means that the hypothesis H_0 must be rejected, which says that the R^2 coefficient is not significant. The calculated coefficient of determination between X_3 and Y_1, X_3 and Y_2, X_3 and Y_3 and X_3 and Y_4 is therefore significant. In the latter case, with a given significance level of 0.05, the regression is statistically insignificant. Its significance occurs when the significance level is increased to α = 0.1.

Scatterplots of variables

Scatterplots show the relationship between the two analyzed features. The graphs below show the correlation between the number of online stores and all analyzed Y. Each of the graphs is a line, point graph. The red line marks the trend line, and the blue points show the place of the given pairs of observations in the coordinate system.

Fig. 1: Correlation between the number of online stores and the average transport distance of 1t of cargo

The above diagram is a scatter plot of the variables X_3 and Y_1. There is a positive relationship between the variables. A positive relationship means that an increase in the value of one variable is accompanied by an increase in the value of the other variable. The function presented in the graph informs us that when the number of online stores increases by one unit, the average transport distance will increase by 4,630 units. The number of online stores is a total value, so we can assume that as the average transport distance of 1t of cargo increases by one kilometer, the number of online stores will increase by about 5. The value of the R^2 determination coefficient equal to 0.9287 indicates a very good fit of the model.

Fig. 2: Correlation between the number of online stores and the number of registered non-public postal operators

The chart presented in Figure 2 shows the positive relationship between the number of online stores and the number of registered non-public postal operators. This means that as the value of the variable X_3 increases, the values of Y_2 also increase. The formula of the linear function presented in the chart provides information on how much the number of registered non-public postal operators will increase in the case of an increase in the number of online stores by one unit. In the case of this interdependence, the number of non-public postal operators will increase by about 3 units. The determined value of the R2 coefficient indicates a satisfactory fit of the model.

Fig. 3: Correlation between the number of online stores and revenues from courier items

The above scatter chart shows the relationship between the two features, which are the number of online stores and revenues from courier services. The correlation between these variables is positive, which can be seen on the basis of the rising trend line. The coefficient next to "x" in the linear function formula presented in the chart determines how much revenue from courier items will increase when the number of online stores increases by one unit. When the number of online stores increases by 1 unit, revenues from courier items will increase by approximately 271 units. The fit of the model is good, which can be seen from the calculated value of the determination coefficient.

Fig. 4: Correlation between the number of online stores and the volume of parcels

The relationship between the number of online stores and the volume of parcels is shown in Figure 4. The designated trend line indicates a positive relationship between these features. This means that in the case of an increase in the results of one variable, the increase in the results of the other variable is equal. In the case of this relationship, increasing the number of e-shops by one thousand will result in an increase in the volume of parcels by about 23 units. The values of the X_3 variable explain the collected data on the dependent variable Y_4 well, which can be found on the basis of the determined R^2 coefficient.

Fig. 5: Correlation between the number of online stores and the number of postal operators in the courie mail segment

The last of the studied relationships is that between the number of online stores and the number of postal operators in the courier items segment (Figure 5). The fit of the model in this case is unsatisfactory. The result is that the growing number of stores alone does not determine the number of postal operators. The factor that has a real impact on the increase in the number of operators are orders generated in these e-stores. In addition, in Poland, despite many companies in the courier parcel sector, for years the leading companies are: DPD, InPost and Poczta Polska. These operators handle almost the entire shipment turnover in the country. The designated trend line indicates a positive relationship between the analyzed features.

Summary

Numerous market studies show that the e-commerce industry is one of the fastest growing in Poland. This is confirmed by the dynamically growing number of consumers who choose this channel of goods exchange in recent years. The

ranking of e-commerce markets in the world with the highest growth, published by Statista Digital Market Outlook, places Poland in 13th place in this ranking. This is confirmed by the results achieved by this industry. Compared to 2018, the value of online sales increased by 6 billion PLN, reaching the result of 51 billion PLN in 2019. There was also a significant increase in the number of people who shop electronically. In 2019, the number of e-consumers was 26.3 million, and the forecasts carried out estimate their growth to 29.5 million by 2023.

The e-commerce industry is closely related to the TSL market. The development of e-commerce is one of the drivers that drives the transport market the most. The growing number of orders in online stores, increasing customer requirements for the quality of deliveries and the development of new logistics technologies place ever greater demands on the transport market, prompting continuous evolution.

The impact and strength of the interactivity of the e-commerce industry and the freight transport market in Poland were examined. The area of the TSL market on which the greatest emphasis has been placed is the courier, express and parcel services (KEP) sector, considered to be the largest beneficiary of the development of online commerce. The performed analysis was based on data obtained from numerous reports and the database of the Central Statistical Office and covered the scope of 9 years, from 2011 to 2019.

The strength of the correlation between the factors shaping e-commerce and transport indicators was tested using a statistical tool, which is the Pearson linear correlation. The highest relationship was observed between the number of e-consumers and the volume of parcels, where the value of the coefficient was 0.994. The dynamically growing number of Internet users shopping via electronic channels translates into an increase in orders placed in e-stores. Due to this situation, suppliers are forced to handle an increasing number of shipments, resulting from transactions concluded on the Internet. The second highest correlation, 0.988, between the value of the e-commerce market and the volume of parcels is directly related to the previously described increase in the number of e-consumers and the transactions they generate. The increase in the value of online sales depends on the growing number of orders, and this affects the increasing volume of shipments.

The results obtained by examining the model fit agree with the results of the Pearson linear correlation. The highest value of the R^2 determination coefficient is achieved for the X_4 indicator, which is the volume of parcels. The result of 99% for the number of e-consumers and the volume of shipments shows that, as can be seen, the almost complete variability of Y_4 is explained by the variability of X_3. The second highest model fit occurs in the case of the value of the e-commerce market and the number of parcels, where 98% of their number is determined by the value of online sales.

The conducted research has shown that the e-commerce industry has a direct impact on the development of road transport in Poland. Additionally, it drives the entire TSL sector. The area that achieves the greatest profits as a result of this evolution is the KEP industry. The transport indicator most affected by e-commerce is the volume of shipments handled by couriers. The current state of the transport market is just the beginning of changes conditioned by the development of e-commerce. This means that in the coming years, transport services will have to become even more flexible to the growing requirements of the e-commerce sector.

Abstract

Machines and software represent technology in the production processes of exporting companies. The competition in the food products market is for technological development and the quality of its products to satisfy the need of consumers for increasingly demanding products. Automation is essential to streamline general product controls and minimum quality requirements in tuber classification. This research proposes as its main objective to put into operation a computer vision system for the classification of the black potato Solanun chaucha. The system is developed with the potato classification tests starting with the digital imaging technique process, followed by the image processing stages; capture, pre-processing, segmentation, description and recognition of images. Obtaining as a result 78.2% of true positives TP, 14.6% of true negatives TN, 0% of false positives FP and 7.2% of false negatives FN. According to the results, the classification time of 0.44 seconds demonstrates the effectiveness of the system. From the data. We can conclude that it is feasible and viable to carry out the classification of black potatoes through the computer vision system.

Introduction

The American market opens up an infinity of opportunities for companies in the agro-export sector, especially those dedicated to trade in products of native biodiversity, which have to meet certain requirements in order to export food products to the North American market (Bio Trade, 2010). Exporting companies must pay particular attention to food safety by complying with health certificates, in this way the US authorities prevent the entry of diseases and protect the consumer. Companies that use technologies in their activities have greater possibilities of increasing the productivity of their processes, generating greater benefits to comply with the regulations of the American market (Lall, 2000). This technological capacity plays a very important role in the trade and growth of agro-export companies because they generate greater competitiveness in export companies. Acquiring these new technologies is key to improving production processes, indirectly measuring process innovation (Valderrama and Neme, 2011). It generates lower costs, process times are greatly reduced, and it provides more information about the process, improving its planning and flexibility. Machine vision is intended to improve the productivity of production systems. It is used for the inspection or review of quality and control of products and of the processes themselves (Nunsys, 2019). It allows establishing procedures to process and understand images of reality through a camera. Image analysis can be performed very precisely and very quickly. This depends on the quality and processing of the camera. Computer vision or machine vision systems consist of the use of images that are captured by the camera and then processed by the software to measure, quantify and identify defective products (Infaimon, 2019). The vision system can make intelligent and automated decisions to reverse errors and discard products, following the parameters that have been programmed. Gro-export companies require industrial automation to improve and streamline quality controls at each

stage of the potato tuber classification process in the black variety whose scientific name is Solanun Chaucha. These companies need to improve compliance with the minimum quality requirements and general control of the product during the export classification process. For these reasons, the research aims to put into operation an artificial vision system for the classification of black potatoes Solanun chaucha. At first, the traditional classification of potatoes began with the application of scales from 0 to 4 for its evaluation. The images are then captured by applying contrast enhancement and noise reduction. Followed by threshold selection and description of the region. Where finally the objects that are not recognized by the artificial vision system are discarded by the conveyor belt, which allows increasing productivity and reducing costs

Theoretical Bases

The vision

Light is considered a wave. According to the wave model, light returns two characteristics: as wavelength and intensity (Moeslund et al, 2006). The organ that captures light is the eye, the light passes through a lens called the lens that affects the retina. The retina in the presence of light generates neural impulses that are sent to the brain through the optic nerve. The brain processes these impulses generating sensations, this is known as visual perception. Visual perception is divided into achromatic perception and chromatic perception.

Acromatic Vision

Achromatic vision is oriented to the brightness and contrast of images, the feeling of brightness is related to two phenomena (Adams et al, 2013). First, a) Sensitivity to intensity: the visual system is able to perceive and distinguish a wide range of brightness levels, but is sensitive when there are many brightness levels involved at the same time, generating a loss of precision in differentiating brightness, needing adaptation periods for each situation. Second, b) Lateral inhibition: This phenomenon is related to disturbances at the borders of intensity change, which is generated when the cells of the retina, when detecting a level of intensity, inhibit neighboring cells, causing the perceived brightness not to be in proportion to physical brightness.

Chromatic Vision

The energy produced by each wavelength is related to the sensation we perceive (Garcia-Sanchez, 2019), this relationship is defined by the nuance; which depends on the dominant wavelength, that is, the one with the most energy in the spectral diagram. While the Saturation; measures the ratio of the dominant wavelength to the rest of the wavelengths. Color is determined when a combination of hue, saturation and brightness is perceived. The theory that three elements are needed to perceive colors is the basis of the tristimulus theory.

Artificial Vision

Artificial vision is the process by which information is extracted from the physical world, to recognize and locate objects from a representation of reality, which provides information on brightness, colors, shapes, and so on (Kurtulmus et al, 2016). These representations are usually in the form of static or moving images, or in some cases with three-dimensional scenes.

Stages of an Artificial Vision System

The first stage consists of capturing or digital images by means of a sensor. The second stage; It consists of the digital treatment of the images (Torregrosa et al, 2014). At this stage using filters and geometric transformations, desired parts of the image are removed or enhanced. The third stage; it is the segmentation, and it consists of isolating the desired elements of a scene to understand it. The fourth stage; This process is where objects with common characteristics within the space are classified. Finally: the stage of recognition or classification is reached, in which the segmented objects are distinguished, through the analysis of certain characteristics that are previously established to differentiate them.

Figure 1: Stages of the process of an artificial vision system.

Confusion Matrix

The confusion matrix is a fundamental tool when evaluating the performance of a classification algorithm, since it will give a better idea of how the algorithm is being classified, based on a count of the successes and errors of each of the classes in the classification (Escobar, 2016). This way you can check if the algorithm is misclassifying the classes and to what extent.

The following table shows the confusion matrix for a classifier into two classes:

TABLE 1: Representative table of Confusion matrix.

		Classificatory	
		+	-
Real value	+	TP	FN
	-	FP	TN

Each column in the matrix will represent the number of predictions for each class made by the model, and each row the actual values for each class. With which the counts are divided into 4 classes, True Positive TP, False Negative FN, False Positive FP and True Negative TN, which mean the following:

True Positives-TP: They are the number of true positives, that is, of correct predictions for class +. False Negatives-FN: They are the number of false negatives, that is, the prediction is negative when the value should really be positive. These cases are also called type II errors. False Positives-FP: They are the number of false positives, that is, the prediction is positive when the value should actually be negative. These cases are also called type I errors. True Negatives-TN: They are the number of true negatives, that is, of correct predictions for the class. Also, with these four categories we can calculate more elaborate metrics such as sensitivity; also called recall or true positive rate. It gives us the probability that, given a really positive observation, the model classifies it and the specificity; also called true negative ratio. It gives us the probability that, given a really negative observation, the model classifies it.

Methodology

For the potato classification tests, each process of the digital imaging technique was taken into account.

Table 2: Traditional potato classification in general.

Classification	Caliber (cm)
Extra	>6.5
Select	5.6 – 6.5
Commercial	4.5 – 5.5
Domestic	3.4 –4.4
Baby	2.6 – 3.3
Chipped, damaged, misshapen	< 2.5 cm

The scale for evaluating processes from 0 to 4.

Table 3: Rating measure.

0	1	2	3	4
None	Bad	Regular	Normal	Good

Stages of Image Processing

It consists on the following Stages (Ma et al, 2017), (Dale et al, 2013).

A. **Acquisition of images.** A smart phone is suitable for our project in image capture.

Table 4. Comparison chart of smart phones.

		Dispositive	
Criterions	**Smart phone Blu C52019**	**Smart phone Y6 Huawei**	**Galaxy S20 ultra**
Resolution	3	4	5
Memorial	4	4	4
Transfer system	4	4	4
Capture speed	3	3	4
Total	14	15	17

B. Preprocessing.

- **Contrast enhancement**. To have a better image in contrast and brightness, the histogram transformation is suitable for this type of process.

Table 5: Contrast chart between contrast enhancement techniques in the preprocessing stage.

Criterions	**Histogram transformation**	**Edge accent**	**Contour detection**
Computational complexity	5	2	2
Uniform distribution of gray levels in the image	5	3	4
Highlight pixels of interest	2	3	5
Total	12	8	11

- **Noise reduction**. To minimize noise in the image and segment the Gaussian filter appropriately, it is the most suitable.

Table 6: Contrast chart between noise reduction techniques in the pre-processing phase.

Criterions	Aperture	Median filter	Gaussian filter
Preserves edges	4	4	3
Reduces impulsive noise	3	3	5
Smooth smoothing	4	3	5
Total	11	10	13

C. **Segmentation.** To analyze the object per image with a minimum cost, the threshold has been selected.

Table 7: Contrast chart of the techniques of the segmentation phase

Criterions	by threshold	Region Characteristics
Threshold selection	5	4
Analytical equations	5	3
Total	10	7

D. **Description.** We have chosen the region description since the figure of the black potato in its composition is many purple and black pixels.

Table 8: Table of contrast between techniques of the description phase.

Criterions	Outline descriptors	Region descriptors
Pixel quantity dependency on the target	4	5
Using clustering	4	4
Object homogeneity	2	3
Total	10	12

E. **Recognition and interpretation.** The theoretical decision technique was chosen for recognition since the adaptation by correlation varies greatly and you must have a database to be able to use it.

Table 9: Contrast table between techniques of the recognition and interpretation phase.

Criterions	Theoretical decision for recognition	Correlation adaptation
Descriptor comparison	4	4
Search by proximity	5	1
Total	9	5

Results

The results obtained when using the vision system based on the algorithms indicated in the methodology. To check the activity of the software, experiments were performed each with 315 images of the black potato, these images were captured in different scenarios, resulting in the following:

True positive (TP): When the image of the potato is identified by the artificial vision system (with the dimensions that meet the standard) it is classified correctly. TP = 78.2%, equivalent to 246 black potatoes.

True negative (TN): When the image of the black potato is identified by the artificial vision system (with dimensions that do not meet the standard). TN = 7.2%, equivalent to 23 black potatoes, is not correctly classified.

False positive (FP): When the image of the black potato is identified by the artificial vision system (with dimensions that do not meet the standard) it is classified correctly. FP = 0%, equivalent to 0 black potatoes.

False negative (FN): When the image of the black potato is recognized by the artificial vision system (with dimensions that meet the standard) it is not classified correctly. FN = 14.6%, equivalent to 46 black potatoes.

Table 10: Results in quantities of sensitivity analysis.

Amounts	Trues	Falses
Positives	246	0
Negatives	23	46

Table 11: Results in percentages of sensitivity analysis.

Percentages	Trues	Falses
Positives	78.2%	0%
Negatives	14.6%	7.2%

Discussion

The research is based on artificial vision to determine the classification of black potatoes, processing the images and analyzing the results, the following was obtained:

The classification of lemons that were correctly detected through artificial vision is sensitivity, showing 84%, which represents 264 images of the black potato of the total of 315. After comparing the results of the software with a manual measurement, we can affirm that the difference in sizes varies between ± 2 millimeters, which can cause a potato to classify another size, which automatically turns a true positive into a false negative. Which is 11.40% lower than artificial vision system for quality control of quinoa (Chenopodium quinoa willd) for export (Pacheco et al, 2020).

When the image of the black potato does not meet the stipulated standards, it should not be assigned a caliber. In this work, the specificity is a true negative whose value is 100%, while in the research (Arias and Sierra, 2016) a specificity of 91.91% was obtained, finding a difference of 9.09% in image processing.

The artificial vision system is viable to perform the classification of black potatoes because the classification time is 0.44 seconds per potato and the effectiveness of a number of hits (true positives and true negatives) that the artificial vision system has, applying the software results in 85.4% of a total of 315 black potatoes.

Conclusions

The result has been favorable due to the influence of the computer vision system for the classification of the Black potato, with the intervention of technology and algorithms.

The expected result in the sensitivity of the artificial vision system was obtained, the element annotated in the 84% image was located and correctly classified.

The expected result was obtained in terms of specificity, the true negative rate is 100%. In this way, it was possible to confirm in a supervised environment, only black potatoes will be analyzed and computer vision will not classify what is not found in the calibers allowed for a black potato.

The result of the time it takes for computational vision to detect and classify a potato of 0.44 seconds and the number of correct answers (true positives and true negatives) as a result of 85.4% was obtained.

A Dichotomy of Processes of Structural Change in The Economic System

Piotr WALĄG

University of Agriculture in Krakow, Mickiewicza Av. 21, 31-120 Krakow, Poland,
e-mail: piotr.walag@urk.edu.pl

Abstract

The occurrence of premature deindustrialisation processes in the employment category would point to a large part of the surplus agricultural labour force that will either remain trapped in this sector or be shifted to low-productivity industries in the informal sector and informal services.
The aim of this work is to show whether the stylized facts of the Polish economy (as an example of a catching up economy) in the years 1995-2018 allow us to state that in the structural changes to the economic system in that period we were dealing with a dual course of deindustrialisation processes.
There is also a hypothesis that the Polish economy is experiencing a dual course of deindustrialisation processes, which may be the main reason for the persistence of over-employment in agriculture (hidden unemployment) and high employment in low-productivity processing industries in the informal sector and in informal services.
The dual course of the processes of structural changes is the main reason for the persistence of a very high unemployment rate in the Polish economy between 1995 and 2015, at an average of 15.5%, and for the emergence and persistence of hidden unemployment in agriculture between 11% and 13% in the whole of the period 1995-2018.

Keywords: Deindustrialisation, Production Structure, Employment Structure, Sustainable Economic Growth, Full Employment.

Introduction

In the literature we can find many definitions of sustainable economic growth depending on the criterion and context in which the problem is being considered. One of the approaches to sustainable economic growth is the approach within the social market economy, promoted by its fathers - W. Eucken [Eucken W. 2003] and, above all, the creator of the German economic miracle L. Erhard [Mączyńska E., Pysz P. 2010]. According to them, sustainable economic growth is understood as economic growth with full employment, from which the economic crises have been permanently eliminated.

The issue of structural changes from the point of view of shaping and at the same time achieving sustainable economic growth through the efficiency of labour resources management (effective allocation) is a key area of research on changes in the structure of the economy as such [Zalewska A., Mickiewicz T. 2006].

At least three important phenomena have been recorded over at least the last decade in the context of structural changes in emerging economies. The first is premature deindustrialisation, followed by jobless industrial development in the formal sector and faster growth in services than industry. [Dasgupta S., Singh A. 2006].

Current literature indicates that the turning point for the share of industrial production and employment in total production and employment is at a much lower *per capita* income level in developing economies than was previously the case in the economies of today's highly developed countries. [Rowthorn R., Coutts K. 2004, p. 767-790; Ocampo J. 2005; Pieper U. 2003, s. 831-850]. The historical turning point took place at a level of about 10,000 US dollars in current prices, currently estimated to occur in countries already catching up at 3,000 US dollars, which is also confirmed by OECD studies on economic structures of economically advanced countries for 1950-1995 [Lipowski A. 1998; Lipowski A. 2000].

It is not clear whether this type of premature deindustrialisation, when the economy has not yet reached an appropriate level of industrial development and therefore a sufficiently high GDP *per capita*, is detrimental or beneficial to long-term sustainable economic growth.

Cite this Article as: Piotr WALĄG " A Dichotomy of Processes of Structural Change in The Economic System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

It should be stressed that it is possible, in view of the stylized facts of today's catching-up economies, for the economy to be deindustrialised in terms of employment and not yet deindustrialised in terms of demand. This dualism of the deindustrialisation process is usually found very often in countries that are catching up with the phenomenon of jobless economic growth. Deindustrialisation in terms of employment should be a cause for concern if its symptoms appear in many developing countries with low *per capita* income levels. The occurrence of premature deindustrialisation in terms of employment would point to a large part of the excess agricultural labour force that will either remain trapped in this sector or be shifted to low-productivity industries in the informal sector and informal services. [Dasgupta S., Singh A., 2006].

The aim of this work is to show whether the stylized facts of the Polish economy (as an example of a catching up economy), in the years 1995-2018, allow us to state that in the structural changes to the economic system in that period we were dealing with a dual course of deindustrialisation processes.

There is also a hypothesis that the Polish economy is experiencing a dual course of deindustrialisation processes, which may be the main reason for the persistence of over-employment in agriculture (hidden unemployment) and high employment in low-productivity processing industries in the informal sector and in informal services.

The presentation of the stylized facts occurring in Poland begins with an analysis of changes in the structure of employment and the factors that are the two main driving forces behind the changes in that structure, i.e.: differences in the rate of growth of labour productivity between sectors of the economy and changes in the structure of demand (for the production of particular sectors and sections of the economy). This will allow to check how these changes (occurring in the Polish economy) differ from the stylized facts that took place in the already highly developed Western economies. Because according to a simple model of deindustrialisation [Rowthorn R., Ramaswamy 1997] of Rowthorn and Wells, based on extensive research and empirical tests [Rowthorn R., Ramaswamy 1997], deindustrialisation in the employment category is the result / consequence of deindustrialisation in the production category. The two driving forces driving structural change are the foundation of the already classic theory of three C-sectors. Clark [Clark C. 1957, p. 492], A. Fischer [Fisher A. G. B., 1945, p. 56; Fisher A. G. B., 1933] and J. Fourastie [Fourastie J. 1972, p. 192], and at the same time constitute the basic criterion for dividing the economy into sectors and sections (its constituent elements).

At the turn of the 1980s and 1990s, new methods of production and delivery of services (information and communication technologies, ICT) emerged as a result of technological and technical developments, which resulted in large differences in labour productivity growth rates in the service sector. These changes, according to W. theory. J. Baumol, S. Blackman and E. N. Wolff have distinguished the sector from progressive, stagnant and asymptotically stagnant activities. In some of the changes in labour productivity rates have remained unchanged, in others they have increased very strongly [Baumol W. J., Blackman E. N., Wolff E. N. 1989]. It should also be noted what has been omitted in W theory. J. Baumol, S. Blackman and E. N. Wolff, that the emergence of new technologies in services and, above all, their wide application has not only changed the structure of demand within the service sector itself, but also in other sectors and in the economy at large.

Technological and technological developments have also caused large differences in the rate of growth of labour productivity in industry, distinguishing between declining industries belonging to traditional industry, such as mining, and new technology industries, such as the computer industry, belonging to the processing industry.

As a result, the classic division of the economy into three sectors (agriculture, industry, services) no longer fully explores the benefits of the criterion for dividing the economy, namely, differences in labour productivity growth rates and changes in demand patterns. Therefore, based on the classification of the CCIs, which currently serves as the basic classification for structural studies carried out by the OECD, the division of the economy into sectors has been made more appropriate for the criterion it adopts. The use of the criterion of this breakdown of changes in the structure of demand and differences in productivity growth rates between sections and divisions (according to the classification of the CCIs) will allow the resulting research benefits to be better explored.

Materials, methods, results and discussion

Based on the classification of PKD - 2007, the analysis of changes in the employment structure and its determinant was separated (after the unification, the ranking for the years 1995 - 2018 comparable data) for the following system of sectors and sections of the economy.

Adopted division of the economy into sectors and sections based on the PKD 2007 classification code:

A - Agriculture, forestry, hunting and fishing.

B - Mining and quarrying.
C - Industrial processing.
D - Electricity, gas, steam, hot water and air conditioning supply. - Water supply; sewerage, waste management and remediation activities.
E - Construction.
F - Wholesale and retail trade; repair of motor vehicles, including motorbikes.
G - Transport and storage. - Information and communication.
H - Accommodation and food service activities.
I - Financial and insurance activities.
J - Real estate activities. - Professional, scientific and technical activities. - Administrative and support service activities.
K - Public administration and national defence ; compulsory social security. - Education. - Human health and social work activities - Recreational, entertainment and cultural activities. - Other service activities.

The analysis of the impact of the prevailing factors[1] on changes in the structure of the economy begins with a study of demand volume indices in the Polish economy in the years 1995-2018, and a GDP per capita index.

Table 1: 1995 constant price demand volume indices and GDP per capita.

Years	Total	A	B	C	D	E	F	G	H	I	J	K	GDPpc
1995	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00	100,00

The analysis of demand volume indices in sectors and sections of the Polish economy in the years 1995-2018 presented in Table 1 shows that the real demand for agricultural production (A), taking into account the whole analysed period, is income-inelastic, although in the first years of the analysed period (1996-1999) it increased with the real income per capita. In addition, the focus on the production of extractive industries (B) was more or less constant over the period considered and did not increase with GDP per capita. However, the lack of relevance of

income growth to the real demand of this sector (B) observed in the table should not be equated as in the case of agriculture with lucrative demand inflexibility, but rather with increasing energy efficiency and decreasing material intensity[2]. In contrast, demand for the production and supply of energy, gas and water (D) increased with GDP per capita, but at a much lower rate (about 40% slower). Demand for the production of process industry (C) grew fastest in all sectors, slower only in the transport and storage section, and information and communication [G] as well as the financial and insurance activities section [I]). As GDP per capita grew, its rate was increasing. Throughout the period considered, this has resulted in demand for processing products growing faster than income per capita. It should be concluded that the real level of development expressed in GDP per capita in the Polish economy is still very far from saturating the demand for real production volumes of the processing industry. Demand for other market services (E, F, H, J) increased with income per capita, except that its growth rate was higher than GDP per capita, but lower than the growth rate of demand for the production of manufacturing, which is rather related to the need for the presence of these services for efficient market development and functioning. Therefore, as can be seen in the table, the demand for market services was much more correlated with the increase in demand for the production of processing industry than with GDP per capita, because on the one hand, the increase in demand for the production of processing industry results in an increase in demand for its services (within the demand side of the market), while the increase in market services enables a greater increase in demand and production of processing industry (within the functioning of the market), on the other hand. Demand for non-market services (K) (other) has grown in line with GDP *per capita* growth, and although its growth has been somewhat smaller (than GDP per capita growth), it is the most correlated with per capita income growth of all sectors and sections.

Assuming that changes in the volume of output are directly shaped/determined by changes in the volume of demand[3], it is legitimate to assume that the increase in total output during the period considered was mainly due to the increase in output of the manufacturing industry, which correlated positively with the increase in market services [4]. The increase in output of non-market services was much smaller than the increase in total output. On the other hand, the real volume of agricultural production and the mining industry remained almost unchanged throughout the entire period considered. This ultimately confirms that in the Polish economy in the period under study, in the category of changes in demand, we were dealing with the process of industrialisation.

The second driving force behind changes in the structure of employment in the economy (the prevailing factor[5]) is the different rates of change in labour productivity in individual sectors and sections of the economy.

Table 2: Productivity volume index at 1995 prices

Source: Own calculations.

The results of the analysis of the productivity volume index contained in Table 2 showed that incomparably the highest increase in the labour productivity rate occurred in the manufacturing industry (C = 455,30 %) and the financial and insurance activities section (I = 461,48 %). Such high growth rates of the productivity volume index in these two sections have driven the growth rate of the productivity volume index for the whole economy. Of the other sectors of the economy, the labour productivity growth rate for market services has been the fastest, with the highest growth rate of the productivity volume index being found in section (J = 348.36%), (G = 289.27%) and section (E = 227.83%), while lower rates of productivity growth have already been found in sections (F = 179.19%) and (H = 149.48%). A positive productivity growth rate, but already lower than the productivity growth rate for the economy as a whole (total = 199.24%), was found for the non-market services sector (K = 111.19%), the extractive industries section (B = 121.02%) and the generation and supply of energy and water sections (D = 174.36%). By contrast, the negative growth rate of the productivity volume index found in the agricultural sector (A = 69,08 %), where, as shown by previous analyses (Table 1), there was a constant level of demand volume (stabilised demand) and thus a constant volume of output throughout the period considered. This could indicate already at the research stage over-employment in agriculture (a symptom of hidden unemployment in this sector) The prevailing factors analysed so far shape / determine the employment structure presented in Table 3.

Having verified the prevailing factors representing the two main drivers of change in the structure of employment (key determinants), we come to the analysis of changes in the share of total employment of sectors and sections of the economy between 1995 and 2018.

Table 3: Employment structure (total economy = 100).

The results of the research in Table 3 showed that, over the whole period analysed, the share of employment in the economy as a whole (total = 100 %) fell in the mining sector (B between 2.67 % and 0.87 %, i.e. 1.8 %), and the manufacturing sector (C between 23.21 % and 17.63 %). The fall in the share of total employment in the manufacturing sector (C by 5.58 %) means that the economy is experiencing deindustrialisation in terms of employment. (to conclude) There has also been a small fall in the share of total employment in the manufacturing sector for the electricity, gas and water and steam supply sections (D 2,01 % to 1,78 %). The share of total employment in the non-market services sector remained stable throughout the period considered (K - around 22%), with fluctuations (19.64% to 23.18%) due to policy decisions taken by state and local authorities. While the increase in the share of total employment has been shown for the market services sector, only the following sections showed a significant increase: real estate activities, professional, scientific and technical activities, administrative and support service activities (J from 4.15% to 9.45%, or 5.3%) and transport and storage, and information and communication (G from 6.27% to 8.04%, or 1.77%). In market services, a slight steady increase in the share of total employment was shown by the accommodation and catering activities section (H between 1.39% and 1.86% or 0.47%), while in the other sections (E, F, I) the share of total employment changed by approximately 0.3%. The study results show changes in the share of total employment of sectors and sections of the economy clearly indicating deindustrialisation processes in the employment category. Moreover, it is important to note the constant share of the agricultural sector in total employment, which in the period under review oscillated at an average of 16%, which, with the declining labour productivity index shown in the analysis, means the trapping of excess labour in agriculture. It can also be noted that the market and non-market services sector was not able to absorb all the labour force pushed out of other sectors of the economy (in terms of the demand side of the labour market), this is the main reason for the persistence of a very high unemployment rate in the years 1995-2015, at 15.5% (CSO data - registered unemployment rate, state according to the last survey in the year).

Summary

The dissertation of the literature and, above all, the results of the analysis of stylized facts in the period 1995-2018 in Poland's economy make it possible to state that we are dealing with a dual course of deindustrialisation processes in structural changes to the economic system. The volume indexes of demand in constant 1995 prices grew the fastest for the manufacturing sector by 339.08% in 2018, while the volume index for the whole economy grew by 261% in 2018. Such a result of the research leads to the conclusion that in the Polish economy in the period under study we were dealing with the process of industrialisation in the category of changes in demand. The productivity volume index in constant prices from 1995 showed that the incomparably largest increase in the labour productivity rate occurred in manufacturing by 455.30% in 2018. with its growth for the whole economy at 199.24% in 2018. This result indicates that in the production processes of manufacturing industry in the analysed years there is a phase of industrialisation. However, the analysis of the structure of employment in the period 1995-2018 in the Polish economy, and in its scope, the study of changes in the share of the manufacturing industry in total employment, showed the greatest decrease of all sections by 5.58% in 2018. Therefore, it should be stated that the economy is experiencing deindustrialisation processes in the employment category.

Therefore, it is entitled to state that the results of the analyses carried out determine that the deindustrialisation process is taking place in Poland's economy on a dual basis.

The results of the analysis then showed, in the scope of the 1995 fixed-price index of productivity volumes. (1995 = 100) a negative growth rate in the agricultural sector of 69.08% in 2018, where the results of the 1995 fixed-price index of the demand volume index showed (1995 = 100), there was a constant level of demand volume over the whole period, and even a small decrease to 95.51% in 2018. (stabilised demand) and thus a constant volume of output. These findings suggest that excess labour has been trapped in agriculture. In addition, the analysis of the structure of employment in the period 1995-2018 in the Polish economy, and in its scope the study of changes in the share of total employment in the agricultural sector, showed for agriculture a constant share in total employment, which oscillated at an average level of 16%, which, with the analysis of the falling index of the volume of labour productivity, means that there was an excess of employment in agriculture. This represents hidden unemployment, which, based on the results of the study, can be estimated at between 11 and 13% for the whole of the period 1995-2018.

On the basis of the results obtained from the analysis, it can also be concluded that the dual course of structural change processes is the main reason why the market and non-market services sector was not able to absorb the entire workforce pushed out of the remaining sectors of the economy, which directly translated in the years 1995-2015 in the Polish economy into a very high unemployment rate, at an average of 15.5%.

[1] the predominant factor occurs and affects (causes real changes in employment) regardless of time and place, and its effects and results accumulate over time
[2]the phenomenon of the end of the 1960s in highly developed economies, caused by the increase in technological progress introducing savings and accompanied by the increase in raw material prices
[3] under the threat of an imbalance between supply and demand
[4] the growth of production in the processing industry entailed a faster growth of market services on the one hand and the growth of market services enabled a faster growth of industrial production on the other
[5]the predominant factor occurs and affects (causes real changes in employment) regardless of time and place, and its effects and results accumulate over time

Abstract

The issue of structural changes from the point of view of shaping and, at the same time, achieving sustainable economic growth through effective management of production factors (effective allocation) is a key area of research into changes in the structure of the economy as such. Sustainable growth is defined as sustainable economic growth at full employment, resilient to shocks and crises in the economy as well as to the shocks in demand and, for catching up countries, eliminates the risk of falling into the medium growth trap.
The aim of this work is to examine whether the dualism of the deindustrialisation process in the Polish economy between 1995 and 2018 was determined by the level of innovation in the industrial sector. How and whether the presence of this phenomenon in the economy may be an appropriate criterion for assessing the level of innovation in the industrial sector in the context of long-term sustainable economic growth.
There is also a hypothesis that in the Polish economy, the key determinant of dualism in the deindustrialisation process, and/or the main reason for the trap of average growth, was the lack of innovation in the processing industry sector. Despite the fact that the growing demand in the Polish economy, and above all GDP per capita, was the most decisive factor determining the share of manufacturing in total employment, and thus its production, causing the largest increase in its share in total production in the whole analysed period 1995-2018. It was the very low level of innovation in the manufacturing sector that caused the decrease in its share in total employment, being the main reason for the emergence of the phenomenon of dualism in the deindustrialisation process, which was a brake on sustainable economic growth and resulted in the economy being stuck in the trap of average growth.

Keywords: deindustrialisation, sustainable economic growth, dualism of the deindustrialisation process, average growth trap, criterion for assessing the level of innovation.

Introduction

The issue of structural transformations from the point of view of shaping and at the same time achieving sustainable economic growth through effective factor management (effective allocation) is a key area of research on changes in the structure of the economy as such [Zalewska A., Mickiewicz T. 2006; Dasgupta S., Singh A. 2006; Baumol W. J., Blackman E. N., Wolff E. N., 1989; Rodrik D. 2016; Giovanni Dosi, Federico Riccio, Maria Enrica Virgillito, 2020] Sustainable economic growth is defined as sustainable economic growth with full employment resilient to shocks and economic crises and demand shocks (financial, commodity, energy, covid 19 crises) and, for catching up countries, eliminates the risk of falling into the average growth trap [Eucken W. 2003; Mączyńska E., Pysz P. 2010]. In the long run, the efficiency of production factors and their allocation is achieved primarily through innovation.[Mazzucato M. 2016; Giovanni Dosi, Federico Riccio, Maria Enrica Virgillito, 2020]. Three important phenomena have been identified in the evolution of economies (structural changes in the economic system). The first is premature deindustrialisation, followed by jobless industrial development in the formal sector and faster growth in services than industry.[Dasgupta S., Singh A. 2006]. In these economies, the industrial sector, in particular, is seeing a low level of innovation, or even a complete lack of innovation. Most of them produce 'crisps' instead of 'micro chips'. [Giovanni Dosi, Federico Riccio and Maria Enrica Virgillito 2020].

Current literature indicates that the turning point for the share of industrial production and employment in total production and employment is at a much lower level of income *per capita* than was previously the case in the economies of today's highly developed countries. [Rowthorn R., Coutts K. 2004; Ocampo J. 2005; Pieper U. 2003]. As well as other deindustrialisation patterns (e.g. South Korea China) where there was no dual process of structural change in the economic system [Giovanni Dosi, Federico Riccio and Maria Enrica Virgillito 2020]. The historical

Cite this Article as: Piotr WALĄG and Maciej GLINIAK " The Dualism of Deindustrialisation and Innovation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

turning point took place at about 10,000 US dollars in current prices, nowadays it is estimated that it occurs in countries that are already catching up at 3,000 US dollars, which is also confirmed by OECD studies on economic structures of advanced countries for 1950-1995 [Lipowski A.; Lipowski A. 2000]. The reason for this phenomenon, as demonstrated by Giovanni Dosi and others, is the lack of innovation in the industrial sector [Giovanni Dosi, Federico Riccio and Maria Enrica Virgillito 2020] . In view of these facts, it is becoming problematic to assess this change. It is not clear whether this type of premature deindustrialisation, when the economy has not yet reached a sufficient level of industrial development and therefore a sufficiently high GDP *per capita*, is detrimental or beneficial to long-term sustainable economic growth.

It should be stressed that it is possible, in view of the stylized facts of today's economies, for the economy to undergo deindustrialisation in terms of employment and not yet deindustrialisation in terms of demand structure. This dualism of the deindustrialisation process is usually accompanied by the phenomenon of jobless economic growth which is very common in the economy. Deindustrialisation in terms of employment should be a cause for concern if its symptoms appear in many economies with low *per capita* income. The occurrence of premature deindustrialisation in terms of employment would point to a large proportion of hidden unemployment in agriculture, which would either remain trapped in this sector or be shifted to low-productivity industries in the informal sector and informal services. [Dasgupta S., Singh A., 2006]. This phenomenon in the economy, as shown by various deindustrialisation patterns, is primarily due to the lack of innovation in the industrial sector [Giovanni Dosi, Federico Riccio and Maria Enrica Virgillito 2020].

The aim of this work is to examine whether the dualism of the deindustrialisation process in the Polish economy between 1995 and 2018 was determined by the level of innovation in the industrial sector. How and whether the presence of this phenomenon in the economy may be an appropriate criterion for assessing the level of innovation in the industrial sector in the context of long-term sustainable economic growth.

There is also a hypothesis that in the Polish economy, the key determinant of dualism in the deindustrialisation process, which was also the main cause of the trap of average growth, was the lack of innovation in the processing industry sector. The study (presentations) of dualism in the deindustrialisation process in the Polish economy presents an analysis of changes in the structure of demand volume and employment structure. Because according to a simple model of deindustrialisation [Rowthorn R., Ramaswamy 1997] by Rowthorn and Wells, based on extensive research and empirical tests [Rowthorn R., Ramaswamy 1997], deindustrialisation in the employment category is the result / consequence of deindustrialisation in the demand structure category. The two driving forces driving structural change are the foundation of the already classic theory of three C-sectors. Clark [Clark C. 1957, p. 492], A. Fischer [Fisher A. G. B., 1945, p. 56; Fisher A. G. B., 1933] and J. Fourastie [Fourastie J. 1972, p. 192], and at the same time constitute the basic criterion for dividing the economy into sectors and sections (its constituent elements). At the turn of the 1980s and 1990s, technological and technological developments led to innovation in services: new methods of production and delivery of services (information and communication technologies, ICT), which resulted in large differences in productivity growth rates in the service sector. These changes, according to W. theory. J. Baumol, S. Blackman and E. N. Wolff have distinguished the sector from progressive, stagnant and asymptotically stagnant activities. In some of the changes in labour productivity rates have remained unchanged, in others they have increased very strongly [Baumol W. J., Blackman E. N., Wolff E. N. 1989]. It should also be noted what has been omitted in W theory. J. Baumol, S. Blackman and E. N. Wolff, that the emergence of innovation: new technologies in services and, above all, their wide application has not only changed the structure of demand within the service sector itself, but also in other sectors and in the economy at large. Innovation, driven by technological and technological progress, has also resulted in large differences in labour productivity growth rates in industry, distinguishing between declining traditional industries, such as mining, and new technology industries, such as renewable energy sources, the computer industry, biotechnologies or nanotechnologies belonging to the processing industry. The 4.0 Revolution has initiated an avalanche of innovation in both product and production sectors, with whole innovative sections and divisions of the industrial sector being separated from each other. The emergence of innovation in industry has not only caused changes within this sector, but has also forced a high level of innovation in services and other sectors and the economy at large [Ślusarczyk B. 2018]. In addition, the emergence of new production technologies and techniques in industry, as well as new technological and technical products, has resulted not only in this sector, but also in an increase in energy efficiency and a decrease in material intensity throughout the economy. This has also resulted in changes in the structure of demand within the industrial sector itself as a whole.
As a result, the classic division of the economy into three sectors (agriculture, industry, services) no longer fully explores the benefits of the criterion for dividing the economy, namely, differences in labour productivity growth rates and changes in demand patterns. Therefore, by referring to the classification of the CCIs, which currently serves as the basic classification for structural studies carried out by the OECD, the division of the economy into sectors has been made more appropriate to the criterion it adopts. The use of this criterion for the breakdown of changes in the structure of demand and differences in productivity growth rates between sections and divisions (according to the classification of the CCIs) will make it possible to better exploit the resulting research benefits.

Materials, methods, results and discussion

Based on the classification of PKD - 2007, the analysis of changes in the employment structure and its determinant was separated (after the unification, the ranking for the years 1995 - 2018 comparable data) for the following system of sectors and sections of the economy.

Adopted breakdown of the economy by sectors and sections based on the PKD 2007 classification code

A - Agriculture, forestry, hunting and fishing.
B - Mining and quarrying.
C - Industrial processing.
D - Electricity, gas, steam, hot water and air conditioning supply. - Water supply; sewerage, waste management and remediation activities.
E - Construction.
F - Wholesale and retail trade; repair of motor vehicles, including motorbikes.
G - Transport and storage. - Information and communication.
H - Accommodation and food service activities.
I - Financial and insurance activities.
J - Real estate activities. - Professional, scientific and technical activities. - Administrative and support service activities.
K - Public administration and national defence ; compulsory social security. - Education. - Human health and social work activities - Recreational, entertainment and cultural activities. - Other service activities.

The analysis of the key determinants of dualism in the deindustrialisation process and the traps of average growth in the Polish economy in the years 1995 - 2018 begins with a study of changes in the structure of the volume of demand for selected sectors and sections of the economy.

Table 1 presents the structure of demand volume for sectors and sections of the Polish economy (years 1995 - 2018)

Table 1: 1995 structure of demand volume in constant prices

Years	Total	A	B	C	D	E	F	G	H	I	J	K
1995	100,00	8,84	3,06	32,37	3,93	7,57	15,42	6,12	0,91	1,81	7,85	12,12
1996	100,00	8,32	2,91	32,88	3,65	7,56	15,78	6,07	1,02	2,42	7,44	11,96
1997	100,00	7,53	2,69	34,14	3,45	7,64	15,75	6,06	1,03	3,06	7,55	10,99
1998	100,00	7,45	2,19	33,97	3,23	8,16	15,57	6,22	1,06	3,05	7,72	10,85

Source: Own calculations.

The conclusions of the analysis of Table 1 can be reduced to the following:

- the largest increase in the share (as well as the relative share) of volume in total demand and thus in total output volume over the period considered was recorded in manufacturing (C), followed by the largest increase in the share of volume in total demand and thus in total output volume in the following sections: financial and insurance activities (I), transport and storage, and information and communication (G), accommodation and food service activities (H) , construction (E), real estate activities, professional, scientific and technical activities, administrative and support service activities (J) , while a decrease in the share of total demand and therefore of total output for market services was found only in the wholesale and retail trade, motor vehicle repair (F) section;
- In contrast, the share of non-market services (K) in the total demand volume and, at the same time, in total output decreased, which proves that their production did not constitute a fixed part of total demand and total output in the Polish economy. However, we must remember that in most cases, the volume of demand, and thus the output of non-market services, is determined by political decisions taken by state and local government units;
- The share of agriculture (A) and mining (B) and, to a lesser extent, of the energy, gas, steam and water supply sections (D) in the total volume of demand and, at the same time, in the total volume of output, with agriculture (A) seeing the biggest drop. The obtained results of the analysis (Table 1) allow us to conclude that the change in the share of particular sectors and sections of the economy in the volume of total demand and, at the same time, in the total volume of output, indicates the presence of characteristics characteristic for industrialisation processes in the Polish economy. Therefore, we can state that in the Polish economy in the analysed period we deal with the process of industrialisation in the category of demand structure (its changes).

Assuming that the structure of output volume is directly shaped/determined by the structure of demand volume[1], it is legitimate to assume that the increase in total output over the period considered was mainly due to the increase in the volume of output of manufacturing, which correlated positively with the increase in market services[2] . The increase in output of non-market services was much smaller than the increase in total output. On the other hand, the real volume of agricultural production and the mining industry remained almost unchanged over the whole period considered. The most important is that studies on the change in the share of total demand in the volume of sectors and sections of the economy additionally confirm the fact that the increase in the total volume of output depends primarily on the increase in the volume of output in manufacturing [A. Lipowski 2000], [Dani Rodrik 2015], and [Giovanni Dosi, Federico Riccio and Maria Enrica Virgillito 2020].

We will then move on to the analysis of structural changes in the economic system in terms of employment structure.

Table 2: Employment structure (total economy = 100)

The results of the research in Table 4 showed that, over the whole period analysed, the share of employment in the economy as a whole (total = 100 %) fell in the mining sector (B between 2.67 % and 0.87 %, i.e. 1.8 %), and the manufacturing sector (C between 23.21 % and 17.63 %). The fall in the share of total employment in the manufacturing sector (C by 5.58 %) means that the economy is experiencing deindustrialisation in terms of employment. There has also been a small decrease in the share of total employment in the manufacturing sector for the electricity, gas and water and steam supply sections (D between 2,01 % and 1,78 %). The share of total employment in the non-market services sector remained stable throughout the period considered (K - around 22%), with fluctuations (19.64% to 23.18%) due to policy decisions taken by state and local government. While the increase in the share of total employment has been shown for the market services sector, only the following sections showed a significant increase: real estate activities, professional, scientific and technical activities, administrative and support service activities (J from 4.15% to 9.45%, or 5.3%) and transport and storage, and information and communication (G from 6.27% to 8.04%, or 1.77%). In market services, a slight steady increase in the share of total employment was shown by the accommodation and catering activities section (H between 1.39% and 1.86% or 0.47%), while in the other sections (E, F, I) the share of total employment changed by approximately 0.3%. The study results show changes in the share of total employment of sectors and sections of the economy clearly indicating deindustrialisation processes in the employment category.

The analysis carried out to date clearly shows that in the period under consideration (1995-2018), there is a dualism of deindustrialisation processes in the Polish economy, which will then allow us to examine the key determinants of this phenomenon. For this purpose, the regression analysis of models of changes in the share of manufacturing in total employment (c) and the developed mesoeconomic and macroeconomic indicators have been used.

Parameters of the model of changes in the share of total employment in manufacturing (C).
Variable X 1 - GDP per capita (current prices)
Variable X 2 - Imports of goods and services (current prices)
Variable X 3 - Value added index (current prices)
Variable X 4 - Domestic demand index (current prices)
Variable X 5 - Exports of goods and services (current prices)
All parameters are statistically significant, which makes their interpretation valid.
Explanatory variable - Share of total employment in manufacturing (C)

The parameters (explanatory variables) in the model presented (Table 5) were selected based on the basic models of deindustrialisation and the published literature, and empirically on the basis of the presented statistical research. This model in 94% describes / explains changes in the share of employment in manufacturing (C). The determination factor R2 = 0.94. All explanatory variables are statistically significant and were generally greater than the critical value. The regression analysis of the presented model showed that an increase of 1% of GDP per capita (parameter X 1) was the most decisive for the increase in the share of manufacturing in total employment (C) causing its increase by 4.33 percentage points, which indicates that the demand for manufacturing production in this economy is still far from saturated, which clearly speaks for the phase of the industrialisation process in the demand category. However, despite the steadily growing GDP per capita, as presented in the analysis of changes in the structure of employment in the economy, there has been a decline in the share of manufacturing in total employment, which indicates that deindustrialisation processes are taking place. This confirms that we are dealing with a dichotomy of the process of structural change, the evolution of the economy, which is the dualism of deindustrialisation processes. The lack of product and industrial innovation in the processing industry has meant that domestic production in an economy undergoing trade liberalisation has lost out to foreign production. An increase in domestic demand (parameter X 4) by 1% resulted in a 2.5 percentage point decrease in the share of total employment in the manufacturing industry (C), determining it most strongly after GDP per capita. Growing domestic demand was satisfied by product and technological innovation of foreign production. Then the lack of product, technical and technological innovation in industry led to an increase in the volume of value added in current prices (the index of industrial value added in the Polish economy grew relatively faster than the index of value added prices in economies with which trade liberalisation took place), hence domestic industrial production was not price competitive. As a result, as shown by a regression analysis, a 1% increase in the index of value added prices in current prices (parameter X 3) resulted in a 2.33 percentage point decrease in the share of total employment in manufacturing (C). On the other hand, a 1% increase in imports of goods and services (parameter X 2) resulted in an increase in the share of total employment in manufacturing (C) by O.91 percentage points, because the greater part of domestic production comes from finished components manufactured abroad, which is a direct result of the lack of technological and technical innovation in domestic industrial production processes. In addition, it should be noted that in the production of the processing industry sector in general, the share of production of the machinery and equipment division is marginal, because due to the lack of product innovation, it has been superseded by competition from abroad, as has the production of motor vehicles, trailers and semi-trailers. As a result of a very low level of innovation, or even a lack of innovation in the industrial sector (C), the 1% increase in exports of goods and services at current prices has resulted in a fall of 0.70 percentage points in the sector's total employment.

Summary

Assuming that the structure of the output volume is directly shaped / determined by the structure of the demand volume, it is justified to assume, on the basis of the results of the study on the structure of the demand volume (the largest increase in the share in the total demand volume was recorded by manufacturing from 32.37% in 1995 to 42.05% in 2018, i.e., by 9.68%), that the increase in total output in the studied period 1995-2018 in the Polish economy was caused primarily by the increase in the volume of output of manufacturing, which additionally forced (necessary to service the increase in demand for manufacturing) the increase in output of market services. On the other hand, the results of the analysis of the structure of the demand volume and employment structure in the years 1995-2018 clearly indicate the phenomenon of dualism of the deindustrialisation process in the Polish economy.
Despite the fact that the growing demand in the Polish economy, and above all GDP per capita, was the most decisive factor in the share of total employment in the processing industry, and thus its production, causing the largest increase in its share of total production in the whole period 1995-2018. It is the very low level of innovation in the processing industry sector that caused: low-processed, or only assembled from finished products with low added value, domestic production of the processing industry to be additionally energetic and labour-intensive without being price competitive, thus losing out in international trade. Therefore, as the regression analysis of the model of changes in the share of total employment in the processing industry showed, an increase in domestic demand translated into a decrease in the share of total employment in this sector. In addition, the lack of innovation in the manufacturing sector resulted in an increase in total added value so low in relation to foreign production that an increase in the value of its index in current prices, as the research has shown, translated into a decrease in its share in total employment. With too low a level of GDP per capita, especially when its main driver of growth is still industry pushed out of it, they were unable to absorb services, which forced unemployment in the Polish economy in 1995-2015 at 15%. This high level of unemployment was an automatic brake on sustainable growth.

As demonstrated by the dissertation of literature and, above all, the results of the analysis presented in it in the years 1995-2018 on the example of the Polish economy, a low level of innovation or lack of innovation in the processing industry for an economy subject to trade liberalisation will lead directly as a result of the takeover of domestic demand (demand) by foreign production to the trap of average growth, as well as indirectly being an automatic brake on sustainable growth.

[1] Supply must match demand (supply equal to demand) under threat of crisis.
[2] the growth of production in the processing industry entailed a faster growth of market services on the one hand and the growth of market services enabled a faster growth of industrial production on the other

Abstract

Our article deals with the issue of financial market prediction, specifically for finding a fair price of a financial instrument on the financial market and its use in the trading process. Today we can find a lot of research focused on methods of analyzing financial instruments with a focus on their effectiveness of prediction and the effectiveness of their use in trading systems. Therefore, we would like to focus our article on pointing out the connection between the analysis tool and the structure of the functioning of the financial instrument pricing process. The aim of our article will therefore be to describe in detail the Volume Profile indicator and identify its connection to the basic microeconomic processes of interaction between supply and demand. In the first chapter, we described in detail the interaction between supply and demand. We also dealt with the theory of the auction process. In the next chapter, we described in detail the Volume Profile method and its use in the process of predicting future price movements of financial instruments in financial markets. In the last chapter, we identified and clarified the connection between the function of this method and the basic microeconomic processes of mutual interaction of supply and demand. We consider the goal of our article to be fulfilled and we believe that it will be valuable in the research process in this area.

Keywords: Fair Price, Trading Volume, Volume Profile

Introduction

If we start to take a closer look at the issue of analysis of financial assets in the financial market, we will come across a large range of various sometimes conflicting indicators and methods of analysis. One of such areas is the area of analysis of the business volume of a financial instrument. This type of analysis falls under the responsibility of technical analysis, which is based on the claim that history repeats itself and that all eventualities are included in the price of a financial instrument. Opinions on technical analysis vary across the scientific spectrum. Some consider it a full-fledged area, others as a kind of "woo-doo finance". In our article, we will therefore explain in detail the background of the Volume Profile method and its connection to the basic microeconomic processes of mutual interaction of supply and demand [10, 15].

The theoretical background

Interaction of supply and demand

For the purposes of our article, we will be based on generally accepted microeconomic theories of demand, supply and market mechanism. One may point out that demand, supply and the market mechanism, as we know it, are not identical in the financial markets as in classical goods. However, on closer inspection, we identify that it is in the conditions of financial markets that we can see the most effective functioning of the market mechanism due to the number of market participants, trading volume and global interconnection [8].

Cite this Article as: Jan CHUTKA and Ladislav VAGNER "Searching for A Fair Price of a Financial Instrument on Financial Markets" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In microeconomic theory, demand can be defined as the amount of goods (or services) that buyers are willing to buy depending on its price (price is decisive, volume is derived from it). Since we consider the price of a good as determining the subsequently demanded quantity (for a specific price) we can describe it as the maximum amount of a good that an individual, group of people or population as a whole is willing to buy, per unit of time (day, month, year, etc.) and under certain conditions (price of goods, price of other goods, size of cash pensions, tastes and preferences of consumers, accumulated wealth, etc.). Of course, demand as such is not only a function of the price of the commodity, and it is also influenced by other factors which were considered to be immutable because the assumption of ceteris paribus has been maintained [4].

If we are to work on the very interaction of demand and supply, we still have to briefly define supply. In our case, we will derive the offer of financial instruments on the financial market from the general function of the offer.
When we begin to look for a definition of an offer, we find that we can generally define it as the maximum quantity of a given good (or service) that a producer or group of producers is willing to deliver to the market per unit time (day, month, year, etc.) and under certain conditions (input prices, technological possibilities of the producer, prices of other goods, state intervention, number of producers on the market, expectations of companies, etc.). As with the demand function, we cannot claim that supply is a simple function of the price of a good. In addition to the basic factor, which is the price of the good, the supply is also affected by other factors which were considered to be immutable because the ceteris paribus assumption was maintained.

The main task of the financial market is to execute individual trading orders as efficiently as possible, in other words, the financial market exists to ensure the best possible interaction of demand and supply of specific financial instruments over time. In the market, the interests of consumers (demand) and the interests of sellers (supply) meet, buyers offer the price of demand, i. max. the price they are willing to pay for a particular good in a given quantity of quality and the sellers who represent the price of the supply, i.e. the minimum price at which they are willing to sell the same goods in a given quantity and quality [1, 4, 14].

The basic result of the interaction of supply and demand is thus the equilibrium itself, in other words the current market equilibrium. The equilibrium of the market is thus defined by the equilibrium which occurs at such a price and such quantity of goods, when supply and demand are balanced and there is no deficit or surplus on the market.

If we start to be interested in the market mechanism in the financial markets, we get the result that the financial market itself can probably be considered as the closest real market to its theoretical description from microeconomic theory. So how do we explain if a market equilibrium emerges in the market, the fact that the price of financial instruments is constantly changing? From the theory of microeconomics we know three market states that can occur, equilibrium, deficit and surplus. However, these stocks may arise from changes in price or non-price factors affecting individual supply and demand functions. It is very important to identify the market imbalance on the basis of what kind of factor [4, 11, 12].

Market imbalance due to a change in the price factor can be like:

Surplus - If the price of goods P is higher than the equilibrium price of goods, there is a surplus of goods, there are almost always buyers who are willing to pay this higher price, but the volume of demand will be much lower than equilibrium volume. Conversely, the number of sellers willing to offer goods at a given price (higher than the equilibrium price) will increase and the volume of supply will increase and will be higher than the equilibrium volume. Sellers are dissatisfied because they cannot sell as much goods as they would like and to get rid of unnecessary goods, they start to reduce the price. As the price decreases, buyers begin to become more active, proving an ever-increasing demand for goods due to the ever-increasing attractiveness of the falling price. This situation will continue until the surplus is "absorbed" and the market is restored to its original equilibrium [4].

Deficit - If the price of the commodity is lower than the equilibrium price of the commodit, there is a shortage of goods on the market. This situation is referred to as excessive demand or deficit of goods. As prices fall below the equilibrium price, buyers will be willing to buy more products than sellers offer. Focusing on active demand, sellers will start to increase the market price. On the other hand, an increase in the market price will reduce the excess demand (the rising price of the good will be less and less attractive for buyers). The result of these processes will be a return to the previous equilibrium [4].

Based on the above dependencies, we see that if only the price factor changes in the market, we can assume the restoration of market equilibrium at the original point.

Distortion of the market equilibrium due to a change in the non-price factor:

Demand change - We assume that the demand curve will shift to the right and up (demand will increase at all price levels). If the market price remains at the original equilibrium level for some time, a deficit will arise as the volume of demand will increase from Quantity of equilibrium to Quantity of demand and supply will remain at the

level of Quantity of equilibrium. Active demand in excess of supply will stimulate price growth and the expansion of production of goods, and this will continue until the price balance is restored, but at a new level. The net effect of shifting the demand curve to the right (growth of demand) will be an increase in price and at the same time an increase in the production of the goods. The opposite reaction would occur when the demand curve shifts to the left (when demand decreases) [4].

Supply change - we assume a shift of the supply curve to the left (decrease in supply). Keeping the price at the original level for at least some time will cause a deficit in the production, because supply will be reduced to Quantity of supply and demand will remain at Quantity of equilibrium. An increase in demand over reduced supply will force the consumer to agree to a higher market price. However, with a higher price, demand will immediately start to decrease, and also a higher price will be an incentive for producers to start expanding production. Eventually, market equilibrium will be restored, but to a new level. The net effect of shifting the supply curve to the left (decrease in supply) will be twofold - inflation, a decrease in production (and the associated rise in unemployment). The opposite reaction would occur when the supply curve shifts to the right (when supply increases) [4].

Auction process on the financial market

Financial markets have undergone a complex development and a number of different changes since their inception. However, when we begin to analyze the financial markets in detail, we identify one constant and unchanging thing, and that is natural competition and, to a greater or lesser extent, the operation of the market mechanism. This competition in any market, in our case specifically in the financial market, is formed by the market participants themselves. The market mechanism in financial markets can be considered extremely fair. The reason is the distribution of the price in the form of an auction process. It is a simple two-party auction process during which the price moves at a given time in order to mediate as many trades as possible, either upwards or downwards, and thus represents a highly rational and efficient process. We can define distribution as the accumulation of individual positions, their distribution or a certain number occurring in a certain space, time or price [2, 3, 13].

A fact that many investors, traders and other market participants are often unaware of is the fact that there is no certainty in the market but only probability. Financial markets react to a large amount of different information, such as companies' results for the last quarter, central bank statements but also to the moods of high-ranking officials, but also to various types of natural disasters, terrorist attacks in different parts of the world and wars that cause different changes. short-term as well as long-term moods of financial market participants. Therefore, nowadays, most modern portfolios of theories are based on risk diversification between individual financial market instruments. In his book, Dalton pointed out that diversification by instrument type is not sufficient and added time-based diversification, in other words time frame [2, 3, 13].

The goal of the financial market can be described as an effort to enable the implementation of individual trades and thus to mediate trades between buyers and sellers. The market strives to transfer these executions in the most efficient way possible and thus to implement the largest possible volume of orders in the shortest possible time. The market, as we have already mentioned, strives for the greatest possible degree of efficiency, which means that it tries to fill as many orders in the market as possible. In the process of trading, over time, accumulated buy and sell orders are matched against each other. There are a huge number of individual participants in the financial market, which means that the market also represents a certain active flow of orders, where only the largest entities participating in the financial market can move the market price with their orders. Price movements are caused by the market mechanism. The market uses a market mechanism to determine whether there is an interest in trading or fulfilling individual sales or purchase orders at higher or lower prices. It follows that the financial market consists of only two basic building blocks, namely supply and demand. We consider this to be key knowledge in trying to predict future price movements in the financial market. In simplicity, it is how much of the underlying asset is offered by one party and how much of the underlying asset the other party is willing to buy. Despite the fact that the market is efficient, this does not mean that it will be fair. The price on the financial markets is highly prone to manipulation. Various large financial institutions or private individuals with a large amount of funds can act to manipulate the price. Thanks to the large volume of capital, they are able to place an enormously large order into the market, the settlement of which will move the market price. The market will mostly move in the direction of the volume of orders waiting to be settled, because, as we have said, the market is trying to make order execution as efficient as possible [2, 3, 6, 7, 13].

The actual auction process on the financial market is very similar to the standard auction process, which is used e.g. when selling antiques. For a better understanding, we will use a simple example. If the auction house wants to sell a certain painting, it will organize an auction with precisely defined rules to which they will try to allow access to as many potential buyers who are interested in the painting, have the necessary funds and agree to participate in the auction in advance. defined rules. The next step will be to determine the starting price, which will be considered the

lowest price at which the owner of the painting is willing to sell the painting. The course of the auction itself is defined by individual events and the growth of the price from its starting level to the level when no auction participant will be willing to offer a higher financial amount for a given image. However, the auction on the financial market is different. In the case of the sale of abrasion, we saw that the price only rose, but in the case of the auction on the financial market, the auction can proceed in both directions. Also, the subject of sale on the financial market is not only one contract, but there are usually a large number of them available, and therefore we can say that whenever there is a shift in the price on the financial market, there has been order execution, ie the sale of a certain amount of financial instruments [2, 3, 9, 13].

Volume Profile

When we start to look in detail at the market mechanism in the financial markets and price prediction, we will most likely come across the Volume Profile method. This method belongs to the predictive methods of technical analysis and is based on monitoring the market structure. This method allows the investor or trader to monitor the market structure of a particular financial instrument based on the display of trading volumes. The prerequisite for the use of this method is a precise definition of its application, both in time and price. In other words, the trader must precisely define the time and price interval of the historical data on which this method is to be applied. Because traders use the method to predict future price movements, they generally use the most up-to-date historical data that they expect to have the most informative validity. Subsequently, this method identifies individual trading volumes at individual prices within a given price range at a selected time interval and at a selected price range. Subsequently, it distributes this distribution of trading volumes in the price range in such a way that it identifies the average price on the basis of the trading volume and within the price interval divides the price level into groups according to the standard deviation. By default - + 3 standard deviations from the identified average are applied. The information thus obtained by applying this method is subsequently interpreted as follows. The average price is considered to be the fairest price in the selected time and price interval, the traders then compare the current price with the fair price [5, 13].

Results

Based on the above findings, we can therefore argue. The financial market can be considered the market that is closest to the theoretical description of the functioning of the net market mechanism. The market mechanism in the financial market seeks to restore the ever-changing market balance and eliminate the surplus and deficit of financial instruments in the financial market. Furthermore, we can say that the price of a financial asset can change based on the theory of demand, supply and their mutual interaction and auction process only if the influencing factors change on the demand or supply itself. By subsequently applying the volume profile, the trader can obtain information about the very structure of the price development of a given financial instrument. Therefore, we can claim that with this method we can identify the fair price of a financial instrument in a preselected time and price interval. This identified price is the price at which the largest volume of a given financial asset was traded within the selected intervals. When we can identify the maximum volume, we can say on the basis of microeconomic theory that this volume is an equal volume and therefore the price that belongs to it is the equal price that belongs to equilibrium and thus the price equilibrium within our chosen interval. The data interpreted in this way can subsequently be very valuable in further predicting price movements. If a trader identifies a market imbalance, he may assume that the market mechanism will seek to eliminate the imbalance. The market equilibrium may then be restored to the original equilibrium point or a new market equilibrium may be established on the market. We can distinguish between these two eventualities on the basis of the identification of a changing influencing factor. We know from microeconomic theory that if the market equilibrium is disturbed due to a change in the price factor, the market equilibrium is restored to the original point, but if the market equilibrium is disturbed due to a change in the non-price factor, the market equilibrium is restored to a new point.

Conclusion

The aim of our article was to describe in detail the Volume Profile indicator and identify its connection to the basic microeconomic processes of interaction between supply and demand. In the first chapter, we described in detail the interaction between supply and demand. We also dealt with the theory of the auction process. In the next chapter, we described in detail the Volume Profile method and its use in the process of predicting future price movements of financial instruments in financial markets. In the last chapter, we identified and clarified the connection between the function of this method and the basic microeconomic processes of mutual interaction of supply and demand.

Abstract

The issue of crime is the subject matter of countless studies and research conducted across the world. Crime is a global problem plaguing mankind in every country and corner of the world. The only aspect that is different is the notoriety of crime and the characteristics of individual crimes. The aim of this paper is to compare crime rates in different EU member states. The paper offers a statistical analysis of crime that reveals the size, dynamics and structure of the most common criminal offences committed in the EU. The research is based on statistical data published by Eurostat, police and individual member states. Analysis of statistical data revealed a significant decline in the number of serious criminal offences, including homicide, assault and robbery that in the 2008-2017 period.

Keywords: Crime, Statistics, European Union.

Introduction

Due to the significant social and economic problems that crime can cause to individuals and communities, the issue of crime has long been the focus of attention of lawyers, sociologists, criminologists and psychologists. Researchers and practitioners from many walks of life are motivated to find new solutions to prevent and counteract crime, and to find effective ways to rehabilitate criminal offenders. It may be even said that crime is one of the most urgent problems of contemporary society. Each single day, in result of unlawful criminal behaviour, people's lives are taken, their health damaged and property lost. In many countries, combating crime has become a priority. Governments fund research connected to crime prevention, explore ways of reducing crime rates and implement novel, often tailor-made, crime prevention schemes (Bąk, 2015, p.44). Crime rates are affected by many factors. Secondary literature highlights that the most important factors driving crime are socioeconomic, such as: unemployment, income inequality, standards of living, family background (Hołyst, 2007; Sztaudynger, 2003, p.128). In contrast, Becker (Becker, 1974) argues that the roots of crime are rooted in economy, and can be explained by the economic theory of crime. Becker believes that the decision to commit crime is based on a national analysis of gains and losses.

Crime, similarly to other social phenomena, has to be analyzed based on statistical data that capture and reflect the problem. The knowledge about rates, structure and dynamics of crime helps in controlling it and informs crime prevention and policing strategies, and in result, helps prevent harmful social behavior. The primary aim of this paper is to provide an overview of the structure and dynamics of crime in the EU states. The secondary aim is to determine which types of crime are most common in the EU-27, and thus provide a comparative angle. The paper is chiefly based on statistical data provided by Eurostat.

It must be emphasized that comparison of cross-country statistical data is a rather difficult task. It is so since the way a country records its crime, which is reflected in official rates of specific crime types, is conditioned by many factors, i.a. legal and criminological setting, legal and customary environment, which determine the way a criminal offence is qualified. Therefore, the reservation must be made that the analysis of data presented in this article are only for reference and should be explored in further research.

Characteristics of crime in the European Union member states

Crime statistics of the EU states is mostly based on statistical data capturing the number of crimes committed most frequently. The most common EU crimes are: homicides, robberies and assaults.

Cite this Article as: Monika NIEDZWIECKA" Crime Rates in The European Union Member States: A Legal and Comparative Analysis" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Homicides

Homicide is generally considered the most serious of all crimes perpetrated against another human being. Indisputably, it also has the most serious consequences for the victim. Human life, as a subject matter of legal and criminal protection, is a value paramount to all other rights and freedoms. The right to life is treated as first-generation right since without the right to life it is impossible to enjoy any other rights and freedoms (Wiak, 2012, p. 748).

The definition of homicide is not uniform across the EU states. Analysis of national laws reveals that European countries differ in what they consider a homicide, and thus the definitions they employ, i.e. they adopt a broad or narrow scope of the basic definition of homicide provided by the European Security Strategy (ESS). According to the ESS, homicide is defined as the intentional killing of a person (Eurostat), including murder, manslaughter, euthanasia and infanticide. However, the definition excludes death by abortion, dangerous driving and by help with suicide. To illustrate the differences in how homicide is defined in various EU countries, it suffices to mention the regulations adopted in the Netherlands and Hungary. In contrast, in some states, under the said regulations, the basic definition of homicide is extended to include abortion as a criminal offence, reflected in country's crime statistics. In Scotland, to illustrate the differences further, crimes classified as homicide include death by help in suicide (Gruszczyńska, Marczewski, Ostaszewski, Więcek-Durańska, 2015, p. 7).

Despite the differences in how homicide is defined across the European Union, still the said definitions vary less between countries than for some other types of crime, therefore homicide figures provided by Eurostat for individual EU states per calendar years may be regarded as comparable and reliable. The Table below presents police-recorded homicides in the 27 EU member states in the years 208-2017. Data on homicide statistics in the Netherlands are missing (not available for the said period).

In the 2008-2017 period, the biggest decline in homicide was recorded in Italy (40%), Poland (40%), Czechia (41%), Estonia (65%), Finland (48%) and Romania (39%). However, the homicide rate in 2017 remained high in France, Germany and Great Britain. France recorded the highest number of homicide in 2008, 2015 and 2016, with over 1,000 crimes of homicide per year. On the other end of the spectrum there is Malta, with less than 10 homicides per year in the 2008-2017 period.

The total number of homicides recorded by the police in the European over the 2008-2017 period declined by 1.100. As the figures presented below imply, since 2011 a continuous decline in homicide crime can be observed. In 2017, in the EU – 27 the total of police-recorded homicides was 5,155, which means that overall homicide rate dropped by 18.3% compared to 2008 (police-recorded homicides was 6,309 in 2008).

Robberies and Assaults

According to the European Sourcebook of Crime and Criminal Justice, robbery is defined as "stealing from a person with force or threat of force". Pick-pocketing, extortion and blackmailing were excluded from this standard definition (Gruszczyńska, Marczewski, Ostaszewski, Więcek-Durańska, 2015, p.46).

In all legal systems, robbery is perceived as one of the most common precipitating crime, and also, one of the most dangerous, whether it is armed, aggravated robbery or the so-called highway robbery. The social danger is implied by the twofold nature of the crime, which is a combination of theft and assault (Wiatrowski, 210, p.62). Robbery and assault, which are serious and violent crimes, are an attack against two fundamental values protected by law: property and human life.

Analysis of statistical data reveals a 20% decline in the overall EU police-recorded robberies and assaults in 2017, compared to 2008. The biggest decline was recorded in Estonia (78%) and Hungary (73%). A significant decline in robbery rates was also observed in Lithuania (68%), Czechia (66%), Slovakia (66%), Poland (62%) and Latvia (58%). In contrast, Luxemburg, Greece and Romania recorded an increase in robbery and assault. The most dramatic increase was seen in Greece, with a 29% rise in robbery in 2017 compared to 2008.

Source: author's own compilation based on official figures published by Eurostat, Crime Statistics, 2008-2017.

Crime statistics in individual EU member states published by Eurostat cover offences by type of crime, so they also include statistics on assaults. As proven by quantitative data, the crime of assault is a common type of crime in the European Union. The highest assault rate was recorded in Great Britain. In 2008 GB recorded a dramatic figure of 373 866 offences classified as assault, and in 2018 the total skyrocketed to 517,775, thus showing an increase of 38%. In 2017, high assault rates were also recorded in France (241,687), Germany (137,058), Belgium (69,363), Italy (65,631) and Spain (18,089). In contrast, in the same year the lowest assault rate was seen in Estonia (76), Cyprus (144) and Lithuania (178). Overall, 2017 figures showed an increase of 11% in police-recorded assaults in the whole of the EU compared to 2008.

Source: author's own compilation based on official figures published by Eurostat, Crime statistics, 2008-2017.

Summary

Based on the research findings, it is safe to conclude that a significant decline in the most serious and violent crimes, such as homicide and robberies, can be observed in the EU member states. Analysis of statistical data reveals some differences between member states with regard to the said crime rates. France, Germany and Great Britain continue to be troubled by the highest rates of homicide and robbery. However, it should be borne in mind that the figures published by Eurostat are based only on police-recorded cases, which means that the real total number of crimes committed in individual EU states is unknown.

Another important point is that national legislation on the said crimes differs within the EU, as does the definition of crimes and legal concepts, a fact that directly affects official crime statistics. According to Wierzbicka, also social and cultural factors play an important role in the reporting of a given crime, i.e. when and where the crime is reported (Wierzbicka, Żółtaszek, 2015, p. 67). Crime rates are also affected by other country-specific factors, such as the freedom to relocate and corruption levels.

Crime is a very complex issue, requiring a multidimensional analysis. As crime has such enormous social and economic consequences, it should be continuously studied and explored from as many perspectives as possible in order to develop universal crime prevention standards. Crime poses a threat to the proper functioning of the state, as it hugely affects the sense of safety enjoyed by citizens. Therefore, it can be concluded that since crime is a global problem, joined national and international efforts are needed to reduce and prevent crime.

Abstract

The article is devoted to the topic of the functioning of the open data portal in the Russian Federation. On the basis of the analysis of the portal characteristics the main imbalances in its functioning are described. Based on this information, a quantitative and qualitative assessment of the effectiveness of the open data portal of the Russian Federation is being performed. Also, the main barriers that reduce the efficiency of the portal functioning have been identified and measures to overcome them have been described.

Keywords: Open data, the Russian Federation, open data portal efficiency, open data set.

Introduction

The wide use of information systems and information technologies in everyday practice and, in particular, in the public sector has led to its critical dependence on these systems and technologies. Governments and public organizations own a significant amount of data that, if being published in reusable open and machine-readable formats, can provide various benefits to individuals, organizations, governments and society at large. Open data are becoming a widespread practice of exchanging government data for reuse, and an open data portal has been created in the Russian Federation. Despite this fact, the number of truly open data sets is still low in comparison with other countries (Table 1).

Table 1: Number of hosted open data sets in different countries for 29.10. 2020

Country	Number of hosted open data sets, units
Canada	224235
the USA	215407
Germany	37841
Italy	36681
France	35538
the United Kingdom	33213
the Russian Federation	24018

GALIGUZOV "On the Issue of The Functioning of The Open Data Portal in The Russian Federation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

As can be seen from Table 1, Russia ranks last in terms of the available open data set, behind the UK by 9,195 sets of open data, while the number of open data sets in Russia is 2.2 times higher than in the UK.

Therefore, to understand how effectively open data is used in Russia, it is important, first of all, to study the functioning of the open data portal, and secondly, to study the barriers affecting the placement and reuse of open data.

The aim of this work is the evaluation of the effectiveness of the open data use in Russia through the analysis and the work of the open data portal in the Russian Federation and the identification of barriers (legal and technical) on the use of open data.

Characteristics of the open data portal of the Russian Federation

The open data portal of the Russian Federation is a state information system located in the information and telecommunication network " the Internet" at data.gov.ru, which implements the main function of centralized storage of descriptive and reference information on open data, as well as individual machine-readable data of the state authorities of the Russian Federation, local authorities and associations acting on the territory of the Russian Federation, and also the function of conducting the summary register (A.A. Golovin, S.A. Statykh, O.I. Solodukhina & Z.A. Vasileva, 2019).

There are three levels of government in the Russian Federation: federal, regional and municipal. Therefore, when examining the number of open data sets, it is necessary to conduct a research on these levels (Fig. 1).

Fig 1. The structure of the open data set by levels of government in the Russian Federation

As can be seen from Figure 1, the main share of open data sets is represented by the regional level (47%), the municipal level - 38% and the federal level 15%. It should also be noted that in terms of the number of publishers, the structure of the number of open data sets has a different composition (Fig. 2).

Fig 2. The structure of a set of open data on public administration publishers in the Russian Federation

As can be seen from Figure 2, the main share is occupied by federal publishers (49%), followed by municipal publishers (40%), in contrast to the amount of data set (15%), regional publishers make up 7%. This discrepancy can be explained by the fact that municipal publishers post open data sets regarding the region. Basically, this may be due to the fact that a certain industry is represented on the territory of one municipality. So, for example, in the Kursk region, mining of minerals (iron ore) falls on the Zheleznogorsk municipal district. In this case, the publisher will be Zheleznogorsk district, but the data set will be presented by the region.

It should be noted that the last posting of new data sets on the open data portal took place in the sections of safety, health, and transport on August 17, 2020. Table 2 shows the composition of open data hosted on the portal.

Table 2: The composition of open data on the open data portal of the Russian Federation for October 29, 2020

Section title	Number of data sets	Number of news	Number of applications	Total open data
The state	15287	433	18	15738
Economy	1566	57	6	1629
Ecology	1298	27	3	1328
Education	1276	46	7	1329
Health	678	15	4	697
Culture	635	13	8	656
Transport	635	30	23	688
Construction	448	9	0	457
Trade	329	14	0	343
Sport	247	4	3	254
Leisure and recreation	218	28	6	252
Tourism	214	12	18	244
Safety	207	16	4	227
Cartography	87	11	5	103
Electronics	29	32	2	63
Meteorological data	9	1	0	10
Total:	23163	748	107	24018

Source: Compiled by the author on the basis of the open data portal of the Russian Federation.

Thus, the bulk of open data placed on the portal up data sets (96.44%), followed for the news (3.11%) and applications are 0.45%. It should be noted that the tourism section contains more applications than news, and the electronics section contains more news than the number of data sets. Regarding the number of open data sets, it is worth noting that the state section occupies the largest share (65.53%), the rest of the sections include less than 10%

of open data sets. This phenomenon is explained by the fact that there are a number of barriers (legislative and technical) for the placement of open data. The establishment of these barriers is caused by the need to protect open data from unauthorized access and use.

Assessment of the open data work of the Russian Federation

Our research has shown that the open data portal of the Russian Federation is a complex system that includes many subsystems (data sets). In this regard, we consider it is important to assess the work of the portal using the methodology of a systematic approach, which makes it possible to give an adequate assessment of the functioning of the portal.

So, there are sixteen subsystems (data sets by category) can be described on the open data portal. As a rating criterion, it is advisable to use the following indicators: the number of data viewed, the number of data downloaded, and the number of user votes. Based on these criteria, there are two main stages in the assessment of an open data portal.

Stage 1. The analysis of reuse of open data sets.

At this stage, we conducted a research not only of the open data posted on the portal, but also of the open data used through views and downloads (Table 3).

Table 3: The research of the quantities of used open data sets on the portal of open data of the Russian Federation for October 29, 2020

Section title	Number of data sets	Number of viewed data	Amount of downloaded data
The state	15287	6114476	161809
Economy	1566	727412	21371
Ecology	1298	611500	16792
Education	1276	610300	17403
Health	678	368977	11296
Culture	635	347890	9465
Transport	635	316265	9157
Construction	448	237437	9309
Trade	329	165406	4492
Sport	247	166050	5766
Leisure and recreation	218	84140	1483
Tourism	214	115148	3877
Safety	207	130899	4562
Cartography	87	62079	4350
Electronics	29	30177	1658
Meteorological data	9	12127	1400
Total:	23163	10100283	284190

Source: Calculated by the author on the basis of the open data portal of the Russian Federation.

As can be seen from Table 3, one set of open data is viewed by users on average 436 times, and downloaded on average 12 times. It should be noted that views of open data are 35.5 times more than downloads. This trend is also observed across sections of open data sets. Regarding the shares, it can be noted that a large share of views falls on the state section - 60.54% and downloads - 56.94%. The rest of the sections include less than 10% of views and downloads by users.

The conducted research on the use of open data sets also indicates the presence of barriers (legislative and technical) to the use of open data sets. This is also evidenced by the structure of requests for open data sets (Figure 3).

Fig. 3: Composition of requests for open data sets

As can be seen from Figure 3, most requests for open data sets were sent to government agencies for processing (40%), only 14% approved by moderators, deviations in the provision of open data sets were 2%.

Stage 2. Assessment of user satisfaction with the quality of hosted open data sets.

On the open data portal of the Russian Federation there is a section on the assessment of a set of public data users through voting. It should be noted that this assessment has a purely subjective assessment. This is also confirmed by the points by which users evaluate open data sets:

1. Description of the set of open data.

2. How would you describe these problems.

3. What benefit, in your opinion, will bring the requested data.

4. Your estimate of the economic and / or financial benefits of publishing this data.

Generalized evaluation results (polling) by collection of open data submitted s in Table 4.

Table 4: Qualitative user assessment of open data sets on the open data portal of the Russian Federation for October 29, 2020.

Section name	Number of votes
The state	-101
Economy	-508
Ecology	+7
Education	+38
Health	-285
Culture	-191
Transport	+2
Construction	+24
Trade	+58
Sport	-208
Leisure and recreation	-129
Tourism	-56
Security	+16
Cartography	-99
Electronics	-30
Weather	-47
Subtotal:	-1509

Source: Calculated by the author on the basis of the open data portal of the Russian Federation.

As can be seen from Table 4, the majority of users rate the usefulness of the posted open data negatively (1509 votes against). So, users believe that the most unprofitable data are open data sets placed in the economy (-508 votes), health (-285 votes) and sports (-208 votes) sections. Users consider the most profitable sets of open data placed in such sections as trade (58 votes), education (38 votes) and construction (24 votes).

Thus, the assessment of the work of the open data portal of the Russian Federation showed its inefficiency in the field of data reuse. This is confirmed by both the lower number of downloads compared to the number of views, and the subjective assessment of users about the usefulness of hosted open data sets.

Assessment of legislative regulation of open data in the Russian Federation

Our research has shown that the main barriers to the placement of open data and reuse are legislation and the technical component. In this regard, we consider it is important to assess the legal regulation of open data in the Russian Federation (I.V. Minakova, M.A. Parkhomchuk, A.A. Golovin & T.N. Bukreeva, 2018).

In the Russian Federation, in April 2012, the process of joining the largest initiative “Open Government Partnership” has begun. Within the framework of this project, the Open Data Concept was developed, it includes the following sections:

1. Goals and prospective results of placing information about their activities on the Internet in the form of open data by state and local self-government authorities.

2. Principles of placing information about their activities on the Internet in the form of open data by state and local self-government authorities.

3. Organization of information placement activities on the Internet in the form of open data.

Further joining “The Open Government Partnership” initiative led Russia to sign “The G8 Open Data Charter” in 2013.

Therefore, the main international legal act governing the open data portal of the Russian Federation is ‘The G8 Open Data Charter” signed in June, 2013. This Charter defines the basic principles for ensuring the availability of open data:

1. Open data by default;

2. Quality and quantity;

3. Use by all;

4. Data publishing for optimizing the management;

5. Data publishing for innovation.

The main regulatory legal acts that regulate the work of the open data portal of the Russian Federation are shown in Figure 4.

Fig. 4: Regulatory legal acts regulating the activities of the open data portal of the Russian Federation.

As can be seen from Figure 4, the regulatory legal acts regulating the activities of the open data portal of the Russian Federation cover all levels of the government. It is important to note that these are not all the regulations governing open data in the Russian Federation. Based on these acts, each department develops its own internal regulations and places them in the appropriate section.

A list of reference sections and open data portals that comply with regulatory legal acts includes the following departments (A.A. Golovin, S.A. Statykh, O.I. Solodukhina & Z.A. Vasileva, 2019):

– Federal Antimonopoly Service;

– Ministry of Culture of the Russian Federation;

– Federal State Statistics Service;

– Ministry of Education and Science of the Russian Federation;

– Ministry of Finance of the Russian Federation;

– Federal Air Transport Agency;

– Federal Road Agency;

– Federal Service for Labor and Employment;

The highest executive authority of state power in the city of Moscow is the Moscow Government.

Table 5 summarizes the structure of the reference sections.

Table 5: Study of the structure of the reference sections of open data

	Order	Data set	Composition of the working group	Departmental plan for the implementation of activities	Data disclosure schedule	Poll / Feedback
Federal Antimonopoly Service	+	-	+	+	+	+
Ministry of Culture of the Russian Federation	-	+	-	-	-	+
Federal State Statistics Service	-	+	-	-	-	-
Ministry of Education and Science of the Russian Federation	+	+	-	-	-	-
Ministry of Finance of the Russian Federation	+	+	+	-	-	+
Federal Air Transport Agency	-	+	-	-	-	+
Federal Road Agency	+	+	+	+	+	+
Federal Service for Labor and Employment	+	+	-	+	-	+
The highest executive authority of state power of the city of Moscow - the Moscow Government	+	+	-	+	-	+

Source: Compiled by the author on the basis of official websites and portals of departments.

As can be seen from Table 5, the reference section of open data on the agency's website should include the following information: orders (documents), data set, composition of the working group, departmental plan for the implementation of activities; data disclosure schedule; feedback. These sections are fully reflected on the website of the Federal Antimonopoly Service. The minimum information that must be accepted according to the requirements is open data sets, which we observe on the website of the Federal State Statistics Service. Considering the sections of open data at the regional level, one can note the same shortcomings as for the departmental sections.

So, the structure of the open data section on the website of the Kursk region administration is presented in Table 6.

Table 6: Composition of the open data section on the website of the Kursk region administration

The subsection of the open data section	Hosted data sets
The state	Multifunctional centers for the provision of state and municipal services
	Civil registration authorities of the Kursk region
	Executive authorities of the Kursk region, exercising powers in the field of promoting employment of the population and the delegated authority to make social payments to citizens recognized as unemployed in the prescribed manner
Wildlife and	Executive authorities of the Kursk region, exercising powers in the field of

hunting	protection and use of objects of the animal world
	State hunting register (information on legal entities and individual entrepreneurs carrying out activities in the field of hunting)
	State hunting register (information on the number of animals and birds classified as hunting resources)
	State hunting register (information on species, location, boundaries, ownership and condition of hunting grounds)
Health care	Executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of public health protection
	Register of licenses for medical activities issued by the executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of public health protection
	Register of licenses for pharmaceutical activities issued by the executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of public health protection
	The register of licenses for activities related to the circulation of narcotic drugs, psychotropic substances and their precursors, the cultivation of narcotic plants, issued by the executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of public health protection
Forestry	Characteristics of forests according to their intended purpose: about protective forests, about their categories, about commercial forests and about reserve forests
	Distribution of forest area and timber reserves by dominant species and age groups
	Composition of forest lands and lands of other categories on which forests are located
	Information about the death of forest plantations
	Fire hazard monitoring data in forests
	Information about contracts for forest plots (lease, permanent (unlimited) use, free use)
	Results of forest pathological examinations
	“Information about the federal state forest supervision “forest protection”
	Register of forest users - debtors on payment for the use of forests to the federal budget
	Information on the amount of financial support and the achievement of the values of indicators (indicators) of the state program "Development of forestry in the Kursk region"
	Information on priority investment projects in the field of forest development
	Summary information on the use of forest plots provided for permanent (unlimited) use on the territory of the Kursk region
	Summary information on the use of forest plots provided for free use on the territory of the Kursk region
	Summary information on the use of forest plots leased in the Kursk region
	Information on the planned provision of forest plots for use
	Information on forest reproduction
	Information on growing planting material and harvesting seeds
Education	Executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of education
	Register of licenses for educational activities issued by the executive authorities of the Kursk region, exercising the delegated powers of the Russian Federation in the field of education
	Register of accredited educational institutions located in the Kursk region
Construction	Executive authorities of the Kursk region, exercising powers in the field of control over the observance of legislation on urban planning by local governments

	The executive authorities of the Kursk region, exercising powers in the field of state examination of project documentation and state examination of the results of engineering surveys
Ecology	Executive authorities of the Kursk region, exercising powers in the field of environmental impact assessment
	The plan for the state environmental impact assessment at facilities subject to state environmental control, carried out by the executive authorities of the Kursk region
	Information on the results of the state environmental impact assessment at the facilities subject to state environmental control, carried out by the executive authorities of the Kursk region

Source: Compiled by the author on the basis of the data presented on the official website of the Kursk Region Administration.

As can be seen from Table 6, on the website of the Kursk region administration in the open data section, there are open data sets for the main industries. The largest number of hosted open source data sets is forestry and the smallest one is construction. The total number of views of the data was 22,529 times, and downloads - 25,686 times.

Thus, the defective design of sections on departmental and regional sites is characterized by the following problems in legal regulation:

1. Low motivation of representatives of state authorities and local governments in publishing open data.

2. Lack of popularization of the use of open data.

3. The list of obligatory open data sets is not clear and detailed.

4. The terms of use of open data are unclear.

4. Assessment of technical regulation of open data in the Russian Federation

It should be noted that along with the legal barriers to the placement and use of open data sets, we have identified technical barriers.

Technical barriers for publishers of open data sets are mainly associated with the algorithm for working with open data on the open data portal of the Russian Federation (Fig. 5).

Fig. 5: Algorithm for working with open data on the open data portal of the Russian Federation

As shown in Figure 5, for publishers some technical difficulties may arise while making applications for extended rights for the publication of open data sets, preparation and downloading files.

The registration stage assumes two options - either authorization through social networks (Contact, Facebook, Instagram); or by indicating the e-mail address, surname, name and patronymic of the registrant.

The stage of applying for extended rights to publish open data sets presents a number of difficulties, as it involves filling in the following fields:

– information about the organization (search for an organization in the data base);

– information about the publisher (last name, first name, patronymic, position, telephone). The problem arises if the organization is not in the database, then you will have to fill in all the details manually. The organization is included in the database after the placement of the first set of open data.

The stage of publishing open data sets is the most technically difficult and involves solving three problems.

Filling out the passport of an open data set involves filling in the following fields:

– the name of the passport of the open data set (the short essence of the open data set);

– the identification number (TIN of the organization and the name of the set of open data in the Latin alphabet);

– the description of the data set (full description of the presented set of open data);

– the organization (the owner of the open data set);

– a responsible person;

– a phone number of the person in charge;

– the e-mail address of the person in charge;

– the date of the first publication of the open data set;

– date of relevance of the set of open data;

– heading;

– license.

It is important to note that the choice of the type of license implies the choice of the degree of information protection, that is, the possibility of re-use with an indication of the author, the possibility of re-use under the same license, the possibility of re-use without restrictions.

Preliminary preparation of a file for downloading with conversion assumes that the following requirements are followed from a technical point of view:

1. The file must contain data in tabular presentation (file format - xls, xlsx).

2. The table should have a flat appearance (the table lacks any hierarchy in columns and rows - there are no merged cells).

3. The table should not contain the table heading and other information (only a completed table with signed columns should be presented).

Uploading a file to the open data portal of the Russian Federation can be done in three ways:

1. The link to the file is used if this set of open data is already placed in the open data section of the departmental or regional website. The link is placed both in the data set field and in the data set structure field.

2. A reference to the API (Application Programming Interface) is used if the departmental or regional site supports the output of data on the API. In this case, two fields are filled in - this is the option for creating a set and a link.

3. Upload a file with or without conversion. It is used without conversion if the data file is prepared according to all the rules. With conversion, it is used if the existing data needs to be converted into a machine-readable format.

The edit data set passport and update public data set stage allows you to make changes if errors were detected. Updating assumes that data can be updated at a certain point in time, or that open data sets can be loaded, if it was not possible to do so at the previous stage.

The stage Re-publication of the open data set allows you to use the html-code of the passport to post it on the official departmental or regional website in the open data section.

Technical barriers for users of the open data set are presented in Table 7.

Table 7: Technical barriers for users of the open data set and ways to overcome them

Technical barrier	Characteristics of the technical barrier	Ways to overcome the technical barrier
Invalid data	Most of the data are placed in the CSV - format that causes the error, including the most popular one - the extra quotation marks and a different number of columns	1. The ability to visualize the data as the author and users want, and not as the system does. 2. The ability to set a data structure, deviation from which will generate an error and prevent data loading. 3. The complicated API and the ability to integrate with various data sources. 4. Community discussion, evaluation and review of data. 5. Data should not be located on servers in one country in order to avoid blocking them by the state.
Data fragmentation and lack of standards	Each service publishes data in any form. In addition, the data is scattered across different resources	
Lack of a single search mechanism	Due to the fragmentation of data, it is not possible to search through all government sources of open data	
Lack of the API for data access	The API that some resources have is not enough to work with data. Moreover, they are not sufficiently reliable for using in real-world projects	

Source: Compiled by the author on the basis of the data presented on the official website of research and forecasts in IT.

As you can see from Table 8, there are basically four main barriers - invalidity, fragmentation, lack of a single search and lack of the API for access. You can solve these problems by changing the visualization, standardization, the API and integration, socialization and internationality.

The possibility of using the Italian experience to improve the efficiency of the open data portal of the Russian Federation

In order to improve the efficiency of the functioning of the open data portal of the Russian Federation, we consider it is important to use foreign experience in overcoming similar problems. This is due to the fact that before the creation of “The G8 Open Data Charter” in 2013 many countries had experienced the same difficulties as Russia, despite the adoption of the Charter (Table 8).

Table 8: Structure of barriers to reuse of open government data in the EU (2012)

Generalized Barriers Category	Quantity, units
Data availability and quality	89
Protection of data and privacy at the legislative level	61
Negative and undesirable consequences	27
Relations and interactions of stakeholders when opening data	25
Coordination, organization, processes and management	24
Benefits and positive impact	24
Resources, costs and financing	22
Leadership, politics and strategy	21
Knowledge, skills and abilities	17
Technologies and tools	9
Total:	319

Source: Translated by the author from Jan Kučera (2017)

As can be seen from Table 8, 319 cases of generalized barriers were found. Issues related to data and metadata availability, accessibility and quality were the most frequently discussed barriers to the publication and reuse of open data. This category was followed by barriers related to legislation, licensing, data protection and privacy. There were also relatively few technological barriers and barriers associated with the availability of suitable tools.

The research of open data portals in most countries shows that they mostly solve the problem of data availability by increasing the number of open data sets hosted. It should be noted that the French open data portal also allows users to vote for the usefulness of hosted data sets. As for the Italian open data portal, it contains "The report on the maturity of open data in Europe" compiled on the basis of a survey in accordance with the PSI Directive.

This report was based on a questionnaire survey, which was attended by 23 state administrations. The questionnaire consisted of two parts (Italian open data portal).

The first part focuses on the reuse of open data and contains questions about information on reuse of public sector data, applications (smartphones, web-based, etc.) developed from open data, about any marginal costs applied by governments to access to information. This part was aimed at stimulating discussion of the possible economic benefits of the actual reuse of open data.

The second part of the survey focused on government-initiated open data policies and regulations for the provision and / or documents produced at the local level.

All administrations that participated in this survey organized and / or joined in communication initiatives and events dedicated to the promotion of open data in all entities operating in their territories. These initiatives have achieved the following results:

1. Developed a public roadmap for the municipality of the city of Rome. Citizens, businesses, civil society and open data experts participated in its development.

2. Promoting open data through an idea competition promoted by the Piedmont region. Within the framework of this competition, digital projects based on open data were considered, revealing the history of the development of Piedmont.

The introduction of this practice allowed Italy, by overcoming the legislative and technical barriers identified during the survey, to increase the number of posted open data sets by more than 4 times in 2013 - 2020. It also allowed to increase the quality of posted open data sets and the satisfaction of users and publishers.

In this regard, we consider that it is possible to apply the Italian experience to improve the efficiency of the open data portal in the Russian Federation.

Conclusions

"The Open Government Data Initiative" was created in many countries around the world, including the Russian Federation. Despite all efforts, many barriers to publishing and reusing open data still persist. Our research shows

that the spectrum of barriers is diverse and that both publishers and consumers of open data face these barriers. However, these barriers are not only diverse, but often interrelated. A perceived lack of clarity about the benefits of open data can weaken the willingness to share and reuse data. Therefore, overcoming barriers requires both an in-depth study of individual barriers in order to find solutions that would correspond to specific problems, and a holistic approach, covering the variety of barriers and the interconnections between them in order to be able to provide comprehensive recommendations to stakeholders. To assist organizations and individuals in solving this problem it is necessary to develop a set of advanced methods of exchanging information in the public sector. National and local governments, as well as international organizations and institutions, are developing their own guidelines for publishing and reusing open data. The future research should explore how these best practices and guidelines are being implemented and how they contribute to overcoming barriers to publishing and reusing open data. Some of the generalized barriers analyzed in this work were present throughout the entire or most of the study period. Future research on these barriers still seems relevant. Therefore, areas of future research should include:

– the quality of open data;

– the availability of open data;

– data protection, privacy restrictions or data security in connection with open data;

– open data licensing, legislation and legal framework for open data;

– stakeholder awareness of open data;

– the benefits of open data and their measurement;

– funding models to ensure sustainable provision of public data, as well as the policies and strategies of open data.

Abstract

Having in mind the significantly increasing importance of logistic processes in production companies and their indisputable impact on the profitability of production, in this article the issues of accounting for logistic costs are presented, as well as a proposal to implement solutions proposed on the basis of research carried out in a production plant. The proposed methodology is based on the Time-Driven Activity Based Costing (TDABC) and is a solution that can be used in many manufacturing companies or become an inspiration to look for solutions pertinent to a relevant enterprise.
In the article a relatively uncomplicated and effective solution is proposed for the settlement of indirect costs in a production plant. On the basis of the research conducted, steps related to the implementation of Time-Driven Activity Based Costing in the area of logistic activities are indicated. It is shown what benefits are obtained from its implementation and how to interpret the obtained results and how to use them in the search for efficiency measures. It is shown how the proposed solution allows to find the unused production capacity within each of the logistic-related activities and to calculate the losses sustained in result, which is the search for efficiency measures related to the work planning in the workstations.

Keywords: Management, Logistics Costs, Cost Accounting.

Introduction

The dynamics of the growing importance of logistic processes in production management in terms of the calculation of the cost of manufacturing a product or providing a service increase the importance of identifying and estimating logistic costs (Kanogporn Suranatthakul & Supaporn Dokmaithong & Ruankwan Intanon & Warawit Phetruen & Nuatip Sumkaew, 2020). Unfortunately, commonly used cost accounting systems do not provide all the necessary information helpful to determine logistics costs, even essential for the proper management of an enterprise, as they are not adapted to explaining the structural and dynamic aspects of the management of logistic activities (Kaplan ,Anderson, 2007). From the accounting point of view, logistic costs are very often marginalised in manufacturing enterprises, as they are not directly production costs, and on the other hand, they are difficult to recognise as fixed costs (Themido & Arantes & Fernandes & Guedes, 2000). As a result, a detailed in-depth analysis of logistic costs is usually not carried out in the company, and very often even the board and managers do not know about their proper level. Enterprises mostly focus on direct production costs, forgetting that these are mainly indirect costs related to production which may affect the profitability of sales and, consequently, the entire conducted activity. They can be a place to look for savings and optimisation as well as obtaining the desired level of profitability, especially in the era when the competitive advantage in the market is built on increasing the cost effectiveness of the organisation. Most of the activities implemented in order to increase the competitiveness require an increase in the flexibility of production, shortening the waiting time, which ultimately influences the increase in the level of customer service (Lesiak, Zarządzania, & Mrp, 2014). However, appropriate tools should be at hand to enable obtainment of the data opening the prospect of looking for changes in areas where it is possible and it will bring proper results. According

to Christhopher (Christopher, 1992), probably one of the most important reasons why the adoption of an integrated approach to logistic and distribution management has proved so difficult for many companies is the lack of appropriate cost information. (Themido, Arantes, Fernandes, & Guedes, 2000)

Cost-effectiveness in the area of logistic costs is grounded on carrying out a specific task at the lowest possible cost, so that the total cost of logistic is minimised with the implementation of many choices (Mahapatra, Panda, & Sana, 2020). Cost-effectiveness analysis can be complicated and controversial, but it is a crucial step in managing the production proces (Meijuan Kang, 2015). In the current era of economic development, manufacturing companies are looking for cost optimisation without negatively affecting the level of customer service (Witchulada Vetchagool & Marcjanna M. Augustyn & Mike Tayles, 2020). In such a context, the need to know logistic costs is also vital for the correct calculation of the cost of the product, which is indispensable in setting the selling price (Mohan & Babu, 2006). In this way, enterprises can control the level of efficiency of the organisation's functioning by establishing the appropriate relations between the volume of production and obtaining unit profit (positive financial result attributable to one unit of production). The aim of the conducted measurement of the effectiveness of the organisation's functioning is to choose and undertake such activities that will lead to the improvement of the organisation's results and an increase in the organisation's effectiveness (Czyż-Gwiazda, 2013). Focusing on the area of logistic is associated with a noticeable trend of the percentage increase in the share of logistic costs in the total costs of an enterprise. Moreover, companies should not focus on individual, isolated logistic activities, but instead they should try to reduce their total costs in this area. Cost reduction in one area may lead to an increase in other costs, e.g. related to environmental protection. Thus a question arises: *Will carrying out a logistic cost calculation improve the cost effectiveness of an organisation?*

Considering the above, it is practically useful and substantively advisable to monitor the level of logistic costs on an ongoing basis and to select an appropriate calculation method for the specific nature of an organisation. In the presented context, the authors of the study put the following research question: How to account for indirect costs, in particular logistical costs? Can the Time-Driven Activity Based Costing (TDABC) model be helpful in this respect? What steps need to be taken to account for logistical costs?

Logistic Costs

logistic costs are a specific category of costs showing in monetary form the consumption of the organisation's assets, caused by the planning, implementation and control of non-productive processes related to the transferring of various materials and products in time and space (Kufel, 1990). These are the consumption of resources, work facilities, living labour as well as external services presented in monetary form, which are related to the performance of logistic processes, as well as financial expenses, extraordinary losses and supposed foregone revenue due to irregularities in the implementation of logistic processes in the company and outside it (Skowronek & Sarjusz – Wolski, 2012). Logistic costs express the key importance of logistic for the entire economic situation of a company (Comelli, Mickael & Féniès, Pierre & Tchernev, Nikolay, 2008).

Logistic costs include a group of costs, which react the same way on any changes in values of certain affecting quantities. Logistic costs further include items, which, when calculating production costs, remain hidden, i.e. not taken into consideration. The goal of each logistic activity is to optimise logistic outputs using logistic components, logistic services and logistic costs. A substantial step in the process of logistic cost monitoring and registering is to define, which costs of corporate processes will be included in logistic costs and to specify the point of their contact with the rest of the units (procurement, production, sales etc.). Once the considered processes are specified it is necessary to select suitable parameters to express logistic outputs. (Kažimírová, Buša, & Eduard, 2015).

The share of logistic costs in the overall costs of enterprises is significant and depends on the industry or the size of an enterprise (Twaróg, 2003). Logistic costs of enterprises, as reported in the literature on the subject, may constitute from 10% to 35% of sales revenues, which makes it an area of potential and, at the same time, significant reserves for savings activities (Nowak, Piecchota, & Wierzbiński, 2004). Logistic costs are a barometer that shows how changes in the costs of individual logistic items affect the company's total costs and profit. Inadequate management when measuring and managing logistic costs leads to lost business opportunities and costly errors as well as reduced economic efficiency. The basic approaches to logistic costs and financial implications in the cost accounting of an organisation can be combined with the criteria for allocating logistic costs (Skowronek & Sarjusz – Wolski, 2012): i.e. layout of costs by type; costs by place of origin; basic phases of logistic process flow; basic components of logistic processes; commercial substance of costs. The adoption of one of these approaches determines the method of accounting records, which is the basis for their further calculation. Considering the above, the reasons for optimising logistic costs in production companies are:

- providing a reliable and credible image of all financial information carriers,

- efficiency management at various levels of its cultivation (economy, production efficiency and market effectiveness),
- learning the intensity of the impact of logistic costs on the profitability of individual products or services,
- optimal determination of the safety margin in estimating and budgeting,
- the need for constant control and monitoring of logistic efficiency,
- monitoring the efficiency level and assessment of production efficiency,
- freedom of accounting for logistic costs,
- ensuring the integration of financial information about the activities and resources of the organizsation by monitoring, measuring performance and making adjustments.

The literature on the subject defines cost accounting as the process of recognising, collecting, processing, presenting and interpreting cost data so that its recipients can evaluate costs and make related decisions (Bogdanoiu, 2009). Cost calculation should not only meet the needs for creating financial statements, but also provide the information needed to manage the organisation (Yu-Cheng Chen & Chiung-Yao Huang & Anchor Y. Lin i Stephanie Wei-Ling Huang, 2010). Cost accounting includes reporting cost accounting and management cost accounting (Świderska, 2003), which is important in efficiency measures. With regard to logistic processes, cost accounting is not widely used, which is a significant cognitive limitation, making it difficult to come to management decisions in this area.

Logistic cost accounting – barriers to recording logistic costs

Logistic cost accounting should be treated as "the process of determining the costs resulting from the implementation of logistic processes and the use of resources for the logistic service of manufactured products, provision of services and performance of various functions in economic activity." (Śliwczyńsk, 2007). When proposing and registering logistic costs and outputs it is necessary to carefully consider specific conditions of the enterprise given as the scope of included processes has a strong influence on the amount of reported logistic costs and their percentage over the total corporate costs. Within a centre, these are logistic outputs, which need to be used in order to execute logistic activities. Logistic costs interconnect corporate economy and logistic.(Kažimírová et al., 2015).

One of the most important issues in the analysis of the production process is the determination of the production cost of the product and its components, carried out within the cost calculation. However, in addition to the precise determination of the costs of products and services, the need is also visible in the field of obtaining accurate data on the course of individual phases of the product or service implementation. Traditional methods of cost calculation do not allow for precise determination of process costs, and without that it is difficult to talk about the success of the process approach, which is currently one of the main concepts in management of modern organizations (Dragomirescu & Solomon, 2011). Without accurate data on the costs of implemented processes, it is impossible to effectively and efficiently manage processes, in particular production processes, and thus their improvement (Kołosowski, 2015). If the recording is to be not only accounting, but also managerial, and at the same time reliable and providing a credible basis for the calculation of logistic costs, a number of barriers to the identification and reporting of logistic costs should be overcome, which include: (Blaik, 2010; Czyż-Gwiazda, 2013; Dianwei , 2006; Farahani, Asgari, & Davarzani, 2009; Hamrol, 2001; Lesiak et al., 2014; Straube & Pfohl, 2008) (Błaszczyk, 2015) (Hajdul, 2011) (Sinha & Anand, 2018)

- the complexity of the management of information flow, conditioning the appropriate efficiency of physical distribution processes,
- the complex nature of accounting records systems,
- difficulties in identifying logistic costs resulting from the complexity of the assortment structure and traditional accounting methods used in enterprises
- too high level of consistency of the processes carried out in the entity causing administrative and organisational difficulties in clearly identifying only the costs related to the company's logistic activity,
- trends in supply chains: in the case of frequent and small deliveries, this results in increasingly higher transport costs, increased traffic volume and consequently contributes to the extension of delivery times
- a complex structure of logistic costs and interrelations within it, which do not allow their calculation in accordance with individual divisions,
- difficulty in identifying logistic costs,
- coordination in a logistic network to ensure the on-time delivery of a product to end customers at low costs with the least environmental impacts,
- large accumulation of logistic costs in all groups of costs in the accounting system, and without their precise identification, it becomes impossible to assess the efficiency of the logistic system,

- The problem with the accuracy of determining the costs of individual processes in enterprises results from the fact that they are not recorded on separate accounts in traditional financial accounting systems of enterprises. They should be carefully selected from a layout of costs by type and from functional one.

The need to identify and calculate logistic costs is related to the determination of the intensity of logistic costs on the profitability of products. (Purdescu, Niculescu, & Purdescu, 2009)
Manufacturing companies support the entire process of accounting records with appropriate ERP systems supporting the processes of calculation and recording of financial and accounting information. Thanks to the rapid processing and data analysis, conditions are created that are propitious for making business decisions good for the enterprise. (Li & Lu, 2009) Each production company in the present times of globalisation is forced to introduce knowledge management, which, when combined with IT technology, is a key success factor for the organisation (Rakesh Narain & RC Yadav & Joseph Sarkis, 2007). As a result, the introduction of logistic cost accounting must be supported by appropriate IT systems. Information and data should be available as quickly and easily as possible (Zheng-Yun Zhuang & Shu-Chin Chang, 2017). In most cases, the biggest problem with them is that they are very extensive and scattered, so that searching for relevant information takes a lot of time (P. Everaert & W. Bruggeman & G. De Creus, 2007). Knowledge management systems are created for the purpose of searching for information so that it is efficient, reliable and trustworthy (Saveta & Anca, 2008). By investing and introducing the latest technologies, the company is able to assess and then innovate the system, which allows it to make the right business decisions. (Gunawan & Kurnia, 2018) Therefore, they can be a tool for effective recording of logistic costs.

When making decisions, you can use a decision support system. The data that is used by such a system can be located in the data warehouse. Such warehouses are used to collect and integrate databases. They focus on providing information that is designed to support decision-making in the enterprise (Sutedja, Yudha, Khotimah, & Vasthi, 2018). The quality of the received management information largely depends on the availability of data that is stored in databases supported by operating systems. (Assis & Martins, 2001)

Storing goods and all accompanying operations are a large part of the total cost that the logistic process generates, when warehouse management is optimised for cost reduction, efficiency increase, flexibility and speed of response of the supply chain (Pereira, Sousa, Ferreira, Sá, & Silva, 2019).

Case study – implementation and measurement of the effectiveness of logistic costs

The considerations, conclusions and proposals for the calculation of logistic costs presented in the further part of this study are based on research on the issues of logistic cost calculation in a railway industry manufacturing company conducted by the research team of Aleksandra Noster and Agnieszka Parkitna. In the company, it was possible to use the potential of records of the ERP program used. The surveyed company, the name of which is not important in the assessment of the collected material, and which can be classified as a medium-sized enterprise, uses a layout of costs by type, which consists of sixteen categories with additional subcategories. The costs are recorded using the SAP IT system. By using the modules of this system, the company is able to check whether the cost information is booked in the appropriate categories, and if not, it transfers them using appropriate movements in the system. The cost recording system is quite detailed, however, due to the fact that it is based only on the layout by type, the costs of individual processes cannot be determined. It is possible to quite accurately determine the direct production costs of products, however, the problem is the settlement of indirect costs, where you can look for optimisation, and thus efficiency improvement of the entire enterprise.

The company in question did not use logistic costs calculation. Therefore, using the potential of the company's IT system, improvements related to the method of calculating logistic costs were proposed as an experiment. Due to the fact that in this enterprise the production is unitary, it produces repetitive products to order, and there is rhythmic form of production organisation, as the production tasks are carried out in a continuous and progressive manner, it was decided that the basis for the calculation of logistic costs will be the Time-Driven Activity Based Costing (TDABC), the task of which is to optimise supply costs, as well as to assess the utilisation rate of resources.

The Time-Driven Activity Based Costing – TDABC is a derivative of the cost-intensive to implement Activity Based Costing (ABC) as it's more perfect development, allowing to determine the cost of the process and the utilisation rate of production capacity. The potential of the ERP system used in the enterprise is propitious for the cost records at an elementary level enabling its proper calculation adapted to the specificity of the production process.

Similarly to traditional activity costing, in the TDABC we use resources, activities and cost objects. The concept of TDABC is a simplification of standard ABC costing and is limited to one type of resource drivers, i.e. the duration driver, which is the unit necessary for the valuation and pricing of various activities. The cost calculation procedure

using TDABC starts with determining the cost of a time unit – the unit cost of production capacity (in Polish: jednostkowego kosztu zdolności produkcyjnych, JKZP),

JKZP (PLN/min) = cost of ensuring production capacity (PLN) / practical production capacity of provided resources (min)

Then, the cost of carrying out the activity should be determined, which is done by multiplying the JKZP by the time needed to perform the activity.

Cost of carrying out the activity = activity time * JKZP

The cost of carrying out an activity is often determined by determining the costs of actions that make up a given activity. Then, for each action, it is necessary to identify the cost driver, determine its floor-to-floor time (time per unit), and by multiplying by the JKZP, the rate of the given cost driver (SNK) can be calculated.

SNK = JKZP * action floor-to-floor time

By specifying the number of cost drivers for a given action, it is possible to multiply them by the floor-to-floor time to determine the total time for the action and by multiplying it by JKZP to determine the cost of a given action, which can also be determined by multiplying the rate of a given cost driver by the number of cost drivers.

Assigned action cost = SNK * number of cost drivers = number of cost drivers * action floor-to-floor time * JKZP

The sum of the assigned costs of actions allows to determine the assigned cost of the entire activity, which is the purpose of the TDABC, and which additionally allows to determine the degree of production capacity utilisation in relation to a given activity by referring to the practical production capacity of the organisation for a given action, which is determined by taking into account the number of employees involved in given activities, the percentage level of involvement in a given activity, or the number of working days in a month.

The presented concept of TDABC requires proper implementation in a specific company, which is not so easy. A solution to this problem was proposed in the further part of this study. Referring to the enterprise in question, an attempt was made to implement solutions allowing to determine logistic costs with the determination of the degree of utilisation of capacities in particular areas, which is an additional benefit from the management point of view.

For accounting purposes, the reference period of one month was adopted, and the time unit of one minute, while the adopted time and cost parameters were based on accounting data from the company and information obtained on the basis of interviews. No tools were used, such as time study, which allow for precise determination of the time of a given action or their number, neither was averaging for different variants of the course of a given action. At this stage it was considered more important to refine how to apply the accounting of logistic costs than to focus on setting individual parameters, which of course is extremely important.

Step 0 – Identification of logistic processes

In accordance with the idea of TDABC, the processes of logistic activity were identified in the first place. It was limited to the supply of materials and delivery to the customer. Then, for each of the indicated processes, its components were determined, and within each activity, the actions necessary in this regard were listed, as shown in Table 1.

Table 1: Processes, activities and actions in the area of logistic in the enterprise in question.

PROCESSES	ACTIVITIES	ACTIONS
Supply of materials	Order of materials	- Preparation of inquiries - Sending inquiries - Offers analysis - Acceptance of offers - Selecting suppliers
	Transportation of materials	- Order processing in the system - Implementation of transportation
	Acceptance of the delivery of materials	- Unloading the delivery - Acceptance of delivery to the system - Placement of materials in the warehouse

		- Invoicing - Payment for materials
	Supply quality control	- Delivering the material to the Quality Control Department - Material inspection - Transfering the material to the warehouse
	Storage	- Stock-taking of materials - Entering the stock-taking results to the system - Stock-to-stock transfers - Entering stock-to-stock transfers to the system
	Issue of material for production	- Call for material by production - Issue of material by the warehouse
	Internal transportation	- Loading the material - Implementation of transportation - Unloading the material
Delivery to the customer	Loading the final product	- Final product packaging - Loading of the final product
	Transport to the customer	- Implementation of transportation - Delivery of the final product to the customer

Identification of processes and their disaggregation to the level of actions is necessary, because the logistic cost calculation account is to allow for the determination of the cost of individual actions, and thus the activities and the entire logistic process together.

Only in the following, appropriate steps, costs will be settled for each activity and the degree of use of the production capacity of a given position responsible for a given action or activity will be determined.

The proposed method of settling costs is presented below for one of the activities, namely for the ordering of materials, which will introduce the methodology used. The procedure relating to the settlement of costs indicated from logistic activities should be repeated for other activities, which, however, would exceed the accepted scope of this paper.

Step 1 – Establishment of the practical production capacity of the activity

In the company in question, it was assumed that „ordering goods" is done by one person. It was assumed that this person is not engaged in any other activities. In accordance with the Labor Code, the average monthly working time is 168 hours, rounding the calculation down. Taking into account breaks at work, for example for breakfast, or physiological needs, an indicator of 90% of effective use of working time for performing assigned actions within a given activity was adopted.

Practical production capacity of the activity „ordering goods" = 168 h * 60 min * 1 person = 10.080 min.

Step 2 – Determinaion of the total cost of ensuring the productive capacity of the activity

In the next step, it is necessary to determine the total cost associated with the implementation of the actions of a given activity, which includes personnel costs together with mark-ups, costs of materials or services used, e.g. telecommunications or IT services. The company had extensive cost records, admittedly in a layout of costs by type, but allowing for a fairly accurate determination of this cost, which was calculated at PLN 8,000.

The cost of ensuring the production capacity of the activity „ordering goods" = PLN 8,000

Step 3 – Determination of the unit cost of a time unit for the activity

The basic measure used in the settlement of logistic costs is the unit cost for a given activity. In this case, the total cost of ensuring the production capacity relating to a given activity is calculated into practical production capacity, which was rounded up to PLN 0.79 for each minute of potential availability.

JKZP = cost of ensuring production capacity PLN 8,000 / practical production capacity 10,080 min = PLN 0.79/min

Step 4 – Establishment of actions within the activity

With regard to the factor „ordering materials", 5 basic actions are distinguished that are performed within it:

1. Preparation of inquiries
2. Sending inquiries
3. Offers analysis
4. Acceptance of offers
5. Selecting suppliers

Step 5 – Determining the time driver for each action and their parameterisation

Each action takes a certain amount of time. Time is devoured by the occurence of time drivers for each activity. For example, in the case of „preparation of inquiries", the number of items in the inquiry will be an important factor that determines the time needed to prepare a single inquiry. By parameterising the determined driver with the necessary time and determining the number of inquiries throughout the month, it will be possible to determine the time allocated to a given action and its cost. With regard to the cost driver for the task „preparation of inquiries", it was assumed that the cost driver in the form of one item in the inquiry requires a time of 25 minutes, and there's the average of 200 items per month in the inquiries. Relying on the cost driver eliminates the problem of different sizes of inquiries.
The approximate course of the procedure was carried out for each action, and the results collected in this regard are presented in the table below.

Table 2: Action and time driver.

Action	Time driver	Floor-to-floor time [min]	Number of drivers per month
- Preparation of inquiries	- item in inquiry	25	200
- Sending inquiries	- inquiry	4	100
- Offers analysis	- analysis	12	150
- Acceptance of offers	- conversation with the supplier	3	80
- Selecting suppliers	- choice	10	50

Step 6 – Determination of Total Run Time

Having collected and calculated data relating to individual actions, the total time used for a given action can be calculated and it's possible to assign it the total cost.
The total time absorbed by the activity „ordering goods" is the monthly sum of the time spent on the individual actions constituting the activity. On the other hand, the time of individual actions is determined by multiplying the determined floor-to-floor time associated with a given time driver and the number of occurrences of a given driver in a month. For the „ordering goods" activity, the total calculated and devoted time per month is 7,940 minutes.

Total time of ordering goods in a month = sum of times of individual actions = sum of product of floor-to-floor time and number of drivers in a month = 25*200+4*100+12*150+3*80+10*50 = 7,940 minutes

Step 7 – Determination of the assigned activity cost

Having the total time for a given activity and having the unit cost of production capacity calculated in the previous step, it is possible to determine the cost of the entire activity in a given month.

Assigned cost for ordering goods = total run time * JKZP =
7,940 min * PLN 0.79 PLN /min = PLN 6,272.60

The presented steps of the procedure allow to determine the cost of the selected activity, and then of the entire process, which is now indispensable when looking for efficiency measures. In management activities, when determining the cost of an activity, it is possible to indirectly determine the rate of the cost driver. For example, for a single item in the query, it will be PLN 19.75, which was calculated by converting the floor-to-floor time associated with a given cost driver (25 minutes) by the unit cost of production capacity (JKZP = PLN 0.79 / min). Determining the rate of the cost driver and comparing it with the number of occurrences of a given cost driver per month allows to quickly determine the areas within which savings should be looked for. Then it is possible to omit marginal cost drivers, the occurrences of which are few, use little time and, consequently, have a small impact on the total assigned cost for a given activity.

Step 8 – Analysis of the use of practical production capacity and determination of the cost of not using it

By comparing the established monthly practical production capacity of the activity „ordering goods" in minutes (10,080 minutes) with the indicated total time of ordering goods in a month (7,940 minutes), it is possible to determine the level of unused production capacity, which in the presented case amounted to 2,140 minutes (10,080-7940), i.e. over 21 % (2,140 / 10,080).
The unused production capacity can be directly converted into its cost, multipling by the unit cost of production capacity (PLN 0.79 / min) or by subtracting from the total cost of ensuring the productive capacity of the activity (PLN 8,000) the determined assigned cost of a given activity (PLN 6,272.60), which amounted to about PLN 1,700. Determination of the unused capacity allows to use the resources better, which lowers the cost of a given activity. For example, 20% of the working time of a person dealing with „ordering goods" may be used for handling complaints. It should be noted, however, that the search for savings should also take place at the stage of analysing the rates of the cost driver described in the previous step and their occurrences. Maybe it is worth considering whether it is possible to limit the number of occurrences of a given cost driver, or how to improve the process and procedures so that the time spent on a given cost driver is shorter.

It should be added here that the analysis carried out in the area of production capacity may show shortages that are „hidden" by employees through overtime work that is not paid, etc., and then it turns out that to improve the quality of service it is necessary to increase the cost of a given logistic activity.

Summary of the Research

The conducted research and the obtained results should be considered in several dimensions. It has been shown how relatively simple and effective settlement of indirect costs in a production plant is possible. On the basis of the conducted research, steps related to the implementation of Time-Driven Activity Based Costing in the area of logistic activities have been proposed. It has been shown what benefits are obtained from the implementation of the aforementioned cost accounting of activities and how to interpret the obtained results and how to use them in the search for efficiency measures. It has also been shown that the implementation of modern solutions in the field of indirect costs settlement can optimise the company's operation. The use of Time-Driven Activity Based Costing does not require a lot of time and is characterised by simplicity, which is extremely important when implementing this solution.

By using Time-Driven Activity Based Costing, the unused production capacities within within each of the logistic-related activities has been further explored and the unnecessary costs associated with these unused capacities have been calculated, which is extremely useful for managers when assigning tasks to workstations. The information obtained as a result of the method used makes it possible to properly develop the parameters of work inputs in each action.

Summarising the contribution of the study from both a theoretical and a practical point of view. In the theoretical as pect the work is a development of research on methods of calculation of indirect costs in the company. A proposal f or settlement of logistic costs was given, a methodology for settlement of logistic costs was proposed on a process b asis. From a practical point of view, the proposed methodology allows for its easy implementation, which has been t ested in the presented practical example. Future research should boil down to further testing of the proposed method ology and its possible improvement.

Conclusions

The introduction of logistic cost calculation in the organisation would facilitate the identification of the effectiveness of logistic processes, would enable reducing unnecessary costs and exercising greater control over logistic costs.

There is no doubt that the calculation of logistic costs in an enterprise can be carried out using the existing cost accounting, and that it can significantly improve the logistic processes in an organisation.

Due to the results of the research, it can be noticed that it is very important to constantly monitor the level of logistic costs and to select the appropriate calculation method for the specificity of the enterprise. By using logistic cost calculations, an organisation can gain a significant advantage over competitors, reduce total costs, and exercise greater control over logistic costs.

Organizational and Economic Efficiency of Microcredit Institutions in Selected European Countries

Abstract

The presence of financial institutions offering microloans has significantly improved access to external sources of financing for SMEs. Microfinance is now considered to be an innovative socio-economic tool to fill a gap in the financial market to combat social and financial exclusion. The aim of the article is to present the differences among the European countries in terms of activity in the field of microfinance. In the process of creating a synthetic measure of the assessment of the phenomenon, a synthetic variable defined in the TOPSIS method was used. The demand for microfinance services in Europe is steadily growing and there is a considerable potential for further growth in the years to come, as shown by the growth in the volume of microcredit granted. As the micro-enterprises take efforts to settle their liabilities to financial institutions on a regular basis, the percentage of non-performing loans and credit losses in most of the countries presented is relatively low. In the future, the fees and interest rates on microcredits should be modified, as in many countries they are higher for SME than for the traditional borrowers.

Keywords: financial efficiency, microcredits, European union countries

Introduction

The idea of microfinance originated in Asian countries, but it has become popular in South America and Africa, reaching also the United States and Europe. Microfinance, so far associated with the countries of a low level of socio-economic development, is now expanding also in the developed countries, although targeted at a narrower population i.e. the poorest, socially discriminated against and often without access to the financial market.

The importance of microcredit for the development of the global economy was emphasized by the United Nations that declared 2005 the International Year of Microcredit (Alińska, Czepirska 2018). Microfinance is recognised by the UN as a mechanism to advance the achievement of the Millennium Development Goals and, in particular, the eradication of extreme poverty (Kot 2008). According to the definition by the UN, "microcredit is linked to the provision of a small amount of money by banks or other institutions. They can be offered, often without additional security, in the form of individual or collective loans" (United Nations, 2004). According to the European Commission documents, microcredit is defined as a loan in the amount of no more than EUR 25 000 granted to new or existing micro-enterprises (Microcredit for European..., 2004, The regulation of Microcredit.., 2007). This consists mainly in microcredits and free financial education provided by banking and non-banking institutions and its main objective is to combat social and financial exclusion (Mikołajczyk 2009). The World Bank reports emphasise that microfinance is not a new form of banking, but an innovative tool of development, designed to achieve social and economic goals (Ledgerwood 1998).

Muhammad Yunus, the founder of the Grameen Bank, often referred to as the social bank, was the pioneer in providing microcredit (Yunus 2012). In Europe, the first microloans were granted in France, to the unemployed in order to stimulate the entrepreneurship, already in the 1980s. Nevertheless, the microfinance initiatives have been more intense in the Central and Eastern Europe than in the Western European countries, which was connected with the political and economic changes. The European Union became more seriously interested in the matter only at the beginning of the 21st century.

The aim of the article is to present the differences among the European countries in terms of activity in the field of microfinance.

Literature Overview

The establishment and development of microfinance institutions in the economy of many countries resulted from the willingness to satisfy the market needs of business entities and social groups operating in areas of a lower level of social and economic development. The microfinance offer is addressed mainly to people living in rural areas and small towns, who are not able not use the services of traditional financial institutions usually represented by commercial banks, insurance companies or investment funds. Robinson characterised microfinance as a small-scale service, including in particular loans and savings granted to persons engaged in agriculture, fisheries or livestock farming in rural and urban areas in the developing countries (Robinson, 2002, Mersland et al., 2013). Benedyk believes that the advantage of the microloan system developed by M. Yunus stems from the opportunity to actively use the social capital, which is defined as a network of neighbours and friends who jointly guarantee regular loan repayments (Benedyk 2006).

Fila emphasises that microcredit products play an important social and economic role in the European countries. On the one hand, they promote social and economic integration of people who are at risk of poverty and counteract financial exclusion, and on the other hand, they help create jobs and stimulate economic development and entrepreneurship, inter alia, by creating conditions for microenterprises to operate (Fila 2011). Fila adds that the basic objective of the operations of such entities is not to earn money or seek to maximise the profits, but to counteract poverty and social and financial exclusion.

Micu concludes that microfinance has proven to be an effective tool for poverty mitigation, helping the poor to increase income, purchase machinery, equipment or materials and reduce vulnerability in emergencies and economic crises (Micu 2010). Kabeer expresses the conviction that the concept of microcredit itself results from a psychological discomfort felt by society regarding the economic and financial conditions of life of the poorest people (Kabeer 2005). The literature also draws attention to the fact that the development of microfinance requires respect for diversity, must comply with legal principles, must provide protection and must provide opportunities for development (Gerakan Bersama Pengembangan Keuangan Mikro, 2005).

The discussion on the exclusion of the poorest from access to financial services leads to two different views, as presented by Usman emphasizing that microfinance services should be tailored to the stakeholders' needs. The first point of view is that the poorest people do not need microfinance services, but direct social assistance. The opponents of this position claim, however, that people in need should have access to microfinance (Usman et al., 2004). Nonetheless, those who advocate this idea emphasise the shift in the paradigm of microfinance from financial support for enterprises in the form of microcredit to microfinance services such as, for example, savings schemes, emergency loans or microinsurance. According to Alińska, microfinance, of which microcredit (microloan) is the most widely recognised instrument, should complement the traditional financial instruments (Alińska 2008).

As emphasised by Ledgerwood, Steven and Moris, microfinance is an important factor contributing to the strengthening and expansion of the formal financial system and complies with the concept of sustainable development (Ledgerwood 1999; Stevens, Morris, 2001). According to Feigenberg, the essence of microfinance is closely linked to the concept of management at the local level. This view is based on the assumption that there are links between community members that facilitate coordination of activities and strengthen cooperation within the group, and are based on the beliefs, norms or rules specific to the group (Feigenberg et al., 2013).

Unfortunately, in many countries the mechanism for granting microloans seems to be too centralised and formalised. As a result, the poorest do not show own initiative, but only depend on government support through social programmes. In order to overcome the weaknesses of the centrally managed policies, some countries are involving religious institutions in the allocation and distribution of funds in order to bring microfinance services closer to the communities with difficult access to formal financial institutions (Abbas, 2010).

Microloans can constitute an additional source of external financing for innovative companies (Waggoner 2014), and may be a desirable element of the innovation system for two reasons (Nugroho and Miles 2009). Firstly, by facilitating access to finance and coaching for start-ups and the smallest companies (e.g. established by young people with no credit history) often offered together with the microloans. A well-developed segment of microloans may support the emergence of "small" product and process innovations on the market. Secondly, the availability of microloans may

foster diffusion of innovation among small companies and thus increase demand for innovative products and services offered by larger entities. (Potencjał innowacyjny... 2016).

Microcredit in European countries

Microfinance appeared in Europe only in the 1980s. Initially, it developed mainly in the countries undergoing economic transformation. Among the countries of the "old" Europe, France and Great Britain were the exception, as they established the microfinance systems relatively early. The 21st century brought about institutional and instrumental advancement in this area. At present, the economic downturn and continuing negative social phenomena increase the interest in microloans.

The characteristic features of microcredits include among others:

- small amount, short term and higher frequency of instalment payments,
- simplified credit acquisition and administration procedures,
- usually no need to provide collateral,
- interest rates higher than in the case of traditional bank loans, but lower than on black market loans,
- beneficiaries are usually the poor, socially excluded, unemployed and women,
- loans are intended primarily for the purposes of establishment or development of microenterprises.
- loans are repaid on time,
- loans are granted by local institutions,
- loans are accompanied by other financial, educational and information services,
- direct relationships between the clients and the financing institution (Mikrokredyty w Europie..., p. 19).

As follows from the research conducted by the European Microfinance Network (EMN), the primary objective of microfinance in Europe is to support the development of microbusinesses by ensuring that excluded entrepreneurs have permanent access to financial services. This objective is achieved through:

- creating jobs and promoting entrepreneurship,
- promotion of small and medium-sized enterprises and development of economy,
- preventing social exclusion and combating poverty.

In the European Union, microfinance is available to two groups of entities:

- people who have lost their jobs, are at risk of losing them, have difficulty entering the labour market, are socially and financially excluded,
- entrepreneurs, mainly those operating on a micro scale, who have problems with obtaining funds to start or develop their business or who require financing in small amounts.

The main features of the microfinance market in Europe are as follows:

- a short period of operations of institutions in this sector,
- a diversity of microfinance institutions, with the dominating role of non-profit institutions,
- as far as banks are concerned, microfinance is granted mostly by private banks,
- most microfinance institutions operate on a micro-scale.

A. Leyson and N. Thrift believe that the emergence of microfinance institutions in the European countries is connected with the restrictions of access to the financial system (Leyson, Thrift 1995). Financial exclusion is also defined as the inability of individuals, households or social groups to use the necessary financial services. This may be due to a low availability of services, their price, marketing or inadequate financial education. Iwanicz-Drozdowska links the concept of financial exclusion to the inadequate or non-existing banking penetration ratio (Błędowski, Iwanicz-Drozdowska, 2010).

According to the report of the European Commission: "Microfinance can be a tool to combat social and financial exclusion and to stop and reduce all its dimensions - poverty, low income, unemployment, which are the major components of and a reason for social exclusion".

In recent years, the microfinance sector has been growing steadily. In 2017, the microfinance institutions reported nearly 1 million active borrowers and the gross value of the microloan portfolio of more than EUR 3.1 billion. This confirms that the demand for microfinance services in Europe continues to increase and there is a considerable poten-

tial for further progress in the years to come, in particular due to a relatively low economic growth and the need to economically integrate those whose are disadvantaged and impoverished (Diriker, Landoni, Benaglio 2018).

The purpose of microfinance is to become an instrument stimulating entrepreneurship, which - by limiting financial exclusion and facilitating access to financial resources for those in need - should result in an increase in the wealth of the poor leading to an increase in their consumption, and thus allowing them to get out of poverty (Adamek, 2013). Adamek puts forward many arguments against the concept of microfinance, most of which are related to the economies of countries where the rule of law is not respected. Nevertheless, it is important to search for and describe the reasons of the inappropriate functioning of the microloans in some countries (Adamek 2014).

Research Methodology

In the process of creating a synthetic measure of assessment of the phenomenon, a synthetic variable defined in the TOPSIS method was used1 (Hwang, Yoon 1981), and a three-stage algorithm was adopted.

First of all, the features describing the activity of European countries in the field of microcredit were selected and described. Then the *n* values of (X_j) features for *N* statistical units (countries) are compiled in an evaluation matrix $[x_{ij}]_{n \times N}$, where x_{ij} - denotes the value of the feature X_j for object *i.*

Next, the features were normalised using the following normalisation method:

$$z_{ij} = \begin{cases} \dfrac{x_{ij} - \bar{x}_j}{S_j}, & X_j \in S \\ \dfrac{\bar{x}_j - x_{ij}}{S_j}, & X_j \in D \end{cases}$$

where: z_{ij} - value of the normalised feature X_j for object *i*; $\bar{x}_j, S_j$ - respectively, the arithmetic mean, a standard deviation of X_j, S, D - respectively, a set of criteria having a positive impact[2] and criteria having a negative impact[3]. The data were further transformed so as to achieve comparability. This is achieved by depriving the measurement results of titres and standardising their orders of magnitude (Walesiak 2014).

In the third stage, the values of the synthetic feature Q_i were determined for each object and for each level according to the following formula:

$$Q_i = \frac{d_i^-}{d_i^- + d_i^+}$$

where:

- $d_i^+ = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_j^+)^2}$ $\qquad z_j^+ = \begin{cases} \max_i z_{ij}, & X_j \in S \\ \min_i z_{ij}, & X_j \in D \end{cases}$
- $d_i^- = \sqrt{\sum_{j=1}^{m} (z_{ij} - z_j^-)^2}$ $\qquad z_j^- = \begin{cases} \min_i z_{ij}, & X_j \in S \\ \max_i z_{ij}, & X_j \in D \end{cases}$

The highest value of Q_i indicates the best object. The values of the synthetic measure will make it possible to establish the ranking of the countries with regard to the level of microcredit development in the analysed countries.

---

[1] The Technique for Order of Preference by Similarity to Ideal Solution.

[2] A criterion having a positive impact is a variable whose high values are a desirable phenomenon from the point of view of evaluation of an object, while low values are not desirable.

[3] A criterion having a negative impact is a variable whose high values are undesirable from the point of view of evaluation of an object, while low values are desirable.

Results and Discussion

In order to examine the imbalances between the European countries in terms of the level of development of the micro-credit market, three levels represented by statistical features were first identified.

Table 1 : Level of development of the microcredit market

Microcredit activity	
	X_1 - Average Annual Percentage Rate (APR),
	X_2 - Percentage of Active Woman Borrowers (PAWB)
	X_3 - Average Value of Microloans (AV)
	X_4 - Dynamics of the value of loans granted in the years 2016 and 2017 (D)
Credit portfolio quality	
	X_5 - PAR 30 credits delayed over 30 days
	X_6 - Write-off ratio
	X_7 - Provision
Financial Efficiency	
	X_8 - Return on Equity (ROE)
	X_9 - Return on Assets (ROA)
	X_{10} - Operational Self-Sufficiency (OSS)

Source: Own calculations

The data for analysis have been gathered from the Eurostat databases and the Microfinance in Europe Report (2018).

First, the relationships between the selected variables were analysed using a matrix of correlation coefficients. In most cases, the correlation between selected variables was not statistically significant. The highest coefficient (0.6) was obtained with regard to ROE and ROA, while in other cases it did not exceed 0.43.

Figure 1: Values of features of activity in the area of microcredit

Source: Own calculations based on Microfinance in Europe Survey Report 2016-2017.

In the analysed group, in the case of four countries the value of microloans granted decreased in 2017 compared to 2016. The largest decrease, by more than 20%, was recorded in Hungary and Poland. An opposite trend can be observed in Greece where the value of microloans granted increased by 46%. A growing increase of interest in micro-credits could also be observed among the inhabitants of Kosovo (28%). The average value of the funding granted

varied between EUR 5312 in Germany and EUR 1020 in Great Britain. The average value of the funds provided in 2017 was 1479 euro, with lesser amounts disbursed only in Romania, Bosnia-Herzegovina and the United Kingdom.

Women play a special role among microfinance beneficiaries, and in many cases they are the target of the offer of institutions supporting the poorest social groups. In many cases, it is the women that become responsible for supporting their families. The women are most active in the UK, where they account for 68% of beneficiaries of the microfinance programmes. Bulgaria is next in line, with the percentage of active women exceeding 50%. Still, in most of the analysed countries the number of women applying for support is lower than the number of men. One can therefore state that the offer is not very attractive for women, or that in most families the traditional model with a working father is preserved.

A very diversified interest rate level is another feature of the microcredit system. The highest cost of microloan is observed in those European countries that have undergone political transformation. The highest interest rates on loans, above 23%, are paid by the inhabitants of Kosovo, Albania and Bosnia-Herzegovina. The most advantageous offer is addressed to the poorest clients in Poland and Hungary, where the interest rate on loans does not exceed 4.3%. In the countries with the lowest interest rates, the average amount of borrowings are the highest. On the other hand, in countries with the highest average loan amounts, the rate of growth in the volume of loans is the lowest.

Figure 2: Values of credit portfolio quality in the European countries

Source: Own study based on the Microfinance in Europe Survey Report 2016-2017.

When assessing the loan portfolio quality, one may note that the largest percentages of overdue microloans (by over 30 days) are recorded in the UK (29%), Spain (27%) and Italy (21%). In 7 countries, however, the percentage of instalments not paid off on time did not exceed 3.5%. The inhabitants of Bosnia-Herzegovina, Belgium and Montenegro were those who repaid their liabilities most on time.

Credit losses entail a much greater risk to lending institutions. The worst situation is observed in Hungary, where the credit losses reach 20%, while the average for other countries is 4%. In the EU-15 countries, the lenders compensate for the losses with high fees.

Figure 3: Values of efficiency in the European countries

Source: Own calculation

In terms of efficiency, one should pay attention to the United Kingdom and Belgium, where very high negative ROE ratios were recorded which confirms losses on invested equity.

The OSS of microcredit organisations is most favourable in Spain, Bulgaria and Germany, indicating the highest performance of institutions operating in these countries.

Figure 4: Ranking of European countries in terms of value of the synthetic measure for evaluation of microcredit activity at each level

Source: Own calculation

In the analysis of data describing the activity of residents in applying for funds from microcredit institutions, one can observe that the United Kingdom, Italy and Bulgaria are the leaders. This is connected with the high activity of women in applying for financial support. Hungary and Poland ranked last due to a decrease in the volume of loans granted.

A relatively unfavourable situation in terms of quality of the loan portfolio is observed in the countries of the "old" EU. The United Kingdom, Greece, Spain and Italy record the highest shares of non-performing loans and credit losses.

In terms of efficiency of the funds granted, the countries of Spain and Germany ranked highest followed by the countries of the former Yugoslavia: Kosovo, Montenegro, Bosnia-Herzegovina, while the “old” EU countries: Belgium, United Kingdom, Italy, Greece and France, took the lowest positions. This may have been affected by the economic recession.

In the European countries, there is a need for microfinance as an incentive for the unemployed to set up their own businesses.

As shown in the report by the William Davidson Institute, the presence of financial institutions offering microcredit has significantly improved access to external sources of finance for SMEs, making Bosnia and Herzegovina the most dynamic market for microcredit services among the Balkan countries.

Summary

In European countries, there is a large number of small entrepreneurs, often sole proprietorships, whose operations are hindered by a lack of initial or investment capital. From the social point of view, it is worth financing projects of people with the lowest incomes living in rural areas, i.e. the segment of customers ignored by commercial banks.

The presence of financial institutions offering microcredit has significantly improved access to external sources of financing for SMEs, and the rate of growth in the volume of loans granted indicates a rising demand for this type of support. SMEs constitute an important group in terms of the economic and social potential in the Central and Eastern Europe, where, due to the specific nature of the previous system, large companies were characterised by low productivity, and efforts were taken to discourage entrepreneurship. Since microbusinesses take efforts to settle their liabilities to financial institutions on a regular basis, the percentage of non-performing loans and credit losses is relatively low in most of the countries presented. Due to the high risk they pose to banks and low revenues in comparison to large companies, in many cases SMEs are deprived of the opportunity to obtain bank funds, and the documents and cash collateral required by banking institutions extend the process of granting credit and significantly increase the related costs. It is important to adjust the amounts of fees and interest charged on microcredits so that they are not too burdensome for start-ups.

Microloans cannot be treated as a remedy for financial exclusion. They are certainly one of the possibilities of activating those social group which are not able to meet the conditions set by commercial banks when granting loans.

Abstract

This research aims to analyze the explanatory variables of the intention to invest in Retail Green Sukuk, an investment product offered by the Directorate General of Budget Financing and Risk Management (DGBFRM), Ministry of Finance of the Republic of Indonesia. In the relationship model proposed, the intention to invest in Retail Green Sukuk can be explained by three variables: the socially responsible consumption of individuals; their perception of personal gain; and their perception of the effectiveness of their actions. The relationships between the variables were analyzed using the Partial Least Squares – Structural Equation Modeling technique. The data were collected through a survey involving 265 respondents in Indonesia who had purchased financial or investment products. Based on the results, the intention to invest in Retail Green Sukuk is explained by the proposed explanatory variables. The socially responsible consumption habits of investors and their perception of the effectiveness of Retail Green Sukuk have a direct and positive effect on the intention to invest in the product. However, the perception of personal gain only has an indirect effect on the intention through the mediation of the perception of the effectiveness of actions. These findings should be taken into account by DGBFRM when designing marketing and communication strategies for Retail Green Sukuk.

Keywords: Retail Green Sukuk, Partial Least Squares, Socially Responsible Consumption, Consumer Behavior, Socially Responsible Investment

Introduction

Indonesia, as a member country of the United Nations (UN), has agreed on the global commitment to the Sustainable Development Goals (TPB/SDGs) 2015-2030. The country is seriously committed to implementing SDGs in order to improve people's economic welfare sustainably; to ensure the sustainability of social communities; improve the quality of the environment; and implement inclusive development and governance that can maintain the improvement in the quality of life from one generation to the next (Bappenas, 2017).

To achieve the stated SDGs, the Indonesian government needs a large budget. In the 2030 Indonesian SDGs Roadmap, the investment financing requirement for Indonesia in the Business as Usual (BAU) scenario in 2020 was IDR 2,778 trillion and would rise to IDR 7,721 trillion by 2030 (Bappenas, 2019). With the 2020 State Budget spending target of IDR 2,540 trillion (Ministry of Finance, 2019), the government faces a tough challenge to achieve the SDGs by relying solely on funding from the State Budget. Therefore, the government needs to make breakthroughs and innovations to find alternative investment financing to achieve its SDG goals.

In the Spring Meetings of the International Monetary Fund - World Bank Group 2019 in Washington D.C., Sri Mulyani Indrawati, the Minister of Finance of the Republic of Indonesia explained how Indonesia mobilized funds to achieve the SDGs through philanthropic actions. The first way is through a blended, or mixed, finance scheme, consisting of funds from the government, public, private sources and philanthropic funds that are integrated into the SDGs Indonesia One platform. The second way is through issuing sukuk as one of the Islamic financing instruments, namely the Global Sukuk Wakalah, which is the first Green Sukuk in Indonesia and Asia. Indonesia was considered to be a pioneer in issuing green bonds in Southeast Asia through the issuance of Green Sukuk worth US$ 1.25 billion in March 2018 (Anggraini, 2018). However, the Green Sukuk were only available for institutional investors and were not yet available for individual or retail investors.

Cite this Article as: Mas DHIRADHARANA and Sri DARYANTI "Analysis of Factors Influencing the Intention of Indonesians to Invest in Retail Green Sukuk" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Retail Green Sukuk ST-006, which was issued in 2019 by the Ministry of Finance's DGBFRM, is the first retail sukuk instrument in the world to be issued using a green concept and made available for individual or retail investors. Retail Green Sukuk is issued to finance or refinance government green projects in accordance with its green framework (DJPPR, 2019). The issuance of Retail Green Sukuk is one of breakthroughs made by the government of Indonesia in terms of financing to support the achievement of SDGs.

However, the yield offered by Retail Green Sukuk is lower compared to other retail investment instruments issued by the Ministry of Finance's DGBFRM throughout 2019. With relatively lower yields than Retail SBN products or other retail SBSNs, the Ministry of Finance's DGBFRM needs to anticipate a diminish in the level of demand for and sales of Retail Green Sukuk, especially from individual investors who only consider traditional criteria, such as financial returns, risk and liquidity, in making their investment decisions.

According to Lozano, Albareda & Balaguer (2016), there is currently a new consumption pattern in which consumers, in addition to considering traditional criteria, also consider the social commitment of companies and brands. In the financial sector, this type of consumer is an investor who does not only consider the criteria of profitability, risk and liquidity when determining what instrument they invest in, but also considers for what purpose their money is invested. In other words, these investors consider social, environmental and ethical issues, both in terms of the financial products they buy and the financial institutions that offer them (Palacios-González, 2018).

As the Retail Green Sukuk product was issued in the context of financing and refinancing green projects established by the government of Indonesia and supporting the achievement of SDGs, the Retail Green Sukuk is, in fact, a socially responsible investment product. Sandberg, Juravle, Hedesstorm & Hamilton (2009) define socially responsible or ethical investment as an action that incorporates environmental, ethical, social and corporate governance criteria in the process of purchasing financial products (savings or investment), by encouraging companies to adopt socially responsible policies and commitments to projects or sectors that support community welfare and contribute to sustainable development.

Although there have been studies analyzing the sociodemographic characteristics of socially responsible investors (Tippet & Leung, 2001; Clark-Murphy & Soutar, 2004; Nilsson, 2009; Cheah, Jamali, Johnson & Sung, 2011; Dorfleitner & Utz, 2014), research that analyzes the attitudes of such investors remains scarce. Several previous studies have shown that the attitude of investors can influence their intention to buy certain financial products (Shanmugham & Ramya, 2012; Sachse et al., 2012; Warsame & Ireri, 2016; Ashidiqi & Arundina, 2017; Kunz et al., 2017). Research on attitudes needs to be strengthened, because the majority of research conducted to date showed that the fundamental difference between socially responsible investors and conventional ones does not lie in their sociodemographic characteristics, but in their attitudes (Williams, 2005, 2007).

Previous research regarding the intention to invest in sukuk in Indonesia has been conducted by Ashidiqi and Arundina (2017) using the theory of planned behavior (Ajzen, 1985, 1991). However, this research was only conducted on student respondents in Indonesia. There has been no research related to the intention to invest in sukuk by the general public in Indonesia, especially relating the characteristics of the sukuk with the behavior of socially responsible investors. In addition, the Retail Green Sukuk product is an investment product which was officially launched on November 1, 2019 by the Ministry of Finance of the Republic of Indonesia, so this research is one of the first empirical studies conducted regarding the intention to invest in the product.

This study adapted research conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who found that the intention to invest in a socially responsible manner is influenced by three attitude variables relating to investors, namely socially responsible consumption, perception of personal gain, and perception of the effectiveness of their action. Understanding the attitudinal factors that encourage individual investors in Indonesia to invest in Retail Green Sukuk will be useful for the Ministry of Finance's DGBFRM as policymaker in developing effective communication and marketing strategies for Retail Green Sukuk.

Theoretical Review

Attitudes towards Socially Responsible Behavior

Most of the research conducted on socially responsible behavior has been based on the theory of reasoned action put forward by Azhen and Fishbein (1975) and its development theory, the theory of planned behavior (Ajzen, 1985, 1991). In this study, the researchers focused on one of the variables in the theories of reasoned action and planned behavior, namely the attitude that shapes an investor's intention to invest in socially responsible investment products. To explain such behavior, several theories related to attitudes are used to analyzed socially responsible behavior. In previous studies, the attitudes that contribute to socially responsible behavior include perceived consumer effectiveness, socially responsible consumption, the perception of personal gain and the perception of the effectiveness of the action.

Perceived Consumer Effectiveness

This variable measures the control perception of an individual; the extent to which consumers believe that the actions of an individual can influence or solve a problem that exists in the individual's environment, be it environmental or social problem (Roberts, 1996). There is agreement in the literature regarding the positive effect of perceived consumer effectiveness on socially responsible behavior. Some of the examples are studies that focus on ecological behavior (Kinnear et al., 1974; Ellen, 1994; Roberts, 1996; Straughan & Roberts, 1999; Akehurst et al., 2012; Izaguirre-Olaizola et al., 2013; Zhao et al. 2014) and studies that focus on ethical behavior (De Pelsmacker et al., 2005; D'Astous & Legendre, 2009), as well as research that analyzes socially responsible behavior in general (Webster, 1975; Antil, 1984; Webb et al., 2008).

Other studies have found that this variable has a positive and significant impact when used in research on the intention to take a specific action: for example, research regarding the intention to book an environmentally friendly hotel (Han & Yoon, 2015); the intention to consume organically (Kabadayi et al., 2015); and the intention to buy products from a sustainable business (Lee et al., 2015).

Socially Responsible Consumption

Webster (1975) defines a socially responsible consumer as one who considers the public consequences of his consumption or someone who attempts to use his purchasing power to bring about social change. Socially responsible consumption is often operationalized by using only items of consumer behavior related to environmental awareness. An example is Webster (1975), who created the Socially Conscious Consumer Index, which is related to the socially responsible consumption of individuals, such as the use of recycling services, reuse of paper shopping bags or use of low-phosphate detergents. In a similar vein, Brooker (1976), Belch (1979, 1982) and Antil (1984) measured socially responsible consumption behavior through scales or indicators that focused on environmental concern.

The research of Roberts (1995, 1996) was the first attempt to involve social aspects in measuring socially responsible consumption. Roberts developed a scale to measure socially responsible consumption based on two dimensions, namely those of ecologically conscious and socially conscious consumer behavior. Later, Crane (2001) created a framework in which ethical augmentation affects products at four different levels, namely at the product, marketing, company and country levels. The framework shows that the concept of socially responsible consumption behavior can consist of four dimensions, namely the characteristics of the product itself, how the product is sold, the behavior of the company, and the country where the product comes from.

Based on these two measurement scales, François-Lecompte and Roberts (2006) conducted a study to determine whether consumers in France showed concern regarding the general social and environmental issues expressed by Roberts (1995, 1996) or instead focused on the specific social and environmental aspects of a product, as claimed by Crane (2001). The François-Lecompte and Roberts (2006) study produced five scale factors for measuring socially responsible consumption behavior, consisting of company behavior, products with causes, small businesses, country of origin, and volume of consumption.

The first scale factor of socially responsible consumption is company behavior, which represents the act of consumption related to irresponsible corporate behavior (François-Lecompte, 2006). These behaviors include company's disrespectful attitude toward employees, harmful to the environment, links with reprehensible organizations, child labor forces, etc.

The second factor is products with cause, which corresponds to the purchase of cause-related products. This factor represents the preference to purchase cause-related products that help the unfortunates, the people from developing countries, or small producers (François-Lecompte and Roberts, 2006).

The third factor, small businesses, represents the willingness of the consumer to support small businesses. Similar with the second factor, this factor represents the social aspect of the consumer. According to the research conducted by François-Lecompte and Roberts (2006), being a socially responsible consumers consists of supporting traditional small businesses as opposed to bigger businesses, such as hypermarkets and supermarkets.

The fourth factor, country of origin, indicates that consumer in France prefers to buy products from their country of origin or from Europe. This factor represents the social aspect of the consumer. This factor has a similarity with 'country of origin level' concept expressed by Crane (2001). According to Crane (2001), the 'country of origin level' of a product is a significant ethical consideration, with positive augmentation for domestic products and negative augmentations for products made in countries with government policies deemed unacceptable.

The last factor, volume of consumption, corresponds to an idea of reducing individual's consumption as a manifestation of environmental concern. According to François-Lecompte and Roberts (2006), this behavior focuses on concerns regarding the impact of consumption on the environment and tries to minimize such impact by reducing consumption.

Perception of Personal Gain

This variable is defined as a subjective assessment of an individual regarding the advantages and disadvantages they receive when they take socially responsible action (Ellen, 1994). Although perceptions of this variable can be expressed in positive language, that is, regarding the expected benefits, most studies define it through questions that are used negatively or conversely to describe feelings of being harmed (such as paying a higher price or needing to spend more time during the purchase process).

Individuals who have a high perception of personal gain have a higher tendency to take socially responsible actions than those who have a low perception of personal gain (Antil, 1984; Ellen, 1994; De Pelsmacker et al., 2005; De Pelsmacker & Janssens, 2007). Moreover, the perception of personal gain affects intention, as shown in the findings of a study conducted by Lee et al. (2015), in which the perception of personal gain affected the intention to buy fair-trade products.

Perceived Effectiveness of Action

This variable refers to the individual's view of the ability of an action to affect the environment and solve the problems in question (Banegi & Chamorro, 2002). An individual who has a certain level of concern for a social problem may have the belief that they will not have any influence on the environment through their actions or behavior, but through some other actions they can contribute efficiently to solving a problem.

This variable can be measured by using positive issues (e.g. sorting domestic waste can help reduce contamination) or negative ones that show distrust or low confidence in the impact of an action (e.g. sorting domestic waste is an ineffective way to save the earth).

De Pelsmacker et al. (2005) and De Pelsmacker and Janssens (2007) analyzed scepticism about fair trade; that is, individuals who do not believe that fair trade companies can operate effectively in a world dominated by capitalist economic models. Their research shows that the variable perceived the effectiveness of the action, which is measured in negative or opposite terms, and has a negative effect on purchasing fair trade products.

Proposed model for the intention to invest in Retail Green Sukuk

This research is aimed to investigate the attitudinal factors that explain the intention to invest in Retail Green Sukuk among investors in Indonesia. With reference to research on intention to invest in a socially responsible manner conducted by Palacious-Gonzalez and Chamorro-Mera (2018), a relationship model, as shown in Figure 1, was developed to examine intention to invest in Retail Green Sukuk.

Fig. 1: Conceptual Framework

The effect of socially responsible consumption on the intention to invest in Retail Green Sukuk

Palacious-Gonzalez and Chamorro-Mera (2018) found that the greater the socially responsible consumption, the greater the intention to invest in a socially responsible manner. This is based on the justification that certain types of socially responsible behavior influence the intention to perform other newer behaviors. Several studies that support

the result of study conducted by Palacious-Gonzalez and Chamorro-Mera (2018) are study of Han and Yoon (2015) on the relationship of individual's recycling and reuse behavior and their intention to visit environmental management certified hotels as well as study of Izaguirre-Olaizola et al. (2013) who found environmental activism and recycling activities have a direct positive influence of the purchase of organic products. Based on these studies, a hypothesis is proposed:

H1: Socially responsible consumption has a positive effect on the intention to invest in Retail Green Sukuk.

The effect of the perception of personal gain on the intention to invest in Retail Green Sukuk

Palacious-Gonzalez and Chamorro-Mera (2018) stated that in the financial sector, perception of personal gain is measured in terms of sacrifice, which relates to the possibility that socially responsible investment entails lower return and greater risk level. However, some other studies that compared the return of the socially responsible investment products and the conventional ones (Hellsten and Mallin, 2006, Renneboog et al., 2008, Ortas et al., 2013; Martí-Ballester, 2015; and Huan, 2016) showed that sometimes the return is greater and sometimes is lower. A study conducted by Jansson and Biel (2011) concluded that investors believe socially responsible investment may provide lower return in the short run compared to conventional investments. In the study, Jansson and Biel (2011) also found that perception of personal gain had a significant influence on the intention to invest in a socially responsible manner, which means the investors have greater intention to invest in socially responsible manner when the socially responsible products have better financial conditions. However, Palacious-Gonzalez and Chamorro-Mera (2018) found that perception of personal gain only indirectly influences the intention to invest in a socially responsible manner through the mediation of perception of the effectiveness of the action.

Based on the mentioned studies, the following hypotheses are proposed:

H2a: The perception of personal gain has a negative effect on the intention to invest in Retail Green Sukuk.

H2b: The perception of personal gain has a negative effect on the intention to invest in Retail Green Sukuk indirectly through the perception of the effectiveness of the action.

The relationship between perception of personal gain and the intention to invest in Retail Green Sukuk is expressed in negative sign as the perception of personal gain is measured in terms of sacrifice in financial conditions (Palacious-Gonzalez and Chamorro-Mera, 2018).

The effect of the perception of the effectiveness of the action on the intention to invest in Retail Green Sukuk

According to Palacious-Gonzalez and Chamorro-Mera (2018), the perception of the effectiveness of the action refers to the belief that socially responsible investment can encourage companies to behave better, hence, help to resolve social and environmental problems. On their study, Palacious-Gonzalez and Chamorro-Mera (2018) also found that the perception of the effectiveness of the action from the investors has positive influence on their intention to invest in socially responsible manner which is similar to the result of studies conducted by Nilsson (2008) and Wins and Zwergel (2015). Based on these findings, the following hypothesis is proposed:

H3: The perception of the effectiveness of the action has a negative effect on the intention to invest in Retail Green Sukuk.

As the previous studies measured the perception of the effectiveness of the action in terms of negative beliefs, the relationship between the perception of the effectiveness of the action and the intention to invest in Retail Green Sukuk is expressed in negative sign.

The effect of socially responsible consumption on the perception of personal gain

Palacious-Gonzalez and Chamorro-Mera (2018) found that the greater socially responsible consumption of an investor, the better their perception of personal gain. Based on the finding, this study proposes the following hypothesis:

H4: Socially responsible consumption has a negative effect on the perception of personal gain.

The relationship between socially responsible consumption and perception of personal gain is expressed in negative sign as the perception of personal gain is measured in terms of sacrifice.

The effect of socially responsible consumption on the perception of the effectiveness of the action

A study conducted by Palacious-Gonzalez and Chamorro-Mera (2018) concluded that the greater the socially responsible consumption of an individual, the greater their perception of the effectiveness of the action. Palacious-Gonzalez and Chamorro-Mera (2018) stated that this is based on the logical thinking that the individuals who behave in socially responsible manner will be more confident that ethical investment can resolve social and environmental problems. Therefore, the following hypothesis is proposed:

H5: Socially responsible consumption has a negative effect on the perception of the effectiveness of the action.

The relationship between socially responsible consumption and perception of the effectiveness of the action is expressed in negative sign as the perception of the effectiveness of the action is measured in terms of negative beliefs.

The effect of the perception of personal gain on the perception of the effectiveness of the action

Palacious-Gonzalez and Chamorro-Mera (2018) found that the greater the perception of personal gain from investing in socially responsible financial products, the greater the perception of the effectiveness of the action. This means that if individuals perceive that socially responsible investment products have better financial condition, they will tend to think that they will be able to help resolve social and environmental problems through socially responsible investment products. Based on the study above, the following hypothesis is proposed:

H6: The perception of personal gain has a positive effect on the perception of the effectiveness of the action.

Based on the studies of Palacious-Gonzalez and Chamorro-Mera (2018) and François-Lecompte and Roberts (2006), the constructs and indicators for this study as shown in Table 1 are developed.

Table 1: Constructs and Indicators

No.	Variables	Dimensions	Indicators	Code	Scale	Sources
1.	Socially Responsible Consumption	Company Behavior	I try not to buy products form illegal companies	CB1	Likert 1-5	François-Lecompte and Roberts (2006)
			I try not to buy products from companies that employ underaged workers	CB2	Likert 1-5	
			I try not to buy products from companies that disrespect their employees	CB3	Likert 1-5	
			I try not to buy products from companies that harm the environment	CB4	Likert 1-5	
			I try not to buy products from companies or businesses affiliated with political organizations that have bad reputation	CB5	Likert 1-5	
		Country of Origin	When I have the choice between purchasing Indonesian and foreign products, I choose to purchase Indonesian products	O1	Likert 1-5	
			I prefer Indonesian products	O2	Likert 1-5	
			I buy fruits and vegetables produced by Indonesian's farmer	O3	Likert 1-5	
			I buy products made in Indonesia	O4	Likert 1-5	
		Products with Cause	I buy products which part of the price is given to humanitarian cause	PC1	Likert 1-5	
			I buy products which part of the price is given to a program to improve small enterprises	PC2	Likert 1-5	
			I buy products which part of the price is given to a good cause	PC3	Likert 1-5	
			I buy fair-trade products	PC4	Likert 1-5	
		Small Businesses	I buy my daily needs from small businesses as often as possible	SB1	Likert 1-5	
			I help the storekeepers in my neighborhood with my purchases	SB2	Likert 1-5	
			I avoid doing all my shopping from big retail companies	SB3	Likert 1-5	

			I go to small markets to support small fruit and vegetable producers	SB4	Likert 1-5	
		Volume of Consumption	I try to reduce my consumption to my needs	V1	Likert 1-5	
			In general, I try to reduce my level of consumption	V2	Likert 1-5	
			I try not buy things that I can provide/make on my own	V3	Likert 1-5	
2.	Perception of Personal Gain		Investing in Retail Green Sukuk entails greater risk than other conventional investment products.	PPG1	Likert 1-5	Palacious-Gonzalez and Chamorro-Mera (2018)
			Working with Ministry of Finance's DGBFRM entails higher risk than other financial institutions.	PPG2	Likert 1-5	
			Working with Ministry of Finance's DGBFRM entails accepting worse financial conditions.	PPG3	Likert 1-5	
3.	Perception of the Effectiveness of the Action		Retail Green Sukuk is only a marketing action that does not truly contribute to resolving social and environment problems in Indonesia.	PEA1	Likert 1-5	
			Retail Green Sukuk is only a marketing action and beyond that, there is no real concern from Ministry of Finance's DGBFRM.	PEA2	Likert 1-5	
			Retail Green Sukuk does not really contribute to Ministry of Finance's DGBFRM having better social and environment behavior	PEA3	Likert 1-5	
			Working with Ministry of Finance's DGBFRM will not help resolving social and environmental problems in Indonesia.	PEA4	Likert 1-5	
			I do not believe that I can contribute to resolving social and environmental problems in Indonesia by investing in Retail Green Sukuk.	PEA5	Likert 1-5	
4.	Intention to Invest in Green Sukuk Ritel		With similar rate of returns, I prefer investing in investment products offered by Ministry of Finance's DGBFRM than other financial institutions.	INT1	Likert 1-5	
			I am willing to invest in Retail Green Sukuk to resolve social and environmental problems with the same rate of returns with other financial institutions.	INT2	Likert 1-5	
			I am willing to invest in Retail Green Sukuk although the rate of returns offered is lower than other financial institutions.	INT3	Likert 1-5	
			I am willing to accept lower rate of returns for investment products offered by Ministry of Finance's DGBFRM.	INT4	Likert 1-5	

			I will recommend my friends and families to invest in Retail Green Sukuk.	INT5	Likert 1-5	

Research Methods

The data required for the study were collected through a questionnaire distributed to Indonesian citizens with the help of the Google Forms platform.. The measurement scale used was a 5-point Likert scale. Only individuals with the status of Indonesian citizens (WNI) were included, considering that only individual Indonesian investors can invest in Retail Green Sukuk. Another criterion set for respondents to be processed in this study was that they had previously invested in financial or investment products. The sample was selected using nonprobability sampling techniques and convenience sampling.

The data collected were then processed using the Partial Least Squares technique - Structural Equation Modeling (PLS-SEM) and SmartPLS 3.0 software. The PLS-SEM method was employed because it is the recommended method when there are reflective and formative latent variables in a structural model (Hair et al., 2017; Chin, 2010). In the proposed research model, the socially responsible consumption variable is a formative latent variable that is formed by five dimensions, namely company behavior, country of origin, the volume of consumption, products with causes, and small businesses (François-Lecompte and Roberts, 2006). Meanwhile, other variables, namely the perception of personal gain, the perception of the effectiveness of action and the intention to invest in Retail Green Sukuk are reflective latent variables.

Analysis, Results and Discussion

A summary of the results from testing the hypotheses using SmartPLS 3.0 software is presented in Table 2.

Table 2: Research Hypothesis Test

	Relationship according to hypothesis	Path Coefficient	T-Statistic (|O/STDEV|)	P-Value	Description	Hypothesis Accepted?
SRC →INT (H_1)	+	0.319	4.455	0.000	Significant	Hypothesis Accepted
PPG →INT (H_{2a})	-	-0.017	0.247	0.805	Not Significant	Hypothesis Rejected
PPG → PEA → INT (H_{2b})	-	-0.118	3.733	0.000	Significant	Hypothesis Accepted
PEA → INT (H_3)	-	-0.380	5.167	0.000	Significant	Hypothesis Accepted
SRC → PPG (H_4)	-	-0.203	3.471	0.001	Significant	Hypothesis Accepted
SRC → PEA (H_5)	-	-0.367	5.678	0.000	Significant	Hypothesis Accepted
PPG → PEA (H_6)	+	0.310	4.026	0.000	Significant	Hypothesis Accepted

The critical t-value used in the one-tailed tests was 1.645, with a p-value of 0.05, and with a confidence level of 95% and $\alpha = 5\%$. The t-value and p- value are used as references in rejecting or accepting the hypotheses formulated for the study.

Based on the results obtained, the hypothesis that socially responsible consumption has a positive effect on the intention to invest in Retail Green Sukuk, as denoted by H1, is accepted. The result confirms the research conducted by Palacious-Gonzalez and Chamorro-Mera (2018), who found that there was a positive effect of socially responsible consumption on the intention to invest in a socially responsible manner. The results of this study also support research conducted by Han and Yoon (2015) which found that the behavior of an individual with regard to recycling and reuse had a positive relationship with the intention to visit a hotel that is certified in environmental management. Han and Yoon's (2015) research showed that socially responsible behavior that already exists in an individual will encourage that individual to take other socially responsible actions.

The hypothesis that the perception of personal gain has a negative effect on the intention to invest in Retail Green Sukuk, as denoted by H2a, is rejected. The result confirms the study conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who found that perceptions of the personal gain of socially responsible investment products did not affect the intention to invest in a socially responsible manner. Neither the results of this study nor that of Palacious-

Gonzalez and Chamorro-Mera (2018) support the research findings of Jansson and Biel (2011) who showed that if investors have the perception that buying socially responsible products does not have a negative impact on their financial condition, they will have a greater intention to invest in a socially responsible manner. On the other hand, the results of this study support the research of Nilsson (2008) who showed that the risk perception of investors regarding socially responsible investment did not have a significant influence on the behavior to invest in socially responsible investment products.

The hypothesis that the perception of personal gain has a negative effect on the intention to invest in Retail Green Sukuk indirectly through the perception of the effectiveness of the action, as denoted by H2b, is accepted. The result is similar to the study of Palacious-Gonzalez and Chamorro-Mera (2018) who found that the perception of the financial conditions of socially responsible investment products does not influence the intention to invest in a socially responsible manner, but does have a significant effect when mediated by the perception of the effectiveness of the action. This indicates that the perception of the returns and risks of Retail Green Sukuk products from the potential investors will affect the intention to invest in Retail Green Sukuk when they believe that investing in Retail Green Sukuk products will help resolving social and environmental problems in Indonesia.

The hypothesis that perception of the effectiveness of the action has a negative effect on the intention to invest in Retail Green Sukuk, as denoted by H3, is accepted. The result confirms previous research conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who showed that perception of the effectiveness of the action has negative influence on the intention to invest in a socially responsible manner. The results of this study also support the research conducted by Nilsson (2008) and Wins and Zwergel (2015, 2016), who showed that investors' perceptions of the effectiveness of a socially responsible investment product in overcoming social and environmental problems has a positive effect on investors' intention to invest in socially responsible investment products. This result also indicates that the more the investors believe that Retail Green Sukuk products would help to resolve social and environmental problems in Indonesia, the more they will tend to invest in them

The hypothesis that socially responsible consumption has a negative effect on the perception of personal gain, as denoted by H4, is accepted. The result confirms research conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who found that there was a negative effect of socially responsible consumption on the perception of personal gain. This indicates that potential investors who have socially responsible consumption habits tend to think that Retail Green Sukuk products have good returns and risks.

The hypothesis that socially responsible consumption has a negative effect on the perception of the effectiveness of the action, as denoted by H5, is accepted. The result is similar to the research conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who showed that socially responsible consumption has negative effect of on the perception of the effectiveness of the action. This indicates that potential investors who have socially responsible consumption habits have more confidence that Retail Green Sukuk products will be able to resolve social and environmental problems in Indonesia. This is because people with such habit have a high concern for the environment and understand that the Retail Green Sukuk investment products are issued to finance government programs for resolving social and environmental problems.

Finally, the hypothesis that the perception of personal gain has a positive effect on the perception of the effectiveness of the action, as denoted by H6, is accepted. The result confirms the study conducted by Palacious-Gonzalez and Chamorro-Mera (2018) who found that there was a positive effect of the perception of personal gain on the perception of the effectiveness of the action. This indicates that investors who have a good perception of the financial conditions of Retail Green Sukuk products tend to think that they can help to resolve social and environmental problems in Indonesia by investing in Retail Green Sukuk.

Conclusions and Recommendations

The results of this study show that respondents' perceptions of the effectiveness of Retail Green Sukuk in resolving social and environmental problems in Indonesia have the most significant influence to the intention to invest in Retail Green Sukuk. Therefore, in preparing advertising messages for Retail Green Sukuk products, the Ministry of Finance's DGBFRM needs to emphasize that Retail Green Sukuk investors are contributing to resolving social and environmental problems by investing their money in Retail Green Sukuk. In addition, the Ministry of Finance's DGBFRM needs to provide real examples of green projects financed by Retail Green Sukuk investment and presents the tangible results from these investments when marketing Retail Green Sukuk.

The results of the study also show that socially responsible consumption has a significant influence on the intention to invest in Retail Green Sukuk. Therefore, community groups that have socially responsible consumption habit and concern about the environment are effective target audiences for the Ministry of Finance's DGBFRM to market Retail Green Sukuk. These communities include individuals who are members of or involved in various communities or institutions that advocate for social and environmental issues in Indonesia.

Although the research results show that the perception of the financial benefits of Retail Green Sukuk products only affects the intention to invest in Retail Green Sukuk products indirectly, the communication strategy of the Ministry of Finance's DGBFRM should still pay attention to the perceptions of the benefits that will be obtained by investors and images related to the financial performance of such products. The message created by the Ministry of Finance's DGBFRM in the promotional materials for Retail Green Sukuk should not give the impression that Retail Green Sukuk gives lower return or worse financial conditions than other investment products. This can be done by presenting a comparison of the returns between Retail Green Sukuk and other investment products that have relatively lower yields (such as savings or deposits). The Ministry of Finance's DGBFRM should also encourage Indonesian people to consider noneconomic personal gain from investing in Retail Green Sukuk, which may include the positive feeling generated when someone has done something socially responsible, or the positive social image that is formed when someone becomes an investor of Retail Green Sukuk. The use of the terms 'Heroes of the Country' and 'Investment Heroes' for Retail Green Sukuk and Retail SBN investors, as has been previously done by the Ministry of Finance's DGBFRM when advertising Retail Green Sukuk, can be one of effective strategies to support the formation of positive social image among the investors.

This study has several limitations that could be a concern and provide an opportunity for further research. For institutions that have access to a list of investors in each province in Indonesia, the use of probability sampling techniques – such as cluster sampling will provide equal opportunities for people in each province to become respondents in further research. This is important to reduce research bias and to increase the representation of respondents from all over the country. In addition, the number of samples involved in this study is relatively small. It is suggested that a larger number of respondents could be involved in future research to further improve the generalization of the results.

Considering that Retail Green Sukuk investment products are financial products based on Islamic financial principles, further research could also involve the variable attitudes of individuals related to Islamic and religious aspects, such as individual's religiosity, perceptions of Islamic financial principles, and other related aspects. Future research could also involve moderating variables related to the sociodemographic aspects of the respondents, such as focusing the research on millennial generation or differences among generations. In addition, further research could also compare the intention to invest in Retail Green Sukuk between respondents who have previously invested in Retail SBN and those who have not.

Future research should note that there may be social desirability bias when the respondents completing the questionnaire, particularly the possibility to overvalue the positive valuation of the socially responsible consumption. Further research could also be conducted on socially responsible investment products issued by non-governmental financial organizations in Indonesia, such as those issued by listed companies that are members of the SRI-KEHATI index, a green index initiated by PT Bursa Efek Indonesia and the Biodiversity Foundation, Indonesia.

Abstract

Climate change is occurring today due to the widespread exploitation of natural resources undertaken by humans in order to meet their needs. To deal with these problems, it is necessary we play an active role in preventing and/or dealing with climate change, such as using alternative energy sources and conducting environmentally-friendly activities. Responsible investment can support action taken against climate change. As a financing instrument in the Islamic economy, green sukuk can support such action by financing environmentally-friendly projects. This study aims to establish the factors that affect the intention to invest in green sukuk by using the theory of planned behaviour (TPB). The study respondents were 377 Indonesian citizens aged over 18 living in the country. The study found that religious values, issuers' reputation and knowledge have a positive and significant effect on attitude, and that subjective norms and perceived behavioural control have a positive and significant effect on the intention to invest in green sukuk.

Keywords*:* Green Sukuk, Intention, Structural Equation Modelling, Theory of Planned Behaviour

Introduction

Climate change occurring in the world today is a serious problem that needs to be addressed. It is even included as the 13th of the Sustainable Development Goals (SDGs), namely climate action, in which humans need to play an active role in preventing and/or dealing with climate change, such as adapting and taking mitigation measures if necessary. Indonesia has shown its commitment to supporting the realisation of the SDG program by linking most of the SDG targets to the national medium-term development plan, or RPJMN. In addition, the signing of Presidential Regulation No. 59 of 2017 concerning the Implementation of Achieving the Sustainable Development Goals is also one of the supporting pillars in realising the achievement of the SDGs in Indonesia. To adapt to these problems, Indonesia established the National Action Plan for Climate Change Adaptation (RAN-API) as a framework for national development planning.

In an effort to realise its commitment, Indonesia has developed various approaches, which include green bonds and green sukuk to fund eligible green projects, ones which, for example, support moves towards lower emission levels, and the growth of resilience to climate change, including mitigation of the problem, adaptation and biological diversity. Green bonds can help overcome the problem of climate change and help conserve the environment (Dupont & Su, 2015). Green sukuk are intended to be a source of financing to support programs that aim to achieve sustainable development in Indonesia. Sukuk are investment instruments that comply with sharia law, which includes the welfare of the earth and everything on it (Moghul & Safar-Aly, 2015).

The 2016 National Survey of Financial Literacy and Inclusion conducted by the Financial Services Authority found that the Islamic financial literacy index of Indonesian people was 8.1%, markedly different from the conventional financial literacy index of 29.5%. Moreover, the Islamic financial literacy index in the financial institution and capital market industry was 0.02%, in contrast to the Islamic banking literacy index of 6.6%. The Islamic financial inclusion index is 11.1%, which is also very different to the conventional financial inclusion index, which is 65.6%. In 2019, the Islamic financial literacy index experienced a slight increase to 8.93%, although there was a decrease in the Islamic financial inclusion index to 9.1%. The two indices are very different from the conventional ones, namely the conventional financial inclusion index of 75.28% and the conventional financial literacy index of 37.72%.

Fig. 1: Development of Sukuk Savings 2016-2019
Source: Ministry of Finance DJPPR (reprocessed)

Indonesia has a population of 267 million (World Bank, 2019) and a Muslim population of more than 207 million (Ministry of Information and Communication, 2017), which makes it the country with the highest Muslim population in the world. The Pew Research Center (2019) projects that the Muslim population will rise to around 230 million, or around 87% of the total population by 2020. The large Muslim population gives the potential for new investors to invest in the sukuk market. However, not only the Muslim community can invest in green sukuk; green sukuk issuance in Indonesia has potential investors who are very similar to state sukuk investors, regardless of their religious background (Suherman & Manzilati, 2016).

The potential for high green sukuk issuance in Indonesia must be managed as well as possible, so it is necessary to conduct research into the public's intention to invest in it, including people from various religious backgrounds, and not limited to ones with investment experience. This study aims to analyse these issues.

Based on the studies previously mentioned, TPB was also used to research the intention of both investors and non-investors to invest in green sukuk, and not limited to those with Islamic religious backgrounds. Many previous studies have examined investment intentions with regard to sukuk, but none has analysed the intention to invest in green sukuk, either by investors and non-investors, and none has examined respondents' religious backgrounds other than Islam.

This research can be used as material for consideration to develop policies to increase the development of sukuk, especially the green type. It aims to provide an overview of what can be improved in order to involve more investors in green sukuk, and also to provide the necessary data to ascertain the intention of certain groups of people to invest in green sukuk. As a result, policies could be well enforced well and remain on target.

Theoretical Review

Sukuk

Sukuk comes from Arabic, and is the plural form of 'sak', which is defined as a document (Iqbal & Mirakhor, 2007). The Accounting and Auditing Organization for Islamic Financial (AAOIFI) defines sukuk as certificates that show proof of ownership of a tangible asset, in the form of benefit rights, services or ownership of the assets of a particular project or investment activity. Based on POJK 18/POJK.04/2015, sukuk are Islamic securities in the form of certificates or proof of ownership of the same value and represent an inseparable or undivided share (syuyu '/ undivided share) of the underlying assets. Another definition of sukuk is found in the MUI DSN fatwa No. 32/DSN-MUI/IX/2002, namely that sukuk (sharia bonds) are long-term securities based on sharia principles issued to sharia bondholders, which oblige the issuer to pay income to the bondholders in the form of profit sharing, margin or fees, and to repay bond funds at maturity. Sukuk are financial instruments issued by government institutions or corporations that aim to finance a variety of projects and have been popular for the past two decades (Mcmillen, 2007). They have

some similarities with conventional bonds, such as cash flow and the element of risk (Miller, Challoner, & Atta, 2007).

Green Sukuk

Green sukuk are an investment instrument in the form of state sharia securities issued by the government, the proceeds of which are used to finance green projects. Sukuk are similar to bonds, but there are differences in the application of sharia principles in them. Green sukuk are in accordance with the government's commitment to dealing with various global environmental issues, considering that Indonesia is very vulnerable to the impact of natural damage.

The emergence of green sukuk originated with the issuance of green bonds by the World Bank in 2008. The Climate Bonds Initiative (CBI), in collaboration with the Clean Energy Business Council of the Middle East and North Africa and Dubai-based Gulf Bond & Association, initiated the formation of green sukuk. They are also known as Socially Responsible Investment (SRI). According to Moody's Investor Service (2019), Indonesia was the second largest sukuk issuing country in the world in the first half of 2019. The issuance of Indonesian sukuk was worth 15 billion USD, equivalent to 1,244 trillion rupiahs, and represents 18% of total world sukuk issuance, behind Malaysia, whose issuance was worth of 36 billion USD, or 41% of total global sukuk issuance.

Theory of Planned Behaviour (TPB)

TPB is a theory which explains that a person's behaviour can be predicted based on the intention to perform the behaviour. Ajzen (1991) defines intention as a tool to measure how strong a person desires to adopt or perform certain behaviours. The theory is a further development of that of reasoned action proposed by Ajzen and Fishbein (1967).

There are four main factors in TPB, namely attitude, subjective norms, perceived behavioural control and intention. This research adds the factors of knowledge, religious values and issuers' reputation as variables that affect attitude.

Research Methods

This research used a conclusive-descriptive approach because it aims to test the hypotheses compiled and to measure and establish the influence between the variables. Primary data were used, obtained directly from respondents using a questionnaire created with Google Forms and then distributed online via social media.

Questionnaires were distributed to a total of 378 respondents. One respondent who was not in accordance with the screening question was eliminated, so the total respondent data for analysis were from 377 respondents. The number of samples required for the SEM method should be five times the number of indicators (Hair, Sarstedt, Hopkins, and Kuppelweiser, 2014). In addition, certain criteria had to be met by individuals to become respondents, namely that they were aged ≥ 18 years, an Indonesian citizen (WNI) and domiciled in the territory of Indonesia.

The respondents were divided into two categories, namely those with Islamic or non-Islamic backgrounds, and those who had invested in an instrument before and those who had not. This was done to observe the differences in intention between those with different religious backgrounds, and those with different investment experience.

Fig 2: Research Model

ource: Authors' Elaboration

The adopted research model was that of Ashidiqi and Arundina (2017) and is a modification of the conceptual framework of TPB. The model aims to determine the effect of religious values, issuers' reputation and knowledge on attitude, and the effects of attitude, subjective norms and perceived behavioural control on the intention to invest in green sukuk. The following research hypotheses are proposed.

H1: Religious values have a significant positive effect on attitude.

Religion is one of the strong factors influencing a person's decision to take action (Kashif, Zarkada, and Thurasamy, 2016). Research conducted by Ashidiqi (2017) found that the variable that most influenced students' intentions to invest in sukuk was attitude, with the most significant influence being the religious factor. Osman et al. (2019) examined the determinants of behavioural intention towards green investment in Malaysia using TPB, finding that religious values had the most significant effect on attitude. Louche et al. (2012), in their research on the behaviour of religious organisations towards sustainable investment, including Protestant Christian, Buddhist and Hindu ones, found that religious investors were pioneers in investments that had a positive impact. Therefore, religious values or factors and their relation to attitude are the basis of H1.

H2: Issuers' reputation has a significant positive effect on attitude.

Barnett, Jermier and Lafferty (2006) examined whether customer behaviour was influenced by customer satisfaction when someone was aware of the reputation of a company. Duqi and Al-Tamimi (2018), in their research on the intention of investors in the United Arab Emirates to invest in sukuk, found that the reputation factor of the sukuk issuer had a positive and significant influence on the intention to make such an investment. Therefore, the relationship between reputation and attitude is examined in H2.

H3: Knowledge has a significant positive effect on attitude.

Research conducted by Valor and Cuesta (2007) in Spain found that a high level of awareness and understanding of sustainable investment influenced investing behaviour in religious groups. In addition, Suki (2016) states that knowledge of green products influences individuals to buy environmentally-friendly ones to help preserve nature. Therefore, knowledge and its relation to attitude are covered in H3.

H4: Attitude has a significant positive effect on the intention to invest in green sukuk.

Warsame and Ireri (2016) found that attitude had a significant influence on intention. Alam and Sayuti (2011) also discovered that attitude, subjective norms, and behavior control had a significant effect on the intention to buy halal products. Therefore, the relationship between attitude and intention is investigated in H4

H5: Subjective norms have a significant positive effect on the intention to invest in green sukuk.

Subjective norms were found to significantly influence the intention of Nigerian consumers to buy insurance (Omar & Frimpong, 2007). Lada et al. (2009) also found that subjective norms had a positive effect on intention. Therefore, the relationship between subjective norms and intention is explored in H5.

H6: Perceived behavioural control has a significant positive effect on the intention to invest in green sukuk.

Alam and Sayuti (2011) found that perceived behavioural control had a significant effect on the intention to buy halal food, while Ashidiqi and Arundina (2017) found that it had a significant effect on student intentions to invest in sukuk. However, research by Hofmann, Hoelzl and Kirchler (2008) found no significant relationship between perceived behavioural control and the intention to invest. Therefore, perceived behavioural control and its relation to intention are analysed in H6.

The data obtained were then analysed using descriptive analysis to establish the frequency distribution, and structural equation modelling (SEM) employed to observe the effect of the independent variables on the dependent variable, namely the intention variable. Different analyses were then made using an independent samples t-test to ascertain the difference in influence between the group of Muslim respondents and those with a non-Islamic background, and between group of respondents with investment experience, and those who had never invested.

Results

The data were then analysed using descriptive analysis, SEM and an independent samples t-test.

Table 1: Variable Descriptive Statistics on Intention to Invest

Variable	Total Mean
Attitude	4.7
Subjective Norms	4.0
Perceived Behavioural Control	4.4
Knowledge	4.4
Issuers' Reputation	4.5
Religious Values	5,0
Intention to Invest	4.4

Source: Authors' Elaboration

Based on the descriptive analysis, all the variables had a total mean of ≥ 4, so it can be seen that the respondents tended to "somewhat agree" with the statements in the questionnaire. Religious values had the highest total mean, 5.0, so it can be concluded that respondents tended to "agree" with the statement on the the religious values variable.

Table 2: Causal Relationships Between Independent Variables and Dependent Variable

Hypothesis	SLF	T-value	Result
(H1) Religious values → Attitude	0.09	**1.87***	Significant
(H2) Issuers' Reputation → Attitude	0.37	**6.05***	Significant
(H3) Knowledge → Attitude	0.52	**7.44***	Significant

(H4) Attitude → Intention to invest in green sukuk	0.39	**5.35***	Significant
(H5) Subjective Norms → Intention to invest in green sukuk	0.37	**5.62***	Significant
(H6) Perceived Behavioural Control → Intention to invest in green sukuk	0.13	**1.80***	Significant

Source: Authors' Elaboration

Based on Table 2, the results of the research hypotheses shown in Table 2 can be analysed by comparing the t-values of the hypotheses with the critical value of ± 1.645 ; it was found that all the hypotheses formulated had a positive and significant effect.

Discussion

Table 3: Research Hypothesis Test

Hypothesis		t-value	Summary
H1	H0 (1): Religious values do not have a significant positive influence on attitude. Ha (1): Religious values have a significant positive influence on attitude.	**1.87***	**Reject H0:** Religious values have a significant positive influence on attitude.
H2	H0(2): Issuers' reputation does not have a significant positive influence on attitude. Ha(2): Issuers' reputation has a significant positive influence on attitude.	**6.05***	**Reject H0:** Issuers' reputation has a significant positive influence on attitude.
H4	H0(4): Attitude does not have a significant positive influence on the intention to invest in green sukuk. Ha(4): Attitude has a significant positive influence on the intention to invest in green sukuk.	**5.35***	**Reject H0:** Attitude has a significant positive influence on the intention to invest in green sukuk.
H5	H0(5): Subjective norms do not have a significant positive influence on the intention to invest in green sukuk. Ha(4): Subjective norms have a significant positive influence on the intention to invest in green sukuk.	**5.62***	**Reject H0:** Subjective norms have a significant positive influence on the intention to invest in green sukuk.
H6	H0(4): Perceived behavioural control does not have a significant positive influence on the intention to invest in green sukuk. Ha(4): Perceived behavioural control has a significant positive influence on the intention to invest in green sukuk.	**1.80***	**Reject H0:** Perceived behavioural control has a significant positive influence on the intention to invest in green sukuk.

Source: Authors' Elaboration

Analysis of the coefficient of determination (R^2) was conducted by analysing the reduced form equation value obtained from the Lisrel output results. This value describes how much variance in the dependent variable can be explained by the independent variables.

- Att = 0.52*Kno + 0.37*Rep + 0.093*RV, Errorvar.= 0.28, R^2 = 0.72
- Int = 0.37*SN + 0.13*PBC + 0.20*Kno + 0.14*Rep + 0.036*RV, Errorvar.= 0.43, R^2 = 0.57

This equation shows that the attitude variable can be explained by the variables of knowledge, issuers' reputation and religious values at 72%, with the other 28% explained by other variables. Furthermore, the variable of the intention to invest in green sukuk can be explained by the variables of attitude, subjective norms and perceived behavioural control at 57%, with the other 43% explained by other variables.

Different analysis using an independent samples t-test obtained the results shown in the tables below:

Table 4: Group statistics based on investment experience

Group Statistics					
Code		N	Mean	Std. Deviation	Std. Error Mean
Int	Never Invested	184	43.8478	9.86791	.72747
	Have Invested	193	43.6269	10.25029	.73783

Source: Authors' Elaboration

Table 5: Independent samples test based on investment experience

Independent Samples Test										
		Levene's Test for Equality of Variances		t-test for Equality of Means						
									95% Confidence Interval of the Difference	
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	Lower	Upper
Int	Equal variances assumed	.108	**.743**	.213	375	**.831**	.22088	1.03710	-1.81837	2.26013
	Equal variances not assumed			.213	374.964	.831	.22088	1.03615	-1.81651	2.25828

Source: Authors' Elaboration

Based on Table 4, there is a difference between the average scores of the respondents who had invested and those who had never invested. As seen in Table 5, the significance value of Levene's Test for Equality of Variances is 0.743. It can therefore be said that the variance between the groups of respondents who had invested and had never invested is homogeneous, as it has a value of > 0.05. The 2-tailed significance value used is the value on the equal variances assumed line, which was 0.831. This indicates that there was no significant difference between the two groups with regard to investment experience, because it has a value of> 0.05. Furthermore, based on the comparison between the t value and the t table, there is no significant difference between the two groups, because it has a t value <t table, which is 0.213 <1.960.

Table 6:1 Group statistics based on religious background

Group Statistics					
Code		N	Mean	Std. Deviation	Std. Error Mean
Int	Non-Muslim	50	36.62	17.819	2.520
	Muslim	327	26.99	20.468	1.132

Source: Authors' Elaboration

Table 7: Independent samples test based on religious background

Independent Samples Test										
		Levene's Test for Equality of Variances		t-test for Equality of Means						
									95% Confidence Interval of the Difference	
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	Lower	Upper
Int	Equal variances assumed	18.984	**.000**	3.149	375	.002	9.632	3.058	3.618	15.646
	Equal variances not assumed			3.487	70.335	**.001**	9.632	2.762	4.123	15.141

Source: Authors' Elaboration

Based on Table 6, there is a difference between the mean scores of respondents with non-Muslim and Muslim religious backgrounds. As shown in Table 7, the value of significance in Levene's Test and Equality of Variances is 0.000. It can therefore be said that the variance between the groups of respondents with non-Muslim and Muslim religious backgrounds is heterogeneous because it has a value of <0.05. The 2-tailed significance value used is the value on the equal variances not assumed line, which is of 0.001. This indicates that there is a significant difference between the groups of respondents with non-Muslim and Muslim religious backgrounds because they have a value of <0.05. Furthermore, based on the comparison of the t value with the t table, there is a significant difference between the two groups because it has a value of t count> t table, which is 3.487> 1.960.

Conclusion

The study aimed to investigate the effect of religious values, issuers' reputation, knowledge, attitude, subjective norms and perceived behavioural control on the intention to invest in green sukuk. The results can be concluded as follows:

- Religious values have a positive and significant effect on attitude.
- Issuers' reputation has a positive and significant effect on attitude.
- Knowledge has a positive and significant effect on attitude.
- Attitude has a positive and significant effect on the intention to invest in green sukuk.
- Subjective norms have a positive and significant effect on the intention to invest in green sukuk.
- Perceived behavioural control has a positive and significant effect on the intention to invest in green sukuk.
- There are differences in influence between respondents with Islamic and non-Islamic religious backgrounds.
- There is no difference in influence between respondents who have invested and those who have never invested.

From the results of the descriptive analysis and the causal relationship analysis it can be concluded that the respondents tended to "somewhat agree" with their intention to invest in green sukuk. The variable with the highest causal relationship was the relationship between the knowledge variable and attitude, which indicates that with a good understanding of green sukuk, the tendency to assess investment behaviour in it will be better, so will increase the intention to invest in it.

It is indicated that the group of respondents who have those characteristics above is the millennials. The millennial generation lives side by side with technological developments, which makes technology an inseparable part of their life. This technology is used for various purposes, one of which is to seek knowledge and information about green sukuk. Therefore, the existence of technology is one of the factors that can increase knowledge.

In addition, the significant and positive influence of the issuers' reputation variable on the attitude variable shows that the good reputation of the green sukuk provider also affects respondents' assessment. The better the reputation of the green sukuk provider, the higher the attitude, which will increase the intention to invest in green sukuk.

However, there is a contradiction that the influence of religious values on attitude is not very strong (t-value = 1.87); even though statistically descriptive, this variable has the highest tendency, with a total mean of 5.0, meaning respondents tended to "agree". In addition, based on the results of the analysis of the difference test, there are

significant differences between Muslim and non-Muslim respondents. This indicates that respondents have a low tendency between their religious values and the behaviour of investing in green sukuk. These findings are similar with those of reference research conducted by Osman et al. (2019), namely that religious values have a positive and significant influence, but there are differences; in the reference research, the religious values variable has a strong influence. It is indicated that this is due to differences in views between Muslim and non-Muslim respondents, and the use of indicators that tend to be universal.

The results of the difference test analysis also show that there is no significant difference between the investor and non-investor respondents. In addition, the influence of the subjective norms variable on investing in green sukuk is the strongest compared to the variables of attitude and perceived behavioural control. Therefore, individuals can invest in green sukuk with the approval of those around them.

The influence of the variable of perceived behavioural control on the intention to invest in green sukuk shows a positive and significant effect, but is weak. This is due to the lack of information that can be retrieved from individuals, so the tendency to judge whether it is easy or difficult to invest in green sukuk is weak. For the millennial generation, this can be overcome by using technology to find sources of information about green sukuk. The assessment also depends on the resources owned by individuals so that they can assess the ability to invest in green sukuk.

Recommendations

Based on the results of the analysis and the conclusions drawn, knowledge has been shown to have a significant positive influence on the intention to invest in green sukuk. This shows that respondents who have more knowledge about green sukuk have a more positive tendency towards investing in green sukuk, so they also have a higher tendency towards the intention to invest in it.

For this reason, it is suggested that public understanding of green sukuk should be increased by providing more widespread and creative information or socialisation which will attract people's attention. Socialisation can be made online on social media, which is widely used by the community, especially the millennial generation, such as Twitter, Instagram and YouTube. Based on *Thematic Gender Statistics: Profile of Indonesian Millennial Generation* published by the Ministry of Women Empowerment and Child Protection, millennials are also the generation who have an interest in continuing their education to a higher level, so socialisation can be conducted in places such as schools or universities. As a result, public literacy regarding green sukuk will be higher, which will increase the tendency of people to invest in green sukuk.

Increasing public understanding of green sukuk will increase people's intention to invest in it, and increasing the number of investors will influence perceived behavioural control. People who have not invested in green sukuk will feel external factors from the people around them who have become green sukuk investors, which could increase the intention of non-investors to invest. In addition, the influence of the subjective norms variable on the intention to invest in green sukuk is strong, which indicates that individuals can invest in green sukuk with the approval of those around them. However, there are not many investors in green sukuk, so this needs to be increased.

In addition, the respondents do not fully agree that investing in green sukuk is based on religious motivation. Although sukuk are an investment instrument in the Islamic economy, they are not limited to Muslim investors, so this is an opportunity to attract investors from various religious backgrounds. With effective socialisation and marketing, it will be easier for the public to obtain information about green sukuk, so they will be able to increase their interest in finding out more and their desire to invest in it.

For future researchers, the authors recommend that the study could be extended by:

- Including other factors that can also influence the intention to invest in green sukuk, such as the risk and return variable, which is not included in this study as it follows the use of indicators in the reference articles that is the research by Osman et. al. (2019), Warsame and Ireri (2016), which also does not include this variable because it aims to include non-investor respondents.
- Measuring the tendency of respondents to be pro-environmental or not.
- Seeking a sample of respondents with more experience in investing in green sukuk to gauge their investment intentions.

Abstract

The paper deals with the influence of "digital economy" development on production efficiency. The place of a country in the international arena and the welfare of its citizens depend on the ability of the state to implement an effective digitalization policy. In a market economy they help to increase the competitiveness of business entities, increase the income of the population and solvent demand for goods and services, expand international economic ties and attract foreign capital, increase the efficiency of production as a whole. Digital technologies are a factor in the growth of innovations that contribute to the creation and application of digital technologies, a digital platform, in today's Russian economy.

Keywords: Digitalization, Production Efficiency, Innovativeness, Competitive Advantages, Innovations.

Introduction

Improving production efficiency is a key issue in the economy, and it receives particular and significant attention. The modern 4th industrial revolution in production efficiency is associated with the emergence of new technical solutions, production technologies, modernisation of organisational and management structures, i.e. improvement of the management system. [5] With the digitalisation of the economy, the development of digital technologies is necessary in order to increase the level of production efficiency and maintain competitiveness in modern conditions. One of the main sources is the possibility and ability to develop, transform and apply knowledge and skills, as well as the continuous search for and use of new methods and areas of their implementation in modern conditions.

With the introduction of digitalisation into the economy, this process has become revolutionary - new digital production technologies have appeared: artificial intelligence, robotics, smart homes, networks and cities. At present, we are witnessing fundamental changes in the nature of production and management, which are called "Industry 4.0", "Society 5.0", based on fundamentally new platform systems.

The current state of the Russian economy already allows us to note positive developments in digitalization. According to J'son & Partners Consulting data, Russia ranks first in Europe in terms of the number of Internet users and fourth in the world in terms of the number of users of fixed broadband Internet (FBI). However, there is still a serious gap from world leaders.

Scientists and researchers such as V.V. are involved in digital production issues. Alexandrov, A.V. Babkin, A.I. Borovkov, Yu.M. Martinov, V.M. Maruseva, Y.A. Ryabov, V.A. Sarychev, Y.A. Sidorenko, Frolov, K. Schwab, A.V. Schmid, A. Venkatesh, etc.

Digital technologies are currently becoming an important factor in economic growth. Digital technologies connect all sectors of the market economy, contributing to its stabilization and balanced development. [2] The efficiency of their operation is manifested in the acceleration of the reproduction process, which inevitably leads to lower costs, maximization of profits, growth in GDP and national wealth. They also contribute to increasing the competitiveness of economic entities, increasing the population's income and solvent demand for goods and services, expanding international economic ties and attracting foreign capital, and increasing the efficiency of production as a whole. In this regard, it is particularly important to actively develop and continuously improve the Russian digital technology market. At present, the digital technology market is beginning to occupy a priority position in the system of market relations. In general, this will contribute to the formation of a qualitatively new economy - the digital economy.

Role of digital technologies in sustainable development

Digital technology is an important factor that determines the level of competitiveness of modern business leaders, as well as of entire countries. They facilitate the integration of business, science, development institutions and authorities and act as a generator of growth in the innovation economy. [3] Countries that are at the forefront of technology development have a high level of competitiveness and sustainable development. The introduction of new digital technologies creates a powerful foundation for increasing economic efficiency. Digital platforms can help solve pressing social and global problems. They are an important lever for economic development, encourage active business participation, improve the effectiveness of management decisions and the role of civil society in the formation of the country's prosperity. The digital economy model helps to increase the speed of exchange, especially the exchange of innovations. [8] Innovation by its nature has a pronounced multiplier effect, which is manifested in its close relationship with the economic and social component. Innovations contribute to the development of the market for new technologies and new products (goods and services). The formation and effective development of the innovation market is one of the important mechanisms of innovative sustainable economic development.

At present, Russia has not yet overcome the consequences of decisions made 30 years ago in the transition from a planned economy to a market system, which led to the destruction of the existing effective research and development system. As a result of these reforms, the innovative potential of the Russian economy has been reduced. As a result, market innovations in Russia are in poor condition and are only now beginning to develop.

In Russia, internal research and development (R&D) expenditure in 2018 was RUB 1,019.2 billion, which is 2.6% higher than in 2017 (in constant prices). The share of expenditures in gross domestic product (GDP) in 2017 increased from 1.1 to 1.11%. On the whole, the dynamics of internal research and development costs in the period 2013-2018 looks positive [4]. In 2018, the costs of implementing technological innovations in industrial production amounted to 848 billion roubles, and over the period 2013-2018 the volume of investments decreased by 10% (in constant prices), to a greater extent the reduction is carried out at the expense of medium-sized technological production organizations [5]. The dynamics of the number of technologies created annually from 2013 to 2018 had a positive trend - the growth rate was 2.9%, but in 2018 the value of the indicator decreased to 11.6%, or by 2.0%. Based on the results of monitoring the development of the information society in Russia in terms of private indicators, it can be noted that the main growth is in 2015 and covers the industrial sector.

Problems and risks of digital technology development in Russia

In today's world, the development of the digital economy is relevant for all countries, as digital technologies have become an integral part of all areas of society. The introduction and use of digital technologies in economic activity has led to structural changes in many areas of business, politics and society, and the emergence of more modern forms of organisation in the public and private sectors of the economy [6].

Russia's digital economy has been developing in recent years, but there are a number of indicators that show that the Russian Federation lags far behind the leading countries. For example, the slow development and introduction of new technologies, low levels of digitalisation, low rates of productivity growth and a small share of the digital economy in the country's GDP. Russia's competitiveness in the development of its digital economy is reflected in the World Digital Competitiveness- ness Ranking. 63 countries were included in the rating. The USA, Singapore, Sweden, Denmark and Switzerland remained in the leading positions for 2019. Russia was placed on line 38 of the rating, while China rose significantly in 8 positions. To determine the competitiveness of the digital economy, such

indicators as knowledge, technology and readiness for the future are considered. Russia's position in the rating is improving every year, but is still insufficient.

With the introduction of digital technologies, it is first necessary to improve the level of economic security; therefore, at this stage it is important for Russia to raise its level of progressiveness relative to developed countries. Many domestic technologies do not conform to the world standard, which is why Russia imports them from abroad, which creates a technological dependence, which will have a negative impact on the stability of the economy in the future.

Russia has a good starting point for the development of the digital economy. Russia's strengths for the development of a digital economy include the availability of information and communication technologies (ICTs), the population's ability to use ICTs, a high level of adult education and literacy, the development of ICT infrastructure, and more [8]. It should be noted that the programme "Digital Economy of the Russian Federation" approved by the Government is still being implemented. [6]. However, this programme is not clear and has not been sufficiently developed. As a result, this programme does not have a holistic concept of its implementation. There is no description of the concept of digital economy, how it should relate to the state economy, the factors that should be taken into account in the implementation of the programme are not specified, there is no clear structure of the programme, and there is no correlation with other national programmes. If these problems are not eliminated in the regulatory framework, it will be rather difficult to accelerate the scientific and technical development of our country. In addition to the problems in the programme, there are other risks and threats that poor implementation of the digital economy entails. Another factor hindering the development of the digital economy in Russia is the lack of specialists in information technology. "Every year, Russian universities produce about 25,000 IT specialists, but only 15% of them are ready for immediate employment", says the report of the National Research University Higher School of Economics "What is the digital economy? Trends, competencies, measurements" [4].

Methodology

The following common scientific methods were used in the research process: deductive and inductive analysis tools, which made it possible to combine the conclusions of individual authors and formulate their vision of the problem and the method of analysis. Modern literature as well as conference proceedings and statistical data were studied. On the basis of the collected and analysed data, an opinion on the problem and possible ways of solving it was formed.

Results

The main directions and priorities for increasing the country's competitiveness are to increase production efficiency through the development of the digital economy. Based on the Digital Economy programme in Russia, it is planned to increase productivity by 30% by 2024 [1] It is necessary to develop innovative companies in such areas as robotics, artificial intelligence, the Internet and the processing of large data. The task is not only to develop high-tech business in key areas of the 4th industrial revolution and its successful entry into high-tech global markets.

Production efficiency can be improved at the enterprise by optimising processes. Digital technologies can improve the efficiency of managing the enterprise's value chain, optimising resource use through data analysis and time management. [7] Digital solutions (advanced data analysis) allow optimisation of resources per unit of production, which in turn can increase productivity. Russian companies seeking to become a digital ecosystem must react as quickly as possible to changes in consumer behaviour and accept new challenges. The digitalisation of the economy generates products, processes and organisational forms that are distributed on a massive scale and which fundamentally change all areas of production, consumption and behaviour in modern society. At the same time, it is appropriate to recall the lessons of the past, when the introduction of computers required a radical overhaul of management processes, the system of education and training of professional staff. In the era of digitalisation of the economy, serious changes must be implemented. By 2025, 5G mobile communication networks should be deployed, artificial intelligence, quantum computing, distributed registers, advanced robotics, a powerful computing and information and telecommunications infrastructure should be in place, and 97% of Russian households will have broadband Internet access. In Russia, the main obstacle hindering its development is the lack of material conditions for the digital development of industrial production.

In order to solve the problems identified, it is necessary to define priorities for the technological development of the digital economy, identify and develop individual areas of the digital economy. It is necessary to involve regional authorities in the implementation of the programme.

It is necessary to stimulate business development related to the digital economy. In order to provide support, the state can provide guarantees for bank loans, establish investment trust funds and provide support through the public procurement mechanism. It is necessary to provide privileges to companies that develop digital technologies and to provide such companies with orders.

In addition, there is a need to increase the number of IT specialists, which will improve the level of specialists' training and eliminate a serious shortage of staff.

Cyber security systems are also important. There is a need to improve legislation on cybercrime [5].

One more task is to strengthen the introduction of STR in the economy. Continuous acquisition of new knowledge, introduction of innovations in production, stimulation of all this by the state will allow to ensure the development of the digital economy on the technical side and will provide a basis for the full development of the digital economy. The development and introduction of scientific and technical developments in the digital economy is one of the most important conditions. Russia has launched a large-scale system programme for the development of Russian companies, scientific, research and engineering centres. The system of education and vocational training must be adapted to digital economy professions.

Thus, in order to make the market economy in Russia effective, it is necessary to ensure rapid growth of digitalization of all its spheres. To achieve this, it is necessary to eliminate the above-mentioned problems in the development of the digital economy. Digital technologies are creating a new digital space. Only in this way will Russia be able to move away from traditional development models and achieve effective modeling in digital technologies.

The development of digitalisation has an impact on production efficiency. Thanks to the process of "digitalization" many companies in the country managed to take the leading positions in the industry: the first place in terms of efficiency in the industry "Energy" in 2016 - 2018 was taken by PJSC Enel Russia, an increase of 9%; JSC "Concern Rosenergoatom" (2nd place, "Energy") - growth of 33%; "Oil Company Rosneft" (11th place, "Oil and Gas Industry") - growth of 18%. [6].

To sum up, the digital economy is the foundation of the fourth industrial revolution. Innovative technologies are the basis for increasing production efficiency. The implementation of the digital economy should contribute to the competitiveness of its economy by making greater use of digital technologies.

Trends in Transport Documentation in International Law

Konrad Garnowski

University of Szczecin, Szczecin, Poland, konrad.garnowski@usz.edu.pl
ORCID 0000-0002-7976-1333

Abstract

The paper deals with the evolution of regulations of international conventions governing transport by rail (CIM Convention), by road (CMR Convention) and by air (Montreal Convention) regarding the issue of transport documentation. The author points out that the regulations concerning the consignment note, as a main document involved in the transportation process, have undergone significant changes over time. However, some of the regulations are better adapted to current socio-economic conditions than the others. The author states that from the perspective of the instructional and informative function of the consignment note the best solution is provided for in the Montreal Convention. From the evidentiary perspective, all of the conventions set forth a similar rule, according to which the consignment note is currently only a proof of contract. Nowadays this is the only rational solution, which deserves credit. From the perspective of the form of the consignment note the best regulations are included in the additional protocol to the CMR Convention. The legitimising function of the consignment note, connected with the right of disposal, is also regulated in a similar way in all of the acts, but in this case the regulations in force raise some doubts. Due to the technical and technological progress the legitimising function is not as important as it used to be and currently it is mainly a reminiscence of the past legal concepts.

Keywords: Contract of Carriage, Consignment Note, CMR Convention, CIM Convention, Montreal Convention.

Introduction

The contract of carriage is documented in a different way than most types of contract. It is a consequence of the specific features of the contract of carriage. First, this contract is often concluded between parties who are not in any close relationship and are not bound by mutual trust. Second, the sender, as a person entrusting the carrier with goods, is deprived of control over the goods for a certain period of time. Due to the risks arising as a result of these two factors the regulations regarding the contract of carriage were created on the assumption that it is necessary to prepare detailed documentation confirming the conclusion of the contract which would also stipulate the condition of the goods and the events occurring during the execution of the contract.

There is no doubt that this approach was fully justified in the past, when the transportation process was relatively long and communication between participants of the carriage was limited. However, due to the technical and technological progress these issues have acquired a different perspective because nowadays the transportation process is faster and the parties are able to communicate directly in real time.

This raises a question whether the regulations in force are in line with the current socio-economic and technical environment or whether they are just legacy of the past. The aim of this paper is to analyse the evolution of the legal norms regarding documentation of the contract of international carriage by rail, by road and by air and to determine if the adopted regulations are still adequate to the requirements of modern day conditions.

Consignment note – the main document in the contract of carriage

Regulations concerning particular branches of transport provide for various carriage documents. Among others, they include the charter party, the booking note or the bill of lading, which are typical for the maritime transport (see more: Aikens, Lord, Bools, (2006), p. 106, Stec, 2011, p. 1093, Ogiegło, 2013, p. 962). Nevertheless, there is no doubt that one of the most important documents connected with the contract of carriage is the consignment note. This document performs an essential role and is present at each stage of transportation, including the conclusion and the performance of the contract of carriage. The regulations regarding the consignment note can be found in legal acts governing most of the branches of transport. On account of this it is possible to compare the regulations present in particular acts and their evolution.

Cite this Article as: Konrad Garnowski " Trends in Transport Documentation in International Law" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Historically, the practice of drawing up a consignment note was an answer to the development of industrial production. Due to the growing demand for services of entrepreneurs who professionally transported goods over a wide geographical area and the need to pass information between the sender and the consignee it became necessary to create relevant documents (Górski, 1959, p. 31). The origin of the consignment note comes from the "regular" note addressed by the sender to the consignee (Górski, Wesołowski, 2006, p. 23; Górski, Mendyk, 2005, p. 42). This document was attached to the consignment in order to provide the necessary information about the goods. This aspect shows the oldest function of the consignment note – the informative function. Moreover, it also performed an instructional function, because the document also contained information on the required conditions of transportation, which was addressed to the carrier.

Apart from the functions described above, two other functions of the consignment note came into light. The participants of carriage began to include information on the condition of the goods. It also served as a document confirming the carrier's acceptance of the goods for transportation. It created a presumption that the content of the consignment note corresponded to the actual state of affairs. This led to the formation of the evidentiary function of the consignment note. As the consignment note evolved, another function became visible. It was the legitimising function, which involved the authority to exercise the right of disposal of goods on the basis of a copy of the consignment note. This right entitled the particular person holding the consignment note to give the carrier binding instructions regarding further transportation.

The development of the four functions described above has eventually resulted in a specific shape of the consignment note and the contract of carriage in general. The contract of carriage has received a formal character, which meant that the consignment note was an obligatory document for the conclusion of the contract. This document was supposed to incorporate the content of the entire legal relationship and provisions not included in it did not have legal effect (Górski, 1983, p. 140; Stec, 2017, p. 1654). At the same time the handing over of goods was another requirement for the contact to be effectively concluded (Górski, 1983, p. 131; Sośniak, 1974, p. 51; Stec, 2017, p. 1653). This solution can be seen in the first international convention regarding rail transport. Provision of Art. 8 (1) of the International Convention Concerning the Carriage of Goods by Rail signed in Berne on 14 October 1890 (CIM 1890) stipulated that the contract of carriage is concluded once the carrier accepts the goods with the consignment note. This regulation raised some practical problems, most important of which was the fact that it was difficult to classify the actions taken before the conclusion of the contract (for example packaging or loading the goods). Despite this, the formal character of the contract of carriage was present for a long time, even in the initial text of the new convention of 1980 (Uniform Rules Concerning the Contract of International Carriage of Goods by Rail (CIM) – Appendix B to the Convention concerning International Carriage by Rail (COTIF) of 9 May 1980 – CIM 1980). This situation lasted until 1999 when the additional protocol to the convention was signed (the Protocol of Modification signed in Vilnius on 3 June 1999). At this point the contract of carriage by rail lost its formal character.

The same issue was regulated differently in other conventions. The first act governing air transport (Convention for the Unification of Certain Rules Relating to International Carriage by Air signed in Warsaw on 12 October 1929) stipulated that the consignment note had to be issued by the sender on the request of the carrier (Art. 5 (1)), but the absence, irregularity or loss of the consignment did not affect the existence or the validity of the contract of carriage (Art. 5 (2)). The same solution was adopted in the Montreal Convention (Convention for the Unification of Certain Rules for International Carriage by Air signed in Montreal on 28 May 1999), which replaced the Warsaw Convention. The authors of the CMR Convention (Convention on the Contract for the International Carriage of Goods by Road signed in Geneva on 19 may 1956) clearly agreed with this approach and Art. 4 CMR provided for a similar provision. As can be seen, in two of the three described branches of transport the contract of carriage was free from any formal requirements from the beginning. The only exception was transport by rail, in relation to which it took over one hundred years to eliminate the formality of the contract of carriage.

Undoubtedly, depriving the contract of carriage by rail of a formal character was an important step towards liberalization of the contract. There should be also no doubt that this change was justified, since currently there is no reason to impose any formal requirements regarding the conclusion of a contract. Moreover, the consensual character of the contract was the solution to the described problem of the actions taken before issuing the consignment note, because within this approach the contract is concluded once the parties reach an agreement and the activities that follow are considered as a part of performance of the contract. Nevertheless, this was only a change regarding the formation of the contract of carriage by rail. There is still a question whether other regulations were also adapted to the current conditions. To clarify this issue, it is necessary to analyse four main functions of the consignment note in the light of the evolution of the regulations regarding the documenting of the process of carriage.

Instructional and informative aspect of the consignment note

The informative and instructional function of the consignment note are closely connected with the issue of the content of the document. The CMR and CIM conventions are similar in this aspect and provide for a long list of mandatory particulars of the consignment note. According to Art. 6 (1) CMR, the consignment note shall contain eleven particulars, which include among others: the date of the consignment note and the place at which it is made out, the name and address of the sender, the carrier and the consignee and charges relating to the carriage. The CIM convention provides for sixteen particulars (Art. 7 § 1 CIM). However, the current wording of CIM is a result of the evolution of the rail convention. CIM 1890 provided for eleven particulars. This number was reduced to eight in CIM 1980 and later it was increased to the current number of sixteen. Admittedly, rail transport is a specific branch of transport, in which some additional information might be necessary (for example the number of the wagon). Moreover, some of the particulars mentioned as mandatory are in fact conditional particulars (for instance the costs relating to the carriage which must be paid by the consignee (Art. 7 §1 o) CIM) or the number of the railway vehicle, if it is handed over for carriage as goods (Art. 7 § 1 k) CIM)). Nevertheless, even if these conditional particulars are omitted, the mandatory content of the consignment note in transport by rail is still extensive. The same applies to the CMR Convention, under which only one particular has a conditional character (Art. 6 (1)(f) CMR) and apart from that there are ten mandatory particulars.

A solution far different from the others is provided for in the Montreal Convention. The mandatory particulars include only the data necessary to determine the application of the convention (Art. 1) and the limits of the carrier's liability which depend on the weight of the goods (Art. 22 (3)). As a result, Art. 5 of the Montreal Convention stipulates that the consignment note should contain only three particulars. The first one is the indication of the places of departure and destination. The second is the indication of at least one place of landing if the places of departure and destination are in the territory of one State Party and one or more agreed places of landing are in the territory of another State. The third particular is the indication of the weight of the consignment. However, the narrow scope of particulars of the consignment note in transport by air was not present from the beginning. According to Art. 8 of the Warsaw Convention in its original version, the scope of data contained in the consignment note was much wider and included seventeen particulars. This number was limited under the Hague Protocol (Protocol to Amend the Convention for the Unification of Certain Rules Relating to International Carriage by Air, signed in Warsaw on 12 October 1929, done in Hague on 28 September 1955) and as the Warsaw system evolved the particulars were changed, but the number remained the same.

The comparison of the solutions adopted in particular conventions shows two different approaches. The wide scope of information in CIM is probably a reminiscence of the time when the consignment note was a mandatory document for conclusion of the contract of carriage, which had to include all of the important data. It also explains the wide range of particulars in CMR, which, although it never provided for the formal character of the contract, is clearly influenced by the wording of the CIM convention. However, in both cases it should be stated that if currently the contract can be concluded in any form and the consignment note is not necessary, it is also not justified to require the parties to include such a wide range of data. Of course including some of the particulars leads to important consequences (for example providing the information on the costs which must be paid by the consignee creates the obligation for the consignee to pay these costs – Art. 13 (1) CMR, Art. 17 § 1 CIM), but the decision on placing such data should be left to the parties of the contract. These arguments speak in favour of the narrow scope of the mandatory particulars in the consignment note present in the Montreal Convention. Bearing in mind the fact that nowadays the consignment note is a document connected with the performance rather than conclusion of the contract of carriage, this solution seems to be more adequate for the current conditions.

Evidentiary aspect of the consignment note

The evidentiary function of the consignment note is one of the most important roles of this document. The consignment note can serve as proof of the conclusion of the contract and its conditions, proof of acceptance of the consignment and its conditions, as well as proof of the execution of the contract (Górski, 1982, p. 117; Górski, Mendyk, 2005, p. 38; Stec, 2005, p. 150; Dąbrowski, 2014, p. 190-193; Dąbrowski, 2015, pp. 134- 137). However, only the first two aspects are regulated in the conventions. Provision of Art. 8 § 3 CIM 1890 stipulated that the consignment note was proof of the contract of carriage. This provision was not present in the original version of CIM 1980, but according to the 1999 version the consignment note is considered as *prima facie* evidence of the conclusion and conditions of the contract of carriage and the taking over of the goods by the carrier (Art. 12 § 1 CIM). A similar solution was adopted under Art. 12 (1) CMR and Art. 11 (1) of the Montreal Convention. Some of the conventions have provisions which favour different parties of the contract of carriage, for example the CIM and Montreal Convention are favourable for the carrier (Art. 12 §§ 3-4 CIM, Art. 11 (2) of the Montreal Convention), while CMR is more favourable for the sender (Art. 9 (2) CMR). Nevertheless, the general concept of treating the consignment note as *prima facie* evidence is the same.

This solution is also connected with the character of the contract of carriage. Applying the concept of *prima facie* evidence means that the consignment note is not a document constituting the contract of carriage, as it used to be under the CIM convention in the past, but it is one of the tools used to document the legal relationship (see also: Hill, Messent, Glass, 2000, p. 65). This regulation is well-balanced, because on the one hand it places the consignment note in a special position, providing the basis for a preliminary hypothesis, but at the same time it does not finally prejudge the issues covered by the document and allows the parties to prove the facts contrary to the information included in the consignment note. This concept, although introduced many years ago, still remains valid and corresponds with the needs of today's socio-economic environment.

The evidentiary aspect of the consignment note should also be analysed from the perspective of the form of the document. Currently all of the acts provide for the possibility of replacing the written form with the electronic form. According to the additional protocol to the CMR Convention (Additional Protocol to the Convention on the Contract for the International Carriage of Goods by Road Concerning the Electronic Consignment Note signed in Geneva on 20 February 2008) it is possible to issue a consignment note with the use of electronic means of communication (Art. 2 (1)), but the document has to be confirmed with a reliable electronic signature (Art. 3 (1)). A more liberal approach is presented in the two other acts. The Montreal Convention allows substitution of the consignment note with any other means which preserves a record of the carriage to be performed (Art. 4 (2)). Provision of Art. 6 § 9 CIM includes the possibility to establish the consignment note in the form of electronic data registration which can be transformed into legible written symbols. This regulation requires the procedure to be equivalent from the functional point of view, in particular from the perspective of evidentiary value. Moreover, in the report of 8 September 2014 containing suggestions of the working group CIM UR (OTIF, 2014) it was proposed to prioritize the electronic form of the consignment note and allow the authentication "by means of an electronic signature or another appropriate method".

From the evidentiary perspective the possibility to replace a written consignment note with an electronic equivalent is fully justified. The obligation to apply the written form would create unnecessary difficulties for the parties, especially since the electronic signature has equal evidentiary value. However, provisions of the CIM and Montreal Convention go a step further and they do not limit the available forms to the written form or the form with an electronic signature. At the same time, in comparison to the additional protocol to CMR, regulations of these two acts are not fully precise, which creates a risk of uneven application of the conventions in various countries, especially considering the possible differences in national law. Taking into account the role of the consignment note as *prima facie* evidence, it is important to set clear boundaries as to what can be considered as this type of document. Consequently, the best regulation is the one adopted by the additional protocol to CMR. This regulation takes into account the opportunities of technical progress, without introducing too far-reaching solutions.

Legitimising aspect of the consignment note

The consignment note performs also a legitimising function, which is connected with the right of disposal. The right of disposal is the right to issue the carrier with binding statements concerning the carriage (Wesołowski, 2013, p. 234, 237). The statement may include, among others, indication of a new destination or another recipient. The right of disposal may be exercised by the sender (Art. 18 § 1 CIM, Art. 12 (1) CMR, Art. 12 (1) of the Montreal Convention), but also by the consignee (Art. 18 § 3 CIM, Art. 12 (2) CMR and Art. 15 (2) of the Montreal Convention). Execution of the right of disposal entails possession of the consignment note. In order to exercise this right, the entitled person should produce a copy of the consignment note to the carrier (Art. 19 § 1 CIM, Art. 12 (5) CMR, Art. 12 (3) of the Montreal Convention).

The above mentioned rule has not changed in any of the acts over time and it is still necessary to produce the consignment note to the carrier. However, these regulations are another reminiscence of the time when the contract of carriage had a formal character and the issuing of the consignment note was essential. Nevertheless, unlike the evidentiary function of the consignment note, the legitimising function of this document has decreased. In the current conditions, due to globalization of transport and shortened transportation time, producing a consignment note to the carrier in many situations is impossible. As a result, this function of the consignment note has minor practical importance. The electronic form of the consignment note may give a chance to restore the meaning of this function, but so far it is mainly used for evidentiary purposes. This may be a sign that the legitimising function is not as important as it used to be in the past.

Conclusion

Despite many changes the consignment note has undergone, it is still one of the most important documents in the process of transportation. Its functions have evolved and nowadays some of them are less important, but there is no doubt that the document itself is necessary. Currently greater emphasis is placed on the evidentiary function, but also on the instructional and informative aspect of the document. The legitimising function, although still present in the

regulations, plays a minor role, which relates not only to the change of the character of the contract of carriage, but also to the development of transportation. This does not mean that the right of disposal is redundant, but it may suggest the need to re-evaluate the connection between the exercise of the right of disposal and the consignment note.

Abstract

Humanity produces gigantic amounts of data every day. By 2020, the amount of information we want to store to keep them will be around 44 trillion gigabytes. So far, however, our traditional databases are limited in the storage and processing of this large and complex data and we do not have a reliable physical storage medium that can withstand the weather. The most obvious solution is of course to multiply storage units. This general principle is not valid for large data and its realization does not flow from source. So, With the advent of Big Data, a new set of data storage technologies has emerged, but their success is limited and it poses a wide range of problems in the coming years. In the interest of saving time and efficiency, many researchers believe that they have found the solution to this problem, either develop and add an intelligent touch to the available technology (Hadoop and REHDFS), or have discovered solutions. effective in the field of chemistry, DNA for example. The objectives of this article are to present a comparative study between two generations of data storage, a classic relational generation and other more advanced generation that we call NoSQL. Thus, a representation of the two future storage solutions with its advantages and value-added analyses by both approaches.

Keywords: Storage, Big Data, REHDFS, DNA

Introduction

Global digital content is growing rapidly and is expected to reach 35 zettabytes over the next decade. A huge amount of data is generated by social networking websites / applications such as Facebook, Twitter and WhatsApp, as well as the growing number of sensors used.

The massive amount of data collected continuously from these sources contains emerging trends in the market / environment. Most organizations can make informed decisions if they can use information on emerging trends. Organizations that traditionally used data mining tools to analyse historical structured data are now investing heavily in development tools to analyses recent, unstructured, rapidly growing data to understand popular market trends and predict customer behaviour. The knowledge gained through the use of these tools helps to improve their decision-making process, refine their current processes and adapt their policies to better compete in the marketplace. These storage and analysis needs represent a challenge for traditional data storage tools and a big challenge for relational databases, so the evolution of Big Data storage and analysis tools is highly desirable.

The first part of this article presents an experiment that aims to compare different databases belonging to different generations (relational and NoSQL). In order to become familiar with these new technologies and extract values added by NoSQL databases.

The second part is devoted to the analysis of two approaches that have the objective of improving the process of storage and management of Big Data. The first solution is an Enhanced HDFS (REHDFS) which explores different placement and block read strategies, proposes a scalable architecture and load-based block access strategies to give

better results than other strategies. extraction of blocks. More features of reading and random writing based on pessimistic and optimistic models. The second solution is the DNA strands, which demonstrate an incredible storage power of thousands of gigabytes in a perfectly reliable manner, and which could be the solution to store a maximum amount of data on a minimum of space.

Related work

The volume of data has increased considerably from various sources (transactions, social networks, geolocation) and the amount of data produced by humanity is increasing rapidly every year and will surely grow very rapidly in the years to come.

In 1987, a group of researchers from the University of California at Berkeley developed RAID technology. they investigated the possibility of having two or more hard drives recognized as a single entity by the system. The result was a storage system with much better performance than single hard drive systems, but with very low reliability and not suitable for big data. (Sharma & Jha, 2020) proposed a secure system for storing data in the cloud virtual space, they determined the architecture of cloud storage platforms, the associated risk when migrating data to the cloud storage platform and different models of security and security analysis of current cloud platforms. (Erraissi & Belangour, 2019) presented Hadoop, the new Big Data storage and processing technology with its different components, as well as a meta-model for the storage layer which aims to allow Big Data distribution providers to offer standard and unified solutions for a Big Data System. But unfortunately, the main problem is that our production of information exceeds our storage and processing capacity and despite the advent of all these technologies, their success and durability is limited and still pose problems in its development path.

Theory

This part is dedicated to introducing the relational model and identifying the most important challenges it faced that led to the emergence of the big data and NoSQL.

The Relational Model

Between 1965 and 1975, with the development of computing in large accounts, the need to organize data according to a model that would allow a clearer separation between the logical representation of data and their physical organization was more and more feel. The relational data model was defined in 1970 by the IBM computer scientist Edgar F. Codd, and published in his article A Relational Model of Data for Large Shared Data Banks. Since the 1990s, the relational data model has been used in the vast majority of databases.

Definition

The relational model was defined in 1970 by Codd. This proposal succeeded hierarchical models and networks, with the aim of defining a model that is easy to understand, based on solid mathematical bases (logic and set theory), and which can lead to an improvement in the performance of the tools. The basic idea is simple: put the data "flat" in arrays, so that every value appearing in the "boxes" of the array is atomic. This simplification is the main explanation for the performance of the relational model, because it avoids recursive processing (traversing complex graphs and trees) (Badri, 2009).

The structure of a relational database is based on set theory. Recall that a set is an unordered collection of distinct elements, to be distinguished from the sequence (when the elements are ordered) and from the multiset (when we accept duplicates).

The relational model makes it possible to represent the data that we are going to manage using a very small number of very simple concepts:

- Relationships or tables: rows and columns
- Value domains: each cell of a table takes a unique value in a predefined domain.
- The keys: there are boxes whose values must be unique and not zero.
- Foreign keys: there are boxes that must take an existing value in the boxes of another table (Crozat, 2018).

ACID Properties

Stability and robustness of databases are evaluated according to their respect for ACID properties:

1. Atomicity: Within databases, the atomicity of transactions means that all changes to data are done totally, or not at all. that is, if a transaction is not completed, the database returns to its initial state.

2. Consistency: Consistency means that transactions must meet the data integrity constraints of the database, so any transaction that begins execution in a database in a consistent state must leave the database in a consistent state.

3. Isolation: Isolation means that a transaction is protected from the effects of other transactions running concurrently, i.e. successful transaction writes and reads will not be affected by writes and reads from other transactions, only they succeed or not (Bastie, 2018).

Limitations of relational DBMS

The relational model is based on a solid mathematical model based on the logic of first-order predicates. It is based on simple concepts that are both strength and weakness.

Distributed storage is a real obligation that weighs on relational systems today, to which is added the complexity of data structures manipulated by systems.

- Relational databases and impedance defect.
- Data type.
- Limitations of SQL Language.
- Non-optimal query problem after using joins (Bloor, 2003).

The emergence of Big Data and NoSQL

Software evolutions naturally follow hardware evolutions. The first DBMS were built around mainframes and depended on the storage capacities of the time. The success of the relational model is due not only to the qualities of the model itself, but also to the storage improvements that reduced data redundancy allows. With the increase in bandwidth on the Internet and the fall in the cost of moderately powerful machines, the generalization of network interconnections, new possibilities have emerged, in the field of distributed computing and virtualization, this is the Big Data and NOSQL.

Big Data

Big Data refers to the explosion in the volume of computer data traveling around the world. This data becomes so large that it can no longer be stored in full-sized databases, leading to the use of increasingly powerful computer tools to store and manage it. Big Data can be defined by its four major characteristics, all starting with the letter V: velocity, variety and volume.

Fig. 1: The three Vs of big data

Each component represented in Figure 1 is shortly expressed below.

1. Variety: Variety refers to the different types of data that we can use, it makes Big Data really big.

2. Volume: Volume or size of data refers to the huge amounts of data generated every second is now more than terabytes and petabytes.

3. Velocity: Velocity refers to the speed at which new data is generated and moves and required not only for big data, but for all processes as well (Sagiroglu & Sinanc, 2013).

NoSQL

Relational databases do not lend themselves well to the demands of massively parallel applications that use large amounts of data. NoSQL (Not Only SQL) databases mark a fairly abrupt break with the way data schemas are conceived in recent decades.

There is a plethora of NoSQL solutions that respond more or less well to special needs. The purpose of this part is to quote the existing solutions. However, these approaches can be broadly grouped into four categories:

1. Key-Value Store: a key-value database (also called a key-value store and a key-value store database) is a type of NoSQL database that uses a simple key / value method to store data. Among the open-source key-value DBMSs are: Memcached, Redis, Riak and Voldemort.

2. Document Store: a document-oriented database contains documents, which are records describing document data, as well as actual data. Document database does not care about simultaneous read and write performance, but rather about ensuring large data storage and good query performance. Typical document databases are MongoDB, CouchDB (Jing, et al., 2011).

3. Column Store: a column-based DBMS is a database management system (DBMS) that stores data tables by column rather than by row. Column oriented databases are HBase, Yale University HadoopDB, Facebook's Cassandra.

4. Graph Store: Offer a model based on graphs with nodes, edges and their respective properties. This category excels at handling data with a high degree of interdependence and allows you to quickly traverse complex data by traversing relationships between nodes (Acheli & Khour, 2017). Neo4J is the most popular graph-based base right now.

The CAP theorem

The CAP was initially presented in the form of "consistency, availability, partition tolerance: choose two"(that is, you can have CA, CP, or AP, but not all three).Many authors now prefer the following formulation: if there is no network partition, a system can be both consistent and available; when a network partition occurs, a system must choose between consistency (CP) or availability (AP) (Kleppmann, 2015).

1. Consistency: Data has only one visible state regardless of the number of replicas.
2. Availability: as long as the system is running (distributed or not), the data must be available.
3. Partition Tolerance: Regardless of the number of servers, any query should provide a correct result.

Experience Environment

This study was conducted in a single-user environment characterized by the following hardware and software aspects:

Software

- Oracle VM VirtualBox
- Cloudera-quickstart-vm-5.13.0-0-virtualbox

Hardware

- Intel (R) Core (TM) i3 CPU -370M 240GHz, 8GB RAM

Comparative study of two generations of database (relational vs NoSQL)

The objective of this part is the presentation of the different storage architectures namely relational storage and NoSQL using several tests on NoSQL databases.

Simulation: relational (MySQL) vs NoSQL (HBase)

This experiment aims to compare the relational database (MySQL) and the NoSQL database (HBase) at the level of data storage and processing and also represents the strengths of HBase compared to the relational model.

Transfer data from a relational database (MySQL) to a NoSQL database (HBase)

The purpose of this test is to transform a database from one MySQL relational architecture to another with a different architecture and operation (HBase), in order to extract the strong points and properties added by the NoSQL databases.

The structure of the retail_db database with which we will work is shown in the following figure.

Fig. 2: Retail_db database

- ***Import the database into HDFS with sqoop***

In order to transform the database from MySQL to HDFS and HBase, we need to find a tool that allows easy transfer of structured data while preserving the structure. Apache Sqoop is the right solution.

```
$ hadoop fs -mkdir -p /staging/mysql/retail_db
```

```
$ sqoop import-all-tables --connect jdbc: mysql: // localhost: 3306 / retail_db --username root -
-password cloudera --warehouse-dir '/staging / mysql / retail_db' -m 1
```

The result:

```
cloudera@quickstart:~
File  Edit  View  Search  Terminal  Help
[cloudera@quickstart ~]$ hadoop fs -ls -R /staging/mysql/retail_db/
drwxr-xr-x   - hdfs supergroup          0 2019-06-28 10:13 /staging/mysql/retail_db/categories
-rw-r--r--   1 hdfs supergroup          0 2019-06-28 10:13 /staging/mysql/retail_db/categories/_SUCCESS

[cloudera@quickstart ~]$
```

Fig. 3: Importation of databases into HDF

- ***Import the database into HBase with sqoop***

The following steps describe how to import the data from the DBMS to the Hadoop HDFS database.

1. Creation of empty tables in HBase.

Sqoop does not use a default table name when importing into HBase. Before all, it is necessary to create tables in HBase of families of columns.

```
hbase(main) :001 :0> create 'departmentsdemo', 'departmentfm'
hbase(main) :001 :0> create 'categoriesdemo', 'categoryfm'
hbase(main) :001 :0> create 'customerdemo', 'customerfm'
hbase(main) :001 :0> create 'order_itemsdemo', 'order_itemfm'
hbase(main) :001 :0> create 'orders', 'orderfm'
hbase(main) :001 :0>list
```

Import the tables

```
& sqoop import   - -conncet jdbc: mysql://localhost/retail_db --table categories --hbase-table
categoriesdemo --column-family categoryfm --hbase-row-key Category_id -m 1
```

The result:

Fig 4: Importation of databases into HBase

The flexibility of the HBase model

HBase does not have a fixed predefined scheme which makes it very flexible. In addition, there is theoretically no limit to the number of column families that can be created and the number of columns in each family. Once again, everything depends on the needs of the client, you the creator of the HBase table and the cluster capacity.

Adding family columns

A new family column is added using the "alter" command

```
hbase(main) :001 :0>alter 'categoriesdemo', {NAME=>'categoryfm_4'}
```

The notion of timestamp in HBase

Compared with other databases, HBase does not differentiate between adding rows to the table (write operation) and updating them (edit rows operation). Each update operation is an addition of a new version of the same data line. The versions of the same row are distinguished using a timestamped value called Timestamp. This Timestamp is the date to the millisecond to which the update was made. By default, HBase stores the last 3 versions of a column value (while automatically removing old versions). The depth of "Versioning" can be controlled and configured (Chokogoue, 2019).

System Properties Comparison HBase vs MySQL

The following table presents a comparison of the different properties between HBase (NoSQL) and MySQL (relational model).

Table 1: Properties Comparison HBase vs MySQL

Name	***HBase***	***MySQL***
Description	Wide-column store based on Apache Hadoop and on concepts of BigTable	Widely used open source RDBMS
Primary database model	Wide column store	Relational DBMS
License	Open Source	Open Source
Implementation language	Java	C and C++
Data scheme	schema-free, schema definition possible	Yes
SQL	No	Yes
Partitioning methods	Sharding	horizontal partitioning, sharding with MySQL Cluster or MySQL Fabric
Replication methods	Master-master replication	Master-master replication
MapReduce	Yes	No
Consistency concepts	Immediate Consistency or Eventual Consistency	Immediate Consistency
Transaction concepts	Single row ACID (across millions of columns)	ACID
Concurrency	Yes	Yes
Durability	Yes	Yes

SQL databases are mainly called relational databases (RDBMS); whereas the NoSQL database is mainly called distributed or non-relational database. Among the key difference between relational (Mysql) and NoSQL (HBase):

- **Schema**: relational databases have a predefined schema while NoSQL databases have a dynamic schema for unstructured data.

- **For the type of data to be stored:** SQL databases are not suitable for hierarchical data storage. However, the NoSQL database is better suited for hierarchical data storage because it follows the key-value pair method to store data similar.

- **For complex queries:** SQL databases are perfectly suited to the environment requiring many queries, while NoSQL databases are not suitable for complex queries.

- **Scalability:** In most situations, SQL databases are vertically scalable. You can manage the increased load by increasing the processor, RAM, SSD, etc. on a single server. On the other hand, NoSQL databases are scalable horizontally. You can simply add a few additional servers easily to your NoSQL database infrastructure to handle heavy traffic.

- **For properties:** SQL databases focus on ACID properties (Atomicity, Coherence, Isolation and Durability), while the NoSQL database follows the Brewers CAP theorem (Coherence, Availability and Partition Tolerance) (Kleppmann, 2015).

Smart approaches for optimal storage management in Big Data

In this part we will present two Big Data storage solution. the first solution is an REHDFS system to improve the HDFS system and the second is DNA, a biological storage medium capable of archiving our data in the long term.

Approach 1: The REHDFS system

The Hadoop Distributed File System (HDFS) is a highly scalable and fault-tolerant distributed file system that can be deployed on low-cost hardware. The content stored in the HDFS system is partitioned into blocks, which are replicated to multiple data nodes. Different block placement strategies can be used to make it highly fault-tolerant and to improve throughput and access time. The HDFS system allows the user to specify the block size to be used to partition a given file, to issue only sequential read and append operations. It does not allow the user to perform random read and write operations. This section provides an enhanced HDFS (REHDFS) that explores different placement and block read strategies, a load-based block-access strategy, pessimistic and optimistic models for performing random read and write functions (Rao Chandakanna, 2018).

This part is dedicated to represent the HDFS system and its additional functionalities compared to the traditional HDFS system.

HDFS: architecture and functionality

Hadoop Distributed File System (HDFS) is a distributed file system that stores and retrieves files in record time. This is one of the basic components of the Hadoop Apache Framework, and more specifically its storage system. HDFS Hadoop is one of Apache's top-level projects.

Due to its massive capacity and reliability, HDFS is a storage system that is very suitable for Big Data. In combination with YARN, this system increases the data management capabilities of the HDFS Hadoop cluster and thus enables the efficient processing of Big Data. Among its main features, there is the possibility of storing terabytes or even petabytes of data.

Fig. 5: Apache HDFS Architecture

HDFS is a distributed file system and follows the master-slave architecture. HDFS uses a cluster to store and manage data. The HDFS cluster includes a master server (Namenode) and the number of slave servers (Datanodes). A master server serves as a name node that manages the namespace of the file systems and accesses the files stored on the file system by the clients while the slave servers contain data nodes that actually store the data files (Bastien, 2017).

Limitation of HDFS storage system and new functionality with REHDFS storage system

HDFS allows the user to perform read and append operations only on files. To modify a single byte of a file, you must create a new file with the modification and replace the old file with the new file. Consider the following scenario. A project team has to manage a larger set of files related to their project. They can be changed by any member of the project team, but consistency is essential and must be highly available and fault tolerant. Project team members must modify these files frequently using different tools to work effectively with the files. Random access and random write features are essential in such scenarios. Applications that support such scenarios should ensure that the data is highly available and fault tolerant.

A group of people or a set of processes that need to work consistently on a set of files can keep the files in HDFS. When data consistency is the most important factor, the current model of copying the file locally from HDFS, making

changes and replacing the file in HDFS will not work. With the current template, one user's changes can be overwritten by changes made by the other user. (Rao Chandakanna, 2018)

Providing the random write operation is a difficult problem to solve in the HDFS context. This involves propagating changes to all replicas (hosted on different data nodes) consistently, coordinating different nodes, enforcing ACID properties, and providing a recovery mechanism for data nodes that were down during a transaction.
The proposed solution is an extended storage system (REHDFS), with equipment added to the HDFS architecture, which solves several problems and allows the user to experiment with various operations at the level of storage and data processing.

The new features provided by the REHDFS system:

- Block placement strategies.
- Choosing the block size.
- Block caching and retrieval strategies.
- Data Node selection strategies.
- Random read and random write.

REHDFS Architecture and Features

The REHDFS architecture is shown in the figure above. Its main components are a name node, a set of data nodes, a client module, a cache module, and a lock / validation manager.

Fig. 6: Extended HDFS architecture based on RMI

In order to achieve additional functionality and support random write operations, a new component called Lock / Validation Manager is added to the HDFD architecture, which supports two models for the implementation of the operation of random writing, one pessimistic model and another optimistic.

Location and access transparency

Each file stored in REHDFS has a unique file path that begins with a well-known prefix (for example, dfs: //) to distinguish itself from file paths used in other file systems. The path to a REHDFS file hides the details of the storage location of the blocks in a given file and gives the transparency of the location. The client module contacts the name node to retrieve the metadata associated with a given file. The end user uses the API of the client module to work on a given file. The Client module provides an API similar to that of a local file system, which provides access transparency (Rao Chandakanna, 2018).

Placing blocks on datanodes

Block placement strategy for achieving maximum fault tolerance is described in Algorithm 1.

Input*: File F to be placed in HDFS, block size BSF, replication factor RF, number of Data Nodes in the primary rack MF, number of racks r, input constraint (RF> r).*

Begin
blockCt = ceiling (NF /BSF);

```
nextDataNode = 1;
For Each i from 1 to blockCt do
  Place one copy of blocki on each non-primary rack;
  Replica = 0;
   For Each replica of blocki form 0 to RF – r do
      Place blocki on the nextDataNode of primary rack;
      nextDataNode = (nextDataNode % MF) + 1;
      replica ++;
   End for
End for
Return
```

Algorithm 1: Block locations for maximum fault tolerance

When you want to place a file in HDFS is divided in one or more blocks, the number of blocks needed depends on the file size and the size of the block, and it is calculated from these last. A copy of each block is placed on each non-primary rack, the remaining replicas are placed on different data nodes in the primary rack to ensure maximum fault tolerance (Rao Chandakanna, 2018).

Retrieving from REHDFS

Different techniques for quickly downloading blocks from data nodes are described in this section.

1. On demand/Look ahead block retrieval

The strategy for recovering blocks from the datanode is described in Algorithm 2.

```
Input: File descriptor (Fdes), buffer to Keep the content (buffer), byte count to read (size)
Begin
currentPosition = getValue (Fdes, '' CurrentPosition '');
blockSz=getValue (Fdes, ''BlockSize'');
lookAheadBlkCt = getValue (Fdes, ''LockAheadBlockCt'');
endPosition = currentPosition + size – 1;
startingBlock = curPos/blockSz;
endingBlock = (endPosition /blockSz);
For Each i from startingBlock to endingBlock do
  If (blocki is not in Cache) Then
     Download blocki from a Data Node that hosts;
    Add the blocki to the Cache;
  End If
End For
Copy the content from download blocks to buffer;
If (lookAheadBlkCt > 0) Then
  Create a thread to download blocks to buffer;
  Add the download blocks to the Cache;
End If
Return
```

Algorithm 2: Location of blocks for maximum fault tolerance

In response to a client's read () request, one or more blocks retrieved and cached by the Client module. As described in Algorithm 2, the client module calculates the block numbers corresponding to the user's read () request. If a block retrieved from a data node is not present in the cache is placed directly to the cache. After specifying the number of look-ahead blocks, the client starts a thread to retrieve the blocks ahead of the current block asynchronously.

2. Data Node selection strategies

When multiple data nodes in the main rack host a block, the download duration of the block depends on the data node selected to retrieve the block. REHDFS supports three strategies, namely First, Random, and Load Based to select a data node in all data nodes in the main rack to download a block.

```
Input: Block id(blockId), Data Nodes hosted the block (dataNodeList), Policy (policy)
Begin
If (policy is First) Then
   dataNode = getNodeAt(dataNodeList,1);
Else if (policy is Random) Then
  m = numberOfNodesIn (dataNodeList);
  selectdIndex = random (1, m);
```

```
  dataNode = getNodeAt (dataNodeList,selectedIndex) ;
Else (policy is LoadBased)
   dataNode = minAvgResponseNode( dataNodeList)
End if
block = donwload (blockId, dataNode);
Record the block download time (dTime) ;
Add the block to the Cache;
          //Revise the average response time
If (policy is LoadBased) Then
   qSize = getQueueLenght(dataNodeName) ;
   avgRespTime = getAvgRespTime(dataNodeName) ;
   EstDownloadTime = (avgRespTime*qSize) + dTime ;
   avgRespTime = EstDownloadTime/(qSize+1) ;
   setAvgResponseTime (dataNodeName, avgRespTime) ;
End If
Return
```

Algorithm 3: Block download based on a load

Random access and random write

The first part of this section covers the details of implementing a customer's non-sequential access requests. The models for implementing random write are discussed in the last part of this section.

1. Random Access

The strategy of random access is described in the algorithm 4.

```
Input: File Descriptor (FId), bytes to move(offset), Relative to begin/end/current (whence)
Begin
      //Calculate the file pointer position w.r.t beginning
If (whence is Begin) then
     FilePosition = offset;
  Else If (whence is End) Then
  FilePosition = FileSize - offset;
Else (whence is current) then
  FilePosition = FilePosition + offset;
End If
If (filePosition is beyond the range) then
  Return error (Invalid seek Parameters);
End If
metadata = get Metadata (FId);
block Size = getBlockSize(metaData);
blockNo = FilePosition/blockSize;
blockId = getBlockId(blockNo,metaData) ;
If (blockId is not in the Cache) then
   dataNodes = getHostingNodes (blockId,metaData) ;
   block = policyBaseddownload (blockId, dataNodes, policy);
End If
setFilePosition(FId, filePosition);
Return
```

Algorithm 4: Random Access (fseek)

The client module offers transparency of access. It allows the user to access a file as if it were a local file, i.e. access any part of the file by issuing an fseek request (fileDescriptor, offSet, whence). HDFS does not support random access and random write (Rao Chandakanna, 2018).

2. Random Write

A file in HDFS is divided into one or more blocks, and each block is replicated to multiple data nodes. Replicas make it difficult to implement random write and are not supported by HDFS. REHDFS offers several models for implementing random writes. Random entries can be made using either an optimistic or a pessimistic approach.

- **File Level Lock with a Pessimistic Model (FLPM)**

As illustrated in Figure 7, a file in a pessimistic model can be in one of three states: closed state, open state, and locked state.

Figure 7: State diagram of a file in a pessimistic model.

Each file starts in a closed state. Opening the file in read (write) mode changes the state from closed to open (locked) and registers the client with the lock manager (LM). the diagram describes the states of a file which change according to the actions and requests of the clients (Rao Chandakanna, 2018).

- **Optimistic model with file level consistency (OMFC)**

As shown in Figure 9, a client of the optimistic model can be in one of four states: inactive, register (register with the validation manager), update (by modifying the read blocks), and record (trying to save the modified blocks). the following diagram describes the states of a file in the optimistic model.

Figure 8: The state diagram of a customer in the optimistic model

- **The FLPM and OMFC comparison**

In the pessimistic model, to modify a file, the client must acquire a lock from the lock/validation manager. In the optimistic model, a client can modify the blocks of a cached file without acquiring a lock. The request to save changes may fail when other clients are running on the same file.

The table compares the two models (FLPM and OMFC) in terms of request overload when several clients are working on the same fil.

Table 2: comparison of FLPM and OMFC

Model	*Issue*	*Description*
FLPM	Deadlock	May occur when multiple clients attempt to operate on multiple files in a specific order.
OMFC	Starvation	May occur when a client's repeated attempts to validate () request fails
FLPM	conflict resolution	The lock associated with the file is issued to only one client. Rest of the clients are put on a waiting queue.
OMFC	conflict resolution	The client with lowest timestamp will succeed and the rest of the clients will rollback (invalidate the blocks in the cache and restart the transaction by calling the open () call.).

Approach 2: DNA genetic storage media

The storage volume of computer data is a challenge but the persistence of data over time is another. Today All of the storage technologies we have developed have limited life cycles and are sensitive. There is therefore a growing need for computer media capable of storing a large amount of data in a sustainable manner. The idea of biological storage of information by DNA comes into play to address these issues and this continuing demand and that sees as an ideal storage medium of choice for the next generation because of their durability and their high density of information.

Fig. 9: DNA-based data storage—the big data storage solution of the future (Church & Edward, 2014)

Presentation and system model of DNA data storage technology

DNA, or deoxyribonucleic acid, is the carrier of the genetic information of all living organisms on the planet. This is a very long, but nevertheless very simple, double helix molecule. Absolutely all the information necessary for the development and functioning of a living being is there.

Modern DNA synthesizers can concatenate the four DNA-based nucleotides to form arbitrary-chain molecules of molecules. Each nucleotide (nt) in such a chain called oligo is considered to represent in principle 2 bits of digital data. Thus, the digital data can be stored in oligos, and even the stored data can be retrieved by reading the data representing oligos with DNA sequencers (Takahashi, et al., 2019).

synthetic DNA is the new technology for data storage, it is extremely dense which can store data up to 1 exabyte/mm3, no electricity is required to operate and has half-life of 500 years in harsh environment.

Fig. 10: Big Data in Synthetic DNA

The model in figure 10 shows the advantages of storing big data in synthetic DNA as compared to other traditional methods. For encoding and decoding Huffman coding is being used. We have also figured out that the cost for encoding data in synthetic DNA is 1.55$ approximately per 1000 Gigabits (125 Gigabytes) of data. Also, the cost for decoding data from synthetic DNA is 0.0275$ approximately per 1000 Gigabits (125 Gigabytes) of data. This model clearly depicts that how beneficial it is to store data in synthetic DNA (Sharma, et al., 2019).

Automated storage on DNA

Before a file can be written into the DNA, its data must first be translated from 1 to 0 into A, C, T, and G. The encoding software module is responsible for this translation and for the addition. the error correction in the sequence of the load. Once the sequence is generated, additional bases are added to ensure that its primary and secondary structure is compatible with the reading process and the DNA sequence is sent to the synthesis module to be instantiated into molecules of Physical DNA (Takahashi, et al., 2019).

Fig. 11: The steps of coding the data on DNA

Storage process

The researchers succeeded in making a machine capable of automatically transforming numerical data (sequences of 0 and 1) into DNA sequences (nitrogenous bases A, C, T and G). The prototype is made with glass bottles where synthetic DNA strands are made, and using an Oxford Nanopore sequencer to decode and reconvert them into digital data (Valdek, 2019).

Fig. 12: Block diagram of a DNA storage system

The system consists of the following components:

- The source data in bits.
- Encoding mechanism including all error correction codes and nucleotide bit modulation.
- Synthesis of the DNA of several strands of DNA.
- PCR amplification of DNA pools
- Storage of DNA archives.
- DNA sequencing.
- Fusion and assembly of several strands of DNA.
- Demodulation and decoding of all codes for reliable recovery (Goela & Bolot, 2016).

Possible approach to the DNA computing for Big Data

The process of storing information in the DNA molecule goes through two stages:
A. Process
B. Encoding / Decoding algorithm (Hakami, et al., 2015).

- Encoding algorithm

1) Read data stream: A
2) Check size of the data [r,c,n] = size (A) where
r = rows, c = columns, n = number of matrix
3) Calculate DNA sequences size for image
4) Create a zero matrix of DNA sequences size
5) While DNA sequences size = max

A. Convert even smallest piece of data to binary form.
B. Insert binary DNA code of an individual data cell to DNA sequence.
C. Continue till all of max size of DNA sequence is reached

- Decoding algorithm:

1) Read DNA sequence
2) Calculate size: length, size of individual cells
Convert DNA to real data decode

A. Convert one cell to data
B. Insert the converted value to template data matrix
C. Stop when entire DNA is converted

Error Correction Code

During the process of storing data in DNA, several types of errors may occur, including insertion, deletion and substitution errors in oligonucleotides, missing DNA strands, synchronization errors on several oligonucleotides with the same address.

in order to overcome these problems and to design a feasible system, several levels of error protection are required. the system equips each oligonucleotide with a unique address code in order to identify it. Digital information is stored on multiple oligonucleotides, protected by modern two-dimensional matrix codes. While accuracy of recovery is paramount, these codes must be effective in reducing the overhead costs associated with DNA synthesis and sequencing (Blawat, et al., 2016).

The benefits of storing DNA data

As mentioned above, global data is growing sharply at an exponential rate. Traditional media cannot sufficiently meet the demands of large data storage. DNA can serve as a digital data storage medium, with its potential advantages such as high density, high replication efficiency, long-term durability and long-term stability.

Information stored in DNA can be recovered even after thousands of years, provided the DNA is stored in dry, dark and cold conditions. The storage process is done by encoding and decoding binary data to and from synthesized short DNA strands and the data is stored in a long virtual DNA molecule. Short strands will allow easy manipulation of the data (Sharma, et al., 2019).

Scientists have managed to recover DNA frozen for 60,000 years, showing that if stored under ideal conditions, it can outlast anything humans have invented. Thus, storing them in DNA media is simple, convenient and cost-free and can maintain data fidelity for a long time (Sun, et al., 2019).

Conclusion

The current production of data at exponential rates has created a demand for better storage devices, and finding new solutions for sustainably storing our data is becoming necessary. So, to store more data, faster, more sustainably, and with less energy. Researchers have turned to new approaches that have the goal of adapting and adding improvements to the technology and the means available, or discovering new, more effective and efficient ways.

In this document, I gave a brief overview of the different solutions that exist today, how they work and, above all, it's added values.

The first approach is a process of improving the HDFS storage system which presents a more powerful REHDFS. Thanks to the algorithms the system is able to perform additional tasks, for example: experimenting with various block placement strategies, access to the blocks proposed according to the load, different levels of lock granularity, random access to a given file, plus the random writing based on two optimistic and pessimistic models. Among the points that can be noticed at the level of the two models of the random writing is that in the pessimistic model (FLPM), a client must acquire a lock on a file before being able to modify it. When a client group wants to modify a set of files, the order in which the requested locks can cause a deadlock. On the other hand, in the optimistic model, all clients are allowed to modify the blocks in their respective caches. However, only the client with the minimum timestamp will be able to save their changes. This makes the OMFC model more than the FLPM model when multiple clients are running on the same file. And in the future, the REHDFS will be expanded to support more detailed random write operations and make it more secure.

The second approach is the DNA memory strands. The solution for a sustainable storage of information that gave us a chance to store a large volume of data on a very small volume. But we are facing a challenge with this technology because it is still very expensive and it requires a large team and high-end hardware.

We have arrived at the end of this paper but we cannot conclude without giving a glimpse of the future and an idea about new research. Researchers in chemistry, biochemistry and computer science at the University of Ghent, Belgium, have developed a revolutionary new data storage technique inspired by the idea of genetic storage of information. Powdered data storage could become a viable alternative and a more environmentally friendly technology.

Data storage in powder is an idea that might seem totally surreal. Yet researchers at the University of Ghent, Belgium, have managed to develop this technology. An innovation that could well replace USB keys and hard drives in the not-so-distant future.

Indeed, unlike traditional storage media, the powder does not require the massive use of heavy metals. In addition, it does not require the use of energy-intensive servers to ensure data security. For more information on this innovation, the full study published in the journal Nature Communications by (Martens, et al., 2018) .

Abstract

The article is devoted to the analysis of correlation between transport infrastructure indicators and social and economic performance in a region. Correlation analysis of the given indicators for 57 subjects of the Russian Federation located in the European part of the country was carried out. As a result, a high correlation between the state of transport infrastructure and services of road transport as its part, and the indicators characterizing social and economic development of regions was identified. The study uses logical and econometric analysis to perform calculations and verify the results. The revealed correlation also confirms the efficiency of regions' transport infrastructure investments in terms of complex social and economic effect. The correlation suggests the transport infrastructure indicators maximally connected with the development of the region for influencing, helps to forecast the impact of the transport infrastructure investments on the development of the economy, growth of the living standards indicators in the region.

Keywords: Region Economy, Transport Infrastructure, Correlation, Service Infrastructure of Road Transport.

Introduction

Transport industry in Russia is a traditionally important and, it seems fair to say, vital industry. According to Analytical center for the government of the Russian Federation (2018) transport industry in 2018 accounted for 6.2% of Russian GDP. 2.6% of all employed people in the Russian economy worked in this industry (estimated by the authors based on Rosstat (2018) and Rosstat (2019)). Transport industry is the basis for the intercommunication and territorial integrity of regions, federal districts and, ultimately, a country, an important part of the infrastructure for population life and activities, for economy functioning, and for commodity exchange.

Transport and logistics are important for increasing the efficiency and competitiveness of the Russian economy. Makarov (2018) mentioned, "Logistical costs is 19% of GDP, while in the Western world it is about 7-11%".

The task to increase the efficiency and competitiveness of the Russian economy has been set at the highest government level for a number of years, and this growth can be achieved not least by increasing the efficiency of the transport industry. The industry is one of the drivers of the economy. Transport industry contribution to the Russian GDP in 2018 was 6.2 % (Analytical center for the government of the Russian Federation (2018)). Average nominal wage for the group of industries is 41% higher and its growth rate is 42.5% higher than the statistically average wage in the Russian economy (refer to Table 1).

PISKOVATSKAYA" The Impact of The Region Transport Infrastructure and Services on The Social and Economic Performance of Russian Regions" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Table 1: Ratio between the main indicators of the transport complex and the Russian economy in 2018 (estimated by the authors based on Rosstat (2018) and Rosstat (2019))

Compared indicators	Russian economy	Transport complex	Ratio between the indicators, %
Growth rate (GDP for Russian economy, and freight turnover for transportation industry), %	2,30	2,80	122
Average gross monthly wage, rubles	39167	55419	141,5
Average gross monthly wage growth rate, %	10,7	15,3	142,5
Turnover per 1 enterprise, thousand rubles	29372	37479	127,6

Let us describe the industry. As reported by Rosstat (2018) the freight turnover of transport in Russia in 2018 grew by 2.8%, outpacing the Russian GDP growth rate of 2.3%.

Road transport is extremely essential in the economy of a region. Service enterprises of regional road transport infrastructure as a component of a road transport system are the most numerous and overwhelm other transport service enterprises in most Russian regions due to the following reasons.

The impact of road transportation in total freight volume in the Russian Federation is sufficient. In 2018, 67% of all cargos (excluding cargos carried by pipeline) and 60.7% of all passengers were carried by road transport (calculated by the authors based on Ministry of Transport of the Russian Federation (2018)).

The number of vehicles in the Russian Federation is growing rapidly and the pace of development of transport infrastructure, including its service component, is insufficient. As per Rosstat (2018) in 2017, the number of registered vehicles (trucks, cars, buses, etc.) increased by 74% as compared to 2005, and the total number of service infrastructure facilities on federal highways increased only by 10%.

Competition in the sphere of motor service and maintenance is extremely intense. At the end of 2018, there were about 76 thousand registered car service centers in the Russian Federation (the figure is presented by the AVTOSTAT analytical agency (Loboda (2018)), and therefore service enterprises of road transport especially need to improve methodological tools for effective development. This task is relevant for most regions.

Methods of Research

The authors have analyzed the interrelationships between the indicators of the region's transport infrastructure, primarily road transport infrastructure, and indicators of socio-economic development of regions. The study is based on the data of a substantial number of regions of the European part of Russia. All the regions are comparable in terms of economic development and transport infrastructure development. The purpose of the analysis is to identify statistical indicators of socio-economic development of the regions, which are most relevant to the indicators of transport infrastructure development in the region.

In the authors' opinion, the identification of such indicators makes it possible to program, evaluate and monitor within the region the impact of the development of transport infrastructure, and service enterprises of transport infrastructure as its' integral part, as well as to assess their impact on the socio-economic development of the region according to the main statistical indicators. It also makes possible to confirm the effectiveness of transport infrastructure investments for the socio-economic growth of the region.

The authors carried out the analysis of interrelation, correlation of transport infrastructure indicators, including service enterprises, and economic indicators of 57 regions of the European part of Russia (Central, Northwestern, Southern, North Caucasian and Volga Federal Districts). The regions were selected for the following reasons. According to Rosstat (2019), these federal districts account for 58.38% of Russia's GDP. The density of their transport infrastructure, homogeneous and complex development of industries allow them to be compared with each other. Meanwhile the Far Eastern and Siberian Federal Districts differ markedly from the districts of the European part of the Russian Federation. The method of indicators selection is based on the logical relationship of the studied indicators of the regional economy with the region's transport system development. These indicators are grouped depending on the aspect of the region's transport development they potentially characterize.

A number of researchers utilized correlation and regression analysis to indicators of the regional transport infrastructure development earlier (the results of study by the co-author of the article are presented by Kosobutskaya (2020)). For example, Terentieva (2016) carried out a similar analysis over the years, but it was limited to one region - the Republic of Tatarstan. Ivanov (2016) carried out the analysis on the federal districts basis but only for one pair of indicators. The analysis showed a high correlation (0.7) between the GRP values and the total length of transportation routes in these districts. The approach of Ivanov (2016) seems to be universal, but contains a number of limitations and assumptions. The calculation of linear correlation on eight pairs of values cannot be recognized as sufficiently reliable (Grjibovski (2017)). The Far Eastern and Siberian Federal Districts differ significantly from other administrative regions of the Russian Federation in many respects, including: geographical extent, a significant length of transport routes and their low road density, low population concentration, specific development of transport and some types of transport infrastructure. These features appeared due to natural and climatic characteristics, a shorter period of development of these regions.

Pearson correlation coefficients r_{xy} are used to measure linear correlation between two variables. They are calculated using the formula (1) and allow estimating the direct impact and interrelationship of the indicators, excluding possible simultaneous influence on the value of the indicator of a group of other indicators.

$$r_{xy} = \frac{\sum_{i=1}^{n}(X_i - \bar{X}) \times (Y_i - \bar{Y})}{(n-1) * \sqrt[2]{\frac{\sum_{i=1}^{n}(X_i - \bar{X})}{(n-1)}} \times \sqrt[2]{\frac{\sum_{i=1}^{n}(Y_i - \bar{Y})}{(n-1)}}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (1),$$

where X_i , Y_i are the values of analyzed regions' variables, indexed from 1 to n, where n is the sample size;
$\bar{X}, \bar{Y}$ are the means for the variables X_i и Y_i.

The analysis revealed indicators that have a positive and high (more than 0.70) paired correlation at 95 % confidence level, calculated using the Fisher z-transformation (Grjibovski (2017)). Moreover, even that correlation was analyzed from the point of view of logic and systems-based approach to regional economy.

The authors believe that the proposed approach provides greater reliability for the following reasons. First, the study examines a large number of regions. Second, due to the selection of akin regions for analysis, the results obtained are characterized by greater reliability and less margin of error. The authors treat the obtained indicators of regional transport infrastructure that have a high correlation with the socio-economic indicators as drivers for regional economies growth.

Results

The following groups of indicators can characterize the regional road transport infrastructure and transport service infrastructure as its component.

Indicators of logistic and maintenance support of regional transport infrastructure. This group of indicators characterizes the physical parameters of transport infrastructure, shows the ability of transport to ensure economic exchange, use of the region's resources both within the region and in economic interaction with other regions, in transit traffic. Some of the proposed indicators are among 49 main indicators of region's competitiveness, presented by Treshchevsky (2009) to characterize the development of transport.

Economic indicators of transport infrastructure performance. This group of indicators characterizes the demand for transportation services, cargo carriage volume and passenger traffic flows. Economic indicators of regions, freight-traffic volume, passenger traffic flows and part of indicators of logistic and maintenance support of regional transport infrastructure have already been used by other researchers, for example, Terentieva (2016).
The complete list of indicators for these groups is presented in table 2.

Table 2: Correlation between transport infrastructure indicators and socio-economic indicators of 57 regions of the European part of Russia taken as a whole in 2017

Transport Infrastructure indicators \ Socio-economic indicators	GRP in 2016, mln rubles	Turnover of organizations by economic activity “ Transport and Communication” , mln rubles	Average annual number of employed, thou. persons	Average per capita money income of population; per month, rubles	Consumption expenditures per capita; per month, rubles	Gross nominal average monthly wages of employees, rubles	Conveyance of goods, mln tones	Passenger traffic, mln persons
Indicators of logistic and maintenance support of regional transport infrastructure								
Density of railway tracks, end of 2017, km per 10,000 sq. km of territory	0.66	0.73	0.17	0.63	0.59	0.63	0.10	0.66
Length of railway tracks, end of 2017, km	0.06	0.10	0.17	0.24	0.30	0.25	0.52	0.18
Density of paved public roads, end of 2017, km per 1000 sq. km of territory	0.73	0.76	0.70	0.61	0.57	0.55	0.09	0.68
Length of paved public roads, end of 2017, km	0.10	0.12	0.28	0.21	0.32	0.00	0.71	0.32
Fixed assets of the regional transport infrastructure, end of 2017; at total book value; mln rubles	0.80	0.83	0.82	0.72	0.71	0.73	0.45	0.79
Economic performance of transport infrastructure								
Enterprises and organizations by economic activity "Transportation and Storage", thou.	0.89	0.92	0.92	0.81	0.79	0.77	0.43	0.91
Average annual number of employed by economic activity "Transportation and Storage" in 2017, thou. persons	0.95	0.96	0.99	0.84	0.83	0.77	0.52	0.97
Conveyance of goods, mln tonnes	0.34	0.35	0.48	0.48	0.50	0.34	1.00	-
Passenger traffic, mln persons	0.93	0.93	0.98	0.81	0.80	0.72	-	1.00

Calculated by the authors based on Rosstat (2019).

Indicators of regional transport service infrastructure. They characterize the capabilities of the transport services infrastructure to ensure efficient operation of transport. These indicators have not been met in the papers of other researchers and are introduced be the authors in accordance with the research objectives. Consumer services - subgroup "Maintenance and repair of vehicles, machinery and equipment", million rubles - is an important indicator of road transport service infrastructure in the region. It is presented in statistics yearbooks of the administrative regions of the Russian Federation, as 96% of motor vehicles and 61% of freight transport are owned by individuals (Rosstat (2018)). The complete list of indicators for this group is presented in Table 3.

The analysis of cross impact and interrelation of regions' socio-economic indicators and regional transport infrastructure indicators was carried out. Values of social and economic indicators of the regions, characterizing the

regional economies, volume of freight and passengers transported, labor force and income standard and level of consumption are given in columns of tables 2 and 3.

Table 3: Correlation between indicators of road transport' service infrastructure and socio-economic indicators of the regions of the European part of Russia in 2017

Socio-economic indicators / Transport service infrastructure indicators	GRP in 2016, mln rubles	Turnover of organizations by economic activity " Transport and Communication" , mln rubles	Average annual number of employed, thou. persons	Average per capita money income of population; per month, rubles	Consumption expenditures per capita; per month, rubles	Gross nominal average monthly wages of employees, rubles	Conveyance of goods, mln tonnes	Passenger traffic, mln persons
Indicators of transport service infrastructure								
Enterprises and organizations by economic activity "Trade, maintenance and repair of motor vehicles and motorbikes", thou.	0.61	0.62	0.66	0.54	0.54	0.50	0.36	0.70
Turnover of organizations by economic activity "Trade, maintenance and repair of motor vehicles and motorbikes", mln rubles	0.99	0.96	0.94	0.79	0.74	0.74	0.28	0.90
Household services by type of services "Maintenance and repair of vehicles, machinery and equipment", mln rubles	0.82	0.87	0.90	0.73	0.75	0.61	0.52	0.88

Calculated by the authors based on Rosstat (2019).

Analysis results. The authors have analyzed the correlation between the transport infrastructure indicators, including the transport service infrastructure, and the economic indicators of 57 subjects of the Russian Federation for 2017. Most of the obtained correlation coefficients are in ranges from 0.5 to 0.69 and 0.7 and above which, according to Chaddock's scale (Chaddock (1925)) demonstrates noticeable and high correlation of observed phenomena. The correlation coefficient 0.70 at sample size n=57 and at the 95 % confidence level (P=0.05) calculated by the authors using the Fisher z-transformation should be in the range from rL=0.53 to rU=0.81. Thus, the analysis meets the necessary reliability condition. Statistical significance for this sample at P=0.01 is 0.25.

Having analyzed the values of correlation coefficients of the indicators of logistic and maintenance support of regional transport infrastructure with the social and economic indicators of the regions (refer to Table 2), we can state the followings. High positive correlation is observed in the indicators of the Density of the paved public roads with such indicators as GRP (0,73) and Turnover of organizations by economic activity "Transport and Communication" (0,76) of the regions, Average annual number of employed (0,7); noticeable correlation (0,68) is observed with Passenger transportation.

This indicates a significant role of automobile transport to ensure economic connectivity and labor mobility of the population in these regions. Average but noticeable correlation with Density of paved public roads is demonstrated by Average per capita money income of population (0.61), Consumption expenditures per capita (0.57) and Gross nominal average monthly wages of employees (0.55). There is a high correlation between Length of paved public roads and Conveyance of goods (0.71). The value of fixed assets of transport infrastructure (roads, bridges, vehicles, garages, etc.) located in the regions characterize the development of infrastructure and logically shows a high positive correlation (0.7 and more) with the majority of regional development indicators from Table 2. The observed positive correlation and values of correlation coefficients allow to conclude that the developed transport infrastructure and, first of all, road transport infrastructure (not the length of roads, but the density of roads and their equipment with fixed assets) are closely interconnected with the economic development of the region. It has a direct impact on the region's economy and, to a high degree, on socio-economic indicators and living standards in the region.

Commenting on the indicators of economic performance of transport infrastructure, it is necessary to note positive and high and very high correlation of GRP with the number of Enterprises and organizations by economic activity "Transportation and Storage" (0.89) and the Average annual number of employed by this economic activity (0.95).
In addition, the regions under study are characterized by quite close correlation of the latter two indicators (Conveyance of goods and Passenger traffic) with indicators of living standards - Average per capita money income of population and Consumption expenditures per capita. The correlation coefficients range within 0.77-0.84. We also observe a logically expected high correlation of the number of transport enterprises, the number of employees employed by them with the impact of transportation in GRP (more than 0.91 for both coefficients), and with the indicator of passengers traffic (0.91-0.97 respectively). It seems logical to conclude that the more developed a region's transport infrastructure is, the higher the value of socio-economic indicators. The converse case is also true. A well-developed regional economy fits with a developed transport infrastructure that is quite efficient for a region.

The results of the impact-analysis of service infrastructure of motor transportation on socio-economic indicators of the region (refer to Table 3) allows to draw the following conclusions. We point out that the indicator “Turnover of organizations by economic activity "Trade, maintenance and repair of motor vehicles and motorbikes"” has positive correlation (high values of correlation coefficients) with such indicators as: GRP (0.99); “Turnover of organizations by economic activity Transport and Communication”" (0.96) of the regions; “Average annual number of employed people” (0.94), and indicators of living standards (0.79 and 0.74 respectively).

Slightly lower, but still high values of correlation with the studied socio-economic indicators also has the indicator Household services by type of services "Maintenance and repair of vehicles, machinery and equipment”. Strong correlation is observed with such indicators as GRP, Turnover of organizations by economic activity “Transport and Communication”, Average annual number of employed, and Passenger traffic. Correlation coefficients are 0.82, 0.87, 0.9 and 0.88 respectively.

Correlation of the number of enterprises and organizations in this economic activity with majority of the socio-economic indicators presented in Table 3 is reliable, positive, and noticeable.

Noticeable correlation of these indicators has logical explanation. The region where more cars are bought and serviced should be more prosperous. The fact that 61% of freight transport and 51% of the bus transport in Russia belong to individuals should be concerned as additional substantiation of high and very high correlation of the indicator Household services by type of services "Maintenance and repair of vehicles, machinery and equipment” with the socio-economic indicators. For the same reason, this indicator was included in the study. Based on the observed values of the correlation coefficient, it can be stated that the efficiency of the region's economy (GRP) and of the region's transport (Turnover of organizations by economic activity “Transport and Communication”) depends on the operation efficiency and development of the transport service infrastructure. It can be estimated with the help of the turnover and household services provided.

Conclusions

The analysis results show that according to the basic statistical indicators: GRP, indicators of employment and level of incomes of the population, volumes of cargo and passenger transportation inside the regions there is a strong mutual influence of transport infrastructure, and service infrastructure of transport as its component, on social and economic development of the region. Thus, it is reasonable to identify a number of transport infrastructure indicators in the region, which can be used as drivers for the development of the region's economy. According to the results of the analysis, the increase in the density of public roads, the growth in the number of transport infrastructure enterprises, including the service enterprises of the road transport infrastructure and their employees, the development of their facilities can be considered as such drivers.

Abstract

The advancing mechanization and digitalization in its current state has a significant impact on many industrial, social and personal facets. Everyday tasks are, and will be even more intensively aided by smart, connected devices and their state-of-the-art machine-learning applications. It was observed that especially the industrialized nations currently boost their efforts in several regulatory and technical fields. Germany should be mentioned here as a prime example, since it has a relatively high manufacturing degree and thus its economy and wealth is highly dependent on +technological superiority. The content of this paper present how processes are being influenced by digitalization. Based on the analysis of a common issue at the production line, the paper presents the possibilities of the implementation of the Industry 4.0 in a selected company. The chosen company is major European automobile manufacturer with its production site in Slovakia. The matter will be structured in an initial explanation of the digitalization in a broader view, including the theoretical basis for terms like the Internet of Things, the Industry 4.0 and the subject of maintenance. The subsequent chapters analyze the conceptional course and the implementation of the IT infrastructure into the selected assembly line equipment, highlighting the underlaying managerial and analytical preparations.

Keywords: Industry 4.0, Management, Analysis, Digitalization, Internet of Things.

Introduction

The digitalization and accompanying developments are generally driven by all sizes of corporations, mainly with a technological background, in order to keep or gain the competitive edge on their specific markets. Often these corporations are seek partnerships with research institutions and universities or establish joint ventures in order to gain know-how and back the immense investments. Additionally, the importance of technological leadership on a nation-wide scale has been understood by political leadership of many developed countries. Public attention and institutional support regarding these tendencies is steadily increasing accordingly. The majority of the developments in digitalization aspects are stated under the headline of the so called the Fourth Industrial Revolution. It is considered a revolution, because in the result it fundamentally changes the way of producing goods and services. These changes are driven by the most precious resource of our days: Data. The ongoing development of new technologies for manufacturing and businesses and their adaption in life is progressing into the era of digitalization. Digitalization of manufacturing is the phenomenon of intelligently connected machines powered by information and digital technologies. (Parida et. al, 2015, Hittmar et. al, 2015, Ferenc et. al, 2017) Gartner business dictionary says that digitalization is the use of digital technologies in a way to change a business model, so that the business will provide new revenue and opportunities. It is the transformation to a digital business. (Gartner, 2020) In another way, digitalization is transforming analogue input, e.g. information carried in tangible formats as paper, into the digital format used by computers. All information is now used and stored in databases, data warehouses or online in

clouds and easily accessible by various electronic devices. Digitalization brought up many new possibilities and opened up space for improvements and raised the efficiency of manufacturing. There is a focus on development toward the future and adaptation to new trends. One of the important outcomes of digitalization became automation. According to Cambridge Dictionary, the term automation means the use of machines that operate automatically, which means independently without human control. (Cambridge Dictionary, 2020) Digital technologies like computers, laptops, tablets, smartphones, robots and many other devices work with data. In order to make this work more efficient, automation involves programming machines and robots and making them work autonomously with a minimum human interaction. Synchronized and seamless movements of the interacting machines is the targeted scenario. (Jankalova, Jankal, 2016, Soviar et. al, 2017) One path that has been trying to achieve this targeted scenario utilizes, in historical terms, a recently invented tool for global data transfer: The Internet. It is not only changing the daily interaction of people, but it plays a major role in digitalization of the business world, in a form that includes all "things" involved in the process.

Literature Review

In the further technological development all possible digital devices can be now connected to the Internet. That enables them to connect with each other as well as to share information. Since these devices are connected to the Internet, this communication is happens online in real-time. This phenomenon is known as the Internet of Things (IoT) introduced in 2000 by Ashton and his colleagues. The main idea driving their vision was ubiquitous automated identification technologies and their applications. They envisioned all kind of electronic devices networked and electronically tagged that would allow remote, wireless communication of their contents. (Sarma et. al, 2000) Since the time of the introduction of this phenomenon and its progressive implementation, people started to discuss this topic frequently and came up with their own understanding of the Internet of Things and definitions. (Dorčák et. al, 2017, Soviar et. al, 2019) The following table summarizes three chosen definitions by different authors (see Table 1).

Table 1: Definitions of the Internet of Things

Reference	Definition
Guido Bartels	"The IoT links the physical and digital worlds. The massive amounts of data that instrumented devices collect provide businesses the opportunity to learn about the environment in which they operate, gleaning insights that can be turned into actions." (Bartels, 2017)
Xiaoge Xu, Niranjan K. Ray, and Ashok K. Turuk, Eds. 2017	"It can be defined as the combination of smart devices communicating with other devices, objects, environments and producing a huge volume of data. These data can be processed into useful actions that provide command and control to the things to enhance the quality of life." (Xu et. al, 2017)
Mehdi Khosrowpour, 2017	"The term "Internet of Things" (IoT) refers to a worldwide network of uniquely identifiable interconnected objects that can seamlessly interoperate using communication protocols like Radio Frequency Identification (RFID), Bluetooth, Near Field Communication (NFC), barcodes, as well as embedded sensors and actuator nodes." (Khosrowpour, 2017)

The Internet of Things is more than just an approach discussing connectivity of devices. It involves many cooperating technologies. For example, wireless sensor networks hardware including Wireless Senor Network (WSN) Protocol Layer, Secure Data Aggregation/Fusion, WSN Middleware Technology and RFID Communication. (Xu et. al, 2017, Jankalova, Jankal, 2018)

The Internet of Things is applied in a wide range of spheres such as healthcare, smart cities, smart homes, sport and other. However, the focus is nowadays on its application in the industry since digitalization has became a business priority for a significant number of organizations worldwide. (GE Digital, 2020) The Internet of Things used in industrial conditions is called the Industrial Internet of Things (hereinafter referred to as IIoT). There are two key trends playing an important role in IIoT Systems. The first one is the spreading of the use of the sensors. The cost of the sensors as well as interfaces is steadily decreasing. This fact is causes the high availability which allows tracking more variables and different types of data. The second trend is the era of distributed processing systems such as PLC (Loop Process Control / Loop process controller). By placing PLC closer to machines, it eliminates bottlenecks and improves the efficiency and flexibility of the production. (ElektronikaB2B, 2020) The potential of

the Industrial Internet to change the industry is undoubtful and GE Digital, subsidiary of the American corporation General Electric, predicts the benefits of the IIoT to the global economy (GE Digital, 2020) as follows:

- 46% of the global economy can benefit from the Industrial Internet.
- 100% impact of the Industrial Internet potential on energy consumption.
- 44% impact of the Industrial Internet potential on global energy consumption.

Besides the demands of the business to business and business to customer markets and the internal requirements for getting the state of data demand are to be considered. Therefore, in order to be able to analyze the state of a machine and make a prediction, a structured data collection is necessary. The important part of the IoT and IIoT are sensors that continuously collect important data about the key parameters involved in the process. The data is collected periodically or when the threshold is exceeded. Sensors send the collected data to a cloud system or database through a wireless gateway. Once the data arrives at the predefined destination, it is processed to extract key parameters and the trending could be visualized. (Khushraj, 2017, Soviar et. al, 2018)

As it is stated above the Internet of Things describes an abstract and generalized subject, including the future way of manufacturing, the connectivity of devices and their collection, handling and analysis of data. The next logical step is the implementation of the IoT subject in a real industry and manufacturing case respectively. In this term, the leading industrial nation Germany, pushed forward on a nation-wide scale, described the term "Industry 4.0" as follows:

The term Industry 4.0 has been known since 2011 when German representatives promoted an initiative to enhance competitiveness in manufacturing industry called die Industrie 4.0. Ideas of this initiative were later adopted by German federal government in High-Tech Strategy for 2020. The digital transformation of the manufacturing plays a significant role in the national development not only in a European scale. However, not every country has an opportunity to expand in the tempo of modern industrialization. It depends on the country's position, competitive advantages and aspirations. Nascent countries have an array of production bases. These can be ranging from a significant production base that is either shrinking or at risk of shrinking, a small base that is growing, or a small base due to limited industrialization. Countries with limited production bases may initially try to capture traditional industrialization. In comparison, countries with larger production bases are more likely to expand into advanced manufacturing. A way of showing the potential of countries to modernize their manufacturing processes utilizes their readiness for those modernization activities. (Company internal documents, 2018, Deloitte, 2020) The understanding of the so called fourth industrial revolution by several authors is summarized in the following table. (see Table 2)

Table 2: Definitions of the Industry 4.0

Reference	Definition
P. Kopacek. 2015	"The basic principle of Industry 4.0 is that by connecting machines, workpieces and systems, it is possible to create intelligent networks along the entire value chain that can control each other autonomously." (Kopacek, 2015)
Cheng-Ju Kuo, Kuo-Cheng Ting, Yi-Chung Chen, Don-Lin Yang, and Hsi-Min Chen. 2017	"The term Industry 4.0 refers to trends in automation and data exchange in the area of manufacturing. It includes analysis of consumer demands, physical monitoring processes, networking multiple machines, predictive maintenance, and quality control." (Kuo, 2017)
Yang Lu. 2017	"Industry 4.0 can be summarized as an integrated, adapted, optimized, service-oriented, and interoperable manufacturing process which is correlated with algorithms, big data, and high technologies." (Lu, 2017)
Australian Government	"Industry 4.0 (the 'fourth industrial revolution') refers to the current trend of improved automation, machine-to-machine and human to-machine communication, artificial intelligence, continued technological improvements and digitalisation in manufacturing." (Australian Government, 2020)

As a leading European country in industrial manufacturing, Germany sets the pace for Industry 4.0 as an example for other countries. The initiative "Industrie 4.0" later converted into a platform uniting economic sectors, professional associations, the scientific community, trade unions, and the government. The platform systematically connects digitalization and production nationally and internationally as one of the largest and most diverse Industry 4.0 networks. It also fosters coordinated processes in the economic sector and in the society through the harmonization of the various perspectives and approaches. It is operated by and for the political stakeholders, the business sector, the scientific community, professional associations, and trade unions and unites all relevant civic stakeholders for the purpose of advancing the digital transformation of the industry. The platform Industrie 4.0 has

prioritized five fields of activity to be worked on and it is Reference Architectures, Standards and Norms, Research and Innovation, Security of Networked Systems, Legal Framework, Work, Education and Training. (Federal Ministry for Economic Affairs and Energy, 2020)

The significant impact of the fourth industrial revolution made its signature in the subject of maintenance. The maintenance plays an important role in the industry and has a reasonable impact on the production. It should not be understood only as a manual laboring work, nor as a managed activity involving Information Technology (IT).

Role of Management in the Industry 4.0

The German Fraunhofer Institute for Material Flow and Logistics uses a 4-Phase-Model tool for a company's management in order to help develop a solution for the management of the Industry 4.0. It is a step by step process, in order to create convincing business cases and management approaches. The model starts with the first phase which is meant to develop a common understanding of the Management of the Industry 4.0. It is called "Kick-off" and deals with topics of centralized and decentralized management, vision, strategy and goals of the focused group. The expected outcome of this start phase is to bring transparency of status quo, fields of action, approaches and objectives. The next phase has a goal to analyze the starting points for the development of innovative business models for the Industry 4.0. Possible important topics in this phase are models for transparency and information quality in the supply chain, innovative organization models supporting fast decision making or models for an increase of flexibility in a supply chain. Desired outcome is the identification of innovative business models for the Management of the Industry 4.0. The third phase is focused on measuring and control models with the goal to deliver conception of optimized measurement and controlling models. After taking a closer look on topics like new planning and optimization assistant systems or models for an increase of productivity, at this stage the connecting factors for a comprehensive Management of the Industry 4.0 should be clarified. The final phase is called Recommendations for Action and its goal is to define approaches for a successful implementation of Management of the Industry 4.0. The topics discussed in this part should be individual business and management model of a company, strategies for conversion into new management model, innovative concepts of knowledge management and learning platforms. The end phase is meant to deliver action framework for the Management of the Industry 4.0. (Daňková, Droppa, 2015, Madzík et. al, 2017, Straková et. al, 2017, Frauenhofer (a), 2020, Frauenhofer (b), 2020)

Action frameworks are usually larger complexes of certain plans. For a more efficient implementation they are possibly split into several projects. The projects then deal with certain specific topics.

Materials and Methods

The paper focuses on the analysis of the possibility of the application of the Industry 4.0 solutions in a selected company. In sequence, the paper describes suitable metrics and elements for implementation of the predictive maintenance. The main goal is divided into partial goals which are supportive in the process of achieving the main goal of the analysis i.e.:

- introduction of the topic of the Industry 4.0 and Predictive Maintenance,
- analysis of the selected company and their approach towards the Industry 4.0,
- analysis of the production process and maintenance approach,
- identification of the suitable objects for the installation of a predictive maintenance solution and identification of the parameters and measuring methods for condition monitoring.

According to studies of the theoretical backgrounds to the topic of the Industry 4.0, general overview of the topic was gained. In the theoretical and analytical part of the paper, book sources, scientific and research articles, analysis performed by companies working on relevant topics, internet sources and internal documents of the cooperating company were used. The cooperation was established with a car production factory located in Slovakia, which brought closer perspective and practical insights to the analysis. During the work on the analysis, working procedures such as search for relevant resources, studies and processing of the resources, selection of the suitable methods and tools for the analytical part of the paper, analysis of the company's internal documents, analysis of current approaches and operations in field~~s~~ of the Industry 4.0. During the work on the analysis, we used methods such as research of available resources and well as deduction based on research, analysis of the current situation in the selected company, structured interviews with responsible employees within the qualitative research, analysis of internal documents of the company, communication with the company representatives and survey on the premises were used. For summarization of the acquired findings about maintenance methods in the company, the method of synthesis was used.

Results

This part of the paper focuses on the introduction of the selected company, analysis of the company's external and internal environment which deals with the issue of the Industry 4.0, the company's main and supportive processes and the maintenance of selected machines. The cooperation with the company was based upon an agreement, that name of the company shall be anonymized, and confidential data will be modified with a Bulgarian constant.

Company Introduction

The selected company is an original equipment manufacturer of the automotive industry. It was established in Slovakia since 1991. It is the biggest and the oldest car production company in the country. In the last quarter of the century the chosen factory in Bratislava became one of the most modern factories of a German concern. Its uniqueness is in innovative technologies and complexity. In 2016 the company reached the historically highest financial return and became then number one in Slovakia. More than 11.000 employees contribute to the production and performance of the factory. The company belongs to a German concern which includes another eleven automobile brands. The Group consists of two divisions. It is the Automotive Division and the Financial Services Division. The Automotive Division comprises the Passenger Cars, Commercial Vehicles and Power Engineering Business Areas. Five different models from five different brands are being produced under the roof of the company's factory seven days in the week. The whole production consists of 57% of SUV models and 43% of city cars models. One version of city car is purely electric. In the beginning of 2018 the company started production of a new model with an annual capacity of 40 000 vehicles. During the time of its existence the factory produced more then 4.5 million cars, 6.8 million gearboxes and 400 million components within the three company's factories in Slovakia. Since the start of the production, 13 different car models were built in the Bratislava factory. In 2016, 388 687 vehicles left the production line. Automobile production makes 35% of the whole industrial export of Slovakia. The cars produced by this company are exported worldwide into 148 different countries. The automobiles of the Slovak~~ian~~ facility were mostly exported to Germany (32%), USA (16%) and China (11%). In 2016 the company reached record turnover of 7.6 billion EUR what represents 5% increase compared to the last year. The net profit margin reached the level of 145.3 million EUR. It was historically the highest level reached in investments. The Factory in Bratislava was built new halls, made reconstructions, and built new infrastructure. In total the company reinvested 550.7 million EUR what represents 33% increase compared to the last year. (Volkswagen Slovakia (a), 2020)

The investments into the development of the company, its infrastructure and technologies have in the last quarter of the 20th century raised by 3.4 billion EUR on record. The automotive industry is progressing along with it is the company too. It is getting ready for the global changes such as is the electromobility, dynamic development of assistance systems and the future of autonomous driving. In order to maintain future shares on the highly competitive car market, more than 550 million EUR were invested for further enhancement of the company, as well as for production processes. According to these enhancements and digitalization aspects, parts of this budget were used for applications in the field of the "Industry 4.0". The company brand is completely repositioning itself with the 2025+ strategy. The focus here is on strengthening the market position across the regions and segments, flanked by a significant increase in efficiency and productivity. At the same time, the brand will invest in e-mobility and connectivity. Furthermore, in the reporting period, the Board of Management and the General Works Council at the company made a pact for the future, which is aimed at initiating the return of the company brand to a profitable course for growth. The program at locations in Germany with around 120,000 employees is intended to significantly increase competitiveness, in addition to ensuring that the company is secure enough to meet future challenges. It creates the prerequisites for the transformation from a pure automotive manufacturer to a successful mobility provider in the age of digitalization and increasing e-mobility. (Volkswagen Slovakia (b), 2020)

Results of Analysis of the External Environment

External environment has a significant influence on the company and should be analyzed in order to clarify its intensity and impact: (Kollar, 2016)

- Market: The three various carmakers in Slovakia produced together 1 043 237 vehicles in 2016. This represents a rise by 4 734 automobiles (+0,46 %) compared to the last year. The second time in row more than one million cars in the year were produced in Slovakia. The car production makes up represents 30% of the whole industrial production of Slovakia. The strong elements of automotive industry are three car production companies and their

supplier networks. The selected company with the factory in Bratislava produced 37% out of the total number of cars made in the country in 2016. In comparison with two other competitors it is more than one third of the whole car production. The percentage of the production made by three car manufacturers is shown in the following graph.

Fig. 1: Ratio of produced vehicles by companies on the market (Kollar, 2016)

- Electromobility: All-important car producing companies are investing significant amounts in the development of electro mobiles. The number of electro mobiles have doubled in 2017 in comparison to 2016. More than one third from the millions of the new cars with electric engine had been sold in China. The Slovakia is trying to support the sale of electro mobiles by sale grants. The support from the country can possibly cover the purchase cost of more than 1000 vehicles. The interest in these grants was indicated by only 300 registered applications. (Kollar, 2016)
- Human resources: The automotive industry plays a strategic role for Slovakia from the point of concentration of the human resources, number of produced cars and ration of the produced cars in the whole industrial production. More than 250 000 working positions are currently connected to the Slovak automotive industry. More than 129 000 people work directly in the production, including 1 470 working positions in research and development. (Kollar, 2016)
- Export: The automobile production represents 35% of the whole industrial export of Slovakia. The Exit of Great Britain from the European Union is a threat for the future development in the automotive industry in case it would happen without agreement about free market. Potential barriers on the USA market could be critical as well. Customs on the imported cars were discussed during the administrative change in the country. (Kollar, 2016)

The external environment sets the company in the position of the leading car manufacturer in Slovakia. The market is growing and it is expecting the increased production and introduction of the electro mobiles, which has an impact on the company development strategy. Adaptation to these external influences requires implementation of new technologies and investments in technological development. This could include technologies connected with the fourth industrial revolution. The analysis of the internal environment of the company should uncover if the company is aware of market expectations and if the company´s position is appropriate.

Results of Analysis of the Internal Environment

Modern, highly efficient car production would be inconceivable without reliable and extensive automation technology. According to the manager of the department of IT Project House, 95% of operations in the bodywork shop are fully automatized. Automation could be considered as a significant step in the industrial development and a solid base for more advanced upgrades. Networking and digitalization in production already played an important role well before the term Industry 4.0 was coined. The company is exploring new technological solutions in many evaluation and implementation projects, including identification, localization and visualization of components, equipment and the whole production, energy management and predictive maintenance and condition monitoring, data-driven analysis and control of production processes, and the use of wearables such as smart glasses in logistics processes. Recently, one of the most modern centers for production flow management was opened in the concern. In the Bratislava factory, the biggest 3D printer in the world for the print of the metal parts was installed. Xline 2000R is currently the biggest three-dimensional laser printer with Selective Laser Melting (SLM) mechanism which is used in the company. The company production in Slovakia was the first in the world which implemented this technology in the operation. SLM is one of the 3D print technologies which uses laser for melting of the metal

dust in the dust cabin. Aluminum and steel are used for printing parts and prototype parts. (Volkswagen Slovakia (c), 2020)

As the automobile manufacturer, the main activity of the company is the production of vehicles. The whole process of production involves several follow-up activities which are operated decentralized in the subordinated divisions. The existence of each automobile production takes place in the press shop where supplied metal coils are concerted in three-dimensional metal parts by several deep-drawing and cutting steps:

- the body construction,
- the paint shop,
- final assembly.

Even though the manufacturing is tightly scheduled, following the pull, just-in time and just-in-sequence principles, in between the production sections there are storages. So, each part, module or body is stored from usually hours up to days till it enters the next level of the production hierarchy. In theory, those buffer storages are unnecessary cost factors. In reality, it would be too risky to set those buffers aside. In the whole chain of actions of an automobile production are just too many possible failures which would affect the following step and eventually negatively influence the overall performance of the factory. If there is for instance a productions stoppage in the body construction shop caused by a mayor failure of the robotics controlling system, it would just affect the stations of the body construction shop. The following paint shop could normally continue, since its production gets fed by the buffer storage between the body construction and the paint shop, for at least one to three days.

Results of the Analysis of Maintenance and Critical Assets

The maintenance process is provided by the specialized maintenance department. Basic maintenance is scheduled and performed according to manufacturer's regulations for the machine maintenance. This planned maintenance is scheduled in SAP system and usually includes inspection, cleaning and lubrication. When the immoderate harm on the equipment is found, a direct fix is provided. The general maintenance approach could be defined as preventive. Apart from the scheduled preventive interventions there are no specific maintenance approaches implemented. Occasionally occurring incidents are approached in a reactive manner. The most common case is when a worker on the assembly line notices a malfunction of the equipment themselves. Each asset in the factory has an identification label with all important information including the name, identification number and a responsible person in case of fault. A faulty machine can be then easily identified and the employee knows who he/she should notify. The notification is usually made by telephone or ~~by~~ transmitter. Some of the more advanced machines are connected to a visualization system and signalize the fault automatically. The system is administrated by a responsible person who assigns incidents to a technician. Afterwards the technicians go on a survey of the incident location and evaluate the range of defect and decide if spare parts will be needed for the fix and if it is possible to fix it on the spot. In any case, they schedule the repairs on the next possible suitable timeslot.

The mapping of the maintenance process was performed on the premises of the company accompanied by interview with the technical personnel staff. During this mapping procedure, maintenance tasks and relations between involved roles intervening in the process were discussed. The whole maintenance process was drawn in to the process map and is visualized on the following flowchart diagram (see Fig. 2).

Fig. 2: The Maintenance Process Map

The maintenance operations are supportive processes of the main production process of the company. Some maintenance activities are outsourced and performed by a specialized service provider. The process owner of the maintenance of the selected machines is the external company. This company is responsible for the immediate reparations of the contracted machines the moment incidents occur and eventually it shall avoid any shut-down of the assembly line. Hence, there need to be a continuous communication line between the company and the service provider, to be able to act and respond instantly and meet the requirements of the instructing party. A state-of-the-

art IT infrastructure and regular meetings help ensure the consistency and quality of the information flow. The outsourced service providers work for the Maintenance department which is responsible for keeping the whole production in technically adequate conditions. The main authority is the head of Maintenance department who is responsible for maintenance strategies, approaches and plans. The head of the Maintenance department is considered as the process owner of the whole maintenance process in the company. External companies have their own organization structures and are organized by a manager from the company Maintenance department.

Conveyors delivering car bodies from the paint shop to the assembly line are maintained by different external company than conveyors and platforms in the assembly hall are. All machines in the assembly line are maintained by only one contracted provider. However, the company has, except external maintenance contractors, its own department responsible for all screwing technics in the factory.

Predictive Maintenance

In order to ensure process stability throughout the whole production line. The company runs a comprehensive maintenance department. Assets must be in top conditions all the time. Continuous operations and availability have a high priority. The issue of predictive maintenance is relatively new in the Slovak branch of the company and up to now there is no solution of this kind that has been implemented yet. Although the company does not have experience in this field, it is open and positively disposed. The approach towards the Industry 4.0 is implemented in the company strategy, so the application of predictive maintenance is the designated way to achieve the set goals. The way of integrating this approach in a larger scale is performed carefully from the company's management side. Before a final decision is made, the concept should be verified in praxis. The company's expectations on the predictive maintenance as a holistic approach focus on the following general, production-wide improvements:

- prediction of production losses,
- predictive maintenance,
- increased production efficiency and productivity,
- reduction of maintenance costs,
- reduction of production losses by 50%,
- increase of the production line availability.

Identification and Selection of the Critical Subjects

Each result of the analysis was consulted with technicians and mechanics. After discussions and consideration of all challenges which could possibly affect the project, the final decision was made. Three machines were chosen representing the best conditions for a successful project implementation with a significant impact on breakdown reduction. The following table (see Table 3) briefly describes the three selected equipment pieces, their function at the assembly line and specifies which of their mechanisms is responsible for the outage times:

Table 3: Equipment characteristics

Machine	Purpose	Defects
Hinges	transport of hanging cars during assembly	prone to faults of bearings in the transportation wheels and electric motor overheating
Platforms	transport of cars placed on the platform during assembly	prone to faults of bearings in the transportation wheels
Transfer Desk	lift pushing the platforms to an appropriate height	prone to faults of electric motors driving the lift mechanism causing the platform tilt/inclination

While the implementation of the project has a direct impact on the production and assembly line, risks and critical aspects should be considered and evaluated in advance. The system failure has a very high effect on the production and high effect on the business considering the cost of the outage. The restoration of the system can take 30 minutes to 4 hours and so it results in significant costs. The connection of the data analysis and a judgement of the experienced specialist brought synergic effect and resulted in the identification of the most suitable equipment to be

monitored. The monitoring of those parts of the assembly line can prevent occurrence of the failures and so save the company from unwanted costs. For the design of the predictive maintenance solution it is necessary to analyze specific equipment functions, their most common faults and the way how they are currently maintained.

Results of Problem Analysis

Each selected equipment has its own significant purpose and a task to accomplish. This chapter describes the function of the equipment, technical issues occurring during its lifetime and statistics about breakdowns and their durations.

- The Platform: The major issue causing breakdowns is the bearing friction of the wheels located under the platform. This friction is causes overheating of the bearing. Inner parts of the bearing are lubricated in order to prevent this friction. Nevertheless, overheating of the bearing causes a reduced functionality of the bearing and eventually causes a blockage of the wheel. This blocked wheel is breaks the platform and subsequently the whole train breaks as well. Faults of this kind are cause vibrations in the platform and noise emissions.
- The Transfer Desk: The critical part of the transfer desk is the lifting mechanism driven by an electric motor. The most incidents are caused by faulty gears or spindles. These is cause the platform to tilt or rather to incline.
- The Hinges: The major breakdowns of the conveyor are caused by wear of the bearing. This causes a blockage of the transportation wheel which is which sits on the trail. The blockage of the wheel could also originate by overheating of the bearing due to a continuous operation of the system and a limited lifespan of the part. A further part prone to fault are the electric motors. Breakdowns are mainly caused by overheating of the motors. These motors are control the motions of the transportation system, including the combination of the whole conveyor plus the car hooked on the hinges. Throughout the whole track the engine thrust must cope with and balance different speeds as well as many inclining and declining segments of the track. Obvious breakdowns are usually recognisable by noise of the bearing and regular visual examinations. In addition, there are sensors measuring heat, flow or vibrations in many places. Their function is to warn when the parts of the system reach critical conditions.

Discussion

In order to meaningfully implement the condition monitoring in a production system, it is firstly necessary to understand the object to be monitored, its structure and mode of operation. In conjunction with the cause identification of the past failures, relevant parameters for the planned monitoring can be derived and defined in order to subsequently select the necessary and to locate them in suitable positions. This approach provides an important basis for the value of the data collected and also contributes significantly to the success of the installed monitoring equipment. In order to evaluate the condition of the observed machines, parameters should be specified as they are critical elements of the system. These individual measured items will provide data repeatedly every certain time period what will create a big picture of the behavior of the machine in the course of time. The following table includes all considered parameters to be monitored and explains the reasons for monitoring them.

Table 4: Parameters to be monitored

Parameter	Reason to monitor
Temperature	Increasing temperature of bearings/wheels and driving electric motors indicates a higher probability of failure.
Vibrations	Changing vibrations pattern indicates incoming failure of bearings in wheels & electric motors.
Barcode	To identify platforms and hinges, scan their position & measure the driven distance (km) without failure.
Electric current	Increasing current consumed by the motors indicates an overload.
Inclination	The increased tilt of the platform on the transfer desk causes the assembly line to stop.
Sound	Accompanying phenomenon of issues with bearings can be used for sound analysis.

Each parameter will be measured using a specific method with the aim to achieve the best results. For this purpose, a specialized sensor technique will be used. Consultations with technicians resulted in specification of the most suitable measuring method and clarified the suitable options for their use. On each of the selected assets, more parameters can be measured at the same time. The following table describes how and where certain parameters will be measured.

Table 5: Measuring methods and placement of the sensors

Parameter	Measuring Method	Placement
Temperature	measured by Infrared (IR) contactless temperature sensors	- 6 wheels/bearings on each platform - 1 electric motor & 2 wheels/bearings of each hinge - 4 electric motors of the transfer desk
Vibrations	measured by special vibration sensor (bearing fault detector)	- 6 wheels/bearings on each platform - 2 wheels/bearings on each hinge
Barcode	read by barcode readers	- at the transfer desk - on selected places along the assembly line
Electric current	measured either by an electric power meter (in the power distribution box) or by contactless current transducers on the power wiring or their combination	- 1 electric motor of each hinge - 4 electric motors of the transfer desk
Inclination	measured by special 1 or 2 axis precision inclination sensors	- 1 sensor on each monitored platform
Sound	features extraction of sound from microphones	- 6 wheels/bearings on each platform

Each machine was surveyed by an IT team and technicians in detail in order to consider the right placement of sensors for monitoring of the discussed parameters. for monitoring of the discussed parameters. Obstacles on the trail system were identified and assessed. The implementation of the condition monitoring system contributes to company strategy fulfilment and prepares the company environment for the implementation of the predictive maintenance in larger scale. The condition monitoring project in a form of proof of the concept verification is a very good way how we can figure out what works for the certain conditions present in the company and test various options in order to evaluate what works better. The documentation of the whole procedure and the related information will help in the future implementation of the Industry 4.0 strategies.

Conclusion

The analysis deals with the internal and external environment of the company what resulted in conclusion that company has favorable conditions for the implementation of the Industry 4.0. The external environment requires technological development and progress in delivering the electro mobiles. The IT organization structure is developed in a good manner to support the company technology needs. The current interest and involvement in projects dealing with issues of the fourth industrial revolution show the way the company has selected. After the analysis of the maintenance process of the selected assembly line parts it could be concluded that there is a reactive maintenance approach with a combination of the preventive maintenance program. A high level of the required reliability and continuous operation of the whole assembly line puts maintenance under the pressure. The maintenance department is open to solutions which will help to prevent any shut down of the assembly line. As it was mentioned earlier, the expectation of the company is the increased production efficiency and productivity, reduction of maintenance costs, reduction of production losses by 50% and rise of the production line availability. This guides to the adaptation of new maintenance program meeting these expectations. The condition monitoring as the first step towards the predictive maintenance can help to better understand machinery conditions by using IoT technology, data analytics and visualization tools. They can enhance to localize faults more quickly and efficiently.

Abstract

Enterprises in the information age are characterized by an integrated approach to managing qualitatively diverse components, such as: technical organization structure, work items, raw materials and semi-finished products, people, databases, etc. Therefore, in order to minimize the risk of management decisions in which the dynamics of significant accompanying phenomena are taken into account, a process approach and modeling of the production process are required. As a result, in assessing the achievement of the company's goals, it is required to use appropriate indicators and measures that will combine economic criteria with key performance indicators appropriate for the organization. Such indicators include rates of accidents at work, employee turnover rates, employee energy expenditure indicators, machine fitness indicators, etc. As can be noticed, the basis for the development of industry 4.0 is modeling the relationships that occur between planned tasks and the closer and distant environment. Understanding the interplay between elements of the production process is the basis for designing feedback. Thanks to them the process variables are regulated due to the accompanying phenomena in the area of work planning, implementation of work tasks, operation of technological devices, in the field of security engineering as well as IT systems and others. That's why, it should be assumed that various categories of resources are equally important for the organization, expressed by technological variables, by the parameters of the employee's functioning and parameters of use of technical facilities, as well as by variables of communication processes. Man and his reliability have a great impact on the process. The multi-faceted description of industrial processes makes it possible to identify critical points in relation to all important enterprise resources. It allows to understand the sources of organizational deficits, but importantly it is the basis for designing regulatory mechanisms and implementing industry 4.0 principles, including: interoperability, visualization, decentralization understood as the ability of subsystems to operate autonomously, real-time attribute, orientation on services and modality.

Keywords: integrated safety management, industry 4.0, smart workplace, human factor, ergonomy

Introduction

Enterprises in the age of information are characterized by an integrated approach to the management of qualitatively diversified components, such as: technical structure of organization, components of operation, raw materials and semi-finished products, people, databases, etc. In relation to the above, in order to minimize the risk of managerial decisions, in which dynamics of the substantial accompanying phenomena are considered, a process-oriented approach and modeling the system relationships is required. A process-oriented approach in organization of work is necessary, in order to include dynamics of phenomena in the supply chain management. Whereas, modeling the system relationships is fundamental for understanding the situational context and risk management. The culmination in its assessment is knowledge of problematic situations and access to all records concerning the effects of adverse events, i.e. including accident scenarios. "A wider analysis of adverse events can only be possible if the organization has an access to the information from a significant number of occurrences" (Ewertowski, 2018).

In order to minimize the risk of adverse events that are not limited to the sole employee, but also to the company, the customer and the society, a universal responsibility for the entire safety of the system should be established and

developed taking into account all interactions between man, the workstation (machines, technical equipment) and the working environment (Górny and Sadłowska-Wrzesińska 2016).

In the integrated safety management, where priority is given to the economic efficiency, a focus is made on regular identification of hazards, occupational risk assessment and precise determination of actions required for the effective prevention of accidents and losses especially through use methods and tools dedicated for this aim/objective (Misztal and Belu 2016). Implementation of the above requires access to the resources of information and the respective technical environment. However, real-time updated data enables the reduced threat of errors, as a response to the following questions: “What should be avoided and what company's goals are being regarded?”; “What actions should be taken to extend time limits for critical decisions, the so-called one-chance decision?”; “Which system relationships are important for improvement in the safety of industrial processes?”

The purpose of this papers is presentation of an innovative approach in the field of integrated system resources, on the basis of monitoring the parameters of employee's operation. The efficiency of planned activities and long duration of tasks is adopted as a control variable during modeling, that is crucial for the improvement of labor safety. IT technologies and safety devices have been determined as the resources that jointly provide new opportunities in the management of safety, in the Industry 4.0.

Unreliability causes for operator's tasks

Among all groups of accident causes, the group related to the human factor constitutes the group with the highest number of classified accidents. According to the data published by the Central Statistical Office in Poland, as much as 61% of accidents is included in this group, which are primarily caused by improper behavior of an employee (Auksztola and Buńko 2019). Lack of attention and nuisance of employees are determined as direct accident causes, thus the factors of human operation and causes for man's unreliability, in the organizational context, should be identified in details, in order to efficiently improve the safety. “More and more frequently, workers function in the operator subsystems whose efficiency (reliability) results from the relationships between a man and a technical system. In such a case, the efficiency of the operator system constitutes a synergic result, which is, at the same time, attributed to a technical device, operator and their common environment as well as the system of the interrelationships” (Mościcka-Teske et al. 2017).

The knowledge of component characteristics, as well as characteristics of system parameters, are fundamental in designing the technical and social systems, with regard to the relationships between these components, as well as the components and their surrounding. The identified mechanisms of errors in a human being are assumed as specific properties of a human being. Conditions accompanying difficult situations, with emphasis on time deficit, are assumed as crucial with regard to the properties of the system. An example of labor method in which the aspects of above system operation are seen as important for the safety, is labor of the diagnostic and safety system operator in the automated manufacturing process. On the diagram illustrated in Fig.1, tasks related to error handling and solving were identified. Such tasks comprise of: process stoppage and reconfiguration, as well as a changes in the algorithm of system operation. Each specified category of the operator's tasks imposes high requirements on the employee, i.e. including stress resistance, high responsibility, involvement and high professional competences. Discontinuation of the process, when a decision on technological chain stoppage is required, is implemented concurrently with the IT system. Whereas, the operator frequently performs a task of the reliable redundant structure component, and operates in the event of technical failure. Reconfiguration of the process requires from the employee much experience, intuition and ability to evaluate the risk, as well as decisions in the conditions of optional solutions. Changing the algorithm of action requires from the operator considerable psychophysical skills. These situations are accompanied by a high level of psychical stress, as a result of the following phenomena: 1) an increase in input information, its complexity, variability and ambiguity; 2) laking relationship between the signal and the reaction; 3) increased participation of the neural system in the course of pursued activities.

Fig. 1: Diagram of the diagnostic and safety system in the industrial process (own research)

The verification of perfecting engineering solutions is carried out during critical tests, during simulation of difficult situations:

- overloads when requirements exceed capacity,

- triggering obstacles, when there are unexpected and problematic stimuli,

- generating conflicts, when there is a conflict of requirements, needs, values, norms, etc.,

- stimulating the conditions of deprivation, when a time deficit, information deficit and lack of resources take place.

Evaluation for the level of mental stress requires the measurements of the system and appropriate indicators, in order to obtain knowledge of factors reducing the requirements imposed on the user of the designed norms, as well as may contribute to the occurrence of unacceptable events.

Human factor as a key element integrating the system

The human factor is still crucial for the industrial safety, despite stable technological advancement, possibility of interaction between individual system components, and possibility of implementing the increasingly complex processes without any direct involvement of a man. When the human factor is under research, not only the operator performing a task should be considered, but also the constructors, people performing repairs, maintenance and management works. In all areas of activity, the human factor will influence on operation of other system resources, on the basis of mutual interactions. Despite direct connections between the devices, a person is simultaneously a general factor affecting their interaction, because a person i.e. programs, operates, maintains and supervises the devices during operation. (Berlik, Dahlke and Sławińska 2018)

There are many human factor models. One model is called the SHELL model and is used in aviation, in order to depict the role of a human factor as a component connecting other resources.

Fig. 2: Diagram of SHELL model [own study based on (Cantamessa et al. 2018)]

In the SHELL model, a man plays a key role integrating the cooperation of other system components. A man interacts with Software (programs, procedures, logistics), Hardware (machines, devices, tools); Environment (surrounding and conditions for operation of all system components - economic, physical, organizational); Liveware (a man with his psyche, knowledge, attitude, conduct, physicality, susceptibility to stress, etc.). A connection between Liveware and Liveware should be noted in this point, i.e. the mutual relationship between the people constituting components of the system. Ignoring the role of a man would be a big mistake, even at a particular instance of the process that is seemingly performed without his involvement. It should be remembered, that the responsibility for planning the process, its supervision, design, device programming and manufacturing of tools, etc., lays in the hands of a man. Paradoxically, autonomy of the process leads to the increased importance of the human factor, as a result of its greater susceptibility to hardly-detected latent errors. (Dąbrowska 2011)

Importance of the integrated safety management in the Industry 4.0

The concept of the integrated management of operational safety is a response to the requirement for the improved efficiency of operation within the organization. It was demonstrated in the research, that improvements in the safety beneficially affect other system components (Górny, Sławińska and Sobczak 2016). Whereas, focusing on the employee is fundamental for the following postulate, namely the operation of the whole system depends on the operation of a single unit, in the systemic approach. Therefore, when emphasis is made on a human being who is a trouble spot of the safety, operation of the whole system can be effectively improved (Górny 2015). Hence, adopting a strategy oriented on the improvements in labor safety is crucial for the effective management of organization. In the safety management, it is necessary to recognize the boundary constituent capabilities and indicate the critical resources enabling proper evaluation for the moment in the system, when it loses its capabilities of operation (Berlik and Ewertowski 2019). Employee's errors, with stipulation of their causes, are identified with regard to the human factor. Each error has its own mechanism, or mechanisms, thus analysis of documented phenomena can lead to knowledge of their causes. It is extremely important to design documents dedicated to such analyses, similarly to the case of ergonomics analysis for interface operation in the sewage treatment plant. The importance of error mechanisms occurring at a human being is identified in the presented concept. The first - generalization (of a stimulus or reaction), which indicates the requirement for individual experiments for each operator. The error is treated as a

natural and unavoidable phenomenon, constituting the operational principle of human nervous system. The second - habituation, namely a decrease in reactivity, an increase in the sensitivity threshold, with respect to the regularly recurring continuously influencing stimuli, at a particular time. It can be clearly observed in so called stand-by tasks. The third - anticipation, i.e. keeping a particular content in the mind until a particular goal is achieved, whereas new information can be omitted at that time. A particular number of errors occurs as a result of lacking control of a human being for two or more information streams, with means of own perception. Fourth - the principle of single-channel conduct limiting synchronization of actions, thanks to which a person may understand why the time required for the reception of a stimulus is much shorter than the time required for the selection of a stimulus. Designing a technique with regard to knowledge of psychological error mechanisms in a human being is based on cognitive ergonomics, or ergonomic engineering (Sławińska 2019). The efficiency of such projects can be evaluated with means of systemic safety indicators and key performance indicators (KPIs), which together enable integration of various rationales into the management decisions. Then, all relationships between the technical and organizational elements and the employee are taken into account. In the context of conditions multiplying fatigue of a human being, the following issues are taken into account:

- tasks are not accepted by an employee,
- negative opinion on labor organization, also with respect to breaks at work,
- excessive exposure to stress,
- unreasonable restrictions on creativity and involvement,
- lack of intuitive tools and means of work,
- forced posture at workplace,
- excessive efforts,
- unacceptable risk of exposure to harmful factors.

A detailed examination for the problems above is crucial for understanding the mutual interaction between the components of the industrial process, planning and implementation of tasks at the workplace, operation of technological devices and safety components, IT systems, as well as other components. This knowledge is implemented in the mechanisms of adjustment, therefore the risk of safety failure can be significantly reduced, as well as completation of the resources can be controlled (Sławińska et al. 2019).

It is impossible to monitor the large scope of diversified phenomena without any support of modern technical solutions (Sławińska et al. 2018). Implementation of modern IT technology in organizations is a must. The Internet of Things solutions should be considered in this respect. The importance of such solutions is prevailing, because it enables the following goals:

1. integration of system elements in the IT system environment,
2. application of safety elements that are used in the industrial processes,
3. monitoring the dynamics of phenomena in the industrial processes,
4. responding to difficult situation indicators,
5. implementing the knowledge of individual error mechanisms of a human being at particular workstations,
6. implementing the preventive mechanisms against adverse events, by supplementing the essential system resources
7. optimizing decisions during operation of utility chains, according to the scale required by decision-makers in the integrated organizational chain.

The consequence of the integrated safety management is application of systemic indicators and measurements, which include: a measuring device determining condition of the human body, such as body temperature, heart rate, measurement devices indicating dynamics of system relationships, thanks to which the mutual influence between operational components of the system can be monitored, as well as trend indicators for critical parameter values determining the efficiency of industrial processes.

The consequence of the integrated safety management is application of systemic indicators and measurements, which include: a measuring device determining condition of the human body, such as body temperature, heart rate, measurement devices indicating dynamics of system relationships, thanks to which the mutual influence between operational components of the system can be monitored, as well as trend indicators for critical parameter values determining the efficiency of industrial processes.

Technical support for the industrial process safety

A separate problem that needs to be solved while improving the safety in the Industry 4.0 is designing the system's resistance to emergency situations, in which the primary importance is assigned to communicational processes during operator's tasks. Authors understand the safety of the system as a feature of system's resistance to the influence of factors triggering the safety threats, which requires a much wider application of technology in the process, in order to support the operator interacting with the interface.

Complex technical and social systems are equipped with safety control devices, with respect to the relevant process parameters. Such devices comprise of safety switches, interlocks, safety sensors, control modules, authorization devices, control devices, etc. They are designed to specific technical solutions, but they can simultaneously provide active support for the required labor ergonomics, as well as they affect the sustainable development in the management of distribution chain. As a result of their design, they integrate system data, thus handling the information for the improvement of labor ergonomics is made easier. Thus, the level of employees' fatigue can be significantly reduced.

Safety switches used for safety guards, that must be closed during device operation. They can also be blocked during a labor break, hindering improper use of such devices. When the cover is opened, the activating element is separated from the safety switch and a message can be displayed, motivating for a respective action, whereas the supervisor simultaneously receives information about such non-compliance.

Electromagnetic safety interlocks operating in conjunction with machine control elements, e.g. motion control modules or modules with a clock unit, that prevent the condition of opening the safety guard until the end of a dangerous condition, i.e. the end of approaching movements, as well as may inform about duration of such interlock and the possible supportive actions at time of waiting for the end of the primary process. Alternatively, the employee can be informed about the relaxing activities in so-called micro-breaks, when he waits for the end of operation. Electromagnetic safety interlocks are also used in the cases, when opening the safety guard constitutes unauthorized interference by third parties. The electromagnetic safety interlocks can be a specific indicator for a problematic situation and indicate the requirement for occupational risk analysis, because they are equipped with safety measures against improper locking condition.

Limit switches with a safety function, which are used at sliding and tilting guards.
Anthropometric features should be here included, in order to eliminate the forced body posture during a specific task, following detection of dangerous machine component movements at time of maintenance works. Their installation in any assembly position provides this feature.

Application of **magnetic safety sensors** is particularly advantageous when an exceptional level of dirt is possible, or when high hygiene standards must be complied with. Possibility of mounting in a location hidden under non-magnetic materials is an advantage. As a result of this, workspaces and storage spaces can be arranged in such a way, that dirt does not accumulate on the edges. When applied, they ensure compliance with the requirements of bio-mechanics, as well as norms pertaining to load limits for body-posture. It is extremely important for the reduction of employee's fatigue.

Immobility control modules are used to securely record machine's inactivity, as well as control the electromagnetic safety interlocks. Depending on the arrangement of external circuits, the safety system may cause the forced switching. Motion control modules are equipped with an Integrated Diagnostic System (ISD) for quick and simple detection of errors. The user receives information from the immobility control module and the sensor, with means of LEDs. Data obtained from such devices is collected in the operational database and constitutes the source of information for anticipation of phenomena accompanying difficult situations, as well as can directly support operators during their labor with means of noticeably reduced stress. Delay clock modules are frequently used against dangerous situations that may occur after deactivation of the machine or installation, for example as a result of approaching movements. Knowledge obtained from these sources is fundamental for reorganization of manufacturing processes with regard to cost accounting, with consideration to biological and environmental losses.

Emergency stop cable switches are mounted on machines and installation sections, that cannot be protected with covers. Unlike mushroom emergency stop buttons, the cable switch enables triggering the emergency stop command at every point of cable. Emergency stop cable switches are activated by pretensioning the cable, e.g. in the case of dynamic logistic tasks within the area of communication routes. The signals recorded from these sources can be interpreted as conditions of increasing fatigue, when mistakes and deviations to stereotypic activities take place.

Authorization device (dead man button), together with other safety measures, are used to protect people from potentially dangerous situations, when machine guards must be completely or partially deactivated in special operating modes. These special situations include configuration of the machine, maintenance works and inspection. The device can be used in designing the labor method with consideration to individual pace of activities of a particular employee, when the button is released by the operator and the machine is safely stopped. The ability to adapt the pace of machine operation to current employee's capabilities is one principle of high-quality ergonomics of labor methods..

IT technologies in the management of the intelligent workplace

A significant advancement took place in recent years, enabling utilization of many new solutions within the same scope. Wireless communication is one important transmission medium for data and information to other devices. Information is sent wirelessly, without any application of cables, by means of electromagnetic waves, radio frequencies and infrared. The authors point out the innovative application of 4G and 5G data transmission standards, that have transformed the cellular telephony and available wireless services, such as the following examples:

- **4G LTE** (Long Term Evolution), a standard that will provide broadband Internet access, fast data transmission, a wide range of mobile services that can be used to e.g. monitor the presence and process of people's relocation with means of supporting devices, as well as registering their relevant technical parameters;
- **Wi-Fi** (Wireless Fidelity), fast wireless connection implemented at short ranges between the Internet and mobile devices, i.e. as a communication channel;
- Bluetooth, a short-range radio standard with means of electromagnetic field, for transmission of signals at short distances between telephones, computers and other devices. This technological standard enables simple communication and synchronization between devices, thus the required stimuli can be communicated, as well as the management of user's operation can be assisted, etc.

These examples of modern technology greatly affect the improvement in labor conditions in the established and dedicated communicational space, with mapping of crucial system relationships in the integrated organizational management, as shown on the diagram (fig. 2). The presented diagram for information processes enables localization of very important feedback loops, when the construction of control model based on accident scenarios is the starting point. The reference point in the constraint-control algorithm constitutes the process model and the control model. Constraint-control algorithms include human error mechanisms, thus the communication system can be generated in compliance with the model of operator's tasks. On the other hand, control functions are implemented with means of variety of sensors, that are intermediary points during the reaction with means of improvement mechanisms. Controlling the course of intended tasks is adequate to the monitoring algorithm for critical system resources.

Fig. 2: The information system diagram for controlling the intelligent workplace (own research)

The concept of using technology in the field of the Internet of Things is an innovative approach that rises the "monitoring" to a higher level, without any additional involvement of employees. A technical support is obtained when controlling the employees' attention and motivating them to safe behavior. Devices and sensors within the manufacturing hall record and generate data in the network, to which individual devices and software are connected, as well as trigger the respective stimuli sources. Most often in the form of human voice, signals imitating the sounds of nature, or images that visually communicate the content desirable for a particular situation. Here proper algorithms are the solution, that can independently take actions on the basis of available data and important control variables, in the context of particular applications and activities.

An example of relevant data is an interactive wristband, by which the employee's activity status is evaluated. The control variable for this status is heart rate, whereas the control variable is comprised between the minimum and maximum values specific to a particular person. At output, an action directed to the employee is triggered, in order to inform about the threats, as well as to the superior, in order to motivate the employee and cause a change beneficial and planned for a particular situation. This enables the pro-active management of labor methods in actual processes, with knowledge of existing constraints and available resources.

The concept of implementing technology in the field of the Internet of Things constitutes a considerable feedback in limitation of the stress induced by dangerous behavior of employees, when a human being who interacts with the industrial process becomes the component of the redundant reliability structure, i.e. a human being performs tasks of the "reserve" element in the event of emergency. As a result, what support should be provided to the operator, in order to make him do the entrusted tasks in the event of the safety threat? Designing the conditions that will provide the respective time that is required for tasks within the framework of emergency procedure is the main difficulty. "Fighting with" deficit of time required for activities securing the system in the event of a safety threat is understood as the interface designed with knowledge of human capabilities. A proper interface translates into time required for operator's tasks. If postulates and requirements for ergonomics are implemented in the IT system, the control of automatics in the labor system will be extended with sustainable resource management modules, that were stipulated in item 4. In this respect, procedure stages are presented on diagram, fig. 4.

At the initial design stage, the analysis for available records of all discrepancies is carried out. Substantial system relationships, that are a decisive factor for occurring problems, are identified. A solution method for a particular problem is searched in the practiced solutions. When such solutions are lacking, a decision can be made to eliminate the source of threat and change the technology of industrial processes. Most often, many potential solutions exist. From the list of identified solutions, a solution demonstrated by economic calculations,that is profitable to a particular organization, is selected. At the decision-making stage for the selection of technical solutions, numerous workstand experiments are carried out, in which system relationships are examined and the complexity of the ergonomics design is verified (Sławińska 2019). The scope of these works determines the size of operational knowledge database and competences relating to risk management. From the point of view of integrated safety management in the Industry 4.0, the areas of human integration should be pointed out in details, as well as tasks should be clearly allocated between the technical elements and the operator's tasks. The major problem pertains to modeling the feedback loops, after inclusion of the intervention range with regard to the reliable structure with functional redundancy. Planning the methods of generating the feedback data guarantees the following effects (Ratajczak 1988):

- reducing the loads imposed on visual organs, with respect to the perception of objects,
- ensuring accurate reception of information transmitted by indicator devices,
- enabling the most comprehensive information synthesis during the executive decision-making tasks,
- inclusion of the appearing information in the man-made subjective model of activities,
- inclusion of additional (supplementary) information sources into the general circulation of information,
- giving a man the opportunity to keep necessary information in the so-called operational memory,
- enabling the development of specific strategies of actions, e.g. the possibility of obtaining additional information.

Summary

Integration of system resources with respect to the human factor requires priorities given in the management of organization, as a result of the process safety and active support of employees. Focusing on difficult situations constitutes the basis during anticipation of the safety failure situations and the accompanying losses. Implementing the resource control projects in organization, with regard to the human factor, is fundamental in terms of increasing the reliability of technical and social systems, and simultaneously enables the efficient exploitation of all system resources. Creating a flexible technical environment on the basis of modern information technologies, as well as

manipulating the information, makes organizations open to new directions of development, also to particularly difficult situations, such as the current state of coronavirus pandemic (Oleśków-Szłapka et al. 2019).

Bozena FRACZEK
University of Economics in Katowice, Katowice, Poland, b.fraczek@ue.katowice.pl

Abstract

This paper discusses the issues of social support and the quality of life of young people with Autism Spectrum Disorder (ADS) - Asperger Syndrome - who are temporarily orphaned due to their father/parents migrating. The paper pays particular attention to social support and the quality of life of migrant families from the perspective of young people with ASD - Asperger Syndrome. The study applied the quantitative method, as well as the Satisfaction With Life Scale (SWLS) created by Ed Diener and adapted by Zygfryd Juczyński, and the Social Support Scale developed by K. Kmiecik-Baran. Participating in the study were 50 young people (39 boys and 11 girls) aged 16-18 whose parents had gone abroad for economic reasons. The results of the research show that the quality of life and social support for temporarily orphaned young people with ASD - Asperger Syndrome are at a low or medium level.

Keywords: Autism Spectrum Disorder, Asperger Syndrome, socioeconomic status (SES), social support, quality of life, migration.

Introduction

During the period of juvenescence in every young person's life, a sense of satisfaction of with one's own life as well as the support obtained from the social environment take on significant importance. These factors have an influence on the formulation of plans regarding the future, and determine future activities. They are also essential for every young person, especially for a person with a disability, in particular when changes occur in the family structure as a result of migration of a parent or parents.

The term "satisfaction with life" is ambiguous, multidimensional and interdisciplinary. The following terms are used by researchers interchangeably and regarded as synonymous: quality of life, contentment with life, well-being, happiness (Argyle 2004, Cegła and Bartuzi 2004, Czapiński 2004, De Walden-Gałuszko 1994, Jaracz 2001, Veenhoven 1991).

According to Czapiński (2004), "life satisfaction" is depicted as the emotional and/or cognitive balance of life at the value level (pleasant-unpleasant, good-bad). Jaracz (2001) defines "satisfaction with life" as a criterion of the quality of life. She regards it as a conscious judgment, the result of evaluation and valuing areas of life and life as a whole. Juczyński (2001) defines "life satisfaction" as the result of a conscious, cognitive comparison of one's own situation with individually determined standards. When the result of such a comparison is positive, a person feels a sense of satisfaction. The above definition is accepted for the aims of this work. Young people with Asperger syndrome have problems with social functioning, resulting from Autism spectrum disorders, a complex neurological disorder, the ethology of which is still unknown. Existing studies identify a series of genetic, neuroanatomic and immunologic anomalies, as well as dysfunctions in the area of activity. In 2013, DSM-5 replaced Autistic Disorder, Asperger's Disorder and other pervasive developmental disorders with the umbrella diagnosis of autism spectrum disorder (ASD) (https://www.psychiatry.org/psychiatrists/practice/dsm). Asperger's syndrome is the mildest form, with a mild spectrum of autism disorders.

In diagnosis of ASD, two axial symptoms must be observed: disorders of communication/social interactions and stereotypical, repetitive behavior.

In the case of Asperger syndrome, there is no retardation or impairment of general language development or cognitive functions. This means that people with ASD - Asperger's, despite normal (or sometimes extraordinary) intelligence face certain difficulties, for example, in accepting the views of other people, regulation of their own behavior based on reactions to their environment, and lack of control over eye contact, facial expressions, body posture or gestures (Cybulska et al. 2016). In addition, people with ASD, especially young adults entering adulthood, experience significant difficulties in achieving independence (including financial independence). An important aspect that is seldom highlighted is that people with ASD, especially young adults entering adulthood, may be afraid of financial responsibility (paying bills, filing taxes, making financial decisions regarding saving, investing or borrowing money etc.) (Cheak-Zamora et al., 2017).

Thus, a social support network is of significant importance in such a person's day to day functioning and in their perception of reality. More and more attention is also being paid to financial education and the importance of incorporating it into early education to empower these people. Research indicates that for people with disabilities, psychological well-being, overall independence and at the same time satisfaction with life may be improved by being able to manage their own finances (Abbott and Marriott 2013; Taylor et al. 2011).

According to Sęk (2005), social support from the functional perspective is regarded as a type of social interaction undertaken by one or both parties, who participate in a situation that can be problematic, difficult, stressful or critical, considering that in the course of such an interaction, an exchange takes place of emotions, information, action instruments and tangible property. Such an exchange can be unilateral or bilateral, and the direction donor-recipient can be constant, but can also change. In a dynamic arrangement of interactions, we can distinguish seeking and supporting persons, and receiving or donating persons. In order that such a social exchange is efficient, it is essential to adjust the type of support to the needs of the recipient. The aim of supporting interactions is to maintain and de-escalate the crisis or level of stress by accompanying the recipient, participating in an exchange of emotions, creating a feeling of identity, safety and hope, working towards a solution to the problem, and overcoming difficulties
Sęk (2001) proposes a classification of types of support depending on the content of the social exchange:

1. Informational support (cognitive), is the provision and exchange of information and the giving of advice, which promote understanding of a situation, of a person's own situation in life, and their problems. This also concerns providing feedback on the efficiency of remedial actions taken by the supported person, as well as the sharing of their own experience by persons undergoing similar problems. Informational support meets the necessity of understanding the essence of critical events and their causes. This type of support is most often provided by persons with whom we have social relations.

2. Instrumental (material) support, consisting of providing direct help in the form of loans, gifts or services. It also includes providing information on particular ways to proceed, and a model of efficient remedial behavior. Such support can take the form of activities that are to the benefit of the people in need: providing meals, shelter, a home, funds or medicines. This type of support, similarly to informational support, is most expected and required in situations such as catastrophes, natural disasters etc.

3. Appraisal support consists of expressing acceptance and respect, and of acknowledging the value of the person. It is often the case that evaluative support can be expressed by supporting parties in non-verbal forms. This can take place in situations when such potential is appreciated and emphasized, such as achievements in various forms of activity: social roles, artistic production, physical achievements and sports rivalry.

4. Emotional support consisting of relaying supporting, calming emotions, being a manifestation of concern, and maintaining a positive attitude towards the supported person. Supporting behavior is also aimed at creating a feeling of belonging, care and increasing self-esteem. Thanks to emotional support, those suffering can be free of their stresses and negative feelings, and can express their fears, anxieties and sadness. This has an influence not only on the improvement of the supported person's self-esteem, but also on his or her state of being. Appropriate behavior on the part of the supporting person also releases a feeling of hope. Such support ensures an individual that he or she is loved and that people care about him or her.

Some authors propose that the division of social support includes two more types based on the structural features of support. These include:

- perceived support, resulting from the convictions of a person and his/her knowledge about from whom and where he/she might obtain support in a difficult situation, as well as the availability of the support network,
- obtained support (provided), which is objectively evaluated by the recipient as the actually obtained type and amount of support (Sęk 2001, Cieślak and Eliasz 2006).

Social support contributes to limiting the negative effects of critical life events, stress, apathy and low self-esteem. Support provided by various existing social bonds gives a feeling of closeness, acceptance and understanding from other people. Contact with other people results in a feeling of belonging, favors social integration, shapes self-evaluation, and has an influence on increasing self-esteem. It also enables wider social contacts, at the same time revealing useful ways of coping with various problems.

In this article, the types of support presented should additionally be analyzed in the context of financial/economic conditions, as disabilities, including intellectual disability among children with ASD - Asperger syndrome, may affect the socioeconomic standing of entire families (Kałużna-Czaplińska et al. 2018).

Socioeconomic status (SES) encapsulates the subjective perceptions of social status and social class, but it also encompasses income, educational attainment and financial security, in other words quality of life attributes (Assari et al. 2019). It should be stressed that the economic/financial possibilities of providing particular forms of social support, as well as the economic situation of a particular family both have an influence on satisfaction with life and social support (Pisula 2017, Singh-Manoux et al. 2003).

In the case of young people with ASD - Asperger syndrome, indispensable therapy provided by professional entities within the scope of particular types of social support or its supplementation requires appropriate financial expenditure [Roddy & O'Neill, 2018; Horlin et al., 2014]. In professional therapy for people with communication disorders, the most commonly used services are adjusted to the needs of particular patients. These services are provided by therapists, nurses, dieticians and psychologists, as well as by providers of alternative therapeutic services, e.g. music therapy, aromatherapy and many more (Ghasemtabar et al. 2015, Helps 2016, Olsson et al. 2013). As elements of indispensable therapy, these services generate relatively high costs. In many cases, the situation also requires additional support in terms of effective application of financial resources (financial consulting).

It should also be mentioned that taking care of children with disorders is a burden on the family budget. The worse economic situation of families with children with Asperger syndrome is a result of both increased expenditure and decreased income (Frączek and Gagat-Matuła 2018). Due to the worsening economic situation of families and the limitations in particular forms of social support, parents often decide that one of them should migrate for economic reasons. The circumstances of the migration of one of the parents cause additional disadvantageous conditions which can have an influence on the satisfaction with life of young people in the period of juvenescence with ASD - Asperger syndrome. Such circumstances determine a particular need for social support.

Meanwhile, social activities conducted as a part of social support for families with children with ASD do not always answer the reliable and comprehensive diagnosis of the needs and conditions required for the functioning of these families, and are also often chaotic, sporadic and incomplete. Additionally, the knowledge and experience of people employed in organizations providing care and rehabilitation services is inadequate in many ways. All these factors together may result in the obtained aid being incomplete and sometimes inadequate (Otrębski et al., 2014).

In relation to these considerations, the aim of this article is to determine the relationship between perceived social support and the satisfaction with life of young people with ASD - Asperger syndrome in families in which parents migrate.

Research Principles

The aim of the study was to determine the relationship between perceived social support and the satisfaction with life of young people with ASD - Asperger syndrome in families in which parents migrate. The aims were expanded in the form of the following research question: *To what degree does social support as perceived by young people with ASD - Asperger syndrome who are temporarily orphaned due to a parent's migration have a relation to their satisfaction with life?* Detailed questions were also developed:

1. What is social support as perceived by young people with ASD - Asperger syndrome temporarily orphaned due to the migration of a parent?

2. What is the satisfaction with life of young people with ASD - Asperger syndrome temporarily orphaned due to the migration of a parent?
3. What is the satisfaction with life of young people with ASD - Asperger syndrome temporarily orphaned due to migration of a parent, who perceive less social support in comparison to those perceiving greater support?

This work does not state a hypothesis to the research problem as the character of the problem is explorative. In order to determine satisfaction with life, *the Satisfaction with Life Scale* (SWLS) by Ed Diener and adapted by Zygfryd Juczyński was used. The Scale of Social Support by K. Kmiecik-Baran was used in order to determine the level of social support. The study was conducted in 2019 at a clinic for people with Autism. The analyzed group was of 50 persons (39 girls and 11 boys), aged 16 to 18, whose parents were economic migrants. Purposive sampling was used in the research.

Analysis of Results

In the first stage, analysis was conducted of the social support provided to young people with Asperger syndrome whose parents had migrated. This presents the level of obtained social support in the general, as well as its particular types. The raw results and results in stens are given.

Table 1: Level of social support perceived by young people with ASD - Asperger syndrome temporarily orphaned due to the migration of a parent

Type of support	M	Sd	Median
General support	130. 99	24.85	126
Informational support	30.01	9.80	32
Instrumental support	34.23	9.43	35
Appraisal support	30.98	9.28	31
Emotional support	32.35	9.22	32

The study results presented in Table 1 show that social support as perceived by young people with ASD - Asperger syndrome is poor in the general scale as well as in its particular types. The total sum of points in this study could amount to: between 48 and 240 in the general scale, and between 12 and 60 in the subscales. Young people with Asperger syndrome temporarily orphaned due to migration of parents had a mean value at a level of 130.99, while the median was 126. Each group consisted of 25 persons.

The next step was to determine the satisfaction with life of young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents. Table 2 presents the results in this area.

Table 2: Basic Satisfaction with Life Scale (SWLS) results statistics for young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents

Satisfaction with Life Scale (SWLS)	Young people with ASD - Asperger syndrome **(N=50)**	
	M	**SD**
1. In most areas, my life is close to being ideal.	20.9	5.55
2. My conditions of life are perfect.	21.7	5.79
3. I am satisfied with life.	21.1	6.01
4. So far, I have completed some important things that I wanted to fulfil during my life.	27.9	6.84
5. If I was to live my life again, I would not change almost anything.	23.2	6.23

The results indicate the average satisfaction with life among the respondents. The highest results were noted in the following scales: *So far, I have completed some important things that I wanted to fulfil during my life.* (M=27.9*); If I was to live my life again, I would not change almost anything*. (M=23.2). *I am satisfied with life*. (M=21.1). The

lowest, but still average, results of young people with Asperger syndrome temporarily orphaned due to the migration of parents were noted for: *In most areas, my life is close to being ideal*. (M=20.09). *My conditions of life are perfect*. (M=21.7).

In order to determine the differences between respondents who perceived poor and high social support in the field of satisfaction with life, the Mann-Whitney U test was used, the values of which were expressed in Z units. Young people with Asperger syndrome temporarily orphaned due to the migration of parents perceived higher social support and higher satisfaction with life in the scale So far, I have completed some important things that I wanted to fulfil during my life. M2=53.99), in comparison to young people who perceived poor social support (M1=50.99). The difference is statistically significant - $p<0.05$. The results for the other scales were not statistically significant.

Table 3 presents an analysis of the dependencies between social support and perceived satisfaction with life of young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents.

Table 3: Dependencies between social support and satisfaction with life

KWS / SWLS	Informational support	Instrumental support	Appraisal support	Emotional support	Overall support
Sum 1	0.020	-0.079	0.133	0.137	0.032
Sum 2	0.030	-0.102	0.135	0.279	0.036
Sum 3	0.031	-0.106	0.139	0.277	0.045
Sum 4	0.229	-0.121	0.129	**0.405****	0.269
Sum 5	-0.089	0.234	-0.237	-0.087	-0.031

A positive relationship of moderate strength was found between emotional support and the scale So far, I have completed some important things that I wanted to fulfil during my life, which was statistically significant at the level of $p<0.05$. This indicates that young people with Asperger syndrome with a higher level of emotional support more often feel fulfilled in life and experience joy in relation to realization of their own plans and dreams. The correlation is significant at the level of $p<0.05$.

Conclusions

1. Social support as perceived by young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents is poor both in the overall scale as well in its particular types.

2. Young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents perceive an average satisfaction with life.

3. Young people with ASD - Asperger syndrome temporarily orphaned due to the migration of parents, who perceive social support to be greater, more often feel satisfaction with life in the scale So far, I have completed some important things that I wanted to fulfil during my life, than young people who perceive social support to be poorer. The former group have plans and dreams that they want to fulfil, and they feel that their lives have sense. The difference between the results of respondents from both groups is statistically significant at the level of $p<0.05$.

4. A statistically significant relationship at the level of $p<0.05$ was found between emotional support and the scale: So far, I have completed some important things that I wanted to fulfil during my life,. Young people with ASD - Asperger syndrome with a higher level of emotional support more often feel fulfilled in life and experience joy in relation to realization of their own plans and dreams.

Abstract

The article is devoted to the study of the income of individuals as a source of the long-term resource base of the Russian banking sector, for the period 1999-2019 and up to the beginning of 2020. It has been established that household deposits are the basis of long-term resources of the Russian banking sector. In the analyzed period, there are fluctuations in the share of long-term deposits of the population in bank liabilities, while the same indicator for the total deposits of individuals demonstrates positive dynamics, which required an analysis of a number of additional factors. It is noted that the introduction of the institution of compulsory deposit insurance had a stronger positive impact on the attraction of long-term deposits of the population by banks, in comparison with the attraction of total deposits of individuals. The influence of taxes on personal income on the structure of financial investments of the population was revealed. It is substantiated that changes in the personal income tax on investments in financial assets affect the investment preferences of the population. It is noted that in the context of a pandemic COVID-19, a reduction in long-term household deposits can have a negative impact on the long-term liquidity of the Russian banking sector. The relevance of the study of the impact of household deposits on the resource base of Russian banks is substantiated, taking into account the practice of taxation of personal income from investments in various financial assets.

Keywords: income of the population; deposits of the population; financial investments of the population; personal income tax; pandemic COVID-19.

Introduction

The change in the technological paradigm, which has led to the digitalization of public life in all areas, requires large-scale long-term investments. In the Russian model of corporate finance, which is based on banks, the latter bear the burden of responsibility for providing long-term resources for the development of the economy at an acceptable pace. This possibility depends not only on the capital base of the banks, but also on the term structure of liabilities.

The modern economy presupposes the formation and subsequent effective use of capital of a mixed structure by economic agents. In addition to its own funds, the bank's capital is formed by liabilities to financial and non-financial counterparties (Manuylenko et al., 2016). In turn, the availability of long-term corporate financing ensures the stability of the corporate sector, reduces the volatility of growth of corporations - borrowers, including in times of crisis (Demirgüc-Kunt et al., 2017). Bank loans play a leading role in this.

Cite this Article as: Olga S. MIROSHNICHENKO, Valery V. GAMUKIN, Natalia V. POKROVSKAIA and Natalya S. VORONOVA "Household Income as A Factor in The Long-Term Liquidity of The Russian Banking Sector: Taking into Account Additional Factors" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Effective decisions on the placement of funds have a positive effect not only on the profitability of an individual bank and the banking sector of the national economy, they contribute to strengthening the banking financial stability, prevent (or significantly reduce) the costs of supporting the banking and financial sector in general, which is especially important in conditions of crises (Pokrovskaia t al., 2020).

A feature of the modern Russian credit market is the increasing role of households as the most important suppliers of domestic resources of various urgency, including long-term ones. At the same time, the predominant form of accumulating free funds of the population is bank deposits.

The purpose of this work is to study the deposits of the population as part of the long-term resources of the domestic banking sector as a source of financing the investment needs of the economy and to reflect the influence on the investment potential of factors caused by taxation of household income from investments in various financial assets.

There is a difference in the purpose of funds attracted by banks for periods of more than a year. Namely, there are differences between the goals of forming bank sources of financing for the long-term needs of the economy and the goals of providing the bank with its own funds. Our work is focused on the study of the long-term resource base in terms of liabilities, and does not affect the attraction of sources aimed at the formation of the bank's regulatory capital. An attempt has been made to substantiate the influence on the investment behavior of the population of the peculiarities of taxation of income of individuals from investments in financial assets, which undoubtedly affects the dynamics of bank deposits of the population.

Review of Relevant Research

The study of household deposits in banks is quite often the object of interest of researchers (Iannotta et al., 2007; Trofimov, 2017; Nielsen and Weinrich, 2019; Miroshnichenko et al., 2020).

Aggregate deposits (including deposits of individuals) have an impact on the financial performance of banks. Thus, when assessing the financial stability of banks, B. Tabak, D.Fazio, K. Paiva and D. Cajueiro (2016) use several indicators that imply the inclusion of deposit indicators in their calculation: balance sheet, the ratio of customer deposits, defined as the percentage of customer deposits to total banking assets / liabilities, is used to assess the financial penetration of the banking sector's deposit operations (as an indicator of the availability of banking services) - total deposits in banks per square kilometer of the country's area. The approach that presupposes the assessment of the financial stability of a single national banking sector operating throughout the state is based on the assumption that banks operate in the same legal and institutional environment (Bouheni and Hasnaoui, 2017). These authors also use the ratio of deposits to total banking assets / liabilities as one of the indicators to assess the cyclical nature of the financial stability of the banking sector.

The work of A. Demirguch-Kunt, T. Beck, P. Honovan (2016) is devoted to the study of the influence of financial penetration on the income of the population. The authors argue that the development of the financial and banking sectors contributes to an increase in the share of incomes of the poorest strata of the population and a decrease in the level of poverty.

Russian researchers M. Malkina and I. Khramova (2017), conducting a country and regional analysis of the factors of the population's savings, argue that the savings rate in a particular country is not related to current per capita income, but ultimately depends on long-term income growth rates and demographic structure of the population.

The study of the behavioral aspects of the choice of an economic person is carried out by V. Ivanitsky and S. Alexandrov (2017). The exogenous conditionality of prices and consumer income is characterized as one of the limitations that must be taken into account when building a model of an economic person; in conditions of incomplete information, a person gives preference to his own interests.

National features of taxation of personal income from investing in financial assets that differ in investment attractiveness are considered both for the purposes of cross-country comparisons (OECD, 2018) and within the framework of characterizing trends in the financial behavior of the population (Abramov et al., 2020). However, the predominant focus of these studies is investing individuals in the stock market.

Thus, studies devoted to the analysis of the relationship between the income of the population and the term structure of bank deposits of individuals are not fully represented in the scientific literature. At the same time, the fact that the dynamics of bank deposits of the population is significantly affected by additional factors, in particular, taxation in the field of income of individuals from investments in financial assets, is overlooked.

Information and Methodological Base of The Research

For the study, a statistical base was formed, including indicators of the banking sector and macroeconomic indicators of the Russian Federation.

The data on the total income of individuals was obtained from the official publication of the Bank of Russia 'Review of the Russian banking sector'.

Data on deposits of organizations in the banking sector, on issued bank certificates (deposit and savings), on the value of assets / liabilities of credit institutions for 1999-2020, on deposits of individuals for the periods 1999-2003. and 2007-2020 obtained from the website of the Bank of Russia, section 'Statistics', subsection 'Banking sector', database 'Indicators of activity of credit institutions. Information on the funds raised '.

According to the regulator's approach and the current reporting standards, the liabilities of credit institutions are divided into the following groups based on urgency: on demand, for a period of up to 30 days, for a period of 31 to 90 days, for a period of 91 to 180 days, for a period of 181 days to 1 year, for a period of 1 to 3 years and for a period exceeding 3 years. In this work, liabilities with maturities from 1 to 3 years and for a period exceeding 3 years were summed up, and further analyzed as long-term.

This author's approach is due to prudential requirements for the fulfillment of mandatory liquidity ratios, and, first of all, the long-term liquidity ratio, the calculation of which involves the use of data on bank liabilities for a period of more than one year, or long-term from the position of liquidity.

To analyze the conditions for taxation of personal income on bank deposits, the information base was presented with statistics from the Global financial development Database of the World Bank, as well as a description of the conditions for taxation of interest income of individuals from EY's Worldwide Personal Tax Guide.

Results

Long-term resources of the banking sector are accumulated as a result of the use of such financial instruments of attraction as deposits and bonds; bank counterparties for the specified financial instruments are individuals, as well as non-financial organizations; bank bonds can be purchased by other credit institutions. Data on the share of long-term deposits of non-financial organizations, the population, and issued bonds in bank liabilities are presented in Fig. 1.

As the data show, since 2001 and throughout the entire subsequent analyzed period, household deposits prevail in the long-term resources of the banking sector. In 2015, there is another decrease in the share of long-term deposits of the population in liabilities, and as of the beginning of 2016, this share corresponded to the share of long-term deposits of non-financial organizations. The share of issued long-term bonds in the composition of bank liabilities is insignificant, in the analyzed period does not exceed 2%.

Fig. 1: Dynamics of the share of long-term resources in the liabilities of the banking sector in 1999-2020, at the beginning of the year

Source: Authors' calculations based on data from the Central Bank of the Russian Federation.

It can be concluded that banks issue long-term bonds for purposes other than the formation of sources of long-term investments in the economy, which is confirmed by research (Miroshnichenko and Tarasova, 2018).

The dynamics of the share of long-term deposits of non-financial organizations is of interest. During the post-crisis recovery period, which fell in 1999-2001. and the period of economic recovery that followed, until 2006, non-financial organizations used long-term resources in their activities, and did not actively place funds in the banking sector. During this period, macroeconomic and global conditions were favorable for the development of the real sector. The progressive development of the economy has led to the formation of an increased volume of long-term temporarily free resources in organizations of the non-financial sector, which not only cover their own needs of non-financial organizations, but are also sent to the banking system.

It seems that this fact should be assessed, rather, as unfavorable, since it indicates a decrease in the investment capacity of the real sector of the economy in the analyzed period, a reduction in the possibility of effective use of long-term resources, and production development. This trend continued until 2016, when non-financial organizations needed funds to maintain their current activities, in the absence of surpluses.

The main source of the formation of the long-term resource base of the domestic banking sector is the funds of the population.

In the analyzed period, there are fluctuations in the share of household deposits in long-term bank liabilities. The increase in the share is typical for 2000-2005, 2009-2010, 2013 and 2016. Growth period 2000-2001 is a period of post-crisis recovery of the Russian economy, which happened much faster than analysts predicted (Greenspan, 2017). The following years (2002-2005) fell on a period of economic growth. Reduction of the share of long-term deposits of the population from the beginning of 2006 to 2008 due to the development of residential mortgage lending, in which deposits previously placed in banks acted as a share of the mortgage borrowers' own funds in the loaned transaction. Growth in household deposits in 2009-2010 largely due to the growth of their foreign exchange component, which took place against the background of the depreciation of the ruble. In 2008, 2011, 2014 and 2017, the points of the beginning of the reduction phases of the analyzed share are marked.

The formation of an unfavorable trend in attracting long-term deposits of individuals by banks is noted. So, if in 1999-2010 the trend of cyclical fluctuations in the share of household deposits in long-term bank liabilities had a positive trend, then after a fall in 2011-2012 and subsequent insignificant, not reaching the value of the beginning of 2011, growth in 2013, there is a negative trend direction.

The dynamics of the ratio of deposits to household income, which has a pronounced upward trend, is indicative. As of the beginning of 2003, when the inflation rate dropped to less than 20%, and during the subsequent period, there is an excess of the ratio of deposits to household income over the inflation indicator, which can be regarded as the beginning of the formation of a savings model of household behavior. The trend is growing due to a historical event for Russia of the same period: in December 2003, Federal Law No. 177-FZ 'On Compulsory Insurance of Deposits in Banks of the Russian Federation' was adopted, which influenced the public's confidence in the banking system as a result of the formation of the deposit insurance institute.

As D. Macmillan (2019) notes, the introduction of a compulsory deposit insurance system, the main goal of which is to level the banking risk associated with the 'flight of depositors', to create equal competitive conditions in the market for household deposits, at the same time neutralizes the depositor's risk; despite the emergence of a high probability of moral hazard (Bouheni and Hasnaoui, 2017). A number of researchers come to the conclusion that the introduction of deposit insurance increases the likelihood of banking crises due to the acceptance of high risks by banks (Allen et al., 2015; Qian et al., 2019; Ji et al., 2018; Macmillan, 2019).

Nevertheless, the institution of compulsory deposit insurance is present in the vast majority of countries. The answer to this paradox is substantiated by Yang Ji, Wenlong Bian and Yiping Huang (2018), who divided the effects of the creation of the institution of compulsory deposit insurance into 'direct' and 'indirect'. The 'direct' effect is to increase the likelihood of banking crises, the 'indirect' effect is to reduce the likelihood of non-bank financial crises. Results based on data from 64 countries over the period 1970–2009. showed that the 'indirect' effect is 2-5 times higher than the 'direct' effect, thereby substantiating the expediency of the most important institution of modern economics.

When comparing the data on the dynamics of the ratio of household deposits to liabilities, and the ratio of deposits to household income, it was found that households with surplus income place deposits in banks, and the presence of such households has not become widespread. The introduction of the institution of compulsory deposit insurance had a more significant positive impact on the attraction of long-term deposits of the population by banks, in comparison with the attraction of total deposits of individuals.

In fig. 2 presents data on the ratio of total deposits of the population and money income of the population in comparison with the Gini index. As evidenced by the data (see Fig. 2), the ratio of the total deposits of the population in the banking sector and money income in comparison with the Gini index has a significant variation in values. The largest number of observations falls on the values of the Gini index in the range of 41% -42%. In other words, in the specified range, there is a higher increase in deposits compared to an increase in income. At the same time, the ratio of the quantities under consideration is not linear. Consequently, in addition to cash income, other factors that require further study also affect the total volume of deposits of individuals in Russian banks, excluding the timing of attracting.

A somewhat different situation is typical for the activity of the population in placing incomes in long-term deposits (see Fig. 3).

It can be concluded that there is a relationship between indicators at minimum and especially maximum values of the Gini index. With the growth of the Gini index, the population is more active in placing income in long-term bank deposits of the banking sector. Thus, long-term deposits in the Russian banking sector determine the incomes of the wealthiest households, which poses a threat to the long-term banking resource base, since with a decrease in rates in the economy, an outflow of funds from banks to other sectors of the financial market is likely.

The preferences of the population in choosing the timing of investing in a bank deposit can be influenced by the system of taxation of bank deposits. In particular, in the Republic of Belarus income from bank deposits since the 1990s were exempt from taxation, but from April 1, 2016, a tax of 13% (a single rate of income tax in Belarus) began to apply on these incomes. Tax is levied only on deposits in Belarusian rubles placed for a period of less than one year, and deposits in foreign currency for a period of less than two years. Demand deposits and current accounts, the interest rate of which is equal to the rate of demand deposits, are not taxed. Thus, through taxation, an attempt has been made to regulate the duration of placing funds on a bank deposit. According to the National Bank of Belarus, in 2015 the share of bank deposits for more than 1 year in national currency was 18.4% of all deposits, in 2016 this share increased to 29.5%, and in 2019 - to 34.5%.

The national policy in the field of taxation of household income from bank deposits and other types of financial investments of the population is associated with the importance of the banking sector. The World Bank calculates the ratio of bank deposits to GDP in the framework of the assessment of global financial development. The corresponding indicator allows comparing the importance of bank deposits as a way of saving, as well as the scale of the banking system, taking into account the economic development of the country.

With total bank deposits accounting for more than half of global GDP, the values for individual regions and countries vary significantly. In seventeen out of one hundred sixty-seven countries for which information on demand, time and saving deposits at domestic deposit money banks as a share of GDP for 2017 is provided, the volume of bank deposits exceeds GDP, in thirty-seven - it is more than 80% of GDP, half of the countries (eighty two) - over 50% of GDP.

Fig. 4: Bank deposits as a percentage of GDP in developed markets in 2017
Source: Global financial development Database. World Bank.

At the same time, when comparing countries in terms of the corresponding indicator, it is important to take into account both the differences in the value of GDP and the focus on actively attracting bank deposits from non-residents (for example, in Luxembourg, Hong Kong, Cyprus, Switzerland, etc.).

The ranked values of the ratio of the volume of bank deposits to GDP for countries with developed and emerging financial markets are shown in Fig. 4 and 5.

Fig. 5: Bank deposits as a percentage of GDP in emerging markets in 2017
Source: Global financial development Database. World Bank.

While the ratios of bank deposits to GDP are similar in selected advanced and emerging market economies (eg Norway and Brazil, Portugal and the UAE, Thailand and the Republic of Korea), the group averages differ. Whereas in emerging market countries the average value of bank deposits in 2017 is about 60% of GDP, in developed market countries this value is twice as high - 121% of GDP.

Tax conditions of taxation of income on bank deposits (Table 1) reflect the degree of development of the financial market. The average tax rate in emerging market economies is lower than in developed market economies. At the same time, there are significant differences within the groups as well. Tax conditions may reflect national (Victorova et al., 2020b) and cultural characteristics (L'vova et al., 2016), the level of digitalization (Victorova et al., 2020a), separation of tax powers (Bannova et al., 2015; Salina, 2011; Pokrovskaia, 2020), level of the shadow economy (Fedotov and Pokrovskaia, 2017) and other economic parameters.

Table 1: Taxation of bank deposits in developed and emerging markets

Country	**Tax rate for bank deposit interest income**
1. Emerging markets	
Brazil	from 15% to 22.5%, depending on term
Chile	35%
China	Non taxable
Czech Republic	15%
Egypt, Arab Rep.	20%
Greece	15%
Hungary	15%
India	10% for interest exceeds INR40,000 and INR50,000 for senior citizens age 60 or older
Indonesia	20%

Malaysia	8%
Mexico	20%
Pakistan	15%
Peru	20%
Philippines	20%
Qatar	10%
Russian Federation	35% for deposit on non-market conditions
South Africa	15% ZAR23,800 and ZAR34,500 for senior citizens age 65 or older
Thailand	-
Turkey	15%
United Arab Emirates	-
Average for emerging markets	17%

Source: compiled by author's on EY, 2019.

Country	**Tax rate for bank deposit interest income**
2. Developed markets	
Australia	10%
Austria	25%
Belgium	15%
Denmark	8% for first DKK50,217 42% for next DKK 507,844 56% over DKK,061
Finland	30%
France	30%
Germany	25%
Ireland	35%
Israel	15%
Italy	26%
Japan	20%
Korea, Rep.	20%
Luxembourg	20%
New Zealand	10.5%, 17.5%, 30% or 33% according to tax identification numbers
Norway	22%
Portugal	28%
Singapore	15%
Spain	19% for first EUR5,999.99 21% for amount from EUR6,000 up to EUR49,999.99 23% for amount from EUR50,000
Sweden	30%
Switzerland	35%
Average for developed markets	22%

Formally, the highest tax rate on income in the form of bank deposits among countries with emerging financial markets and economies in transition is set in the Russian Federation - 35% (the rate is applied from 1997 to 2020). However, the specified rate is applied in Russia not to all bank deposits, but only to deposits whose interest rate exceeds a certain limit - the refinancing rate (since 2016 - the key rate), increased by 5 percentage points (for deposits in rubles), or 9% (for deposits in foreign currency); in other cases, income from bank deposits is exempt from taxation. In other words, at a nominally very high tax rate, in reality it is not paid in most cases. Since this restriction was conceived as an obstacle for bank deposits attracted on non-market conditions, the specified tax rate is intended to play only a regulatory role, and that has lost its relevance due to the development of tax legislation in terms of determining conditions based on the results of transactions between related parties. At the same time, the existing taxation procedure for income from bank deposits in Russia has repeatedly shown its disincentive influence during periods of financial crises, primarily in 2008 and 2014, incl. due to the shortcomings of using the refinancing rate as a benchmark for raising funds from the population.

At the same time, despite the challenges of the COVID-19 pandemic for the Russian banking system, the vector of personal income taxation is changing from 2021. Interest on bank deposits in Russian banks will be taxed at the base income tax rate of 13% with tax exemption for interest on deposits of up to 1 million rubles for each tax resident of Russia. The declared goals of this innovation is to increase the fiscal significance of the tax in the framework of ensuring social justice. However, if the significance of potential tax revenues for solving urgent problems of the state raises doubts, then the negative consequences of the outflow of private savings from the Russian banking system can be observed already at the end of 2020.

As a result of the study, it was found that among the long-term liabilities of the banking sector, which provide financing for the investment needs of the non-financial sector of the economy, there are deposits of individuals, organizations, and also long-term bonds. At the same time, deposits of individuals prevail in the structure of long-term bank liabilities. Differences in the activity of the population to place income in bank deposits, depending on the term, were revealed. Incomes have a greater impact on the activity of the population in placing long-term deposits than on the activity in placing in aggregate, without specifying the term for attracting, bank deposits.

The institution of insurance of bank deposits, introduced in Russia in mid-2004, is not a primary factor in the placement of income by the population in bank deposits. The ratio of long-term deposits of the population and bank assets / liabilities is characterized by the nature of fluctuations, while a similar indicator calculated for total deposits without taking into account the term of attraction shows an unambiguous positive trend. An unfavorable trend was noted in relation to long-term deposits and liabilities of the banking sector.

The revealed tendency does not contribute to strengthening the long-term resource base of the domestic banking sector, which funds long-term investment loans to non-financial organizations. In the context of the COVID-19 pandemic and the expected decrease in household income, it is very likely that the population's long-term deposits in banking resources will decrease, which should be reflected in the adjustment of banking policies and taken into account by the regulator when controlling the risk of long-term liquidity of the banking sector

Abstract

The article defines the essence and content of social health. It has been shown that reproduction of health reflects birth process of healthy generation, the basis of which is a full-fledged set of genes and hereditary factor. Health preservation is not only a biological problem. Health is directly related to the level, mode and quality of life of each person and the population of the country as a whole.

Keywords: Social Health, Social Risks, Human Capital, Pandemic, Coronavirus.

Introduction

The problem of social health, without exaggeration, is one of the significant problems of modern society. Health is a fundamental value of a person. This concept is associated with "life" has an antonimic relationship with the concept of "disease". In general, it is an estimated category by the functional optimum of human body. Therefore, health, its criteria, properties and its protection cause not only medical but also multidisciplinary scientific interest. Health of each member of the society increasingly suggests functioning effectiveness of each sphere of life. Russian scientist V. Kolesov, considering the problem of human social health, notes that its relevance is due to a number of important reasons such as: global changes in socio-economic situation, changes in familiar life stereotypes, profound changes in the society consciousness and huge information flows that affected the vast majority of citizens. It is naturally that many difficulties appear in such conditions and people have to adapt to rapid changing conditions of nature and the society [Kolesov, 2009, p. 218].

At the beginning of the 21st century, the intensity and diversity of risks increased. Therefore scientists began to talk about risk as an integral part of modern society which can lead society to destruction and death. Over the past decades, a number of new risks have appeared and become a part of modern life. Today, society creates new types of risks that lead to instability and self-destruction. The problem, however, is not only to consider the diversity of risks, their scale and focus, but also that safety sometimes becomes a danger or becomes a risk. In general, risks to the social health of population are formed in the process of social interaction and "become determinants of behavior".

Among many global risk-related problems of humankind that actualize the study of social health, pandemic phenomenon has a special place. The pandemic is one of the constant things of humanity's existence since ancient times. This is evidenced both by texts of a religious-mythological orientation and recorded events in historical existence. The pandemic has always been and it is an emergency situation that threatens the existence of humanity. Today's situation with coronavirus has become a significant threat factor to social health for the entire world community. Now coronavirus pandemic, with all the medium-term uncertainty of the outcome, seems to be a milestone event that has broken not only economies of many countries, but also the most comfortable model of socio-cultural development related to the protection of social health of population.

Research Methods

The methodological program of the study has a comprehensive interdisciplinary character, combining the main strategies such as: social phenomenology; terminology analysis to define such basic concepts as "social health," "risk society," "social risks." To analyze the phenomena of social health and risk, systemic and interdisciplinary approaches

Cite this Article as: Lyudmila KILIMOVA, Michail CHERKASHIN and Olga NISHNIANIDZE“ Social Health in The Context of Phenomenological Risks” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

were used and made it possible to combine theoretical achievements of scientific discourses of the society, risk and social health in a single semantic field. The application of systemic principles and structural-functional analysis made it possible to study the phenomenon of social health comprehensively, to distinguish its main substantive characteristics.
Methods of analysis, synthesis, generalization, comparison, analogy and historicism were used to clarify main substantive characteristics of social health. Complementary application of these methods made it possible to outline problematic field of social health and indicate meaningful characteristics of its components.

Results

Describing the category "social health," it should be emphasized that its semantic field is very wide and polysemic. It accumulates a wide range of social, economic, psychological, cultural and other indicators. T. Parsons and E. Fromm interpreted health as a complex social phenomenon, formed in the process of interaction of a particular social group, personality with the society and reflecting one or another level of this interaction [Parsons, 1997; Fromm, 2011]. The concentration of attention on social health as a certain state of personality, group and the society is described by foreign researchers [Herzman C., Boyce T., 2010; Trenton, 2017].

The integral nature of "health" should be noted. In the Constitution of the World Health Organization (WHO), the concept "health" is formulated as "the state of complete physical, mental and social well-being but not only the absence of physical defects or diseases". This interpretation made scientists look differently at the essence of "health" concept itself. In this context we are talking not only about a person's lack of certain deviations at the somatic level, but also about the significance of mental and social components of person's health. "Health" is regarded not only as the absence of disease, but also as the state which characterizes internal (psychological) characteristics in the context of outside attitude to life, taking into account its social aspects. As we can see, the social component of health is clearly traced. Social well-being which is in the basis of "health" definition, according to the World Health Organization, directly points to the importance of social component of health. [Charter (Constitution) of the World Health Organization, 1946]

Physical health should be understood as the perfection of self-regulation of body functions, optimal physiological processes and maximum adaptation to various factors of external environment. Mental health is the harmony of mental processes and functions, as well as denial and overcoming diseases. Social health reflects the degree of social activity, person's active attitude to the world, his social relevance. A narrow interpretation of health as a purely medical concept is not correct.

It should be noted that recently (10-20 years) the problem of social health in general and the essence of the concept "particular" is gradually beginning to develop in various fields of sciences, including pedagogy, psychology, sociology, social pedagogy, medicine, economics and others. Nowadays, two main areas of study of "social health" concept have developed. One of the directions is the definition of social health of the population (society as a whole). The second direction is the definition of individual social health (personal social health) [Lisitsin, 2015, p. 341]

Characterizing the concept of social health, R. Ovcharova identifies it with personal. "Social (personal) health, in her opinion, is a certain level of development, formation and perfection of forms and methods of individual interaction with the external environment (adaptation, balancing, regulation), the level of mental and personal development, which allows you to realize this interaction successfully [Ovcharova, 2003, p. 78].

It should be noted that social health of a person is ensured not only by physical and mental well-being of a person, but also by the state of spiritual health of social environment. A harmoniously developed person (with a high level of health culture) is able not only to resist the effects of sick society, but also to promote its recovery. One of the signs of social health is the desire for public welfare, active participation in public work, the ability to be interested in solving social problems.

Let us dwell more on social health of the society as a whole. Reproduction of health reflects the process of healthy generation birth. The basis of which is a full set of genes and a hereditary factor. Maintaining health is not only a biological problem [Nishnianidze et al. 2019]. Health is directly related to the level, mode and quality of life of each person and the population of the country as a whole. The production of health and its improvement is carried out by the forces and means of medical institutions, ensuring the accessibility of medical care, necessary for its volume and quality, requires resource capabilities strengthening of the health system. The essence of health is in the fact that any loss of health leads to inevitable costs of its restoration. Therefore, economic assessment of health is carried out in terms of harm that society can suffer as a result of its decline. Health is an efficiency resource, both for the individual

and for the population as a whole. Improving the level of health and increasing life expectancy becomes not only a personal goal, but also an indicator of social well-being and success of the country [Kilimova L. et al. 2019].

Studying human potential of the economy, I.V. Soboleva characterizes it, first of all, as the reserve of physical and moral health accumulated by the population. The author defines a long healthy life as a basic need, associating the possibility of its satisfaction not only with external factors and an income factor, but also with internal resources of a person accumulated human capital. From a replicated point of view, the process of meeting needs increasingly implies not a simple reproduction of labor force (reimbursement of spent physical and nervous energy), but the development of human potential and the accumulation of intangible wealth embodied in people (in contrast to the objective component of intangible wealth (knowledge, information) is preserved on tangible media). According to I.V. Soboleva, the increase in health care costs in the structure of an employee reproduction cost is an investment component necessary to improve the workforce. The author connects this factor with the growth and dynamics of changes in the requirements for quality characteristics of a person as a producer [Sobolev, 2007].

Studying health of employed population, I.B. Nazarova groups possible approaches to the study of the category "health" from the point of view of capital theory, the theory of social status, the theory of inequality and social justice [Nazarova, 2007, p. 12-56]. Capital theory allows considering health from the point of view of human and social capital, taking into account their conversion into each other. G. Becker defines the health of an individual (physical and psychological) as a component of human capital, as a certain resource [Becker, p. 56-57]. Another approach is proposed by V.V. Radaev, considering physical capital as one of the independent forms. The incorporated state of which is the ability to work [Radaev, 2002, p. 20-22]. Social capital in support of a physical resource – health- can be considered as a system of connection networks and support: related, friendly, administrative, etc. It can also be as an access to necessary resources in preserving the life and health of the individual. Thus, social capital can be seen as an institutional aspect of the reproductive process of population health.

Inequality theories and social justice of population health level are associated with the individual's access to adequate living conditions, when opportunities depend on the level of justice and the degree of inequality. The main predefined variables that determine a person's life at birth are income and parents' level of education, living in a city or in a village, sex and race of a child. When markets are imperfect, inequality in power and wealth is transformed into inequality of opportunities. As a result productive capacity is not fully used and resources are not allocated efficiently. Inequality concept in health is related to inequality in access to various benefits: medical care, safe working conditions, and eco-friendly products. Research analysis about of mortality and socioeconomic interconnection, behavioral factors affecting health showed that their structure and health status are mainly associated with two indicators: lifestyle and health.

The individual not only poses a demand for health but also produces it. It inherits an initial health margin that is amortized over time, but every person can invest in maintaining health and boost its margin. At the same time, it should be noted that the consumer needs health and not only medical services. Demand for health services in this way is an indirect demand for health. The production of health also requires time from the individual, tearing off both market and non-market activities. Thus, a person not only buys health but actively participates in its production, combining resources in accordance with the state of knowledge and the level of technology. [Chubarova, 2008, p. 11].

The modern system of social reproduction exists in conditions of limited traditional resources and economic growth is increasingly dependent on the use of information resources and sources. It is necessary to determine that human capital in modern conditions of social reproduction is the main value of the society and the main factor in economic growth. The process of human capital forming requires considerable costs from the society and the person himself. S.A. Dyatlov defines human capital, using functional-targeted approach, as formed investment complex of knowledge, skills, abilities, motivations, which are usefully used in a particular sphere of social reproduction, contribute to the growth of labor productivity and production efficiency and thereby affect earnings (incomes) growth of a person [Dyatlov, 1992, p. 26].

Therefore, it is important that scientists distinguish, first of all, "health" component in the structure of human capital. In any field of professional activity, each person needs immunity to diseases, qualitative increase in active labor activity, endurance and physical strength for productive activity.

Investment in human capital is the only action that enhances person's professional skills and productive abilities and thus his or her productivity. Expenditures that promote human productivity can be investments because recurrent costs are expected to be compensated many times by an increasing flow of income in the future.

The prospects for rapid changes in social development cannot be considered without reasonable investments in people. Maintaining efficiency by reducing morbidity, increasing the productive period of life, should become necessary factors for investment attractiveness. The normal turnover of labour in production depends largely on effective investment. Investments in health ensure a normal turnover of workforce. Health capital is an integral part of human capital.

Thus, general social need to maintain health of all members of the society, regardless of their material level, guarantee equal access to a minimum set of the most important types of medical care, especially in threat to life and makes it possible to classify social health as a public good. The cost of medical care is determined not only by market factors, but, above all, by socially necessary costs for the production and reproduction of medical care, without recognizing their public usefulness by the market.

Numerous studies in the field of medicine conclude that the main content of "health" concept is maintenance of a certain level of response and adaptation of human body to environmental conditions, in which negative (destructive) effects of external environment on the body are neutralized. This interpretation of health goes back to well-known doctrinal definition of English scientist A. Campbell: health is "autonomy sufficient to adapt a person to changing conditions of human life and training in how to cope with the reality of suffering and death...» [Campbell, 1995, p. 257].

This interpretation of health is heuristic in the context of the study of various risks affecting the social health of the society. According to G. Behmann, "the concept of risk has recently made a dizzying career in the field of social theory" [Behmann, 2010, p. 73]. A society of risk arises on the basis of the destruction of traditional forms of social order, transformation of social structure, the role and significance of social, class, value-normative system and system of social protection. As a result uncertainty, unpredictability and insecurity arise in the life of individuals and groups. A risky situation is a kind of uncertainty, for example, when there is a possibility of possible events and this probability can be estimated. In a risk situation, it is possible to quantify the effects of decisions, which cannot be done in a situation of uncertainty. So this is a key factor that distinguishes risk and uncertainty. Uncertainty is expressed in the impossibility of exhaustive knowledge of dynamically changing reality, in the reduction of the possibility of forecasting remote and even near future. At the individual level, there is a sense of uncertainty and constant need to take risks. At the same time, survival in conditions of risk and payback for its consequences becomes a direct individual character, contributing to the individualization process. At an objective level, individualization is expressed in the independent design of one's own life with individually determined trajectories in various areas (work, education, leisure, marriage, etc.).

Risks impose responsibilities on those who try to evade them and force communication about risks between those who do not want to interact with others. In this sense, risks break through "self-referencing" of some systems in economics, science, politics, as well as risks radically change priorities in the actions of enterprises and establish relationships between competitors.

Risk can be defined as systematic interaction with threats and hazards that are generated by the modernization process. Based on the fact that the production of risks is carried out in all spheres of life (economic, political, social), it is impossible to distance from risks in modern world. Therefore there is a problem of minimizing risks and managing them.

E. Giddens sees specifics of the society in a special risk status. This status is not simply an increase in risks, but in that the concept of risk has become a property of expert and mass consciousness. E. Giddens points out that the concept of risk becomes central in modern society [Giddens, 2004, p. 111]. Society recognizes itself in the categories of risk, uncertainty and the need for choice. At the same time, any situation can be risky, even inaction.

Today's situation with coronavirus pandemic has shown that traditional risk management does not work well. Coronavirus pandemic was in the form of a global socio-ecological epidemiological system that ensures the preservation and spread of infection on a planetary scale. The pandemic found inequalities in access to health care, both within and between states, gaps in social protection and above all, the international community's lack of preparedness for the global health crisis. This was stated by UN Secretary General António Guterres, presenting his recommendations on ensuring universal coverage of medical services. General coverage in the UN is understood as follows: all inhabitants of the planet should be able, if necessary, to receive high-quality medical care in spite of unbearable financial burden. This right is stated for every person by World Health Organization. WHO Member agreed with this document by signing the Alma-Ata Declaration in 1978.

From the point of view of a civilized society, the main indicators that determine the activities of health care system are the availability and quality of medical care. The Amsterdam Declaration of the WHO European Office on Patients'

Rights defined the availability and quality of health services as the basic social rights of citizens that European states should maximize in their health systems.

The analysis shows that Russian citizens are not protected from financial impoverishment when they are ill, despite the fact that Russia spends a significant portion of its budget on medicine. But, despite a slight increase in budgetary financing of the health sector in recent years, its per capita amount remains rather low. Social organizations work poorly: many citizens cannot fully realize their professional knowledge, find a good job.

Potential of people who have fewer abilities or limited physical abilities to work, who find it difficult to join standard working conditions and labor relations, is not fully realized. There is an excessive inequality in income and in access to resources and public goods in the society. A certain degree of differentiation is natural in a mature market economy, but an excess gap is perceived as injustice and becomes a source of social tension. Despite a number of reforms implemented in the field of health and education, availability and quality of services are not adequately ensured.

Conclusions

One of the most important problems of state regulation of the innovative development of health care system is the need to create conditions that would make heterogeneous socio-economic system capable of self-transformation in the context of network formation of multi-organizational management structures. Activities of such structures are designed to increase the level of social justice in health care system, to introduce an intersectoral approach with the involvement of various sectors of national economy on the basis of accepted standards, rules and measures designed for building health potential and focusing on maintaining healthy lifestyle.

In this case, public confidence in government, social solidarity and a scientific approach to problem solving can play an important role in overcoming the crisis associated with the pandemic, in addition to various medical interventions.

Abstract

The abusive calls subdivision of the non-emergency calls made to the 112 emergency system represent a concern for the administrators of other such services worldwide, since they generate suboptimal use or even waste of resources. Preventing this scenario requires countermeasures to limit the impact of such calls on the operational performance of handling genuine emergency cases.

In this article, we intend to formulate recommendations for improving the operational performance of the 112 emergency system in Romania.

To this purpose, we have conducted a study focused on the abusive calls generated specifically by adults. Our study solely included aspects of quantitative analysis, while those arising from qualitative methods will form the subject of a separate article.

In the first stage, we performed an analysis of the calls directed 112 between January 2017 and May 2018, so as to detect whether there existed any spatial pattern of distribution across the different administrative jurisdictions of Romania. We also conducted a more detailed analysis of call distribution across months, days and hours.

Based on this, we focused our analysis onto the class of abusive calls generated by adults, with the purpose of subdividing it further into lesser categories such as frivolous, malicious and prank calls. Taking the above steps allowed the administrator of the 112 emergency system to target the right audience in order to reduce the number of abusive calls.

Keywords: characteristics of calls, quantitative comparison, 112, emergency calls, non-emergency calls, abusive calls, public safety answering points, single national emergency number.

Introduction

Emergency call numbers such as 911 in the Americas, 112 in Europe and parts of Asia, or 111 in Australia and New Zeeland, are implemented worldwide so as to provide citizens with a single point of contact for reaching first responder agencies (e.g. the Police, Fire Rescue or Medical Emergency Services) whenever they need state authority support related to their personal lives, premises or even their environment.

Having a single number to be dialed in any emergency situation is very convenient and comfortable for a caller under duress because it shortens the intervention time and reduces the impact of crime and other critical matters through a faster emergency service.

The International Telecommunications Union recommends that member states selecting a primary or secondary emergency number choose either 911, 112 or both (ITU, 2008). The 112 systems operated throughout the European Union are managed and financed by each of the member states, who also decide on their implementation models and on the organizational architecture of the emergency call centers. Candidates for EU accession and members of the European Economic Area agreement have also adopted the 112 emergency number.

In Romania, the Special Telecommunications Service is the administrator of the 112 Single National Emergency Call System, as appointed through Government Emergency Ordinance no. 34/2008. At the present time, the 112 system has been running across Romania for approximately 16 years. Throughout its operation, one of the areas consistently marked for improvement by the system administrator has been a reduction in the number of non-emergency calls, which would result in a tangible improvement on the overall quality of the service it delivers to citizens dialing 112.

All emergency services across the world are affected by such false or non-emergency calls. Every time someone dials an emergency number in an unsubstantiated manner – whether deliberately or not – the timely intervention of life-saving services for those who are in real need will undoubtedly be affected. In addition to the toll erroneous calls take on the victims of true emergencies, they also cause an important financial burden as well. Every time emergency services respond with an intervention to a false alarm, they are expending valuable tangible and financial resources (Boyle, 2012).

Non-emergency calls made to the 112 system directly contribute to the depreciation of its quality of service and represent a considerable waste of resources. The administrator of the 112 emergency system therefore aims to decrease the volume of non-emergency calls made every year by analyzing their characteristics, such as the callers' age range, as well as geographical and time distribution.

This research paper aims to discuss a specific category of non-emergency calls, namely those generated by adults in comparison to those generated by children, by exploiting a large volume of data recorded within the emergency system's archive.

In the first stage, we analyzed the non-emergency calls addressed to the 112 emergency system between January 2017 and May 2018, in an attempt at identifying any geographical similarities between their patterns of origin.

In the next step, we narrowed down our study to detect if any preferred period of time existed for such incoming calls, focusing our analysis from December 2017 until May 2018. Those six months were selected in such a way as to cover both the winter and spring seasons, which host large holidays such as Christmas and New Year's Eve, as well as the school spring break. Furthermore, we also chose that particular period in order to cover the naturally higher tonus and willingness to work felt by citizens during the more accommodating spring temperatures. We aimed to detect whether any correlation existed between the abusive calls and their distribution over time, across months, days of the week or even hours of the day. If successful, such an analysis could calibrate the media awareness messages about the scope of the 112 service to reach their intended audience in a more efficient way.

Following that, we went further in our analysis and considered the abusive calls subclass of non-emergency calls, analyzing its main categories of frivolous, malicious and prank calls. Our aim was to better understand their proportion within the larger volume of abusive calls, along with their associated financial impact, so as to devise better countermeasures for reducing the number and duration of these abusive calls.

Literature Review

Currently, there exists no standard or uniform definition of what constitutes a false or abusive call, which makes it difficult to compare or aggregate different studies on this matter.

The larger category of false emergency calls includes unintentional false emergency calls (misdials, pocket calls, inappropriate judgement of emergencies, etc.) as well as deliberate emergency calls.

According to Sampson (2004), the problem of misuse and abuse of the 911 emergency number has been broken down into unintentional calls, misdials, hang-up calls, and prank calls. Their study differentiated between the "misuse" and "abuse" of 911, categorizing accidental dialing or multiple reports of the same event differently than those calls that were intentional.

A representative study on false emergency calls was conducted by the European Emergency Number Association (EENA), which included a definition of this type of calls and proposed measures and procedures to deal with such situations.

According to EENA (2011, p. 5), an abusive call represents the event in which a person deliberately contacts the emergency services in a rude or insulting manner toward the public-safety answering point (PSAP) call-taker, without actually reporting an emergency incident.

The concept of false emergency and abusive calls is not always the same across the emergency services employed by European countries (EENA, 2011).

False emergency calls that are made intentionally form the most pressing concern for authorities. There are many instances when citizens call simply as a joke, to be abusive to dispatchers, or simply to ask for information regarding unrelated concerns. Children have been known to call as well while playing with the phone and emergency phone numbers, thinking it is all a matter of fun and games.

In Romania, by false emergency calls we understand abusive calls, unintentional calls, information calls and silent calls (EENA, 2011, p. 14).

We would like to specify that a search conducted throughout the Web of Science and Scopus databases using keywords such as false emergency calls, single national emergency call system, prank calls, abusive calls, and misuse calls led to an extremely small number of existing publications that corresponded with the scope of the present study.

A similar literature search carried out on Google Scholar using the same keywords also failed to produce multiple results.

Various studies were conducted to analyze how citizens use emergency medical services and to characterize the frequent users of emergency department services (Pines at el. 2011). Other authors tried to identify the factors and reasons that play an important role in the non-urgent use of this type of service (Lee et al., 2000) and to explore socioeconomic and geographical determinants of inappropriate emergency department use (Noura et al., 2019)

Many researches focused on the resources allocated to dealing with non-emergency situations (Rudman, Clarke and Metzl, 2003; Blackstone, Buck, and Hakim, 2007, Honigman et al., 2013), on the characteristics of non-urgent emergency callers (Honigman et al., 2013; Lehm, Andresen and Riddervold, 2016) or the characteristics of frequent users of emergency departments (Afilalo et al., 2004; Milbrett and Halm, 2009).

The study coordinated by Rudman, Clarke and Metzl (2003), under the auspices of the Council of Foreign Relations of the United States of America (USA), showed that responding to false calls made to police, firefighting, and ambulance services formed a significant part of the resource consumption registered by said departments.

Blackstone, Buck and Hakim (2007) have studied the economics of emergency response in the USA. Based on previous studies, the authors concluded that false alarms formed 10 to 20% of all calls made to police services, while 94–99% of police responses were to false calls. In terms of costs, the average cost to the police ranges from $60 to $100 per call. Non-valid fire responses represent 58% of all responses at an average cost of $365–$1050 per call and false ambulance responses comprise 25% of all calls at an average cost of $100 per call (Blackstone, Buck and Hakim, 2007).

Even though globally there has been a decrease in the number of false calls made to emergency systems throughout the previous years, the issue continues to remain in the attention of practitioners and researchers.

The widespread nature of mobile phone technology has made important contributions to the development of emergency service call centers. Dispatchers believe that the number of calls is on the rise mostly because of the accessibility of said mobile technology. It has become increasingly easier to dial 911 on a cell phone, and so pocket dials abound. Nowadays, mobile networks are also available almost everywhere to help citizens initiate an emergency call and maintain communication in emergency situations (Landoni, Biselli, Maj and Zangrillo, 2007).

Among the researchers' concerns is the issue of finding the most efficient measures for reducing the number of these false calls. Legislation dedicated to the fight against abuse in emergency services has thus far made no significant contributions, so the concern of the specialists in the field has steadily moved toward investigating means of increasing population awareness and employing technical preventive measures.

A more recent study by Blushtein, Siman-Tov and Magnezi (2019) measured the effect of a call tracking technology, developed and implemented by the Israeli emergency system since 2005 for the diminution of harassment calls. The authors performed a statistical analysis based on a retrospective interventional study of all emergency calls made to Israel's national Emergency Medical Service (EMS) during the years 2012–2016. Their study demonstrated that abusive calls were gradually minimized, and even almost eliminated altogether, without increasing the number of human resources. The above conclusion also provided a confirmation of the fact stipulated by any criminology course on the subject: it is not the value of the penalty fees that discourages abusive calls but rather the probability of having one's call traced by location and being apprehended by the authorities.

Gomes et al. (2019) analyzed a real data set from an emergency call center from a Brazilian city, in order to evaluate the impact of failures on an emergency call system. They considered service-level metrics such as the number of affected calls per failure and the time an emergency service took until it recovered from a failure. Among the authors' contribution, we would highlight the cost analysis regarding how different data center architectures can improve the availability of emergency services.

Regarding the most universally used research methods, we noticed either the statistical methods or the analysis of conclusions from interviews with dispatchers or patients.

Naouri et al. (2019) applied a multilevel logistic regression model of determinants of inappropriate use of emergency departments throughout France.

The conclusions of the study developed by Blushtein, Siman-Tov and Magnezi (2019) were based on a series of statistical calculations made on a large data sample.

Lehm, Andersen and Riddervold (2017) use descriptive statistics on the characteristics of level-E (i.e. not serious) patients who called the emergency medical communication center in the Central Denmark Region from August 2013 to July 2014. This study brought to light new knowledge regarding non-urgent 112 callers and included the capability of following a patient's course by using their unique civil registration number, as well as other routinely and prospectively collected data.

Honigman, Wiler, Rooks and Ginde (2013) performed a cross-sectional statistical analysis of the 2006-2009 National Hospital Ambulatory Medical Care Survey in the USA and analyzed resource utilization, including diagnostic testing, treatment, and hospitalization within five acuity categories representing immediate, emergent, urgent, semi-urgent, or non-urgent events, based on a triage nurse's judgment about the patient's need for immediate evaluation, stabilization, and/or treatment.

The scholars and practitioners mentioned diverse measures for reducing false emergency service calls.

One of the best ways of reducing false emergency calls is to educate citizens on the proper use of emergency numbers and the tremendous cost resulting from those times when emergency calls are made in error. Serious sanctions applied to those who abuse emergency phone numbers, the charging of heavy penalties and following through with prosecution could also be included in the legislation (EENA, 2011).

School-based education, public service announcements and a greater degree of care with each call that is received by dispatchers can also contribute to reducing false emergency calls (EENA, 2011; https://www.emergencymentors.com/false-emergency-services-calls/).

In addition to automatic call sorting systems – depending on the characteristics of the respondents – numerous other technical measures were mentioned: an automatic greeting that will screen erroneous calls before they are patched through to dispatchers, warnings, callbacks, etc.

Weinlich et al. (2018) researched the use of smartphone geolocation data and a worldwide emergency call support system for improving the intervention in cases of disorientation and language barriers.

Even if, from a technological point of view, many solutions can lead a reduction in the number of abusive calls, a thorough study performed on the characteristics of the calls and callers can provide valuable insights for designing more appropriate measures to deal with this unfortunate phenomenon.

Data collection and Research Methodology

Data collection on non-emergency calls. Spatial distribution of non-emergency calls

Romania has a surface area of 238,397 km^2 and a population of 20,121,641 (according to the census of 2011), thus resulting in a population density of 84.4 people per km^2.

The country is administratively split into 41 local jurisdictions, as depicted hereunder. In each county, there is a Public Safety Answering Point (PSAP) receiving the 112 calls generated by the inhabitants or visitors of the county. Figure 1 represents the population density for each county (darker shades of blue representing higher ratio values).

Fig. 1: Population density per county (population per km^2)

Source: the authors

We automatically collected the incoming calls received by each PSAP from December 2017 to May 2018, meaning a total of 5,956,240 calls. From that large volume of records, genuine emergency cases represented only 45 .

The collected data has been processed and represented in graphs, by using Microsoft Excel features and the ESRI GIS Desktop application.

The incidence of non-emergency calls expressed as a ratio from the total number of calls received per counties is represented in Figure 2 below. One could easily observe that the ratio of non-emergency calls per counties is different reported to the total volume of calls per counties, and the calculated values do not reveal a correlation to the number of their inhabitants, but rather one tied in with the citizen's personal awareness and their attitude and behavior toward the 112 emergency service. This particular representation can aid the 112 system administrator in focusing their awareness campaign on the most troublesome counties.

We must note that the white color surrounding Bucharest is actually the county of Ilfov. Bucharest and Ilfov have a metropolitan PSAP that receives all calls generated from their regions, and that is why we will continue to see this white color around Bucharest when referring to calls.

Fig. 2: Non-emergency calls per county (Jan 2017 – May 2018)

Source: the authors

It is indeed concerning to note that in 35 counties the number of non-emergency calls represents more than 50% of the total calls made. Such figures must definitely be corrected, or the emergency services might not be able to bring any actual value to the safety and security of people.

The highest percentage of non-emergency calls are recorded in Mureș (71%), Covasna (68%), Vrancea and Gorj (65%), while the lowest percentages were recorded in Cluj (38%), Bistrița-Năsăud (43%) and Timiș (46%). In the Capital of Romania, Bucharest, 41% of calls made to the 112 emergency number proved to be non-emergencies.

This geographical representation shows us at glance which counties must be first approached in terms of a communications campaign meant to increase the awareness of people on the scope and role of the 112 emergency system.

Types of non-emergency calls. Calls timestamp and their pattern

From December 2017 until May 2018, we inserted a specific field into the file case screen of the 112 call takers, so as to allow them to discriminate between the different types of non-emergency calls.

The classes added to the newly created field in the interface comprised of a choice between informative, unintentional, associated, abusive, and other type of calls, but not genuine emergency calls.

Calls were diverted to the informative category if the callers asked questions unrelated to their safety and security of life, premises or environment, thereby giving the operators the opinion that the actual scope of the 112 emergency system was not known by enough people.

Unintentional calls were recorded by the 112 call takers whenever they faced pocket dialing or dialing by mistake, with no intention from the caller of actually reporting an emergency.

Associative calls were those calls reporting a real emergency that was already attended to, for instance repeated calls for the same fire or car crash reported by different individuals. Such calls border on the precipice between real emergency and non-emergency calls. Still, we ultimately chose to list them as non-emergency calls due to the fact that the real emergency was already known and in progress of being tended to by first responders by the time they were made.

The abusive call class was selected by 112 call takers if the received call had been intentional and of a frivolous, malicious or prank nature.

In the "other calls" class we included those calls generated by technicians, conference calls between 112 call takers and other such test and supportive calls.

The distribution of these categories of calls in the six months beginning in December 2017 is depicted hereunder:

Fig. 3: Types of non-emergency calls per county (Dec 2017 – May 2018). From bottom to upper side: abusive, informative, unintentional, associated, others. Source: the authors

Data collected throughout this period revealed 3,275,932 non-emergency calls, cumulating a total wasted time of 10,967 operator hours. A number of 661 call takers responded to these non-emergencies and the incoming calls had been generated by 1,008,140 callers.

On average, the 112 system recorded 18,000 non-emergency calls per day, representing 60 hours of discussion between 5,500 callers and 380 operators. Moreover, a significant percentage (66%) of calls were pocket dials (11,510 daily calls) and 35 hours were therefore lost by 112 call takers listening to these unintentional calls.

The geographical distribution of informative calls (expressed as a ratio reported to the total number of non-emergency calls) highlighted those counties with a lack of knowledge about the scope of the 112 emergency service. These counties are to be approached immediately with a targeted public communications campaign.

Mureș county is above all other counties based on this criteria, followed by some other neighboring counties, mostly located in Transylvania.

Fig. 4:Informative calls per county (Dec 2017 – May 2018). Source: the authors

For unintentional calls, the map in Figure 5 shows a dispersion of those calls all over Romania.

Pocket and unintentional dialing form common causes of generating 112 calls in all of the other EU member states, across different types of phone and smartphone terminals. It bears mentioning that we encountered some hardware configurations and software patches that automatically started dialing PSAPs for unknown reasons upon reboot. These phone types have been reported by the administrator to the National Regulatory Agency for further investigations and we will hopefully detect less and less of such calls to 112 as a result.

Fig. 5: Unintentional calls per county (Dec 2017 – May 2018).

Source: the authors

The abusive call distribution shows a more dispersed ratio for this type of calls, which asked for more research work to be performed in order to obtain a more accurate picture.

Fig. 6: Abusive calls per county (Dec 2017 – May 2018).

Source: the authors

When analyzing abusive calls further, the first action we undertook had been to set up a new field to be completed by the call takers so that they could discriminate between children and adult initiators. This age flag was particularly easy for the operators to set, after performing a quick analysis of the caller's voice by tone and the vocabulary used.

For our analysis, we considered adults those callers above the ages of 16-18. This means that those teenagers whose voices had changed were considered adults for the purposes of our research.

The representation of abusive calls distributed via age thematic maps show different ratio as follows:

Fig. 7: Abusive adult calls per county (Dec 2017 – May 2018).

Source: the authors

Fig. 8: Abusive children call per county (Dec 2017 – May 2018).

Source: the authors

If the above spatial representation gave us relevant information as to which county will be approached with the awareness campaign first, the time pattern indicated how the message should be shaped, to whom it should be addressed and at what time it would be more effective in reaching its audience.

The graph distribution per months showed no significant variance in volume across four months (dark blue – Dec 2017, lighter blue – May 2018):

Fig. 9: Abusive calls per months (Dec 2017 – May 2018).

Source: the authors

The distribution of non-emergency calls per hours revealed that the calls arrived at the 112 PSAPs in a higher number from 7 AM to 10 PM, meaning the active period of the day for both adults and children. People working night shifts and feeling lonely or those people needing to communicate with someone else during nighttime generated a much smaller percentage, as expected.

Fig. 10: Non-emergency calls per hours (Dec 2017 – May 2018)

Source: the authors

For the category of abusive calls, we registered a shift of 1-2 hours toward the right side of the time spectrum compared to the non-emergency calls depicted above in Figure 10.

County	Distribution of abusive calls per hours [%]

Fig. 11: Abusive calls per hours (Dec 2017 – May 2018)

Source: the authors

A very clear representation of time windows for adult abusive calls versus children abusive calls is shown in the figures below.

Most abusive calls generated by adults were registered in the afternoons or following the working hours (i.e. between 2 PM and 10 PM), while for children, the time window with heaviest numbers was between 12 AM and 4 PM, when they were mainly bereft of adult supervision.

Fig. 14: Abusive calls per hour initiated by adults versus children (Dec 2017 – May 2018)
Source: the authors

For each category, we hardly observed a higher intensity of colors during the working days compared to the weekends.

Insights on abusive calls generated by adults, their distribution and main findings.

After we formed preliminary conclusions based on the above spatial and time distribution on the class of non-emergency and abusive calls, we began rolling the awareness campaign in high-percent counties, primarily in schools, so as to target children during school hours. These campaigns resulted in a significant decrease in the national percentage of abusive calls generated by children.

We then focused our research on the adult sub-category of abusive callers. For that reason, we appended three new predefined categories of calls, which could be selected by the call takers during their interview with the caller – either frivolous, malicious and prank calls. Our research began by collecting data from 1st September 2018 until 31st December 2018 (i.e. the 4th quarter of 2018).

The differences between frivolous, malicious and prank calls are detailed below, as follows:

a) Frivolous Calls – when incoming calls are initiated either for fun, or by accident while playing with a phone's keypad, or testing a phone's various functionalities;

b) Malicious Calls – when incoming calls address the emergency service or the 112 operators using insults or gratuitous verbal attacks;

c) Prank Calls – when incoming calls are intentionally dialed for reporting false alerts that ask for the field intervention of 112 agencies (Police, Gendarmerie, Medical Emergency Services or Fire brigades).

We found the distribution of abusive calls according to the matrix presented in Table 1 below.

Table 1: Abusive Calls distribution per type of call (4th quarter of 2018)

Month	Frivolous Calls	Malicious Calls	Prank Calls
September	13,976	6,544	805
October	13,684	7,385	808
November	12,946	7,382	667
December	16,299	8,593	621

Source: the authors

The total number of abusive calls generated by adults throughout the analyzed quarter was 89,710, having systematically the highest percentage of frivolous calls (about 65%), followed by malicious calls in the range of 32% and the smallest percent being the prank calls (approximately 3%).

It is noticeable that in December the number of frivolous and malicious calls increased, but the number of prank calls decreased. It seemed that citizens did not entertain the idea of spending money to pay fines in December, but had instead a good appetite for jokes, or checking the functionality of their newly purchased phones compared to the rest of the year.

Fig. 15: Time series for categories of abusive calls (4th quarter of 2018).

The split in the number of abusive calls directed to 112 by adults per each Romanian county is represented in Figure 15. The X-axis depicts the county codes, while the Y-axis represents the number of abusive calls.

Reducing the number of abusive calls is essential for the proper operation of PSAPs, particularly in times of widespread disasters, including the current COVID-19 pandemic, when 112 acts as a primary contact point for reporting illness. The representation below supports the administrator in prioritizing the launch of public awareness campaigns in the most affected counties.

Fig. 16: County distribution of abusive calls (4th quarter of 2018).

Source: the authors

The normal distribution in the number of adult abusive calls across the counties in Romania is depicted in Figure 17 below.

Fig. 17: Normal distribution of the number of adult abusive calls per counties in Romania

Source: the authors

The calculated median value is 2,284 and the standard deviation σ is 1,817.6. In 28 out of the 41 counties, the observed numbers are below the mean, while only 13 range above this value, with notable numbers recorded for the capital and the adjacent Ilfov county that are treated as one metropolitan region. Nevertheless, it is important to note that the capital does not amount for the largest observed number of calls.

The impact of abusive calls on operational performance and financial losses

The histogram of the average time of non-emergency conversations shows large variations, ranging from 11 seconds to 50 seconds for dealing with such calls. Even at the national level the operators have the same job description and receive the same instructions on how to handle this type of calls, so it is a must to reinitiate training courses with all call takers on that aspects, in order to achieve a similar way of handling the calls all over the country.

Furthermore, at the time of the analysis, the number of operators on duty per shift were the same, except for the Bucharest PSAP which employed a higher number of call takers.

Fig. 18: Distribution of average time of conversation (clustered into seconds).

Source: the authors

The waiting time in the queue is an important parameter of any emergency call center's performance, due to the fact that its value represents the duration of time someone in real need has to wait before they can report a genuine emergency. Considering that emergency calls are still coming in between those large numbers of non-emergency calls, it becomes mandatory that the 112 administrator takes operational and technical actions in order to decrease call waiting times as much as possible.

The number of abusive calls made to the 112 system in the 4th quarter of 2018 collectively amounted to a total call duration of about 1 entire month. This time was essentially wasted by the operators having to deal with such non-substantiated calls.

One month of non-valuable conversation time per quarter could occupy a shift of 5 call takers, since each quarter (25) of the total conversation time to 112 is wasted on answering abusive calls generated by adults.

In financial terms, considering that frivolous and malicious calls are not transferred to first responder agencies, the direct cost of non-emergency calls is actually represented by the call takers' salaries. We estimated that the authorities are paying one shift of 5 operators to deal just with those categories of calls for 1 month per quarter. If their salaries cost around 5,000 EUR per month in each quarter, then losses of up to 20,000 EUR per year can be incurred only to answer frivolous and malicious calls. The opportunity costs associated with those categories of calls are much higher in reality, because non-emergency calls render call takers unavailable to handle real emergencies for people in need.

However, the most important direct financial losses are incurred because of prank calls made to the 112 systems. First responders are generally mobilized due to this particular type of calls, as they usually request the dispatch of resources to the place of reported incident (e.g. officers, medical staff, firefighters equipped with specific tools and devices, automobiles, motorcycles and even helicopters). If we only take into consideration that figure of 2,900 prank calls per quarter, in Q4 of 2018 the estimated cost of unnecessary intervention could be easily approximated to 500 EUR per call, resulting in total losses of 1.45 million EUR per quarter and approximately 5.8 million EUR per year.

We would like to note that our particular calculation is still likely optimistic, considering that in the case of long-range or heavy conditions interventions requiring the cooperation between more than one first responder agency the costs could rise up to even thousands of euros per call.

Recommendations

The most significant volume of non-emergency calls remains that generated by pocket dialing. This could be addressed both from a technological perspective (via countermeasures or actions to be addressed by mobile

networks/device manufacturers allowing emergency calls to be initiated even when the terminals are locked), but also through an awareness campaign informing people to lock their phones when not in use.

Abusive calls represent the second most important source of unjustified calls – and the costliest ones. The cases encountered are varied, but most stem from a lack of civic responsibility and information on behalf of the callers. Both of these facets are addressable through targeted awareness campaigns. Upon investigating the archive of emergency calls, we even found situations with people who had called 970 times over a period of 6 months. For such isolated cases, an education campaign would likely have no effect, but a fine might prove more effective in diminishing the numbers of calls.

One recommendation that is likely to greatly bolster the responsibility of callers is the modification of the national legislation regarding the purchase of prepaid SIM cards. In this respect, the mandatory declaration of the the purchaser's identity at the shopping desk should be considered.

In order to decrease the number of abusive calls, the 112 service administrator in Romania will continue to run the media campaigns on the role and scope of the 112 emergency number. Considering the results of our research, it appears especially important to continue fine tuning these in terms of message content, wording, representations and time spots to reach the right audience more effectively.

The quality of the service will be augmented by activating either temporary or permanently a number of supplementary call centers to deal with the issue of special calls, such as the one for medical assistance and support for COVID-19, or for chronic issues that do not actually represent real emergencies.

Communication about the 112 service must be performed to large audiences and adapted to the modern lifestyle, via official websites, TV, digital media, social networks, search engines, etc.

Conclusions

In the present study, we collected data pertaining to incoming 112 emergency calls in Romania, conducting an analysis over an extended period of time, and then focusing on the specificity of non-emergency calls. Ultimately, we concentrated on studying the abusive calls generated by adults.

The scope of our research was to identify the dominant characteristics of the abusive calls, which would in turn allow the 112 administrator to target the right audience, using the right channels at the right time.

By implementing the proposed solutions, we succeeded in decreasing the volume of non-emergency calls under the value of 50%, from 2019 until the time of writing. We will continue to increase the quality of services in terms of availability and the performance delivered by the Public Safety Answering Points as well.

Our results showed that the most important number of abusive calls originated by adults were frivolous calls. We also calculated that the time wasted by the operators taking abusive calls generated by adults amounts to about one month lost per quarter. To combat this type of calls, we would need a dedicated shift of 5 operators specifically tasked with taking only abusive calls.

All of these non-emergency calls incur costs, which turn into real financial losses for the national budget. These losses shall be presented to the citizens in an attempt at making them aware of the situation, as well as of the huge opportunity cost of involving first responders in prank calls.

Therefore, the steepest financial cost and impact on the public budget comes from the prank calls category, with a total estimated cost of at least 5.8 mil EUR per year.

The information on the spatial distribution of non-emergency calls per county, weekdays and hours is useful for optimizing the process of allocating different numbers of operators per counties, so as to reduce the waiting time for emergency calls on a nationwide basis.

It would seem though that our findings and insights have already begun to bear fruit. According to the data collected by the PSAPs of the 112 emergency system, during the period January - November 2019, there were in total 10,437,328 calls made to 112, out of which 5,404,650 (51.7%) reported real emergencies. Due to the efforts of the 112 administrator, it is for the first time in 16 years of operating the 112 system that we are above the 50% line of real emergency calls made to 112. We will of course continue to optimize our efforts so as to maintain this trend of decreasing non-emergency calls in the following years as well.

Abstract

The global financial market is influenced by relatively new technologies such as cryptocurrencies Bitcoin, Ethereum, Litecoin, and others. Cryptocurrencies are a challenging area in finance that requires additional attention from the academic community as they can have a potentially large impact on society and the economy. The aim of this study is to investigate the usability of digital money among the citizens of Saudi Arabia. Various factors that are related to user behaviour and have an impact on user intent towards cryptocurrencies based on a combined approach are analysed. The basis from which we started is The Theory of Reasoned Action (TRA), together with four other constructions: perceived risk (consisting of privacy risk, financial risk, and security risk), perception of enjoyment, perceived usefulness, and personal innovation. The method used to collect the data is a questionnaire. The results showed that variables such as subjective norms, security risk, perception of utility, and enjoyment influence the adoption and use of cryptocurrencies. A row of these variables includes the perception of pleasure as well as the perception of utility.

Keywords: Cryptocurrency, Technology Adoption, TRA.

Introduction

A cryptocurrency is a digital currency and represents digital records of certain values stored in digital databases. The goal of developing cryptocurrencies is to suppress printed money from the market and to establish a system that will not be under the supervision and control of the state and government. Bitcoin is the first cryptocurrency that was developed in 2009 (Satoshi, 2008) whose value is extremely growing, so it is often called digital gold. In 2017, the value of cryptocurrencies was almost $ 800 billion (Alzahrani, and Daim, 2017) while in May 2019, bitcoin reached a market capitalization of close to $ 100 billion (Kaspersky, 2019). Some estimates suggest that by 2024 the number of Bitcoin users will reach as high as 200 million (Alzahrani, and Daim, 2017). According to the Kaspersky Lab report, only 10% of people understand the meaning, significance, and system of cryptocurrencies, while 35% of people believe that cryptocurrencies are a trend (Kaspersky, 2019). The data from this report has shown that 19% of people were hacked, and 15% of respondents were victims of cryptocurrency fraud. The lack of rigorous standards that can prevent fraud and hacking of cryptosystems is a factor that leads to concerns and a lack of trust (Kaspersky, 2019) when it comes to the use of cryptocurrencies. Also, the biggest obstacle to understanding this whole system is ignorance of computer technology, terminology that is almost exclusively in English as well as lack of knowledge about cryptocurrencies (Kaspersky, 2019).

Before implementing any new technology, it is necessary to assess the possibility of its adoption. The founder and pioneer of the Bitcoin Investment Trust, Barry Silbert, argues that the adoption of cryptocurrencies is a process that occurs in five phases (Charalambos et.al, 2015): (i) the experimentation phase, (ii) the early adoption phase, (iii) the venture capital phase, (iv).) wall street phase and (c) global consumer adoption phase. However, although theoretically, these phases are necessary, the actual adoption of cryptocurrencies depends on many other factors specific to each country and its economy. This research aims to assess how people in Saudi Arabia view the process of adopting cryptocurrencies and what intentions they have. to achieve this, we explored the TRA and related factors, namely subjective norms (SN), attitude (AT), and intent to adopt cryptocurrency (IACC). Besides, we investigated the perceived risk (PR), perceived usefulness (PU), perceived enjoyment (PE), and personal innovation (PI). TRA's model explains how the various factors associated with one's attitude relate to a particular behavior. According to this model, each individual will act without inhibitions and restrictions after the intention's formation, and changes can

Cite this Article as: Saad ALAKLABI and Kyeong KANG "Factors Influencing Intention to Adopt Cryptocurrency" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

occur by including additional explanations. This theory has shown high validity with the possibility of comparing the results obtained in other studies. In this research, TRA will be the basis with which we will try to get answers to the formed hypotheses. This model has a good foundation and literature support and allows authors to identify gaps and draw correct conclusions. The TRA model is reliable in determining users' affinity towards the use of cryptocurrencies, especially since it is a new technology. This research introduces three new aspects of this model:

1. It explores the factors that influence the intention of Saudi citizens to become cryptocurrency users.
2. The study includes participants who use social networks such as Twitter, which implies that they are technologically literate.
3. This study includes participants who already have some prior knowledge of cryptocurrencies, which will provide new insights into how people who already know the new technology perceive it and how likely they are to become users.

Theoretical Background and Model Development

Related Works

Many studies have used these models or a combination of these models to investigate influential factors not only in the field of cryptocurrencies but also in other areas. Concerning cryptocurrency adoption, the authors aimed to investigate the degree of acceptance of blockchain technology for financial transactions. The study involved 277 participants, of whom 72% were men and 28% women (Albayati, Kim, and Jeung Rho, 2020). This study's findings showed that trust is the main variable influencing the acceptance of new technology, while regulatory support and experience affect trust (Albayati, Kim, and Jeung Rho, 2020). In contrast, in work of Ku-Mahamud et al. (2019) the results showed that most respondents believe that blockchain technology and cryptocurrencies are stable and secure. The study aimed to analyze the factors influencing the adoption of cryptocurrencies (i.e., Awareness, Adoption, and Trust) in Malaysia on a sample of 304 respondents (Ku-Mahmud et al., 2019).

Sohaib et al. (2019) developed a model analyzed factors such as technological readiness (optimism, innovation, discomfort, and uncertainty), acceptance of technology, perceived ease of use and utility, and intention to use cryptocurrency on a sample of 160 participants (56% men and 44% women). The main impacts were estimated using partial least squares SEM (PLS-SEM), while artificial neural networks (ANN) were used to rank the most significant factors (Sohaib et al,2019). The results of the study showed that perceived ease of use is positively correlated with optimism, while perceived ease of use is negatively correlated with discomfort, followed by uncertainty. The results also showed that perceived ease of use has the strongest effect on perceived utility, while perceived utility has a highly significant positive effect on the intention to use cryptocurrencies (Sohaib et al., 2019).

The adoption of bitcoin from the monetary exchange attitude was investigated in Wood et al. (2018) using TAM and the development innovation diffusion theory. The study was conducted on 121 respondents and showed that relative advantage, easy use, visibility, and compatibility have a big positive impact on bitcoin utilization (Wood et al.,2017).

Wood at al. (2017) explored the seen advantage and chance related to bitcoin utilization. The authors created TAM based on a test of 86 respondents (95% were male). The results showed that the fluctuating esteem, the hazard of money-related misfortunes, and the need for customer assurance are the most influencing people's purposeful to utilize bitcoin. But, ease of utilizing has the weakest impact on bitcoin utilization (Abramova & Böhme, 2016). The acceptance of Bitcoin was too examined in work of Lee Won (2018) utilizing TAM, which included 224 respondents. The comes about appeared that seen convenience has the most grounded impact on the deliberate to utilize Bitcoin (Lee Won, 2018).

In the study of Ayedh et al. (2020), elements affecting the investment in the Bitcoin market were investigated. The study covered 200 Muslim respondents (25% male and 75% female) in Malaysia, and the factors have been investigated using SEM. The factors that were determined were extracted from TPB, TAM, and diffusion of innovations theory. It was observed that facilitating conditions, awareness, and compatibility have a tremendous effect on making investments in Bitcoin [25]. On the contrary, trust, profitability, subjective norms, and ease of use had been discovered not to have a widespread effect on Bitcoin funding (Ayedh et al., 2020).

Al Shehhi, Mayada Oudah, and Zeyar Aung (2014) analyzed the factors that affect the popularity and value of cryptocurrency. The study looked at eight cryptocurrencies: Bitcoin, Litecoin, Ripple, Peercoin, Dogecoin, Kittehcoin, Darkcoin, and Vertcoin. The sample included 134 online users, with 95.5% male and 4.5 % female participants. Studies show that young participants choose cryptocurrency based on name and logo. Additionally, participants believe that ease of mining, strong community, privacy, anonymity, value, popularity, and possibly better use of cryptocurrency (Al Shehhi, Mayada Oudah, and Zeyar Aung, 2014).

Zarifis et al. (2018) Investigated consumer confidence in digital currency transactions using a sample of 41 participants (23 men and 18 women). The results suggest that those who understand technological innovations have more confidence in these technologies than those who do not. It has also been shown that confidence can be boosted if the government is involved and regulates (Zarifis et al., 2018).

The factors associated with Litecoin cryptocurrency were examined using a sample of 119 participants (Gibbs, and Suwaree Yordchim. 2014). This study explores four main factors. The first deal with future professional training should be in Litecoin development, while the second factor suggests that the concept of digital currency should be more understandable, and its benefits should be presented. The third factor indicates the need for education in cryptocurrency, while the last factor indicates that the sample did not know what Litecoin was, which in turn indicates the need for education (Gibbs and Suwaree Yordchim, 2014).

Model Development

To evaluate cryptocurrency users' behavior, we adopted the TRA model and included three additional constructs - PR, PU, and PE. TRA was developed by Fishbein in 1967 and aimed to explain the relationship between a particular subject or action and human attitudes toward human behavior (Fishbein, 1967). It is used to predict actions based on people's behavior and past behavior. The main concepts of TRA are attitude, subjective norms, and behavioral objectives.

The purpose of the behavior is the main factor influencing behavior and is driven by attitudes and norms. If the attitude towards that behavior is strong, and if subjective norms allow such behavior, the person will behave. The behavioral objective (Hale et al., 2002) can be expressed as:

$$BI = (AB)W_1 + (SN)W_2$$

where AB is a person's attitude toward behavior, SN is a person's subjective norm related to a particular behavior, and W is the weights. The attitude towards AB behavior can be expressed as (Ajzen, and Albarracín. 2007:

$$AB = \sum b_i e_i$$

where bi is the strength of the belief that a particular behavior will have a certain outcome i, and ei is the evaluation of outcome i. Furthermore, the subjective norm can be expressed as:

$$SN = \sum nb_i mc_i$$

where nbi are normative beliefs connected to a certain outcome i, and mci is the motivation to comply to the particular behavior.

Attitudes can be defined as beliefs towards a particular behavior (Ajzenm and Albarracín. 2007). When these beliefs come together, they create a positive, negative, or neutral attitude toward behavior (Ajzenm and Albarracín. 2007). The literature suggests that if a person believes that the result of the behavior will be positive (Ajzenm and Albarracín. 2007; Fishbein. 1967) and vice versa, he will develop a positive attitude towards a particular behavior. A study by Agustina (2019) showed that this behavior significantly affects the intent to use cryptocurrency trading applications. Therefore, to examine the effect of attitude on Saudi citizens' intention to adopt cryptocurrencies, the following hypothesis has been proposed:

H1: Attitude has a positive effect on the intention to adopt cryptocurrencies.

Behavior is also influenced by subjective norma, which can be defined as "perceived social pressure to perform or not perform the behavior" (Ajzen, and Albarracín. 2007). These social pressures stem from expectations from major groups and individuals' views, and they shape the perception of the individual's behavior. People mingle with their environment and social sector. Therefore, it is important to consider the need to conform to others' perceptions following subjective standards (Fishbein, and Ajzen, 1975) Social influence has been found to influence behavioral intention to introduce cryptocurrency. In this study, the following hypothesis is proposed:
H2: Subjective norm has a significant positive effect on introducing cryptocurrency.

As mentioned above, in addition to TRA constructs, this study also looked at PR, PU, and PE. PR shows how consumers are aware of the risks associated with using this technology. This can be defined as the notion of the undesirable consequences of purchasing or using a particular product/technology (Faqih, 2016). PR covers many aspects, including privacy risk, security risk, and financial risk. Privacy risk is the privacy of your information, and security risk refers to your uneasiness about using certain technologies. Economic risk is related to the cost of using

technology. In previous studies, PR uses several technologies, including mobile banking (Thakur and Srivastava, 2014; Kishore and Sequeira. 2016). Internet banking (Martins, Oliveira, and Popovič, 2014) and e-commerce (Belkhamza, and Wafa, 1970; Lai and Tang, 2018), as well as consumer purchasing intent [David et al., 2001; Kannungo, and Jain, 2004.). It is shown to influence intent. Considering that cryptocurrencies carry potential risks that can affect user attitudes and behavior, the following hypothesis are proposed.

H3a: Privacy Risk has significant negative effect on attitude.
H3b: Security Risk has significant negative effect on attitude.
H3c: Financial Risk has significant negative effect on attitude.
H4a: Privacy Risk has significant negative effect on intension to adopt cryptocurrency.
H4b: Security Risk has significant negative effect on intension to adopt cryptocurrency.
H4c: Financial Risk has significant negative effect on intension to adopt cryptocurrency.

PU is interested in people's opinions about how behavior improves people's performance (Davis, 1989). Davis found that PU had a weak relationship with attitude (Davis, 1989). He added that the intention to adopt this technology has a strong and direct impact on PU. PU is also affected by the cost-effectiveness model (Davis, 1989.) This is explained by the fact that people make decisions based on the effort required to use the technology and its benefits. Also, PU has been shown to have a significant impact on using cryptocurrencies (Ajay, Shrestha, and Vassileva, 2019). PUs is so subjective (Davis at al., 1989) that they are highly dependent on the user's capabilities and cannot be used independently of other components to explain the use of technology. Therefore, considering the importance of the combined approach, we will investigate the relationship between PU, trends, and the purpose of adopting cryptocurrencies and propose the following hypothesis.

H5: Perceived Usefulness has significant positive effect on attitude.
H6: Perceived Usefulness has significant positive effect on intension to adopt cryptocurrency.

PE can be defined as "engaging in an activity" because of an individual's interest in or performance. Numerous studies have shown that PE influences using technologies such as mobile services (Moon, and Kim,2001) mobile learning (Al-Zoubi, and Ali, 2019; Huang, Lin, and Chuang, 2007) and financial services. When considering cryptocurrencies, it is understood that the repurchase of bitcoins and cryptocurrency are significantly affected by enjoyment. PE has been found to have a strong influence on perceived efficacy (Shrestha and Vassileva, 2019). Therefore, to investigate the impact of adopting PE and cryptocurrency in Saudi Arabia, the following hypotheses have been suggested:

H7: Perceived Enjoyment has significant positive effect on attitude.
H8: Perceived Enjoyment has significant positive effect on intention to adopt cryptocurrency.

Personal innovation (PI) is one of the personality traits that researchers believe plays a role in adopting technology (Agarwal and Prasad 1998). It is defined as "the degree to which an individual or other adoption unit adopts new ideas relatively earlier than other members of the social system" (Rogers 2003, p. 22). Personal innovation can also be used to reach a group of people who are normally at risk of using an innovation. The link between personal innovation and behavioral intentions is present in the literature (Lu, 2014). As discussed in the literature review, PI was included to predict people's behavioral intention to use technology. For example, individual differences, including the level of risk and personal innovation, have been associated with implementing e-commerce technologies (Agarwal and Prasad 1998; Alalwan et al. 2018; Thakur and Srivastava 2014; Williams 2018) and they are also used in the context of electronic commerce. In Saudi Arabia (Al-Jabri 2015) and mobile learning (Al-Hujran, Al-Lozi & Al-Debei 2014). Besides, among previous studies that confirmed the importance of intellectual property, there were several concerns in which the information security literature suggested contextualizing the use of public relations. For example, public relations can be used differently depending on the context and innovation under study. The following hypotheses were proposed:

H9: Personal innovation will have a positive effect on attitudes towards the adoption of cryptocurrency in Saudi Arabia.

H10: Personal innovation will have a positive effect on Saudi Arabia's intention to introduce cryptocurrency. The proposed model is presented in Figure 1.

Figure 1: The proposed model

Research Methodology

The research methodology included a survey consisting of validated elements and concepts from previous studies. The proposed model is a combination of factors related to TRA (i.e., subjective standard, attitude, and intent to adopt the technology) and perceived risk, usefulness, enjoyment and personal innovativeness (as shown in Figure 1). All constructs consist of several elements from the literature.

The survey was conducted by a questionnaire method. An online survey created and was consisted of three parts: questions related to demographic data, profiles of knowledge about cryptocurrencies, and model building questions. Survey responses were collected from September to November 2019. According to social media statistics published by Global Media Insight (2019), 56% of Saudi Arabia's population has active Twitter accounts (18.96 million people), so a link to the survey was posted on Twitter and cryptocurrency users Shared with (that is, users who tweeted and commented on cryptocurrencies). The selection criteria included cryptocurrency users who lived in Saudi Arabia, used Twitter, and were 18 years of age or older. The Qualtrics platform was used to poll participants on the Internet, encouraging participants to participate in the survey. After receiving 562 participants, we removed the incomplete questionnaire, resulting in 368 questionnaires included in the analysis. Respondents agreed to participate by filling out the question. The questionnaire was anonymous and kept secret throughout the study.
The data collected were analyzed using SPSS, and the SEM was constructed using AMOS.

Results

Descriptive Statistics

Table 1 shows the descriptive statistics of the respondents' profiles. We can see that 95% of the respondents are male. This percentage of respondents using cryptocurrencies represents the population of people using cryptocurrencies.

Considering the respondents' age, we can see that 45% of the respondents are 30-39 years old, followed by 20-29 years old (36%) and 40-49 years old (16%). Cryptocurrencies rely on the Internet, and the first cryptocurrency, Bitcoin, was developed in 2009, making it more attractive to young people (Alaeddin and Altounjy, 2018).

In terms of nationality and language, 88% of respondents are Saudi Arabians. Therefore, 88% of respondents are expected to speak Arabic, and 12% are expected to speak English (Table 1). Besides, 61% of respondents have a bachelor's degree, followed by 19% with a graduate degree and 12% with a university degree. Only 8% of respondents have a high school degree.

In terms of location, the maximum number of participants who participated in this survey and knew about cryptocurrencies is in the central (35%) and western (24%) of the country. This is in line with current development statistics. The central region of Saudi Arabia has the highest Human Development Index in the country, followed by the north and west regions. In addition, 15% of respondents are from the east of the country, 14% are from the north, and 13% are from the south.

Table 1: Descriptive statistics of the dataset

Item	Values	Frequency	Percentage
Gender	Male	367	95.3
	Female	18	4.7
Age	< 20	7	1.9
	20-29	130	35.6
	30-39	165	45.2
	40-49	59	16.2
	≥ 50	4	1.1
Nationality	Saudi	337	88.2
	Non-Saudi	45	11.8
User language	English	47	12.2
	Arabic	339	87.8
Education	High school	29	7.8
	College degree	44	11.9
	Bachelor's degree	226	61.1
	Postgraduate degree	71	19.2
Part of Saudi	Centre	130	35.0
	South	48	12.9
	West	87	23.5
	North	52	14.0
	East	54	14.6

Cryptocurrency knowledge profile

In relation to the cryptocurrency knowledge profile, ie, participants' knowledge of cryptocurrencies, various aspects were reviewed (Table 2). It is important to note that the questions in this section attempt to gauge participants' familiarity with cryptocurrencies. First, participants were asked if they had a technical background. Participants are almost evenly distributed because 52% of them have a technical background, and 48% do not have a technical background. This is an interesting finding as it suggests that participants may be interested in cryptocurrencies regardless of their professional or educational background. Also, participants had to rate their knowledge of cryptocurrencies, and the results showed that most participants (69%) knew, followed by 21.5% of participants who rank themselves in the initial rank. Only 9.3% of participants said they are cryptocurrency experts, while 0.3% said they do not know cryptocurrency. These findings confirm the need for this technology and the participants' interest in learning more about it and entering into the cryptocurrency market. More than half (52.7%) respondents have already participated in cryptocurrency activities such as trading, investing, analytics, etc., mostly with Bitcoins (10.9%), followed by Ethereum (9.6%). In practice, this situation means that people with practical knowledge of cryptocurrency may differ in their response. Therefore, an additional study of respondent representation is necessary to determine statistical bias. The other types of cryptocurrencies (REBL, Litecoin, Tron and others) are much less represented in the observed population.

Table 2: Cryptocurrency knowledge profile

Item	Values	Frequency	Percentage
Do you have any technology background?	Yes	184	47.8
	No	201	52.2
How do you classify your knowledge about cryptocurrency?	No knowledge	1	0.3
	Beginner	83	21.5
	Knowledgeable	266	68.9
	Expert	36	9.3
Have you ever participated in cryptocurrency activities?	Yes	202	52.7
	No	181	47.3
Which cryptocurrency have you participated in?	Bitcoin	42	10.9
	Ethereum	37	9.6
	REBL	15	3.9
	Litecoin	14	3.6
	Tron	11	2.8
	XRP	7	1.8
	Binance	7	1.8
	Cardano	5	1.3
	Others	66	17.1

Construct Reliability and Internal Consistency

The reliability of the first scale needs to be verified to work with new factors. Cronbach developed Cronbach's Alpha as a measure of the internal consistency of the test/scale [62]. It can take values in the range of 0 to 1, with 1 indicating good reliability. However, Cronbach's most popular alpha values range from 0.70 to 0.95 (Nunnally, 1994).

Cronbach's first construction had an alpha PR of five items, valued at 0.92, indicating the items' high reliability inside the construction. The SR consists of two items with an alpha value of 0.817, which confirms the element's reliability. The FR construct consists of five items with an alpha value of 0.884. For PE, the obtained alpha value is 0.913, with four items. The PU consists of five items with an alpha value of 0.908, while SN Construction has an alpha value of 0.844 with two items. Looking at the perspective, Cronbach's Alpha got a value of 0.90 with five construction items. Finally, the IACC construction consisted of four items value of 0.887 Cronbach's.

Considering each item element's loading, all loads are above 0.6, which indicates a strong relationship between constructs and constructs items. These results are presented in Table 3.

Table 3: Reliability of constructs

Latent variable	Indicators	Factor loading	Cronbach's alpha
PR	PR1	0.783	0.920
	PR2	0.934	
	PR3	0.876	
	PR4	0.849	
	PR5	0.752	
SR	SR1	0.645	0.817
	SR2	0.976	
FR	FR1	0.7	0.884
	FR2	0.897	
	FR3	0.834	
	FR4	0.724	
	FR5	0.615	

Latent variable	Indicators	Factor loading	Cronbach's alpha
PE	PE1	0.802	0.913
	PE2	0.9	
	PE3	0.908	
	PE4	0.772	
PU	PU1	0.793	0.908
	PU2	0.853	
	PU3	0.908	
	PU4	0.903	
	PU5	0.637

	AT2	0.812	
	AT3	0.813	
	AT4	0.734	
	AT5	0.768	
IACC	IACC1	0.765	0.887
	IACC2	0.888	
	IACC3	0.67	
	IACC4	0.594	

Model Results

The following table shows the compatibility indices of the structural model. The Chi-Square value of the conceptual model is significant ($\chi2 = 1114.486$, $p = 0.000$), ensuring a good model fit. The GFI value shows a satisfactory fit with a value greater than 0.8 [64]. The TLI, CFI, and IFI values should be close to 1 to indicate the best fit, as the results of Table 4 show (Hair et al., 2010).The RMSEA shows a good fit, as the value is less than 0.05 (Hair et al., 2010). The most important measures to note is the AIC or Akaike Information Criterion. Taking this value into account, the model obtained a score of 1324.49.

Table 4: Model results

Fit indices	Value
$\chi2$	1114.486
df	636
ANOVA p	0.000
GFI	0.865
TLI	0.949
CFI	0.953
IFI	0.954
RMSEA	0.044
AIC	1324.486

Hypothesis Testing

We can observe the t-value and its corresponding significance (p-value) to decide whether to accept or reject the hypothesis (Table 6).

The first hypothesis, "Attitude has a significant positive impact on the intent to adopt cryptocurrencies," is supported based on significant t-values (t = 9,116, p = 0.000). This result supports most of the results in the literature. In particular, Doblas (2019) found that attitudes had a significant impact on adopting cryptocurrencies. "One unit increase in attitude increases the probability of hiring 11.49 times while other variables are constant." Kings. Wang, Dou, and Zhou (2008) also found that attitudes had a significant impact on product adoption, and Mutamarba (2019) found a significant positive effect of attitudes on the intent to adopt cryptocurrencies.

The second hypothesis, "subjective norms have a significant positive effect on the intent to adopt cryptocurrencies," is also supported (t = 2.189, p = 0.029). The construction of subjective norms related to cryptocurrencies was studied in work of Mutambara (2019) and had a negative effect, but not statistically significant. On the contrary, Schaupp, and Festa (2018) found that subjective norms are an important factor influencing the intent to use cryptocurrencies. This supports our assumptions and hypothesis.

There was not enough evidence to support assumption that privacy risk has a significant negative effect on behavior (t = −1.405, p> 0.05), nor does security risk have a significant negative effect on behavior. (t = -0.556, p = 0.578). This finding is consistent with the literature (Walton and Johnston, 2018) where researchers found that the security risk does not affect attitudes to the intent to use bitcoin. The H3c hypothesis, "Financial risk has a significant negative effect on behavior," does not support 95% confidence interval (t = .61.648, p = 0.099), so it can be rejected. Furthermore, there was not enough evidence that the adoption of cryptocurrency (t = 0.503, p = 0.615) is impacted by privacy. Still, there was also evidence that cryptocurrency (t =2.510, p=0.012) is negatively affected by a security risk. 2.510, p = 0.012).

Considering H4c, it cannot be concluded that the adoption of cryptocurrency is negatively affected by the severity of the financial risk, as the value of value exceeds 0.05, while the t value is less than ±2. These results are in line with some studies in the literature which show that the intention to use PR construct is not important enough to explain using cryptocurrency (Oliva, Pelegrín-Borondo, and Matías-Clavero, 2019; Gibbs and Yordchim,2014). This means that people who use cryptocurrencies expect to be at risk, so they may not feel threatened as an important factor when

deciding to use cryptocurrencies. These results also show that people are generally more concerned about the loss of money and information (i.e., security risk) than current costs (i.e., financial risk) and loss of personal information (i.e., privacy risk).

This study found that the perceived usefulness (t = 5.499, p = 0.000) was positively correlated with the intention to adopt cryptocurrency (t = 4.558, p = 0.000). Considering the factors that influence the adoption of cryptocurrency, this is in line with some of the literature findings, where PU positively affects the intensity and behavior of cryptocurrency adoption (Sohaib et.al., 2019; Won, 2018). Albayati et al. (2020) found a statistical effect of strategic orientation, social impact, self-efficacy, and novelty on two mediation variables (perceived usefulness and ease of use). Furthermore, they found that the two mediation variables had a significant effect on adopting blockchain technology (Nuryyev et.al., 20120). The results obtained in this study validate these findings, as the perceived utility has a significant effect on adopting cryptocurrency. Furthermore, Mendoza-Tello et.al (2018) have found that the most influential factor in adopting cryptocurrency is perceived usefulness.

Predictable enjoyment also positively affects the trend (t = 5.241, p = 0.000) and the intensity of adoption of cryptocurrency (t = 4.558, p = 0.000). PE has been found to influence the decision to use technology in numerous studies, including the significant influence of PE on intent to repurchase bitcoins (Athar Nadeem et al., 2020), mobile instant messaging (Guych Nuryyev et al., 2020), social networks (Zong, Yang, and Bao, 2019), or use of blockchain technology (Shrestha, and Vassileva, 2019). Finally, individual innovation's positive effect on trends is not conducive to a 95-confidence interval (t = 1.900, p = 0.057), thus dismissing this assumption. The same effect was observed in the last hypothesis, where the effects of individual innovation on adopting cryptocurrency were examined. The results show that the hypothesis is not supported (t = 1.640, p = 0.100).

Table 6: Hypothesis test results

Hypothesis	Path	Path coefficient	t-value	p-value	Result
H1	AT → IACC	0.565	9.116	0.000	Supported
H2	SN → IACC	0.058	2.182	0.029	Supported
H3a	PR → AT	-0.080	-1.405	0.160	Not supported
H3b	SR → AT	-0.031	-0.556	0.578	Not supported
H3c	FR → AT	-0.093	-1.648	0.099	Not supported
H4a	PR → IACC	0.026	0.503	0.615	Not supported
H4b	SR → IACC	0.126	2.510	0.012	Supported
H4c	FR → IACC	-0.022	-0.432	0.665	Not supported
H5	PU → AT	0.255	5.499	0.000	Supported
H6	PU → IACC	0.201	4.558	0.000	Supported
H7	PE → AT	0.262	5.241	0.000	Supported
H8	PE → IACC	0.068	4.558	0.000	Supported
H9	PI → AT	0.079	1.900	0.057	Not supported
H10	PI → IACC	0.061	1.640	0.100	Not supported

Discussion and Conclusion

The purpose of this research was to assess the factors influencing the adoption of cryptocurrencies. In particular, this study used an integrated approach by combining the TRA model with three other constructs, mainly PR, PU, and PE, to observe the influence of these factors on cryptocurrency users' attitudes and their intention to use them. Cryptocurrency. Eight hypotheses were tested using data from a survey. The results showed that the intention to introduce cryptocurrency is influenced by attitudes, subjective norms, perceived benefits, and enjoyment. In personal innovation, privacy risk, and financial risk, which are the dimensions of perceived risk, are not associated with intention to adopt cryptocurrency, rather the security risk affects behavioral intent. In light of attitudes, this study shows that perceived risk does not affect users' attitudes towards using cryptocurrencies. In contrast, perceived usefulness and perceived entertainment significantly affect consumer attitudes. These results are not surprising. Cryptocurrency represents a relatively new technology, so not enough information is available to the general population. That being said, consumers are expected to be influenced by others' opinions (i.e., thematic theories). Furthermore, consumers are attracted to technologies that help them work faster and understand them. It's easy. When

deciding to use cryptocurrencies, consumers are more concerned about the security of their data and accounts. The intention to adopt cryptocurrencies in Saudi Arabia is influenced by the consumer's attitude, which is greatly influenced by the benefits of technology and the consumer's satisfaction from using such technology.

Our goal was to identify the factors affecting cryptocurrency adoption through a questionnaire involving questions related to TRA. There were more males than females in our sample, which can be considered a limitation of the study, but this is also consistent with the literature findings, such as in work of Shehhi, Oudah, and Aung (2014) where the reasons for choosing cryptocurrency were investigated, and 95% male participants were male. Another study that examined cryptocurrencies, in particular, found that the usefulness of bitcoins included more men than women (75% of the sample), confirming that cryptocurrencies were mostly male-dominated. Women are also represented below in the cryptocurrency trade(Alshamsi, and Andras,2019). A study by Vejacka and Palova(2019) examined gender differences among Slovak citizens, which affect their attitudes towards cryptocurrencies. Male respondents generally have more information about cryptocurrencies, using cryptocurrencies more frequently for payments and are significant. Cryptocurrencies are more likely to be mined than women. In general, men were judged to be more positive about cryptocurrencies than women (Vejacka and Palova, 2019) which explains why women are underrepresented and generally not interested in cryptocurrencies.

Another possible limitation of this study is that the sample was composed of younger people; hence the results might not represent the older population well. Comparing these proportions to the proportion of educated people aged between 20-39 years old, the participants in this study have higher educational shifts, and respondents with high school degrees or college degrees have a small representation in the sample compared to known data of General Authority for Statistics in Saudi Arabia. This shows that people who know about cryptocurrency are well educated compared to the Saudi population. The majority of people who were involved in the study are highly educated, and their behavior may differ from the general population because it was shown that educated people are more prone to adopting new technologies easier (Welch, 1970; Lleras-Muney, and Lichtenberg, 2002; Riddell, and Song, 2017) Additionally, the study focused on people who already know about cryptocurrency so that the results can be applied only to a specific population segment. This may add biases to the results, as the opinions are not referring to the general population. Hence future studies will focus on other population segments.

This research has several implications. This study's results can be used by governments, corporations, and other decision-makers by incorporating the experimental factors into the development of cryptocurrency systems and strategies. Special attention should be paid here to security risks by regulating the use of cryptocurrencies so that users have a clear understanding of the security risks they may face and how they can be protected. Also, users are likely to embrace the new technology if they can see its benefits. It is, therefore, necessary to provide accurate information about the system. Since the model must offer the possibility of connecting the practical and theoretical aspects, the model's implication also includes the possibility of connecting the model with real situations. Because the presented model provides sufficient clarity to be used and understood for various technology-related studies, new research in cryptocurrency adoption should be able to use this model as a theoretical basis. Finally, developers and decision-makers must consider the usefulness of cryptocurrency in developing such systems.

Abstract

A startup is a business form that is designed to implement original business ideas that are based on new technologies and the Internet. They represent an attractive alternative for young entrepreneurs compared to traditional employment in a company. They succeeded thanks to the success of companies that were founded at universities or in the garage, and today their founders are the richest people in the world. Technical progress, the opportunities of today's entrepreneurs, and positive examples from the past have influenced the increase in the number of this type of business. Especially in the first stages of a company's life, it is necessary to secure sufficient funds. The main goal of the article is to examine possible alternative possibilities of obtaining financial resources for startups, as well as earnings of startups. Based on this information, it is then possible to determine the advantages or the disadvantage of individual sources of financing, to determine which source of financing is the most used among this type of enterprise. The article uses methods of analysis to obtain the necessary information and methods of comparing the results obtained. The result of the research is a summary and mutual comparison of individual financing options for startups.

Keywords: Startups, Financing, Earnings

Introduction

Today brings many new stimuli, ideas, trends, but also opportunities. New companies, individuals, or teams are entering the market. Who start their business in an environment of rapid development, in an environment of the information society, social networks, and technical progress. It is technical progress and innovations that form the basis for building new business units - start-ups.

From an economic point of view, start-ups not only bring with them innovations, new ideas, or improvements to the already established ones, but they have considerable potential to lift the national economy through entry into a global business, production of innovations, and cultivation of human capital, they have new opportunities for job creation. Currently, the number of countries whose governments support start-ups as a source of employment and innovation is also increasing. The popularity and importance of start-ups are also growing significantly in the Slovak Republic, thanks to information technology, media, support from state and non-state entities.

It is the impact of startups on the country's economy that is the main reason for choosing a given topic for further and more detailed research. In the first phase of the research, we focused on examining the possibilities of financing startups in individual phases of the life cycle.

The concept and the essence of business startup

The usage of the term start-up refer to a specific type of business originally spread in the United States during the so-called dot-com bubble between 1997 and 2001 - a period of the unhealthy rapid growth of technology and software companies. However, the definition of a start-up is still not uniform.

According to entrepreneur and one of the founders of Viaweb, the first software in the form of a service company, Paul Graham, the start-up is: "a company designed for rapid growth". However, it is not a fast-growing company, but one that commits to growing rapidly, and this commitment accepts the potential for growth rather than a factual description (Kiska, 2014).

Cite this Article as: Veronika JURICKOVA and Elena GREGOVA " Alternative Sources of Financing and Earnings of Startups" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Steve Blank, the “godfather” of the start-up, came up with the most quoted definition: “A start-up is a temporary organization used to look for a repeatable and scalable business model”, adding that such an organization is: “temporary because the goal of the start-up is paradoxically not to be a start-up, but to become a large organization, or to fail as soon as possible and find another opportunity in the market.” (Blank, 2011).

Erik Ries, entrepreneur and founder of the Start-up Lessons Learned blog and author of a new kind of approach to business, Lean Start-up, says: "Start-up is a people-made institution designed to create a new product or service under extremely uncertain conditions." He adds that the definition is incomplete, as it does not deal with the size of the company, industry, or economic sector (Ries, 2015). "The success of a start-up is not the result of good genes or being in the right place at the right time. A successful start-up should be driven by following the right process, which means it can be learned, which means it can also be taught.”

Luger and Koo (2005) define three criteria defining the framework for start-ups: 1. new, 2. active, and 3. independent:

1. new - only newly established entities registered in the Commercial Register are considered start-ups. Companies with a business history that have only changed their name, ownership structure, registered office, or legal status do not meet this condition.
2. active - another defining criterion is the active participation of newly registered companies in business relations. This attribute excludes companies that, for various reasons, appear only "on paper".
3. independent - the category of newly established/registered companies active in business relations may also include subsidiaries controlled by the parent company. For this reason, the authors also apply the criterion of independence that excludes these branches.

Neil Blumenthal, a successful businessman and founder of Warby Parker, described the start-up as "a company that seeks to solve a problem for which there is no clear solution yet and whose solution is not guaranteed in any way" (Obehmed, 2013).

Senor and Singer (2009) define start-ups as a small company developing a new innovation that has great commercial potential. At the same time, the authors emphasize that innovation is not necessarily linked to new technology. For example, a business model that applies to a given start-up can be innovative. The authors emphasize innovation, which, however, does not have to consist of the development of radically new technologies. Start-ups can in an innovative way combine existing available technologies and thus have a significant competitive advantage over established companies or other start-ups (Gray-Hawkins, Michalkova, Suler, Zhuravleva, 2019).

Multinational institutions understand the term start-up as any start-up business. The OECD uses a similar definition in its regular publications Entrepreneurship at a Glance, where it defines a start-up as a company that has not been in place for more than two years. The public, the start-up community, and professional literature has a common definition that emphasizes the innovative potential of this type of business (OECD, 2017).

Bednar and Tariskova (2016) focused on the difference between income in a traditional company and a start-up. Start-ups operate in the blue ocean, which means in a completely different new market, where business rules are still being formed. The term blue ocean was described by Kim and Mauborgne (2009), where the blue ocean represents a new, undemanding market space where new demand is created and competition becomes irrelevant.

In terms of strategy and leadership, Ljudvigováa (2016) examined start-ups, who considers the inability to create a quality team to be one of the most common causes of start-up failure. The founder of the start-up is also the bearer of a business idea and vision, but he is no longer enough to implement them himself, but he needs to create a quality team.

There are factors necessary for the stability and competitiveness of the start-up. The most important are a simple, scalable, and marketable product, brand value, the right and diversified source of funding (Whittle, Gregova, Podhorska, Rowland, 2019).

Methodology

The main goal of the article is to theoretically describe the individual possibilities of financing and achieving earnings in startup companies. The article defines the very concept of the startup from the perspective of several authors of institutions and organizations. At the same time, the article evaluates the individual financial possibilities for these companies, the advantages, and disadvantages of individual sources for obtaining finance. The method of analysis was used in the writing, we started from a general evaluation of the problem to reach concrete results. Based on theoretical knowledge we reach the conclusion. The information used in writing the article was obtained from the Web of Science Core Collection, conference articles, and articles in economic journals of the Slovak Republic, books of domestic and foreign literature. The reason for choosing the topic was the authors' interest in the issue, its topicality,

and the effort to bring the topic closer to the general public. The contribution of the article lies in the theoretical summary of the issue of alternative sources of finance and achieving earnings in startups.

Results

In general, alternative sources of funding are those that are used to finance enterprises in smaller quantities than from own and external sources, and most enterprises have little or no information on their nature and acquisition process (Michalkova, Frajtova Michalikova, Tanase, 2019). They are considered as new forms of business financing. Alternative sources of financing are understood as a novelty in the Slovak Republic, but this does not apply to Western Europe and countries using the Anglo-Saxon banking system (Gregova, Valaskova, Adamko, Tumpach, 2020). There are these alternative sources of funding commonly used.

Family, friends, fools

FFF (family, friends, fools) - family friends and fools are investors who bring the first external investments to the start-up. They often make their investment decisions not only for the purpose of potential appreciation but are largely based on personal relationships and mutual sympathies. It is therefore likely that the level of risk is not sufficiently assessed, and for moral reasons, the founder should warn his family members, friends, and supporters that the investment is unlikely to return (Moyer, 2016).

Venture capital

SBA (Slovak Business Agency) characterizes venture (venture and development) capital as “Venture capital is a means of financing a company's start-up, development or expansion, where a venture capital investor acquires an agreed share of the company's equity for a certain amount of financial capital. It is primarily a partnership between entrepreneur and investor. Investment in the form of risk capital is not a one-time provision of funds, but a several-year process of coexistence of a business entity with a venture capital investor ”(SBAGENCY, 2020).

According to Vlachynsky (2009) "Venture capital enters small and medium-sized enterprises in order to acquire a stake in a company implementing a promising, albeit risky, project."

If we plan to establish, expand, or restructure a business, or to buy a business or part of a business, private venture capital can help us meet our goals. Compared to the USA, venture capital is less developed in Europe. From the point of view of the Visegrad Four, venture capital is the least developed in Slovakia (Podhorska, Siekelova, Olah, 2019). Venture capital financing is different from standard loan financing. Banks require the repayment of borrowed funds, accrued interest, and also remuneration for the risk incurred, to which they are legally entitled (Dengov, Tulyakova, Gregova, Sviridov, 2020). All this happens regardless of whether the company is prospering or not.

Business angels

Another possibility of support in the first stages of a business is to obtain assistance from the so-called business angels or business angels. These are natural persons who have free financial resources, mostly up to 1.5 mil. € and bring to the company, in addition to capital, also their own experience. These are people looking primarily for a suitable space for investment and business challenges. They usually choose promising projects in areas they understand and enter into a partnership with an entrepreneur not only with financial support but also with business and management boards (Pisar, Bilkova, 2019).

Nevertheless, these projects have only a 25% success rate. The success of every fourth project should not only offset the costs of the unsuccessful but also ensure a profit. Business angels usually leave companies between the ages of three and five. They sell their stake either to a strategic investor, a venture capital fund, or to the original co-owners. We meet business angels through organized networks, widespread especially in Anglo-Saxon countries. Here we find agencies organizing the so-called Exchange of promising projects, where the first contacts with business angels are mediated (Okruhlica, 2013).

Crowdfunding

Crowdfunding is one of the emerging alternative forms of financing, directly connecting those who have funds available and want to borrow or invest them with those who need funds to finance a specific project. As the English term itself suggests, crowdfunding campaigns work on the principle of collecting smaller individual contributions from a large number of people, respectively crowd, mostly via the Internet. Projects usually focus on funding relatively smaller objectives, but there are exceptions.

On the one hand, in a crowdfunding transaction, there is a person (the project owner) with a project idea who will prepare a crowdfunding campaign, and on the other hand, there is a "crowd" of people who give money to implement this idea, the so-called contributors. A huge driving force of crowdfunding is the rise of the Internet, which has enabled

and facilitated access to a large number of people for money from many small contributors, instead of a few large ones. For this purpose, internet crowdfunding platforms are being set up, where individual projects are presented (Hecht, Valaskova, Kral, Rowland, 2019).

However, Crowdfunding is still in its early stages of development, and so its various models, benefits, and risks are constantly changing. The constant increase in popularity and use of crowdfunding can also be seen in the expansion of crowdfunding platforms, which operate on the basis of a certain fee from project owners. It is estimated that there were more than 200 crowdfunding platforms in Europe in 2012. The most famous are Kickstarter, Indiegogo, Fundedbyme, Gofundme (SBAGENCY, 2014).

Finetrading

The name finetrading is composed of the English words "finance" and "trade", ie trade finance. It is a relatively clear and unbureaucratic tool for financing stocks and purchasing. The company agrees with its supplier in the country or abroad on the terms of trade as it is customary. At this point, when sending the goods, a finetrading company enters the store, which immediately pays the supplier the invoiced amount. The buyer of the finetrading company (finetrader) sets a maturity of up to 6 months for consumer goods and up to 12 months for investment units.

Finetrading is used especially in cases where the company is experiencing rapid expansion and needs to buy a large amount of stock, as well as sudden seasonal discounts on raw materials when the company needs to quickly buy a larger amount of these raw materials, i. from. pre-stock, and spread the payment for that purchase over months, or if the bank refuses to finance a particular business transaction. Finetrading is also used in obtaining the so-called discount from customers, which is a discount on the purchase price when paying in cash.

The main advantages of finetrading include the possibility of obtaining additional liquidity, creating a time reserve, improving the company's image, increasing security, and improving the company's creditworthiness (Finetrading, 2020).

Hedge funds

Hedge funds are financial institutions for collective investment. Their origin is most often associated with the name of Alfred W. Jones, who founded a hedge fund in 1949, after the adoption of the Investment Company Act of 1940, which tightened the regulation of investment funds in the United States. They were identified as funds that were not registered under the law and used financial instruments and strategies to hedge investors from losses in the event of "falling" markets. The aim was to regulate all mutual funds. However, the existence of one exception, where legislators considered that if the investor is rich enough, then he does not have to be protected. People with more than $ 1 million were considered a wealthy investor. Those funds that did not have at least 100 such investors and did not provide advice were exempted from the regulatory rules (National Bank of Slovakia, 2007).

The $ 1 million limits exists to protect retail investors. From a macroeconomic point of view, the money will be transferred to the poorer people, who will spend it first, which would not be the case for the rich. This promotes economic growth. As wealthy investors do not experience temporary losses so intensely and, of course, they have a better supply of important information about the fund itself and its investment strategy. On the contrary, if a small investor loses a significant amount of his invested money, this loss has several times greater impact on him and his family (Jilek, 2006).

Today's hedge funds focus on far more diverse trading strategies in order to achieve an absolute positive return regardless of the direction of the markets. Hedge funds differ from traditional collective investment schemes, which are also known to Slovak investors, mainly by the low degree of direct regulation and the use of relatively large financial leverage (Khuong, Liem, Minh, 2020). Over the last few years, the volume of financial assets managed by these institutions has grown rapidly and their weight within the financial systems has been increasing.

Defining hedge funds is not easy because there is no clear and generally accepted definition (including legal). For this reason, most publications on the topic of hedge funds only list their most general features:

• use of a wide range of trading strategies, techniques, and financial instruments, including short selling, arbitrage, derivatives, and leverage,
• they are not correlated with stock and bond markets, as they aim to achieve a positive absolute return (not a relative return to a benchmark),
• their investor base consists mainly of wealthy individuals and families, and increasingly institutional investors (pension funds, private banks, foundations, insurance companies),
• they often use the outsourcing of all their activities except for decisions on trades with prime brokers (execution, clearing, and settlement of trades, risk and liquidity management),
• generally have a relatively high minimum investment limit,

• the investor can monetize his share mostly on a periodic basis after the lock-up period,
• managers, in addition to the management fee (1-2% of assets), also receive a "performance" fee (15-25% of revenue),
• often invest significant amounts of the fund manager's own resources,
• do not disclose information about themselves,
• for tax and regulatory reasons, they are mostly located in offshore jurisdictions, while the fund managers themselves are based onshore (in Europe, especially in London).
However, such a definition of hedge funds is also rather embarrassing (especially from the regulator's point of view), as many of these characteristics, including the financial instruments used and trading strategies, also apply to other types of financial companies (National Bank of Slovakia, 2007).

Sources of financing of startups

The following figure shows the usage of individual sources of financing by startups in the conditions of the European Union.

Fig. 1: Sources of financing of startups in EU
Source: Steigertahl, L., Mauer, R., et al., 2018.

Based on the figure, it can be stated that the most used source of financing for startups is the savings of the founders, up to 77.8%. The reason is precisely the fact that it is a cheap and quickly available source of finance, as there is no need to pay interest on it and repay it. The disadvantage may be the fact that the founders run the risk of losing their own funds, which will not be returned to them and they could invest these funds in other projects. In second place was the source of funding - friends, family and fools - 30.2%. Again, this source of funding is quickly available. Friends, family, and fools are often unaware of the risks they are taking and their funds may not be returned to them. On the other hand, the founder of the startup is protected from starting his own finances. Another important source is the business angels. In most cases, these are business units that have sufficient financial resources and thus provide their free funding for the development of start-ups. For startups, this relationship has the advantage that such an entrepreneur provides him with valuable information, know-how. The disadvantage for a startup is the fact that every such entrepreneur expects a return of their investment. A very interesting source of finance for startups are internal sources - earnings - 15.7%. This means that the startup is already able to produce its own earnings, and thus has partially established itself on the market and creates its own internal resources to finance its activities (Durana, Zauskova, Vagner, Zadnanova, 2020). The disadvantage of this source is that it is not possible to expect it right at the beginning, but only after a certain period of time.

Table 1: Advantages and disadvantages of sources of financing

	Advantages	Disadvantages
Family, Friends, Fools	quick access to finance, no interests	the relationship may deteriorate
Venture capital	permanent support of the venture capital investor, uses knowledge and experience its manager, contracts,	repayment of loans, share of ownership in the company

Business angels	obtaining advice, support and assistance of business angel	return of investment, share of ownership in the company
Crowdfunding	flexibility and speed of fundraising	limited amount of funding, risk of theft and realization of the idea
Finetrading	improving business indicators	higher costs compared to long-term loans, limited funding volumes

Source: processed by authors

Conclusion

Startups are understood as new companies or companies that are in the initial stages of creating a business plan. However, a definition of this type is not is complete or accurate. The word startup has recently been associated with the public with start-up companies, which do business in various areas of services or goods, but only a small percentage of them can consider it a real startup. This type of business also has a significant impact on the country in which it is established. From an economic point of view, start-ups not only bring with them innovations, new ideas, or improvements to the already established ones, but they have considerable potential to lift the national economy through entry into a global business, production of innovations, and cultivation of human capital, they have new opportunities for job creation. Currently, the number of countries whose governments support start-ups as a source of employment and innovation is also increasing.

The main goal of the article is to theoretically describe the very concept of a startup from the perspective of several authors. The article also contains a description of several alternative sources of financing for this type of business, advantages, disadvantages, and the use of individual sources of financing in startup companies within the European Union.

The contribution of the article lies mainly in the description of the basic characteristics of selected possibilities of obtaining funds in startups and the evaluation of their positive and negative aspects. The article provides the information needed to decide on a suitable option for financing a business plan. At the same time, the use of alternative financing options in the article is also shown through a graph. The reason for choosing the topic was mainly the authors' interest in the given area of research. In the future, we would like to deepen research in the field of financing and profits of startups and focus on obtaining finance in the Visegrad Four countries, or Slovakia.

Abstract

The article deals with the problem of using the cost analysis method for evaluating innovative technologies and managing innovative projects in the field of reforestation and growing forest seedlings. Using the method of cost analysis based on the calculation of cost and evaluation of the significance of functions, the operations of innovative technology for growing oak seedlings with a closed root system in one and two crop rotations in greenhouses are studied. The expert method was used. the selection of functions is made according to the ranking and the largest discrepancy between significance and cost.
The study allows us to develop a methodology for cost analysis in relation to the assessment of innovative technologies in the field of reforestation. Using the organizational scheme of the seedling growing process in addition to the cost analysis method allows you to more fully study all operations in innovative technology, assess their significance and identify "problem" functions in the technology of growing forest seedlings.
Using the methodology of cost analysis allows you to set the most expensive functions and manage the innovation process taking into account reliable information. the use of cost analysis reduces the cost of innovative technologies. The effectiveness of the va method for evaluating innovative technologies in forestry is achieved primarily due to a new, different from the traditional, cost classification, reliable and sufficient information. The introduction of the va method in the practice of reforestation provides cost savings while improving the quality of growing forest seedlings.

Keywords: Innovation, Value Analysis Methodology, Reforestation, Cost, Management Analysis.

Introduction

A distinctive feature of the development of economic systems in modern conditions is its focus on the creation and use of innovations as a factor providing competitive advantages. There is a direct link between the effects of the choice of innovation and the state of the company. Shakina (2020) notes the formation of competitive advantages among companies applying innovations and investing in innovative activities. Innovation as a key economic category is the engine of economic growth of companies and employment of the population of the regions.

This is relevant not only for high-tech industries, but also for all sectors and economies, including forestry (Jarský, V., 2015).

Cite this Article as: S.S. MORKOVINA, E.A. PANYAVINA, I.V.SIBIRYATKINA, V.D. PETROVA and P.A. MAKSIMCHUK " An Analysis of Value Management in Forestry Practice " Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Climate change and its consequences pose serious challenges to the global community in terms of forest ecosystems. Therefore, European countries are actively discussing the implementation of environmental innovations in forest management. The ability to innovate and put it into practice is critical to the success of enterprises in traditional sectors such as forestry (Štěrbová, M. et al., 2019).

So in the work of Rodriquez J. and Wiengarten F. (2017) it is noted that the creation of environmental innovations presupposes the availability of both resources (i.e. internal and external research and development, the acquisition of machinery, equipment, software, patents and licenses) and new knowledge, which contributes to the development of innovative processes. Most often, innovation is associated with the development of production methods, followed by innovation in the field of goods and services (Lovrić, N. at al., 2020). At the same time, innovations in forest management should be assessed primarily in terms of their functions for solving environmental problems.

Value management (VM) was first introduced in the United States of America around the 1940s, and the method was initiated by the development of the Soviet engineer Yu.M. Sobolev (element-wise economic analysis) and the American Miles L.D. (value analysis / value engineering, VA / VE) (1972). In the works of Miles L.D. focused on the choice between functions and their cost (Kassa, A.O., 2018).

VA has been known for over 60 years and is a powerful and versatile approach to evaluating processes, products, and production planning (Jay, C.I. at al., 2015). The use of VA in construction and design is noted in the works of Kelly J. et al. (2004) and Oke A.E. et al. (2011), however, Bowen P. et al. (2010) emphasize that it is possible that in practice the results of its application may be exaggerated. In the works of Green S.D. and Liu A.M.M. (2007) and Spaulding W.M. et al. (2007) noted the value of the method from the standpoint of individual projects, in particular, ensuring their viability, return on investment, accessibility to stakeholders and the possibility of adjusting to account for changing conditions. The successful application of the VM method for project funding management purposes is noted in the studies of Liu G. and Shen Q. (2005).

Bowen P.A. et al. (2009), assessing the impact of investment projects on the environment, noted the promise of using the value management (VM) method. These projects address environmental and socio-economic issues and involve multiple functions that need to be assessed.

In a number of works, Ellis R.C.T., et al. (2005) indicated that VA is part of design and planning, which improves investment efficiency and productivity.

At the same time, Morkovina S.S. et al. (2018) argue that the cost analysis process is a separate process that does not depend on design and standards and can be used to evaluate any process, including the creation of innovative products and technologies. This is especially important for forestry, where traditional forestry processes are strictly standardized and the introduction of innovative technologies is limited by climatic and natural factors.

Crosbya A.D. has demonstrated the wide application of VA based assessment of the significance of various functions. et al. (2020) when they used his methodology to develop a strategy for the conservation of avian biodiversity in the western Upper Peninsula of Michigan, USA. The development of VA / VM is associated with the recognition of its versatility in various systems, including for the purpose of assessing the effectiveness of creating innovations in the forest sector of the economy.

Thus, the problem is that VA / VM usage priorities are shifted towards construction, engineering and design, which creates a practical and theoretical gap in other areas of expertise. In our study, we focus on assessing the possibility of using the VA / VM method as an alternative way to manage innovations in forestry and evaluate innovative biotechnologies.

Accordingly, this article is primarily aimed at analyzing the value analysis (VA) method in forestry, both from a theoretical point of view and from the point of view of the possibility of practical application for the purpose of assessing innovative technologies and managing innovative projects in the field of reforestation and growing forest seedlings. Secondly, the identification of cause-and-effect relationships between the functions of the production process of seedlings of woody plants using innovative technologies and their cost, taking into account the influence of unfavorable environmental factors. Thirdly, to analyze individual functions as part of the considered innovative technologies for the purpose of reforestation from the standpoint of their significance and cost. Finally, the identification of the functional and cost mismatch in the performance of separate operations as part of each function.

The rest of the document is organized as follows: Section 2 analyzes and systematizes possible influencing factors on the relationship between the functions of creating seedlings of woody plants using innovative technologies and their cost, and provides an overview of the relevant literature, Section 3, using the VA methodology, presents an analysis and ranking of individual functions (main, auxiliary and final) as part of innovative technologies for the purposes of reforestation from the standpoint of their importance and cost. The process of forming production costs for growing seedlings with a closed root system is described.

Section 4 describes the results of our study. Finally, the last section provides some concluding remarks and suggestions for further research.

Theoretical, Informational, Empirical, and Methodological Grounds of the Research

The need to assess innovation in terms of causal relationships between functions and costs in forestry is due to a number of reasons. Climate change and population growth lead to significant losses in forest ecosystems. The response to these changes is the systematic reforestation and afforestation activities in all countries of the world.

The growing demand for timber and timber products requires accelerated growth of trees and new species of tree species with growth rates and resilience.

Growing forest seedlings requires investments, the payback period of which is significantly extended in time and can be calculated in tens of years.

All of this necessitates not only the creation of innovative technologies, but also their economic assessment, taking into account the influence of these factors.

The condition of forests has changed significantly over the past decades. The Russian Federation retains its leadership in forest area - 815 mln ha, or 20.4% of the total forest area in the world. The share of the forest area in Brazil is 12.3%, Canada - 8.7, USA - 7.7%, China - 5.2%. Globally, the world's forest resources continue to decline as population grows and demand for food and land increases. In 1990, there were 4128 million hectares of forest in the world; by 2015, this area had decreased to 3999 million hectares. (FAO, 2015.). The land area occupied by forests has decreased by 30.6%.

While forest area declined by 5,135.5 thousand hectares between 1990 and 2015, the world's population has increased, which means that forest area per capita is declining - a trend that has existed for millennia. For fifteen years, the area of forests per inhabitant has decreased by 10 - 30%.

The most significant losses are incurred by the equatorial countries of Brazil and Indonesia, where the loss of forest resources amounted to 30 percent or more. The only exception is China, where forest area per inhabitant has increased by 7% over the past fifteen years (Table 1).

Table 1: Trends in forest areas per capita in countries

Country	Forest area, ths ha					Population, mln human		Forest area per inhabitant, ha / human	
	1990	2000	2005	2010	2015	2000	2015	2000	2015

Zambia	52800	51134	50301	49468	48635	15,2	16,4	3,36	2,96

The problems of forest reproduction at the level of the countries of the world are relevant against the background of significant climate changes and population growth. The decline in forest area per capita, coupled with a steady increase in demand for timber and forest ecosystem services, indicates that the pressure on forests will increase in the coming years. To solve these problems, it is necessary to accelerate the processes of reforestation and afforestation.

The annual deforestation is 1.4 mln ha, which is approximately 0.1%. Understanding the threats of deforestation is forcing countries to increase reforestation areas. The average annual growth rate of reforestation in 2010–2015 amounted to 3.2 mln ha per year. The main area of reforestation was in the USA, RF, Indonesia and Brazil, with annual reforestation from 0.5 to 3.0 mln ha of forest (fig.1).

Fig. 1: Distribution of countries by area of reforestation in 2015

The dynamics of reforestation in the Russian Federation is shown in the graph in figure 2. Despite the growth in reforestation over a ten-year period, a stable imbalance in the disposal and reproduction of forests in the RF remains.

The current imbalance between reforestation and deforestation of territories, as well as low growth rates of forest planting, are explained by many reasons, including economic ones.

Fig. 2: Dynamics of reforestation volumes in the regions of the Russian Federation, ths ha

In the structure of costs for reforestation, the largest share is the cost of growing tree seedlings (fig. 3). The traditional process of growing forest seedlings is highly labor-intensive, which affects the cost of the grown seedlings. However, it is not possible to solve them by traditional methods of reforestation in a short time, and, therefore, innovative technologies of forest growing are in demand.

Fig. 3: Reforestation cost structure

These technologies must be high-tech, which will reduce the cost of growing seedlings and provide a solution to environmental problems - accelerated reforestation and resistance of forest seedlings to adverse environmental factors.

In recent years, there has been a certain breakthrough in forestry in terms of innovative technologies for growing seedlings of woody plants. However, the areas in need of reforestation in the Russian Federation are 31749.9 ths ha, about 1000 ths ha are restored annually, while the share of forest crops created by planting material with improved hereditary properties does not exceed 5%.

In the Russian Federation, the issues of reforestation and afforestation are acute, and at least 15% of all forestry costs are allocated annually for their solution. The structure of costs for the maintenance, protection and reproduction of forests in the Russian Federation is shown in figure 4.

In these costs, innovative technologies and their development account for no more than 4%, mainly these are funds carried out in the course of R&D by scientific organizations and universities.

Fig. 4: Dynamics of costs for reforestation, including the use of innovative technologies, €

Companies that use forests and logging practically do not invest in the development of innovative technologies. In a number of regions of the Russian Federation, in order to ensure reforestation, forest selection and seed-growing centers have been created on the basis of greenhouses, which make it possible to increase the number of grown forest seedlings due to all-season work. However, the forest seedlings grown on their basis have a high cost and are not competitive, first of all, in terms of price. In this regard, it is necessary to study the processes of formation of the cost of seedlings with improved hereditary properties. Justification of the application of innovative technologies for the purpose of reforestation requires an analysis of not only the technology as a whole, but also individual functions in its composition from the standpoint of their significance and cost.

The methodology of functional-cost analysis allows to indicate possible ways to improve cost indicators. Calculating the cost of a separate function in the FSA allows you to get a large amount of information for making a decision.

In the course of the analysis, they find out what functions the object should perform and what functions it actually performs. All functions of the object are formulated, systematized and evaluated. The peculiarity of conducting VA when assessing innovative technology is to establish the appropriateness of a set of functions that make up the entire process of creating a new product.

The assessment of the effectiveness of the results of the creation of new technologies in forestry is based on the following principles:

- when comparing the results of different technologies, their comparability should be ensured;
- when comparing alternative solutions, preference should be given to the one with the greatest effect value;
- When evaluating the effectiveness, the time factor should be taken into account, i.e. inequality of different costs and results (preference is given to earlier results and later costs);
- taking into account only forthcoming costs and receipts;
- taking into account all the most significant consequences of the use of technological solutions, both directly economic and silvicultural;
- taking into account the impact of inflation (changes in prices for various types of products and resources during the creation and commercialization of the results of the introduction of new technology);
- taking into account the influence of risk factors of various nature.

In this research study, we used the VA method to estimate the cost of each function in growing woody seedlings with a new technology.

The object of our research was the processes and operations of innovative technology for growing seedlings in forest seed-breeding centers, based on greenhouses.

An innovative technology was adopted for growing oak seedlings with a closed root system in a forest selection and seed-growing center, based on greenhouses.

At the same time, two options were considered for an innovative technology for growing oak seedlings with a closed root system in a forest selection and seed-growing center, on the basis of greenhouses - with one rotation and with two rotations. In the technology with two rotations of seedling growing, the production load and an increase in the number of grown seedlings during the year twice as much as with one rotation was provided.

Functional-cost analysis to assess the innovative technology of growing seedlings with a closed root system in a greenhouse is implemented in stages, and at the first stage, the sequence of functions necessary for the production of seedlings is determined.

Closed-root planting material is grown in greenhouse complexes for one year. In this case, the following types of work are carried out:

- cleaning, processing and drying of acorns;
- treatment of acorns before sowing with fungicides;
- preparation of a substrate for growing seedlings, fertilization;
- filling cassettes with nutrient substrate;
- planting acorns in cassettes;
- forming a stack of cassettes;
- transportation of packs of cassettes to the greenhouse;
- watering seedlings;
- fertilizing with mineral fertilizers;
- spraying oak seedlings with fungicides;
- selection of seedlings, sorting, accounting and packing.

In the second phase of the VA implementation, for each function, the total annual costs and number of work hours are determined. For each type of work on growing seedlings, the required amount of machines and tools, fuel, electricity, water, fertilizers was determined. The need for workers and maintenance personnel was also calculated. For each attracted resource, the norms of time of its use were determined for performing the operation using the method of time observation. The process of making time observations includes:

- preparation for observation;

– monitoring and measuring the cost of working time;
– processing time observations and setting standards;
– analysis and systematization of the received material for the purposes of rationing.

The whole process of growing seedlings with a closed root system was represented by an organization diagram (fig. 5).

Fig. 5: Organizational diagram of the process of growing seedlings with a closed root system

For each function in the presented diagram, a separate operation is defined for which, using the norms of time and resources, a quantitative characteristic is determined - the cost of its implementation. In forestry, all costs are usually divided into production and overhead.

The organization chart reflects the process of generating production costs. To calculate production costs, the study used flow charts. In these maps, the composition of work, the system of machines, standard-forming factors, production rates, wage grades of work and wage rates, the need for mechanisms, the labor costs of workers in man-days, the need for materials were determined. After all the costs for all functions have been determined, a full calculation of the costs for growing seedlings with a closed root system is carried out.

The VA methodology included the following sequence of works:

1. building a functional and structural model of processes;
2. building a functional-cost diagram and ranking functions but their significance and costs based on their greatest mismatch;
3. building a diagram of the interaction of functions.

The next important step was the expert assessment of the significance (ranking) of the evaluated functions. At the first stage, the data array is generated, i.e. of all functions, only those are identified that affect the achievement of the goal - making the right management decision related to changing the management object.

To minimize the cost of implementing the VA method for growing forest seedlings, the number of experts should be optimal. The solution to this problem within the framework of a scientific study is based on a survey of thirty experts in the field of growing forest seedlings in a greenhouse. The selection of functions is made according to ranking and the greatest mismatch between significance and cost.

In the regional context, the existing costs for the production of seedlings with a closed root system differ significantly (fig. 6).

Fig. 6: Histogram of the cost level for growing seedlings with a closed root system in forest seed-breeding centers and greenhouses of the regions of the Russian Federation

Differences in the cost of growing seedlings are a consequence of differences in the cost of the resources involved. Taking into account the fact that in the conditions of forest selection and seed-growing centers and greenhouses the process of growing seedlings with a closed root system is standardized, we determined the costs of growing oak seedlings with an open root system (traditional technology) and a closed root system (innovative technology) (Table 2).

As a typical, we used the following grouping of costs for growing oak seedlings according to the following cost items:

- «Materials»;
- «Expenses for wages of workers»;
- «Expenses for the maintenance and operation of machinery and equipment».

The article «Materials» included the costs of materials used directly during the work on growing oak seedlings, mineral fertilizers, plant protection products, fuel, electricity, water and other types of material resources.

Table 2: Costs of growing oak seedlings with open root system (traditional technology) and closed root system (innovative technology)

Indicator name	Costs of growing seedlings with an open root system (ORS)	Costs of growing seedlings with a closed root system (CRS)	
		One rotation	Two rotations
Maintenance of machinery and equipment, €	1123.10	128009.23	193650.38
Wages of workers, €	3163.30	10177.63	20269.45
Materials, fuel, electricity, €	1537.60	21567.81	43135.63
Total costs, €	5824.01	159754.69	257055.46
Yield of standard planting material, ths pcs / ha	5.80	37.57	75.13
Production cost of one seedling, €, incl. costs for:	0.01	0.05	0.04
Maintenance of	0.002	0.040	0.030

machinery and equipment			
Wages of workers, €	0.006	0.003	0.003
Materials, fuel, electricity, €	0.003	0.007	0.007

The item «Expenses for the wages of workers» reflected all the costs of wages for production workers employed directly in the work of growing oak seedlings, calculated according to the wage systems adopted in the forestry of the Russian Federation.

The item «Expenses for the maintenance and operation of machinery and equipment» included depreciation deductions for the full restoration of machines and mechanisms, as well as production fixtures and equipment accounted for in fixed assets, the cost of maintenance, maintenance and repair.

It has been established that the largest share of costs in traditional technology is for workers' wages, while in innovative technology the largest share is occupied by the costs of maintaining machinery and equipment. The most expensive is the production of seedlings with a closed root system in one rotation. With an increase in the number of growing rotations, the volume of produced seedlings increases to 6.48 ths pcs / ha and the production cost is reduced to 0,04 €.

In order to identify the most costly operations, the entire process of growing senets with a closed root system was presented in the form of a structural-elementary model. This approach made it possible to establish the most costly functions and identify functional-cost mismatch.

Results

The main elements of the process of growing seedlings with SCS are preparatory work, the main work on planting acorns and growing seedlings with CRS, final operations on the selection of seedlings, sorting, packing (fig.7).

Fig. 7: Structural and elementary model of growing oak seedlings with a closed root system

The functions of the technology for growing oak seedlings with a closed root system in one rotation are presented in Table 3.

Table 3: Functions of the technology for growing oak seedlings with CRS

Name of operation	Functions	Code
Growing an oak seedling one rotation	Main	F0
Preparatory work	Basic	F1
Cleaning, processing and drying acorns	Supporting	F1.1
Etching acorns before storing TMTD	Supporting	F1.2
Planting acorns and growing oak seedlings	Basic	F2
Treatment of acorns before sowing TMTD	Supporting	F2.1
Filling and feeding the substrate, mixing the substrate and fertilizers with a mixer	Supporting	F2.2
Filling cassettes with nutrient substrate	Supporting	F2.3
Sowing acorns in cassettes	Supporting	F2.4
Forming a stack of cassettes	Supporting	F2.5
Removal of packs of cassettes to the greenhouse	Supporting	F2.6
Watering crops	Supporting	F2.7
Fertilizing with mineral fertilizers	Supporting	F2.8
Transportation of packs of cassettes to an open landfill	Supporting	F2.9
Spraying oak seedlings with fungicides	Supporting	F2.10
Seedling selection works	Basic	F3
Selection of seedlings, sorting, accounting and packing	Supporting	F3.1
Washing and disinfection of cassettes	Supporting	F3.2
Loading and unloading fertilizers, seeds, chemicals	Supporting	F3.3

The study analyzed the cost of functions in the context of the main, auxiliary and final processes associated with the cultivation of forest seedlings with closed and open root systems. (Table 4).

Table 4: Costs of functions and significance when growing oak seedlings

Indicator name	Code	Technology costs, €			Significance of functions by technology, %		
		Traditional	Innovative, one rotation	Innovative, two rotations	Traditional	Innovative, one rotation	Innovative, two rotations
Full prime cost of growing seedlings	F0	5757.3	157923.7	254109.3	100	100	100
Preparatory work	F1	3339.2	79.0	122.0	58	50	48
Main process (sowing seeds, watering, leaving)	F2	1727.2	66.3	114.3	30	42	45
Selection, sorting, packing of seedlings	F3	690.9	12.6	20.3	12	8	7

As the results of the expert assessment showed, the significance of functions in the processes of growing seedlings with open and closed root systems is different. According to experts, in traditional technology, preparatory functions are the most important, while in innovative technologies the importance of the main processes increases. Thus, the performed work on the functional-cost analysis of growing oak seedlings with a closed root system made it possible to establish that the traditional technology of growing oak seedlings is inconsistent and requires significant changes.

The function «Preparatory work» in an innovative technology with one rotation has the greatest discrepancy and ranks first in terms of the sum of costs and significance.

The function «Planting acorns and growing oak seedlings» in the second rotation has the greatest discrepancy and ranks first in terms of the sum of costs and importance.
In general, it is necessary to modernize the identified «problem» functions in the technology of growing oak seedlings with a closed root system.

Conclusions and Recommendations

The use of the VA method in assessing and planning innovations in reforestation has great prospects. Thanks to this method, it becomes possible to establish the most costly operations throughout the entire technological process, as well as to identify mismatched ones among them.

The VA method used to evaluate the innovative technology of growing oak seedlings made it possible to establish the advantages of two rotations when growing seedlings in a greenhouse. This advantage comes from an increase in the number of grown seedlings, the so-called economies of scale and more efficient organization of production.

The VA method used to assess innovative technology made it possible to establish that the innovative technology of growing oak seedlings in two rotations, concentrated on the main processes, is more balanced, including in terms of the costs of performing certain functions.

Thus, the effectiveness of the VA method for assessing innovative technology in forestry is achieved, first of all, due to new, different from the traditional, cost classification, reliable and sufficient information.

At the same time, the experience of using the VA method in forestry is ambiguous: studies have shown that, along with the positive results achieved, the introduction of this method is associated with certain difficulties.

In some cases, the scale of tasks and the nature of the analyzed objects do not correspond to the specifics of the method itself. Functional value analysis is a time consuming and complex analysis tool that requires well trained, highly skilled workers. Its introduction into management practice is possible on the basis of large industrial enterprises.

Abstract

Purpose: Ukraine is undergoing a systemic reform of public administration, which does not bypass public finances. This article is devoted to the formation of a modern system of state control, which aims to ensure optimal supervision over the formation and use of public resources / finances. Conceptual principles of public financial control are evolving in accordance with structural and procedural reforms in public authorities. We should consider existing practices and procedures, as well as identify in a timely manner the need to revise approaches to modern forms and methods of control activities. Legislators and officials must take into account the peculiarities of the development of public administration since independence, the presence of negative features of Ukraine as a state. Corruption, economic crisis, and outflow of investment require changes in the methodology of control actions from formal procedures to performance audits. **Methodology**: During the study, a systematic approach was used, which allowed to consider the form and the content of modern public financial control in Ukraine. The historical approach allowed us to study the evolution of the system of state control since independence. The method of extrapolation made it possible to use world and European experience in building an effective system of internal and external financial control in developed economies. **Conclusions**: The result of the study presented reasonable vision of how to build an effective system of public financial control in the country with a Soviet past, the signs of corruption in government, the raw materials economy. The features and characteristics of the post-Soviet system of state financial control with its inherent features, forms and content are clearly defined. A new concept of building an effective system of controlling bodies is proposed, the work of which is aimed at meaningful and effective supervision over the filling of the state's financial resources and their reasonable and rational use. **Implications**: Clearly defined directions for reforming the system of public financial control allow the relevant authorities to exercise internal control over the effective use of public finances by budgetary institutions, as well as to establish effective procedures for conducting independent external public financial control. As part of public administration reform, new approaches, forms and methods of conducting control procedures are emerging.

Keywords: public administration reform, public financial control, internal and external financial control, efficiency audit.

Introduction

Public administration reform implies radical changes in the activities of public authorities in accordance with the area of competence of each of them.

There is a problem of designing and implementing a comprehensive system of public financial control, focused on economic development, optimization of public infrastructure. Public financial control is currently undergoing the transformation and needs to work out processes and obtain the first practices that meet the new regulatory framework. Ukraine is taking measures to bring its national legislation in accordance with EU legislation in the relevant areas, particularly in public financial management.

It should also be borne in mind that Ukraine is implementing the reform of decentralization of power (LOGICA, 2019), which implies:

- transfer of powers and finances from state authorities as close as possible to the people - local governments;
- transition from the classic (article-by-article) system of planning and spending of budget funds to the program-target method, which is focused on achieving specific results (hereinafter - PCM).
-

According to Oleg Shevchuk (Shevchuk, 2017), in order to carry out a single public financial policy effectively, financial bodies of the state power should function as a system, as only a systematic approach allows to make financial control an unalienable part of social and economic life of society, to analyze and take account of all significant factors influencing the economic development of the state, professionally assess and predict the consequences of the decisions made related to the financial and material sphere. The systematic approach to public financial control provides, in the first place, for the search of the ways of constructional interaction of controlling bodies of different levels, legislative ensuring of their organization and functioning, a single methodology of common activity, creation of a single information space.

Andrew Lawson, Co-Director of Fiscus Limited, argues (Lawson, 2015) that effective public service delivery is closely linked to poverty reduction and growth; countries with strong, transparent, accountable public financial management systems tend to provide services more efficiently and equitably and regulate markets more effective and fair way. In this regard, good public finance management is a necessary, if not sufficient, condition for most development results.
A key element of statehood is the ability to pay taxes fairly and efficiently and to spend money responsibly. These are the main characteristics of "inclusive" public institutions that generate trust, promote the development of innovative energies and allow society to prosper.

Efficiency improvement of the public financial management system leads to broad and long-term benefits and, in turn, can enhance societal shifts towards inclusive institutions and, consequently, stronger states, poverty reduction, greater gender equality and balanced growth.

Volodymyr Pikhotskyi in his fundamental research (Pihotskyi, 2015) notes that in a market economy and in the transitional stage of its development, research on the functioning of public financial control should be carried out on the basis of a systematic approach, which provides, along with researching the essence of public financial control, clarification of its functions, classification criteria, principles and objectives.

According to experts of the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ, 2020), the structure of public finances provides for two levels, due to the administrative-territorial structure of Ukraine, namely the division into national and local finances.

Ukrainian researchers also insist on the need to use modeling tools in public administration, given the effects of the pandemic on replenishment of the budget, for example, at the expense of funds from labor migration (S. Kozlovskyi, D. Bilenko, M. Kuzheliev, 2020). Due to quarantine in almost all developed host countries labor migration that has been established over the years may change significantly. New conditions call for new methods never used before, such as, modeling new economic development scenarios taking into account the spread of viruses. Further development of epidemic model can be associated with attempts to create simulation models. There are two types of simulation models, one of them is system dynamics, and the other one is agent-based model.

Public financial control, according to Andriy Khmelkov (Khmelkov, 2013), is seen as an integral part of good governance of public finances, a set of measures aimed at ensuring legality, financial discipline and efficiency of formation and spending, including budget, and other assets in the process of possession, disposal, use and alienation

of state property, compensation for damages and the establishment of liability in case of violation of financial, including budgetary, legislation.

As part of their activities, the main audit bodies - the State Audit Office of Ukraine and the Accounting Chamber of Ukraine - actively analyze the functioning of economic entities and the results of public policy in various areas («National Economic Strategy 2030», 2020). During 2019 and January-September 2020, the State Audit Office conducted 2103 audits of financial and economic activities, 223 inspections of procurement, 16010 monitorings of procurement, 617 state financial audits, including 321 audits of business entities and 119 audits of local budgets. The Accounting Chamber has conducted more than 20 comprehensive audits of the efficiency of budget funds.

The inspections revealed financial violations and shortcomings totaling UAH 625.1 billion. Ukraine is one of the largest countries in Europe in terms of territory and population, but at the same time one of the poorest countries in the region. Despite the fact that we rank 56th in the world in terms of GDP in absolute terms, Ukraine ranks only 119th in terms of GDP per capita.

At the same time, since the last century, the world community has been based on the postulate that quality management control systems are important for a well-managed organization.

Experts of the joint initiative of the OECD and the EU (SIGMA – Support for Improvement in Governance and Management) believe that Creating effective management control procedures is difficult in any organization. The more complex the management system and the relationship with other parts of the economy is, the broader and more complex the necessary management tools are. (SIGMA Papers No. 4, 1996). Management control can be summarized as the organization, policies, and procedures, used to ensure that government programs achieve the intended results; that the resources used to implement these programs correspond to the stated goals and objectives of the relevant organizations; that programs are protected from waste, fraud and mismanagement; and the fact that reliable and timely information is received, stored, communicated and used for decision-making. Effective management control is undoubtedly important for the success and well-being of government organizations, both as protection against waste, abuse and fraud, and as a means of ensuring that the organization implements the policies set out by senior management. However, even the most carefully designed management systems have their limitations, in part because, although they allow top managers to control the organization, they do not control the top managers themselves. Constant vigilance is required to ensure that systems are not undermined by fraud or unresponsiveness to changing circumstances and operating procedures.

Conceptual principles of formation of the Ukrainian system of state financial control

Having functioned for almost 30 years as an independent state, Ukraine is moving towards European community via a radical reorganization of public administration. The legal framework is being formed and improved, state institutions are being transformed, the content of the work of public authorities in the direction of adaptation and harmonization with EU legislation and the implementation of effective world practices in the field of public administration is being revised.

Control and accountability are the two main concepts that ensure the efficient use of public funds and are implemented through a wide range of mechanisms. Over the past few years, a number of measures have been introduced in Ukraine to improve the system of control over public finances. Today, the Public Financial Control (PFC) system is extensive and has been established in several institutions at different levels. It is mainly a section on internal and external control / audit functions in relation to state or local budgets. Therefore, it is necessary to conduct a thorough review of the current situation in financial management at the state level to understand the role of key stakeholders – Ministry of Finance / Department of Harmonization of Public Internal Financial Control, Accounting Chamber of Ukraine, State Audit Office of Ukraine. The task of the state is to form a culture of public finance management that will ensure the effective, legal and appropriate use of public resources for the welfare of the population and sustainable socio-economic development of the country. Poor management and lack of proper financial and organizational control create preconditions for inefficient or illegal use of public finances. The driving mechanism for improving the mechanisms for managing budget funds and state assets is the introduction of effective systems of internal control and internal audit in the executive branch.

In the early 1990s, Ukraine inherited the regulatory framework, organizational structure, and methodology for conducting state financial control from the Soviet Union. The main subjects of control were control and audit departments and other specialized bodies of state control: tax inspections, financial departments and so on. Despite the stagnancy, planned approach and certain corruption, this was the basis for restructuring, and during the first ten years both infrastructural and substantive changes took place. Entrepreneurs experienced a meaningful liberalization of relations with inspection bodies for the first time, when in 1998 the Decree of the President of Ukraine “On some measures to deregulate business activities” was issued, which declared the norm that the “right to conduct a scheduled

on-site inspection of the subject of business activity is provided only in the event that no later than ten calendar days before the date of the inspection, a written notice was sent to it, indicating the date of inspection".

Public financial control with all its components in practical terms should be considered as a multifaceted system of monitoring and verifying the legality, feasibility, rationality and efficiency of the formation and use of financial resources at any level of government to assess the effectiveness of management decisions and achieve economic progress (Pihotsky, Rysin, 2019). For completeness and integrity, it must be complemented by control over the use of state property. When considering the state financial control as a whole, consisting of parts, it should be noted that one of its stages must be to establish the accuracy of accounting and reporting data and other documentation of the audited entity, regardless of its form of ownership to determine its actual financial condition, establishing the efficiency and effectiveness of activities, ie conducting an audit, which is an integral part of public financial control. At the same time, the authors acknowledge that Ukraine is in the first stage of implementing a state audit.

Myroslava Bedrynets believes that «a serious obstacle to the successful implementation of economic reforms is the rather cumbersome structure of public financial control bodies. We believe that an important issue in improving control is to eliminate duplication of actions of control bodies, which is to perform different functions of different bodies (Ministry of Finance, Accounting Chamber, State Financial Inspection of Ukraine) in relation to the same objects of control. The tasks of public financial control bodies are not specific enough, the limits of their responsibility are blurred, and activities are poorly coordinated. They must work more closely together while maintaining the responsibility of each body for its area of control» (Bedrynets, 2015).

In any field of activity control has its types and forms. Therefore, first of all, it is necessary to provide a certain list of features that classify control in general and public financial control in particular. There are previous, current and subsequent (next, retrospective) control. By regularity – scheduled and unscheduled; according to data sources – documentary and factual. The form of control depends on the depth of clarification of the issue – audit or verification. There are also continuous and selective control.
If we distinguish features within the state control, including financial, it can be argued that there is independent (external) and internal control.

Control is an undividable part of the budget process system. It aims to identify deviations from accepted standards, identify violations of legality, resource efficiency, bring perpetrators to justice, and take measures to prevent or reduce such violations in the future.

The key subjects of state financial control in Ukraine are:

- Ministry of Finance of Ukraine;
- Accounting Chamber of Ukraine;
- State Audit Office of Ukraine;
- State Treasury Service of Ukraine.

The object of state financial control is what the subjects enter into a controlling legal relationship and what the control activity is aimed at. Such an object is all the money that is formed in the process of cost distribution, redistribution and use of centralized financial resources. Thus, the object of public financial control is the financial activities of economic entities (Pikhotskyi, 2015).

Each subject of control has its own powers from the implementation of a unified state policy in the field of control to the targeted, effective and efficient use of budget funds.

In recent years, there has been a serious convergence of the format and approaches to the implementation of activities in accordance with the rules established by international control institutions. Several concepts for the development of the state financial control system have been developed and are being implemented. For example, the CONCEPT of Development of Public Internal Financial Control till 2017, which declares the separation of internal control and internal audit, insists on managerial responsibility for management and development of the entity as a whole, defines the components of the internal control structure (CONCEPT, 2008). In 2018, the Prime Minister of Ukraine initiates and the Cabinet of Ministers approves the CONCEPT for the implementation of public policy in the field of reforming the system of public financial control until 2020. From now on, the efficiency and effectiveness of the use of budget funds will be studied from the standpoint of measuring the socio-economic consequences of the budget manager and its management decisions, including the level of achievement of goals, efficiency of tasks in the relevant field, achievement of social goals, expected results and so on. The concept is aimed at the development of the State Audit Office of Ukraine (CONCEPT, 2018).

In addition, over the past ten years, the Ministry of Finance has developed and implemented a list of guidelines, manuals, forms of documents, reports, codes and standards governing the work of public controllers and auditors and forming new institutions of public financial control. Systematic work and comprehensive coverage of methodological issues allowed to form the basis of new methods and content, for example, internal control by managers of budget funds (BASIC PRINCIPLES, 2018).

Each of the participants in this process, from manager to executor, should have a certain minimal level of specialized skills in the field of control. The high competence of specialists allows to implement reforms and direct control actions towards determining the effectiveness of controlled objects. Competence allows you to correctly interpret the law, optimize control procedures and find rational solutions based on its results.

Competence is formed by comprehensive perception and understanding of the procedures, which take place in the control system.

In the work "Control and Audit" (Pavlyuk, 2006), it is indicated that “control as a control element is a complex process aimed at verifying the compliance of objects with the proposed requirements and parameters. Elimination of detected deviations is also a task of control. By detecting deficiencies in the activity of the object being inspected, the control signals the imperfection of certain parts of its mechanism. The subject of management (of control) uses the information obtained to make effective management decisions”.

As part of the training of modern specialists in management, control and audit, economics in Ukraine, the young controller should be given a clear idea of the content and form of control over the procedures. So, considering the differences of various forms of control, you can view them graphically, while providing verbal definitions. For example, they demonstrated a wide coverage of data during the audit and the depth of their study during inspections (Fig. 1).

The graphic image of the revision and checkup shows the desire of the controllers:

- when conducting a revision - to cover the maximum number of stages of the reproduction process, using selective control;
- during the checkup - to maximize the coverage of data on one process or type of operation, based on the benefits of continuous control

The same clarity should be maintained when training specialists in methods of control.

Fig.1: Coverage of data by various forms of control

Source: built by the authors based on materials Pavliuk, 2001.

Relevant training of specialists allows to develop clearer recommendations on the methodology of control, choosing its most effective forms in accordance with the object of control and the task.

At the same time, the evolution of the system of public financial control is quite slow. This is due to the complex crisis in the political and economic spheres. The "old system" is trying to maintain its viability. However, we will attempt to demonstrate positive examples and positive vectors of reforming public financial control on the way to efficient use of budgetary resources, as well as find and identify the most promising formats for effective public financial control in general.

Development of the system of state financial control in modern Ukraine

The evolution of the modern system of public financial control involves the integrated development of its components/elements/components. The Verkhovna Rada, the Cabinet of Ministers, and the Ministry of Finance should elaborate certain characteristics (signs), methods and forms of control, creating appropriate regulations and monitoring the gradual implementation of changes. This will facilitate functioning of each body of state financial control. The formal addition of content into the control processes is not enough, it requires charisma, desire and perseverance of both managers and performers.

The materials discussed above allow us to state that the system of public financial control in Ukraine is established and functioning. The institutional transformation has already been carried out and the first stage of methodological and normative-legal support of the activity of control bodies has been passed.

However, uncertainty and constant transformations of the conditions of functioning not only of the market, but also of public administration, require the formation of a flexible and mobile, in terms of the functions, system of public financial control.

Based on the new international standards, guidelines and regulations for the public audit sector developed by INTOSAI, as well as the guidelines for control of the Lima Declaration, we will consider the significance of current achievements in public administration reform, as well as identify priorities for the second stage of development of a new system of state control in Ukraine.

One of the main focuses of changes in the SFC system is the introduction of internal control over the activities of budgetary institutions (PIFC). Internal control is a means to ensure transparent and accountable management, which aims to obtain information on compliance with regulations and regulations, confirmation of the reliability of financial statements and efficiency, economy in the implementation of budget programs (LOGICA, 2019).

A sufficient number of scientific and practical studies are devoted to the principles and standards of INTOSAI, the content of the Lima Declaration and world practices of implementing internal control systems, so we consider it appropriate to give examples of successful Ukrainian initiatives that have positively influenced the development of state control.

Example 1. The case of the Ministry of Economic Development and Trade during the tenure of Minister Aivaras Abramavičius shows how the executive branch can perform not only basic functions, but also focus on establishing an internal control system within the institution, using monitoring, inspection and communicative information environment. After analyzing the structure of the ministry and the number of staff, the minister team concluded that public resources are used sparingly, which affects the efficiency of the institution. At the same time, the available human resources do not provide a high level of efficiency of the state body. During the year, the staff was reduced by 50 percent, and the released resources are aimed at increasing wages and stimulating the efficient work of officials. The creation of an information web portal for exporters has been initiated, which informs and serves as a platform for quick feedback, despite the time and distance, because exporters are the very people who directly support the Ukrainian economy.

Example 2. The second case is not only about one ministry, but about the whole system of procurement, which was created in Ukraine on the initiative of Deputy Minister of Economic Development and Trade Maxim Nefedov. According to him, there is no difference between fixing ineffective public administration or business. In both cases, you need to analyze existing business processes and develop more efficient ones. He and his team made a systematic reform of the tender process in e-procurement in Ukraine - Prozorro System "Everyone sees everything" - the official slogan of the reform. After the end of the tender in the electronic system you can see all the information about the submitted proposals of all participants, the decisions of the tender commission, all qualification documents, etc. This information is available for the general public through a convenient analytics module. This system solution immediately affects the quality of public administration and leads to: eradication and systemic prevention of corruption, transparency of the entire tender process, inadmissibility of discrimination of applications, objective evaluation of tender applications, simplicity and ease of application of tender procedures, transition to electronic document management, full reporting and analysis of all public procurement, open decision-making procedures, wide

public involvement, creation of private electronic platforms. Prozorro received the International Public Sector Procurement Award for the creation and implementation of an electronic system with a unique architecture. During the first three years of operation, the Prozorro Public Procurement System allowed the state to save about UAH 86 billion on procurement (RBC.UA, 2019). As for today, Prozorro has been integrated into a number of government agencies and registries.

Example 3. Within the activities of public authorities there is a significant demand for the possibility of coordinated and effective interaction between different institutions. A number of laws have their own definitions of interoperability. The Ministry of Digital Transformation of Ukraine together with other public authorities, local governments and international partners is working to ensure interoperability - the principle when different information resources can interact with each other on the basis of unified interfaces and protocols. That is, automated information interaction of public authorities is consciously a priority of public administration reform and will undoubtedly contribute to the efficiency, transparency and, as a consequence, the effectiveness of public financial control procedures.

We have deliberately cited various examples of public administration reform, which show the optimization of processes in the use of state financial resources. The more transparent and simple the activities of officials become, the more citizens associate themselves with the state and become responsible taxpayers.

External (independent) financial control in Ukraine has an established list of entities that exercise their powers within the statutory functions. But budget managers must independently ensure the legality and efficiency of the use of allocated state resources. Therefore, the organization of internal public financial control should be considered as a strategic task of the next stage of reforms.

The internal environment, risk management, control measures, monitoring, information and communication are elements of the internal control system in public administration. And for independent Ukraine, such issues as risk management, information and communication component and the organization of permanent monitoring of activities are quite new and unfinished components of public financial control. Building a modern internal environment is also a rather complex task that requires management to work out a set of issues regarding the organizational structure, staff, resources, technology and understanding of the goals and objectives (functions) of the budget institution.

Decentralization of public administration leads to decentralization of state control. There are new requirements for control directly in the state institution together with the concept of "internal control", the terms "financial audit", "audit of administrative activities" appear.

Public Internal Financial Control (PIFC) is a structured model for guiding national governments in creating a state-of-the-art control environment in their revenue and expenditure centers. It aims to provide reasonable assurance that operations comply with the principles of sound financial management, transparency, efficiency, effectiveness and economy, as well as relevant legislation and budget descriptions. Public Internal Financial Control (PIFC) systems aim to provide adequate and transparent methods and organizations to provide reasonable assurance that public funds are being used for purposes chosen by the budgetary authority (ie the government and parliament). In addition, the modern internal control environment is an effective tool for preventing corruption and fraud. (Welcome to the world of PIFC, 2006).

Transparency is a manifestation of the principle of government accountability to the public, which has elected it to generate revenue and expenditure on its behalf. Modern internal control is focused on transparency both in terms of clear boundaries of responsibility and in terms of harmonized methodology and standards. The traditional post-Soviet system of public financial control emphasizes the legality and regularity of expenditures. However, the modern system of state internal control must consider the criteria of economy, efficiency and effectiveness in the management and control of public funds.

Taking into account the conceptual apparatus of the audit of administrative activities, a basis for determining the next stages of modernization of internal financial control is created. Efficiency is the ratio between a product (service) and the resources used to produce it. Economy is the minimization of the cost of activity-oriented resources, given the appropriate quality. Effectiveness is the results compared to the goals compared to the resources used to achieve these goals.

Formal establishment of internal control and audit units in a state institution will not lead to their effective work. The key indications of successful "modernization" will be high-quality content of the new organizational structure, building quality communication, establishing boundaries of communication, the correct placement of competent personnel who are aware of all the risks of control activities. Identification of risks consists of their systematic

detection and study in each structural subdivision of the budgetary institution for elimination or neutralization. In a changing environment, competent risk management effective control procedures possible.

Today the system of public financial control in Ukraine is at the stage of development and accumulation of content of the subsystem of internal control (audit) of public institutions. Performance audits and compliance audits should be disseminated both at the central government and at the local government level.

At the central level, these are usually already established institutions that need to work out the activities of audit units quickly. The local level is being transformed so intensively as part of decentralization reform and new powers that local governments need to re-establish or re-establish all internal control units, while providing quality administrative services and verifying the legality, timeliness and efficiency / quality of their provision.

At both levels of public financial control, internal audit becomes a priority. This is due to the implementation of market / business control tools in public administration. Along with the program-target method, the project method is intensively implemented. Efficiency audit forces government agencies and their management to prove the effectiveness of their work, not just to justify the legality of the use of public finances.

Conclusions

The study proved that the system of public financial control in Ukraine is established and functioning. Institutional transformation is taking place in the direction of European integration processes and the use of world experience in the creation of state control bodies and the methodology of its implementation. The first stage of organizational restructuring, methodological and regulatory support of the activities of public financial control took place.

The traditional system of public financial control in Ukraine was focused on verifying the targeted use of resources, legality and timeliness of transactions. The creation of modern state control in the field of finance requires consideration of economical issues, efficiency and effectiveness of each financial control body.

First, it can be done through the introduction of effective control methods in accordance with the functions of the entity; creation of meaningful communication within the framework of information interaction of control bodies and within a state institution during internal control measures; ensuring the transparency of the activities of public authorities and the results of control obtained during the relevant activities.

Secondly, the shift of emphasis towards internal financial control, which allows to assess the effectiveness and efficiency of the public administration as a whole, its management, and to analyze the activities of a particular unit. The creation of internal audit departments intensifies the development of new approaches and areas of control, allows to assess the effectiveness of management decisions, the effectiveness of the institution's use of budget funds and increase the responsibility of officials for the implementation of delegated powers.

Decentralization reform directs a significant amount of budget funds to the field and therefore the establishment of internal control units in local governments is a mandatory measure and requires the development and implementation of new procedures for controlling resources, generated locally, and aimed at financing territorial development.

Areas of further research will be an in-depth study of the methodology of internal audit in public administration, namely performance audit and compliance audit. In addition, a separate area of research will be the development of optimal methods of work of internal financial control units in local governments.

Abstract

The manuscript focuses on the fact that creating shared value (CSV) is a new managerial practice of improving the financial efficiency of a business and ensuring the effective cooperation between the state, business, and society. The correlation of relative volumes of positive and negative factors of influence on balance level is presented. It has been proved that it is necessary to modify state influence on innovative and investment activity to create shared value. Important indicators of CSV are analyzed. The necessity of forming of terms for market self-regulation of the financial system is described. The importance of solving problems of the creation of a favorable investment climate of the state, achievement of its financial balance, and support it on a due level is proved.

Keywords: financial balance, investment, innovation, creating shared value.

Introduction

In modern society, most successful international companies are aimed not only at profit but also at the creation of shared value. The concept of shared value has been built on the fact that markets are formed not only by economic but also by social needs, such as quality nutrition, better health care, ecology, etc.

Principles of shared value apply to commercial companies, non-profit organizations, and government bodies. Attention is accentuated not on the costs that have been invested or on the work that has been accomplished, but on the result that has been achieved (human needs satisfying, new markets servicing, and so on). As for Ukraine, only a few domestic companies think about their activities from the side of usefulness for society and nature. State bodies aren't ready to help companies to take care of society.

And the problem of financial balancing in Ukraine defines a condition of state security in the financial sphere from the influence of multifactorial threats. They are conditioned by insufficiency and disbalance of financial resources. (Baranovsky, 2004) examined financial balancing not only from a position of achievement of a certain condition of the financial system but also from a position of the process of achievement and maintenance of the necessary financial system condition on the due level.

The article's purpose is to considerate the world experience of creating shared value (CSV) and features of CSV in Ukraine with the purpose of financial balancing.

There are scientific articles that include some aspects of CSV between the state and business, taking into account their role in the process of creating society's value. Particulars of state and private institutions' development and the collaboration of public administration and business during the forming of a strategy of CSV were described by scientists for the moment.

Let's start with the definition of the term "shared value". (Porter, 2011) noted that the term "shared value" is determined as a management practice of increasing the financial efficiency of a business, which combines getting profits and giving all the best for society. The main task of a business is profit for its owners. So, companies in the process of CSV should build their strategy to search for profitable types of activities to improve life quality.

Cite this Article as: Natalia S. SYTNYK, Andrij V. STASYSHYN and Olena V. GERASYMENKO "Financial Balancing in Creating Shared Value in Ukraine" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The creation of shared value should begin with the adoption of a business strategy, a rethinking, and reconciliation of social and financial goals. An important step is to identify the strong and weak sides of the business to solve social problems. The company must choose a social problem to take care of, using its resources, the situation in society, and the market. But the company certainly needs the support of the state and the attraction of innovative and investment resources.

The actuality of innovations' research continues to grow in Ukraine because of the proclamation of an innovative model of development of the economy.

And the category of innovations, which is closely connected with CSV, is characterized by the presence of a wide spectrum of definitions. Some authors consider innovation as its practical realization. Others consider them a cycle from the occurrence of an idea to its commercial development. But some authors believe that innovations are "all-new" (each idea, activity, or material result, which considerably differs from existing forms).

According to the Law of Ukraine "About innovative activity" (2002), innovation is a new created (introduced) and (or) advanced competitive technologies, products or services, and also organizational-technical decisions of industrial, administrative, commercial, or other characters which essentially improve the structure and quality of manufacture and (or) social sphere.

Some researchers don't deny that innovation is a complex process. It unites science, technics, economy, business, and management. So, according to (Zvjagintseva, 2013), "the innovation extends on a new product (service), a method of their manufacture and realization, any innovation in organizational, financial, research sphere, and any improvement which provides economy of expenditure or creates conditions for such economy" (p. 144).

(Neurov, 2014) offers the following definition: innovation is a complex process that consists of creation, working out, reduction to commercial use and distribution of the new organizational, technical, marketing, logistical, or other innovative decision satisfying the certain requirement and leading to qualitative changes in the manufacture and advancement of production.

Investments are the basis of financial materialization. Thus, there is a necessity of activation of investment processes for providing extended recreation, creation of potential of positive changes in the conditions of intensifying of socio-economic contradictions, threats of self-development, and independence of the state.

According to (Avci, 2020), "FDI (foreign direct investment) affects development directly/indirectly as an external source of capital/through its effect on domestic investment" (p. 171).

So, it's important to analyze the dynamics of investments and innovations data to realize their influence on financial balancing in the process of CSV.

Results and presentation of key research findings

It's impossible to imagine a process of CSV of the state, business, and society without investment and innovative processes.

Innovative and investment politics and strategy in Ukraine are in close intercommunications. Negative dynamics of indexes of innovative and investment components creates the threat of disbalance of the financial system. In the given context authors consider expedient to trace interrelation and interference of variation of innovative and investment processes and level of financial balance.

One of the variants of evident reflection of the concept of balancing, Shubin (2014, p. 261) (the correlation of relative volumes of positive and negative factors of influence on balancing condition) describes the dynamic of balancing levels over time. The investigated period is broken into three parts: negative disbalance, long-term balance, and positive disbalance. There are lines of ideal balance and borders of maximum deviations on the figure. With the help of top and bottom borders of maximum deviations, we can see if there is a balance at the moment or not.

A line of the chart in the zone of negative disbalance (through the predominance of negative factors of influence above positive) is below the border of ideal balance. In the zone of positive disbalance, a line of the chart is higher than the border of ideal balance (through the predominance of positive factors of influence above negative). The zone of balancing is characterized by being of the line of the presented chart in this period in borders of disbalance.

And borders of disbalance are the mathematical category of error of calculation of balancing level due to rounding, predictable unauthenticity of data through ignoring a certain row of factors that actually can have a substantial influence on the eventual value of the balancing level. Thus, borders can deviate from a certain middle level in time. It helps to get more exact results of current and long-term levels of balancing with greater probability to investigate the dynamics of balancing level. Also, it allows doing prognoses of future variation of balancing level.

Even the ideal balancing can't remain permanent and have the appearance of a horizontal line. So, balancing is the middle value of indexes of positive and negative factors (although in the short-term period mainly expedient is the establishment of a certain permanent size of ideal balancing, it follows to reach).

The predominance of positive or negative factors influences on the result (presence or absence of balancing).

Disbalance as something imperfect exists from society's origin. Even at constant tracing of negative tendencies in the ideally balanced financial system, any factor can essentially infringe a condition of balancing and lead to the disbalance. It's important to note that self-balancing is possible only at minimum state influence on the financial processes. But it's impossible because of external influence and the necessity of fulfillment state functions.

According to the authors of the article, CSV as a result of effective interaction between the state, business, and society is closely linked to the assessment of the balancing level of the financial system. In this case, the financial system is the close relationship between the state, business, and society in the financial market. Therefore the balancing level may be an indicator of CSV.

The methodology for calculating the balancing level of the financial system has already been presented in several periodicals. In particular, we're talking about (Gerasymenko, 2012). The balancing level of the financial system (BLFS) depends on the relative values of the factors of positive (RVFPI) and negative impact (RVFNI), as well as on the relative value of the comparative indicator (RVCI). The balancing level of the financial system is calculated according to formula (1):

$$BLFS = (RVFPI - RVFNI) / RVCI \quad (1).$$

Relative indicators (the basis for calculating all other indicators) to calculate the balancing level are the amount of cash income and expenditure of the population of a given area. They are the most important factors indicating the area's current financial condition.

The balancing level is calculated based on group indices, which greatly simplifies the elucidation of the causes of disbalance, and also the search for ways to achieve financial balancing.

The territory of the country or region is divided into areas, for each of which group indicators of financial balance are calculated.

Next, the balancing level of the financial system of each of the study areas is calculated. After that, the overall balancing level of the financial system of each region is calculated. And based on the last indicators the state balancing level of the financial system is defined.

The process of CSV is at regional and national levels. This confirms the possibility and expediency of correlating the level of financial balancing and the current situation of CSV. This issue is especially relevant in the context of decentralization processes.

In this case, we are interested in the national level of financial balancing and the peculiarities of CSV at the global level.

As for Ukraine, it sensitively reacts to any influence factors (especially external). Therefore it is difficult to predict any processes with high accuracy and on long prospects under these conditions. For evident submission of the last assertions fig. 1 was built. It displays dependence between indicators of Ukraine's financial system balancing, GDP, and volumes of innovative and investment incomes in it.

Figure 1: Comparative dynamics of volumes of investment and innovative incomes, GDP and balance value of Ukrainian financial system

Source: Built by the authors based on data of the State Statistics Service of Ukraine (2019), and data of the World Bank Group (2019)

From fig. 1, we trace that the GDP level is unstable and there isn't visible dependence between GDP and balancing level. At the increase of foreign direct investment receipts, the negative disbalance of the state financial system increases too. This constantly has been deepening since 2003. But there is a stabilization of the balancing level during the last years. However, it can be the consequence of the reduction of receivables of foreign direct investments and the reduction of financing of innovative activity.

The authors consider that the tendency is a result of the irrational use of investments. Therefore the financial system feels the increasing requirement of a search for effective methods of rebalancing. With the help of a reasonable influence on the use of foreign direct investments, it will be possible to receive a desirable result for a short time.

Also, it does not follow to ignore the different opinions of scientists about the role of foreign investing. In particular, (Podvysotskyj, 2009) marks that the receipt of direct foreign investments, at least at certain terms, has a substantial positive influence on economic development (additional capital investments, receivables of the newest technologies, foreign currency, that is especially actual during a crisis). (Berezhna, 2011) accents attention to the role and value of foreign investments in the conditions of global world integration.

And a favorable investment climate is providing the important constituent of investment activity.

For today Ukraine's investment climate is in the negative position that is confirmed by basic international indexes on which investors are oriented. A part of foreign direct investments in a general volume diminishes constantly. The threat of capital outflow abroad and difficulties in bringing in additional foreign investments to Ukraine can result in the financial disbalance of the country.

Process of forming of investment projects that need state support is not integrated into a general budgetary process. A crisis considerably narrowed internal sources for investments. International financial resources became almost inaccessible. In turn, international investors force to behave carefully about the risks of the country. So, (Moskal, 2012) noted that the low investment image of Ukraine makes the state less attractive for international capital.

To provide foreign capital inflow in the real sector of the economy increase, it is necessary to create a favorable investment climate. The corresponding program of bringing in foreign investments is not worked out yet. That would contain the methodology of determination of the priority of investments in industries of the economy.

In this context, the issues of CSV of business, the state, and society are particularly relevant. (Bakumenko, 2015) distinguishes three levels of CSV:

- rethinking (for the public interests) identifying markets with unmet needs, analyzing social utility or harmfulness of products, developing profitable products that meet customer needs, and improving the quality of customers' life;
- rethinking productivity in the value chain – increasing the productivity of the company or its suppliers with the simultaneous solution of social and environmental constraints in the value chain;
- promoting the development of local clusters - increasing the productivity of the company by the encirclement of the environment, the solution of existing social problems in the places of basic dislocation of the company.

After entering the first level, the second and third options are open to the company. Its own economic and social results are tracked for each level. Among the expected economic gains, it is advisable to name: growth of incomes, reduction of expenses, increase of market share, and among social gains – increase of educational quality of the population, diminishing the quality of food, reducing the level of water consumption. Also, all three levels of shared value creation mutually reinforce one another.

However, for the effective operation of the company in CSV, the strategy is not enough. It is necessary to remember that the process of CSV of business and society is impossible without communication with the state authorities.

Now there are employees in the staff of corporations whose functional duties include cooperation with the government's representatives. Also, business representatives have the opportunity to influence state processes through the public sector, business associations, expert and public councils, foundations, associations, etc. Their goal is business support and development activities. In their turn, the state government authorities are creating transparent communications at the ministries, local authorities, where business representatives can open their position, point to existing issues, and propose ways of cooperation.

Among the most important indicators of CSV quality are corruption level, population, and GDP per capita growth (fig. 2).

Figure 2: Dynamic of corruption level, GDP per capita and population growth as indicators of creating shared value

Source: Built by the authors based on data of the World Bank Group (2019) and Transparency International (2019)

As we can see on the fig. 2, the lower corruption level causes a higher population and GDP per capita growth (example of Poland). Higher corruption level causes lower (or negative) population growth and unsuitable GDP per capita growth (example of Ukraine).

It should be noted that Ukraine, Poland, and Belarus are quite comparable countries in mentality, climatic conditions, and development prospects. But they differ slightly in the area and population density.

As the experience of foreign countries shows, the active involvement of society in the process of dissolving and realizing public management solutions leads to the creation of transparent relations between the state and society. (Sytnyk, 2019) marks that the system of communication interaction between the state and society doesn't eliminate the diverse and inadequate coordination of the activities of various departments.

During the last years, an effective system of communicative interaction between the state and society was formed in the developed countries of the world.

The ideal model of communications of the state and business presupposes the existence of dialogue for the sake of assistance. Also, an important step towards effective communication between business and the state during CSV can be the development of GR (government relations) communications.

(Kislov, 2015) noted that GR is a social or public activity, the purpose of which is seeking alternatives to mutually beneficial cooperation with the state, development of the state-private partnership, legal lobbying of interests of certain structures or organizations.

GR instruments are actively used in communication between the state and business in economically developed countries. They have not only led to effective cooperation but have become instruments of transparent relations between business and the state.

Conclusions and Recommendations

Summarizing the above, we have to note that CSV is a way of doing business that combines the profit of the company with the decision of social problems. Such a concept can’t solve all social problems, but it allows the companies to become leaders of social progress. The creation of shared value is an innovation for many countries for the moment, including Ukraine. But over time, this concept becomes standard practice. So, companies will be able to build a profitable and sustainable business that will be better than a traditional practice. And domestic companies should restructure their business strategy for maximizing profits and minimizing costs. They can improve nature quality and solve social problems. In turn, governments should promote the conduct of business with the creation of shared value to improve the life quality of each society member.

The analysis of the data of Ukraine, Poland, and Belarus improves that there is a negative disbalance of the financial system of Ukraine. This country needs special attention and support in the process of CSV.

And there is a necessity of modification of state influence on innovative and investment activity with the aim of CSV in Ukraine. Simplification and organization of state administration, forming of terms for market self-regulation of innovative and investment components of the financial system are necessary for solving different problems (creation of a favorable investment climate of Ukraine, the achievement of its financial balancing, and its support on a due level).

For support of innovative and investment components of Ukraine's financial system on a due level, it is necessary: to create corresponding financial terms for providing the regular investing of innovative projects; to provide functioning of legislative mechanisms of protection of rights for domestic and foreign investors; to modify the structure of the Ukrainian economy for passing to producing high technology innovative products; to create economic terms for investing modernization and innovative piling up of basic capital.

Providing a proper level of financial balance in Ukraine is possible on the condition of a complex approach with a determination of reasons of the negative phenomena of its basic components. Using the correction of negative influences, it is possible to define positive processes in the financial system of the state. Without neutralization of the educed threats and financial disbalance, it will be difficult to provide balanced development of the state and to create shared value.

Prospects for further research are to calculate and compare the level of financial balancing of the countries of Eastern Europe and Central Asia to identify problem areas for CSV. The authors plan to find ways to improve the efficiency of the process of CSV.

Abstract

The main objectives of this study is to investigate how board characteristics and director ownership affect real earnings management. In this study, we specifically examine how board size, board independence, duality role and director ownership influence real earnings management practices of Malaysian listed firms. Consistent with prior research, this study uses three proxies to measure real earnings management; abnormal cash flow from operations, abnormal production costs and abnormal discretionary expenses. Using a sample of 1,878 firm-year observations from 2000 to 2007, the results show that board independence and director ownership are significantly negative associated with proxies of real earnings management. Duality role, however, is not associated with real earnings management.

Keywords: board characteristics, managerial ownership, real earnings management, Malaysia.

Introduction

Board of directors play a key role in the implementation and oversight of controls to mitigate corporate misconducts (Nguyen 2016). Indeed, prior studies have highlighted that managerial misconducts such as financial fraud, financial restatement, and opportunistic earnings management can be attributed to the board monitoring failures in corporate financial reporting (Virk, 2017; Subair et al., 2020; D'onza, & Rigolini, 2017). Opportunistic earnings management is one of the managerial misconducts that occurs when managers use judgment in financial reporting to alter accounting number to either mislead some stakeholders about the underlying economic performance of the company or to influence contractual outcomes (Healy & Wahlen, 1999). According to Fields, Lys and Vincent (2001), managers can influence reported accounting numbers by managing accounting choices using real-based transactions which also known as real earnings management (REM). Examples of REM include reductions in discretionary spending such as research and development (R&D), advertising and maintenance expenditures, aggressive price discounts to increase sales volumes, overproduction to report lower cost of goods sold (COGS) and repurchase common share. Given the fiduciary responsibility of the boards to monitor management against managerial opportunistic behaviour, thus, this study attempts to examine the impact of board characteristics and director ownership on real earnings management.

The remainder of the paper is organized as follows. Section two reviews the literature and develops the research hypothesis. Section three elaborates the research design. Section four presents and discusses the findings. The final section provides the summary and conclusions.

Literature Review

Real Earnings Management and Board Independence

Fama and Jensen (1983) theorised that the board of directors is the highest internal control mechanism responsible for monitoring the actions of top management. However, they argue that the ability of the board to act as an effective monitoring mechanism depends on its independence from management. Independent directors are believed to be able to monitor managers as they have incentives to develop their reputations as experts in decision control (Agrawal & Chadha, 2005). Thus, the presence of independent directors on the board is seen as the check and balance mechanism in enhancing a board's effectiveness and constraining opportunistic behaviour among managers.

Consistent with these views, prior studies found evidence that supports the effective monitoring role played by independent directors in deterring accounting fraud (Beasley, 1996) and earnings management via discretionary accrual (Davidson et al., 2005; Klein, 2002; Peasnell et al., 2005; Su, 2001). For example, a study by Beasley (1996) revealed that dominant non-executive directors on the board are less likely to be related to the fraudulent practices of U.S. firms. Further, in a study involving family-controlled firms in Taiwan, Su (2001) showed that family-controlled firms without independent directors on the board are likely to have more abnormal accruals. In a similar vein, Peasnell et al. (2005), Davidson et al. (2005) and Klein (2002) also found that the probability of abnormal discretionary accrual decreases as the proportion of outside (independent) directors increases for a sample of U.K., Australian and U.S. boards, respectively. On the other hand, some authors such as Chtourou et al. (2001), Siregar and Utama (2008), Saleh et al. (2005) and Abdul Rahman and Ali (2006) found that independent boards for public firms in the US, Indonesia, and Malaysia have no significant influence on abnormal discretionary accrual. Despite this conflicting result, this study predicts a negative association between board independence and earnings management practices as the theory suggests.

H_1: Board independence will be negatively related to real earnings management.

Real Earnings Management and Board Size

Jensen (1993) and García-Meca and Sánchez-Ballesta (2009) suggest that the number of directors is one of the important factors in the effectiveness of the board. There are two views regarding this issue. Proponents of agency theory believe that a larger board has more opportunity to control and monitor the actions of management as it has a greater number of people with more expertise (Dalton et al., 1999), and valuable experience (Xie et al., 2003) to prevent or limit managerial opportunistic behaviour. Further, Finkelstein and D'Aveni (1994) noted that a larger board has more problem-solving capabilities as the burden of the directors is equally shared among them.

However, a larger board, as proposed by agency theory, also has drawbacks. For example, Lipton and Lorsh (1992) and Jensen (1993) argue that a larger board size beyond seven or eight people is less likely to function effectively. That is because the ability to process problems competently reduces as board size becomes larger (Jensen, 1993).

Empirical evidence generally shows a link between board size and discretionary accruals (Bradbury et al., 2006; Chin et al., 2006; Abdul Rahman & Ali, 2006; Xie et al., 2003). Nevertheless, results regarding the effect of board size on discretionary accruals are conflicting. While Chin et al. (2006) and Rahman and Ali (2006) found a positive association between board size and abnormal accruals in Hong Kong and Malaysia, respectively, other authors report a negative association between both variables (Bugshan, 2005 in Australia; Bradbury et al., 2006 in Malaysia and Singapore; Xie et al., 2003 in the US). Due to the conflicting results, this study does not predict any direction on the association between board size and earnings management.

H_2: Board size will be related to real earnings management.

Real Earnings Management and Duality Role

CEO duality or the 'dominant personality' phenomenon occurs when the same person holds the two most dominant posts in the firm, namely those of CEO and chairman. Advocates of agency theory argue that CEO duality—which implies CEO dominance over the board—promotes CEO entrenchment and hence, can lead to opportunistic and inefficient behaviour that reduces shareholder wealth (Jensen & Meckling, 1976). Nevertheless, empirical evidence on the association between CEO duality and earnings management seems not to support this theory as most authors do not find any significant relation (Bradbury et al., 2006; Bugshan, 2005; Davidson et al., 2005; Abdul Rahman &

Ali, 2006). Due to that, this study does not predict the sign of the relationship between duality role and real earnings management.

H_3: Duality role will be related to real earnings management.

Real Earnings Management and Director Ownership

Jensen and Meckling (1976) argue that shareholdings by management including firm's directors would reduce agency costs as high insider-ownership implies a greater alignment of interests between management and shareholders. This would reduce the opportunistic behaviour of managers. According to the incentive-alignment argument, managerial or director ownership can be seen as a mechanism to constrain the opportunistic behaviour of managers as insiders will become more involved in the company when they own greater shares of the firm and, consequently the need for outside monitoring will be reduced. Nonetheless, excessive management shareholdings could lead to management entrenchment. Fama and Jensen (1983) postulate that firms that are controlled by management are more likely to manage earnings.

Empirical results on the association between managerial ownership and earnings management are mixed. While Warfield et al. (1995) and Salleh et al (2005) find negative relationship between managerial ownership and discretionary accrual in U.S. and Malaysia firms, Gabrielsen et al. (2002), and Bradbury et al. (2006) fail to find significant empirical evidence for Danish, and Singaporean firms respectively. Due to the conflicting results, this study does not predict a direction for the association between director ownership and earnings management.

H_4: Director ownership will be related to real earnings management.

Research Design and Methodology

Sample Selection and Data Collection

The sample for this study covers Malaysian firms listed on Bursa Malaysia from 2000 to 2007. Data required for computing earnings management and control variables measures are collected from Thompson Reuters Datastream. Other non-financial data were collected from the companies' annual reports. We exclude firms in the banking and finance sector because they have different guidelines and governance systems (Abdul Rahman and Mohamed Ali, 2006). We also exclude firm-year observations with missing earnings management measures data. This procedure yields 1,878 firm-year observations.

Operationalisation of the Dependent, Independent and Control Variables

Dependent Variables: Real Earnings Management

Following to Roychowdhury (2006) and Cohen and Zarowin (2010), this study refers real earnings management as actions managers take that deviate from normal business practices. Consistent with prior research (Roychowdhury, 2006; Cohen & Zarowin, 2010), this study employed three metrics to examine real earnings management, namely the abnormal levels of cash flow from operations (RCFO), abnormal production costs (RPC) and abnormal discretionary expenses (RDE).

Consistent to Roychowdhury (2006), the study estimates RCFO, RPC and RDE as the residual from the following model respectively.

$$CFO_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2[Sales_{it} / A_{it-1}] + \beta_3[\Lambda Sales_{it} / A_{it-1}] + \varepsilon_{it}$$

Where,

CFO_{it}	Cash flow from operation in period t
A_{it-1}	Total assets of firm i in year t-1;
$Sales_{it}$	Sales of firm i in year t
$\Lambda Sales_{it}$	Sales of firm i in year t less revenues of firm i in year t-1;
ε_{it}	A residual term that captures the level of abnormal cash flow of firm i in year t.

$$PROD_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2[Sales_{it} / A_{it-1}] + \beta_3[\Lambda Sales_{it} / A_{it-1}] + \beta_4[\Lambda Sales_{it-1} / A_{it-1}] + \varepsilon_{it}$$

Where,
$PROD_{it}$ The sum of cost of goods sold and change in inventory of firm i in year t;
ε_{it} A residual term that captures the level of abnormal production cost of firm i in year t.

$$DISCEXP_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2 [Sales_{it-1} / A_{it-1}] + \varepsilon_{it}$$

Where,
$DISCEXP_{it}$ The sum of R&D expenses and SG&A of firm i in year t;
ε_{it} A residual term that captures the level of abnormal discretionary expenses of firm i in year t.

Control Variables

To test the hypothesis, this study controls for firm-specifics characteristics. First, the study controls for firm size. Large firms often receive more media attention, have higher analyst following and face regular political scrutiny (Ahmed & Duellman, 2007; Watt & Zimmerman, 1978). Therefore, they would tend not to manage their earnings upwards. Second, the study controls for debt. Firms with higher levels of debt would have their earnings scrutinized by debt providers or their agents, e.g., trustees, such that they do not inflate earnings to benefit the shareholders or mangers at the expense of the debt providers through dividends and earnings-based compensations (Ahmed et al., 2002). Third, the study controls for growth. Growth firms are likely to have higher accruals because of increased revenue-generating activities, such as credit sales. Fourth, the study controls for profit. Abdul Rahman and Ali (2006) note that firms with low performance (ROA) have more incentive to engage in earnings management.

Multivariate Regression Models

A multiple regression analysis was employed to test the research hypothesis. The following three multiple regressions were estimated to investigate the impact of board characteristics and director ownership on each proxy of real earnings management. The regression equations are as follows:

$$REM_{ft} = \alpha\alpha + \alpha_1 BODIND_{ft} + \alpha_2 BODSIZE_{ft} + \alpha_3 DUALITY_{ft} + \alpha_4 DIROWN_{ft} + f(control\ variables) + \xi\varepsilon \quad (1)$$

Where,
Dependent variables:
REM proxies:
$RCFO_{ft}$ Natural log of absolute value of abnormal cash flows of firm *f* in year *t*, or
RPC_{ft} Natural log of absolute value of abnormal production costs of firm *f* in year *t*, or
RDE_{ft} Natural log of absolute value of abnormal discretionary expenses of firm *f* in year *t* computed on the basis of RDE Model (Roychowdhury, 2006),

Independent variables:

$BODIND_{ft}$ 1 if the proportion of independent directors on the board more than 50 percent and 0 otherwise,
$BODSIZE_{ft}$ The number of directors on the board,
$DUALITY_{ft}$ 1 if CEO is board chair and 0 otherwise,
$DIROWN_{ft}$ Total percentage of director shareholding,
Control variables:
$SIZE_{ft}$ Natural log of total assets of firm *f* in year *y,*
$LEVERAGE_{ft}$ Natural log of total liabilities to total assets of firm *f* in year,
$GROWTH_{ft}$ Natural log of market to book ratio of firm *f* in year *y,*
$PROFIT_{ft}$ Earnings (EBIT) to total assets
$YEAR_{ft}$ Year,
IND_{ft} Industry.

Results and Findings

Multivariate Analysis

Ordinary least squares procedures (OLS) are used to estimate the models stated in Section 3.3. The results of the above models are reported in the following subsections.

Real Earnings Management and Board Characteristics and Director Ownership and Control Variables

Table 4.1 reports the results of the regression of board characteristics, and director ownership on the REM proxies and control variables.

The results show that BODIND has significant negative association with REM proxies; RCFO and RDE. The results indicate that firms with with a higher composition of independent directors on the board (more than 50 percent) are less likely to engage in real earnings management practices involving cash flow from operations and discretionary expenses. In addition, the results reveal that DIROWN has significant negative association with RPC.The significant association infers that the director ownership deter real earnings management practices involving production costs in Malaysian listed firms. With regards to the board size, the significant positive association found between RPC and BODSIZE. The findings indicate that firm has large number of board members are less likely to mitigate REM via production costs. The results consistent prior studies found evidence that supports a larger board size beyond seven or eight people is less likely to function effectively in limiting managerial opportunistic behaviours (Lipton & Lorsh, 1992;Jensen ,1993).

For the control variables, all REM proxies have significant negative association with SIZE (except for RPC) and POFIT. The results in line with the findings of previous studies that argue information asymmetry is often smaller for large firms because they produce more public information. This in turn limit earnings management practices. In addition, there are positive associations found between REM proxies with LEVERAGE and GROWTH, consistent with the findings of Sweeney (1992) documented that managers of firms approaching debt covenant default are more likely to make income-increasing changes in periods before the violation. She also found that managers continue to make income-increasing changes in years following the first year of default.

Table 4.1: Results of the Relation between REM and Board Characteristics and Director Ownership and control variables

$$REM_{ft}=\alpha\alpha+\alpha_1 BODIND_{ft}+\alpha_2 BODSIZE_{ft}+\alpha_3 DUALITY_{ft}+\alpha_4 DIROWN_{ft}+f(control\ variables)+\xi\varepsilon \quad (1)$$

Summary and Conclusion

The purpose of this paper is to examine the association between board characteristics, director ownership and real earnings management. To capture real earnings management, the study uses three different measures: the abnormal cash flows, the abnormal production costs, and the abnormal discretionary expenses developed by Rochowdhury (2006). The study employs a sample of 1,878 Malaysian listed firm-year observations from 2000 to 2007.

Overall, the results of the study support the view that board characteristics and director ownership limit real earnings management. In particular, the findings indicate that there is a significant negative relation between BODIND and two measure of real earnings management: RCFO and RDE. The results show that Malaysian firms with a larger composition of independent directors on the board are less likely to manage accounting number by using abnormal discretionary cash flow from operation and abnormal discretionary expenses.

In general, the findings are consistent with the findings of Liu and Tsai (2015), Zgarni et al. (2014), Hsu and Wen (2015) and Chouaibi et al. (2018).who find that some board characteristics affect real earnings management practice which in turn increase the quality of accounting numbers.

Abstract

In recent years, the adoption of proactive environmental strategy (PES) in addressing the environmental challenge and maintain firms' competitiveness have gained more acceptance by many countries. PES embraces minor improvements to the current technology in the existing products and process, and innovative solutions to reduce material and energy consumption. This paper presents an empirical assessments on the current state of PES implementation in Malaysian manufacturing firms. A questionnaire based survey was conducted among 224 managers of Malaysian firms. Descriptive statistics was utilised to basic features of variables used. The result shows that greening strategy is moderately practiced in Malaysian manufacturing firms. It was found that manufacturing firms are paying higher attention to greening strategy as compared to beyond greening strategy. The study adds to existing literature by introducing business development indicators within beyond greening strategy. Tested measure of PES shall help managers to assess their state level of PES to achieve their competitive and sustainability goals. Further, some important managerial and policy implications are discussed in this study.

Keywords*:* proactive environmental strategy, greening strategy, beyond greening strategy

Introduction

The proactive environmental strategy (PES) has progressively gained acceptance as the means of addressing the environmental issues and achieving firms' competitive advantage. Over the years, the diffusion of PES has spread to several region in the world, including emerging economies like Malaysia. The transition from reactive and short term approaches to proactive approaches encompasses complex organizational changes to solving environmental

Cite this Article as: Naimah AHMAD YAHYA, Roshayani ARSHAD, Amrizah KAMALUDDIN, Rahayu ABDUL RAHMAN and Mohd Taufik MOHD SUFFIAN "Proactive Environmental Strategy: A Study of Malaysian Manufacturing Firms" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

inefficiencies into innovative environmental behaviours (Fraj, Matute and Melero, 2015; Aragon-Correa and Rubio, 2007)

This study addresses the above research area in the manufacturing sector because many pollution issues have been connected with the manufacturing process through their supply chain activities such as procurement, production, and distribution (Yahya, *et al.*, 2019; Kuppusamy and Behrooz, 2015; Eltayeb, Zailani and Ramayah, 2011). As highlighted by Porter and Van der Linde (1995), pollution is the concrete evidence of incomplete material utilisation, inefficient and ineffective use of resources. The process of converting raw materials into useful goods in manufacturing firms produces by-products of manufacturing waste materials left over or substances that contribute to air and water pollution (Hassan, Ashari and Nordin, 2016). The inefficient use of these materials is harmful to the environment due to the difficulty to reuse and reprocess these hazardous substances for other purposes (Osibanjo and Nnorom, 2007).

The empirical studies have shown that the implementation of PES, which is based on the innovative technology is highly associated with competitive advantage of improvement in process and product innovation (Banerjee, 2001), product differentiation (Sellers, 2009), enjoy price premium (Nishitani and Itoh, 2016), and higher revenue and lower cost (Lopez-Gamero and Molina-Azorin, 2016; Masoumik, Abdul-Rashid and Olugu, 2015). In contrast, the reactive environmental strategy such as pollution control does not effectively reduce waste and pollutants, but enforce manufacturing firms to incur additional cost of handling, storage, processing and disposal of discharges that reduces their competitiveness (Porter and Van der Linde, 1995).

To date, the PES strategy have been practiced widely in the developed countries where the firms have more resources to implement proactive systems and technologies (Sambasivan, Bah and Jo-Ann, 2013). Therefore, we cannot presume that perception or receptive on PES in Malaysia is similar with the developed countries. Porter and Van der Linde (1995) contended that firms from developed countries are more competent in addressing environmental issues as compared to developing countries. Lack of developing country perspectives in the PES literature has prompted this study to fill the gap in the current literature. In addition, evidence about PES implementation in Malaysia is still lacking. Thus, this research attempts to investigate the current state of PES implementation in firms within manufacturing industry in Malaysia.

Literature Review

Proactive Environmental Strategy

The proactive environmental strategy model was drawn from Natural Resource-Based View (NRBV) developed by Hart (1995). The NRBV highlights that firms' competitive advantage depends on how resources and innovative technology solutions or PES are managed to address the environmental issues (Hart, 1995). The NRBV outlined three key strategic capabilities namely pollution prevention, product stewardship and sustainable development (Hart and Dowell, 2011; Hart, 1997; Hart, 1995). These three key strategic capabilities were later separated into two group namely greening strategy and beyond greening strategy. Greening strategies constitute pollution prevention and product stewardship, which focus on minor improvements or adjustments to the current technology in the existing products and processes.

Pollution prevention is related to product or process adaptation that involves with modification to existing product design or basic changes to the manufacturing process with a purpose of reducing any negative environmental impact on the environment at any stage of manufacture, use, disposal or reuse (Klassen and Whybark, 1999). This strategy seeks to prevent waste and emissions by reducing the use of hazardous material, using waste produced as input for internal processes or outside parties and modifying existing processes or products to reduce the production of pollutants, rather than cleaning them up (Sharma and Vredenburg, 1998).

Product stewardship expands the scope of pollution prevention to incorporate the entire value chain or life-cycle of the firms' product systems (Hart and Dowell, 2011). Product stewardship associated with minimizing the products impact on the environment throughout its life-cycle involving the whole process of designing, manufacturing, distributing, usage and disposal stages by using materials that are easily composed, reused or recycled (Eltayeb and Zailani, 2009; Fowler and Hope, 2007; Hart, 1997; Hart, 1995)

Beyond greening strategy or also known as sustainable development is classified into clean technology and base of pyramid. The focus of the strategy is on the application of future technologies or innovative solutions that can reduce the material and energy consumption which lead to future market opportunities (Hart and Dowell, 2011; Hart, 1997). The strategy does not only restrict to environmental concerns, but also producing product in a way that can be maintained indefinitely into the future and focusing on economic and social benefits (Hart and Dowell, 2011).

Clean technology calls for firms to reduce the toxic materials, natural resources and energy consumption by building up the internal development and venturing into more sustainable technologies to position the firms for competitive advantage in the market (Hart and Dowell, 2011; Hart and Milstein, 2003). The main purpose is to reduce material and energy consumption to ensure sustainable future market by substituting the traditional energy sources with renewable energy sources, and reducing energy consumption through better maintenance procedures and changes in process technology. Recently, there is a growing interest in clean technology commercialisation or business development, which involves entrepreneurial activity and venture capital investment (Hart and Dowell, 2011). Successful commercialisation process enables companies to explore opportunities for trade and market expansion, maximise return on inventions and gain competitive advantage (Shakeel, Takala, and Lian-Dong, 2017). Nonetheless, previous scholars did not find clear indicators or suggestions to measure base of pyramid strategy.

Practice of PES in Malaysian Manufacturing Firms

A study on waste management method practiced by Malaysian industries was conducted by Mallak and Ishak (2012). The study found that Malaysian industries practiced end of pipe management system rather than other management options. They suggested that management system of waste management should be changed towards more sustainable management regime. They further suggest the necessity of mandatory or legal measures with suitable guidelines to be introduced to provide framework for practicing waste minimisation or pollution prevention among Malaysian industries. Sambasivan *et al.*, (2013) highlighted that a lot of firms in Malaysia have employed a combination of proactive and reactive strategies.

Eltayeb and Zailani (2009) investigated the adoption of product stewardship or green supply chain initiatives by ISO 14001 certified manufacturing firms in Malaysia. The paper studied the strategy initiatives specifically in terms of green purchasing, eco-design and reverse logistics. The result revealed that eco-design strategy has higher level of adoption, as compared to green purchasing and reverse logistic. The result also shows that participating firms in green interested associations have significantly higher level adoptions of green supply chain initiatives as compared to firms that do not participate in associations.

A study conducted by Masoumik, Abdul-Rashid and Olugu (2015) indicated that Malaysian manufacturers paid more attention to perform pollution prevention strategy, as compared to product stewardship and clean technology. It may be caused by the regulatory pressures in Malaysia that encourage firms to focus on pollution prevention. Pollution prevention also results in greater environmental performance as compared to product stewardship and clean technology, but imposes lowest impact on competitive benefits.

In the area of clean technology, the Third National Agriculture policy, Fuel Diversification Policy and the introduction of Feed-in-Tariff Scheme under Renewable Energy Act have boosted renewable energy such as biomass, biogas, municipal waste, solar and mini hydro and in the promotion of cleaner production in industrial manufacturing (Mat Sahid *et al.*, 2011; Hezri and Hasan, 2006). Malaysia has been highlighted as having the highest renewable electricity potential compared to its share of the ASEAN population (Kardooni, Yusoff and Kari, 2016).

The imposition of stricter international environmental regulations that requires Malaysian manufacturers to export greener products (Devadeson and Chenayah, 2010) and the introduction of green technology policy in 2009 that promotes sustainability and safety of the environments should be able to gear momentum for Malaysian manufacturing firms to embrace the PES (Ridzuan and Chew, 2018; Bujang, Bern and Brumm, 2016; Fan *et al.,* 2016). This is due to the notion that the industry relies on global market that consider environmental impact of its operation to stay competitive.

Research Method

Measurement Instrument

The development of measurement scales involved suggestions from 16 numbers of industry professional and subject experts in the relevant area. The purpose of asking for expert review is to establish questionnaire's content validity and reliability. This process led in further purification of the items and improvement in the structure and content of the questionnaire draft. The revised questionnaire draft was then continued for pre-testing to establish test of face validity. In total, twenty three (23) of the questionnaire drafts were evaluated in terms of respondents' answers and comments. In the pre-testing phase, out of 25 items, only 12 variable items of PES were identified as the items to be employed for the pilot study. The pilot study was carried out with 110 respondents. A pilot study assist researcher to conduct a larger study or examine particular aspects of the research to see whether the selected procedures will actually worked as expected. During pilot phase, a total of 7 variables for greening strategy (Table 3) and 5 variables for beyond greening strategy (Table 4) were sorted out after factorial analysis. Finalised measurement scales were

used to gather data. Respondents were asked to indicate their answers on a Likert scale of seven-points (1- strongly disagree to 5-strongly agree).

Measurement scale of greening strategy was designed with the indicators identified in the pertaining literatures (Eltayeb and Zailani, 2009; Carter and Ellram, 1998; Sarkis, 1998; Sharma and Vredenburg, 1998). In beyond greening strategy, clean technology was measured on a modification scale derived from literature (Sharma and Vredenburg, 1998). However, the available literatures and expert review did not find clear indicators or suggestions to measure base of pyramid strategy. Thus, the base of pyramid trait was excluded in the questionnaire. Surprisingly, during the expert review session, a new component of beyond greening strategy was highlighted by the participants known as business development, which was referred by Hart and Dowell (2011) as commercialisation of clean technology. As a result, the scale was updated to include the dimensions and definition. Consequently, as indicated in Table 1, items (11, 12) were developed and items (1, 2, 3, 4, 5, 6,7, 8, 9, 10) were modified.

Data Collection and Sampling

This research attempts to investigate the current state of PES adopted by Malaysian manufacturing firms. Consistent with the purpose of the study, it attempt to examine the Malaysian manufacturing sector as a population of interest. The sample of this research was drawn from Federation of Malaysian manufacturers (FMM) directory that provides a list of manufacturing firms in Malaysia. The sampled manufacturing firms comprise food products and beverages, fabricated metal products, chemicals and chemical products, coke, refined petroleum products and nuclear fuel, wood and cork, motor vehicles, trailers and semi-trailers, publishing, printing and reproduction of recorded media, rubber and plastic products and many more. The unit of analysis of the study was a 'firm'.

The study utilised simple random sampling, which involves random selection of sample in such a way that every element in the population has the same probability of being selected (Awang, 2012; Sekaran and Bougie, 2010). In the data collection process, the questionnaires were mailed to 1200 managers of the selected manufacturing firms. Focus of questions are directed to the state of PES implemented by the manufacturing firms and demographic profile of respondents and firms.

Out of 1200, only 235 questionnaires were returned and usable for the data analysis. This represented an effective response of 19.58%. 11 questionnaires out of 235 were removed due to outliers, represented a final sample of 224. The highest response was received from chemicals and chemical products (17.02%), followed by food products and beverages (11.9%), rubber and plastic products (10.2%), fabricated metal products(8.09%), electrical machinery (7.23%), motor vehicles, trailers and semi-trailers (7.23%) and other types of manufacturing firms (38.33%).

In total, about more than half of the respondents worked in firms that have been established more than 25 years. In terms of certification, more than half (56.6%) of the firms have environmental management certification. Majority of the respondents are male (76.3%) and the remaining (23.7%) are female. The respondents are top management and middle management level of managers dealt with environmental management (40.2%), manufacturing and production (31.7%), general management (12.8%), research and development (5.8%) and others (6.4%).

Data analysis techniques

This research utilised the Statistical Package for Social science (SPSS) version 22.0. Screening the data entry was performed to examine the accuracy of data entry, missing values, outliers and normality. Factor analysis was conducted to ensure content validity and construct validity of the variables being measured in developing valid instruments. This is of particularly important since the items of the main variables were developed based on various sources including adaptation of items used in previous studies and interviews.

Exploratory Factor Analysis (EFA) was conducted on each of the two proactive environmental strategies identified in the study. Table 1 explains the factor loadings and the percentage of variance explained of PES. For greening strategy, the varimax rotated exploratory analysis produced one component which showed 53.601% of the total variance. The varimax rotated exploratory analysis for beyond greening strategy also produced one component which showed 60.302% of the total variance. All the factor loadings are greater than 0.4 which meet the minimum requirement for sample size around 200 as suggested by Hair et al., (2010). Bartlett's Test of Sphericity was significant and Kaiser-Meyer-Olkin Measure of Sampling Adequacy was 0.842 and 0.755 for both strategies, which was above the recommended value of 0.6.

Table 1: Final structure of Proactive Environmental Strategy strategy questionnaire

PES strategy	Description of variable	Factor loading	Cum % of variance explained
Greening strategy			53.601%
Pollution prevention	1. Our company reduces the use of hazardous material	0.828	
	2. Our company uses waste produced as input, whether for internal process or to outside parties	0.786	
	3. Our company modifies existing process or product to reduce the production of pollutants	0.746	
Greening strategy; product stewardship	4. Our company uses life-cycle assessment to evaluate the environmental impact of its product	0.738	
	5. Our company produces products that have reused or recycled materials in their contents such as recycled plastics, glass and paper	0.695	
	6. Our company produces products that are free from hazardous substances such as lead, mercury, chromium and cadmium	0.681	
	7. Our company collects used products for recycling, reclamation of materials or reuse	0.633	
Beyond greening strategy			60.302%
Clean technology	8. Our company substitutes the traditional energy sources with renewable energy sources	0.826	
	9. Our company reduces energy consumption through better maintenance procedures	0.728	
	10. Our company reduces energy consumption through changes in process technology	0.807	
Beyond greening strategy: Business development	11. Our company ventures into business development in environmentally related activities which is directly related to our core business	0.822	
	12. Our company ventures into business development in environmentally related activities which is indirectly related to our core business	0.836	

In order to determine the internal consistency among the items or indicators in summated scale, a reliability test was conducted. The main purpose is to ensure that all indicators are measuring the same construct and be highly correlated (Hair *et al.*, 2010).

As shown in Table 2, the reliability coefficient for “greening strategy” and “beyond greening strategy” were above 0.7 which indicate the acceptable level of consistency.

Table 2: Reliability Coefficients (Proactive Environmental Strategy)

Proactive Environmental Strategy	N	Cronbach's Alpha	N of items
Greening	224	0.847	7
Beyond Greening	224	0.832	5

Results and Discussions

In this study, descriptive analysis is used to assess the state of PES implementation in Malaysian manufacturing firms. Descriptive statistics is normally used to describe characteristics of research sample including mean, standard deviation and range of scores (Pallant, 2013). As highlighted in Table 3, Malaysian managers fairly agreed that the "greening strategy" with mean score of 3.68 and "beyond greening strategy", mean score of 3.36, was practiced in their organisation. Nevertheless, the "greening strategy" has higher mean score as compared to "beyond greening strategy".

Table 3: The Descriptive Statistics of Greening Strategy, Beyond Greening Strategy and Overall Proactive Environmental Strategy

Variables	N	Min	Max	Mean	Std. Dev
GS: Greening Strategy	224	2.00	5	3.68	.67
BGS: Beyond Greening Strategy	224	1.00	5	3.36	.74
PES: Proactive Environmental Strategy	224	2.00	5	3.55	.62
Scale: Strongly disagree (1) to strongly agree (5)					

Greening Strategy

As shown in Table 4, the greening strategy practiced by Malaysian manufacturing companies involving pollution prevention are reducing the use of hazardous material (mean of 4.05), using waste produced as input (mean of 3.51) and modifying existing process or product (mean of 3.73). Product stewardship strategy are using life cycle assessment (3.36), creating products that have reused or recycled materials in their contents (3.49), manufacturing products that are free from hazardous substances (3.88) and collecting used products from customers for recycling, reclamation of materials, or reusing (3.73). In general, the greening strategy is moderately practiced in Malaysian manufacturing firms. Among the seven greening theme, the mean for "reducing the use of hazardous material" is higher than other greening strategy indicators.

Table 4: The Descriptive Statistics of Greening Strategy

Variables	N	Min	Max	Mean	Std. Dev
Greening Strategy	224	2.00	5.00	3.68	.67
hazardous material	224	2.00	5.00	4.05	.73
waste as input	224	1.00	5.00	3.51	.88
modifies process	224	2.00	5.00	3.73	.80
life cycle assessment	224	1.00	5.00	3.36	.92
recycle materials	224	1.00	5.00	3.49	1.08
free hazardous	224	1.00	5.00	3.88	1.04
collects used product	224	1.00	5.00	3.73	1.01

Beyond Greening Strategy

Beyond Greening Strategy as highlighted by Hart (1997) and Hart and Dowell (2011) refers to sustainable development that includes clean technology and base of pyramid, which focus on tomorrow's technologies and markets. Based on literatures and expert reviews conducted in developing the survey instrument, only clean technology strategies have been widely practised by Malaysian manufacturing companies in recent years. Therefore,

this study excludes the base of pyramid strategy measures. However, based on responses in the phase of expert review, this study has developed new items to measure another dimension for beyond greening strategy that is business development, which can be described as commercialisation of clean technology.

As indicated in Table 5, the beyond greening strategy practiced by Malaysian manufacturing companies that involve clean technology are renewable energy sources (mean of 3.08), reducing energy consumption through changes in process technology (mean of 3.76), business development in environmentally related activities which is directly related to their core business (mean of 3.07) and business development in environmentally related activities which is indirectly related to their core business (mean of 2.97).

The managers slightly agreed that beyond greening strategy are being practiced in their firms. The indicator of "reducing energy consumption through changes in process technology" shows the highest mean among the five beyond greening strategy theme. As compared to greening strategy, beyond greening strategy shows lower adoption by Malaysian manufacturing firms. One possible reason could be due to lack of institutional capacities to enable R&D and commercialisation of innovation in developing countries. Significant studies have found that expensive international licensing, exclusionary rights and patents are significant barriers to the diffusion of clean technologies from developed countries to developing countries (Raiser, Naims and Bruhn, 2017).

Table 5: The Descriptive Statistics of Beyond Greening Strategy

Variables	N	Min	Max	Mean	Std. Dev
Beyond Greening Strategy	224	1.00	5,00	3.36	.74
renewable energy	224	1.00	5.00	3.08	1.12
maintenance procedures	224	2.00	5.00	3.94	.72
process technology	224	2.00	5.00	3.76	.79
direct business development	224	1.00	5.00	3.07	1.03
indirect business development	224	1.00	5.00	2.97	1.07

The research finding that indicate manufacturing firms are paying higher attention to pollution prevention and product stewardship as compared to clean technology is consistent with Masoumik (2015). However, this study has contributed to the new finding about the state of business development practiced by Malaysian manufacturing firm, which is absent in previous studies.

Conclusion and implication of the study

In general, Malaysian manufacturing managers fairly agreed that the greening strategy and beyond greening strategy were in practiced in their organization. However, it appears that greening strategy has been practiced more widely among the manufacturers as compared to beyond greening strategy. It was revealed that the adoption of substitution of the traditional energy sources with renewable energy sources, venturing into business development in environmentally related activities directly or indirectly related to their core business have been lacking behind as compared to other proactive environmental strategy practices in the manufacturing firms.

This study contributes to the existing literature of NRBV, especially in the non-western context. The practice of PES, especially in beyond greening strategy is relatively low. Therefore, the government should find ways to increase the growth of PES practice. In order to address the lower practice of beyond greening strategy, government should take several courses of actions to control market risk and reduce the cost of renewable energy technology. The measurement of PES in this study contributes to the financial accounting and reporting practices. The design of survey instrument involved development of preliminary items adapted from literatures, expert review, pre-test and pilot study before the actual survey was conducted. The new measurement of business development indicators highlighted during the expert review is useful to fill in the deficiency of such measurement and indicators in the available reporting method.

Limitations and Recommendations

This study is not without limitations. Firstly, generalisation of the findings should be cautioned because the questionnaire was specially designed for the manufacturing industry. To conduct study in different industries, the questions would have to be redesigned for the purpose at hand. In addition, the sample of this research was taken from the Federation of Malaysian Manufacturers' (FMM) directory. Whereby firms that were not listed in the directory were excluded. Therefore, the current study cannot generalise the findings of this study to all manufacturing

firms in Malaysia. Finally, a future research should also consider investigation on the relationship between PES with important outcomes such as environmental and financial performance.

Abstract

This study examines the effects of managerial ownership on real earnings management and company's performance in Malaysia. By utilising the data from 646 Bursa Malaysia-listed companies that were active from 2013 until 2017, the panel results show that managerial ownership have negatively significant relationship with real earnings management proxy by abnormal cost of goods sold and negatively significant with company's performance proxy by Tobin's Q. This result aligned the Agency Theory that concerns the problems between managers and shareholders. The result also depicts that the earnings management is strongly related to the performance of the company. It is an essential resource for any market participant since it provides a reduced volume of information asymmetries between managers, investors, regulatory agencies, society and other stakeholders. The current findings can be treated as tools to lessen the earnings management activities and to increase the company's performance by the management and stakeholders by applying monitoring mechanisms on companies through managerial ownership which have to curtail opportunistic behaviour among the management.

Keywords*:* Managerial Ownership, Earnings Management, Company's Performance.

Introduction

Managerial ownership means that the manager has direct or indirect shares in the company. Jensen and Meckling (1976) suggest that CEOs diverge from aiming for the goal to maximising the shareholders' wealth by consuming perquisites when they do not have an ownership stake in the company. Consequently, in order to restrict managers' value-reducing (or non-value-maximising) behaviour when ownership and control are distinct, there will be written contracts, often containing accounting-based constraints that the managers need to adhere (Warfield et al., 1995). Hence, lower managerial ownership has greater incentives to manage accounting numbers to relieve or relax the behavioural constraints imposed in accounting-based contracts (Warfield et al., 1995). Previous studies have found a significant negative affiliation between managerial ownership and earnings management (Alves, 2012; Ebrahim, 2007; Klein, 2002; Warfield et al., 1995). It is supporting the alignment of interest hypothesis, which proposes that the higher the managerial ownership, the lower the level of discretionary accruals (Ali, Salleh, & Hassan, 2008; Banderlipe & Mc Reynald, 2009; Dhaliwal, Salamon, & Smith, 1982). This suggests that managers who own a

Cite this Article as: Mohd Taufik MOHD SUFFIAN, Rahayu ABDUL RAHMAN, Zuraidah MOHD SANUSI and Naimah AHMAD YAHYA "The Effects of Managerial Ownership on Real Earnings Management and Company's Performance in Malaysia" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

significant portion of equity in a company have less incentives to manipulate reported accounting information, and that large shareholders reduce the scope of managerial opportunism.

Ownership structure has a significant influence on company performance. Companies with high ownership concentration can increase the company performance as they wield the authority in the management. A study by Abramov, Entov and Chernova (2017); and Wang and Xiao (2009) found a negative relationship between government ownership and company efficiency, meaning that a lower level of ownership structure can boost the company's performance. The association between ownership structure and company performance provides an idea about the effectiveness of alternative corporate governance mechanisms (Mandacı & Gumus, 2010). Significant managerial ownerships can align managers' interests with those of the outside shareholders so that managers can have strong incentive to pursue value-maximizing behaviour (alignment effects). In contrast, Demsetz (1985) argued that too much an ownership stake by managers could potentially lead them to worry more about their self-interests, not those of outside shareholders; thus, decreasing the company's value (entrenchment effects).

Previous studies have found contending results on the relationship between managerial ownership and company's performance. A study done by Jensen and Meckling (1976) have identified that when managerial ownership increased, the company's performance will increase as the conflict would decrease. On the other hand, Fama and Jensen (1983); and Morck et al. (1988) argued that greater stock ownership by managers increased the power of the internal owners and decreased the power of the external owners in terms of influencing performance. Nonetheless, the result will appear insignificant when accounting profit rates were used as an alternative performance measure. Due to the lack of studies in these areas, it provides an opportunity to scrutiny the effects of managerial ownership on real earnings management and company's performance.

Literature Review and Hypothesis Development

Managerial ownership means that the manager has direct or indirect shares in the company. Hence, lower managerial ownership has greater incentives to manage accounting numbers to relieve or relax the behavioural constraints imposed in accounting-based contracts (Warfield et al., 1995). Previous studies have found a significant negative relationship between managerial ownership and earnings management (Alves, 2012; Ebrahim, 2007; Klein, 2002; Warfield et al., 1995). It is consistent with the alignment of interest hypothesis, which suggests that the higher the managerial ownership, the lower the magnitude of discretionary accruals (Ali et al., 2008; Banderlipe & Mc Reynald, 2009; Dhaliwal et al., 1982). This means that the managers will entrench when their increment in the managerial share ownership excessive certain percentage. In other words, the managers will favour maximizing their personal benefits than minority shareholders, which is in line with entrenchment hypothesis (Morck et al., 1988). This suggests that managers who own a significant portion of equity in a company have less incentives to manipulate reported accounting information, and that large shareholders reduce the scope of managerial opportunism, which is consistent with both the alignment of interest hypothesis and the efficient monitoring hypothesis.

According to Jensen and Meckling (1976), managerial ownership is negatively related to agency cost and yet is positively associated with the company's performance. This finding is supported by Gordon et al. (2004) that is aligned with the conflict of interest hypothesis. It is supported by the agency theory, as it claimed that managerial ownership could reduce the agency conflict due to the separation of stock ownership and control between managers and stockholders. It is noticed that if management ownership rises, then the interest of shareholders and managers begins. Managerial ownership is an internal monitoring mechanism. In managerial ownership, EM practices are inversely proportional to the company's performance. The agency theory is supported by the positive relationship between managerial ownership and the company's performance (Fauzi & Locke, 2012). Furthermore, MANOWN does not create a conflict of interest between the owners, managers and employees. In return, MANOWN increases the performance of the company as the managers' priority is to maximise the company's wealth.

Therefore, lower managerial ownership presents greater incentives to manage accounting numbers to alleviate behavioural constraints due to accounting-based contracts (Warfield et al., 1995). Previous studies have found significant negative associations between performance and manipulation of earnings (Alves, 2012; Ebrahim, 2007; Klein, 2002; Warfield et al., 1995). It supports the coordination of the hypothesis of interest, suggesting that the higher the ownership of the manager, the lower the level of discretionary accrual (Ali, Salleh, & Hassan, 2008; Banderlipe & Mc Reynald, 2009; Dhaliwal, Salamon, & Smith, 1982). Managers with majority of equity in the company have less incentive to manipulate reported accounting information and that large shareholders reduce the scope of manager opportunism, consistent with the alignment of the interest hypothesis and the efficient monitoring hypothesis.
Hence, this study hypothesizes that:

H1*: There is a negative association between managerial ownership and earnings management.*

Previous studies have found mix results on the relationship between managerial ownership and company's performance. A study by Jensen and Meckling (1976) argued that as management ownership increased, corporate performance would increase with a downturn in conflict. On the contrary, greater ownership of shares among the managers increases internal ownership and decreases external ownership in terms of performance (Amran & Ahmad, 2013; Fahlenbrach & Stulz, 2009). There is a zigzag trend for concentrated ownership and the company's performance. Consequently, the association increased between 0% and 5%, decreased between 5% and 25%, and increased more than 25% (Vroom & Gimeno, 2007). The result was also significant when other control variables such as R&D and advertising ratios, leverage, size, growth and industry statues were incorporated into the model. However, the results were insignificant when accounting profit rates were treated as alternative performance measures. Currently, there is a limited study on the effect of managerial ownership on company performance.

H2*: There is a positive association between managerial ownership and company's performance.*

Research Methodology

This study is using a quantitative data taken from annual report of public listed companies. The data covers from year 2013 until 2017. There were 646 listed companies in Bursa Malaysia out of a total of 3,260 company-observations in this study. The data were analysed using STATA Software version 14. This study is using panel data based on Fixed Effect model. This study also includes five control variables which are current ratio, financial distress (Altman Z-score), firm size, leverage and growth. Below are the models for real earnings management:

(A) The normal level of Cash Flow from Operations (CFO)

$$CFOt / At\text{-}1 = \alpha 0 + \alpha 1\ (1 / At\text{-}1) + \beta 1\ (St / At\text{-}1) + \beta 2\ (\Delta St / At\text{-}1) + \varepsilon t \quad (1)$$

Where: CFOt = Cash flow from operations (current year)

At-1 = Total assets (previous year)

St = Sales (current year)

ΔSt = Change in sales (current year)

εt = Residual value

Equation 1 is based on study conducted by Roychowdhury (2006). The residual value is the suspected companies that were engaged in abnormal CFO. Residual value is said to exists is the usual CFO intensity varies with the actual CFO amount. Suspected companies are those companies based on linear regression with the residual values.

(B) The normal level of Cost of Goods Sold (COGS)

$$COGSt / At\text{-}1 = \alpha 0 + \alpha 1\ (1 / At\text{-}1) + \beta 1\ (St / At\text{-}1) + \varepsilon t \quad (2)$$

Where: COGSt = Cost of goods sold (current year)

At-1 = Total assets (previous year)

St = Sales (current year)

Equation 2 is based on study conducted by Roychowdhury (2006). The residual value is the suspected companies that were engaged in abnormal COGS. Residual value is said to exists is the usual COGS intensity varies with the actual COGS amount. Suspected companies are those companies based on linear regression with the residual values.

(C) The normal level of Discretionary Expenses (DISEXP)

$$DISEXPt / At\text{-}1 = \alpha 0 + \alpha 1\ (1 / At\text{-}1) + \beta 1\ (St\text{-}1 / At\text{-}1) + \varepsilon t \quad (3)$$

Where: DISEXPt = Discretionary expenses (current year)

At-1 = Total assets (previous year)

St-1 = Sales (previous year)

Equation 3 is based on study conducted by Roychowdhury (2006). The residual value is the suspected companies that were engaged in abnormal DISEXP. Residual value is said to exists is the usual DISEXP intensity varies with the actual DISEXP amount. Suspected companies are those companies based on linear regression with the residual values.

The coefficients derived from each model are then added to the model to generate the normal operating cash flow, production costs and discretionary expenses. Then, the real coefficient value earlier is decreased by the usual values

in order to obtain the abnormal values of each calculation used as a proxy for REM (Darmawan, Sutrisno, & Mardiati, 2019). According to Cohen et al. (2008), each value was summed up, and then abnormal operating cash flows and abnormal discretionary costs are multiplied by −1 to match the relationship with REM. The REM model is estimated using the example below;

(D) The Aggregate Real Earnings Management

$$AREM = (ABCFO*-1) + ABCOGS + (ABDISEXP*-1) \quad (4)$$

Where,
AREM = A combined measure of abnormal real earnings management
ABCFO = Abnormal cash flow from operation
ABCOGS = Abnormal cost of goods sold
ABDISEXP = Abnormal discretionary expenses

Results and Discussions

Multiple Regression on Earnings Management

The result of regression on EM is shown in Appendix 21. The regression results showed that MANOWN's findings were mixed with EM. Nevertheless, only ABCOGS was significantly associated with EM in a positive direction of 10% (t-value= 0.25). It evidenced that the companies show an increase in earnings as well as in earnings are less vulnerable to EM. Generally, CEOs and senior management are often compensated by equity incentives to align shareholder goals with managerial objectives and to provide space for agency conflicts (Coles et al., 2006). Such opportunistic behaviour could increase if there is a direct relationship between these incentives and the financial benefits of company management. Hence, this study is rejecting hypothesis 1.

Multiple Regression on the Company's Performance

The results for regression are shown in Table 4.2. MANOWN was significantly negative correlated with TOBINSQ at 5% (t-value= -1.09). Previous studies have found significant negative relationships between managerial ownership and company's performance (Alves, 2012; Ebrahim, 2007; Klein, 2002; Warfield et al., 1995). This relationship is parallel to the hypothesis of importance, which indicates that the higher the ownership, the lower the company's performance. The finding supports the findings by Amran & Ahmad (2013) and Fahlenbrach & Stulz (2009) that found the managers build upon their increased shares in managerial ownership. In other words, managers prefer to maximise the benefits for themselves at the expense of minority shareholders. This situation is a manifestation of the hypothesis of incorporation (Young, Peng, Ahlstrom, Bruton, & Jiang, 2008). Managers who own a majority of equity in the company have less incentive to manipulate accounting information. Furthermore, the presence of large shareholders helps to reduce the room for opportunistic behaviour among the managers. These situations are consistent with the alignment of the interest hypothesis and the efficient monitoring hypothesis. Therefore, this study is rejecting hypothesis 2.

Conclusion

This study examines the effects of managerial ownership on company's earnings management and performance. The findings found a significant positive relationship between managerial ownership and earnings management; but only through abnormal cost of goods sold. The finding indicates that the managerial ownership in the company did not reducing the level of earnings management activities. However, there is a significant negative relationship between managerial ownership and company's performance through Tobin's Q. This indicates that the company's performance is reducing when the company is having a managerial ownership.

It is an essential resource for any market participant since it provides a reduced volume of information asymmetries between managers, investors, regulatory agencies, society and other stakeholders. The current findings can be treated as tools to lessen the earnings management activities and to increase the company's performance by the management and stakeholders by applying monitoring mechanisms on companies through managerial ownership which have to curtail opportunistic behaviour among the management.

The Evolution of Economies – Changes in The Structure of The Real Economic System

Piotr WALĄG
University of Agriculture in Krakow, Mickiewicza Av. 21, 31-120 Krakow, Poland,
e-mail: piotr.walag@urk.edu.pl

Abstract

The article reflects the diversity of issues related to real changes in the structure of the economic system in market economies of highly developed countries, which underwent a strong phase of industrialisation, and then relocations of industrial production (to countries with cheaper labour factor), revealing as the first (the United States and the United Kingdom) in their economies the presence of the deindustrialisation process. As well as in the evolution of the market economy of developing countries, which are entering the deindustrialisation phase prematurely. The presentation of the most important issues of structural changes at the cognitive level allows us to attempt to outline possible interpretations of the effects for the countries under study and to assess the evolution of their economies, and above all the changes in the structure of employment at the empirical level, as well as to identify the main determinants, their individual patterns of changes in the structure of the economic system, and development. On the basis of the analysis of changes within the main sectors of the economy, changes in their share in total employment for the whole economy in the period 1970-2019 were examined for selected key countries. Using the regression analysis of structural change models, the main determinants of individual development patterns and the course of evolution of economies were examined and interpreted based on the results of the research.

Keywords: industrialisation, relocation, deindustrialisation, economic evolution, employment structure, patterns of changes in the structure of the real economic system.

Introduction

The transformations of fundamental rights and economic mechanisms which are often reduced to the phenomenon of the constitution of a new paradigm of economic development have their origin in the natural conditions associated with the structural changes in market economies, understood as changes in the real structure of production and employment, which is the essence of the evolution of the economy and the entire socio-economic system. Technical progress and changes in the structure of population consumption, inherent in the essence of the functioning of a market economy, lie at the heart of the mechanism of real structural changes. The uniformity of these changes, which only manifests itself in long research periods, does not deprive them of the profound specificity that lies behind individual national circumstances. The most striking feature is the diversity of structural change processes in the group of highly developed countries and those which are still developing. Naturally, the changes which are taking place, leading to increases in production and employment in the services sector at the expense of their share of the industrial sector in the earliest industrialising countries, which have so far recorded relatively high social welfare, should not induce developing countries today to 'jump over' the stage of industrialisation of the economy in conditions of competition on global markets.

The following are the subject of real structural changes and their patterns in economies that have experienced strong industrialisation under market conditions and those that have not undergone this kind of intensive phase of industrialisation and are already seeing symptoms of deindustrialisation.

The structure of work includes four main chapters. The first two chapters present the effects of research in the literature on structural changes that have taken place in market economies today and in developing economies. The analytical chapter presents changes between the main sectors of the economy, which transparently reflect the course of the process of real structural changes in the economic system of selected economies. It also analyses the impact of key determinants of the economy's evolution and presents interpretations of the results obtained in the study. The fourth chapter describes more important conclusions.

"Prevailing factors" and changes in the structure of market economies in highly developed countries.

The scale of changes in the shares of individual sectors in the development of market economies today's highly developed ones was clearly driven by two factors which were considered to be common to many complex phenomena and whose cumulative effects were clearly observable over time, despite the action of other variables. Technological progress (measured by productivity) and changes in the structure of consumption are mentioned as determinants of structural changes in market economies (Fourastie, 1972; Fisher, 1945; Fourastie, 1954; Clark, 1957; Kwiatkowski, 1980). Productivity increases in agriculture resulted in increasing food production volumes. At the same time, there was a continuous increase in income *per capita*, which caused changes in the structure of consumption. As income increased, the share of food in total expenditure decreased. There was also a shift in demand from agricultural products to industrial products and then services. Growing demand for industrial products increased production levels in the industrial sector, mainly in industrial processing. Initially, with low productivity, this growth was mainly through employment gains. In this way, the industrial sector absorbed labour out of agriculture, a process which became all the more pronounced the greater the difference between the productivity growth rate (initially slow) and the growth rate of demand in the industrial sector. Accelerating productivity growth rates in industry through the inventions of the first and second industrial revolutions narrowed the gap between achievable production volumes and demand. As production volumes driven by increasing productivity exceeded the levels of reported demand for industrial products, employment began to fall. Just as in the final phase of the agrarian era, large increases in productivity and production were causing increasing income growth already at the peak of industrialisation (Fisher, 1952: 828). The Caldor, on the basis of empirical material provided by Kuznetz and Chenery and Syrquin, pointed to the importance of analysing economic growth through structural changes in agriculture, industry and services, as well as through their mutual relations. He argued that industry (alongside agriculture) has contributed most to stimulating growth. In industry, due to the absorption of technical progress, relatively high productivity growth rates are recorded (Kaldor, 1967). Through the strongly manifesting scale effects in industry, dispersion effects, easy vulnerability to international trade (Dasgupta, Singh, 2005), as well as the absorption of poorly qualified labour resources (Rodrik, 2016: 19-20), increasing the share of industry brings with it great pro-growth opportunities. Technological advancement has been a factor in productivity growth in industry and, for the most part, in job losses in this sector (Rodrik, 2016: 4, 27). In industrialisation, management processes were dominated by the imperative of efficiency. Higher productivity of machinery, introduction of the principles of 'scientific management', better use of working time was supposed to lead to higher production, higher profits and increased welfare. These changes clearly indicated that the emerging system would lead to almost 'unlimited production possibilities' and the displacement of labour (technological unemployment) (Rifkin, 2001: 73, 112). The income increases that have taken place have generated further changes in the structure of demand, from basic products to higher-level products (Fisher, 1952: 828). This resulted in a change in the structure of expenditure, in which the amount of industrial goods decreased and the amount of services increased. This constant increase in demand for services, with relatively low or no productivity growth in the sector, resulted in the whole labour force being absorbed, driven out of industry during the period of deindustrialisation. In the services sector, employment determines the volume of production above all. Due to the constantly growing, virtually unlimited, demand for services and the achievable rate of productivity growth at relatively low levels, the service sector continues to be the sector taking over labour from agriculture and industry. However, the observation of growth processes in many developed countries (industrialised and with strong comparative advantages), as well as developing countries (e.g. India), suggests that the conclusions drawn so far on the role of the services sector in productivity growth in the economy as a whole should at least be approached with caution. It is pointed out that services such as information technology services, financial services, retail, telecommunications, business services and transport have strong dispersion effects in the economy, create new products and processes, are often trade-sensitive (Dasgupta, Singh, 2005: 28) and can thus make a significant contribution to productivity growth. On the other hand, however, the growth of some services seems to depend on the scale of development of manufacturing (Dasgupta, Singh, 2005). However, the high heterogeneity of the services sector makes analyses of this sector, conducted at a high level of aggregation, of little use in providing knowledge about the essence of services (Piketty, 2015: 116) and their contribution to the productivity developments of individual economies.

Structural change in developing countries

Many developing country economies are registering faster growth in the services sector than in the industrial processing sector. Such symptoms of structural change as deindustrialisation are also found in the literature and are often accompanied, with significant GDP growth, by jobless economic growth (Dasgupta, Singh, 2005).

The historic turning point in the transition of today's highly developed economies from the dominance of industrial production to the production of services was almost USD 10 000 at current prices. It is now estimated that it is already at USD 3 000 in some (developing) countries. In view of these facts, it is becoming problematic to assess this change. It is not clear whether this type of premature deindustrialisation, when the economy has not yet reached an appropriate

level of industrial development, is harmful or beneficial to the long-term development of the country. It should be stressed that it is possible for the economy to undergo deindustrialisation in terms of employment, while, at the same time, deindustrialisation in terms of production (measured by added value or global production) has not yet taken place. This dualism of the deindustrialisation process is possible with the phenomenon of jobless production growth that is very common in developing countries. Deindustrialisation in terms of changes in production and changes in employment is not negative if it is the result of a natural response to changes in income and technology. However, this phenomenon can be a cause for concern if its symptoms appear at low levels of income *per capita (Dasgupta, Singh, 2006: 5-6)*. Rodrik points out that, without proper industrialisation, developing countries face the negative symptoms of 'premature deindustrialisation', which has serious negative effects on the structure of employment and the strengthening of economic growth. The effects of these negative symptoms are declines in average productivity in the economy, with declines in the income and welfare of the population, poor absorption of unskilled labour, weakening export opportunities. While in today's highly developed countries, structural change, including deindustrialisation, has been determined mainly by technological progress and a change in the structure of demand determined by income growth, in today's developing countries deindustrialisation in terms of employment is mainly driven by trade liberalisation, as demand for industrial production and the real volume of that production are still growing rapidly there. A particularly unfavourable situation arises in this respect in developing countries which do not have strong comparative advantages. Under such conditions, these countries not only become net importers of industrial processing goods, but are exposed to unfavourable trends in relative prices. The pressure to reduce the prices of goods from the processing industry in countries with a high level of technological progress is also spreading through trade to countries that import these goods. As a result, developing countries are recording declines in the share of industrial processing in employment and production. Depending on the extent to which developing countries have a solid comparative advantage in the production of processed goods, the balances of changes in the impact of technology and trade will significantly reduce the shares of production and employment in industry in developing countries. A stronger impact of technological advancement in these countries will increase the shares of production and employment in industry, while the dominance of the impact of foreign trade in these countries will reduce these shares accordingly (Rodrik, 2016). Different scenarios of the evolution of the economy are possible, and the greatest differences in the pattern of the changes in the real structure of the economy are observed among the economies of developing countries (G. Dosi, F. Riccio, M. Virgillito, 2020).

Analysis of structural changes in selected economies

The evolution of economies is perhaps most evident in the real changes that are taking place between their main sectors. The analysis of structural changes in selected key economies begins below with the presentation in Table 1 of the study on the evolution of employment structure in the period 1970 - 2019 for the economy, the UK, Germany, Poland and the United States.

Table 1: Employment structure in selected market economies in the years 1970-2019 (shares of particular sectors in total employment).

Table 1 illustrates the changes in the structure of employment for selected highly developed market economies and the Polish economy. In the analysis of data from the period between 1970 and 1980, deindustrialisation processes were first observed in the most developed economies, i.e. the United States, Great Britain and Germany. These processes were further strengthened by the pursuit of a demand policy towards industry in the 1960s, which undoubtedly contributed to the crisis of the 1970s, which was compounded by the rise in raw material prices. This crisis was characterised by rising prices and stagnation. The liberalisation of world trade, which began in the 1970s, accelerated the processes of deindustrialisation by relocating the production of mature industries in which the rate of productivity growth was significantly slowed down and their share of world consumption was dependent on the price of labour, from highly developed countries to developing countries. Instead of the relocation of mature industries, in line with industrial development, new industries were created with very high productivity growth rates. All in all, since the 1970s, industrial productivity in the United States, the United Kingdom and Germany have started to grow even faster and, with it, the share of industry in total employment has started to fall, as demand for its products in the most developed countries was already heavily saturated.

The long-term shift in employment from industry to services since the early 1970s (de-industrialisation) has proven to reflect mainly the impact of differences in productivity growth between manufacturing and services. For, if the real output of manufacturing does not tend to grow faster than the real output of services in the long term, and productivity in manufacturing, caused by rapid changes in production technologies, increases disproportionately faster than in services, then the employment structure will shift from manufacturing to services. The services sector will have to absorb a larger proportion of total employment in order to keep the real volume of production on a par with the real volume of industrial production. Rising employment in services will have to lead to a relatively faster increase in the price of their production than that of products from manufacturing, and therefore a change in the structure of production at current prices.

Productivity growth has been sustained at a faster rate in some (technologically progressive) activities than in others (technologically stagnant) . Industrial processing is, in general, technologically progressive, which is why its importance to the economy seems to be undoubtedly the most important. Such characteristics of industrial processing are associated with its internal attributes, i.e. ease of standardisation, the possibility of formalising information necessary for production into easily repeatable information packages. Services, on the other hand, are significantly different from manufactures in this respect. For example, *non-personal* (*impersonal)* services, such as telecommunications, have characteristics similar to industry and can be qualified as 'technologically progressive'. Personal services (non-market services), however, such as medical care, for example, cannot easily be standardised, cannot be subject to mass production methods and are therefore called 'technologically stagnant'. (Baumol, Blackman, Wolff, 1989). The development of the world market as well as technology gives more and more dynamics to those features of services which previously closed them within the boundaries of internal markets. Increasing the commercial capacity of services additionally strengthens the role of the service sector in the path of economic development of countries (more: Kłosiński, 2011: 213-215).

The literature assumes, at the theoretical level, that productivity growth in industry is likely to be less important than before for the increase in overall productivity and living standards in advanced economies due to the stabilised consumption of its products (saturation of demand). However, in developing economies, it will be the main driver of economic growth due to its strong technological progress and increasing consumption and increasing globalisation.
As the process of deindustrialisation continues, productivity growth in the economy will increasingly depend on productivity growth in the service sector, not so much on productivity growth in industry. In contrast, the evolution of service sector productivity will depend on future developments in areas such as information technology and changes in the competitive structures of the sector (Rowthorn, Ramaswamy, 1997: 22; Dasgupta, Singh, 2006). However, according to Kaldor, the rate of productivity growth in the whole economy depends on the expansion of the industrial sector, which not only leads to faster productivity growth in industry, but has a dispersal effect on the whole economy (operation of Verdoorn's law). In a context of trade liberalisation and globalisation of commodity flows in the economies of highly developed countries, despite the almost saturated demand for industrial goods, the industrial processing sector (and its rate of productivity growth) continues to be the most important for the growth of GDP *per capita* and the overall productivity of the economy, as Kaldor believed. After an increase in total employment in market services (including primarily banking services) in the UK by around 10% in the 1990s and the first period of 2000, and a decline in total employment in the industrial sector from around 20% in the US and 26% in the UK to almost 30% in the German economy, the emergence of the crisis in 2007-2008 forced the industrial policy support in these economies and stopped the decline in the share of manufacturing in total employment. These measures have prevented these countries from falling sharply in terms of GDP *per capita* growth. This sustained, albeit very slow, GDP *per capita* growth has allowed these countries to increase the share of non-market services in total employment, as in the US, for example, through increased government spending on health and education, in the face of a collapse in global demand and rising unemployment.

Observing the highest GDP per capita growth in Germany's economy and its slowest slowdown during the 2007/2008 crisis in the context of structural changes, there emerges an almost 100% higher share of total employment in the industrial sector (at around 24%) than in the UK and US economies (at around 10% to 12% on average), which are at similar GDP *per capita* levels.

In order to examine the main determinants and determine the causes of real changes in the structure of the economic system, a regression analysis of models of changes in the share of the industrial sector in total employment of selected key economies for this process was conducted, successively: United Kingdom, Germany. The United States and Poland. The results of the research are presented in the Table appropriate for the economy of the analysed country: 2, 3, 4 i 5.

Own calculations based on Data extracted on 11 Nov 2020 23:35 UTC (GMT) from OECD.Stat

Parameters of the model of change in the share of total employment of industry in the UK economy.
Variable X 1 -- Gross domestic product (expenditure approach) UK.
Variable X 2 -- GDP per capita at current prices and current PPPs, US dollars (UK).

All parameters are very statistically significant, which makes their interpretation valid.
Explained variable - Share of total employment of industry in the UK economy.
Variable Y -- Employees in industry (UK).

The parameters (explanatory variables) in the model presented (Table 2) (as well as other models presented in Tables 3, 4 and 5) were selected based on the basic models of deindustrialisation and study of the literature on the subject, and empirically on the basis of statistical studies of stylized facts occurring in the analysed economies. This model in 97% describes / explains changes in the share of total employment in the industry sector. Determination factor R2 = 0.97. All explanatory variables are very statistically significant being significantly higher than the critical value. The regression analysis of the presented model showed that an increase by 1% of GDP - expenditure approach (parameter X 1) strongly determined the increase in the share of employment in the total economy of the industry sector, causing

its growth by 1.13 percentage points, which indicates that the demand for industrial production is not fully saturated. However, domestic production in the UK, losing in a liberalised market since the 1970s, was relocated to countries with cheaper labour costs (labour). Hence, as shown in Table 1, the share in total employment of industry since 1970 from 40.68% dropped to 11.89% in 2019, while the increase in GDP per capita (parameter X 2) by 1% resulted in a very significant decrease in the share in total employment of the industry sector by as much as -2.11 percentage points. This may be the reason for an increase in the demand for services, and therefore the demand for labour and employment in the service sector, on the one hand, and may suggest a very large increase in income inequality on the other.

Table 3: Regression analysis of the model of changes in the share in total employment of industry in the economy Germany between 1970 and 2019.

Estimation method: CMSS
Observations used 1970-2019
Dependent variable: Y (ln) share in total employment in the industrial sector in the German economy.

Parameters of the model of changes in the share of total employment in industry in the German economy.
Variable X 1 -- Gross domestic product (expenditure approach) Germany.
Variable X 2 -- GDP per capita at current prices and current PPPs, US dollars (Germany).

All parameters are very statistically significant, which makes their interpretation valid.
Explained variable - Share of total employment in industry in the German economy.
Variable Y -- Employees in industry (Germany).
For the German economy, the regression analysis of changes in the share of total employment in the manufacturing sector showed that the model presented in Table 3 is not statistically significant. Both variables GDP (expenditure approach) and GDP per capita are smaller than the critical value. This shows that in the German economy, the manufacturing sector is strongly supported in all dimensions by active state policies. This clearly shows that the share of total employment in the industrial sector is shaped by German industrial policy. Hence, as previously shown in the studies in Table 1, the share of manufacturing in total employment (at around 21.83%) is clearly more than 100% higher in the German economy than in the UK (at around 11.89%) and the US (at around 10.04%), which are at similar levels of GDP *per capita*.

Table 4: Regression analysis of the model of changes in the share of industry in total employment in the economy The United States between 1970 and 2019.

Estimation method: CMSS
Observations used 1970-2019
Dependent variable: Y (ln) share of total employment of manufacturing in the US economy.

Own calculations based on Data extracted on 11 Nov 2020 23:35 UTC (GMT) from OECD.Stat

Parameters of the model of changes in the share of total employment in industry in the United States economy.
Variable X 1 -- Gross domestic product (expenditure approach) US.
Variable X 2 -- GDP per capita at current prices and current PPPs, US dollars (US).

All parameters are very statistically significant, which makes their interpretation valid.
Explained variable - Share of total employment of industry in the US economy.
Variable Y -- Employees in industry (US).

The regression analysis of the model in Table 4 showed that 97% describes / explains changes in the share of total employment in the industry sector. The determination factor R2 = 0.97. All explanatory variables are very statistically significant, being significantly higher than the critical value. Regression studies of the presented model showed that an increase by 1% of GDP - expenditure approach (parameter X 1) very strongly determined the share of the total employment of the industry sector in the economy, causing its decline by as much as -4.3 percentage points. Because, as Krugman has already shown in its research, the balance of US trade, especially for manufacturing, has always been negative. Krugman clearly indicated that Japan's policy, with which the states had the highest trade turnover in industrial production, was to reduce the exchange rate of the yen (the Japanese currency from the US dollar), which gave a price advantage to Japanese products (they were pushing US production out of the market).

On the other hand, an increase in GDP per capita (parameter X 2) by 1% resulted in a very large increase in the share of total employment in the industry sector, by as much as 4.6 percentage points, which argues for a yet insufficiently saturated demand for industrial products on the one hand, and a relatively smaller increase in income disparities on the other hand (in relation to the UK). In the United States and the United Kingdom, the countries in which the process of deindustrialisation was the earliest to occur, industry currently plays a relatively smaller role than, for example, in the German economy. In the UK, industrial companies (parent companies) only have their headquarters, to which profits are transferred. Real production in the UK, as in the United States, based on labour (production that is no longer affected by technological progress) was already the end of the 1970s relocating to other countries where labour costs were lower. In Germany, on the other hand, relocation processes did not begin until the 1990s, and were further severely restricted by state policy.

Parameters of the model of changes in the share in total employment of industry in the Polish economy.
Variable X 1 -- Gross domestic product (expenditure approach) Polend.
Variable X 2 -- GDP per capita at current prices and current PPPs, US dollars (Polend).
Variable X 3 -- Real Gross domestic product (GDP), volume, 2001=100

All parameters are very statistically significant, which makes their interpretation valid.
Explained variable - Share in total employment of industry in the Polish economy.
Variable Y -- Employees in industry (Polend).

The model presented in Table 5 describes / explains changes in the share of total employment in the industry sector in about 93%. The determination factor R2 = 0.9269. All explanatory variables are statistically significant, being larger than the critical value. The regression analysis of the presented model showed that an increase by 1% of GDP - expenditure approach (parameter X 1) determined the change in the share of employment in the total economy of the manufacturing sector, causing its decrease by -0.32 percentage points. Also, an increase in GDP per capita (parameter X 2) by 1% resulted in a decrease in the share in total employment in the industry sector, by -0.58 percentage points, which resulted directly from the subjection of the Polish economy to trade liberalisation, with very large differences in productivity in the industrial sector with highly developed countries. In addition, the Polish currency has been subject to constant depreciation. Therefore, domestic production which was not competitive in terms of price and quality was very strongly pushed out of the market by imports. However, for the Polish economy, a model with a real GDP (X 3) volume parameter turned out to be statistically significant, whose 1% increase translated into a 1.32 percentage point increase in the share of total employment in the industry sector. Because the increase in real GDP, the volume of which was drawn primarily by the industrial sector, with constant or even decreasing employment per unit of production, meant an increase in productivity, which translated into an increase in the price competitiveness of domestic production, and thus an increase in its sales, volume and employment, which ultimately translated into an increase in the share of total employment in the industrial sector.

Summary

The excessive increase in the share of financial services in the added value of economies generated by their nominal profits in the 1990s and the demand crisis initiated by the collapse of the financial markets in 2007/2008 update the applicability of Kaldor's views on the role of the expansion of the manufacturing industry, as it leads to an increase in average productivity throughout the economy. The increase in the share of industry in the structure of the economy leads not only to a faster increase in real productivity in industry itself, but also has the physical effect of its dispersion into the real sphere of the whole economy. In developing countries, industrial processing is the area of the economy which potentially absorbs the resources of the low-skilled workforce most quickly. As the experience of the recent crisis has shown, the industrial sector continues to be the most important guarantor of sustainable economic growth for the economies, and this seems to be a supranational issue. Economic analyses show that only with a sufficiently high level of GDP *per capita is* the service sector able to absorb all the labour force pushed by new technologies from agriculture and industry. Indeed, the emerging system will lead to almost 'unlimited production possibilities' and the displacement of labour (Rifkin, 2001: 112). In some approaches to the analysis of the possible effects of these changes, this makes it necessary to reformulate the social contract in relation to employment and create conditions for social participation away from the market (Rifkin, 2001: 299-301). A new essence is given to structural change by the vision of a strong multiplier effect resulting from the 'synergy between the pillars of the industrial revolution', which is to be based on renewable energy sources and the Internet as growth areas (Rifkin, 2011). Despite Rifkin's pessimism in the mid-1990s (Rifkin, 2001), the aspirations for the new energy and communication structure of economies presented by him in the second decade of the 21st century quite clearly indicate the hopes that are still placed in the reindustrialisation of economies.

Industrialisation and Deindustrialisation and The Real Divergence of The Polish Economy

Piotr WALĄG
University of Agriculture in Krakow, Mickiewicza Av. 21, 31-120 Krakow, Poland,
e-mail: piotr.walag@urk.edu.pl

Abstract

Socio-economic processes initiated by industrialisation are leading to the natural effect of deindustrialisation in this age of development. This stage of shaping the structure of economies, particularly in terms of employment, has brought with it a wide range of ambiguities, including negative ones, from the displacement of the labour force from industry to growing wage and income inequalities, to losses in economic growth potential.
The main aim of the study is to show the course of structural change processes in the conditions of Poland as an economy (subjected to systemic transformation processes), which, entering the phase of deindustrialisation, has not yet fully exhausted the potential offered by industrialisation, with still not saturated internal demand for industrial goods and unused opportunities to develop stronger comparative advantages than before and, most importantly, to reduce the very significant distance of divergence of the real economy.
On the basis of a theoretical presentation of the problems of industrialisation and deindustrialisation of economies, an analysis of the conditions of the Polish economy was conducted. Simple measures were used, such as those from the first Kaldor law, measures of saturation of sectoral demand, GDP per hour worked, GDP *per capita*.
The conclusions obtained during the analysis point to industrialisation as an important source of growth in labour productivity and income in Poland and justify the approach to reindustrialisation as an element of economic policy in the process of developmental catching up, through the faster pace of real convergence processes with the economies of highly developed countries, with which, as the results of research have shown, the Polish economy is more than 40 years apart. The fast pace of the convergence processes and the reduction of the divergence distance between the real Polish economy and those countries is a necessary condition for obtaining economic benefits from economic liberalisation.

Keywords: Industrialisation, Deindustrialisation, Reindustrialisation, Systemic Transformation, Real Economic Divergence, Economic Convergence Processes.

Introduction

The first industrialising countries - introducing new production techniques and product innovations - have seen significant changes in labour productivity, contributing to initiating the process of changing the structure of expenditure and production in the economy. These changes have led the national economy to develop broad opportunities for increasing the economic welfare of society. From the 19th century onwards, new manufacturing methods such as innovation spread from the UK to other countries, strengthening their industrialisation processes, with positive economic and social consequences. In contrast, production in developing countries remained largely dominated by an agricultural sector with very low productivity levels. Economic growth in industrially based developed countries (United Kingdom, United States, Belgium, Switzerland, France, Germany, Japan) has generated growing demand for services that are primarily related to the functioning of product markets. They have also abandoned the production of old industries such as mining and labour-intensive production in agriculture. Transport and ICT communication, which expanded trade channels, strengthened exports of agricultural and mining products to developed economies from catching up countries. These goods processed in industrial countries were then re-exported to developing countries, largely depriving them of the potential to shape their own industrial expansion in production with high added value and product innovation. The post-war years of the 20th century brought opportunities for developing countries to quickly catch up with economic growth, which was strongly linked to the phenomenon of late industrialisation stimulated by globalisation processes or the expansion of technology transfer opportunities[1].

Industrialisation, with the division and specialisation of labour that it undoubtedly involved, has created the conditions for stable productivity growth in the currently highly developed countries[2]. Industry has been a driving force in the catching up process in countries such as Japan, Taiwan and South Korea. However, the social and economic processes triggered by industrialisation are leading to the natural effect of deindustrialisation in this age of development. This stage in the structure of economies, particularly in terms of employment, has brought with it a wide range of ambiguities, including negative ones, from the displacement of the labour force from industry to growing wage and income inequalities, to losses in economic growth potential. In terms of demand and production, deindustrialisation has developed as a less drastic and more uniform phenomenon in individual countries (D. Rodrik 2016).

Both the problem of (re-)industrialisation and deindustrialisation have many analytical threads. The aim of this work is to show one of the approaches to the problem of economic growth, which is addressed from the point of view of structural changes in the economies, including the Polish economy.

(PL) Mr President, at the heart of the mechanism for structural change in the highly developed countries today was mainly technical progress and changes in the structure of demand / consumption of the population. In countries catching up, increased international trade as a result of trade liberalisation (late industrialisation stimulated by the development of technology and globalisation) played an important role. Both the sources of structural change are inextricably linked to the essence of the functioning of the market economy.

The research question boils down to an assessment of the correctness of structural changes and the desired direction of these changes for the economies catching up with Poland as an example.

The main aim of the study is to show the course of structural change processes in the conditions of Poland as an economy which, entering the phase of deindustrialisation, has not yet fully exhausted the potential offered by industrialisation, with still not saturated internal demand for industrial goods, and with not outlined, developed and used opportunities to develop stronger comparative advantages than before.

Following the example of Kaldor's approach (on the production side) and using simple macroeconomic indicators (on the demand side), the argument has been put forward for the justification for reindustrialisation in Poland in order to strengthen the foundations of economic growth in that country and reduce the real divergence between Poland and economies such as the United States, Germany or the United Kingdom, and, above all, with highly developed EU countries with which Poland has entered into trade liberalisation.

The first part of the work covers the theoretical basis of the problems considered, which will then be analysed and concluded later in the study. The subject of theoretical considerations is mainly such issues as the effects of deindustrialisation and industrialization of economies, which are anchored in the literature. The distinction between these effects will be presented for developed and developing countries, which will allow to strengthen later conclusions for the Polish economy. Then, in the empirical part of the article, simple measures and economic dependencies were used (first Kaldor's law, state of saturation of demand, GDP per hour worked, GDP per capita), on the basis of which interpretations were made in order to outline the possible advancement of industrialisation and deindustrialisation in Poland.

Theoretical conditions of the economic consequences of industrialisation and deindustrialisation of market economies

Industrialisation is understood as an increase in the share of industrial processing in production and employment of a given economy.

Socio-economic processes triggered by industrialisation lead over time to the natural effect of deindustrialisation[3] As deindustrialisation continues, productivity growth in the economy increasingly depends not so much on productivity growth in industry as on productivity growth in services. However, the evolution of productivity in the service sector will depend on the future development of areas such as information technologies and changes in the competitive structures of the sector. Technological development means that certain types of services will develop at a much faster rate than others, and therefore significant structural changes are taking place in this sector over time. It should be

[2] Level of net national income (GNI) per capita above USD 12,736 calculated using the World Bank Atlas method (as of 1 July 2015); http://data.worldbank.org/news/new-country-classifications-2015 (19 May 2016).

[3] De-industrialisation can be classified in two categories - measured by the relative decline in industry's share of total production or measured by the relative decline in industry's share of total employment.

noted, however, that product innovation in industry will continue to play an important role because of the dispersion effect that will promote productivity growth in services (R. Rowthorn, R. Ramaswamy 1997).

The table below summarises the main effects of the process of industrialisation and deindustrialisation of market economies.

Table 1: Summary of the main disclosed effects of industrialisation and deindustrialisation of market economies

breakdown criterion	affecting changes in the production structure	affecting changes in the structure of employment
Industrialisation		
caused by technological progress	productivity gains in industrial processing generate *a structural change bonus in the* form of *per capita* income gains	reallocation of resources from agriculture to industry
	favourable conditions for capital accumulation in the industrial processing sector (more than in agriculture or services) through greater opportunities for concentration in this sector	mass access to the labour market of low-skilled labour resources
	favourable conditions for the disclosure of economies of scale	
	favourable conditions for technological development both in terms of tangible and intangible progress	
	technology diffusion from industry to other sectors of the economy and within industry itself (*spill over effects*) - positive externalities from investment in knowledge and technology	
	strong *linkage* effects - positive externalities resulting from investments in a given sector	
caused by changes in consumption patterns	the increase in per capita income results in a decrease in the share of expenditure on agricultural products in total expenditure, and the share of expenditure on industrial products increases	
deindustrialisation		
caused by technological progress	relatively low increases in labour productivity in services reduce the possibility of generating income comparable to that of the industrial sector	a declining share of employment in industrial enterprises in developed economies
	relatively weak productivity growth results in a relatively large increase in the price of current services	stagnation of average real wages in services and increase in wage inequalities
	den investments - collapse of old industries	Declining trade union strength
caused by trade and globalisation	the rapid growth of trade cooperation and capital mobility between developed and developing countries	as the reallocation of input resources to the service sector increases, the economy's revenues tend to fall
	relocation of mature industries to developing countries	the massive increase in unemployment in most developed

		European economies since the early 1970s
caused by changes in consumption patterns	income growth is changing the structure of consumption towards an increase in the use of services, these are relatively expensive (low productivity) and therefore a correspondingly high per capita income is necessary for their demand for the economy	opening up new employment opportunities as soon as sufficient demand for services is reported

Source: study based on: Shirmai 2012, pp. 410-417; Norton R. D., Industrial Policy and American Renewal, Journal of Economic Literature, vol. XXIV, 1996, p. 17;

With the shifting of production factors between sectors (from industry to services) as well as between countries (from highly developed countries to developing countries), new phenomena emerge that occur on their own or coexist with earlier phenomena - wage inequalities, the weakening role of trade unions, a massive increase in unemployment among the uninvolved and low-skilled.

The general process of structural change in economies is revealed in the sequence of economic changes. The emerging variations in the rate of change in labour productivity between sectors, sections or divisions of production in the economy trigger changes in employment, and these entail changes in prices (inverse of productivity) and changes in the structure of nominal production (the level of real production remains stable).

Consequences of deindustrialisation in developing countries

Most highly developed economies are in a phase of structural change, which, as a result of natural reallocation processes, is registering deindustrialisation trends, especially in the area of employment changes. Over the last century, the productivity-driven industrialisation of these countries has enabled multiple increases in purchasing power (different for individual goods) (T. Picketty 2015).

The growing role of the service sector in the structure of the economy, in which the national income generated so far has not allowed for a stable increase in the sale of services, is a significant burden on the path of rapid economic growth. This situation mainly concerns developing economies without strong comparative advantages.

The identified negative effects of premature deindustrialisation come down mainly to highlighting the advantages arising from the activities of the processing industry sector:

1. Production activities developed in the processing industry are strongly pro-efficient, which is due to the possibility of technological progress (this phenomenon is much less observed in the services sector)
2. The processing industry sector absorbs significant amounts of unskilled labour;
3. Goods resulting from processing production are easily marketable and, in a low-income economy where demand is very insatiable, there is no demand restraint (D. Rodrik 2016).

In highly developed economies, deindustrialisation has become more apparent in employment than in production. Technological progress in these countries remains the main determinant of these structural changes. However, a large proportion of the labour redeployment concerns unskilled workers, who are being pushed out of production processes by increasingly advanced technologies.

In developing economies, however, as in developed economies, the share of technological progress in deindustrialisation processes is less obvious. D. Rodrik is more inclined to explain these changes by the adjustment of relative prices (a fall in the prices of relative processing goods as a result of differing technological progress) as a result of increasing trade cooperation between countries and globalisation. At the same time, economies that have been successful in developing strong comparative advantages on international markets have seen a weak impact of deindustrialisation on employment (D. Rodrik 2016).

Materials, Methods, Results and Discussion

Analysis of industrialisation conversions in Poland

Methodological Approach

Kaldor's indication of a strong relationship between growth rates of industrial processing and GDP growth is included as Kaldor's first law (production-side approach). It says that the more production growth in manufacturing exceeds GDP growth, the higher the GDP growth (S. Dasgupta, A. Singh 2006; N. Kaldor, 1966 i 1967). Based on this relationship, the discrepancy between growth rates in industrial processing and services and GDP growth rates in Poland between 1995 and 2018 will be shown. This approach will also illustrate de- and industrialisation trends in that country.

On the basis of data on the development of changes in demand / demand for industrial processing products in the country, the state of saturation of markets with industrial goods produced in Poland will be shown (approach from the point of view of changes in the demand / demand structure).

The changes in the structure of employment between 1995 and 2018 for particular sectors of production in Poland will allow to illustrate the intensity and direction of de- and industrialisation trends.

Data on GDP per hour worked as a percentage of the US level (US=100) and on GDP per capita in constant prices, PPS, USD, GDP p. c. (USA = 100) will additionally shed more light on the analysed dependencies in the context of the overlap of real convergence processes of the Polish economy.

Outline of the conditions for changes in the industrial sector in Poland

The years of economic transformation in Poland have brought significant damage to the industrial potential of the Polish economy. Among production entities in industry established before 1949, and those built in the years 1949-1989, 43% of the number of plants (subject to the survey) was recorded, as a result of which 37% of assets, 38% of production and almost 50% of jobs in the surveyed plants in this sector were lost (70% of the total number of plants in industry was surveyed). The whole sectors - light industry, mining, metallurgy, electronics, IT, shipyards, mechanical engineering in the Śląskie, Mazowieckie, Łódzkie and Dolnośląskie Voivodships - suffered a particular loss. As a result, during the 24 years of economic transformation, the industry's output sold grew by an average of 3.6% per annum, which was twice as high as during the industrialisation of the socialist economy.

Currently, in Poland, the processing industry is significantly based on small and medium-sized enterprises (20% of employees in industry, a 9-fold increase in production sold since 1989), which does not, however, lead to the formation of a stable basis for the growth of production capacity with a strongly developed development and research base (the number of people working in research and development in the majority of large enterprises in 2012 was 14.5 thousand, in 1988 it was 60.5 thousand). As a result, production in industry in Poland (mainly in the automotive, electronics and engineering industries) is not able to carry out the "full cycle of final production" and is mainly based on assembly of industrial products from imported components. Such a picture of the economic situation of the industry is not without influence on such economic figures as: about 2 million of registered unemployed people (reaching even 3 million in some periods of transformation), over 2 million emigrants - working people, in 40% with higher education (S. Paradysz 2015).

Conclusions of the study

The ratio of changes in real production (measured by volume of added value) in manufacturing and services to changes in real production in the whole economy is to show, on the basis of Kaldor's observations, the intensity of industrialisation processes in a given country. For the Polish economy, this relation is presented in Table 2.

Table 2: Value added volume index (1995 constant prices) for the years 1995-2018 in sectors and sections of the Polish economy

Years	Total	A	B	C	D	E	F
1995	100	100	100	100	100	100	100

Adopted division of the economy into sectors and sections based on the PKD 2007 classification code:

A - Agriculture, forestry, hunting and fishing.
B - Mining and quarrying.
C - Industrial processing.
D - Electricity, gas, steam, hot water and air conditioning supply. - Water supply; sewerage, waste management and remediation activities.
E - Market services.
F - Non-market services (social and personal).

The first Kaldor's law is revealed the more variables are presented for years distant from the base year (1995), i.e. the weaker the impact of prices is reflected in variables. Thus, it can be concluded that on the production side of the Polish economy there is a strong industrialisation process. In market services (those inextricably linked to the growth of manufacturing output of the processing industry), the excess of the growth rate of value added is also significant, which indicates that there are ongoing processes of servicing in the economy, which are included from the production side / category.

As shown in the theoretical part, industry, especially industrial processing, is a key determinant of the economic growth process (G. Dosi, F. Riccio, M. E. Virgillito 2020). As long as global production and imports increase (along with employment), a process of industrialisation is observed. Once the saturation point is reached (when

manufacturing output in manufacturing begins to stabilise and productivity continues to increase), there is a natural reallocation of the labour factor to the service sector.

The inclusion on the demand side (Table 3) will aim to indicate whether there has been a state of saturation with industrial processing production and thus whether it is possible to conclude on the natural pace and direction of the structural changes in question.

Table 3 is shown:

- domestic demand volume index (fixed prices 1995),
- industry output volume index (C) (in constant 1995 prices),
- GDP volume index (fixed prices 1995),

for the period (1995-2018).

Table 3. Volume index:
- domestic demand,
- industrial output (C),
- GDP at constant 1995 prices.

In Poland, global production in industrial processing continues to grow, and these changes are the main source of economic growth in Poland (measured by GDP) and naturally create demand for market services. This means that demand is not saturated with industrial products.

Moreover, although the demand in the economy (global production plus imports) of Poland is growing, mainly in the processing industry, employment in this sector is decreasing the most (see Table 4).

Table 4: Employment structure in the years 1995-2018 (total economy=100)

This type of pattern of structural change, which is characteristic (in most cases) of developing countries, is revealed mainly in the conditions of trade liberalisation of these countries with highly developed countries. Under such conditions, because growing demand is met by competitive production from developed countries.

In highly developed countries, changes in employment in industry are strongly dependent on the demand for industrial products. With increasing demand, the industrial sector absorbs the labour force, and the reallocation of labour from industry to the services sector follows the stabilisation of demand for industrial products, which has been reflected in these countries with relatively high GDP *per capita*.

In Poland's economy, there are large changes in output, but without an increase in the share of total employment in the processing industry. Observing the structure of demand, industrialisation processes are revealed in the economy. On the employment side, structural changes indicate deindustrialisation.

As a result, when comparing the Polish economy with the market-advanced economies of the euro area or the UK, a real development gap appears - a conclusion based on the data / research results presented in (Table 5, Table 6).

Own calculations.

The data presented in Table 5 are from the 1970s (since 1970), because this is the period of the highest growth of the industrial phase (exactly the beginning of deindustrialisation processes) in the US and UK economies, where deindustrialisation processes were the first to occur. In the German economy, industrialisation has lasted the longest, and its processes are strengthened by active state policy to this day (the share of industry in total employment in the German economy is on average about 10% higher than in the UK economy, and highly developed economies of EU countries (19 countries). Hence, the GDP per hour worked index used in the research is on average about 10% to 15% higher for the German economy. The income and productivity measure used in Table 5 indicates the average level of labour productivity in the economy reflected in income (or nominal value added), drawn by large (the largest of all sectors) industrial productivity growth rates (R. Rowthorn, K. Coutts 2004). In the Polish economy, which entered the deindustrialisation phase very earlier (at a relatively very low level of GDP per capita in relation to highly developed countries, as presented in Table 6), the GDP per hour worked ratio was (at the beginning of the deindustrialisation process in Poland) in 1995 at 32,4% and was more than 100% lower than the level of this indicator (69.4%) for the German economy in 1970 (35 years earlier), while in the equivalent year 1995 it was already almost 200% lower than the German economy (at the level of 99.2%), and the EU 12 most developed economies (88.5%) and the UK (87.2%) It is puzzling that with such drastic differences in the level of real development of the economy (differences in the development of the real structure of the economy), Poland's economy was liberalised with that of the EU-12, and above all, trade liberalisation. Despite submitting to international competition under such unequal conditions of real economic development, in 2019, the Polish economy reduced the differences in the level of GDP per hour worked (57.1%) to the highly developed countries, which are 97% in Germany, 87.2% in the EU-12 and 83.9% in the UK.

Own calculations.

The GDP per capita index in 1995 for the Polish economy, which, as indicated above, was entering a phase of deindustrialisation at that time, was 12092.2, which is almost 300% lower than that of the United States, 250% from Germany, 200% from the EU of 19 countries and the United Kingdom. Comparing the GDP per capita of the Polish

economy in 1995 with the GDP per capita of the 1970s (35 years of difference) of the highly developed countries that were undergoing deindustrialisation in those years, the difference in the levels of this indicator was around 250% to the United States, 200% to Germany and 160% to the United Kingdom respectively. According to the studies presented, the delay in changing the structure of Poland's real economy to highly developed countries in 1995 was around 35 years, while the real divergence is already over 40 years. Despite such a long delay in the real development of the Polish economy in 2019, the difference in GDP per capita has narrowed, but the delay in real economic development still remains significant.

The measures / criteria adopted for the development gap indicate even twice as low a level of GDP per hour worked or GDP per capita at constant prices. This means not only poor opportunities to develop Poland's comparative advantages with these countries, but also the need to conduct trade policy carefully. Such a significant real divergence indicates unambiguously the risk of deepening economic integration by monetary integration with these countries (the risk of Poland adopting the common currency, the euro) on equivalent terms.

Summary

If deindustrialisation is treated as a state of equilibrium at a low level of growth caused by imperfections resulting from failures of coordination at the level of state policy, then the validity of the approach to an active industrial policy towards reindustrialisation is strengthened.

Basing economic growth models appropriate to the economic conditions in question on pillars other than those consistent with industrialisation may lead a country on a path of average economic growth or to economic stagnation (G. Dosi, F. Riccio, M.E. Virgillito 2020). Building growth on services, even "technologically progressive" ones (i.e. finance, communication and information technology, robotics, research and development) and easily transferable could largely be an equivalent alternative to industrialisation, but resource requirements (highly qualified labour) tend to disqualify developing countries in this approach (D. Rodrik 2016). It should also be borne in mind that their share of total added value is only about 10%. On the other hand, the establishment of the basis for the production growth of developing economies on services, which are characterised by low levels of productivity and poor commercial capacity (e.g. personal services), is limited by the income of the economy and thus cannot lead to the achievement of the goals set in the catching-up process (A. Karpiński, S. Paradysz, P. Soroka, W. Żółtkowski 2015). Concentrating political resources and intellectual efforts on developing a stimulation of industrial development that is appropriate for the Polish economy is an important element of pro-development activities in the country for the next decades. W. Eucken in the first half of the 20th century pointed to industrialisation as social and economic processes which particularly revealed the need to develop national economic governance (rules and rules of the market game) appropriate to the given economic conditions. The contemporary complexity and dynamics of the economic changes taking place (population movements, successive stages of the manufacturing apparatus, revolutionary role of technical knowledge) have far exceeded the area of economic behaviour, which additionally emphasizes the need to adjust economic policy. One of the proposals of economic policy is to safeguard competition and to focus on "respecting the regularities that are revealed in the economic process and clearly intend to activate them (W. Eucken 2005). In such an orderly economy, economic decisions are determined by the market, which is headed by a law that consistently blocks all manifestations of monopolisation of economic power (E. Mączyńska, P. Pysz 2003).

Regulations in The Economy and The Change of The Real Structure of The Economy Under Conditions of Systemic Transformation

Piotr WALĄG

e-mail: piotr.walag@urk.edu.pl

Abstract

The economies of transforming Central and Eastern Europe, as countries burdened with multiple barriers, which are the remnants of the socialist economic system, are included as an area of research into the possible impact of regulation on the directions and pace of change in employment and production structures. It is often possible to point out certain significant similarities between the changes taking place in these countries and those taking place in countries that are advanced in the development of a market economy. Changes in economic structures are the result of numerous, varied and separate processes. The legacy of the planning economic system is the backwardness associated with the development of the services sector, which has made up for its development significantly in response to the needs of developing business in the country and the freedoms carried by law for private enterprises. Deregulation has been widely undertaken, often as part of a structural adjustment programme, mainly with the aim of relieving market economy mechanisms of their regulatory constraints and making fuller use of their developmental potential. The scale of the impact of regulation on economic growth was strongly determined by the regulation of key sectors of the economy.

The aim of the article is, on the basis of the analysis of key economic measures, to indicate and determine the possible relationship between the regulatory burden, generally understood as state control, restrictions on entrepreneurship, free trade and investment, and the shape of the structure of selected CEE economies.

Keywords: real structure of the economy, deindustrialisation, reindustrialisation, deregulation, regulation, systemic transformation, economic governance, market competition.

Introduction

The regulation is a response to the socio-economic challenges posed by market structures. However, although the regulatory framework must take into account the intra-sectoral structure, the relationships between actors in the individual markets and in the sector as a whole are a decisive factor in shaping the sector's performance. Regulation is only a stimulating or blocking element in this process and rarely becomes a determining factor (J. Stern 2006). Economic development is always seen in terms of new products and processes, but it seems to overlook the fact that every new product replaces both the old one and the old processes. Economic change is inextricably linked to the process of destruction. Those who lose out in economic growth want to eliminate these losses, but this can only be done by halting growth, which threatens to create losses. Thus, either individually or in groups, society's search for economic security leads to a reduction in the real rate of growth by generating a tendency to create a ossified society which is largely unable to adapt to new conditions. For example, L. Thurow calls this phenomenon the inability to play a zero-sum economic game (L. Thurow 1980). The economies of developing countries undergoing economic transition are a good laboratory for assessing the impact of alternative economic policy approaches and market evolution on the economic health of enterprises (M. Bałtowski, M. Miszewski 2007).

The transforming economies of Central and Eastern Europe are countries with multiple barriers that are the remains of the socialist economic system. However, it is often possible to point out important similarities between the changes taking place in these countries and those taking place in countries which are advanced in the development of a market economy. The changes in economic structures are the result of numerous, significantly different and separate processes. The legacy of the planning economic system is the backwardness associated with the development of the services sector, which has made up for its development significantly in response to the needs of developing business in the country and the freedoms carried by law for private enterprises. Deregulation has been widely undertaken, often as part of a structural adjustment programme, mainly with the aim of relieving market economy mechanisms of their regulatory constraints and making fuller use of their developmental potential. The scale of the impact of regulation on economic growth was strongly influenced by the quality of state management, including sectoral regulation (H.

Jalilian, C. Kirkpatrick, D. Parker 2006).The aim of the article is to indicate and determine the possible relationship between the regulatory burden, generally understood as state control[1], restrictions on entrepreneurship, prohibition of free trade and investment, and the shape of the structure of selected Central and Eastern European economies.

The conditions for structural change in transforming economies.

The economic transformation of post-socialist countries has forced the reallocation of their production factors. The transformation is often presented in Polish literature as "a process of successive elimination of structural deformations" remaining after the period of functioning of centrally planned economy. Companies were "sensitized to efficiency" (P. Glikman 2002; P. Glikman, A. Lipowski 1997; S. Gomułka 1998).

The literature has identified numerous factors determining the evolution of the structure of the economies of the transforming countries. As in developed economies, structural changes are caused by two main factors, i.e. changes in labour productivity caused by technological progress and changes in the structure of consumption. These variables were influenced - in turn - by a series of events that, by changing their sequences and intensity, shaped the final picture of the structure of the economy. Table 1 presents the most important factors shaping the structure of the economy by influencing changes in productivity and consumption structure in the developing economies of Central and Eastern Europe.

Source: Own study

The deepest changes in the product structure of the economy occurred in the industrial sector. Industry has been the one that has seen the strongest change in labour productivity, and it is also the one that has seen the most income changes in the economy. Alongside changes in the volume of internal demand, exports were a strong factor of change. The reorientation of exports took place against the background of a sharp decline in exports of highly processed goods, i.e. machinery (previously exported to the Comecon countries[2]), towards unprocessed and partially processed products, which were in demand in the competitive markets of Western European economies. In Poland, there was mainly a decline in the production of goods previously exported to eastern markets, and over time, the production of machinery and products from the chemical industry gradually gained positions in western markets. In Hungary, the 1995 reform package resulted in a decline in textile, chemical and several other industries, but exports included the production of more technologically advanced goods. In the Czech Republic, on the other hand, many more industries were reduced after the cessation of trade with the Comecon countries, and the largest resumption of production took

place in the transport sector. In Slovakia, the greatest fall was recorded in arms production. Signs of trade revival in the country were seen in foreign investment in the transport and light industry.

In post-socialist countries, the emergence of new, smaller companies, the use of existing technology and equipment for contracts with Western companies, the emergence of new foreign investment, mainly in the automotive, electronics and electrical sectors[3], has resulted on the one hand in increased industrial production dynamics. On the other hand, however, it has made production in these countries largely dependent on foreign capital, which, based on low labour costs, has drained profits and wages abroad.

In the market economies of today's highly developed countries, the impact of two decisive factors on changes in the structure of production and employment has varied from changes in productivity to profitable elasticity of demand (Engel's law) or saturation of demand (J. Fourastié 1972) to changes in the structure of demand. In post-socialist transformation economies, the main factors of changes in the structure of employment remained most often unchanged (changes in productivity, changes in the structure of demand), while the broadly understood specificity of the transformation process itself, as well as completely different economic conditions, meant that the stylized facts occurring in transformation economies differed from those that took place in today's already highly developed world economies. The specificity of the post-socialist transition process with regard to structural change was based more on the emergence of market demand for products and services as a result of the market price mechanism (marketisation of prices) than on a change in global demand as a result of an increase in society's income (E. Kwiatkowski 1980; A. Lipowski 1994; A. Karpiński, S. Paradysz, J. Ziemiecki 1999). The structure of demand revealed in this way, after a break in the development of the market economy during the socialist period (which did not result from an increase in GDP *per capita* and real economic changes, but from the marketisation of prices[4]), led directly to changes in the structure of production and employment. In addition, increased competition led to an increase in productivity, mainly due to an increase in economic rationality of labour factor management (decrease in over-employment) (A.B. Czyżewski, W.M. Orłowski 2000). Organisational changes in forms of economic activity resulting from divisions and bankruptcies of state-owned enterprises[5] had their significant share in the increase in labour productivity. The opening of the economy to the world and the inflow of foreign capital, as well as the liberalisation of trade, and in particular the process of integration with the European Union, implied changes in the structure of demand (related to trade) and the structure of production, and thus also the structure of employment (E. Kwiatkowski 1980), and, moreover, opened developing economies to competition from highly developed economies. As a result of these changes, productivity growth determined the extent to which individual sections of the economy could benefit from increased demand, increasing production and employment. Production, whose productivity levels were outstripping external competition, was eliminated from the market by imports, which resulted in an increase in domestic production and thus employment below that of demand.

Materials, methods, results and discussion

In the post-planning economies of Central and Eastern Europe, changes in the structure of employment have not been accompanied by sufficiently strong phenomena of a decrease in the share of agriculture in production and employment. The share of industry in production and employment remained, however, at a level which moderately stimulated increases in labour productivity. However, phenomena characteristic of premature deindustrialisation and servicing have begun to appear.

Table 2 presents an outline of changes in the structure of production and employment in selected post-socialist transformation countries.

On the basis of the results of research on changes in the real structure of the economy presented in Table 2. a very unfavourable situation can be observed in the Polish economy in relation to the agricultural sector. Although its share in total production in 2019 was relatively low (2.6%), with (2.8%) in Slovakia and the lowest in the Czech Republic at 2.2%. It is among the four analysed countries that, in terms of employment, the agricultural sector in Poland remained at worryingly high levels, reaching more than three times higher than in the economies with the lowest shares (Slovakia, the Czech Republic) or on average in the euro countries. This reflected the poor performance of productivity factors in this sector of the Polish economy. The Slovak economy, where the decrease in the share of agriculture in total output was the largest among the countries analysed, recorded the highest increase in the share of the services sector in total output, while the share of industrial production decreased. In Slovakia, the processes of deindustrialisation and servicing have been most pronounced, including the strongest in 2005-2015, and even more so than in developed euro area countries. Signs of de-industrialisation have also clearly emerged in the Hungarian and Polish economies, with a fairly stable or slightly declining share of industry in both production and employment. The transfer of labour from agriculture and industry to services seems to have been fairly smooth in the economies of the Czech Republic, Hungary and Slovakia. The production and employment structure of the analysed economies, which was the most suitable to the structure of developed economies, for which the group of 19 euro countries was assumed in this article, was formed in the Czech Republic. In the Czech economy in the whole analysed period 1995-2018, on average about 25% was the share of industry in total production, and the share in total employment was on average over 26%, and was higher than the share in total employment of the Euro area-19 countries, while the share in total employment of agriculture decreased from 5.3 % in 1995 to 3 % in 2018. This shows that the transfer of labour from agriculture to services was relatively efficient, because the service sector was able to absorb all labour force displaced from other sectors of the economy. It can therefore be concluded that the mechanism for changing the real structure of the Czech economy worked very smoothly, just as it did in highly developed countries. Slovakia and Hungary are the economies which, as the next in the analysed group of countries, have most developed similar structures to those in developed countries. Poland remains among the analysed countries the economy with the most unstable, even inhibited transfer of labour from agriculture to industry (more than 9% of the employed in agriculture in 2019 and on average in the whole analysed period 1995-2019 at about 15%, with the share of agriculture in total production at 2.6% in 2019). This indicates that a large labour force has been trapped or is stored in the agricultural sector, as services are unable to absorb the entire labour factor pushed out of the sector. Therefore, it is legitimate to say that the mechanism of changes in the real structure of the Polish economy did not proceed as in the highly developed countries, causing a clear real divergence with them. In the Polish economy, the phenomenon of immature servicing is also manifested - a relatively high share of services in production, with a relatively low share of services in employment.

Measuring economic regulation in the markets

The presence of the State in the process of pro-growth stimulation is manifested, firstly, as to stimulate and safeguard competition in naturally competitive markets and, secondly, to create and guarantee the smooth operation of mechanisms to ensure conditions close to competition in markets where monopolisation brings socio-economic benefits. The sources of structural change can, therefore, be seen in the form that the regulation of the most important areas of the economy, the regulation of markets in individual economies, has taken.

Two types of regulation indicators will therefore show the scale of the regulatory burden in selected post-socialist economies. The indicator relating to the regulation of product markets consists of a set of component indicators which measure the extent to which state policy intensifies or inhibits competition in naturally competitive product markets. These indicators reflect consistent measures of regulation across the economy and the market environment for 1998, 2003, 2013[6] and 2018[7].

The General Indicator for *Product Market Regulation (*PMR) includes three indicators reflecting areas that directly determine the strength of regulation, such as: *State Control, Barriers to Enterprise Development, Trade and Investment Development Barriers*. Each of these three areas of economic regulation is made up of formative factors. The *State Control framework* includes data on *Public Property* (Scopes of State Enterprises, Government Involvement in Network Industries, Direct Control of Enterprises, Governance of State Enterprises), Involvement in Business Operations (Price Controls, Ordinance and Control Regulations). The measurement of *Barriers to Enterprise Development* includes *the Complexity of Regulatory Procedures* (Licensing and Authorisation System, Communication and Simplification of Rules and Procedures), *Start-Up Administrative Burden* (Administrative Burden on Corporations, Administrative Burden on Sole Operations, Service Sector Barriers), *Regulatory Protection of Incumbent Entrepreneurs* (Legal Entry Barriers, Antitrust Exemptions, Network Sector Barriers). Indicators reflecting the state of regulation relating to *Trade and Investment Development Barriers* measure *Open Trade and Investment Barriers* (Foreign Direct Investment Barriers, Customs Barriers) and *Other Trade and Investment Barriers* (Different Treatment of Foreign Suppliers, Trade Enhancement Barriers) [8].

Regulatory load indicators in the network sectors, i.e. energy (electricity, gas), transport (aviation, rail, roads), communications (post, telecommunications). The measurement of regulation at sectoral level is carried out within several categories of regulation: *Input Regulation, Public Property, Vertical Integration, Market Structure, Price Control*. However, entry regulation, public ownership, vertical integration, market structure is measured for the entire energy sector and rail transport, entry regulation and public ownership is measured for air transport, entry regulation, public ownership and market structure is measured for the communication sector, entry regulation and price control is measured for road transport[9].

Regulation in selected developing economies

When assessing structural changes according to economic criteria, it is possible to focus on analyses of the direction and pace of changes in the structure of the economy itself (qualitative and quantitative structural changes and correlations between those changes and the impact of institutional factors - market or state regulation), as well as on analyses of the efficiency and effectiveness of economic institutions in the context of their impact on the structure of production (direct causal relations between changes in institutions and structural changes taking place with them) (W. Jakóbik 2000).

Tracking developments in product markets, which are characterised by natural competitiveness, and in network industries with strong monopolistic burdens, can be an important part of the structural changes taking place in the socialist economies.

Table 3: OECD indicator for regulation of product markets from selected countries for years: 1998, 2003,2013, 2018

Source: http://www.oecd.org/economy/reform/indicators-of-product-market-regulation/ (as at 05.11.2020)

Of those analysed, the economy that was most burdened with regulations turns out to be the Polish economy - an economy with a production and employment structure that is most distant from that of developed countries. However, the Czech Republic's economy, classified as the one with the closest real structure to that of the euro area countries (where the mechanism of changes in the structure of the real economy followed the patterns of developed countries), cannot be classified as one with the lightest regulations, which is particularly evident in the regulations of network sectors. Hungary and Slovakia, respectively, show the weakest regulation in comparison with other analysed countries. The results of the presented studies indicate that there is a clear correlation between the course of the process of changes in the structure of real CEE economies and the level, and particularly the relevance (analysis of the Polish economy *versus* the Czech Republic), measured by the economic efficiency of regulation. The effectiveness of the desired and intended effects of regulations determines, as indicated by the analysis, the direction and pace of structural changes, especially in economies undergoing systemic transformation.

Too early, rigid regulation may hamper initial productivity increases, cost reductions and profit increases. However, regulation is necessary in the initial periods of growth, in a situation of threat from dominant market players. Appropriate identification of appropriate paths of interdependence between capital and labour in the simple pursuit of higher investment lays the foundations for the degree of efficiency of structural change in the country. The regulations are integrated into the pattern of structural policy in the country, where the factors stimulating and impeding the development of the economy are hidden in the structure of production and employment. These factors, which are conditioned by the historical context, are strongly interlinked, so that overcoming certain constraints may provide a good basis for opening up new opportunities on the one hand, while exploiting certain stimulating

opportunities may give rise to production structures that are not burdened by constraints on the other. The intensity of these interdependencies depends on the degree of diversity of production systems at different levels of aggregation of production activities (A. Andreoni, R. Scazzieri 2014).
This reveals the need to be cautious, to constantly observe how society, the economy and the political system react to the stimuli created by regulations.

Summary

G. Majone pointed to a redefinition of the role of the state as a key economic actor, leading to structural changes (G. Majone 1997; G. Majone 1994). Different levels of economic development determine the roles of the different drivers of economic growth and the different role the state has to play. Tracing the competitiveness levels of economies distinguished by M. Porter (factor-based growth stage, investment stage and innovation stage) shows the evolution of the state's participation in the economy from providing stability and basic legal and economic infrastructure for success in the first stage of development, through activation in the area of supporting industries and enterprises with the highest growth potential and in the area of the permeability of financial channels, labour markets, existing education and technology, to the creation of the right set of institutions combining the capabilities of the government, the educational system, the academic research base and private enterprises for each country. A special role is played by the entire regulatory system when it comes to the constitution of an innovation economy where the market does not function, because you simply do not have it. For example, the emergence of a market (demand and supply) for energy from renewable sources requires appropriate regulations which, as in most innovations, must create / guarantee primary supply and demand until the innovation becomes a mass product (M. Mazzucato 2016). Imported productivity increases in the economies under consideration, based to a great extent on incentives for foreign investors in the form of low wages, are approaching or have already run out of potential, and the attention of the governments of these countries is now being focused on domestic sources of multiplication of innovation seen as an engine of development. Further growth is seen in strengthening the industrial sector of the economy towards innovation.

[1] State presence through public ownership and interference in economic decisions.
[2] The Council for Mutual Economic Assistance existed between 1949 and 1991. Its aim was to integrate the Eastern Bloc countries under the leadership of the Soviet Union. Particular emphasis in the statute of the GCC was placed on accelerating technical progress, industrialisation, labour productivity and economic prosperity in the Member States.

Abstract

OECD research into the production structures of highly developed countries for the years 1950-1995 shows that they are subject to the phenomenon of agrarianisation, industrialisation, stabilisation of industry's share of GDP, deindustrialisation and servicing. The most recent research of the economies of the catching up countries for the years 1995 -2020 has shown that the course of these processes may have different patterns, and the direction of structural changes, as well as economic effects.
The aim of the article is to define the criteria for the desired structural changes, and to assess the difference between economies in the real structure of the economy, that is to say the course of economic evolution processes.
In its initial part, the evolution of changes in the structure of employment (evolution of the economy) is presented in the context of its directions and main determinants. In the further part, the role and importance of industry in the structural changes of market economies is described. In the final part, different from the literature presented so far, the assessment of structural changes in the context of their economic consequences is outlined.

Keywords: prevalent phenomena, prevalent factors, real price, agrarian era, evolution of economy, allocation of production factors.

- ***"If society is to benefit from the effects of technological and economic progress, there must be a continuous transfer of factors of production in a dynamic economy in the most efficient way, under the threat of economic crises.***

Introduction

OECD research into the production structures of Western countries for the years 1950-1995 shows that they are subject to the phenomenon of agrarianisation, industrialisation, stabilisation of industry's share of GDP, deindustrialisation and servicing. The agrarianisation in connection with the domination of agriculture in the initial stages of economic development of Western countries, with the need to intensify development rather than expansion due to natural barriers and with changes in the structure of population consumption as it moves towards higher and higher levels of income to the detriment of the share of food is "an over-systemic regularity of any economy" . Industrialisation has taken place in more developed countries (France, Austria, Italy) at around USD 8 000 to 12 000 of GDP per capita (at constant 1990 prices), in poorer countries (Spain, Greece, Portugal) at around USD 3 000 to 6 000. The stabilisation of the share of industry in GDP shows the saturation of the structure of demand in the economy with industrial production, which in the first group of countries mentioned above was around USD 12-15 000 of GDP *per capita*, in the second group at around USD 6-8 000. The deindustrialisation achieved in economically more advanced countries[1]at around USD 15 000 of GDP per capita, in less developed countries at around USD 8 000 of GDP *per capita* resulted from the installation of dynamically developing sectors in the structure of the economy more than industry and agriculture, which was also fuelled by the relocation (*reemployment*) of processing industry. The servicing accompanying deindustrialisation is the result of the expansion of mainly financial and business services, accompanied by the advancement of market institutions (A. Lipowski 1998; 2000). Recent studies of catching up economies for the years 1995-20-20 have shown that these processes can have different patterns and direction of structural change as well as economic effects (G. Dosi, F. Riccio, M.E. Virgillito 2020). The aim of the article is to define the criteria for the desired structural changes, and to assess the difference between economies in the real

structure of the economy, that is to say the course of economic evolution processes. In its initial part, the evolution of changes in the structure of employment (evolution of the economy) is presented in the context of its directions and main determinants. In the further part, the role and importance of industry in the structural changes of market economies is described. The final part outlines the concepts, different from those presented in the previous literature, of the assessment of structural changes in the context of their economic consequences.

Theoretical Basis, Methods, Results and Discussion

Changes in the structure of employment in market economies - directions and factors of change.

In the humanities and social sciences, there is no uniform time - there are no periods at the end of which events are repeated identically (events never have the same form in time), which means that time is different. None of the periods defined in time is therefore homogeneous. Moreover, events are distinct and autonomous even when they are not independent, which means that they have their own characteristics, evolutions and *sui generis* behaviour. Therefore, it is impossible to know the overall problems (general price movements, global crises, general competition, global production), as countless factors would have to be specified. J. Fourastie proposes to look for autonomous events and prevailing phenomena in economics. Preponderant phenomena are characterised by two basic characteristics. Firstly, these phenomena are common to a large number of complex phenomena. Secondly, they accumulate, which means that they cause effects that grow despite changing circumstances at the time and place. It should be borne in mind, however, that if time is not homogeneous in social sciences, the prevailing phenomena will not be constant over time, which means that when they occur over a very long period (one hundred years, for example, in economics) they are poorly captured in the medium term (five years) and completely insignificant in the short term (six months), and it should be noted that their severity will depend on the pace of change in economic conditions. Following this line of reasoning, it would be unreasonable to seek to identify the desired changes in the structure of the economy before first exposing the key determinants of its changes (phenomena / prevailing factors) and understanding the mechanism of the process of evolution of economic structures. Figure 1 below shows how productivity, on the one hand, and consumption at the turn of 200 years, on the other, shape employment in agriculture.

Figure 1

Source: Own calculations based on; OECD, GUS (Statistics Poland)

Productivity, consumption and employment in relation to one basic reference product in the agricultural sector or for the agricultural sector as a whole.

This graph shows how the employment equation: *e-t* stands in contrast to the productivity equation: ^{et}. Thus, we obtain one type of employment curve as in the graph (whether for a given agricultural product or for agricultural production as a whole), where productivity results in production levels outweighing consumption, and a completely different type of curve would be formed under conditions where consumption levels outweigh production levels.

As can be seen in the graph, the change in employment is the ratio of the change in consumption to the change in productivity ($\Delta S / \Delta W = \Delta Z$, where S - consumption, W - productivity, Z - employment), and that, in reality, supply and demand should balance under the threat of crisis and unemployment for each product, the volume of production, which is the measure of supply, must equal the volume of consumption, which is the measure of demand. Assuming that productivity is the ratio of the change in production to the change in employment ($\Delta Q / \Delta Z = \Delta W$, where Q - production), we can say that the condition of balancing supply and demand causes a greater increase in ΔS than an increase in the ratio of$\Delta Q / \Delta Z$ will result in an increase in production, an increase in employment. On the other hand, a smaller increase ΔS than an increase in the ratio $\Delta Q / \Delta Z$ will cause a decrease in employment while increasing production.

The stagnation of food consumption at a constant level was argued by J. Fourastie in the economies developed today by a steady or small increase in population and a physical reduction in the consumption of food products by individuals. In the first stages of the period of industrialisation, the rapidly increasing rate of demand for industrial goods with a much slower rate of productivity growth in industry resulted in a large increase in employment in the sector. This situation is presented in -

Figure 2

Source: Own calculations based on; OECD, GUS (Statistics Poland)

They resulted in strong productivity gains in industry. Looking at the graph above, we see that, over time, productivity growth is beginning to overtake consumption, causing production to start exceeding demand. Then the employment equation contrasts, as in the previous case, with the productivity equation, and begins to fall, which ultimately gives the employment curve a pathway to asymptote 0. In manufacturing, although consumption does not stay constant as in agriculture, productivity growth is still increasing, (technical progress has the strongest impact) while consumption growth is decreasing. This ever-growing gap between the productivity growth rate and the consumption growth rate causes employment in industry to start to fall, as industrial production starts to outweigh demand.

Figure 3

Source: Own calculations based on; OECD, GUS (Statistics Poland)

As can be seen from the graph above, ever-increasing consumption and small to zero productivity increases in services are causing the sector to experience continuous employment growth, first at the expense of the agricultural sector and then of industry. As demand in services is constantly increasing and as it seems to be unlimited, with very little impact of technological progress, this sector will continue to absorb labour displaced from agriculture and industry. The increase in production in services will depend on employment in the other two sectors.

A phenomenon that has transformed the world over the last 200 years and has also been a predominant factor has been technological progress. The second factor is the changing structure of demand. The distinction between the three major types of response to changes in technology and consumption[2] is a fundamental criterion for separating the main sectors of the economy, because productivity and consumption are those phenomena in the economy that also determine the changes in the structure of the economy as adopted. Due to the three types of response, the entire economy can be divided into three sectors. Agricultural products, although not all of them, of course, but most of them, have a primary response, so agriculture as a whole will be the first sector of the economy. The second sector of the economy, which has a secondary response, although, as in agriculture, not all its products have this type of response, is industry as a whole. Services in which the tertiary response is predominant will constitute the third sector of the economy(J. Fourastie 1972; 1954).

Figure 4

Source: Own calculations based on; OECD, GUS (Statistics Poland)

The chart of primary goods illustrates employment in the agricultural sector, secondary goods in industry and tertiary goods in services. Analysing the typical employment trends in these three sectors, it becomes apparent how technological progress and changes in demand shape the structure of employment in the long term. Employment in the third sector (services), with no restrictions on the demand side, is determined by employment in the other two sectors. This means that services will absorb all the labour force, driven out of the other sectors.

The above table shows in more detail, in relation to Figure III, the changes in the structure of employment for selected of the most developed economies, and the Polish economy. Noteworthy here is the period between 1960 and 1970, where, although employment in agriculture fell in the most developed economies and services grew, there was a steady increase in the share of total employment in industry, and even in some countries compared to 1950, such as the United States, its growth. This was mainly due to a demand-driven policy towards industry, which undoubtedly contributed to the crisis of the 1970s, compounded by the rise in raw material prices. This crisis was characterised by rising prices and stagnation. The liberalisation of world trade, which began in the 1970s, accelerated deindustrialisation processes through relocations from highly developed countries to developing countries, mature industries in which the rate of productivity growth was significantly slowed down and their share of world consumption was dependent on the price of labour. In their place, in line with industrial development, new industries (industrial innovations) were created, recording very high rates of productivity growth. All in all, since the 1970s, industrial productivity started to grow strongly and with it the share of industry in employment started to fall. The exception for highly developed countries is the increase in the share of industry in employment (between 1990 and 1995 in the German economy). However, this phenomenon is explained by a large and sudden increase in consumption resulting from the merger of Germany (West Germany) and the GDR (East Germany belonging to the block of socialist countries before the merger), where (in the GDR) the demand for industrial products was highly insatiable. The causes of the crisis of 1990 and 2007 also have their structural origins, but they overlap with the fight against inflation and the liberalisation of financial services, which is beyond the consideration of this work.

Changes in the production structure in market economies, directions and factors of change - importance of industry.

As we have seen so far, increasing productivity and stagnant (or slightly increasing) consumption are leading to a decline in employment. By contrast, a fall in employment inevitably entails a fall in prices. For if income per head is taken as one, price is the quotient of employment divided by the volume of production. Thus, if employment falls and production volumes rise, prices must fall (as a result of productivity growth). The supply-demand balance condition is that, when consumption stops at a constant level and there is a continuous increase in production, there is a continuous increase in productivity, resulting in a fall in employment and therefore in prices. The price evolution is shown in Figure 5.

Figure 5

Source: Own calculations based on; OECD, GUS (Statistics Poland)

The price changes over time are represented by real prices, which are the quotient of the current price divided by current hourly wages. The price scale, on the other hand, determines the value of the ordinates for the relevant years, so it will be different for each of the three curves. This is not a matter of accuracy in detail, but rather of plotting the different types of price responses of agricultural, industrial and service products in time and space to changes in productivity and consumption. As can be seen from the graph below, the prices of agricultural products have been starting to fall in the long term since 1800. Before 1800, they varied little from country to country. Today, however, these differences are very large. For example, the real price of a quintal of grain before the first industrial revolution was 200 wage hours, and by 1950 it was 25 wage hours in the most developed economies. By contrast, it was at a much higher level in the less developed economies. Therefore, today the price differences between countries are very serious. An example of this is not only grain, but also potatoes, fruit and vegetables. We can also see how the prices of industrial products show a strong downward trend over time, under the influence of technological progress. As in the case of agricultural products, in the past, the range of prices for industrial goods between countries was small, but today it is even extremely high as a result of differences in productivity levels between different economies. If, before 1800, the price of the mirror in all countries was 36 600 wage hours, then in 1950 it was already 200 wage hours in the most developed economies. The price of iron, aluminium, electricity and cars is also an example. We see a fundamentally different type of reaction for the price of services. They do not change at all, or very little even over a very long period of time, because the impact of technological progress on them is very small. As the prices of services have not changed over time, they have not changed in space either. Therefore, they are the same for highly developed and less developed countries. An example of this is the decorative fabric. Only differences in exchange rates make them expensive in highly developed countries and cheap in countries at a lower level of development. The current situation of economies at different levels of development is presented in the projection (A-Poland, B-Spain, C-France) on curves representing the most developed countries (US, UK, Germany). Thus, through differences in real prices, a lag in development (caused by differences in productivity levels) is visible. As a result, prices for agricultural and industrial products will be higher in countries with lower levels of development. For example, the lag in Poland's economic development means that the prices of products affected by technological progress are at the same level as they were in the most developed countries about 30 to 40 years ago.

Changes in the structure of employment and changes in relative prices between different sectors of the economy change their share of total output at current prices. As can be seen in Figure VI (below), there is a continuous decline in the share of agriculture. The share of industry first increases to a maximum and then begins to decrease. The share of services has a growing trend throughout the period. The shares of individual sectors in total output in current prices coincide with their shares in total employment. However, the fall in the share of agricultural production is not due to a fall in real production, but to the fact that it has remained stable and prices have fallen. By contrast, the decline in the share of industry is mainly due to the fall in prices. And, the real volume of production is constantly increasing, as a result of constant increases in productivity. The increase in services is due to increased employment and rising prices.

Source: Own calculations based on; OECD, GUS (Statistics Poland)

The table below, which describes in more detail the changes in the shares of individual sectors of the United States economy in output at current prices and in constant prices between 1970 and 20018 , shows clearly that, despite declines in the shares of industrial production in current prices, its value in constant prices (adopted even in 2000) does not change. The same is true of agricultural production. We can therefore say that, despite the declines in the industry's share of total output in current prices, its real production volume is constantly increasing.

Table 2 Share of sectors in total production, in % for US between 1970 and 2018

As the process of deindustrialisation continues, productivity growth in the economy will increasingly depend, not so much on productivity growth in industry as on productivity growth in services. In contrast, the evolution of service sector productivity will depend on future developments in areas such as information technologies and changes in the competitive structures of the sector (R. Rowthorn, R. Ramaswamy 1997). However, according to Kaldor, the rate of productivity growth in the whole economy depends on the expansion of the industrial sector, which not only leads to faster productivity growth in industry (operation of Verdoorn's law[3]), but has a dispersion effect on the whole economy.

In Search of a Pattern of Change in Employment Structure

The assessment of structural change from the point of view of its impact on opportunities for increasing economic prosperity is a key area of research into economic structures. Therefore, the issue of developing reliable criteria for evaluating these changes remains strategic. Comparing changes in the structure of employment in Poland with

changes in economic structures in more advanced countries, i.e. such as the EU, for example, is burdened by the mistake of imposing structures that have already been formed in advance (in conditions that are sometimes completely incomparable) and the lack of argumentation from economic facts (stylised facts - data provided by statistical offices) to support them, because from where the crises and the impossibility of ending them come. Accepting as model structures established in EU economies, without reference to the specific internal conditions of a given economy and external conditions, leads to errors of doctrination and is not supported by both theoretical and empirical foundations, which will be done in this chapter. On the other hand, from almost 200 years of development of free market economies, we can adopt the main determinants of these changes (explain the prevailing factors), which will then make it possible to define the criterion of positive structural changes, both objective and desirable at a given time and economic conditions.

When we add to the theoretical analysis of the aforementioned phenomena accompanying the changes in the structure of production and employment observed in developing countries, the changes in the structure of consumption (because its size is both a determinant of these changes and a criterion for the desired directions of these changes), the question of defining positive structural changes for the long-term development of the economy will be more transparent. For, as was shown earlier in the theoretical part, it is only when an increase in productivity results in the volume of industrial production exceeding the volume of demand for its goods, which means that demand has been saturated and the rate of growth of production exceeds the rate of growth of consumption, that the condition of balancing demand and supply causes employment to fall there and prices to fall with it. After all, until the moment when demand for industrial goods was not saturated in today's highly developed countries, production and employment grew, and industry was the most important engine of economic growth. This was because the order of things is that it was the large and constantly growing demand for industrial goods that caused the increase in production and employment in industry, and that the impact of technological progress (as has been shown earlier) is the greatest there, the increase in industrial production causes the greatest rate of GDP *per capita* growth. Therefore, if, with a large and dynamically growing consumption of industrial goods, production increases only as a result of productivity growth, and employment falls (economic growth without employment in industry should take place only with a stabilised consumption of industrial production in a given economy), there will be (unfavourable changes) - labour force will be displaced from industry (deindustrialisation with a very small GDP *per capita*) and there will be no possibility of its complete absorption by services. In such an economy, instead of dynamically growing also due to the increase in employment in industry at a stage when the consumption of industrial goods is growing faster than the production volume, it is growing much more slowly due to the unemployed growth of industrial production, although sometimes due to erroneous comparisons its rate seems to be impressive (e.g. comparisons with the current rate of growth in highly developed countries). Too low a level of income *per capita* means that the increase in the consumption of services is not so great that the demand for labour can rise there in order to absorb all the labour force pushed out of industry. We know (from previous considerations) that an increase in income causes a change in the structure of expenditure and an increase in demand for services, which increases the demand for labour in this sector. The phenomenon of deindustrialisation at a very low level of income *per capita* and jobless growth of industrial production in developing countries (in some cases) can be explained by the liberalisation of trade with real structures (productivity levels) too far removed from the highly developed countries.

Competition from products imported from highly developed countries is insurmountable in the short term, so that production growth only takes place under the influence of productivity growth, caused by a fall in employment. As a result, developing countries in which the growing consumption of industrial production is not used to increase employment and production, but is taken over by imports, are unable to achieve the high level of GDP per capita that the developed countries had at the time of deindustrialisation. With increasing imports, there is a trade deficit, which must be offset by exports or a surplus in the capital balance. If this is done by exports, it is mostly labour-intensive production in developing countries. And if the balance of trade between developed and developing countries were to be offset in man-hours (depending on differences in productivity levels) it would be: 200 man-hours to 20 man-hours. This looks much worse when the trade deficit has to be reduced by a surplus in the capital balance, as this in turn forces an increase in the interest rate, which weakens investments (e.g. what a large return on investment would have to be in Poland in 1995, when the interest rate was 30%) and a currency appreciation, which further increases imports. Penetration of developing economies by imports also takes place when, ignoring the differences in real structures, the nominal structures are being sought to equalize. Worrying phenomena related to structural changes in developing countries may also be caused by the policy of equalizing nominal structures at all costs (e.g. constantly strengthening the national currency) before full real convergence - costs are disproportionate to profits - as is the common currency with widely differing real structures. However, a full (satisfactory) explanation of why deindustrialisation is taking place in developing countries with very low *per capita* income levels and jobless industrial growth requires, in addition to a broader theoretical analysis, an empirical analysis of the factors of structural change in specific economies, which goes beyond the framework outlined in this article.

Summary

To sum up, the theoretical considerations on the criteria for desired structural change, and they are so transparent that we can say that there are positive structural changes based on both productivity and consumption, which determine the desired structural change if society is to benefit from technological progress, if the industry's share of production falls only as a result of falling prices when real production increases, and its share of employment falls when demand for its products stabilises (when production volumes exceed demand) and there is a sufficiently high level of income *per capita to allow* it to absorb all the labour force pushed out of industry.

[1] with the exception of Italy, where the share of industry has been increasing throughout the 45 years of the OECD study

[2] three types of reference reactions: primary, secondary and tertiary. The first type of reaction - primary, characterises products that have a triple property: they are agricultural products, they have been affected for 150 years by major technical progress, but less than most industrial products, their per capita consumption has reached its maximum in highly developed countries. The secondary one, the next type of reaction, forms the majority of industrial goods, where technical progress has a very high impact and consumer demand has a growing tendency. And the last, tertiary reaction type characterises products and services that have a dual property draw very little from technical progress, and consumer demand is growing strongly without signs of slowing down.

[3] faster production growth increases productivity due to increasing economies of scale

Abstract

Virtual tools that allow the implementation of innovative solutions (e.g. in the configuration of the arrangement of machines or room re-planning in order to modernize the production plant) come to the rescue. The result of a system analysis of technological processes is the need for a rational and safe arrangement of machines, devices and technical equipment. To assess the functioning of all components in the conditions of computer simulation. In the process of designing technical systems, computer programs that enable the visualization of implemented projects play an increasingly important role. One such program is the Factory I/O.

Keywords: warehouse, transport, mechanical engineering, organization

Introduction

The dynamic technological development causes that new development concepts are constantly being created, and the time of their implementation should be as short as possible (Sacco et al., M., 2010). In fact, however, this time is still long, due to many factors. One of them is the need to build prototypes, projects presenting functionality (Drath and Horch 2014). Virtual tools that allow the implementation of innovative solutions (e.g. in the configuration of the arrangement of machines or room re-planning in order to modernize the production plant) come to the rescue (Jiang et al. 2014). The result of a system analysis of technological processes is the need for a rational and safe arrangement of machines, devices and technical equipment. To assess the functioning of all components in the conditions of computer simulation. It takes on particular significance in internal linking and locations in the spatial white technical systems, processes, transport, handling and organization of surface storage (Riera et al. 2016). Construction of a production plant requires the creation of a new spatial layout on production lines or warehouses. Often, the high complexity of a production plant makes it difficult to analyse the current state of a given system of production or logistic units and the forms of their internal connections in a purely theoretical manner. Computer software for building a digital model or a virtual factory can be helpful in solving such problems (Bengtsson et al. 2010).

In the process of designing technical systems, computer programs that enable the visualization of implemented projects play an increasingly important role. One such program is the Factory I/O (Arango et al., 2008). It represents advanced and modern development environment, which makes it possible to create and simulate the real-time industrial systems using the most popular technologies automatically (Rüßmann and Lorenz 2019). It allows you to design and program the operation of the production line, transport systems on production lines and high-bay warehouses. It is possible to connect to a PLC controller and test the operation of such a system in computer simulation conditions (Wiendahl et al. 2015). Thanks to high-quality graphics and sound as well as implemented physics, this fully interactive simulation perfectly reflects the industrial reality (Fig. 1).

Fig. 1: An example of a project showing a warehouse stacker crane

The program is ready for more than 20 scenes that can be used in designing through their modification, of course you can create your own e scene from the ground (Fig. 2).

Fig. 2: Program library with ready-made scenes

The tool library used for programming contains elements that are necessary to build and simulate technological processes. There are: conveyors, sensors, manipulators, buttons, control panels, fences, platforms, palletizers, stacker cranes and tanks. In addition, it contains details that can be used in the simulation of sorting and transport systems. In total there is there p thence 80 industrial machinery and equipment.

Fig. 3: Examples of the tool library items

The control program in the visualization program can use PLC controllers of most manufacturers (they communicate with the program via the Ethernet interface) or a dedicated CONTROL I/O extension. It allows you to program visualizations using a virtual driver. For programming, the program uses a method that resembles Functional Block Diagram (FBD) programming in its structure, appearance and operation. The program is modelled on schematic diagrams, and it consists in an appropriate combination of blocks and control elements, which corresponds to the programmed function. These include timers, counters, Bool's algebra blocks, flip-flops and memories.

Design assumptions of the designed sorting system

Internal transport is one of the main pillars without which none of the manufacturing companies would be able to exist on the market. Such transport consists of activities aimed at continuous or intermittent flow of elements (materials), taking place on the premises of a given enterprise.

A properly designed, automated transport system, combined with its efficient and effective operation, ensures smooth production and increases efficiency, thus improving the company's results, which is important in its location on the production market. Internal transport is also referred to as internal or close transport. It takes place in large numbers on belt conveyors.

Conceptual system presenting a capability in the design of transport systems. It realized by control and computer visualization of the process of sorting, transport to the warehouse and automated it distribution of pallets on shelves Fig. 4. The system has been divided into two closely cooperating technical systems: sorting packages into individual pallets with palletizers and a transport line to a high-bay warehouse with stacker cranes.

Fig. 4: Pallet distribution on the warehouse shelves

Parcel Sorting System

Sorting packages on the designed technological line is carried out in two stages. The first stage is the detection and classification of parcels according to their height. In the second stage, the mass of the objects is considered. There are four types of packages in the program library. Each of the released emitters of packages differs from each other in terms of dimensions (Fig. 5).

Fig. 5: Packages used in the project: A - size S, B - size M, C - size L, D - size XS

The complete sorting line is shown in Fig. 6. It was built of a system of conveyors delivering sorted packages to four palletizers, located at the ends of conveyor belts. Palletizers place parcels on a pallet, which, when full, are sent to the warehouse with the transport system.

Fig. 6: Line for packages sorting

The process of sorting starts ny is by measuring the amount of packaging by means of the light barrier (Fig. 7A) and said segregation is carried out first. The parcels are divided into two groups, the smaller parcels are moved to the side conveyor (fig. 7B). The first group consists of S and M size parcels, and the second group includes XS and L size parcels. The next stage is segregation, this time in terms of weight. In both groups, the packages are separated. The final stage is palletization, i.e. stacking sorted packages on pallets.

a) b)

Fig. 7: Sorting packages using a light barrier: B - light barrier, B - piston cylinder moving the package onto the conveyor

In Factory I/O it is possible to program functions for stacking loads on pallets. Implementation of positioning and laying realizes palletizer by means of the actuators. Fig. 8 shows the operation of two such devices.

Fig. 8: Stacking packages on a pallet

The automated warehouse of high storage

In the program, it is possible to build a high-bay warehouse from ready-made racks to be joined and stacker cranes. They allow for the automated movement of goods placed on pallets and their placement on racks in specific places. Stacker cranes are in the form of one or two columns on which a gondola with forks moves along the vertical axis. The whole structure moves in the corridors between the racks on rails placed on the floor and under the roof supporting frame. Instead of the standard forks, the following can be used: telescopic forks with three-fold storage depth, a roller conveyor or a gripper for round bales. The technical parameters that determine the possibilities of the stacker crane are also important: lifting capacity, maximum dimensions of the load, lifting/lowering height, speed of movement, degree and speed of fork extension. The advantages of these devices include: automation of the entire storage process, constant monitoring and identification of assortment in stock, elimination of human errors, the possibility of working in unfavourable conditions. e.g. in freezers, cold stores, sterile drug stores. Thanks to automation and management programs, it is possible to coordinate the course of production and warehouse processes. Figure 9 shows the warehouse stacker crane available in the Factory I/O program.

Stacker crane on rails used for storing heavy loads. It includes a trolley, vertical platform and two forks that can be moved to both sides. Two laser rangefinders placed on the trolley and the platform measure the horizontal and vertical position of the platform. Racks are vertical steel frames connected by horizontal steel beams to store loads. The available rack is a single depth rack, also known as a selective rack, which only allows loads to be stored down to a depth of one pallet. Loads can be stored on both sides of the rack.

Each rack must be flush with one end of the rails so that the stacker crane stops in the correct position. The stacker crane can be controlled with digital, numerical and analog values according to the selected configuration. Virtual stacker crane parameters:

- s bun carriage: 1.2 m,
- s bun trolley 10.5 m,
- s bun platforms: 6.625 m,
- p nd the speed of carriage: 1.4 m/s,
- p nd the speed of carriage: 0.5 m/s,
- p nd the speed of the platform: 1.7 m/s,
- pallet on the shelf 18,
- pallet which can handle one rack 108.

Fig. 9: Stacker crane with a system of shelves

The stacker crane is controlled by several variables, shown in Figure 10. First, the place where the pallet is stored - in the presented example, it is marked as 1 (Stacker Crane 1 Target Position). The next step is to start the conveyor drive through the Forced task. If the rack is next to the place of storage pallets, pickup truck with a pallet over the place (the variable - Stacker Crane 1 Lift), then pull out the fork with t s left (Stacker Crane1 Left), has left SCIC trolley (Stacker Crane 1 Lift). The palette will sit on the orange rails. Now you can slide the forks back into the forklift and safely withdraw the forklift to its home position (Fig. 11).

Fig. 10: Placing the load on the pallet place

Fig. 11: Basic position of the stacker crane trolley

The complete high bay warehouse is shown in figures 12 and 13. There are 2,160 pallet places in it, served by 20 stacker cranes. All stacker cranes are connected by a system of conveyors responsible for delivering and collecting loads from stacker cranes. One of the most important functions is controlling three different cameras. S sluice to navigate the 3D space and are key to the interaction of the components or to create new scenes. Three types of cameras can be used: orbiting, flying - drone and first-person view.

Fig. 12: High bay warehouse - view from the drone

Fig. 13: High bay warehouse - conveyor belts for distributing loads

Control I/O Control Program

The control program in the visualization program can use PLC controllers (Fig. 14) of most manufacturers (they communicate with the program via the Ethernet interface) or a dedicated CONTROL I/O extension. It allows you to program visualizations with a kind of virtual driver. For programming, the program uses a method that resembles Functional Block Diagram (FBD) programming in its structure, appearance and operation. The program modelled on schematic diagrams, and it consists in an appropriate combination of blocks and control elements, which corresponds to the programmed function. These include timers, counters, Bool's algebra blocks, flip-flops and memories.

Fig. 14: Selection of the PLC control system

Figure 15 shows a fragment of the pallet sorting control program with a specific program structure in the form of address blocks, OR, NOT and AND functions as well as binary memory blocks.

Fig. 15: CONTROL I/O view

Each sensor or actuator has one or more tags. Tags are used to link the values of actuators and sensors to the controller. However, tags can also be used to manually control actuators.

The tag consists of a name and a value. When creating parts, names are automatically assigned to tags. It is usually good practice to rename tags with short and descriptive names as they will be used when mapping actuators and sensors to the external controller. Tags can have three different data types depending on the type of sensors and actuators and configuration:

- Boolean for on / off values,
- Float for analog values (real numbers),
- Integer for specific data.

The system control program was created as a block diagram. 41 input addresses were used, which are assigned to sensors and buttons and 27 output addresses, they were assigned executive elements such as: conveyors, transferand stacker cranes and warning devices. The whole, together with function blocks, is about 200 elements, they are: logical blocks, flip-flops, edge-controlled, timers, counters and memory blocks, as well as blocks that perform operations on numbers. The entire structure has been divided into several cooperating parts.

Summary

The use of a virtual circuit design target for logistic processes abolition of the you to the assessment adopted in a new system based on agreed criteria and constraints. The presented system solution can be assessed in virtual work conditions, which is already an aspect of logical validation of the technical solution. A key aspect of the so-called c A compact industrial revolution (also known as the digital industrial revolution) is a high degree of flexibility and the application of modern, intelligent information technologies at every stage of the production chain, from the design phase to the production of final products. Digitization of production plants, which is the basic assumption of the Industry 4.0 concept, allows companies to more effectively cope with potential disruptions occurring at every stage of the supply, production and distribution chain, and allows for rapid changes in production and logistics processes. The implementation of the virtual factory concept enables you to digitize resources, create your own libraries, animate and move around in virtual plants in 3D space, which facilitates and accelerates the execution of planned real activities (Back et al.,2010).

With reference to the above arguments, a computer visualization of a virtual logistics warehouse was designed in the FACTORY I/O program. It shows package sorting process as regards height, stacking them on pallets using palletisers and placing on the high-bay warehouse, which have been executed. In addition, CONTROL I/O has been programmed to control technical devices in order to accurately reproduce the operation of the whole.

The system simulation is mostly automated, the operator has access to the control panel, where his role is to turn on the system and observe the entire process from a platform located on the platform. Two displays inform about the stock levels of the stored pallets. For safety reasons, appropriate fences, barriers and balustrades as well as warning lights were used. The visualization shows the process in the so-called virtual reality, it allows you to simulate the operation, it will facilitate the scaling/calibration of sensors and analog actuators, as well as other software blocks under real conditions. It is worth noting the possibility of connecting a programmed PLC controller to a virtual factory model, which will also eliminate errors in the implementation of the actual technological line.

Abstract

Energy efficiency has become the main purpose of energy policy in the world. It has conditioned a policy towards energy-intensive sectors such as road transport. However, improving energy efficiency can lead to changes in the demand for energy services that would offset some of the energy savings obtained. As a result, the projected energy savings may be overestimated. The article analyzes the energy efficiency of road transport in a model service company in Poland. A common methodology was used to estimate the energy demand function using the algorithm described in EN 16247-4 Energy audits: Part 4 - Transport. The obtained results indicate that the achieved energy efficiency is largely maintained.

Keywords: Transport, Organization, Efficiency, Energy, Mechanical Engineering

Introduction

One of the common problems with sustainable development is the increase in transport volumes around the world. Transport causes many environmental problems, the most serious of which are carbon dioxide (CO_2) emissions, causing climate change and the depletion of fossil fuels. Scientific research also shows that, compared to other economic sectors, the transport sector's contribution to environmental degradation has deepened over the years (Hysing 2009). Moreover, it has been argued that transport is one of the most important sectors for the overall achievement of sustainable development (Berger et al. 2014, Lorek and Spangenberg 2001). To meet its sustainability and policy challenges, the European Union (EU 2012) has set several targets to reduce carbon dioxide emissions and increase the share of renewable fuels in transport system. Individual EU Member States, such as Sweden, for example, have decided on environmental targets and policies to increase the share of renewable fuels and promote the socio-technical transition to a less environmentally harmful transport system (Söderholm K. and Wihlborg 2015). One of the best examples is the Swedish environmental transport policy "Fossil Fuel Independent Car Fleet until 2030" This policy is about replacing fossil fuel cars with alternative fuel vehicles. The policy announced in 2009 has so far been discussed, and in some cases criticized, for being too ambitious, given the lack of real measures taken so far to achieve it (Sköldberg et al. 2013). This policy has been systematically implemented since its announcement, but little is known about supporting it by taking appropriate action. This is a problem because previous research shows that in addition to policy coherence and commitment to policy, understanding public responses to policy is important to increasing its chances of successful implementation (Hysing 2015, Cools et al. 2012, Sovacool and Hirsh 2009). Moreover, users, in this case car owners, contribute to shaping public opinion, which often shapes actions at the political level (Perlaviciute et al. 2016, Puhe and Schippl 2014).

Cite this Article as: Maciej GLINIAK, Sławomir KURPASKA, Janusz TABOR and Krzysztof GÓRKA " The Impact of Energy Efficiency of The Transport Process on The Organization and Maintenance of Vehicles in The Small Company" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

In recent decades, there has been growing interest in adopting new energy and environmental policies that stimulate the reduction of energy consumption. The main goals of these policies are to reduce dependence on fossil fuels and reduce pollutant emissions and greenhouse gas (GHG) emissions. In 2010, freight transport accounted for around 43% of global energy consumption in transport, which in turn accounted for 12% of total energy consumption and 10% of energy-related CO2 emissions. The amount of fuel used by the transport industry is expected to increase in the US and the EU, where cars emit 67% of transport-related GHG (Mitigation… 2013, McKinnon 2010).

The main way to solve these problems is to promote energy efficiency. Different countries have adopted different goals and policies to achieve energy and environmental goals. In the European Union, where transport is responsible for 25% of energy-related greenhouse gas emissions, the European Commission has adopted specific guidelines for this sector. Since the introduction of Council Directive 88/77/EEC in 1988, followed by other legislation, the implementation of the Euro standards and the 2001 White Paper on Transport, the goal of reducing energy consumption has been partially achieved. An additional target was to reduce greenhouse gas emissions by 80-95% below 1990 levels by 2050. The European Commission concluded that specific targets for the transport sector should be lowered to 60% due to its complexity (Walnum et al. 2014, White Paper… 2011). The development and implementation of new and more efficient technologies remains one of the main strategies to achieve these goals.
This article presents the energy efficiency of different kinds of transport devices in a small company from Poland.

Materials and Methods

To prepare an energy audit for transport devices, the PN-EN 16247-4 Energy audits: Part 4 - Transport standard was used, describing the procedures for various means of transport, transport of various ranges and various transported goods. This European Standard covers the performance of energy audits of movable property, e.g. vehicles, railways, ships, aircraft as well as mobile installations. It details the requirements, methodology and results specific to carrying out work in this field, regardless of who is the operator and whether they are involved in transportation only or not. It also includes information on both the issue of optimizing energy for each mode of transport as well as choosing the best mode of transport for each situation.

Due to the mobility of assets in the transport sector, energy audit in this area is particularly demanding (it is more difficult to carry out an inspection, focus resources for verification, etc.). The classification included in the regulation in question allowed, however, to distinguish aspects specific to each of the means of transport. According to the definitions, transport is defined as the activity of moving people or goods from one place to another by means of vehicles, that is, energy-consuming transport objects that may include a container, trailer or cart. Energy used in transport includes fuels including biofuels, electricity from regeneration / regeneration of energy from braking etc. (the standard excludes raw material such as aqueous urea, i.e. Adblue ISO 22241-1).

In relation to PN-EN 16247-4 Energy audits: Part 4 - Transport, an assessment was carried out based on information provided from small company, which is the owner of the vehicle fleet. According to the provision in art. 37 sec. 2 points 2 of the Energy Efficiency Act of 20/05/2016, fuel consumption in the company is not subject to detailed verification.

As part of the cooperation, due to the complexity and time criticality, the leading auditor was provided with access to appropriate personnel responsible for the implementation and control of transport processes in the company, as well as access to records and documentation. The following sampling method was adopted for the audit in question: vehicle type / model / year of production / average fuel consumption / kilometres travelled / types of energy carriers in monthly periods over the period 2014÷2016, which was considered to be representative of the fleet and justified from the point of view of the effects to be achieved. In addition, as part of the interview, general information was obtained on: criteria used to plan transport operations tasks, description of routes performed, operator training, specificity of operations in the field of optimizing transport productivity, procurement criteria for suppliers and sub-suppliers, activities in the field of development and testing of new techniques and methods reducing greenhouse gas emissions by reducing energy use or using alternative sources. The work related to the audit consisted in the coordination of the following departments: operational, technical, maintenance and financial, thanks to which the obtained data was appropriate for the process being conducted. After receiving the complete documentation, conducting an on-site inspection, it was found that the presented historical data are reliable and there is no need to re-verify with the use of recorders, records from on-board computers and other devices used to record the routes. It was also not considered necessary for the auditor to perform a test run with the operator.

Results

Information on the means of transport received from the Company was used to assess the energy condition of transport. The information received concerns the means of passenger, truck and special transport owned in 2014-

2016, which had 54 transport devices grouped into three categories (Fig. 1). The identified vehicles are equipped with internal combustion engines that run on both gasoline and diesel oil.

Fig. 1: Quantitative list of vehicles in the company

The identified vehicles are equipped with internal combustion engines that run on petrol, diesel oil and LPG (Fig. 2). Vehicles powered by a gasoline engine have fuel consumption in the range of 8.9-10.0 ltr·100km^{-1}. The vehicles have 2 to 5 seats and can carry 1-4 passengers at a time. Diesel powered vehicles are mainly forklift trucks. Fuel consumption is in the range of 12-14 ltr·100km^{-1} and 1.7-5.9 ltr·mth^{-1}. In the years 2014-16, traveled a total of 374,689.00 km or worked 43,083.00 mth. Due to the specificity of the enterprise in the field of production, parameters such as loading factor, planning, schedules, road topography choices, the influence of various energy influences on productivity, evaluation of energy efficiency resulting from outsourcing some activities to a transport company.

Fig. 2: List of vehicles in the years 2014-2016 by fuel type

The company has identified 12 types of electric devices for internal transport – forklifts (13 devices). The total installed power in these devices is 437.20 kW. Based on the information provided to the Company, the electricity consumption for intra-company transport was estimated at 354,561.00 kWh per year.

The following indicators were used to evaluate the energy efficiency of the owned rolling stock (their selection was dictated by the measurability criterion adopted by the standard for non-electric transport devices used in the organization) - Table 1. The balance of electricity and fuels used for transport is presented in Table 2.

Table 1: Indicators of the energy performance of transport

Indicator	Unit	Average value for years 2014-2016
average annual operating speed of the vehicle	[km·h^{-1}] [mth·h^{-1}]	48.40 5.75
fuel consumption	[kgoe·km^{-1}] [kgoe·mth^{-1}]	0.10 3.52
energy consumption index	[kWh·km^{-1}] [kWh·mth^{-1}]	1.19 40.92

Table 2: Consumption of energy carriers in transport

Energy type	Average Energy consumption for years 2014-16 [GJ·rok^{-1}]	Final Energy consumption [kgoe·rok^{-1}]
Diesel	2,302.19	55,252.6
Gasoline	228.30	5,479.3
LPG	0.57	13.7
Electricity	1,203.55	28,885.2
Summary	**3,734.61**	**89,630.8**

Due to the specificity of the company's operations, an efficient and economically profitable fleet is one of the areas on which it should focus. Due to the fact that cars are in good technical condition and with different service life (years of production from around 2000 for trucks and from around 2006 for passenger cars), it is suggested to consider renewing the fleet of trucks. In the case of fleet renewal and extension plans, one should consider the availability of certain types of vehicles on the domestic market and their equipment with an engine meeting the EURO6 exhaust emission standard. Based on the analyzes of the company's fleet, it was found that there was no possibility of substituting means of transport or using the multimodal option due to the lack of available infrastructure and the location of the company's headquarters.

In the recommendations offered for reducing energy consumption, specific points of transport are considered:
